

IBM Tivoli Storage Productivity Center
Version 5.1.1

User's Guide

IBM Tivoli Storage Productivity Center
Version 5.1.1

User's Guide

Note:

Before using this information and the product it supports, read the information in "Notices" on page 1553.

This edition applies to version 5, release 1, modification 1 of IBM Tivoli Storage Productivity Center (product numbers 5725-F93, 5725-F98, and 5725-G33) and to all subsequent releases and modifications until otherwise indicated in new editions. This edition replaces SC27-4048-00.

**New for Tivoli Storage Productivity
Center Version 5.1.1 xix**

New for Tivoli Storage Productivity Center
Version 5.1 xxiii

Chapter 1. Getting started 1

Chapter 2. Product overview 11

Introducing IBM Tivoli Storage Productivity Center 11
 Architecture 11
 IBM Tivoli Storage Productivity Center summary 13
 Product licenses for Tivoli Storage Productivity
 Center 14
 User interfaces to Tivoli Storage Productivity
 Center 21
 Data Manager 46
 Disk Manager 48
 Tape Manager 50
 Fabric Manager 50
Tivoli Storage Productivity Center for Replication 51
 Architecture 53
 Interfaces for Tivoli Storage Productivity Center
 for Replication 53
 Tivoli Storage Productivity Center for Replication
 integration with Tivoli System Automation
 Application Manager 54
Tivoli Integrated Portal 55
Key concepts 55
 Single sign-on 55
 Launch and launch in context 58
 User roles 70
 User tasks 72
 Data collection 76
 Session Types. 77
 Alerts 109
 SAN Planner Overview 110
 Reporting. 116
 Fabric and zones 116

Agents 120
Security 127
SAN Volume Controller 128

Chapter 3. Scenarios 137

Monitoring and reporting on I/O utilization 137
Storage provisioning by using workflows 140
Archive and delete files 144
Create a profile with a filter 148
Creating a performance threshold within an alert 150
Determine application performance problems 153
Identifying performance hot spots 158
Retiring underutilized storage systems 160
Tivoli Storage Productivity Center for Replication
scenarios 162
 Identifying and investigating a suspended
 Metro Mirror session 163
 Performing planned maintenance scenarios 166
 Recovering from a disaster scenarios 169
 Practicing disaster recovery scenarios 172

Chapter 4. Administering 177

Starting Tivoli Storage Productivity Center 177
 Starting the Tivoli Storage Productivity Center
 stand-alone GUI 177
 Starting the Tivoli Storage Productivity Center
 web-based GUI. 180
Starting Tivoli Storage Productivity Center for
Replication 181
Starting the Tivoli Storage Productivity Center
family of products through Tivoli Integrated Portal. 182
Overview of required user IDs for initial log on to
the Tivoli Storage Productivity Center family of
products 183
Administering DB2 185
 Backing up the Tivoli Storage Productivity
 Center database 185
 Starting the Control Center. 186
 Using the command line on UNIX and Linux 186
 Manually starting DB2 on Windows. 187
 Manually stopping DB2 on Windows 187
 Monitoring DB2 188
Adding a Tivoli Storage Productivity Center user
group name to Tivoli Storage Productivity Center
for Replication 189
Backing up and recovering all the Tivoli Storage
Productivity Center for Replication 189
Administering Tivoli Storage Productivity Center 190
 Checking the Tivoli Storage Productivity Center
 version 190
 Viewing and managing services 190
 Starting and stopping the Tivoli Storage
 Productivity Center services 198
 Starting and stopping the Tivoli Integrated
 Portal server. 202

Checking Tivoli Storage Productivity Center status	202	Working with alerts	386
Increasing memory allocation	203	Creating alerts	386
Setting timeouts values for the Device server	205	Configuring alert destinations	397
Changing passwords	206	Deleting alerts	398
Checking for a fully qualified host name . . .	217	Disabling an alert	399
Granting local administrative privileges to a domain account	219	Editing alerts	399
Importing SSL certificates for VMware	220	Renaming alerts	400
SQL access to Tivoli Storage Productivity Center views	221	Viewing alerts	401
Repocopy tool	224	Viewing alert logs	405
Service tool: collecting information	227	Viewing tape library alerts	406
Administering Tivoli Integrated Portal	232	Checking storage configurations	406
Tivoli Integrated Portal port numbers	232	Using configuration history	406
Changing the user authentication configuration	234	Using configuration analysis	411
Changing the LTPA token expiration for single sign-on	251	Planning and modifying storage configurations .	421
Administering data sources	252	Configuring a provisioning plan by using SAN Planner	421
Checking the health of your data sources . . .	252	Working with storage resource group sessions	433
CIM agents	252	Optimizing storage configurations	434
Storage Resource agents	259	Storage Optimizer overview	434
In-band Fabric agents	281	Using the Storage Optimizer	435
Out-of-band Fabric agents	282	Optimizing tiered storage	443
Tivoli Storage Productivity Center servers . .	284	Enforcing storage policies	445
Storage systems	289	Setting storage usage quotas	447
VMware data source	298	Storage usage for Network Appliance quotas	467
Managing schedules, jobs, and runs	300	Setting file constraints	472
Job Management - Recommendations	307	Scheduling script-based actions	481
		Archive and backup functions	486
		Working with storage resource groups	491
		Storage resource group management	491
		Create or Edit a Storage Resource Group	492
		Working with scripts	495
		Running scripts with alerts	495
		Running scripts using scheduled actions	496
		How scripts are run	498
		How the server and agent resolve script names	500
		Using the topology viewer	501
		The topology viewer	501
		Arranging entities in a group	514
		Checking the status of entities and groups . . .	515
		Creating custom groups	524
		Defining properties for grouping entities	525
		Displaying data paths from one endpoint in the topology to another	525
		Displaying membership in zones and zone sets	533
		Displaying detailed information about entities	534
		Displaying storage resource connections	534
		Filtering entities based on health status	535
		Labeling entities	536
		Starting element managers	536
		Launching SAN Planner	537
		Starting Storage Optimizer	537
		Locating storage resources in the topology . . .	538
		Managing Storage Subsystems	538
		Managing Zone Control	538
		Pinning entities	539
		Printing information from the topology viewer	539
		Refreshing views	539
		Removing entities from the database	540
		Removing deleted entities	540
		Selecting entities in graphical and table views	541
		Showing Alerts	541
Chapter 5. Managing resources in the stand-alone GUI	309		
Adding resources for monitoring	309		
Configuring storage subsystems	310		
Configure fabrics and switches	320		
Configure computers	322		
Configure tape libraries	324		
Discovering storage resources	326		
Discovery overview	326		
Discovering computers in the Windows domain, NAS, and SAN File System	333		
Discovering computers	334		
Discover storage subsystem, tape library, and fabric information with CIM agents	334		
Discovering fabrics with Storage Resource agents	336		
Discovering storage subsystems and switches	337		
Collecting data	339		
Collecting storage statistics	339		
Collecting storage statistics from Tivoli Storage Productivity Center servers	344		
Collecting storage usage and trending information	347		
Determining the availability of storage resources	367		
Data collection groups	371		
Working with groups of resources	374		
Collecting performance data	378		
Monitoring switch performance	378		
Monitoring storage-subsystem performance . .	379		
Monitoring tape libraries	384		
Viewing performance data	384		

Showing the monitoring status of entities	541	Viewing information about internal and related resources	636
Working with tape libraries in the topology viewer.	541	Monitoring the status of resources	637
Managing disk storage	543	How status is determined	638
Working with workload profiles	543	Viewing the overall status of resources	641
Working with provisioning profiles	546	Viewing the status of top-level resources	642
Thin provisioning profiles	550	Viewing the status of internal resources	643
Managing storage subsystems	553	Acknowledging the status of resources	643
Managing virtual disks	564	Viewing data paths	646
Managing volumes	572	Resources that you can view in a data path	647
Managing fabrics	578	Navigating in a data path	650
Working with zones	578	Viewing information about top-level resources	650
Working with zone sets	581	Viewing information about internal resources	650
Working with zone aliases	583	Zooming in	650
Managing Tape Libraries	586	Zooming out	651
Discovering tape libraries	586	Changing the layout	651
Viewing tape library information	587	Saving the display settings	651
Monitoring tape libraries	587	Printing a view	652
Managing DS8000 storage systems using element managers.	587	Exporting a data path to a file.	652
Configuring the DS8000 element manager	589	Viewing jobs	652
Configuring other element managers for DS8000	593	Configuring the display of jobs	653
Managing other storage systems using element managers.	594	Viewing all jobs	654
Adding element managers using CIMOM discovery.	595	Viewing jobs for a type of resource	654
Modifying other element managers	598	Viewing jobs for a specific resource	655
Starting other element managers	598	Viewing job logs	655
Testing the connection to other element managers.	599	Managing alerts	656
Adding user-defined element managers for other storage systems.	599	Alert severities	657
Removing user-defined element managers for other storage systems.	600	Viewing all alerts	658
Launch and launch in context	600	Viewing alerts for a type of resource	659
Inbound launch in context feature	601	Viewing alerts for a specific resource	659
Outbound launch and launch in context features	608	Removing alerts	660
External tools	612	Acknowledging alerts	660
Adding external tools	612	Opening the management GUI for a resource.	661
Modifying external tools.	613	Exporting information about resources, jobs, and alerts	661
Starting external tools	614	Customizing lists of resources, jobs, and alerts	663
Removing external tools	614	Filtering lists	663
Working with invoices	615	Sorting lists	664
Planning for chargeback.	616	Showing, hiding, and reordering columns in lists	665
Setting up invoices	617	Chapter 7. Managing replication 667	
Generating an invoice	618	Administering	667
Viewing and printing invoices.	618	Starting and stopping Tivoli Storage Productivity Center for Replication	667
Sample Invoices	619	Verifying that components are running	669
Chapter 6. Managing resources in the web-based GUI. 625		Identifying the version of IBM Tivoli Storage Productivity Center for Replication	670
Configuring resources for monitoring	626	Backing up and restoring IBM Tivoli Storage Productivity Center for Replication configuration data.	670
Resources that you can monitor in the web-based GUI.	627	Managing management servers	674
Display differences in the interfaces	630	Management servers	674
Viewing information about resources	631	SNMP alerts.	676
How information is organized.	631	Setting up a standby management server	679
Viewing summary information about all resources	633	Applying maintenance to an active management server	680
Viewing information about top-level resources	635	Reconnecting the active and standby management servers	681
		Performing a takeover on the standby management server	681

Configuring SNMP	682
Adding SNMP managers	682
Changing the standby management server port number	682
Changing the client port number	683
Managing storage systems	683
Storage systems	683
Storage connections	684
Protected volumes	688
Site awareness	688
Adding a storage connection	689
Removing a storage connection	690
Removing a storage system	691
Modifying the location of storage systems	692
Modifying storage connection properties	692
Refreshing the storage system configuration	693
Setting volume protection	693
Restoring data from a journal volume	694
Managing host systems	694
Adding a host system connection	695
Modifying a host system connection	695
Removing a host system connection	696
Removing a session from a host system connection	696
Managing logical paths	697
Viewing logical paths	697
Adding logical paths	697
Adding logical paths using a CSV file	698
Removing logical paths	699
Setting up data replication	699
Sessions	699
Session Types	706
Session commands	738
Site awareness	753
Preserve Mirror option	754
Creating sessions and adding copy sets	755
Using the Metro Mirror heartbeat	763
Exporting copy set data	766
Importing copy set data	766
Exporting historical data for Global Mirror role pairs	767
Modifying the location of session sites	767
Removing sessions	768
Removing copy sets	768
Migrating an existing configuration to Tivoli Storage Productivity Center for Replication	769
Practicing disaster recovery	772
Practice volumes	772
Practicing disaster recovery for a Metro Mirror Failover/Failback with Practice session	772
Practicing disaster recovery for a Global Mirror either Direction with two-site Practice session	773
Practicing disaster recovery for a Global Mirror Failover/Failback with Practice session	774
Practicing disaster recovery for a Metro Global Mirror Failover/Failback with Practice session	774
Monitoring health and status	775
Viewing the health summary	775
Viewing SNMP alerts	775
Viewing sessions	775
Viewing session properties	783

Viewing storage system details	807
Viewing storage connection details	807
Viewing volume details	807
Viewing logical paths	807
Viewing console messages	808
Security	808
Users and groups	808
User roles	809
Adding the IBM Tivoli Storage Productivity Center for Replication Administrator role to the IBM Tivoli Storage Productivity Center	811
Superuser group	811
Granting access privileges for a user	812
Viewing access privileges for a user	812
Modifying access privileges for a user	813
Removing access privileges for a user	813

Chapter 8. Reporting in the stand-alone GUI 815

Choosing a reporting type	815
Choosing a report category	817
What can I find out using reports?	823
Report considerations and limitations	827
Working with reports	831
Generating and viewing reports	831
Sorting report columns	832
Printing reports or charts	832
Including charts in reports	833
Drilling down a report row	836
Navigating tabs	836
Trending with historical data	837
Working with user-defined online reports	840
Generating reports	840
Using reporting groups	848
Data Manager reports	851
Data Manager for Databases reports	981
Data Manager for Chargeback reports	1010
Disk Manager reports	1010
Fabric Manager reports	1023
Tape Manager reports	1030
System reports	1030
Generating and viewing system reports	1030
System reports - Data	1031
System reports - Data Manager for Databases	1045
System Reports - Disk Manager	1057
System reports - Fabric Manager	1074
Batch reports	1081
Creating batch reports	1082
Editing batch reports	1093
Viewing job information for a batch report	1093
Displaying log files for a batch report	1093
Displaying batch reports from the saved directory	1093
Viewing CSV batch reports with spreadsheet applications	1094
Exporting and importing settings that you define	1094
User ID (saved) reports	1095
Creating a user-defined report	1095
Displaying user-defined reports	1095
Editing user-defined reports	1095

Rollup reports.	1095
Generating rollup reports	1096
Rollup Reports - Asset	1097
Rollup Reports - Database Asset.	1126
Rollup Reports - TPC Server Storage Space	1132
Rollup Reports - Database Capacity	1149
Data source reports - overview	1153
Data source reports - CIMOM agents	1153
Data source report - By CIMOM Agent	1154
Data source report - By Managed Device	1155
Tivoli Storage Productivity Center Monitoring	
Agent reports	1157

Chapter 9. Reporting in the web-based GUI 1163

Viewing predefined and custom reports	1163
Creating and viewing reports from the web-based GUI	1164
Accessing report features in Tivoli Common Reporting	1165
Setting options for reports.	1165
Showing the package version number and build ID.	1166
Predefined reports about resources	1166
Relationship reports	1167
Server reports	1171
Storage virtualizer reports.	1176
Storage system reports	1188
Predefined reports about performance.	1200
Switch reports.	1200
Storage virtualizer reports.	1206
Storage virtualizer performance details reports	1215
Storage system reports	1231
Storage system performance details reports	1241
Predefined reports about historical information	1252
Running the Storage Virtualizers - Historical Space Report	1253
Storage Virtualizers - Historical Space Report	1253
Running the Storage Virtualizer - Pools Historical Space Report.	1255
Storage Virtualizer - Pools Historical Space Report	1255
Running the Storage Virtualizer - Volumes Historical Space Report.	1257
Storage Virtualizer - Volumes Historical Space Report	1258
Running the Storage Systems - Historical Space Report	1259
Storage Systems - Historical Space Report	1260
Running the Storage System - Pools Historical Space Report	1262
Storage System - Pools Historical Space Report	1262
Running the Storage System - Volumes Historical Space Report.	1264
Storage System - Volumes Historical Space Report	1265
Predefined reports about storage tiering	1266
Configuring back-end pools for MDisk groups and threshold values for workload activity reports	1267

Running the MDisk Groups - Workload Activity Report	1272
MDisk Groups - Workload Activity Report	1272
Running the MDisk Groups - VDisk Workload Activity Report	1277
MDisk Groups - VDisk Workload Activity Report	1277
Running the MDisk Group - VDisk Workload Activity Details Report.	1281
MDisk Group - VDisk Workload Activity Details Report.	1282
Running the Storage Virtualizer - VDisk Workload Activity Report	1286
Storage Virtualizer - VDisk Workload Activity Report	1286
Running the Storage Resource Group - VDisk Workload Activity Report	1290
Storage Resource Group - VDisk Workload Activity Report	1291
Running the Storage Resource Group - VDisk Workload Activity Details Report	1295
Storage Resource Group - VDisk Workload Activity Details Report.	1295
Running the MDisk Group Details Report	1299
MDisk Group Details Report	1300
Running the VDisk Details Report	1302
VDisk Details Report	1303
Running the Volume Migration Recommendation Report	1305
Volume Migration Recommendation Report	1306
Custom reports about performance.	1307
Creating custom performance reports in Tivoli Common Reporting	1307
Data and properties in performance reports	1308
Custom reports about resources	1410
Creating custom resource reports in Tivoli Common Reporting	1410
Data and properties in resource reports	1416
Troubleshooting reports	1464
Setting up multiple connections to the TPCDB data source.	1467

Appendix A. Reference. 1469

Alerts and schedules associated with monitoring groups and templates	1469
Supported Fabric Agent Types	1476
Supported storage systems providing full disk encryption and solid-state drives	1477
Frequently Asked Questions	1477
General and Migration Information	1478
Data Manager.	1479
Fabric Manager	1479
Disk Manager	1482
Arguments and window locations available with the inbound launch in context feature.	1482
Launch in context parameters	1482
Launch in context task parameters	1484
Available windows	1485
Alerts	1488
Triggering conditions for alerts	1489
Alert suppression actions	1504

Triggered actions for alerts	1504
Alert display colors	1506
Performance data.	1508
General performance guidelines.	1508
Performance thresholds	1508
Performance metrics.	1519
Protocols and standards	1541
Web Based Enterprise Management	1541
Storage Management Initiative Specification	1542
Service Location Protocol	1543
Simple Network Management Protocol	1543
Fibre Channel Methodologies of Interconnects	1544

Glossary	1557

Preface

IBM® Tivoli® Storage Productivity Center is a software product that manages storage infrastructure by centralizing, automating, and simplifying the management of complex and heterogeneous storage environments. With the information in this publication, you can use Tivoli Storage Productivity Center to manage storage capacity, determine availability of storage resources, and monitor storage-device events in your enterprise environment. Topics in this publication also help you to assess performance data, control the storage-management assets, and obtain predefined or user-defined reports. Other topics describe the automated, policy-driven tools for storage management that Tivoli Storage Productivity Center provides, thereby offering the ability to detect potential problems and automatically make adjustments based on the policies and actions that you define. Tivoli Storage Productivity Center also includes IBM Tivoli Storage Productivity Center for Replication, a product that you can configure to manage data-copy functions.

Who should read this guide

The audience of this publication is administrators or users who have already installed the product and are now using Tivoli Storage Productivity Center. This publication provides an overview of how to use the product and detailed information about various topics.

Administrators and users must be familiar, or become familiar, with the following concepts:

- IBM DB2
- IBM Tivoli Common Reporting
- IBM Tivoli Enterprise Console®
- IBM Tivoli Integrated Portal
- Storage Area Network (SAN)
- Simple Network Management Protocol (SNMP)
- Tivoli Storage Productivity Center
- Tivoli Storage Productivity Center for Replication

Publications

This section lists publications in the Tivoli Storage Productivity Center library and other related publications. It also describes how to access publications online, how to order publications, and how to submit comments about publications.

The publications are available from the IBM Publications Center at <http://www.ibm.com/e-business/linkweb/publications/servlet/pbi.wss>.

Accessing publications online

Publications for this product and other related products are available online.

Information about installing, configuring, upgrading, and uninstalling Tivoli Storage Productivity Center and related products is available online. Use Table 1 to view and download these publications. Translated documents are available for some products.

Table 1. Locations of publications for Tivoli Storage Productivity Center and related products

Note: If you print PDF documents on other than letter-sized paper, in the Print window select Fit to Printable Area in the Page Scaling field. This option is available when you click File > Print . Fit to Printable Area ensures that the full dimensions of a letter-sized page print on the paper that you are using.	

IBM Redbooks

The IBM Redbooks[®] are publications about specialized topics.

You can order publications through your IBM representative or the IBM branch office serving your locality. You can also search for and order books of interest to you by visiting the IBM Redbooks home page at <http://www.redbooks.ibm.com/>.

Translation

Translated publications are available from the information center which is available in certain translated languages. It is displayed in the language that is appropriate for the browser locale setting.

When a locale does not have a translated version, the information center is displayed in English, which is the default language. Translations of the PDFs are available when the information center is translated.

Contact your service representative for more information about the translated publications and whether translations are available in your language.

Ordering publications

Information is provided for the ordering of IBM publications on the Internet or by telephone.

You can order many IBM publications online at <http://www.ibm.com/e-business/linkweb/publications/servlet/pbi.wss>.

You can also order by telephone. In the United States and Canada, call 800-879-2755. In other countries, contact your IBM service representative.

Providing feedback about publications

Your feedback is important to help IBM provide the highest quality information. You can provide comments or suggestions about the documentation from the IBM Tivoli Storage Productivity Center Information Center.

Go to the information center at <http://publib.boulder.ibm.com/infocenter/tivihelp/v59r1/index.jsp>. From any topic page, click the **Feedback** link.

Conventions used in this guide

This section provides information about the conventions used in this publication.

This publication uses several conventions for special terms and actions, and operating system-dependent commands and paths.

The following typeface conventions are used in this publication:

Bold

- Flags that appear with text
- Graphical user interface (GUI) elements (except for titles of windows and dialogs)
- Names of keys

Italic

- Variables
- Values you must provide
- New terms
- Words and phrases that are emphasized
- Titles of documents

monospace

- Commands and command options
- Flags that appear on a separate line
- Code examples and output
- Message text
- Names of files and directories
- Text strings you must type, when they appear within text
- Names of Java methods and classes
- HTML and XML tags also appear like this, in monospace type

For syntax notations, remember the following:

- In UNIX, the prompt for the root user is #.
- In UNIX and Linux, the commands are case sensitive, so you must type commands exactly as they are shown.

Contacting the IBM Support Center

You can contact the IBM Support Center by phone, and you can register for support notifications at the technical support website.

- Go to the IBM Tivoli Storage Productivity Center technical support website at http://www.ibm.com/support/entry/portal/Overview/Software/Tivoli/Tivoli_Storage_Productivity_Center

To receive future support notifications, sign in under **Notifications**. You are required to enter your IBM ID and password. After you are authenticated, you can configure your subscription for Tivoli Storage Productivity Center technical support website updates.

- Customers in the United States can call 1-800-IBM-SERV (1-800-426-7378).
- For international customers, go to the Tivoli Storage Productivity Center technical support website to find support by country. Expand **Contact support** and click **Directory of worldwide contacts**.

You can also review the *IBM Software Support Handbook*, which is available at <http://www14.software.ibm.com/webapp/set2/sas/f/handbook/home.html>.

The support website offers extensive information, including a guide to support services; frequently asked questions (FAQs); and documentation for all IBM Software products, including Redbooks and white papers. Translated documents are also available for some products.

When you contact the IBM Support Center, be prepared to provide identification information for your company so that support personnel can readily assist you. Company identification information might also be needed to access various online services available on the website. See “Reporting a problem.”

Reporting a problem

Provide the IBM Support Center with information about the problems that you report.

Have the following information ready when you report a problem:

- The IBM Tivoli Storage Productivity Center version, release, modification, and service level number.
- The communication protocol (for example, TCP/IP), version, and release number that you are using.
- The activity that you were doing when the problem occurred, listing the steps that you followed before the problem occurred.
- The exact text of any error messages.

New for Tivoli Storage Productivity Center Version 5.1.1

Use this information to learn about new features and enhancements in IBM Tivoli Storage Productivity Center Version 5.1.1. This information highlights the changes since the last release of Tivoli Storage Productivity Center.

Storwize V3500 and Storwize V3700 data replication

Tivoli Storage Productivity Center and Tivoli Storage Productivity Center for Replication 5.1.1 provide data storage and replication management for the IBM Storwize V3500 and IBM Storwize V3700 storage systems. These virtualized storage systems are the newest additions to the IBM Storwize family of disk systems.

Except for the Storage Optimizer feature, Tivoli Storage Productivity Center and Tivoli Storage Productivity Center for Replication features that are available for IBM Storwize V7000 are also available for Storwize V3500 and Storwize V3700.

For more information about these storage systems, see the following information centers:

- Storwize V3500 http://pic.dhe.ibm.com/infocenter/storwize/v3500_ic/index.jsp
- Storwize V3700 http://pic.dhe.ibm.com/infocenter/storwize/v3700_ic/index.jsp

IBM SONAS wide area network caching

Wide area network (WAN) caching is a scalable, high-performance remote file data access function across a WAN that is integrated with IBM SONAS. You can use WAN caching to distribute data transparently among data centers and multiple remote locations without disruption to applications. Remote operations for WAN caching are run on the local system by one or more interface nodes. These nodes are configured as gateway nodes by using Tivoli Storage Productivity Center CLI commands. The CLI commands use network file system (NFS) protocols to read and write data from interface nodes in the remote home system.

For more information, see the Tivoli Storage Productivity Center information center at <http://publib.boulder.ibm.com/infocenter/tivihelp/v59r1/index.jsp> and search for *planning sonas* and *wan caching*.

More information about IBM SONAS is available at the IBM SONAS information center at <http://pic.dhe.ibm.com/infocenter/sonasic/sonas1ic/index.jsp>.

Opening the management GUI for a resource

Resources such as storage systems and switches can have their own management GUIs or element managers. In the web-based GUI, you can open the start page for these resource GUIs on the Storage Systems page and Switches page.

For more information about opening a management GUI in the web-based GUI, see “Opening the management GUI for a resource” on page 661.

Viewing the data path for a resource

In the web-based GUI, the data path view shows the connectivity between host connections, servers, hypervisors, virtual machines, storage systems, and the fabrics through which they share storage. You can use this view to

monitor status and pinpoint problem areas in selected data paths. This view includes graphical and tabular representations of the top-level resources in a data path.

For more information about viewing data paths in the web-based GUI, see “Viewing data paths” on page 646.

Additional information and alerts for thin-provisioned environments

In the web-based GUI, more information and alerts are available for thin-provisioned volumes, the pools that contain thin-provisioned volumes, and the associated storage systems.

Information about thin-provisioned environments

You can use the new information about thin-provisioned environments to complete the following tasks:

- Identify the pools and volumes where the amount of over-committed space is at a critically high level. Shortfall percentage represents the percentage of the committed virtual space that is not available in a pool.
- Determine the percentage of physical space in pools that is committed to the total virtual capacity of the volumes. In thin-provisioned environments, the virtual allocation percentage exceeds 100% if a pool or storage system is over committed (over provisioned).
- Determine the amount of space that is reserved, or allocated, for a volume. The space that is allocated for a thin-provisioned volume is less than its virtual capacity.
- Determine the percentage of physical space that is reserved for a volume. For example, if the space that is reserved for volumes is 50 GiB for a volume size of 200 GiB, physical allocation is 25%.
- Determine the total storage space on volumes, on all the volumes in a pool, or on all the volumes in a storage system. For thin-provisioned volumes, the total volume capacity includes virtual space.

Alerts for thin-provisioned environments

You can use the new alerts for thin-provisioned environments to complete the following tasks:

- Set warning and critical boundaries for a storage system so that you are automatically alerted when the shortfall percentage for a pool exceeds the boundaries. When alerted, you can correct the problem before the thin-provisioned volumes in a pool run out of space and cause an application to become unavailable.
- Set warning and critical boundaries for a storage system so that you are automatically alerted when the virtual allocation percentage for a pool exceeds the boundaries. When alerted, you can control the amount of over-provisioning on storage pools.
- Set warning and critical boundaries for a storage system so that you are automatically alerted when the available space in a pool falls below the boundaries. When alerted, you can correct the problem before space in a pool is no longer available.

For detailed descriptions of all the new information that is available for volumes, pools, and storage systems in thin-provisioned environments, access the online help for the Volumes page, Pools page, and Storage Systems page in the web-based GUI.

For a complete list of the alerts that you can define for pools and storage systems, see “Triggering conditions for storage system alerts” on page 1495.

Web-based GUI reports

The following features are new for reports that are in the web-based GUI.

Maximum values for pools and volumes

In custom reports about performance, you can include column headings that show the maximum values, such as the maximum read and write I/O rates, for pools and volumes that are on storage virtualizers.

For more information, see “Statistics for storage virtualizer pools in performance reports” on page 1401 and “Statistics for storage virtualizer volumes in performance reports” on page 1372.

Version information for report packages

You can view version information about report packages in the Tivoli Common Reporting GUI.

For more information, see “Showing the package version number and build ID” on page 1166.

Space statistics for thin-provisioned volumes

Additional information is provided about thin-provisioned volumes on storage virtualizers and on storage systems. The following reports show information about thin-provisioned volumes:

- Storage Virtualizers - Space Report
- Storage Virtualizer - Pools Space Report
- Storage Virtualizer - Volumes Space Report
- Storage Systems - Space Report
- Storage System - Pools Space Report
- Storage System - Volumes Space Report

For more information, see “Storage virtualizer reports” on page 1176 and “Storage system reports” on page 1188.

Assigned host alias for volumes

In the predefined reports and in custom reports about resources, the name of the port on the server that volumes are mapped to is identified.

For more information about predefined reports, see “Storage Resource Relationships Summary Report” on page 1168 and “Storage Relationships Summary Report (Configurable)” on page 1170. For more information about custom reports, see “Data for storage virtualizer volumes in resource reports” on page 1443 and “Data for storage system volumes in resource reports” on page 1459.

Installing Tivoli Storage Productivity Center on a Windows domain

You can install Tivoli Storage Productivity Center by using a Windows domain user account or a local user account.

For more information about installing Tivoli Storage Productivity Center on a Windows domain, see the Tivoli Storage Productivity Center information center at <http://publib.boulder.ibm.com/infocenter/tivihelp/v59r1/index.jsp> and search for the following topics:

- *Windows domain and local user accounts*
- *Preparing to install Tivoli Storage Productivity Center in a Windows domain*
- *Installing Tivoli Storage Productivity Center on a Windows domain*

New for Tivoli Storage Productivity Center for Replication Version 5.1.1

Use this information to learn about new features and enhancements in IBM Tivoli Storage Productivity Center for Replication Version 5.1.1. This information highlights the changes since the last release of Tivoli Storage Productivity Center for Replication.

Support for the SAN Volume Controller 6.4 option to move volumes between I/O groups

To support this new IBM System Storage SAN Volume Controller feature, Tivoli Storage Productivity Center for Replication includes the following changes:

- The I/O group was removed from the volume ID.
- The volume ID or the volume name can be used as a CLI command volume parameter for SAN Volume Controller, Storwize V3500, Storwize V3700, IBM Storwize V7000, and IBM Storwize V7000 Unified storage systems. The following CLI commands were updated to reflect this change:
 - **chvollspair**
 - **lscpset**
 - **lsvol**
 - **mkcpset** (where applicable for the specific volume parameter)
 - **importcsv**
 - **exportcsv**
 - **rmcpset**
 - **showcpset**

For more information, see the Tivoli Storage Productivity Center for Replication for System z information center at <http://publib.boulder.ibm.com/infocenter/tivihelp/v59r1/index.jsp> and search by the command name.

HyperSwap[®] options available for Metro Global Mirror with Practice sessions

The session properties for Metro Global Mirror with Practice sessions include the same HyperSwap options that are available for Metro Global Mirror sessions.

For more information, see “Metro Global Mirror with Practice session properties” on page 800.

System Storage DS8000 consistency groups that are created for FlashCopy sessions

For FlashCopy sessions, Tivoli Storage Productivity Center for Replication creates FlashCopy consistency groups in IBM System Storage DS8000. The consistency groups are created automatically during the creation of the FlashCopy session. You are no longer required to quiesce an application before you issue the **Flash** command for FlashCopy sessions.

New for Tivoli Storage Productivity Center Version 5.1

Learn about new features and enhancements in IBM Tivoli Storage Productivity Center Version 5.1.

New Features

The following features are new in Tivoli Storage Productivity Center 5.1:

Graphical user interfaces

Tivoli Storage Productivity Center provides two graphical user interfaces for managing the storage infrastructure in an enterprise environment: the stand-alone GUI and the web-based GUI. Each GUI provides different functions for working with monitored resources.

To view a comparison of the functions that are available in each GUI, see “Available functions and report information in the interfaces” on page 21.

Viewing reports from the web-based GUI

From the web-based GUI, you can now run the following types of report in Tivoli Common Reporting:

Resources reports

Show the relationships between storage resources in your environment. Resources reports also provide a snapshot of the capacity, available space, and used space on servers, storage virtualizers, storage systems, and related storage resources.

Performance reports

Show performance statistics for the most active storage resources in your environment over a specified period. Performance reports also provide detailed statistics for specific storage resources.

Historical space reports

Show how space is used over a specified period on storage virtualizers, storage systems, and related storage resources.

Storage tiering reports

Show volumes that might require migration from a pool in a storage resource group to a pool in another storage resource group. You also use the Tivoli Storage Productivity Center web-based GUI to view the workload activity reports for managed disk groups and virtual disks.

Creating and designing reports from the web-based GUI

From the web-based GUI, you can create custom reports and design custom reports. You can create and design the reports in report tools in Tivoli Common Reporting.

Custom reports can contain detailed information about the relationships between monitored resources, the properties of monitored resources, and detailed information about the performance of monitored resources. Unlike predefined reports, you can select the information that you want to include in custom reports.

You can create reports with basic formatting, or you can design more complex reports with advanced formatting features. The advanced formatting features include inserting charts that you can customize in reports, and inserting links that open related reports.

Installing Tivoli Storage Productivity Center

You can install Tivoli Storage Productivity Center in one of the following ways:

Installation wizard

The installation wizard provides a graphical user interface for installation.

Command-line interface by using silent mode

In silent mode, you run a command and provide the installation values in a response file. A silent-mode installation is useful if your system is running from a terminal that cannot display graphics.

Installation configurations

When you install Tivoli Storage Productivity Center, your system can be configured in one of the following ways:

Single server

All Tivoli Storage Productivity Center components are installed on one server.

Multiple servers

In the multiple-servers environment, you can have these configurations:

- DB2 and the Tivoli Storage Productivity Center database repository on a remote server and the rest of the Tivoli Storage Productivity Center components on a local server.
- DB2 and the Tivoli Storage Productivity Center servers, stand-alone GUI, command-line interface, and Storage Resource agent on one server, and IBM Tivoli Integrated Portal, Tivoli Common Reporting, and web-based GUI on a remote server.

Installation components

When you install Tivoli Storage Productivity Center, the following components are included:

- Database repository
- Data server
- Device server
- Replication server
- Stand-alone graphical user interface
- Web-based graphical user interface
- Command-line interface
- Storage Resource agent
- Tivoli Integrated Portal Version 2.2
- Tivoli Common Reporting Version 2.1.1

Lightweight Directory Access Protocol

You no longer have to configure Lightweight Directory Access Protocol (LDAP) as an authentication method during the installation. You configure LDAP as a post-installation task. The Tivoli Storage Productivity Center installation program establishes a default authentication configuration by using the federated repositories feature of the WebSphere Application Server.

For more information about LDAP and how to add an LDAP repository, see the Tivoli Storage Productivity Center information center and search for *Administering Tivoli Integrated Portal*.

Tivoli Storage Productivity Center licenses

The following licenses are available in Tivoli Storage Productivity Center 5.1:

IBM Tivoli Storage Productivity Center

This license contains the following functions:

- Data management. Data management includes enterprise-wide reporting and monitoring, and automated capacity provisioning for direct-attached storage (DAS), network-attached storage (NAS), and storage area networks (SAN) environments.
- Disk management. Disk management helps you manage SANs and heterogeneous storage from one console.
- Fabric management. Fabric management helps you manage the SAN fabric that connects the host systems and applications to the storage devices. This feature includes automatic resource and topology discovery, monitoring, alerts, and zone control.
- Tape management. Tape management helps you manage your tape libraries that must be SMI-S compliant.

Tivoli Storage Productivity Center for Replication

All of the Tivoli Storage Productivity Center for Replication functions, including the functions that were previously in the Two Site and Three Site Business Continuity licenses.

- Performance management. Disk and Fabric performance management functions.
- Device support. For the devices that you can use with Tivoli Storage Productivity Center, see <http://www.ibm.com/support/docview.wss?rs=40&uid=swg21386446>.

IBM Tivoli Storage Productivity Center Select Edition

This license contains all the functions of the IBM Tivoli Storage Productivity Center license.

IBM Tivoli Storage Productivity Center Advanced

This license contains all the functions in the Tivoli Storage Productivity Center license plus these additional analytical functions:

- Configuration Analysis
- Configuration History
- SAN Planner
- Storage Optimizer

Tivoli Storage Productivity Center for data-related functions

- Scans
- Policy management
- Server probes
- Profiles
- Data Manager for Databases
- Data Manager for Chargeback

IBM Scale Out Network Attached Storage

IBM Scale Out Network Attached Storage (IBM SONAS) manages repositories of information in enterprise environments that require

large capacities, high levels of performance, and high availability. IBM SONAS uses up to 2 petabytes (PB) of storage in a large file system.

Policy-based storage tier reports

Use the Tivoli Storage Productivity Center command-line interface to issue commands that create user-defined storage tiering policies. Storage tiering policies set the conditions that must be met to determine whether a volume requires migration to another pool.

New for Tivoli Storage Productivity Center for Replication Version 5.1

Use this information to learn about new features and enhancements in IBM Tivoli Storage Productivity Center for Replication Version 5.1. This information highlights the changes since the last release of Tivoli Storage Productivity Center for Replication.

Failover operations that are managed by other applications

Applications such as the IBM Series i Toolkit, VMware Site Recovery Manager, and Veritas Cluster Server manage failover operations for certain session types and storage systems. If an application completes a failover operation for a session, the Severe status is displayed for the session. An error message is also generated for the role pairs for which the failover occurred.

For more information, see “Failover and failback operations” on page 705.

Additional support for space-efficient volumes in remote copy Tivoli Storage Productivity Center for Replication sessions

You can use extent space-efficient volumes as copy set volumes for the following IBM System Storage DS8000 session types:

- FlashCopy® (System Storage DS8000 6.2 or later)
- Metro Mirror (System Storage DS8000 6.3 or later)
- Global Mirror or Metro Global Mirror (System Storage DS8000 6.3 or later)

For more information, see “Copy sets” on page 700.

New features

The following features are new for Tivoli Storage Productivity Center for Replication version 5.1.

Reflash After Recover option for Global Mirror Failover/Failback with Practice sessions

You can use the **Reflash After Recover** option with System Storage DS8000 version 4.2 or later. Use this option to create a FlashCopy replication between the I2 and J2 volumes after the recovery of a Global Mirror Failover/Failback with Practice session. If you do not use this option, a FlashCopy replication is created only between the I2 and H2 volumes.

For more information, see “Global Mirror Failover/Failback with Practice session properties” on page 794.

No Copy option for Global Mirror Failover/Failback with Practice and Metro Global Mirror with Practice sessions

You can use the **No Copy** option with System Storage DS8000

version 4.2 or later. Use this option if you do not want the hardware to write the background copy until the source track is written to.

For more information, see “Global Mirror Failover/Failback with Practice session properties” on page 794 and “Metro Global Mirror with Practice session properties” on page 800.

Recovery Point Objective Alerts option for Global Mirror sessions

You can use the **Recovery Point Objective Alerts** option with IBM TotalStorage Enterprise Storage Server® Model 800, System Storage DS8000, and System Storage DS6000. Use this option to specify the length of time that you want to set for the recovery point objective (RPO) thresholds. The values determine whether a Warning or Severe alert is generated when the RPO threshold is exceeded for a role pair. The RPO represents the length of time in seconds of data exposure that is acceptable in the event of a disaster.

For more information, see “Global Mirror Single Direction and Failover/Failback session properties” on page 793, “Global Mirror Either Direction with Two-Site Practice session properties” on page 795, “Global Mirror Failover/Failback with Practice session properties” on page 794, “Metro Global Mirror session properties” on page 796, and “Metro Global Mirror with Practice session properties” on page 800.

StartGC H1->H2 command for Global Mirror sessions

You can use the StartGC H1->H2 command with TotalStorage Enterprise Storage Server Model 800, System Storage DS8000, and System Storage DS6000. This command establishes Global Copy relationships between site 1 and site 2, and begins asynchronous data replication from H1 to H2.

This command is available only for Global Mirror Failover/Failback and Global Mirror Failover/Failback with Practice sessions.

For more information about this command, see “Session commands” on page 738.

Export Global Mirror Data command for Global Mirror role pairs

You can use this option to export data for a Global Mirror role pair that is in a session to a comma-separated value (CSV) file. You can then use the data in the CSV file to analyze trends in your storage environment that affect your recovery point objective (RPO).

For more information, see “Exporting historical data for Global Mirror role pairs” on page 767.

New chsess command parameters

The command-line interface command **chsess** has new parameters:

- **-reflash**
- **-dsRPOwarning**
- **-dsRPOsevere**
- **-enableHardenedFreeze**

For more information, go to the Tivoli Storage Productivity Center for Replication information center at <http://publib.boulder.ibm.com/infocenter/tivihelp/v59r1/index.jsp> and search for *chsess*.

Related tasks:

“Running the Volume Migration Recommendation Report” on page 1305

To see volumes that might require migration to other pools, run the Volume Migration Recommendation Report.

Related reference:

“Volume Migration Recommendation Report” on page 1306

The Volume Migration Recommendation Report, shows the volumes that comply with the criteria for migrating volumes to a pool in another storage resource group. Use the report to identify volumes that might require migration based on the conditions that are set in tiering policies.

Chapter 1. Getting started

Use this task list as a getting started guide for installing and using IBM Tivoli Storage Productivity Center. The tasks are in sequential order to help you learn how the product works and how to get started administering and managing your storage environment.

Complete the following tasks as shown and click the included links to learn more about the capabilities of Tivoli Storage Productivity Center. Follow the tasks as outlined: planning, installing, configuring, administering, managing storage resources, and reporting. Troubleshooting contains procedures for debugging any problems that you might encounter.

Learn more: See the topics about planning and installing the Tivoli Storage Productivity Center in the IBM Tivoli Storage Productivity Center Information Center (<http://publib.boulder.ibm.com/infocenter/tivihelp/v59r1/index.jsp>).

Task	Description	When and how often must I complete this task?
Determine prerequisites and plan for installation.	<p>The first installation task is planning for Tivoli Storage Productivity Center. The time that you invest in planning directly affects your ease of implementation. Planning includes:</p> <ul style="list-style-type: none">• Ensuring that your systems meet hardware and software requirements• Determining where to deploy Storage Resource agents• Ensuring that ports are open for use by Tivoli Storage Productivity Center components• Granting privileges to the user ID used to install the Tivoli Storage Productivity Center components• Setting up for LDAP Support	Perform this task before you install Tivoli Storage Productivity Center.

Task	Description	When and how often must I complete this task?
Install Tivoli Storage Productivity Center.	<p>The second task is installing Tivoli Storage Productivity Center.</p> <p>You can install all the Tivoli Storage Productivity Center components using typical installation or custom installation. It is recommended that for a production environment you use the option for custom installation.</p> <p>Tivoli Storage Productivity Center has the following installable components:</p> <ul style="list-style-type: none"> • Database schema • Data server • Device server • Graphical user interface (GUI) • Command-line interface (CLI) • Storage Resource agent • IBM Tivoli Integrated Portal 	<p>Perform this task after you complete planning and ensuring that you meet the installation prerequisites. You can also install components separately depending on your needs, so you might complete a portion of the installation process a number of times after the initial installation. For example, you can install Storage Resource agents at any time on the computers whose storage you want to monitor.</p>

Task	Description	When and how often must I complete this task?
Start and Configure Tivoli Storage Productivity Center.	<p>Perform this task after you install Tivoli Storage Productivity Center to configure it according to the standards within your organization, including:</p> <ul style="list-style-type: none"> • Starting the Tivoli Storage Productivity Center GUI. • Running the Configuration Utility as a guide to help you through the steps that are required to configure and manage Tivoli Storage Productivity Center for your environment. • Using the Help menu to access online help, start the product information center, and access information about the appropriate levels of software, firmware, and hardware that is needed to run the product. • Assigning roles to individuals who use the product. • Entering licensing information. • Setting SNMP and email alerts. • Entering retention settings for log files, resource history, and removed resources. • Defining rules for generating email addresses of quota violators. • Scheduling history aggregation and agent upgrades. • Setting up NAS filer access. • Setting up IBM TotalStorage Enterprise Storage Server or SAN Volume Controller access. • Using configuration history to analyze historical data that identifies possible problems with a storage area network (SAN) configuration. • Using configuration analysis to determine whether an existing SAN configuration complies with predefined best practices. 	Typically, complete this step immediately after you install the product. When Tivoli Storage Productivity Center is configured, you do not have to complete this step again unless changes within your organization require it.

Task	Description	When and how often must I complete this task?
Administer DB2 and Tivoli Storage Productivity Center.	<p>When Tivoli Storage Productivity Center is installed and configured, complete the following tasks as needed:</p> <ul style="list-style-type: none"> • Authorizing users. • Managing Agent Manager. • Administering data sources (agents): CIMOM, Data, Storage Resource, Inband Fabric, Out of Band Fabric, Storage Subsystems, TPC Servers, VMWare VI. • Starting and stopping Tivoli Storage Productivity Center services • Increasing the memory allocation and checking the status of Tivoli Storage Productivity Center components. • Setting timeout values for the Device server. • Changing passwords for Tivoli Storage Productivity Center components • Configuring the launch of the IBM Tivoli Storage Productivity Center for Replication GUI and other web GUIs or local executable files. • Collecting information with the service tool. 	<p>Perform administrative tasks at any time during the use of Tivoli Storage Productivity Center. These tasks are meant to provide you with the tools to maintain a successful implementation of the product during its lifecycle.</p>
Configure storage resources for monitoring.	<p>Before you can use Tivoli Storage Productivity Center to monitor the storage resources in your environment, you must configure them in the stand-alone GUI. Configuring resources includes the following tasks:</p> <ul style="list-style-type: none"> • Discovering resources. • Including resources in monitoring groups (optional). • Defining data collection schedules. • Determining the conditions that must occur before you are alerted to a problem related to the resources you are monitoring. 	<p>Perform this task when you want to configure storage resources for monitoring by Tivoli Storage Productivity Center. You can configure resources that are already known to Tivoli Storage Productivity Center but not included in a probe schedule, or configure resources that were not discovered.</p>

Task	Description	When and how often must I complete this task?
Discover storage resources.	<p>Perform discovery to detect the storage resources and network topology within your environment. Discovery schedules collect basic information about the storage resources, including computers, CIMOMs, storage subsystems, fabrics, filers, clusters, and tape libraries.</p> <p>To discover storage resources, use either of the following methods:</p> <ul style="list-style-type: none"> • Use the discovery step in the Configure Devices wizard to automate the detection of storage resources. • Go to the Administrative Services > Discovery node in the navigation tree and manually define a schedule for the resource type that you want to detect. 	<p>You must run discovery schedules before you can collect more detailed information about storage resources. When discovery is complete, use data collection schedules such as probes, scans, and pings to collect more detailed information about the discovered storage resources.</p> <p>For more information, see Discover resources in your system.</p>
Define monitoring groups for related storage resources.	<p>Organize related storage resources into groups (optional). Use groups when you want to apply the same action against multiple resources. For example, if you create a group that contains all the storage systems for the Sales division within your organization, you can include that group in a data collection schedule. The schedule then collects information about the all the storage systems in the Sales group without requiring you to add them individually to a schedule.</p> <p>As new resources are introduced into the environment, you can add them to existing groups. The same actions that are already associated with the group are then applied to the new resources.</p> <p>To create groups, use either of the following methods:</p> <ul style="list-style-type: none"> • Use the monitoring group step in the Configure Devices wizard to automate the grouping of resources. • Use the Monitoring > Groups facility within each of Tivoli Storage Productivity Center managers to define a group that corresponds to that manager. For example, use Disk Manager to create storage subsystem monitoring groups; use Fabric Manager to create fabric groups; use Data Manager to create computer, file system, directory, user, and OS user monitoring groups. 	<p>Create monitoring groups before you complete the following tasks:</p> <ul style="list-style-type: none"> • Define data collection schedules (probes, scans, and pings) to collect information about storage resources. • Define Data Manager quotas and constraints to enforce storage policies. <p>Creating groups is not required, but they are meant to help you better organize your storage resources for monitoring in a large environment.</p> <p>For more information, see the following topics:</p> <ol style="list-style-type: none"> 1. "Data collection groups" on page 371 2. "Working with groups of resources" on page 374

Task	Description	When and how often must I complete this task?
<p>Determine the information that you want to gather about the resources in your environment and define the appropriate data collection schedules.</p>	<p>Determining what information you want to gather about the storage resources within your enterprise is critical to helping you implement a storage management strategy.</p> <p>When you determine the types of information you want to collect about your storage resources, you can use data collection schedules to gather that information. Use the following schedules to collect data about storage resources:</p> <ul style="list-style-type: none"> • Probes: collect detailed statistics about storage resources. • Scans: collect data about the usage and trending of your storage consumption. • Pings: collect information about the availability (uptime) of computers. • Performance monitors: collect statistics about the performance of storage subsystems, switches, or fabrics. • TPC Server probes: gather the information that was collected by multiple Tivoli Storage Productivity Center servers. <p>To create data collection schedules, use either of the following methods:</p> <ul style="list-style-type: none"> • For creating probes and pings, you can use the data collection step in the Configure Devices wizard. • Go to the Monitoring > <i>schedule_name</i> node available in each manager, where <i>schedule_name</i> represents the schedule type (for example, probe, scan, ping, performance monitor). For example, to create a scan, go to the Data Manager > Monitoring > Scan node in the navigation tree. 	<p>Define data collection schedules after you determine the type of data you want to collect. You must collect data about storage resources before you can complete the other tasks within Tivoli Storage Productivity Center, such as viewing reports, enforcing storage policies, setting alerts, using the topology viewer, and managing storage subsystems.</p> <p>After you define a data collection schedule, you are not required to redefine that schedule in the future unless you want to add or remove resources. The schedule runs at the times you specified in its definition.</p> <p>For more information, see the following topics:</p> <ul style="list-style-type: none"> • Collect data from system resources • “Collecting storage statistics” on page 339 • “Collecting storage usage and trending information” on page 347 • “Determining the availability of storage resources” on page 367 • “Collecting performance data” on page 378 • “Managing fabrics” on page 578 • “Collecting storage statistics from Tivoli Storage Productivity Center servers” on page 344

Task	Description	When and how often must I complete this task?
<p>Determine the conditions that must occur before you are alerted to a problem within your environment.</p>	<p>Determining when and how you are alerted to conditions within your storage environment is important to helping you maintain and administer storage resources. Tivoli Storage Productivity Center provides an extensive list of conditions from which you can choose. See “Triggering conditions for alerts” on page 1489 for a list of triggering conditions for storage resources.</p> <p>When a condition is met and alert is triggered, you can choose to be notified through an SNMP trap, IBM Tivoli Enterprise Console event, log in notification, event log (Windows), syslog (UNIX), or email.</p> <p>To associate alert conditions with storage resources, use either of the following methods:</p> <ul style="list-style-type: none"> • Use the Configure Devices wizard to guide you through the steps for associating alert conditions with the storage resources that you want to monitor. • Go to the Alerting node available in each manager to manually associate a specific type of alert condition with storage resources. For example, to associate alert conditions with computers, go to the Data Manager > Alerting > Computer Alerts node in the navigation tree. 	<p>Define alerts:</p> <ul style="list-style-type: none"> • After you define data collection schedules • Based on the information that is gathered by data collection schedules <p>Alerts are checked whenever a probe or scan schedule collects data about storage resources. Computer, fabric, switch, and endpoint alerts are triggered by probes. Directory and storage subsystem alerts are triggered by scans. File system free space alerts are triggered by both probes and scans. All other file system alerts are triggered only by probes.</p> <p>After you define an alert, you are not required to redefine it in the future (unless you want to change it). Defining an alert is a one-time only task.</p> <p>For more information, see “Working with alerts” on page 386.</p>

Task	Description	When and how often must I complete this task?
Determine the storage policies that you want to enforce.	<p>Enforcing storage policies within your organization can be critical to ensuring the most cost-effective use of your storage resources. Use the following policy management functions to set policies for resources that are monitored by Tivoli Storage Productivity Center:</p> <ul style="list-style-type: none"> • Use quotas to define limits on the amount of storage that a user or a group of users can use. • Use Network Appliance Quotas to import, view, and report on the NetApp Quotas that are defined on NAS filers. • Use constraints to define the acceptable and unacceptable file types, file sizes, and file owners for a computer or a set of computers in your environment. • Use scheduled actions to run scripts against storage resources on a schedule that you define. 	<p>A quota runs according to the schedule that you specified. Because quotas look at the information that is gathered by scans to determine quota violations, you must schedule quotas to run after the appropriate scan. For example, if you want to restrict the amount of space that is consumed by users on specific computers, run a scan on those computers to collect usage information before you run the quota.</p> <p>Constraints are automatically checked whenever a scan is run against the storage resources to which the constraint applies.</p> <p>Schedule file system extensions after you run probes on the related storage resources and file systems.</p> <p>Run scheduled actions immediately, once at a specified time, or repeatedly according to a schedule you specify.</p> <p>For more information, see the following topics:</p> <ol style="list-style-type: none"> 1. Creating and enforcing storage policies 2. “Setting storage usage quotas” on page 447 3. “Setting file constraints” on page 472 4. “Scheduling script-based actions” on page 481
Manage storage systems and fabrics.	<p>Use the following functions to manage the storage systems and fabrics that are monitored by Tivoli Storage Productivity Center:</p> <ul style="list-style-type: none"> • Use the Storage Optimizer identify performance bottlenecks and suggest changes to improve performance. • Use the SAN Planner to help the end-to-end planning of fabrics, hosts, storage controllers, storage pools, volumes, paths, ports, zones, and zone sets. • Define storage resource groups to logically group related storage entities such as hosts, storage subsystems, fabrics, and switches. • Define element managers for storage subsystems. • Manage virtual disks: assign host ports, create virtual disks, delete virtual disks, add a managed disk to a managed-disk group, view virtual-disk information. • Manage volumes: assign host ports, create volumes, delete volumes, view information about volumes. 	<p>You can manage storage subsystems at any time after you collect information about them through discovery and monitoring jobs.</p> <p>For more information, see the following topics:</p> <ul style="list-style-type: none"> • “Optimizing storage configurations” on page 434 • “Planning and modifying storage configurations” on page 421 • “Working with workload profiles” on page 543 • “Managing storage subsystems” on page 553 • “Managing virtual disks” on page 564 • “Managing volumes” on page 572

Task	Description	When and how often must I complete this task?
Charge for storage usage.	Use the storage usage information that is gathered by data collection schedules to generate invoices that charge back for storage usage.	Generate invoices whenever you want to charge users or groups of users in your organization for their storage usage. For more information, see “Working with invoices” on page 615.
Set up and manage replication.	Use Tivoli Storage Productivity Center for Replication to manage the advanced copy services for storage system through the following tasks: <ul style="list-style-type: none"> • Setting up management servers • Adding storage connections and paths • Creating sessions and copy sets • Setting up data replication • Performing planned maintenance • Recovering from a disaster 	Access the Tivoli Storage Productivity Center for Replication user interface at any time to set up management servers and connections to storage systems. For more information, see Chapter 7, “Managing replication,” on page 667.
View information about storage resources in the topology viewer.	Use the topology viewer to see a graphical representation of the physical and logical storage resources that were discovered in your environment. You can view the health status, performance, and other details about storage resources through this function. The topology viewer includes a graphical view and a table view. The table view shows the same information as the graphical view, but in a tabular format.	You can use the topology viewer at any time after monitoring jobs to collect information about your storage environment. For more information, see “Using the topology viewer” on page 501.
View information about storage resources in predefined, user-defined, batch, and rollup reports.	Use reports to view the information that is gathered by data collection and quota schedules. Consider the following steps when you determine how to best use Tivoli Storage Productivity Center reports: <ol style="list-style-type: none"> 1. Determine how you want to generate and view reports by selecting a reporting type that best meets your needs. 2. Identify which reports contain the most important information about your storage environment. 3. Run the appropriate data collection schedules. 4. Generate the reports that you want to view. 	Perform this task after the appropriate data collection schedules are run and you want to view information about your storage resources. For more information, see the following topics: <ol style="list-style-type: none"> 1. “Choosing a reporting type” on page 815 2. “Choosing a report category” on page 817 3. “What can I find out using reports?” on page 823 4. “Working with reports” on page 831
Troubleshoot problems.	Use troubleshooting tips to resolve any problems you might have with Tivoli Storage Productivity Center.	Perform troubleshooting tasks when you encounter problems. Troubleshooting information is meant to help you with resolving issues that might occur when you use the product.

Chapter 2. Product overview

IBM Tivoli Storage Productivity Center provides a set of policy-driven automated tools for managing storage capacity, availability, events, performance, and resources. It can reduce the complexity of managing a storage environment by centralizing, simplifying, and optimizing storage tasks that are associated with storage systems, storage networks, replication services, and capacity management.

Because it is policy-based, Tivoli Storage Productivity Center can detect potential problems and automatically adjust storage and resources based on the policies and actions that you define. For example, it can notify you when a server or storage system is running out of disk space or warn you of impending storage hardware failure. By alerting you to these and other issues that are related to your stored data, you can use Tivoli Storage Productivity Center to prevent unnecessary system and application downtime.

Tivoli Storage Productivity Center provides the following benefits and functions:

- Simplifies the management of storage infrastructures
- Manages, configures, and provisions SAN-attached storage
- Monitors and tracks performance of SAN-attached devices
- Monitors, manages, and controls (through zones) SAN fabric components
- Manages the capacity utilization and availability of file systems and databases

For select IBM hardware orders only, IBM Tivoli Storage Productivity Center Limited Edition, limited to 2 TB of managed storage, is provided at no charge, and with one-year software maintenance. IBM Tivoli Storage Productivity Center Select Edition includes support for TS3500 and limited support for 3494 tape libraries.

Introducing IBM Tivoli Storage Productivity Center

This section provides an overview of IBM Tivoli Storage Productivity Center.

You can use Tivoli Storage Productivity Center to identify, evaluate, and monitor the resources in your storage environment. Learn about the architecture, licenses, and components that provide the framework for its functions.

Architecture

The IBM Tivoli Storage Productivity Center consists of several key components. This topic identifies these components and shows how they are related.

Data server

This component is the control point for product scheduling functions, configuration, event information, reporting, and graphical user interface (GUI) support. It coordinates communication with and data collection from agents that scan file systems and databases to gather storage demographics and populate the database with results. Automated actions can be defined to perform file system extension, data deletion, and Tivoli Storage Productivity Center backup or archiving, or event reporting when defined thresholds are encountered. The Data server is the primary contact point for GUI user interface functions. It also includes functions that schedule data collection and discovery for the Device server.

Device server

This component discovers, gathers information from, analyzes performance of, and controls storage subsystems and SAN fabrics. It coordinates communication with and data collection from agents that scan SAN fabrics and storage devices.

Replication server

This component coordinates communication and processes tasks that are related to replication and Tivoli Storage Productivity Center for Replication.

Database

A single database instance serves as the repository for all Tivoli Storage Productivity Center components.

Agents

Storage Resource agents, CIM agents, and Out of Band fabric agents gather host, application, storage system, and SAN fabric information and send that information to the Data Server or Device server.

Tip: Data agents and Fabric agents are supported in V4.2. However, no new functions were added to those agents for that release. For optimal results when using Tivoli Storage Productivity Center, migrate the Data agents and Fabric agents to Storage Resource agents.

GUI Tivoli Storage Productivity Center provides two graphical user interfaces for managing the storage infrastructure in an enterprise environment. a stand-alone GUI and the web-based GUI. Each GUI provides different functions for working with monitored resources. To view a comparison of the functions that are available in each GUI, see “Available functions and report information in the interfaces” on page 21.

CLI Use the command-line interface (CLI) to issue commands for key Tivoli Storage Productivity Center functions.

Tivoli Integrated Portal

The Tivoli Storage Productivity Center installation program includes IBM Tivoli Integrated Portal. Tivoli Integrated Portal is a standards-based architecture for Web administration. Tivoli Integrated Portal enables developers to build administrative interfaces for IBM and independent software products as individual plug-ins to a common console network. The installation of Tivoli Integrated Portal is required to enable single sign-on for Tivoli Storage Productivity Center. *Single sign-on* is an authentication process that you can use to enter one user ID and password to access multiple applications. Single sign-on integrates with launch in context features so you can move smoothly from one application to another application.

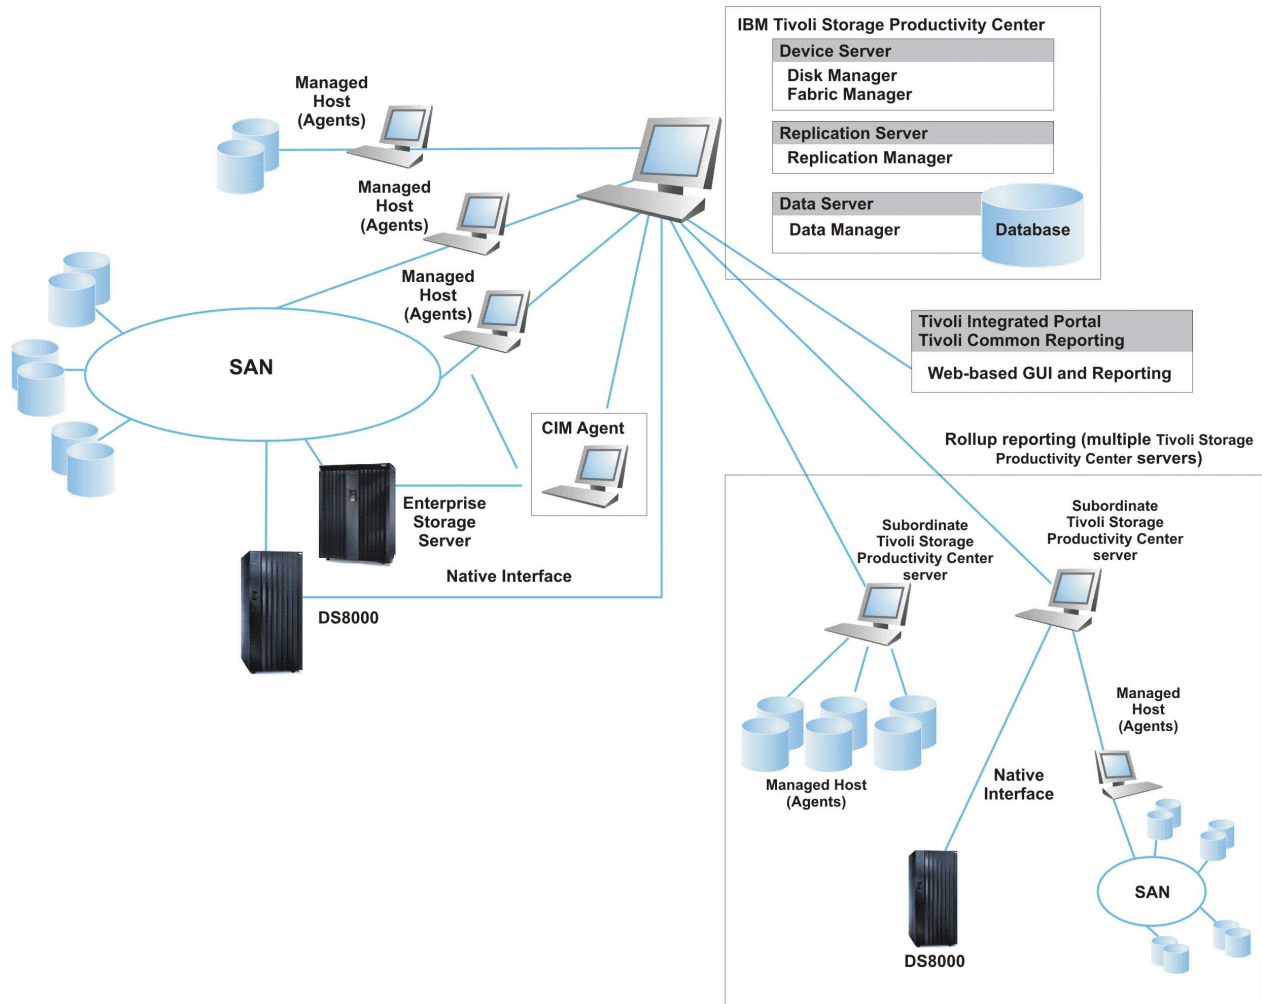

Figure 1. Tivoli Storage Productivity Center components

IBM Tivoli Storage Productivity Center summary

A summary of the functionality for Tivoli Storage Productivity Center is provided.

The Tivoli Storage Productivity Center functions are shown in Table 2 on page 14.

Table 2. Tivoli Storage Productivity Center summary of functions

Data management	Disk management	Fabric management	Tape management
Host-centric: <ul style="list-style-type: none"> • Discovery of storage resources • Monitoring of storage resources • File system extension • Enterprise-wide reporting Application-centric: <ul style="list-style-type: none"> • Monitoring of relational databases DB2, Oracle, SQL Server, Sybase • Chargeback 	For storage subsystems: <ul style="list-style-type: none"> • Discovery of storage resources • Monitoring of storage resources • Configuration (for example, creating volumes) • Performance management 	For fabrics: <ul style="list-style-type: none"> • Discovery of storage resources • Monitoring of storage resources • Configuration (for example, zoning) • Performance management 	For tape libraries: <ul style="list-style-type: none"> • Discovery of storage resources • Monitoring of storage resources

Product licenses for Tivoli Storage Productivity Center

Product licenses are available for IBM Tivoli Storage Productivity Center. Each license determines the functions that are accessible in the stand-alone GUI, command-line interface, and the API. You can review the functions that are included with each license and determine which license meets your storage management needs.

IBM Tivoli Storage Productivity Center

This license contains the following functions:

Data management

A file and capacity management solution for heterogeneous storage environments. Data management includes enterprise-wide reporting and monitoring, and automated capacity provisioning for Direct Attached Storage (DAS), network-attached storage (NAS), and Storage Area Network (SAN) environments.

Disk management

Disk management helps you manage SANs and heterogeneous storage from one console.

Fabric management

Fabric management helps you manage the SAN fabric that connects the host systems and applications to the storage devices. This feature is a comprehensive management solution for multi-vendor SANs and includes automatic resource and topology discovery, monitoring, alerts, and zone control.

Tape management

Tape management helps you manage your SMI-S compliant tape libraries.

Tivoli Storage Productivity Center for Replication

This license includes all the Tivoli Storage Productivity Center for Replication functions.

Performance management

Disk and Fabric performance management functions.

Device support

You can see a complete list of devices that can be used with Tivoli Storage Productivity Center at <https://www.ibm.com/support/docview.wss?uid=swg21386446>. Click the appropriate release under **Storage**.

IBM Storage Productivity Center Select Edition

This license contains all the functions of the IBM Tivoli Storage Productivity Center license. This license is priced by enclosure rather than by capacity.

IBM Tivoli Storage Productivity Center Advanced

This license contains everything in IBM Tivoli Storage Productivity Center license and the following functions:

Analytical functions

- Configuration analysis
- Configuration history
- SAN Planner
- Storage Optimizer

Tivoli Storage Productivity Center for data-related functions

- Scans
- Policy management
- Server probes
- Scans
- Profiles
- Data Manager for databases
- Data Manager for Chargeback

Use the following tables to view the specific functions, reports, and elements of the user interface that are available with each license.

User interfaces to Tivoli Storage Productivity Center

Tivoli Storage Productivity Center provides multiple user interfaces for managing the storage infrastructure in an enterprise environment.

The following user interfaces are provided:

- A stand-alone GUI for completing all the storage management tasks that are available in Tivoli Storage Productivity Center. This interface is the same interface that was used in previous versions, and provides full access to all the new functions (except for web-based GUI reporting) and existing functions in the product.
- A web-based GUI for monitoring and troubleshooting the condition of storage resources in your environment. From the web-based GUI, you can view predefined reports, create custom reports, and design custom reports about storage resources. This new, improved interface provides quick access to key storage asset, status, and performance information that is collected by Tivoli Storage Productivity Center. You can access this interface from anywhere that you have a web browser and connectivity to a network.
- A command-line interface for running Tivoli Storage Productivity Center commands from a command prompt.

Each GUI provides different functions for working with monitored resources. Determine which GUI to use based on the tasks that you need to complete.

Related concepts:

Chapter 6, “Managing resources in the web-based GUI,” on page 625
You can use the web-based GUI to monitor the condition, capacity, and relationships of the monitored resources within your storage environment.

Available functions and report information in the interfaces

IBM Tivoli Storage Productivity Center 5.1 provides two graphical user interfaces (GUI) for managing the resources in a storage environment: a stand-alone GUI and a web-based GUI. Each interface provides different functions for working with monitored resources.

GUI overview

Use the following information to determine which interface best helps you complete your storage-management tasks.

stand-alone GUI

This interface contains the functions that you can use to monitor the condition of storage resources, and all the tools to manage data, disk, fabric, tape, and replication. The stand-alone GUI is the same interface that is available in previous versions of the product, and provides full access to all the functions that were available in those versions.

web-based GUI

This interface provides quick access to pages that you can use to monitor the condition, capacity, and relationships of the resources within your storage environment. Specifically, use the web-based GUI to complete the following tasks:

- View and acknowledge the status of resources that are monitored by Tivoli Storage Productivity Center. Resources include storage systems, servers, hypervisors, fabrics, and switches. Use this information to quickly determine the state of your storage environment.

- View summary and detailed information about resources, including properties, storage usage, storage capacity, and several key performance metrics. Use this information to monitor the storage on your hardware. For example, when migrating large amounts of data, you can identify the target resources that have enough storage capacity to accommodate the data and require the least amount of reconfiguration.
- View the relationships and storage mapping among resources. For example, you can view the resources such as servers and hypervisors to which volumes from a storage system are assigned.
- View the connectivity between host connections, servers, hypervisors, virtual machines, storage systems, and the fabrics through which they share storage. You can use this view to monitor status and pinpoint problem areas in selected data paths. This view includes graphical and tabular representations of the top-level resources in a data path.
- Identify potential problems and troubleshoot existing problems in a storage environment. For example, you can locate the internal resources of a storage system that might be causing a bottleneck in storage utilization.
- In the reporting, web-based interface, use a drag-and-drop approach to design custom reports that contain detailed information about the properties and performance of monitored resources. All the performance metrics from the stand-alone GUI are available in the reporting interface. For example, you can drag key metrics into a report to create and generate a performance chart for a specific volume of a storage system. The reporting interface also includes a set of predefined reports that provides quick access to preformatted data about resources.

Configuring and administering

Use the following list to view the specific configuring and administering tasks that you can complete in each GUI.

Table 6. Available configuring and administering tasks in each GUI

Tasks	Available in web-based GUI	Available in stand-alone GUI
Adding and managing data sources, including agents	No	Yes
Discovering resources for monitoring	No	Yes
Configuring resources for monitoring	No	Yes
Configuring Tivoli Storage Productivity Center	No	Yes
Starting element managers		
<ul style="list-style-type: none"> • Storage systems • Switches 	<ul style="list-style-type: none"> • Yes, the start page • Yes, the start page 	<ul style="list-style-type: none"> • Yes, in context • Yes, in context
Administering Tivoli Storage Productivity Center services	No	Yes
Managing Tivoli Storage Productivity Center jobs:		
<ul style="list-style-type: none"> • Viewing information about jobs • Administering jobs 	<ul style="list-style-type: none"> • Yes • No 	<ul style="list-style-type: none"> • Yes • Yes

Monitoring

Use the following list to view the specific monitoring tasks that you can complete in each GUI.

Table 7. Available monitoring tasks in each GUI

Tasks	Available in web-based GUI	Available in stand-alone GUI
Creating data collection schedules and groups	No	Yes
Creating storage resource groups	No	Yes
Managing replication	No	Yes
Viewing information about the following resources: <ul style="list-style-type: none"> • Storage systems • Servers • Hypervisors • Switches • Fabrics • Tape libraries • Databases 	<ul style="list-style-type: none"> • Yes • Yes • Yes • Yes • Yes • No • No 	<ul style="list-style-type: none"> • Yes • Yes • Yes • Yes • Yes • Yes • Yes
Viewing the following information about resources: <ul style="list-style-type: none"> • Status • Capacity (including used and available space) • Relationships between resources • Data paths 	<ul style="list-style-type: none"> • Yes • Yes • Yes • Yes 	<ul style="list-style-type: none"> • Yes • Yes • Yes • Yes
Exporting information about resources to a file	Yes	Yes
Running analytics: <ul style="list-style-type: none"> • Configuration history • Storage optimizer • SAN Planner • Configuration analysis 	<ul style="list-style-type: none"> • No • No • No • No 	<ul style="list-style-type: none"> • Yes • Yes • Yes • Yes
Managing zones and zone sets	No	Yes
Viewing a visual topology of resources	No	Yes
Viewing data paths for resources	Yes	Yes
Creating storage policies	No	Yes
Charging back for storage usage	No	Yes

Alerting

Use the following list to view the specific alerting tasks that you can complete in each GUI.

Table 8. Available alerting tasks in each GUI

Tasks	Available in web-based GUI	Available in stand-alone GUI
Creating alerts	No	Yes
Viewing alert conditions that are detected on monitored resources	Yes	Yes
Acknowledging the status of alerts	Yes	Yes
Removing alerts	Yes	Yes

Reporting

Use the following lists to view the specific reporting tasks and information that you can complete in each GUI.

Reporting tasks

Table 9. Available reporting tasks in each GUI

Tasks	Available in web-based GUI	Available in stand-alone GUI
Accessing the web-based reporting interface	Yes	No
Saving reports	Yes	Yes
Scheduling reports	Yes	Yes

Reporting information

Table 10. Available reporting information in each GUI

Information	Available in web-based GUI	Available in stand-alone GUI
Resource properties	Yes*	Yes
Performance	Yes	Yes
Capacity (including used and available space)	Yes	Yes
Historical capacity	Yes	Yes
Storage tiering	Yes	No
Policy violations	No	Yes
Rollup servers	No	Yes
File statistics	No	Yes
Tape libraries	No	Yes
Data sources	No	Yes
Databases	No	Yes
Note: * Information about the properties of fabrics is not available.		

The stand-alone GUI

Use the stand-alone GUI to complete all your storage management tasks. The main window for this interface is organized into two main sections: the navigation tree and the content pane.

Navigation tree

The navigation tree is displayed on the left side of the main window. You can expand, select, and collapse the nodes in the tree to navigate through the interface. Each node represents a function or task for managing storage.

<p><i>Figure 2. Navigation tree</i></p>  <p>Navigation Tree</p> <ul style="list-style-type: none">- Administrative Services<ul style="list-style-type: none">+ Services+ Data Sources+ Discovery+ Configuration- IBM Tivoli Storage Productivity Center<ul style="list-style-type: none">Configuration UtilityConfigure DevicesJob Management+ Reporting+ Topology+ MonitoringStorage Resource Group Management+ Analytics+ Alerting- Data Manager<ul style="list-style-type: none">+ Monitoring+ Alerting+ Policy Management+ Reporting+ Data Manager for Databases+ Data Manager for Chargeback+ Disk Manager+ Fabric Manager+ Tape Manager+ Element Manager+ Replication Manager	<p>When you start Tivoli Storage Productivity Center, the navigation tree is expanded to show all the high-level functions in the product. To view the nodes within each high-level function, click the expand icon next to the node or double click the name of the node.</p> <p>Expanding and collapsing the navigation tree: If the navigation tree gets too large, or if you want to return it to its original state, right-click on the major nodes of the tree and select Collapse Branch or Expand Branch. For example, right-click the IBM Tivoli Storage Productivity Center node and select Collapse Branch to collapse all the nodes in that branch of tree. To expand all the nodes in the IBM Tivoli Storage Productivity Center branch, right click the node and select Expand Branch.</p> <p>Printing the navigation tree: Right-click on a node and choose Print Branch to print all the subnodes within that node.</p>
--	--

Content pane

The content pane is displayed on the right side of the main window. When you select a node in the navigation tree, a corresponding panel is displayed in the content pane. Use the panels in the content pane to complete tasks such as configuring Tivoli Storage Productivity Center, creating data collection schedules, defining alerts, and viewing reports.

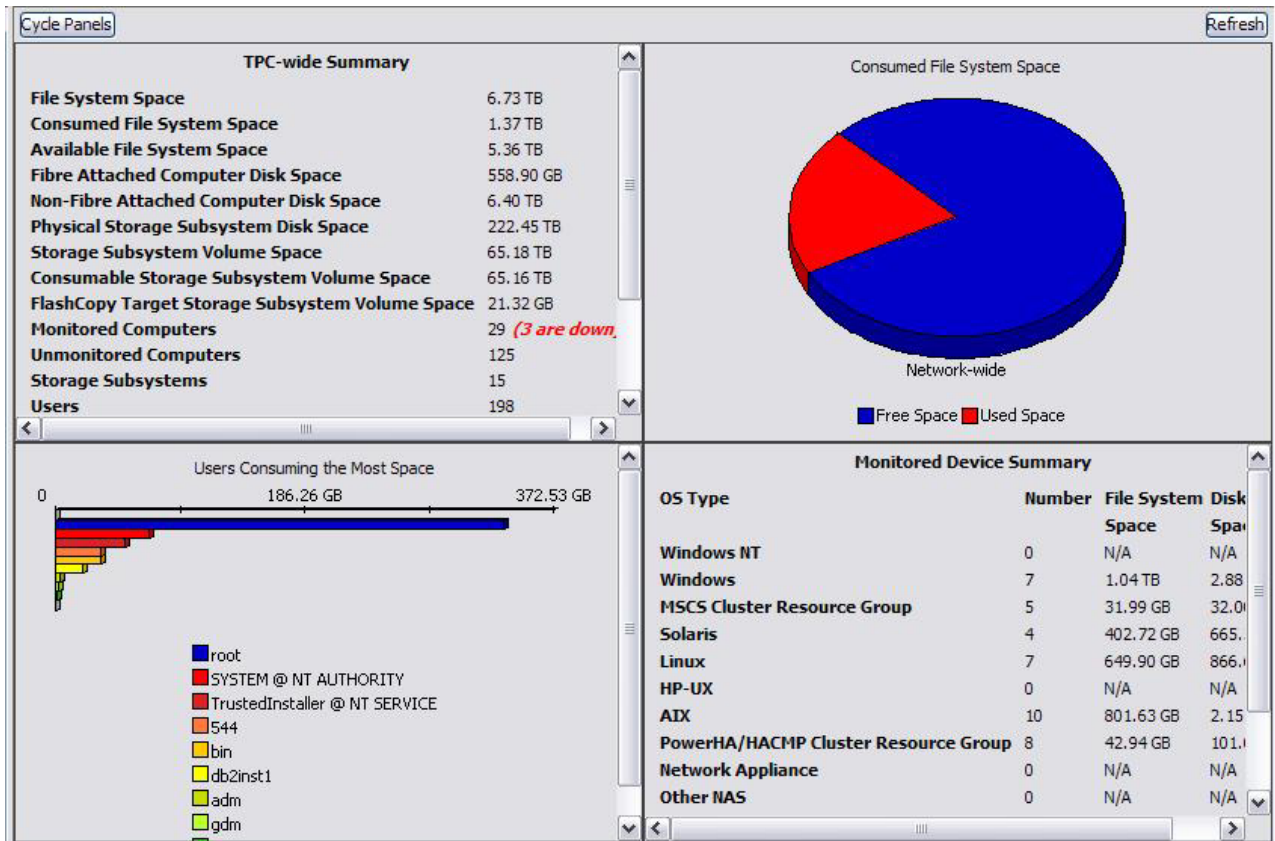

Figure 3. Content pane

Navigation tree:

The navigation tree shows all of the available resource management tasks, which are organized by major topic nodes for Administrative Services, IBM Tivoli Storage Productivity Center, Data Manager, Disk Manager, Fabric Manager, and Tape Manager.

Administrative Services

Provides product configuration functions for Tivoli Storage Productivity Center.

This node is always present.

Tivoli Storage Productivity Center

Provides operational functions for Tivoli Storage Productivity Center.

This node is always present.

Data Manager

Provides operational functions for the Data Manager.

This node is present when Data Manager is installed and licensed.

For Data Manager functions, you must use Storage Resource agents to collect data about your storage resources. For example, use scans, pings, and probes to collect data about the computers on which the agents are installed.

Data Manager for Databases

Provides operational functions for Data Manager for Databases.

This node is present when Data Manager is installed and licensed.

Data Manager for Chargeback

Provides operational functions for Data Manager for Chargeback.

This node is present when Data Manager is installed and licensed.

Disk Manager

Provides operational functions for the Disk Manager.

This node is present when Disk Manager is installed and licensed. A subset of the functions is provided when you install the Data Server.

For Disk Manager functions, the subsystem CIMOMs and data collection are required (for example, through probes), except for devices that use the native API connection, for example: System Storage DS8000, SAN Volume Controller, and the XIV system.

Fabric Manager

Provides operational functions for the Fabric Manager.

This node is present when Fabric Manager is installed.

For Fabric Manager functions, the available agent types are CIM agents, in-band fabric agents, out-of-band fabric agents, and Storage Resource Agents. You must run a data collection job (for example, through probe jobs). If you want to complete zone control actions, the in-band fabric agents for QLogic and Cisco fabrics must be deployed. For Fabric Manager features such as zone control and performance monitoring, you must collect data from performance monitors. For a list of current agent types that are supported for the Switch Performance Management functionality and the Fabric Zone Configuration functionality, see “Fabric Manager” on page 1479.

Tape Manager

Provides operational functions for the tape library.

This node is present when the Device server is installed.

For Tape Manager functions, the library CIMOMs and data collection are required (for example, probes).

Element Manager

Provides access to the **Element Manager** tab of the Configuration Utility where you can configure and administer IBM System Storage DS8000 and other storage subsystems.

Replication Manager

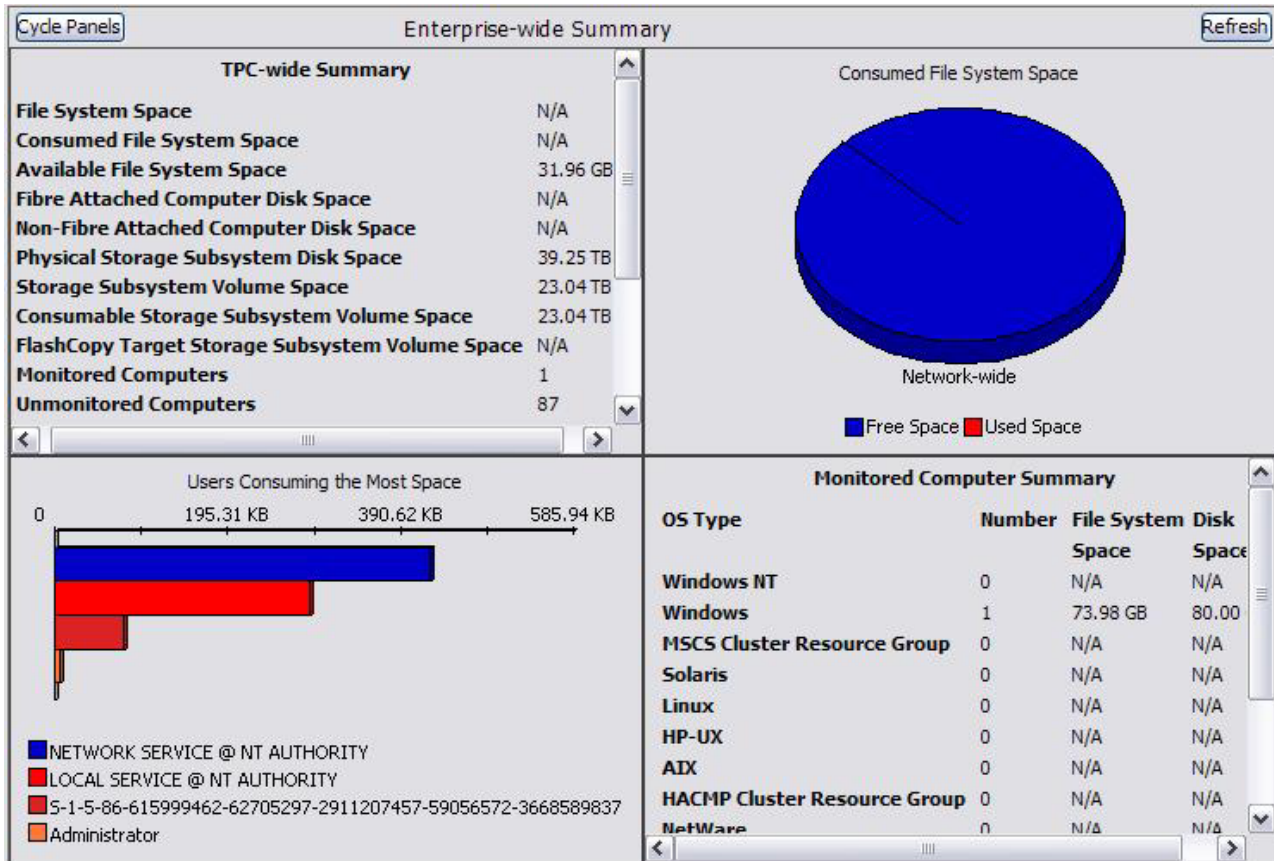

Provides access to the **Replication Manager** tab of the Configuration Utility where you can manage IBM Tivoli Storage Productivity Center for Replication and to set the triggering condition and actions for alerts that are associated with Tivoli Storage Productivity Center for Replication.

Dashboard:

The dashboard provides a concise, yet detailed overview of the health of your storage environment. It quickly points out potential problem areas that need further investigation.

When you first log in to IBM Tivoli Storage Productivity Center you are asked if you want to collect statistics. You must answer yes in order for the dashboard information to be displayed. The dashboard then appears whenever you start the product or close all the active windows in a running session.

The dashboard contains four display areas and seven panels that you can cycle through to view your environment's storage information.

Using the dashboard:

Use the dashboard to monitor the overall status of your storage resources.

Purpose

When you first log on to Tivoli Storage Productivity Center or close all of the active panels, the topic pane shows the dashboard. The dashboard provides a concise, yet detailed overview of the status of your storage environment. Use the dashboard to show potential problem areas that need further investigation. The dashboard contains four displayable areas and eight panels to view the storage information that is collected for your environment.

Keep in mind the following considerations when you view information about the dashboard:

- The information in the dashboard is collected by data collection schedules and aggregated by the history aggregator. To ensure that the latest information is displayed in the dashboard, run the history aggregator regularly. See the information center for instructions about how to create and schedule history aggregator jobs.
- The value in the **All** field on the Alerts Pending panel might be higher than the sum of the alerts that are shown in the other fields on that panel. This situation occurs because some alerts are not associated with a specific category, and are reflected in the value that is shown in the **All** field only.

- The names of some fields were updated. For your reference, the original names of the fields are shown in parentheses () next to the new names.
- Click **Refresh** to update the displayed panels. You must click **Refresh** to ensure that the latest information from the history aggregator is displayed in the dashboard.
- Click **Cycle Panels** to cycle through the panels in the dashboard and view information about your storage assets.

TPC-wide Summary panel

Use the TPC-wide Summary panel to view an enterprise-wide summary of your storage. The following values are provided:

File System Space (Capacity)

The total amount of unique file system storage space on computers where a Storage Resource agent is installed. Tivoli Storage Productivity Center does not include the following file systems in its calculation of the value for this field:

- File systems that are missing after a probe
- File systems that are discovered on virtual machines where an agent is installed
- File systems that are mounted remotely and are not identified to a network-attached storage server
- File systems that are not mounted

Consumed File System Space (Filesystem Used Space)

The total amount of unique file system storage space that is used by the computers where a Storage Resource agent is installed. Tivoli Storage Productivity Center does not include the following file systems in its calculation of the value for this field:

- File systems that are missing after a probe
- File systems on discovered hypervisors that are assigned to virtual machines where an agent is installed
- File systems on virtual machines where an agent is installed, but the hypervisors for the virtual machines are not discovered, and the total used space exceeds the capacity of the total file system
- File systems that are mounted remotely and are not identified to a network-attached storage server
- File systems that are not mounted

Available File System Space (Filesystem Free Space)

The total amount of unique file system storage space that is available to the computers where a Storage Resource agent is installed. Tivoli Storage Productivity Center does not include the following file systems in its calculation of the value for this field:

- File systems that are missing after a probe
- File systems that are mounted remotely and are not identified to a network-attached storage server
- File systems that are not mounted

Fibre Attached Computer Disk Space (Computer Fibre Attached Disk Space)

The total amount of unique disk space on computers where a Storage Resource agent is installed and the disks are attached through a fibre

channel port. Tivoli Storage Productivity Center does not include the following disks in its calculation of the value for this field:

- Computer disks that are behind a fibre channel port that was not identified by an agent
- Computer disks that are not behind a fibre channel port
- Computer disks that are discovered on virtual machines where an agent is installed
- Computer disks that are missing after a probe

Non-Fibre Attached Computer Disk Space (Computer Non-fibre Attached Disk Space)

The total amount of unique disk space on computers where a Storage Resource agent is installed and the disks are not attached through a fibre channel port. Tivoli Storage Productivity Center does not include the following disks in its calculation of the value for this field:

- Computer disks that are behind a fibre channel port
- Computer disks that are discovered on virtual machine where an agent is installed
- Computer disks that are missing after a probe

Physical Storage Subsystem Disk Space (Storage Subsystem Physical Disk Space)

The total amount of unique internal physical disk space on the storage subsystem arrays that are monitored by subordinate servers and the master server. Tivoli Storage Productivity Center does not include the following storage space in its calculation of the value for this field:

- Storage subsystem disks that are missing after a storage subsystem probe
- Back-end storage volumes on monitored storage subsystem virtualizers (such as SAN Volume Controller) that are attached from a storage subsystem.
- Storage subsystem disks that are on storage subsystems that were not probed by the subordinate servers or the master server.

Storage Subsystem Volume Space (LUN Capacity)

The total amount of unique storage subsystem volume space and virtual storage volume space on the storage subsystem arrays that are monitored by subordinate servers and the master server. Tivoli Storage Productivity Center does not include the following volumes in its calculation of the value for this field:

- Storage subsystem volumes or virtual storage volumes that are missing after a storage subsystem probe
- Storage subsystem volumes or virtual storage volumes that Tivoli Storage Productivity Center identifies as back-end storage volumes on monitored storage subsystem virtualizers (such as SAN Volume Controller).
- Storage subsystem disks that are on storage subsystems that were not probed by the subordinate servers or the master server.

Consumable Storage Subsystem Volume Space (Usable LUN Capacity)

The amount of storage space for a file system. The total amount of unique storage subsystem volume space and virtual storage volume space on monitored storage subsystem arrays that can be assigned or are assigned to systems within the network. Tivoli Storage Productivity Center does not include the following columns in its calculation of the value for this field:

- Storage subsystem volumes or virtual storage volumes that become missing after a storage subsystem probe
- Storage subsystem volumes or virtual storage volumes that are used as FlashCopy targets
- Storage subsystem volumes or virtual storage volumes that are identified as Business Continuance Volume extended (BCVx)
- Storage subsystem volumes or virtual storage volumes that are used as a Volume Configuration Management (VCM) database
- Storage subsystem volumes or virtual storage volumes that Tivoli Storage Productivity Center identifies as back-end storage volumes on monitored storage subsystem virtualizers (such as SAN Volume Controller).

FlashCopy Target Storage Subsystem Volume Space (FlashCopy Target Capacity)

The total amount of unique storage subsystem volume space and virtual storage volume space on monitored storage subsystem arrays that is identified as FlashCopy target space. Tivoli Storage Productivity Center does not include the following volumes in its calculation of the value for this field:

- Storage subsystem volumes or virtual storage volumes that are missing after a storage subsystem probe
- Storage subsystem volumes or virtual storage volumes that are not used as FlashCopy targets

Monitored Computers (Servers)

The total number of computers where a Storage Resource agent is installed and are detected by the Data server. Tivoli Storage Productivity Center does not include the following systems in its calculation of the value for this field:

- Systems where an agent is installed, but was not started, or was unable to communicate with the Data server
- Systems where an agent is not installed
- Systems where an agent is installed, but that agent communicates with a different Tivoli Storage Productivity Center server
- Systems that have been removed from the Administrative Services > Data Sources > Storage Resource agents panel.
- Hypervisors

Unmonitored Computers (Servers)

The total number of computers that are found in a Windows domain that do not have a Storage Resource agent communicating with the Data server. Tivoli Storage Productivity Center does not include the following systems in its calculation of the value for this field:

- Systems that are not running a Windows operating system
- Systems that are not in a Windows domain
- Systems where an agent is installed and is communicating with a Data server

Storage subsystems

The total number of storage subsystems that were discovered and probed. Tivoli Storage Productivity Center does not include the following storage subsystems in its calculation of the value for this field:

- Storage subsystems that were discovered but not probed
- Storage subsystems that were not discovered

- Storage subsystems that were removed from the Disk Manager > Storage Subsystems panel.

Users The total number of user accounts that are discovered by Storage Resource agents.

Disks The total number of unique disks that are discovered by Storage Resource agent probes, hypervisor probes, network storage filer probes, and storage subsystem probes. The value does not include disks that have become missing after a successful probe.

Storage Subsystem Volumes (LUNS)

The total number of unique storage volumes and virtual storage volumes that are discovered by storage subsystem probes. This value does not include storage volumes or virtual storage volumes that have become missing after a successful storage subsystem probe.

File systems

The total number of unique file systems that are discovered by probes. This value excludes file systems that have become missing after a successful probe.

Directories

The total number of directories that are discovered by scans. Tivoli Storage Productivity Center does not include the following directories in its calculation of the value for this field:

- Directories within file systems that were discovered by a probe but were not scanned
- Directories that have become missing after a successful probe

Files The total number of files that are discovered by scans. Tivoli Storage Productivity Center does not include the following files in its calculation of the value for this field:

- Files within file systems that were discovered by a probe but were not scanned
- Files that are missing after a successful probe

Rollup Summary panel

Use the Rollup Summary panel to view a summary of information that is collected by the master server and by Tivoli Storage Productivity Center servers that are subordinate servers.

File System Space (Capacity)

The total amount of unique file system storage space on the computers that are monitored by subordinate servers and the master server. Tivoli Storage Productivity Center does not include the following file systems in its calculation of the value for this field:

- File systems that are missing after a probe
- File systems that are discovered on virtual machines where the Storage Resource agent is installed
- File systems that are mounted remotely and are not identified to a network-attached storage server
- File systems that are not mounted
- File systems that have not been probed by subordinate servers or the master server

Consumed File System Space (Used Space)

The total amount of unique file system storage space that is used by the computers that are monitored by subordinate servers and the master server. Tivoli Storage Productivity Center does not include the following file systems in its calculation of the value for this field:

- File systems that are missing after a probe
- File systems on discovered hypervisors that are assigned to virtual machines where the Storage Resource agent is installed
- File systems on virtual machines where the Storage Resource agent is installed, but the hypervisors for the virtual machines have not been discovered and the total used space exceeds the capacity of the total file system capacity
- File systems that are mounted remotely and are not identified to a network-attached storage server
- File systems that are not mounted
- File systems that have were not probed by subordinate servers or the master server

Available File System Space (Filesystem Free Space)

The total amount of unique file system storage space that is not available to the systems that are monitored by subordinate servers and the master server. Tivoli Storage Productivity Center does not include the following file systems in its calculation of the value for this field:

- File systems that are missing after a probe.
- File systems that are mounted remotely and are not identified to a network-attached storage server
- File systems that are not mounted
- File systems that were not probed by subordinate servers or the master server

Physical Storage Subsystem Disk Space (Storage Subsystem Physical Disk Space)

The total amount of unique internal physical disk space on monitored storage subsystem arrays. Tivoli Storage Productivity Center does not include the following storage space in its calculation of the value for this field:

- Storage subsystem disks that are missing after a storage subsystem probe
- Back-end storage volumes on monitored storage subsystem virtualizers (such as SAN Volume Controller) that are attached from a storage subsystem

Storage Subsystem Volume Space (LUN Capacity)

The total amount of unique storage subsystem volume space and virtual storage volume space on monitored storage subsystem arrays. Tivoli Storage Productivity Center does not include the following volumes in its calculation of the value for this field:

- Storage subsystem volumes or virtual storage volumes that are missing after a storage subsystem probe
- Storage subsystem volumes or virtual storage volumes that Tivoli Storage Productivity Center identifies as back-end storage volumes on monitored storage subsystem virtualizers (such as SAN Volume Controller).

Consumable Storage Subsystem Volume Space (Usable LUN Capacity)

The total amount of unique storage subsystem volume space and virtual storage volume space on storage subsystem arrays that are monitored by subordinate servers and the master server and can be assigned or are assigned to systems within the network. Tivoli Storage Productivity Center does not include the following storage space in its calculation of the value for this field:

- Storage subsystem volumes or virtual storage volumes that are missing after a storage subsystem probe
- Storage subsystem volumes or virtual storage volumes that are used as FlashCopy targets
- Storage subsystem volumes or virtual storage volumes that are identified as Business Continuance Volume extended (BCVx)
- Storage subsystem volumes or virtual storage volumes that are used as a Volume Configuration Management (VCM) database
- Storage subsystem volumes or virtual storage volumes that Tivoli Storage Productivity Center identifies as back-end storage volumes on monitored storage subsystem virtualizers (for example, SAN Volume Controller)
- Storage subsystem disks that are on storage subsystems that have not been probed by the subordinate servers or the master server

Monitored TPC Servers

The total number of subordinate servers that are monitored by the master server.

Monitored Computers (Servers)

The total number of computers that are monitored by Tivoli Storage Productivity Center and are detected by the subordinate and the master server. Tivoli Storage Productivity Center does not include the following systems in its calculation of the value for this field:

- Systems where an agent is installed but was not started, or was unable to communicate with the Data server
- Systems where an agent is not installed
- Systems where an agent is installed, but that agent communicates with a Tivoli Storage Productivity Center server that is not a subordinate server or the master server
- Systems that have been removed from the Administrative Services > Data Sources > Storage Resource agents panel.

Storage subsystems

The total number of storage subsystems that were discovered and probed by subordinate servers and the master server. Tivoli Storage Productivity Center does not include the following storage subsystems in its calculation of the value for this field:

- Storage subsystems that were discovered but not probed
- Storage subsystems that were not discovered
- Storage subsystems that were removed because of the storage subsystem settings on the Removed Resource Retention panel.

Consumed File System Space (Filesystem Used Space) panel

Use the chart on this panel to view the total amount of used file system storage space across the entire network.

Users Consuming the Most Space (chart) panel

Use the Users Consuming the Most Space (chart) panel to view the following information:

- A list of the users consuming the most space within your environment
- A graphical view of the amount of space they are consuming

The chart on the Users Consuming the Most Space (chart) panel shows information about users across the network. If multiple hosts contain the same user name, the value displayed for that user represents the space consumed on all the hosts. For example, if the user "root" exists on three hosts that are monitored by Tivoli Storage Productivity Center, then the value displayed on this chart represents the space consumed by "root" on those three hosts.

Note: The space usage of administrative users within your environment is not included as part of this dashboard report.

Monitored Computer Summary panel

Use the Monitored Computer Summary panel to view the following information:

- The number of monitored computers that run each type of operating system
- The total amount of file system capacity and disk capacity for each type of operating system

Filesystems with Least Free Space Percentage panel

Use the Filesystems with Least Free Space Percentage panel to view the monitored computers with the least percentage of free space, including the following values:

- Percent of free space on each computer
- Total file system capacity on each computer
- Name of the computers, file systems, and mount points

Users Consuming the Most Space Report panel

Use the Users Consuming the Most Space Report panel to view the following information:

- A list of the users consuming the most space within your environment
- The total amount of storage each user is consuming

Alerts Pending panel

Use the Alerts Pending panel to view the active alerts that are still pending.

Note: The number of alerts on this panel might be less than the number of alerts shown in the IBM Tivoli Storage Productivity Center > Alerting > Alert Log. Alerts for failed jobs (pings, probes, and scans) are not listed in separate rows on this panel, but are included in the total displayed in the All row.

These alerts are organized into the following categories:

- All
- Computer
- Disk
- Filesystem

- Directory
- User Quota
- OS User Group Quota
- Directed to *user*
- Storage Subsystem
- Switch
- Fabric
- Endpoint Device
- External
- Tape Library
- Hypervisor
- Authentication Configuration
- Replication
- Configuration Analysis
- NAS Node
- NAS File Set
- Export

Working with the navigation tree and content pane:

This section describes some methods for working with the nodes and windows in the navigation tree and content pane.

Right-clicking and pop-up menus:

Right-click nodes in the navigation tree to access menus that contain actions you can perform.

As you navigate through the IBM Tivoli Storage Productivity Center user interface, notice that you can right-click nodes in the navigation tree to access menus that contain actions related to that node. Use these actions to quickly access many product functions.

The following actions are available for the nodes in the navigation tree:

Option	Description
Create <object>	Create an object, including a group, data collection schedule, policy, batch report, or alert.
Delete	Delete the selected object definition, such as a data collection schedule, policy, batch report, group, or alert. This action is not available for definitions owned by TPCUser.
Rename	Rename the object definition. This action is not available for definitions owned by TPCUser.
Refresh	Refresh the list of objects in the navigation tree. The navigation tree is not updated automatically. You must click Refresh for a node to view the latest objects related to that node. For example, right-click the Tivoli Storage Productivity Center > Monitoring > Probes node and select Refresh to update the probe schedules that are listed in the navigation tree.
Job History	View the list of jobs related to a data collection or batch report schedule on the Job Management panel.

Option	Description
Run Now	Run a data collection or batch report schedule immediately.
Collapse Branch	Minimize the navigation tree under the selected node.
Expand Branch	Open the navigation tree under the selected node.
Print Branch	Print the contents of the navigation tree under the selected node.

Selecting panels in the content pane:

The content pane is displayed on the right side of the stand-alone GUI. When you click a node in the navigation tree, a corresponding panel is displayed in the content pane. Use the panels in the content pane to complete storage management tasks.

Each time you select a node in the navigation tree, the panel for the previously selected node is not deleted. Instead, it moves into the background and is

accessible by clicking  and  on the toolbar. You can also select currently active panels from the **Window > Show Window List** in the menu bar.

In the **Window** menu, a > is shown next to the name of the active panel. Objects that you are editing (such as data collection schedules) are marked with a black arrow if they have no pending changes; a solid red arrow indicates objects that have pending changes.

Menu bar:

Use the menu bar of the main window to access some of the main functions within IBM Tivoli Storage Productivity Center.

The following sections describe the options available from the menu bar.

File menu:

Use the options in the File menu to save objects and jobs, export report data, print, refresh alerts, close the current window, and exit the product session.

Menu Option	Description
Save	Save the changes for the current object (for example, groups, profiles, etc.) or job (for example, probes, scans, pings, etc.) that you are editing.
Save As	Save the changes for the current object or job that you are editing under a different name.
Export Data	Export the report data to other formats: <ul style="list-style-type: none"> Formatted Report file (.txt) Comma delimited file (.csv) Comma delimited file with headers HTML file <p>This allows you to import the data to another application, such as Excel, if needed.</p>
Print	Print the current data in the content pane. You can print tabular reports or report charts. You can also save the output to a PDF file or HTML file, and print those files at a later time.

Menu Option	Description
Print Tree	Print the expanded contents of the navigation tree. You can also save output to a PDF or HTML file, and print those files at a later time.
Refresh Alerts	Refresh all the alerts from the database repository and update the GUI by highlighting the appropriate objects and showing all the new alerts in the alert logs.
Close	Close the current window that occupies the content pane.
Exit	End the current session.

View menu:

Use the options in the View menu to hide or show the navigation tree and highlight the node in the navigation tree for the currently open window.

Menu Option	Description
Tree	Hide and show the navigation tree. If you want to increase the size of the content pane to occupy the entire window, clear the check box for the Tree option. To redisplay the navigation tree next to the content pane in the main window, select the Tree option.
Current Page in Tree	Display the highlighted node on the navigation tree that was responsible for displaying the data on the content pane. Use this option to reorient the navigation tree with the window that is currently displayed in the content pane.

Connection menu:

Use the option in the Connection menu to end the current session and establish a new connection to the same IBM Tivoli Storage Productivity Center server or to a different server.

Menu Option	Description
New Connection	Initiate a new connection to a server from the current GUI session. For example, use this option to connect to the same server using a different user ID, or to a completely different server.
	All the current changes that are unsaved in the open windows will be lost when you establish a new connection.

Preferences menu:

Use the options in the Preferences menu to change the appearance of the user interface, edit the way the product manages open panels, determine what alerts are shown upon login, select what tab appears first when generating reports, and specify what unit of measurement to use when displaying storage sizes in reports.

Menu Option		Description
Look and Feel	Windows	Set the look and feel of the GUI to appear like Microsoft Windows GUI.
	CDE/Motif	Set the look and feel of the GUI to appear like the UNIX Motif interface.
	Metal	Set the look and feel of the GUI to appear like Metal, the cross-platform Java look and feel.
Edit General	Panel Retention	<p>The Panel recall depth value specifies the number of windows that are linked in the content pane for access via the</p> <p></p> <p>and</p> <p></p> <p>buttons on the toolbar. The default is 20.</p> <p>The Panels kept in memory field specifies the number of windows to store in memory, which helps to optimize the system performance. The default is 2.</p> <p>Note: Any open views in the topology viewer (for example, an L2:Storage Subsystem view, an L0:Computers view) are considered part of the topology viewer panel and are listed as tabs on the topology viewer panel. If the value in this field is a low number, such as the default of 2, then opening additional non-topology panels can exceed the number of panels that are kept in memory. This can result in the topology viewer panel refreshing and any tabbed views being closed. To avoid this situation, change the value in this field to a higher number, such as 10.</p>
		<p>On login, show Control which alerts you will view upon logging in to a user interface session.</p> <p>You can select:</p> <ul style="list-style-type: none"> • No Alerts • Alerts Directed to <Userid> • All Active Alerts
	Initial Reporting Tab to Display	<p>Control what tab will be displayed when you first generate and view a report. You can select:</p> <ul style="list-style-type: none"> • Selection tab • Report tab • Chart tab (if Available)

Menu Option	Description
Advanced Options	<p>Select the unit of measurement that should be used to reflect the storage sizes included in IBM Tivoli Storage Productivity Center reports. This setting affects the results in online, exported, and Batch reports. You can choose from the following options:</p> <ul style="list-style-type: none"> • As Appropriate: Choose this option to automatically determine the unit measurement (KB, MB, GB, TB) to display for storage sizes in a report. • Kilobytes (KB): Choose this option to display storage sizes in reports using the kilobyte unit of measurement. For example, if the storage capacity for a computer is 100 megabytes, it is shown as 102400.00 KB in a capacity report. • Megabytes (MB): Choose this option to display storage sizes in reports using the megabyte unit of measurement. For example, if the storage capacity for a computer is 1 gigabyte, it is shown as 1024 MB in a capacity report. • Gigabytes (GB): Choose this option to display storage sizes in reports using the gigabyte unit of measurement. For example, if the free space on a computer is 500 megabytes, it is shown as 0.49 GB in a free space report. • Terabytes (TB): Choose this option to display storage sizes in reports using the terabyte unit of measurement. For example, if the free space on a computer is 350 gigabytes, it would be shown as 0.34 TB in a free space report.

Window menu:

Use the options in the Windows menu to close all the open windows that do not have any changes, display the dashboard, and list all the open windows.

Menu Option	Description
Close all Windows Without Changes	Close all of the open windows that do not contain any modifications. Any windows that contain active changes to editable objects will not be closed.
Show Dashboard	Display the IBM Tivoli Storage Productivity Center dashboard.
Show Window List	<p>Lists names of all open windows active in the content pane. Select one of these options to view the corresponding window.</p> <p>Beside each window name is an icon that indicates the status of the window:</p> <ul style="list-style-type: none"> • no icon - No changes were made to the window • solid red circle - Changes were made, but have not been saved • black arrow (>) - Current window displayed. No changes were made • solid red arrow (>) - Current window displayed. Changes were made, but have not been saved

Help menu:

Use the options in the **Help** menu to access the online help, open the information center, open the product support page, open the demonstrations page, and display product information (such as the version number).

Menu Option	Description
Help Topics	Open the welcome page of the online help for IBM Tivoli Storage Productivity Center in a separate window. Use the online help to view information about how to use the product.
Help for Displayed Panel	Open the online help for the panel that is displayed. You can also press F1 to access the help for the panel.
Launch Information Center	<p>Open the information center for IBM Tivoli Storage Productivity Center Information Center in a web browser. The IBM Tivoli Storage Productivity Center Information Center contains detailed instructions that explain how to install, upgrade, configure, maintain, and use the Tivoli Storage Productivity Center product.</p> <p>See “Web browser support” for information about web browser support for opening the IBM Tivoli Storage Productivity Center Information Center.</p> <p>An internet connection is required to access the information center. For information about web browser support, see “Web browser support”.</p>
Supported Products Data	<p>Open the product support page in a web browser. Use this page to view a list of operating systems on which you can run Tivoli Storage Productivity Center and the resources that you can monitor.</p> <p>An internet connection is required to access the product support page. For information about web browser support, see “Web browser support”.</p>
Tivoli Storage Productivity Center Demos	<p>Open a web page that contains flash demonstrations of Tivoli Storage Productivity Center. These demonstrations introduce the product, explain the business and storage administrator challenges that it can help you meet, and describe its features and functions.</p> <p>An internet connection is required to access the web page for flash demonstrations. For information about web browser support, see “Web browser support”.</p>
About	<p>View the following information about Tivoli Storage Productivity Center:</p> <ul style="list-style-type: none">• Version information• Copyright information• Trademark information

Web browser support:

IBM Tivoli Storage Productivity Center starts a web browser when you access web pages from items in the Help menu, start another application using its launch-in-context feature, or start IBM Tivoli Storage Productivity Center for Replication from its user interface.

Note: The Tivoli Storage Productivity Center software is bundled with its own IBM Java™ JRE. When you use the Java Web Start method of remotely accessing the stand-alone GUI, you must use the IBM Java.

Before you start Tivoli Storage Productivity Center, ensure that you are using a supported web browser. For a list of web browsers that you can use with Tivoli Storage Productivity Center, see the support matrix at <http://www.ibm.com/support/docview.wss?uid=swg21386446>. In the **Agents, Servers and GUI** column, click the version of Tivoli Storage Productivity Center that you are installing. On the next page, click **Web Browsers** to find the web browsers that you can use.

If you do not have a web browser configured for use with Tivoli Storage Productivity Center when you access a web page from its user interface, the Configure Element Launcher window is displayed. Use this window to configure a web browser for use with the product.

Tip: For information about the web browsers that you can use with the DS8000, see the DS8000 Information Center at <http://publib.boulder.ibm.com/infocenter/dsichelp/ds8000ic/index.jsp>. Search for **Internet browser support**.

Tip: The web GUI requires the use of cookies to manage user preferences, such as table customization and frequently viewed charts. Ensure that cookies are enabled to make use of these features.

Browser-specific information:

The software to block pop-up windows must be turned off in Windows Internet Explorer for any application to start the graphical user interface (GUI) for the following storage systems:

- SAN Volume Controller
- Storwize V3500
- Storwize V3700
- Storwize V7000
- Storwize V7000 Unified
- IBM SONAS

For example, if you are in Tivoli Storage Productivity Center and you want to start the Element Manager of the SAN Volume Controller GUI, you must configure Internet Explorer with the following settings.

1. Open Internet Explorer.
2. From the Internet Explorer toolbar, click **Tools > Pop-up Blocker > Turn Off Pop-up Blocker**.

Browser-specific information:

If the Internet Explorer Information Bar displays a message that content is blocked because it was not signed by a valid security certificate, click the Information Bar and select **Show blocked content**.

Web browser support for Tivoli Storage Productivity Center for Replication

When you start Tivoli Storage Productivity Center for Replication from within the Tivoli Storage Productivity Center, its user interface is displayed in a web browser. Depending on the configuration settings for the web browser on your computer,

Tivoli Storage Productivity Center for Replication is displayed within a tab of an existing browser session or it is displayed within a new browser session.

In Firefox, you can configure how Tivoli Storage Productivity Center for Replication is displayed when started from Tivoli Storage Productivity Center. To configure Firefox, complete the following steps:

1. Start Firefox.
2. Select **Tools > Options** from the menu bar.
3. Select **Tabs**.
4. Select **a new window** to indicate that you want start Tivoli Storage Productivity Center for Replication in a new web browser session. Select **a new tab** to indicate that you want to start Tivoli Storage Productivity Center for Replication in a new tab of an existing web browser session.

Note: For Internet Explorer, Tivoli Storage Productivity Center for Replication is always started in a new web browser session.

Note: If you start Tivoli Storage Productivity Center for Replication from within Tivoli Storage Productivity Center, you might be logged out of the Tivoli Storage Productivity Center for Replication user interface unexpectedly. This action occurs when you use Tivoli Storage Productivity Center to start a session of Tivoli Storage Productivity Center for Replication in an Internet Explorer web browser and then open and close a wizard or secondary window in that Tivoli Storage Productivity Center for Replication session.

To work around this problem, use one of these solutions:

- Start Tivoli Storage Productivity Center for Replication from Tivoli Storage Productivity Center using Firefox
- Start Tivoli Storage Productivity Center for Replication from Tivoli Integrated Portal
- Start Tivoli Storage Productivity Center for Replication by entering its web address directly in a Firefox or Internet Explorer web browser.

Web browser support for Help menu items

Tivoli Storage Productivity Center provides a number of items in its **Help** menu that you can click to learn more about how to use the product. When you click one of these items, Tivoli Storage Productivity Center starts a web browser and displays the appropriate web page. You must have an internet connection on the system where you are running the Tivoli Storage Productivity Center user interface. You must also have a default browser configured to successfully access these web pages.

Toolbar:

The toolbar on the Tivoli Storage Productivity Center main window provides one-click access to key commands.

Click the following buttons on the toolbar to access key commands in the product:

Button	Description
Element Management	Click this button to open the Element Manager page in the Configuration Utility. Use the Element Manager page to configure and start the element managers that are visible to Tivoli Storage Productivity Center. Element managers are programs that enable you to configure and maintain your storage devices. An example of an element manager is DS8000 Storage Manager, which is the default element manager that is provided with IBM System Storage DS8000.
Back 	Click this button to move backward through the active panels in the content pane.
Forward 	Click this button to move forward through the active panels in the content pane.
Save 	Click this button to save the current object that you are editing. The object changes are saved to the database repository.
Print 	Click this button to print the current data or report chart that is displayed in the content pane.
Cancel edit session 	Click this button to discard the contents of the content pane. If content pane is in an edit session and changes have been made, a prompt notifying you that a change has been made is displayed.
Configure devices 	<p>Access the Configure Devices wizard. Use the wizard to configure the following storage devices for monitoring by Tivoli Storage Productivity Center.</p> <ul style="list-style-type: none"> • Storage systems • Fabrics and switches • Computers • Tape libraries <p>The wizard guides you through the process of adding a storage device as a data source, running a discovery, applying alert conditions, and including the device in data collection schedules.</p>
Manage jobs, schedules, and runs 	Access the Job Management panel. Use this panel to view and manage the schedules, runs, and jobs related to the storage devices that are monitored by Tivoli Storage Productivity Center.

Button	Description
Stop current server request 	<p>Click this button to stop the current server request. This button becomes active when a request is made to the server and the user interface is waiting for a response.</p> <p>During the server request wait time, the cursor arrow is displayed as an hourglass. If you decide the current request is taking too long or you do not want to wait any longer, click this button to cancel that request and regain control of the GUI.</p> <p>Note: If you click this button, the current request continues to run, and the resources that are used by it on the server are not released until it completes. Frequent use of this button during a session might exhaust the resources on the server and cause the user interface to stop responding.</p>

Schedules, runs, and jobs:

Use schedules, run, and jobs to manage and monitor the storage entities in your environment. These objects form the framework of job management within Tivoli Storage Productivity Center. Use the Job Management panel to view and manage the schedules, runs, and jobs related to the storage entities that are monitored by the product.

In previous versions of Tivoli Storage Productivity Center, a schedule and its related runs and jobs were displayed as nodes in different parts of the navigation tree. In v4.2 and later, all schedules, runs, and jobs are displayed in the Job Management panel. Use this panel to perform the following tasks:

- View information about all schedules, runs, and jobs in one central location.
- Identify all the schedules, runs, and jobs that are encountering problems when executing.
- Ensure that a storage entity is fully monitored by Tivoli Storage Productivity Center.
- Edit, rename, delete, and run schedules.

Schedules

A schedule is a definition of a monitoring task that collects data about storage devices. Monitoring tasks include scans, probes, pings, quotas, discovery, and performance monitors. For example, define a probe schedule to collect data about storage subsystems; define a scan schedule to collect file-level information about hosts.

Schedule definitions are displayed in the navigation tree under their corresponding type. For example, probe schedules are displayed under the **IBM Tivoli Storage Productivity Center > Monitoring > Probes** node; scans are displayed under the **Data Manager > Monitoring > Scans** node. You can click a schedule in the navigation tree to view or edit its definition at any time.

Runs A run is a single invocation of a schedule. For example, if a probe schedule is set to collect data once per day, there is one run of that schedule per day. Runs for a schedule are displayed on the Job Management panel.

Jobs A job is a unit of work within a run for a schedule. One run might have multiple jobs. For example, a subsystem probe schedule has one job created for each subsystem for which it collects data. Jobs for a run are displayed on the Job Management panel.

Data Manager

Data Manager is a comprehensive file and capacity management solution for heterogeneous storage environments. Data Manager includes enterprise-wide reporting and monitoring, policy-based management and automated capacity provisioning for Direct Attached Storage (DAS), network attached storage (NAS), and SAN environments.

Data Manager helps you improve storage utilization, plan for future capacity, and ensure availability by providing storage on demand for file systems. Use Data Manager to perform the following functions:

- Discover and monitor disks, partitions, shared directories, and servers.
- Monitor and report on capacity and utilization across platforms to help you to identify trends and prevent problems.
- Provides a wide variety of standardized reports about filesystems and storage infrastructure to track usage and availability.
- Provide file analysis across platforms to help you to identify and reclaim space used by non-essential files.
- Provide policy-based management and automated capacity provisioning for filesystems when user-defined thresholds are reached.

Using these functions, Data Manager helps you reduce storage costs by:

- Improving storage utilization
- Enabling intelligent capacity planning
- Helping you manage more storage with the same staff
- Supporting application availability through computer uptime reporting and application database monitoring.

Information collected by Data Manager helps you understand what is really going on with data on your servers and in your storage environment. View when files are created, accessed, and modified, and by what group or user. This type of information helps system administrators map storage resources to the consumers of the resource. The ability to map storage consumption to storage hardware has become increasingly important as the size of open systems environments has increased.

In addition to understanding the current consumption and usage of data within the enterprise, Data Manager tracks the information over time. Not only does this historical view of storage consumption and utilization show usage trends over time, the system administrator can also see a projected use of storage in the future. System administrators can prepare for the need to purchase additional capacity in a planned proactive manner rather than reacting to out-of-space emergencies.

Use Data Manager policy functions to help you evaluate and control the usage and status of your enterprise storage management assets. Because Data Manager is policy-based, it has autonomic self-healing capabilities that can detect potential problems and automatically make adjustments based on the policies and actions you have established. Use the capability to provision storage based upon storage policies to expand a file system, and to allocate storage to a volume.

For example, Data Manager can notify you when your system is running out of disk space or warn you of impending storage hardware failure. By alerting you to these and other issues related to your stored data, Data Manager enables you to prevent unnecessary system and application downtime.

Data Manager for Databases

Data Manager for Databases provides a set of policy-driven automated tools for managing storage capacity, availability, events, performance and assets in your relational databases. It can help you identify, evaluate, control and predict the storage needs of Relational Database Management Systems (RDBMSs), which include Oracle, Sybase SQL Server, Microsoft SQL Server, and UDB/DB2.

Data Manager for Databases is policy-based and through its autonomic self-healing capabilities it can detect potential problems and automatically make adjustments based on the policies and actions you have established. For example, it can notify you when your database tables are running out of storage space or warn you of a dropped tablespace. By alerting you to these and other issues related to your stored data, it enables you to prevent unnecessary system and application downtime.

The following table lists the RDBMS objects whose storage usage is monitored by Data Manager for Databases.

Oracle	SQL Server	Sybase	DB2/UDB
Instances	Instances	Instances	Instances
Databases	Databases	Devices	Databases
Tablespaces	Datafiles	Databases	Tablespaces
Datafiles	Tables	Fragments	Containers
Tables	Indexes	Tables	Tables
Indexes	Log Files	Indexes	Indexes
Extents			
Segments			
Redo Log files			
Control Files			
Archive Log			
Directories			

Note: Data Manager for Databases does not currently support the monitoring of clustered database applications.

Data Manager for Databases collects information about RDBMS storage assets and performs tasks against the RDBMS storage assets. Methods for managing and automating capacity utilization of your databases help you:

- Monitor storage assets associated with enterprise-wide databases and notification of potential problems before they occur
- Make intelligent capacity management decisions based on current and trended historical data
- See how much storage is being consumed by users, groups of users and OS's within the database
- Create policy-based management for databases when user-defined threshold is reached
- View storage utilization management from a database and application perspective

Data Manager for Chargeback

Data Manager for Chargeback uses the storage usage information gathered by Data Manager and Data Manager for Databases to generate invoices that chargeback for storage usage.

With Data Manager for Chargeback you can collect usage information on a departmental, group, or user level. You can allocate costs by storage usage by user, disk capacity by computer, tablespace, or file system/physical device. You can create cost centers by creating user, computer, or tablespace groups, allowing organization to chargeback individuals or business units for their storage usage. By understanding the costs associated with existing and future storage usage, you can improve the use of that storage and reduce the costs associated with its maintenances and upgrades.

Using Data Manager, you can run monitoring jobs that gather detailed statistics about the usage and trending of the storage consumed by the users and user groups within your organization. Using Data Manager for Databases, you can run monitoring jobs that gather detailed statistics about the usage and trending of the storage consumed within RDBMS Instances by the users and user groups within your organization.

In addition to providing invoicing for storage usage, Data Manager for Chargeback also integrates with the chargeback systems already implemented in your environment. It provides you with a higher level, application-specific CIMS output format which can be imported into CIMS applications. With Data Manager for Chargeback, you can export chargeback data for direct import into CIMS, giving you the ability to integrate your storage usage data with other enterprise chargeback information and processes.

Disk Manager

Disk Manager helps you manage SANs and heterogeneous storage from a single console.

With Disk Manager you can manage network storage components such as:

- IBM System Storage SAN Volume Controller
- IBM Storwize V7000
- Storwize V7000 Unified
- IBM TotalStorage Enterprise Storage Server (TotalStorage Enterprise Storage Server)
- Tivoli Storage Productivity Center disk systems (DS4000, DS5000, DS6000, and DS8000 series)
- IBM XIV Storage System
- IBM SONAS
- Other storage subsystems that support the SMI-S standards

For those devices that use the native interfaces (DS8000, SAN Volume Controller, Storwize V7000, IBM SONAS, and XIV) device discovery is performed when the device is added to Tivoli Storage Productivity Center.

For those devices that use the SMI-S standards, device discovery is done using the Service Location Protocol (SLP), as specified by SMI-S. Configuration of the discovered devices is possible in conjunction with CIM agents associated with those devices, using the standard mechanisms defined in SMI-S. Disk Manager also gathers events, and can launch an element manager specific to each device.

Disk Manager can:

- Collect and store performance data and provides alerts
- Provide graphical performance reports

- Help optimize storage allocation
- Provide volume contention analysis

Through the use of data collection, setting of thresholds and use of performance reports, performance can be monitored for the TotalStorage Enterprise Storage Server, DS4000, DS5000, DS6000, DS8000, SAN Volume Controller, Storwize V7000, XIV, and any other storage subsystem that supports the SMI-S block server performance subprofile. The performance function starts with the data collection task, which captures performance statistics for the devices and stores the data in the database.

After data collection is done, you can set thresholds to identify exceptions for certain performance metrics, depending on the type of device. Threshold checking is performed during data collection, and when performance is outside the specified bounds, alerts can be generated.

After performance data has been collected, you can configure Disk Manager to present graphical or text reports on the historical performance behavior of specified devices, or of specific internal components of those devices. The performance reports provide information about past period performance metrics or current performance in graphical form.

Note: Tivoli Storage Productivity Center supports discovery of and reporting on both FB and CKD volumes (and pools and arrays), but can create only FB volumes. Tivoli Storage Productivity Center does not support the creation of CKD volumes.

Managing TagmaStore CIM agents

The TagmaStore CIM agents are provided by Hitachi Data Systems for the TagmaStore storage subsystem. The TagmaStore CIM agent collects information from the TagmaStore storage system.

IBM Tivoli Storage Productivity Center supports the Hitachi Data Systems TagmaStore CIM Agent. For information about the CIM agent level supported, see http://www.ibm.com/support/docview.wss?rs=40&q1=support+matrix&uid=swg21386446&loc=en_US&cs=utf-8&lang=en. Click the appropriate version under **Storage**. Tivoli Storage Productivity Center also supports the TagmaStore as a Storage Virtualizer. Tivoli Storage Productivity Center can display information for virtual disks and local disks.

Tivoli Storage Productivity Center cannot provide correlation information between the virtual storage used by TagmaStore and the volumes created on the storage due to an existing limitation of the CIM agent 5.8 from Hitachi Data Systems. However, Tivoli Storage Productivity Center reports correctly display the correlation between volumes created on the local storage and the local disks. This limitation has no impact on the topology but it does affect several reports that show the correlation:

- **Data Manager > Reporting > Asset > By Storage Subsystem > <HDS_device> > Disks > Volumes** (does not show the relation between the disk and Volume or volume in the tree)
- **Disk Manager > Reporting > Storage Subsystem > Volume to Backend Volume Assignment**
- **Disk Manager > Reporting > Storage Subsystem > Computer Views** (because Tivoli Storage Productivity Center cannot populate the information for volumes created on the virtual disks)

All volumes are created from a storage pool that is allocated from a primordial storage pool and an imported primordial pool. A volume cannot be created over both local and virtual extents.

For volume correlation, the host computer must have the Storage Resource agent deployed and the TagmaStore device must be in the same SAN fabric. There must also be a zone configured in the active zoneset between the ports of the host computer and the ports of the TagmaStore device. The Storage Resource agent must be configured for the fabric to which the host is connected.

For back-end correlation, the TagmaStore device ports and back-end subsystem ports must be in the same zone and the back-end subsystem has assigned storage volumes to all ports of the TagmaStore device.

Tape Manager

IBM Tivoli Storage Productivity Center Tape Manager helps you manage your SMI-S compliant tape libraries.

Tape Manager lets you manage those tape libraries which are based on SMI-S 1.1 profile for tape libraries.

You must have at least Tape Operator authority to access the functions in the Tape Manager node. To view your authority level, open the "Role to Group Mappings" window in the **Administrative Services > Configuration** node in the navigation tree.

With Tape Manager you can:

- Discover SMI-S compliant tape libraries attached to your SAN fabrics
- View tape library information
- Monitor tape libraries by probing for data and viewing alerts
- Create and view asset and capacity reports using data collected from your tape libraries
- Use the topology viewer to view information about tape libraries

Fabric Manager

Fabric Manager helps you manage the SAN fabric that connects the host systems and applications to the storage devices. It is a comprehensive management solution for multi-vendor SANs and includes automatic resource and topology discovery, monitoring and alerts, and zone control.

Fabric Manager is an enterprise scalable solution architected to ANSI SAN standards, allowing you to choose the appropriate products for your environment. It helps you:

- Simplify the task of SAN management and configuration
- Ensure SAN availability
- Improve SAN return on investment

Fabric Manager is able to do SAN fabric performance and capacity management reporting and monitoring. Zoning is one of many SAN security options. Zoning is the only configuration supported for this release. Along with subsystem based volume masking, it is almost universally employed to ensure that only systems that are authorized can access selected data. Zoning is provided by the switch at

the port level, so that, for example, a host on port X can access the subsystem connected by port Y. When business needs change, often zones must change also.

Zone control is enabled from a centralized location. Existing zones can be discovered and the members that make up the zone can be viewed and modified by adding or deleting them. New zones can be created and existing zones can be deleted. Fabric Manager makes working with zones easy by providing a GUI that discovers SAN devices and makes them available to add or remove from zones as individual devices.

The ability to do switch performance and capacity management reporting and monitoring can help you to determine if more bandwidth is needed. Wide-area and local-area IP networks, and storage area networks (SANs) move data from one place to another. The management of the bandwidth is needed to continually monitor for link utilization and errors. Data needs to be gathered to tune resources, balance workloads, and do capacity planning.

With Fabric Manager, the comprehensive management of multi-vendor SANs can help simplify the IT infrastructure by providing automatic resource and topology discovery, monitoring, and alerts, and zone control. It brings all the sources of information about SAN topology and configuration into a single place, and creates topology mapping of the SANs. This topology offers both host-centric and device-centric views that can be displayed graphically. The SAN topology display tracks all topology and configuration changes through in-band, out-of-band, and SMI-S monitoring. Without this type of centralized topology, information from a number of sources, such as Element Management tools, device logs, and SNMP traps would have to be continually monitored and manually correlated to determine the current SAN configuration and topology.

Fabric Manager provides you with the ability to view events happening in your SAN environment and records state changes. The events are displayed in a color-coded fashion and can be further customized to reflect organizational priorities. It will forward events signaling topology changes or updates to the IBM Tivoli Enterprise Console, another SNMP manager, or both. Source side filtering by the Fabric Manager enables you to control what events get sent to your centralized console. Filtering helps ensure that the administrators get the information they need and are not overwhelmed by extraneous information.

Tivoli Storage Productivity Center for Replication

Tivoli Storage Productivity Center includes Tivoli Storage Productivity Center for Replication. Tivoli Storage Productivity Center for Replication manages copy services in storage environments. *Copy services* are features that are used by storage systems such as System Storage DS8000 to configure, manage, and monitor data-copy functions. Copy services include IBM FlashCopy, Metro Mirror, Global Mirror, and Metro Global Mirror.

Tivoli Storage Productivity Center for Replication provides copy services management for the storage systems and session types that are listed in the following table:

Storage system	Session type
System Storage DS8000	<ul style="list-style-type: none"> • Basic HyperSwap • FlashCopy • Metro Mirror Single Direction • Metro Mirror Failover/Failback • Metro Mirror Failover/Failback with Practice • Global Mirror Single Direction • Global Mirror Either Direction with Two-Site Practice • Global Mirror Failover/Failback • Global Mirror Failover/Failback with Practice • Metro Global Mirror • Metro Global Mirror with Practice
System Storage DS6000	<ul style="list-style-type: none"> • Basic HyperSwap • FlashCopy • Metro Mirror Single Direction • Metro Mirror Failover/Failback • Metro Mirror Failover/Failback with Practice • Global Mirror Single Direction • Global Mirror Either Direction with Two-Site Practice • Global Mirror Failover/Failback • Global Mirror Failover/Failback with Practice

Architecture

Tivoli Storage Productivity Center for Replication consists of several key components.

Tivoli Storage Productivity Center for Replication server

The Tivoli Storage Productivity Center for Replication server is the control point for the sessions, storage systems, hosts, and other components that are managed by Tivoli Storage Productivity Center for Replication.

Database

A single database instance serves as the repository for all Tivoli Storage Productivity Center for Replication data.

An embedded database is provided with Tivoli Storage Productivity Center for Replication.

GUI The graphical user interface (GUI) is used to manage all Tivoli Storage Productivity Center for Replication functions.

CLI The command-line interface (CLI) is used to issue commands for key Tivoli Storage Productivity Center for Replication functions.

Interfaces for Tivoli Storage Productivity Center for Replication

Tivoli Storage Productivity Center for Replication provides a graphical user interface (GUI) and a command-line interface (CLI) for managing data replication and disaster recovery.

Graphical user interface

The Tivoli Storage Productivity Center for Replication GUI contains the following features:

Navigation tree

The navigation tree provides categories of tasks that you can complete in Tivoli Storage Productivity Center for Replication. Clicking a task opens a main page in the content panel.

Health Overview

The **Health Overview** area is under the navigation tree and shows a status summary for all sessions, storage systems, host systems, and management servers that Tivoli Storage Productivity Center for Replication is managing.

Content area

The content panel displays content based on the item that you selected in the navigation tree.

You can view help for the currently displayed panel by clicking the ? icon.

You can view the information center by clicking the ⓘ icon. You must have Internet access to view the information center.

When you log on to the GUI, the **Health Overview** panel is displayed in the content area.

Command-line interface

You can use the Tivoli Storage Productivity Center for Replication CLI by using the **csmlcli** utilities. You can use the CLI directly or as a script for automating functions.

For security, the CLI runs only on the Tivoli Storage Productivity Center for Replication management server. You can run the CLI remotely using a remote-access utility, such as Secure Shell (SSH) or Telnet.

For Tivoli Storage Productivity Center for Replication on Windows, you can specify remote access to Linux or AIX® terminals if you enabled Telnet on your Windows server.

Tivoli Storage Productivity Center for Replication integration with Tivoli System Automation Application Manager

IBM Tivoli System Automation Application Manager includes a Distributed Disaster Recovery (DDR) feature that uses IBM Tivoli Storage Productivity Center for Replication to provide a data replication and disaster recovery solution for distributed systems. The DDR feature is available in Tivoli System Automation Application Manager version 3.2 or later and requires Tivoli Storage Productivity Center for Replication version 3.4.1.8 or version 4.1.1.1 or later.

Tivoli System Automation Application Manager automates the availability of information technology resources. The DDR feature and Tivoli Storage Productivity Center for Replication provide a full end-to-end solution for site switching on distributed systems at the application level.

For more information about the integration of Tivoli Storage Productivity Center for Replication with Tivoli System Automation Application Manager, including the steps required to perform the integration, see the *Tivoli System Automation Application Manager Administrator's and User's Guide*. The administrator's guide is provided in the Tivoli System Automation Application Manager information centers by version at <http://www.ibm.com/developerworks/wikis/display/tivolidoccentral/Tivoli+System+Automation+Application+Manager>.

Tivoli Integrated Portal

The IBM Tivoli Storage Productivity Center installation program includes IBM Tivoli Integrated Portal. Tivoli Integrated Portal is a standards-based architecture for Web administration. Tivoli Integrated Portal enables developers to build administrative interfaces for IBM and independent software products as individual plug-ins to a common console network. The installation of Tivoli Integrated Portal is required to enable single sign-on for Tivoli Storage Productivity Center and to access the web-based GUI.

Tivoli Integrated Portal and single sign-on

Single sign-on is an authentication process that you can use to enter one user ID and password to access multiple applications. For example, you can access Tivoli Integrated Portal and then access Tivoli Storage Productivity Center and IBM Tivoli Storage Productivity Center for Replication from Tivoli Integrated Portal using a single user ID and password. Single sign-on integrates with the launch and launch in context features to enable you to move smoothly from one application to another application.

Related concepts:

“Single sign-on”

Single sign-on is an authentication process that enables you to enter one user ID and password to access multiple applications. For example, you can access IBM Tivoli Integrated Portal and then access IBM Tivoli Storage Productivity Center and IBM Tivoli Storage Productivity Center for Replication from Tivoli Integrated Portal using a single user ID and password. Single sign-on integrates with the launch and launch-in-context features to enable you to move smoothly from one application to another application.

“Launch and launch in context” on page 58

The launch and launch in context features are used to start IBM Tivoli Storage Productivity Center and to start other applications from Tivoli Storage Productivity Center. The terms inbound and outbound are used to differentiate starting Tivoli Storage Productivity Center (inbound) and starting another application from Tivoli Storage Productivity Center (outbound).

Chapter 6, “Managing resources in the web-based GUI,” on page 625

You can use the web-based GUI to monitor the condition, capacity, and relationships of the monitored resources within your storage environment.

Key concepts

To help you understand and use IBM Tivoli Storage Productivity Center effectively, an overview of key concepts is provided.

Single sign-on

Single sign-on is an authentication process that enables you to enter one user ID and password to access multiple applications. For example, you can access IBM Tivoli Integrated Portal and then access IBM Tivoli Storage Productivity Center and IBM Tivoli Storage Productivity Center for Replication from Tivoli Integrated Portal using a single user ID and password. Single sign-on integrates with the launch and launch-in-context features to enable you to move smoothly from one application to another application.

For the current version of Tivoli Storage Productivity Center, single sign-on is available for the following applications:

- Tivoli Storage Productivity Center for Replication
- IBM System Storage DS8000
- IBM System Storage SAN Volume Controller
- IBM Storwize V7000

For Tivoli Storage Productivity Center for Replication Storage Manager, single sign-on is enabled by default.

For DS8000 Storage Manager, SAN Volume Controller, and Storwize V7000, single sign-on must be enabled.

To enable single sign-on, see the following topics in the Tivoli Storage Productivity Center information center:

- Configuring Tivoli Storage Productivity Center for DS8000 LDAP authentication
- Configuring Tivoli Storage Productivity Center for SAN Volume Controller and Storwize V7000 single sign-on

How single sign-on works

A single sign-on environment requires a centralized authentication repository that is accessed by all applications within the environment. When you log on to either Tivoli Integrated Portal or Tivoli Storage Productivity Center, a Lightweight Third-Party Authentication (LTPA) token is created and used for single sign-on authentication when you start other applications from within the Tivoli Storage Productivity Center GUI. LTPA is the security technology that is used in the IBM WebSphere Application Server for passing the user authentication information between applications. To use the LTPA tokens, each application must have the same set of public keys to encrypt the user's information. The authenticating service uses the corresponding private keys to decrypt the user's information for authentication. As an additional security mechanism, LTPA tokens expire after a determined amount of time. By default, the tokens expire after 8 hours. You can change the LTPA token expiration time using the Tivoli Integrated Portal user interface.

During the period between when you log on to Tivoli Storage Productivity Center and when you start other applications, such as element managers, from the Tivoli Storage Productivity Center GUI, the following conditions might occur:

Condition	Explanation
The user password that was used to log on to Tivoli Integrated Portal or Tivoli Storage Productivity Center is changed in the user repository.	Under this condition, the original user credentials that were used to log in to Tivoli Integrated Portal or Tivoli Storage Productivity Center are used to access other applications until the timeout period for the LTPA token that is used for single sign-on expires. When the LTPA token expires, you are prompted to reenter your user ID and password when you attempt to start another application using single sign-on.
The user ID that was used to access Tivoli Integrated Portal is changed in the repository or removed from the user repository.	Under this condition, the single sign-on feature does not work. You are always prompted to reenter your user ID and password when you attempt to start another application through single sign-on.

Condition	Explanation
The user repository is not accessible.	Under this condition, the single sign-on feature does not work. You are always prompted to reenter your user ID and password when you attempt to start another application through single sign-on.

Tivoli Storage Productivity Center and IBM Tivoli Storage Productivity Center for Replication use their respective IBM WebSphere Application Server instances to authenticate LTPA tokens. However, other applications, such as the IBM System Storage DS8000 element manager and other element managers that do not run within an IBM WebSphere Application Server instance use the authentication service that is provided with Tivoli Integrated Portal. The authentication service client is typically embedded in these other applications and the client communicates with the authentication service server in Tivoli Integrated Portal for all authentication requests.

The single sign-on feature is not supported by the Tivoli Storage Productivity Center command-line interface (CLI).

Selecting the user authentication method to use with single sign-on

During the installation, Tivoli Storage Productivity Center uses the operating system (OS) users and groups on the server where Tivoli Storage Productivity Center is installed for authentication and authorization. After the installation, you can configure Tivoli Storage Productivity Center to use LDAP as the authentication and authorization repository.

OS Authentication

This method authenticates the user against the users that are defined for the local operating system (OS).

LDAP/Active Directory

This method authenticates the user against a Lightweight Directory Access Protocol (LDAP) or Microsoft Active Directory repository.

If OS authentication is selected, the use of the single sign-on feature is limited. OS authentication does not support single sign-on for element managers, even when the element manager is installed on the same computer as Tivoli Storage Productivity Center. LDAP or Microsoft Active Directory authentication supports single sign-on for element managers regardless of where they are installed.

You can change the user authentication method using the Tivoli Integrated Portal graphical user interface (GUI).

During installation, you can specify that Tivoli Storage Productivity Center use an existing Tivoli Integrated Portal instance rather than the instance that is installed with Tivoli Storage Productivity Center. In this case, Tivoli Storage Productivity Center uses the authentication repository that is used by Tivoli Integrated Portal (LDAP or the operating system).

Related concepts:

“Changing the user authentication configuration” on page 234

The Tivoli Storage Productivity Center installation program establishes a default authentication configuration using the federated repositories feature of the WebSphere Application Server. If you want to change the user authentication configuration, follow these procedures.

Related tasks:

“Changing the LTPA token expiration for single sign-on” on page 251

For single sign-on, the user authentication information is passed between applications using Lightweight Third-Party Authentication (LTPA) tokens. By default, the tokens expire after eight hours. You can change the LTPA token expiration time using the Tivoli Integrated Portal user interface.

Launch and launch in context

The launch and launch in context features are used to start IBM Tivoli Storage Productivity Center and to start other applications from Tivoli Storage Productivity Center. The terms inbound and outbound are used to differentiate starting Tivoli Storage Productivity Center (inbound) and starting another application from Tivoli Storage Productivity Center (outbound).

Inbound launch in context refers to starting Tivoli Storage Productivity Center at a specific point in the graphical user interface (GUI). You can use inbound launch in context in either of the following ways:

- Configure an application such as Tivoli Enterprise Portal to start Tivoli Storage Productivity Center at functionally related locations in the Tivoli Storage Productivity Center GUI.
- Start Tivoli Storage Productivity Center from Java Web Start, the command line, or the Windows Start menu using parameters to specify the starting location in the Tivoli Storage Productivity Center GUI.

Outbound launch in context refers to starting other applications, such as administrative applications for storage systems and switches, from functionally related points in the Tivoli Storage Productivity Center GUI.

Launch refers to starting an application at the starting point for that application. Launch primarily refers to starting applications from the Tivoli Storage Productivity Center GUI. Starting applications from Tivoli Storage Productivity Center is referred to as an outbound launch.

Related concepts:

“Inbound launch in context feature”

With the inbound launch in context feature you can start IBM Tivoli Storage Productivity Center at a specified point in the graphical user interface (GUI).

“**Outbound launch and launch in context features**” on page 65

With the outbound launch and launch in context features, you can start the administrative applications for devices such as storage systems and switches from various points in the graphical user interface (GUI).

Inbound launch in context feature

With the inbound launch in context feature you can start IBM Tivoli Storage Productivity Center at a specified point in the graphical user interface (GUI).

Prerequisite: You must have View and Modify permissions to use the launch in context feature.

You can use the launch in context feature to perform the following tasks in Tivoli Storage Productivity Center:

- Create a volume or VDisk
- Open the storage area network SAN Planner
- Create a capacity report
- Create a wasted space report

You can run the launch in context feature in the following ways:

- **Use Java Web Start** from a Web browser. See “Launch with Java Web Start.”
- **Use the command line on Windows, AIX, Linux, or UNIX** to enter the command and arguments on the command line. See “Launch from the command line” on page 61.
- **Use the Windows Start menu.** See “Launch from Start menu” on page 62.
- **Use the Tivoli Enterprise Portal GUI** to define, edit, and launch commands. See “Launch from Tivoli Enterprise Portal” on page 63.

The launch in context feature has a number of parameters. See “Launch in context parameters” on page 1482, “Launch in context task parameters” on page 1484, and “Available windows” on page 1485.

Launch with Java Web Start:

Using Java Web Start, you can use the launch in context feature from a Uniform Resource Locator (URL).

The launch in context feature requires Java Web Start 6 on the computer that is running the Web browser. If the correct release of Java Web Start is not present, you receive an error message when you enter the URL. The message states that you must download the Java Runtime Environment, which includes Java Web Start. Follow the link provided in the message to install the required software.

If you are using Internet Protocol Version 6 (IPv6) and are using Java Web Start to start IBM Tivoli Storage Productivity Center on a Windows system, use a system host name such as **tpc332.storage.newyork.xyz.com:9549** in the Web browser address field rather than an IPv6 address such as **[2001:DB8:0000:1234:0000:0000:5678:ABCD]:9549**.

To use the launch in context feature to perform a task or display a window on a remote server from your browser, complete the following steps:

1. Open your browser and type the launch in context command.

URLs cannot include spaces. In the command, a parameter and its value are separated by an equal sign (=). Parameter=value pairs are separated by an ampersand (&).

The format of a command to create a volume is:

```
https://device_server:device_port/ITSRM/jsp/jnlp/tpcgui.jsp?consoleClass=com.ibm.usmi.console.lic.tpc.LICConsole&-server=server:port&-function=disk.create_volume&-subsystem_id=ESS-2105-17844-IBM&-name=myvol&-number=2&-size=10&-unit=MB
```

The format of a command to view a window on a remote server is:

```
http://device_server:device_port/ITSRM/jsp/jnlp/tpcgui.jsp?consoleClass=com.ibm.usmi.console.lic.tpc.LICConsole&-server=server:port&-function=window_name
```

Tip: The Data server port value is 9549. The port value for the Device server is 9551 for https and 9550 for http. If the wrong the Device server port value is used, the return page cannot be interpreted by the browser. If the wrong Data server port value is used, the following error message is returned.

Unable to connect to the server

2. The first time a window or task is started, you receive a security warning informing you that the downloaded jar files have been digitally signed using a certificate from a trusted company. To prevent this message from being displayed in the future, select **Always trust content from this publisher** and click **Run**. If the Tivoli Storage Productivity Center graphical user interface (GUI) has not been downloaded on the local computer using Java Web Start, or the local computer does not have the latest version of the Tivoli Storage Productivity Center GUI, the GUI is downloaded.
3. If you included the user ID and password in the command, the sign-in dialog is bypassed, otherwise log on to the Tivoli Storage Productivity Center GUI. The Tivoli Storage Productivity Center GUI navigates to the tree node corresponding to the window name that you specified. You are connected using the user name and password that you entered. Depending on the value you specified for the `-function` parameter, the following actions might occur:
 - The specified window opens
 - For `disk.create_volume`, depending on the parameters, the Create Volume wizard or Create VDisk wizard opens.
 - For `disk.san_planner`, the SAN Planner panel opens with the given SAN plan ID.
 - For `data.filesystem_capacity_by_computer`, the Capacity Report opens.
 - For `TPC.reports_data_wasted_space`, the Wasted Space Report opens.

Restrictions:

- When you open a plan in the SAN Planner using launch in context, you must enter the exact name of the plan. The value for the `-plan_id` parameter is case-sensitive and must match the name of the plan when it was created. For example, if you created a plan named **UserPlan1**, you must specify `-plan_id UserPlan1` in the launch in context command.
- There is a known limitation when you launch the Filesystem Capacity > By Computer report using launch in context, you must specify the ID for the computer upon which you want to report. For example:

```
http://tpcserver14:9550/ITSRM/jsp/jnlp/tpcgui.jsp?consoleClass=com.ibm.usmi.console.lic.tpc.LICConsole&-server=tpcserver14.storage.xyz.com:9549&-function=data.filesystem_capacity_by_computer&-computer_id=tpcserver14
```

The value you enter for the `computer_id` parameter might not match the ID for that computer that is stored in the Tivoli Storage Productivity Center database repository. You receive a warning message if the ID for the computer that you enter in the URL does not match the ID that is stored in the data repository. To ensure that this report is displayed properly when you run from the launch in context facility, enter an ID for the computer that matches the ID that is displayed for it through the Topology Viewer or appropriate report in the product user interface.

Use the information in the following links to enter parameters. If any of the parameters are spelled incorrectly, an error message indicates the incorrect parameter.

“Launch in context parameters” on page 1482

You can use the launch in context parameters, definitions, and examples.

“Launch in context task parameters” on page 1484

Use the launch in context feature task parameters to perform tasks.

“Available windows” on page 1485

You can use windows with the inbound launch in context feature to start IBM Tivoli Storage Productivity Center. These windows are called with the -function *window name* argument.

Launch from the command line:

This topic describes how to start windows and tasks from the Windows AIX, Linux, or UNIX command line.

The bat file `tpc.bat` is used for Windows operating systems. The .sh file `TPCD.sh` is used for AIX, Linux, or UNIX systems. The parameters follow the file name. Parameters are separated by spaces. Parameters are optional and can appear in any order. See “Launch in context parameters” on page 1482, “Launch in context task parameters” on page 1484, and “Available windows” on page 1485 for the parameters.

Frequently used commands can be saved as unique command files and rerun as needed.

1. In the Command Prompt window, type the command for the action that you want to take, and press Enter.
The action occurs on the remote Data server. The graphical user interface (GUI) window for that action opens on the local computer.
2. Enter parameters if you previously did not enter any parameters. If you do not provide a user name, password, or server name, the IBM Tivoli Storage Productivity Center GUI opens the connection dialog box. If you do not provide these values, the GUI presents an error message box and requests the values. If you specify incorrect parameters, you receive an error message.

The following example launches a task from the Windows command line:

```
tpc.bat -user admin -passwd password1 -server  
tivoli122.storage.usca.ibm.com:9549 -function  
data.filesystem_capacity_by_computer -computer_id <computerID>
```

The following example uses the launch in context feature to view a window on the remote machine:

```
tpc.bat -user admin -passwd password1 -server  
tivoli122.storage.usca.ibm.com:9549 -function disk.storage_subsystem
```

Restrictions:

- When you open a plan in the SAN Planner using the command line or a Web browser for launch in context, you must enter the exact name of the plan. The value for **-plan_id** in the command line is case-sensitive and must match the name of the plan when it was created. For example, if you created a plan named **UserPlan1**, you might enter the following command on the command line:

```
./TPCD.sh -user administrator -passwd passw0rd -server  
tpcserver14.storage.xyz.com:9549 -function disk.san_Planner -plan_id  
UserPlan1
```

- There is a known limitation when you start the Filesystem Capacity > By Computer report using launch in context. To start this report, you must specify the ID for the computer upon which you want to report. For example:

```
./TPCD.sh -user root -passwd "passwd" -server
tpcserver14.storage.xyz.com:9549 -function
data.filesystem_capacity_by_computer -computer_id tpcserver14
```

The value you enter for "computer_id" might not match the ID for that computer that is stored in the Tivoli Storage Productivity Center database repository. You will receive a warning message if the ID for the computer you enter in the command line does not match the ID stored in the data repository. To ensure that this report is displayed properly when run from the launch in context command line or through Java Web Start, make sure to enter an ID for the computer that matches the ID that is displayed for it through the Topology Viewer or appropriate report in the product's user interface.

Launch from Start menu:

This topic describes how to start windows and actions from the Windows Start menu.

The bat file, `tpc.bat`, is used for Windows operating systems. The parameters follow the bat file name. Parameters are optional and can appear in any order. To use the launch in context feature from the Windows Start menu, complete the following steps:

1. Click **Start > Programs > IBM Tivoli Storage Productivity Center**, right-click **Productivity Center** and select **Properties**. The Productivity Center Properties window opens.
2. Enter the command-line arguments in the **Target** text field and click **Enter**.
If the Data server is remote, the action occurs on the Data server and the graphical user interface (GUI) window the action opens is on the local computer.
3. Enter the parameters if you did not previously enter the necessary parameters. If you do not provide the user name, password, or server name, the Tivoli Storage Productivity Center GUI opens the connection dialog box. If you do not provide these values, the GUI presents an error message box and requests the values.

The following example starts a task from the Windows Start menu:

```
"C:\Program Files\IBM\TPC\gui\tpc.bat" -user admin -passwd password1
-server tivoli122.storage.usca.ibm.com:9549 -function
data.filesystem_capacity_by_computer -computer_id computerID
```

The following example uses the Windows Start menu to view a window on the remote server:

```
"C:\Program Files\IBM\TPC\gui\tpc.bat" -user admin -passwd password1
-server tivoli122.storage.usca.ibm.com:9549 -function
disk.storage_subsystem
```

For more information see:

“Launch in context parameters” on page 1482

You can use the launch in context parameters, definitions, and examples.

“Launch in context task parameters” on page 1484

Use the launch in context feature task parameters to perform tasks.

“Available windows” on page 1485

You can use windows with the inbound launch in context feature to start IBM Tivoli Storage Productivity Center. These windows are called with the -function *window name* argument.

Launch from Tivoli Enterprise Portal:

This topic shows you how to start an existing launch definition from the Tivoli Enterprise Portal graphical user interface (GUI).

You must configure Tivoli Enterprise Portal before you can use the launch in context feature. For information on prerequisites and details on how to configure the launch in context feature with Tivoli Enterprise Portal, see “Configuring Tivoli Enterprise Portal.” After Tivoli Enterprise Portal has been configured, you can start the application from the configuration window or use **Launch** from the Tivoli Enterprise Portal navigation tree.

If you use the Tivoli Enterprise Portal navigation tree, **Launch** will open the Tivoli Enterprise Portal graphical user interface with your predefined launch in context commands. To use one of these commands, complete the following steps:

1. In the Tivoli Enterprise Portal window, expand **Enterprise > Windows Systems *your_server_name* > Windows OS**. Right-click **Disk** and select **Launch**. Disk is one of several values you can select. Values include Disk, Network, Enterprise Services, Memory, Printer, Process, Processor, and System.
2. The Create or Edit Launch Definitions window opens showing a list of defined launch definitions in the **Existing Launch Definitions** area.
3. Select the launch definition you want to use from the list and click **Launch**. The window or task that is defined by that launch definition opens.

For information on editing the launch in context command with the Tivoli Enterprise Portal GUI, see:

Related tasks:

“Editing launch definitions” on page 65

You can edit an existing launch definition with the Tivoli Enterprise Portal graphical user interface (GUI).

Configuring Tivoli Enterprise Portal:

You can configure Tivoli Enterprise Portal so that you can use the launch in context feature.

To configure Tivoli Enterprise Portal complete the following steps:

1. The initial steps depend on whether you are going to open a window or perform a task.
 - a. If you are opening a window, in the Tivoli Enterprise Portal navigation window on the local computer, select where you want the launch definition to originate from. This opens the corresponding view on the target computer. Right-click one of the following locations.
 - The navigator item
 - A row in a table or situation event console view
 - A slice of a pie chart

- A bar of a bar chart

If the launch definition originates from a table, chart, or situation event console view, open the workspace containing the view. If you think you might edit the argument later, create the launch definition from a table or chart view.

- b. If you are going to perform a task, create a launch definition for one of the following tasks:
 - Create a volume or VDisk
 - Open the SAN Planner
 - Create a capacity report
 - Create a wasted space report
2. In the Tivoli Enterprise Portal window, expand **Enterprise > Windows Systems > your_server_name > Windows OS**. Right-click **Disk** and select **Launch**. Disk is one of several values you can select. Values include Disk, Network, Enterprise Services, Memory, Printer, Process, Processor, and System.
3. The Create or Edit Launch Definitions window opens. Click **Create New**.
4. In the **Name** text field, type a descriptive name for this launch definition. This name is used in the definition list.
5. In the **Target** text box click **Browse** to locate the tpc.bat file. The Select files for directories for Launch Definitions window opens. A typical location for Windows systems is C:\Program Files\IBM\TPC\gui\tpc.bat. Select the correct directory and click **OK**.

When you start a launch definition from the command line, if any part of the path contains spaces, enclose the entire entry in quotation marks.
6. In the **Arguments** text field, enter any parameters that will be added when the application is started. Arguments are entered as *-parameter value*. In the Create or Edit Launch Definitions window, click **Browse** next to **Arguments** to locate the parameters that you want to use. The Select Browser Options window opens. Click **Substitutable Items** and then click **OK**. Select parameters from the **Selected Context** and **Extended Context** lists.

The **help** argument lists the available **function** values. You must type the help parameter by itself into the **Arguments** text field or into the form tpc.bat -help functions on the command line for Windows or TPCD.sh -help functions for UNIX. The **-help functions** parameter provides a window that lists the nodes in the navigation tree that are available to start. If you type **-help** without the **functions** parameter, it results in an error message.

When all parameters have been selected, click **OK** to return to the Create or Edit Launch Definitions window.
7. If the parameters can be changed at launch time (for example, you want to change the system ID), check the **Edit arguments before execution** box.
8. Specify a value for the **Start in** location. Click **Browse** to locate the IBM Tivoli Storage Productivity Center installation and select the folder **gui** where tpc.bat is located.
9. Click **Evaluate** to see how the command resolves when the application starts. Correct any of the parameters that are incorrect and reevaluate the command.
10. When you are satisfied with the launch definition, click **Apply** to save your changes. This keeps the window open so that you can start the current launch definition or create a new one. Click **OK** to save the launch definition and close the window.

11. To start the current definition, select **Launch**. The Tivoli Storage Productivity Center graphical user interface (GUI) with the function parameter that you have provided is opened.

Related reference:

“Launch in context parameters” on page 1482

You can use the launch in context parameters, definitions, and examples.

“Launch in context task parameters” on page 1484

Use the launch in context feature task parameters to perform tasks.

“Available windows” on page 1485

You can use windows with the inbound launch in context feature to start IBM Tivoli Storage Productivity Center. These windows are called with the `-function window name` argument.

Editing launch definitions:

You can edit an existing launch definition with the Tivoli Enterprise Portal graphical user interface (GUI).

If the **Edit arguments before execution** box was checked when a launch definition was configured, you can edit the launch definition by changing the attribute values. To edit a launch definition, complete the following steps:

1. In the Tivoli Enterprise Portal window, expand **Enterprise > Windows Systems > your_server_name > Windows OS**. Right-click **Disk** and select **Launch**. Disk is one of several nodes you can select. Nodes include Disk, Network, Enterprise Services, Memory, Printer, Process, Processor, and System.
2. The Create or Edit Launch Definitions window opens showing a list of launch definitions in the **Existing Launch Definitions** area.
3. Select the launch definition that you want to edit. The values are displayed.
4. Make the necessary changes in the text fields.
5. Click **Evaluate** to see how the arguments will resolve when the application starts. Correct any incorrect arguments and re-evaluate the command.
6. Click **Apply** to save the changes and keep the window open. Click **OK** to save the launch definition and close the window.

If you do not want to overwrite the existing launch definition, save the new launch definition with a unique name.

Outbound launch and launch in context features

With the outbound launch and launch in context features, you can start the administrative applications for devices such as storage systems and switches from various points in the graphical user interface (GUI).

There are two options for starting an application from Tivoli Storage Productivity Center. The option that is available depends on the device that you want to start.

The launch feature starts an application at the starting point for that application.

The launch in context feature starts an application at a functionally related location in that application. Launch in context is available for the following applications:

- Tivoli Storage Productivity Center for Replication
- SAN Volume Controller 6.1 or later
- Storwize V3500
- Storwize V3700

- Storwize V7000
- Storwize V7000 Unified
- IBM SONAS

Launch menu

When you right-click one of the following entities in Tivoli Storage Productivity Center GUI, you see a launch menu for that entity. The content of the launch menu varies as described in “Launch menu items” on page 67.

- Alert Log Viewer. Each row of the alert log is enabled for a launch in context menu. The context is determined by the type of the alert. Alert types include:
 - Replication
 - Storage Subsystem
 - Computer
 - Fabric
 - Switch
 - Port
 - Tape Library
- Disk Manager Storage Subsystems table
- Fabric Manager Fabrics table
- Tape Manager Tape Libraries table
- Element Manager page (of the Configuration Utility)
- Topology Viewer objects. To see the icons that are associated with each Topology Viewer object, refer to the following list.

Topology Viewer objects

Topology Object	Icon
Fabric	
Switch	
Switch port	
Tape library	
Storage subsystem	
Storage subsystem port	
File system volume	

Topology Object	Icon
Storage disk	
Storage pool	

Launch menu items

The following are the possible menu items that can be displayed in the launch menu:

Launch in context defined application

This menu item is displayed for each application that is defined by a launch descriptor file. Tivoli Storage Productivity Center provides launch descriptor files for the following applications:

- DS8000 Storage Manager
- The management console for the storage systems that are listed under **Management GUI**.
- Tivoli Storage Productivity Center for Replication

If the corresponding launch descriptor files are found for the applications, the following menu items are displayed:

DS8000 Storage Manager

Click this menu item to start DS8000 Storage Manager.

Management GUI

Click this menu item to start the management console for the following storage systems:

- SAN Volume Controller 6.1 or later
- Storwize V3500
- Storwize V3700
- Storwize V7000
- Storwize V7000 Unified
- IBM SONAS

Replication Storage Systems Overview

Click this menu item to start Tivoli Storage Productivity Center for Replication. The window that is opened in the Tivoli Storage Productivity Center for Replication GUI depends on the context for the entity that you selected. For example, if you right-click a storage device on the **Element Manager** tab of the Configuration Utility and click **Replication Storage Systems Overview**, the Tivoli Storage Productivity Center for Replication Storage Systems window opens.

If the launch descriptor file cannot be found, the **Launch file items error** menu item is displayed. Click this item to view a description of the problem. The **Launch file items error** menu item is also displayed in situations such as the IBM Tivoli Integrated Portal server is not installed or is not accessible, the Tivoli Storage Productivity Center Data server is not accessible, or another system error occurred.

External Tools

This menu item shows any external tools that are defined in the Configuration Utility. Examples of external tools include web-based user interfaces and local executable files. For example, you might add the address of a website that you frequently access or an application that you often use such as a text editor or a spreadsheet.

Element Manager

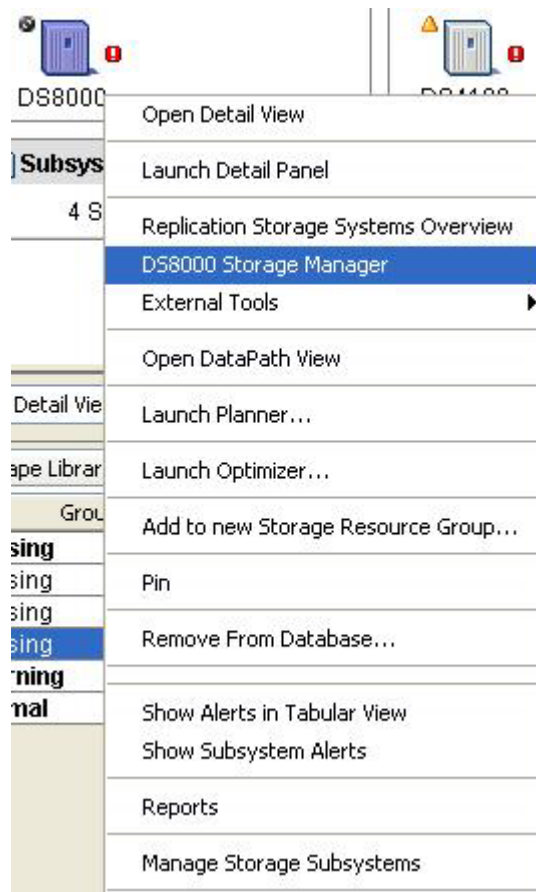

This menu item shows any element managers that were discovered for the device by a Storage Management Initiative Specification (SMI-S) query. To avoid menu item duplication, this item is not displayed when the associated element manager is defined by a launch descriptor file. In this situation, the element manager is displayed as a separate menu item.

User Defined Tools

This menu item shows any user-defined element managers that are defined in the Configuration Utility. These element managers differ from the element managers in the **Element Manager** menu because they are user-defined and are not discovered by an SMI-S query.

Example launch menu

The following figure shows an example launch menu for a storage system in the **L0:Storage** topology view. In this example, the menu items **Replication Storage Systems Overview**, **DS8000 Storage Manager**, and **External Tools** are displayed. The **Element Manager** menu item is not displayed because no element managers other than **DS8000 Storage Manager** were discovered. The **User Defined Tools** menu item is not displayed because there are no user-defined element managers that are defined in the Configuration Utility.

Using the single sign-on feature with launch or launch in context

Single sign-on is an authentication process in which you can access more than one system or application by entering a single user ID and password. Single sign-on enables you to start applications from Tivoli Storage Productivity Center without providing logon credentials for the application. Single sign-on is available only for Tivoli Storage Productivity Center for Replication, DS8000, SAN Volume Controller 6.1 and later, and Storwize V7000.

For Tivoli Storage Productivity Center for Replication Storage Manager, single sign-on is enabled by default. For DS8000 Storage Manager, SAN Volume Controller, and Storwize V7000, single sign-on must be enabled.

To enable single sign-on, see the following topics in the Tivoli Storage Productivity Center information center:

- Configuring Tivoli Storage Productivity Center for DS8000 LDAP authentication
- Configuring Tivoli Storage Productivity Center for SAN Volume Controller and Storwize V7000 single sign-on

Related concepts:

“Single sign-on” on page 55

Single sign-on is an authentication process that enables you to enter one user ID and password to access multiple applications. For example, you can access IBM Tivoli Integrated Portal and then access IBM Tivoli Storage Productivity Center and IBM Tivoli Storage Productivity Center for Replication from Tivoli Integrated Portal using a single user ID and password. Single sign-on integrates with the launch and launch-in-context features to enable you to move smoothly from one application to another application.

User roles

IBM Tivoli Storage Productivity Center provides user roles that can be mapped to user groups contained in the authentication repository, which is either the local operating system or an LDAP-compliant directory, depending on the choice of authentication mechanism made during the Tivoli Storage Productivity Center installation. The roles determine the user's ability to see and act upon specific nodes in the navigation tree of the GUI. Other factors that affect the user's capability are the components that are licensed, installed, and running.

The superuser is the highest level role and can be used to install IBM Tivoli Storage Productivity Center and to initially set up the product. The superuser has authority over all the other roles in Tivoli Storage Productivity Center:

Figure 4. User roles in Tivoli Storage Productivity Center

The functions that are visible for the user roles require that the following components be licensed and installed as shown in Table 11.

Table 11. Functions that require components to be licensed and installed

Function	Component
Data Manager	IBM Tivoli Storage Productivity Center for Data
Disk Manager (requires Device server installation)	IBM Tivoli Storage Productivity Center for Data or Tivoli Storage Productivity Center for Disk or IBM Tivoli Storage Productivity Center for Fabric
Disk performance function (requires Device server installation)	Tivoli Storage Productivity Center for Disk
Fabric Manager (requires Device server installation)	IBM Tivoli Storage Productivity Center for Fabric or IBM Tivoli Storage Productivity Center for Data or Tivoli Storage Productivity Center for Disk

Table 11. Functions that require components to be licensed and installed (continued)

Function	Component
Fabric performance function (requires Device server installation)	IBM Tivoli Storage Productivity Center for Fabric
Tape Manager (requires Device server installation)	IBM Tivoli Storage Productivity Center for Fabric or IBM Tivoli Storage Productivity Center for Data or Tivoli Storage Productivity Center for Disk
Element Manager	IBM Tivoli Storage Productivity Center or IBM Storage Productivity Center Select or IBM Tivoli Storage Productivity Center Advanced Edition

Table 12 shows the GUI nodes that require special roles to view, edit, and act upon the services. The Productivity Center administrator or superuser is required for viewing configurations.

Table 12. GUI nodes that require special roles or licenses

GUI node	Special roles
Administrative Services	All roles can see this node but the user must be a Productivity Center administrator or superuser to edit and act upon the services (for example enable or disable tracing, shut down services, delete services, and so forth).
Administrative Services - Configuration - Role-to-Group Mappings	Only the Productivity Center administrator or superuser can see this node.
Administrative Services - Configuration - License Keys	Only the Productivity Center administrator or superuser can see this node.
Tivoli Storage Productivity Center - My Reports - System Reports - Data	Requires the data administrator role to create or edit objects, or to run jobs, (for example, pings and scans). Requires the data operator role to view reports.
Tivoli Storage Productivity Center - My Reports - System Reports - Disk	Requires that the disk performance function be installed and the disk operator role.
Tivoli Storage Productivity Center - My Reports - System Reports - Fabric	Requires the fabric administrator role to create or edit objects, or to run jobs (for example, pings and scans). Requires the fabric operator role to view reports. This includes being able to view the fabric assets, port connections, SAN switch report, switch port errors, and switch ports (packet rate and data rate).
Tivoli Storage Productivity Center - My Reports - Batch Reports	Requires any administrator role to create the batch reports.
Tivoli Storage Productivity Center - Monitoring - Probes	Requires any administrator role to create or edit probes.

Table 12. GUI nodes that require special roles or licenses (continued)

GUI node	Special roles
Tivoli Storage Productivity Center - Alerting - Alert log	Requires any administrator role to delete or clear alerts. The Storage subsystems node appears if any disk array is installed.
Data Manager	Requires the data administrator role to create or edit objects, or to run jobs (for example, pings and scans). Requires the data operator role to view reports.
Data Manager for Databases	Requires the data administrator role to create or edit objects, or to run jobs (for example, pings and scans). Requires the data operator role to view reports.
Data Manager for Chargeback	Requires the data administrator or data operator role.
Disk Manager	Requires the disk administrator role to create or edit objects, or to run jobs (for example, pings and scans). Requires the disk operator role to view reports. The Storage Subsystem Performance Monitors node requires that the Disk performance function is available.
Disk Manager - Monitoring - Subsystem Performance Monitors - Profile Management - Reporting - Storage Subsystem Performance	Disk performance function must be available.
Fabric Manager	Requires the fabric administrator role to create or edit objects, or to run jobs (for example, pings and scans). Requires the fabric operator role to view reports.
Fabric Manager - Monitoring - Switch Performance Monitors - Reporting - Switch Performance - Constraint Violations	Fabric performance function must be available.
Tape Manager	Requires the tape administrator role to create or edit objects, or to run jobs (for example, pings and scans). Requires the tape operator role to view reports.
Element Manager	All roles can view and edit objects and run jobs.

User tasks

This section provides an overview of the key IBM Tivoli Storage Productivity Center tasks that you can perform. It includes tasks that are common to all configurations and tasks that require that specific components be installed and licensed.

Common tasks

Perform common tasks on any Tivoli Storage Productivity Center configuration. These tasks are available under the **Administrative Services** and **IBM Tivoli Storage Productivity Center** nodes in the navigation tree.

- View and manage the services for the Data server, Device server, and Replication server.
- Configure devices for monitoring by Tivoli Storage Productivity Center.
- Manage agents and data sources, including CIM agents, Storage Resource agents, Data agents, Fabric agents, storage systems, Tivoli Storage Productivity Center servers, and VMware VI.
- Discover storage devices that are visible to Tivoli Storage Productivity Center.
- Configure and customize Tivoli Storage Productivity Center for your environment using the functions available under the **Administrative Services > Configuration** node in the navigation tree.
- Authorize users by associating user groups with roles (requires superuser role).
- Deploy Storage Resource agents on hosts that you want to monitor.
- Manage all the schedules, runs, and jobs that are related to the monitoring of storage devices by Tivoli Storage Productivity Center.
- Define probe schedules to collect information about storage devices and other Tivoli Storage Productivity Center servers.
- Create batch reports for information that you want to view on a regular basis in an output file.
- View System Reports that contain key information about the devices that are monitored by Tivoli Storage Productivity Center. These reports are automatically generated when data collection schedules are run.
- Generate Rollup Reports to view information that has been collected by Tivoli Storage Productivity Center servers if you have multiple servers installed in your environment.
- Create and manage groups of related storage entities. Use storage resource groups as input into the SAN Planner.
- Analyze storage subsystems, identify performance bottlenecks, and recommend changes to improve performance (Storage Optimizer).
- Create end-to-end planning for fabrics, hosts, storage controllers, storage pools, volumes, paths, ports, zones, zone sets, and replication (SAN Planner).
- Determine whether existing SAN configurations violate defined best practices or policies (Configuration Analysis).
- Check the alert log to see detailed information about alerts.
- Access a topology view of your storage infrastructure.
- Use Tape Manager to view tape libraries, create tape library groups and run probes against those groups, and view tape library alerts.

Data Manager tasks

Data Manager tasks are tasks that are specific to the Data Manager, Data Manager for Databases, and Data Manager for Chargeback components.

The following tasks are available under the **Data Manager**, **Data Manager for Databases**, and **Data Manager for Chargeback** nodes in the navigation tree:

- Create monitoring groups that contain related storage devices. Use groups when you want to perform the same action against multiple devices, such as collecting

data with a scan or probe. In Data Manager, you can create groups of computers, file systems, directories, users, OS user groups, databases, tablespaces, and tables.

- Define ping schedules to collect availability information about computers and clusters.
- Define scan schedules to collect detailed information about storage usage and trending for computers, file systems, directories, and clusters.
- Create profiles to define the files that are scanned during a file systems scan and the statistics that are gathered.
- Create and manage alerts for computers, file systems, directories, database instances, tablespaces, and tables. Use alerts to be notified of conditions that are detected on storage devices.
- Establish quotas and constraints to define storage use limits for users and user groups.
- Automatically extend local file systems of managed hosts.
- Generate and view data system reports.
- Use Data Manager for Chargeback to generate invoices that charge back for storage usage.

Disk Manager tasks

The Disk Manager tasks are tasks that are specific to the Disk Manager component.

The following tasks are available under the **Disk Manager** node in the navigation tree:

- Configure storage systems for monitoring by Tivoli Storage Productivity Center.
- Create and manage virtual disks and volumes.
- Define and launch element managers for storage systems.
- Use the Storage Optimizer to identify performance bottlenecks and recommend changes to improve performance for storage systems.
- Use the SAN Planner to perform end-to-end planning for fabrics, hosts, storage controllers, storage pools, volumes, paths, ports, zones, zone sets, and replication.
- Create monitoring groups that contain related storage systems. Use these groups when you want to perform the same action against multiple storage systems, such as collecting data with a probe.
- Define performance monitors to collect performance data related to storage systems.
- Create and manage alerts for storage systems. Use alerts to be notified of conditions that are detected on storage systems.
- Create workload profiles to be used by the SAN Planner to describe characteristics of the volumes to be created.
- Create provisioning profiles to be used by the SAN Planner to define the actual capacity (and security - zoning) characteristics of whatever the profile happens to be associated with.
- Create thin provisioning profiles to specify the parameters for thin provisioned volumes to be created through SAN Planner.
- Generate and view detailed reports about the storage systems that are monitored by Tivoli Storage Productivity Center.

Fabric Manager tasks

Fabric Manager tasks are tasks that are specific to the Fabric Manager component.

The following tasks are available under the **Fabric Manager** node in the navigation tree:

- Configure fabrics and switches for monitoring by Tivoli Storage Productivity Center.
- Create and work with fabric zones, zone aliases, and zone sets
- Create monitoring groups that contain related fabrics. Use these groups when you want to perform the same action against multiple fabrics, such as collecting data with a probe.
- Define switch performance monitors to collect performance data related to switches.
- Create and manage alerts for fabrics, switches, and endpoint devices. Use alerts to be notified of conditions that are detected on these storage devices.
- Generate and view fabric system reports and switch performance reports.

Tivoli Storage Productivity Center for Replication tasks

You can use Tivoli Storage Productivity Center for Replication to obtain continuous availability and disaster recovery solutions by using point-in-time replication, which includes FlashCopy, and Snapshot, and continuous replication, which includes Metro Mirror and Global Mirror.

You can set up Metro Mirror and Global Mirror sessions to replicate data in both the forward and reverse directions.

Use Tivoli Storage Productivity Center for Replication for the following tasks:

- Manage Tivoli Storage Productivity Center for Replication servers
- Create and monitor storage system connections
- Create and monitor logical paths
- Create and manage sessions for performing these types of data replication.
 - FlashCopy (ESS, DS6000, DS8000, and SAN Volume Controller)
 - Snapshot (the XIV system)
 - Global Mirror Single Direction (ESS, DS6000, DS8000, and SAN Volume Controller)
 - Global Mirror Either Direction with Two-Site Practice (ESS, DS6000, and DS8000)
 - Global Mirror Failover/Failback (ESS, DS6000, DS8000, SAN Volume Controller, and the XIV system)
 - Global Mirror Failover/Failback with Practice (ESS, DS6000, DS8000, and SAN Volume Controller)
 - Metro Mirror Single Direction (SAN Volume Controller)
 - Metro Mirror Failover/Failback (SAN Volume Controller, and the XIV system)
 - Metro Mirror Failover/Failback with Practice (SAN Volume Controller)
 - Metro Mirror or Global Copy (ESS, DS6000, and DS8000)
 - Metro Mirror Failover/Failback or Global Copy (ESS, DS6000, and DS8000)
 - Metro Mirror Failover/Failback with HyperSwap (ESS, DS6000, and DS8000)
 - Metro Global Mirror Failover/Failback (DS8000)
 - Metro Global Mirror Failover/Failback (ESS and DS8000)
 - Metro Global Mirror Failover/Failback with Practice (ESS and DS8000)
 - Metro Global Mirror with HyperSwap (ESS and DS8000)

Note: Metro Global Mirror is available only with the IBM Tivoli Storage Productivity Center license, and requires a license key.

- Practicing recovery procedures while maintaining disaster recover capability

Data collection

Determining what information you want to gather about the storage resources within your enterprise is critical to helping you implement a storage management strategy. Create data collection schedules to gather information about the storage resources in your environment. There are different data collection schedules within Tivoli Storage Productivity Center depending on the type of information that you want to gather and from which types of resources the information is retrieved: discovery, probes, scans, pings, and performance monitors.

You must run discovery schedules or use the Configure Devices wizard before you can collect more detailed information about storage resources. After a storage resource is discovered by Tivoli Storage Productivity Center, use probes, scans, pings, and performance monitors to collect detailed information about those resources. You do not need to run discovery schedules for devices that use native API connection.

The data and statistics gathered by data collection schedules are stored in the database repository. You must define and run schedules before you can perform the other tasks within Tivoli Storage Productivity Center, such as viewing reports, enforcing storage policies, setting alerts, using the topology viewer, and managing storage subsystems.

The following types of data collection schedules are available in Tivoli Storage Productivity Center:

Availability Monitoring

Use pings to collect information about the availability of the storage assets in your enterprise. You can run pings against servers and computers only. Pings are unavailable for storage subsystems and other devices.

Asset Collection

Use probes to collect statistics about the storage assets in your enterprise, such as computers, disk controllers, hard disks, file systems, storage subsystems, fabrics, switches, hypervisors, and RDBMS objects.

Usage Monitoring

Use scans to collect statistics about the usage and trends of your actual storage consumption. Scans provide all the data for usage reporting, quota analysis, and constraint analysis. They gather information at the file and directory level. You can run scans against servers and computers only. Scans are unavailable for storage subsystems, switches, fabrics, and other devices.

Switch Performance Monitoring

Use fabric probes and switch performance monitors to collect information about switches and their performance.

Storage Subsystems Performance Monitoring

Use storage subsystem probes and subsystem performance monitors to collect information about storage subsystems and their performance.

Tivoli Storage Productivity Center Server Monitoring

Use TPC Server probes to collect the storage asset and capacity information that has been gathered by other Tivoli Storage Productivity Center servers

in your environment. Create master and subordinate relationships among servers to use a single interface to generate reports based on data and metrics collected by multiple servers.

You can create groups and profiles to use with data collection schedules to more efficiently monitor storage resources.

Monitoring Groups

Use monitoring groups to ping, probe, or scan multiple storage resources using the same schedule. You can create named groups of computers, storage subsystems, file systems, directories, fabrics, databases, table spaces, tables, users, and OS user groups.

For example, to gather information about all of the computers in a payroll department, create a computer monitoring group named Payroll and populate that group with the computers from the payroll department. Then, to collect information about those computers, select the computer monitoring group named Payroll when defining a data collection schedule. As computers are added or removed from the payroll department, update the Payroll computer monitoring group with those changes. Any data collection schedule that uses Payroll automatically collects information about the new computers in the group during its next run.

Profiles

Use profiles to fine-tune and control the files to be scanned during a file system scan and to specify the statistical information to be gathered.

Default profiles are supplied with Data Manager with Data Manager for Databases. With the default profiles, you can select a specific statistic that you want to gather. If you want to scan a computer or file system and gather all the available statistical information, select all of the default profiles when you create your scan.

You can also use profiles with **Reporting > Usage** reports to determine what information is displayed in those reports.

Session Types

Tivoli Storage Productivity Center for Replication provides several methods to replicate data. The type of data replication that is associated with a session is known as the *session type*.

The session types that are available depend on the storage system type and the edition of Tivoli Storage Productivity Center or Tivoli Storage Productivity Center for Replication that you are using as shown in this topic.

Basic HyperSwap

Basic HyperSwap is a copy services solution for IBM z/OS® version 1.9 and later. Basic HyperSwap provides high availability of data if a storage system failure occurs.

The Basic HyperSwap session type enables Tivoli Storage Productivity Center for Replication to manage Basic HyperSwap by using Metro Mirror or Metro Global Mirror replication.

For more information about the Basic HyperSwap session type, see “Basic HyperSwap (ESS, DS6000, and DS8000)” on page 83.

Basic HyperSwap sessions are available for the following Tivoli Storage Productivity Center for Replication editions and storage systems.

Table 13. Basic HyperSwap

Supported editions	Supported storage systems
<ul style="list-style-type: none"> • Tivoli Storage Productivity Center for Replication Basic Edition for System z • Tivoli Storage Productivity Center for Replication for System z 	<ul style="list-style-type: none"> • TotalStorage Enterprise Storage Server Model 800 • System Storage DS8000 • System Storage DS6000

FlashCopy

FlashCopy replication creates a point-in-time copy of the data on a source volume to a target volume. Data that existed on the target volume is replaced by the copied data.

For more information about the FlashCopy session type, see “FlashCopy” on page 84.

FlashCopy sessions are available for the following Tivoli Storage Productivity Center and Tivoli Storage Productivity Center for Replication editions and storage systems.

Table 14. FlashCopy

Supported editions	Supported storage systems
<ul style="list-style-type: none"> • Tivoli Storage Productivity Center for Replication Basic Edition for System z • Tivoli Storage Productivity Center for Replication for System z • All editions of Tivoli Storage Productivity Center 	<ul style="list-style-type: none"> • TotalStorage Enterprise Storage Server Model 800 • System Storage DS8000 • System Storage DS6000 • SAN Volume Controller • Storwize V3500 • Storwize V3700 • Storwize V7000 • Storwize V7000 Unified

Snapshot

Snapshot replication creates a point-in-time copy of a volume or set of volumes without having to define a specific target volume. The target volumes of a Snapshot session are automatically created when the snapshot is created.

For more information about the Snapshot session type, see “Snapshot” on page 85.

Snapshot sessions are available for the following Tivoli Storage Productivity Center and Tivoli Storage Productivity Center for Replication editions and storage systems.

Table 15. Snapshot

Supported editions	Supported storage systems
<ul style="list-style-type: none"> • Tivoli Storage Productivity Center for Replication Basic Edition for System z • Tivoli Storage Productivity Center for Replication for System z • All editions of Tivoli Storage Productivity Center 	The XIV system

Metro Mirror Single Direction

Metro Mirror is synchronous replication that operates between two sites that are up to 300 KM apart. The source volumes are on one storage system and the target volumes are on another storage system.

Metro Mirror replication maintains identical data in both the source and target volumes. When a write operation is issued to a source volume, the changes are propagated to the target volume before the write operation finishes processing.

With the Metro Mirror Single Direction session type, Metro Mirror replication is available only from the primary site.

For more information about the Metro Mirror Single Direction session type, see “Metro Mirror” on page 86.

Metro Mirror Single Direction sessions are available for the following Tivoli Storage Productivity Center for Replication editions and storage systems.

Table 16. Metro Mirror Single Direction

Supported editions	Supported storage systems
<ul style="list-style-type: none"> • Tivoli Storage Productivity Center for Replication for System z • All editions of Tivoli Storage Productivity Center 	<ul style="list-style-type: none"> • TotalStorage Enterprise Storage Server Model 800 • System Storage DS8000 • System Storage DS6000 • SAN Volume Controller • Storwize V7000 • Storwize V7000 Unified

Metro Mirror Failover/Failback

Metro Mirror Failover/Failback replication enables you to switch the direction of the data flow so that you can use your secondary site as your production site. You can then copy changes that are made at the secondary site back to the primary site.

For more information about the Metro Mirror Failover/Failback session type, see “Metro Mirror” on page 86.

Metro Mirror Failover/Failback sessions are available for the following Tivoli Storage Productivity Center for Replication editions and storage systems.

Table 17. Metro Mirror Failover/Failback

Supported editions	Supported storage systems
<ul style="list-style-type: none"> • Tivoli Storage Productivity Center for Replication for System z • All editions of Tivoli Storage Productivity Center 	<ul style="list-style-type: none"> • TotalStorage Enterprise Storage Server Model 800 • System Storage DS8000 • System Storage DS6000 • SAN Volume Controller • Storwize V7000 • Storwize V7000 Unified • The XIV system

Metro Mirror Failover/Failback with Practice

Metro Mirror Failover/Failback with Practice replication combines Metro Mirror Failover/Failback and FlashCopy capabilities to provide a point-in-time copy of the data on the secondary site. This session type provides volumes that you can use to practice for disaster recovery without losing your disaster recovery capability.

For more information about the Metro Mirror Failover/Failback with Practice session type, see “Metro Mirror” on page 86.

Metro Mirror Failover/Failback with Practice sessions are available for the following Tivoli Storage Productivity Center for Replication editions and storage systems.

Table 18. Metro Mirror Failover/Failback with Practice

Supported editions	Supported storage systems
<ul style="list-style-type: none"> • Tivoli Storage Productivity Center for Replication for System z • All editions of Tivoli Storage Productivity Center 	<ul style="list-style-type: none"> • TotalStorage Enterprise Storage Server Model 800 • System Storage DS8000 • System Storage DS6000 • SAN Volume Controller • Storwize V7000 • Storwize V7000 Unified

Global Mirror Single Direction

Global Mirror is asynchronous replication that operates between two sites that are over 300 KM apart. The source volumes are on one storage system and the target volumes are on another storage system.

Global Mirror replication maintains identical data in both the source and target volumes. When a write operation is issued to a source volume, the changes are typically propagated to the target volume a few seconds after the data is written to the source volume.

With the Global Mirror Single Direction session type, Global Mirror replication is available only from the primary site.

For more information about the Global Mirror Single Direction session type, see “Global Mirror” on page 92.

Global Mirror Single Direction sessions are available for the following Tivoli Storage Productivity Center for Replication editions and storage systems.

Table 19. Global Mirror Single Direction

Supported editions	Supported storage systems
<ul style="list-style-type: none"> • Tivoli Storage Productivity Center for Replication for System z • All editions of Tivoli Storage Productivity Center 	<ul style="list-style-type: none"> • TotalStorage Enterprise Storage Server Model 800 • System Storage DS8000 • System Storage DS6000 • SAN Volume Controller • Storwize V7000 • Storwize V7000 Unified

Global Mirror Either Direction with Two-Site Practice

Global Mirror Either Direction with Two-Site Practice enables you to run Global Mirror replication from either the primary or secondary site. This session type provides volumes on the primary and secondary site that you can use to practice for disaster recovery without losing your disaster recovery capability.

For more information about the Global Mirror Either Direction with Two-Site Practice session type, see “Global Mirror” on page 92.

Global Mirror Either Direction with Two-Site Practice sessions are available for the following Tivoli Storage Productivity Center for Replication editions and storage systems.

Table 20. Global Mirror Either Direction with Two-Site Practice

Supported editions	Supported storage systems
<ul style="list-style-type: none"> • Tivoli Storage Productivity Center for Replication for System z • All editions of Tivoli Storage Productivity Center 	<ul style="list-style-type: none"> • TotalStorage Enterprise Storage Server Model 800 • System Storage DS8000 • System Storage DS6000

Global Mirror Failover/Failback

Global Mirror Failover/Failback replication enables you to switch the direction of the data flow so that you can use your secondary site as your production site. You can then copy changes that are made at the secondary site back to the primary site.

Global Mirror Failover/Failback sessions are available for the following Tivoli Storage Productivity Center for Replication editions and storage systems. For more information about this session type, see “Global Mirror” on page 92.

Table 21. Global Mirror Failover/Failback

Supported editions	Supported storage systems
<ul style="list-style-type: none"> • Tivoli Storage Productivity Center for Replication for System z • All editions of Tivoli Storage Productivity Center 	<ul style="list-style-type: none"> • TotalStorage Enterprise Storage Server Model 800 • System Storage DS8000 • System Storage DS6000 • SAN Volume Controller • Storwize V7000 • Storwize V7000 Unified • The XIV system

Global Mirror Failover/Failback with Practice

Global Mirror Failover/Failback with Practice combines Global Mirror Failover/Failback and FlashCopy capabilities to provide a point-in-time copy of the data on the secondary site. This session type provides volumes that you can use to practice for disaster recovery without losing your disaster recovery capability.

For more information about the Global Mirror Failover/Failback with Practice session type, see “Global Mirror” on page 92.

Global Mirror Failover/Failback with Practice sessions are available for the following Tivoli Storage Productivity Center for Replication editions and storage systems.

Table 22. Global Mirror Failover/Failback with Practice

Supported editions	Supported storage systems
<ul style="list-style-type: none"> • Tivoli Storage Productivity Center for Replication for System z • All editions of Tivoli Storage Productivity Center 	<ul style="list-style-type: none"> • TotalStorage Enterprise Storage Server Model 800 • System Storage DS8000 • System Storage DS6000 • SAN Volume Controller • Storwize V7000 • Storwize V7000 Unified

Metro Global Mirror

Metro Global Mirror replication provides continuous, remote data replication that operates between three sites that are varying distances apart. Metro Global Mirror combines Metro Mirror synchronous copy and Global Mirror asynchronous copy into a single session, where the Metro Mirror target is the Global Mirror source. Metro Global Mirror replication enables you to switch the direction of the data flow so that you can use your secondary or tertiary site as your production site.

For more information about the Metro Global Mirror session type, see “Metro Global Mirror (ESS and DS8000)” on page 97.

Metro Global Mirror sessions are available for the following Tivoli Storage Productivity Center for Replication editions and storage systems.

Table 23. Metro Global Mirror

Supported editions	Supported storage systems
<ul style="list-style-type: none"> • Tivoli Storage Productivity Center for Replication for System z • All editions of Tivoli Storage Productivity Center 	<ul style="list-style-type: none"> • TotalStorage Enterprise Storage Server Model 800 (only H1 site) • System Storage DS8000

Metro Global Mirror with Practice

Metro Global Mirror with Practice combines Metro Mirror, Global Mirror, and FlashCopy capabilities to provide a point-in-time copy of the data on the tertiary site. This session type provides volumes that you can use to practice for disaster recovery without losing your disaster recovery capability.

For more information about the Metro Global Mirror with Practice session type, see “Metro Global Mirror (ESS and DS8000)” on page 97.

Metro Global Mirror with Practice sessions are available for the following Tivoli Storage Productivity Center for Replication editions and storage systems.

Table 24. Metro Global Mirror with Practice

Supported editions	Supported storage systems
<ul style="list-style-type: none"> • Tivoli Storage Productivity Center for Replication for System z • All editions of Tivoli Storage Productivity Center 	<ul style="list-style-type: none"> • TotalStorage Enterprise Storage Server Model 800 (only H1 site) • System Storage DS8000

Basic HyperSwap (ESS, DS6000, and DS8000)

Basic HyperSwap is a copy services solution for z/OS version 1.9 and later. It provides high availability of data if a disk storage system failure occurs. Basic HyperSwap does not replace a disaster recovery solution. If a session is suspended but the suspend operation was not caused by a HyperSwap trigger, the session is not frozen to ensure that it is consistent.

When HyperSwap is combined with Metro Mirror and Metro Global Mirror replication, you can prepare your system for disaster recovery and ensure high availability of data. If a session is suspended but the suspend operation was not caused by a HyperSwap trigger, the session is frozen to ensure that it is consistent.

Restriction: This replication method is only available on ESS, DS6000, and DS8000 storage systems, and on management servers that run IBM Tivoli Storage Productivity Center for Replication Basic Edition for System z or IBM Tivoli Storage Productivity Center for Replication for System z.

Basic HyperSwap replication performs the following actions:

- Manages CKD volumes in Metro Mirror to manage synchronous peer-to-peer remote copy (PPRC) relationships.
- Permits only CKD volumes to be added to the HyperSwap session. The graphical user interface (GUI) shows only CKD volumes when you add a copy set. The command-line interface (CLI) does not add a copy set if a fixed block volume is specified.
- Monitors events that indicate a storage device failed.

- Determines whether the failing storage device is part of a Metro Mirror synchronous PPRC pair.
- Determines the action to be taken from policy.
- Ensures that data remains consistent.
- Swaps the I/O between the primary logical devices in the consistency group with the secondary logical devices in the consistency group. A swap can occur from the preferred logical devices to the alternate logical devices or from the alternate logical devices to the preferred logical devices.

Metro Mirror Failover/Failback with HyperSwap

Metro Mirror Failover/Failback uses HyperSwap to configure and manage synchronous PPRC pairs.

Metro Global Mirror with HyperSwap

Metro Global Mirror with HyperSwap is a z/OS replication feature that provides the three-site continuous replication that you can use if a disaster occurs.

Restriction: If a HyperSwap event occurs when you run a Metro Global Mirror operation with a HyperSwap session, a full copy operation of the data occurs to return the system to a full three-site configuration. If you issue a HyperSwap command when you run a Metro Global Mirror operation with a HyperSwap session, a full copy operation does not occur. A full copy is required only for an unplanned HyperSwap session or a HyperSwap-initiated session by using the z/OS **SETHS SWAP** command.

Example

Jane is using multiple DS8000 storage systems. The host applications run on a z/OS operating system and the z/OS environment is connected to the DS8000 storage systems. She has a site in Manhattan and a secondary DS8000 in Hoboken. While it is not required that she has a disaster recovery solution in effect, she does need to have a high-availability solution to keep her applications running all the time. Jane is worried that if a volume fails on the DS8000 in Manhattan, her database application might fail. Even a small downtime can be costly to Jane.

Jane uses a Basic HyperSwap session to mirror the data on the DS8000 in Manhattan to the secondary DS8000 in Hoboken. If a volume at the Manhattan site fails, Basic HyperSwap automatically directs application I/O to the mirrored volumes in Hoboken.

FlashCopy

FlashCopy replication creates a point-in-time copy in which the target volume contains a copy of the data that was on the source volume when the FlashCopy was established.

The ESS, DS6000, and DS8000 provide multiple logical subsystems (LSSs) within a single physical subsystem, while the following platforms provide multiple I/O groups:

- SAN Volume Controller
- Storwize V3500
- Storwize V3700
- Storwize V7000

- Storwize V7000 Unified

All platforms can use local replication in which the source volume is located in one LSS or I/O group and the target volume is located in the same or another LSS or I/O group. Using the FlashCopy feature, you can reference and update the source volume and target volume independently.

The following figure illustrates how a FlashCopy session works.

Example

Jane works for a bank. Jane uses a FlashCopy session to make a point-in-time copy of the customer data in existing international accounts. Every night, the bank's servers start batch processing. Jane uses the FlashCopy session to create checkpoint restarts for the batch processing if the batch processing fails. In the batch processing, the first step is to balance all international accounts and to make a FlashCopy point-in-time copy of the resulting data. The second step in the batch processing is to complete the international disbursements.

If the second step in the batch process fails, Jane can use the data from the FlashCopy session that was taken of the first step to repeat the second step. In this way, Jane does not have to begin the entire process again. Jane also uses a CLI script that performs a FlashCopy operation every night at 11:59 PM, and another script that quiesces the database. She backs up the data to tape on the target storage system, and then sends the tape to the bank's data facility for storage.

Snapshot

Snapshot is a session type that creates a point-in-time copy of a volume or set of volumes. You do not have to define a specific target volume. The target volumes of a Snapshot session are automatically created when the snapshot is created.

The XIV system uses a snapshot session to create a large number of volume copies without affecting system performance. By using the snapshot function to create a point-in-time copy, and to manage the copy, you can save storage. With the XIV system snapshots, no storage capacity is used by the snapshot until the source volume or the snapshot is changed.

The following figure illustrates how a Snapshot session works.

Example

Jane's host applications are using an XIV system for their back-end storage. With the XIV system, Jane can create a large number of point-in-time copies of the data. The snapshot function ensures that if data becomes corrupted, she can restore the data to any point in time.

Jane sets up a Snapshot session by using Tivoli Storage Productivity Center for Replication and specifies the volumes on the XIV system that are used by the host applications. Jane does not have to provision target volumes for all the snapshots she intends to make. She can quickly configure a single Snapshot session.

When the session is configured, Jane uses a CLI script that runs a **Create Snapshot** command to the session every two hours. If a problem occurs, such as data becoming corrupted, Jane can find a snapshot of the data from a time before the problem occurred. She can restore the data to that point.

By creating a set of snapshots of the data, Jane can also schedule batch processing against that data every day. She can use the batch processing to analyze certain trends in the market without affecting the host applications.

Metro Mirror

Metro Mirror is a method of synchronous, remote data replication that operates between two sites that are up to 300 KM apart. The source is located in one storage system and the target is located in another storage system.

Attention: If you have Tivoli Storage Productivity Center for Replication for System z sessions that contain Metro Mirror relationships, ensure that the session does not contain system volumes (such as paging volumes) unless you select the **Manage H1-H2 with HyperSwap** or the **Enable Hardened Freeze** option for the session. By using these options, z/OS Input/Output Supervisor (IOS) manages freeze operations for the volumes in the session, which prevents Tivoli Storage Productivity Center for Replication from freezing the volumes and possibly freezing itself.

Metro Mirror replication maintains identical data in both the source and target. When a write operation is issued to the source copy, the changes made to the source data are propagated to the target before the write operation finishes processing. If the storage system ends, no data is lost when you use Metro Mirror if data must be used from the recovery site.

A Metro Mirror session in Global Copy mode creates an asynchronous relationship to accommodate the high volume of data that is migrated. As a result, the data on the target system might no longer be consistent with the source system. The Metro Mirror session switches back to a synchronous relationship when Metro Mirror reissues a **Start** command. In addition, you can start a Metro Mirror session in Global Copy mode and toggle between Metro Mirror and Global Copy modes to accommodate periods in which you require host I/O response time over data consistency.

Tip: To determine whether there is any out-of-sync data that must to be copied before the session is consistent, check the percent that is complete in the session details page.

Metro Mirror Single Direction

The following figure illustrates how a Metro Mirror Single Direction session works.

Metro Mirror Failover/Failback

Using Metro Mirror Failover/Failback, the data exists on the second site, which is less than 300 KM away, and you can switch the direction of the data flow. You can use this session type to run your business from the secondary site, and to copy changes made at the second site back to the primary site when you want to resume production at the primary site.

The following figure illustrates how a Metro Mirror with Failover/Failback session works.

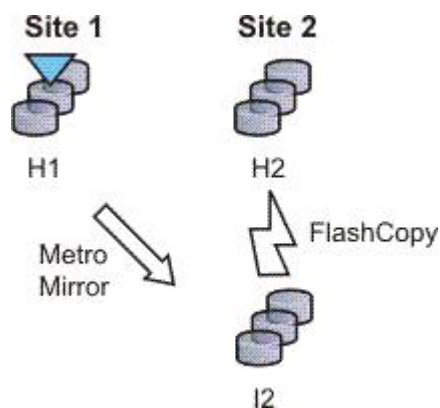

Metro Mirror Failover/Failback with Practice

A Metro Mirror Failover/Failback with Practice session combines Metro Mirror and FlashCopy features to provide a point-in-time copy of the data on the remote site. You can use this session type to practice what you might do if a disaster occurs, without losing your disaster recovery capability.

This solution consists of two host volumes and an intermediate volume.

The following figure illustrates how a Metro Mirror Failover/Failback with Practice session works.

Metro Mirror Failover/Failback with HyperSwap

You can enable a Metro Mirror Failover/Failback session to have HyperSwap capabilities. To enable the HyperSwap feature, the following conditions must apply:

- The session is running on an Tivoli Storage Productivity Center for Replication server that runs on IBM z/OS.
- The volumes are only for TotalStorage Enterprise Storage Server, DS6000, and System Storage DS8000 systems.
- The volumes are count key data (CKD) volumes that are attached to the z/OS system.

Metro Mirror Failover/Failback with HyperSwap combines the high availability of Basic HyperSwap with the redundancy of a two-site Metro Mirror Failover/Failback solution when managing count key data (CKD) volumes on z/OS. If the primary volumes encounter a permanent I/O error, the I/O is automatically swapped to the secondary site with minimal effect on the application.

A swap can be planned or unplanned. A planned swap occurs when you issue a HyperSwap command from the **Select Action** list in the graphical user interface (GUI) or when you issue a `cmdsess -action hyperswap` command.

The following figure illustrates how a Metro Mirror Failover/Failback session that is enabled for HyperSwap works.

Metro Mirror Failover/Failback

For more information about enabling HyperSwap, see “Managing a session with HyperSwap and Open HyperSwap replication” on page 100.

Metro Mirror Failover/Failback with Open HyperSwap

You can enable a Metro Mirror Failover/Failback session to have Open HyperSwap capabilities. To enable Open HyperSwap processing, the following conditions must apply:

- The volumes in the session are System Storage DS8000 5.1 or later volumes.
- The volumes in the session are fixed block and are mounted to IBM AIX 5.3 or AIX 6.1 hosts with the following modules installed:
 - Subsystem Device Driver Path Control Module (SDDPCM) version 3.0.0.0 or later
 - Multi-Path Input/Output (MPIO) module (the version that is provided with AIX version 5.3 or 6.1)
- The connections between the AIX host systems and the Tivoli Storage Productivity Center for Replication server are established.

Metro Mirror Failover/Failback with Open HyperSwap combines the high availability of Basic HyperSwap on z/OS for fixed-block AIX volumes with the

redundancy of a two-site Metro Mirror Failover/Failback solution. If the primary volumes encounter a permanent I/O error, the I/O is automatically swapped to the secondary site with minimal effect on the application.

A swap can be planned or unplanned. A planned swap occurs when you issue a HyperSwap command from the **Select Action** list in the GUI or when you issue a `cmdsess -action hyperswap` command.

The following figure illustrates how a Metro Mirror Failover/Failback session that is enabled for Open HyperSwap works.

Metro Mirror Failover/Failback

For more information about enabling Open HyperSwap, see “Managing a session with HyperSwap and Open HyperSwap replication” on page 100.

Examples

Read the following scenarios for information on using Metro Mirror for synchronous, remote data replication between two sites.

Metro Mirror Single Direction

At the beginning of a work week, Jane is notified that between 10:00 AM and 11:00 AM on the next Friday, power in her building is going to be shut off. Jane does not want to lose any transactions during the power outage, so she decides to transfer operations to the backup site during the outage. She wants a synchronous copy method with no data loss for the critical business functions, so she chooses Metro Mirror, which can be used between locations that are less than 300 KM apart.

In a synchronous copy method, when a write is issued to change the source, the change is propagated to the target before the write is posted. This method of replication maintains identical data in both the source and target. The advantage of this method is when a disaster occurs, there is no data loss at the recovery site because both writes must complete before signaling completion of a write to the source application. Because the data must be copied to both System Storage DS8000 devices before the write is completed, Jane can be sure that the data is safe.

The night before the planned outage, Jane quiesces the database and servers in San Francisco and starts the database and servers in Oakland. To accomplish this task, Jane issues the **Suspend** and **Recover** commands, and then issues the **Start** command on the secondary site. She shuts down the equipment in San Francisco to avoid any power spikes when she restarts the system after the power is turned on.

Metro Mirror in Global Copy mode

At the beginning of a work week, Jane is notified that between 10:00 AM and 11:00 AM on the next Friday, power in her building is going to be shut

off. Jane does not want to lose any transactions during the power outage, so she decides to transfer operations to the backup site during the outage. She wants a synchronous copy method with no data loss for the critical business functions, so she chooses Metro Mirror, which can be used between locations that are less than 300 KM apart.

Jane wants to limit the effect on any applications while completing the initial Metro Mirror synchronization, so she begins the session in Global Copy mode. After she sees that approximately 70% of the data is copied, Jane decides to switch the session to Metro Mirror mode, assuring data consistency.

Metro Mirror with Practice

Jane wants to run a Metro Mirror with Practice from San Francisco to Oakland. She wants to verify the recovery procedure for the Oakland site, but she cannot stop running the Metro Mirror session while she takes time to practice a recovery. By using a Metro Mirror with Practice session, Jane can practice the disaster recovery scenario in Oakland while the Metro Mirror session runs uninterrupted. By practicing running the applications at the Oakland site, Jane is better prepared to recover data if a disaster occurs at the San Francisco site.

While her session is running in Prepared state, Jane practices a recovery at the Oakland site by issuing the **Flash** command. This command momentarily pauses the session and starts a FlashCopy to the H2 volumes. As soon as the FlashCopy is started, the session is restarted. These FlashCopy files create a consistent version of the data on the H2 volume that she can use for recovery testing, while the session continues to replicate data from San Francisco to Oakland. As a result, she can carry out the recovery testing without stopping the replication for any extended duration of time.

If, at some point, the Metro Mirror session is suspended because of a failure, Jane can use the practice session to restart the data replication process. She maintains a consistent copy of the data at the Oakland site, in case of a failure during the resynchronization process. When the session is suspended, she can issue a **Recover** command to create a consistent version of the data on the H2 volumes. After the **Recover** command completes, she can issue the **Start H1->H2** command to resynchronize the data from the San Francisco site to the Oakland site.

If a failure occurs before the restarted session is in Prepared state, she has a consistent version of the data on the H2 volumes. She only has to issue the **Recover** command to put the session into Target Available state and make the H2 volumes accessible from the servers. If the session was not in Prepared state when it was suspended, the subsequent **Recover** command does not issue the FlashCopy files to put the data on the H2 volumes. This means that the consistent data on the H2 volumes is not overwritten if the data to be copied to them is not consistent.

Metro Mirror Failover/Failback enabled for Open HyperSwap

Jane wants to run a Metro Mirror with Practice from San Francisco to Oakland. She wants to verify the recovery procedure for the Oakland site, but she cannot stop running the Metro Mirror session while she takes time to practice a recovery. By using a Metro Mirror with Practice session, Jane can practice the disaster recovery scenario in Oakland while the Metro

Mirror session runs uninterrupted. By practicing running the applications at the Oakland site, Jane is better prepared to recover data if a disaster occurs at the San Francisco site.

While the session is running in a Prepared state, Jane practices a recovery at the Oakland site by issuing the **Flash** command. This command momentarily pauses the session and starts a FlashCopy to the H2 volumes. As soon as the FlashCopy is started, the session is restarted. These FlashCopy files create a consistent version of the data on the H2 volume that she can use for recovery testing, while the session continues to replicate data from San Francisco to Oakland. As a result, she can carry out the recovery testing without stopping the replication for any extended duration of time.

If the Metro Mirror session is suspended because of a failure, Jane can use the practice session to restart the data replication process while she maintains a consistent copy of the data at the Oakland site, in case of a failure during the resynchronization process. When the session is suspended, she can issue a **Recover** command to create a consistent version of the data on the H2 volumes. After the **Recover** command completes, she can issue the **Start H1->H2** command to resynchronize the data from the San Francisco site to the Oakland site.

If a failure occurs before the restarted session is in Prepared state, she has a consistent version of the data on the H2 volumes. She only has to issue the **Recover** command to put the session into Target Available state and make the H2 volumes accessible from the servers. If the session was not in Prepared state when it was suspended, the subsequent **Recover** command does not issue the FlashCopy files to put the data on the H2 volumes. This means that the consistent data on the H2 volumes is not overwritten if the data to be copied to the volumes is not consistent.

Selecting a HyperSwap session

A global insurance company decided to use Tivoli Storage Productivity Center for Replication to manage its disaster recovery environment. Jane wants minimal data exposure, both for planned outages such as routine maintenance, and for unplanned disasters. They have CKD volumes on System Storage DS8000 devices, and use z/OS operating systems. They have two data centers in New York.

Jane chooses a Metro Mirror recovery solution, because her priority is to protect the system from regional disasters. Jane decides to use Metro Mirror solution, because her company has two data centers located near each other. Jane realizes that because she uses a z/OS operating system, CKD, and System Storage DS8000 hardware, she can also use a HyperSwap solution. Using Metro Mirror Failover/Failback with HyperSwap, Jane can minimize the effects on any applications, while she maintains the failover process to the secondary site. Jane decides Metro Mirror Failover/Failback with HyperSwap is the best solution.

After installing and configuring Tivoli Storage Productivity Center for Replication on z/OS, Jane starts the Tivoli Storage Productivity Center for Replication GUI. She adds the Tivoli Storage Productivity Center for Replication storage devices that she intends to use on all sites. From the Session Overview page, Jane uses the Create Session wizard, and selects the **Metro Mirror Failover/Failback** session type. She selects the **Manage H1H2 with HyperSwap** option. After finishing the wizard, Jane clicks **Launch Add Copy Sets Wizard**. She completes this wizard, and issues a **Start H1->H2** command. After the initial copy is completed, Jane can safely

replicate the data between both sites. She can also issue the **HyperSwap** command between sites 1 and 2 to switch sites with minimal effect on the application during either a disaster or maintenance period.

Performing a planned HyperSwap

Jane's company used Metro Mirror Failover/Failback with HyperSwap sessions for the past three months. However, Jane needs to perform maintenance on an H1 volume. During this time, Jane does not want the applications or replication to be interrupted. To prevent this interruption, before the maintenance is scheduled to begin, Jane uses the Tivoli Storage Productivity Center for Replication GUI to perform a HyperSwap operation to the H2 volumes. This process transitions the applications so that the data is written to H2. To perform a planned HyperSwap operation, Jane issues a **HyperSwap** command.

Understanding what happens when an unplanned HyperSwap occurs

Several weeks after the planned maintenance at Jane's company is completed, an incident occurs at the H1 site. A disk controller fails, causing one of the H1 volumes to encounter a permanent I/O error. Jane's data is safe because she used Metro Mirror Failover/Failback with HyperSwap, and the H2 volume is an exact duplicate of the H1 volume. When the permanent I/O error is detected, a HyperSwap is triggered. The application transitions to write data to the H2 volumes. The applications are not interrupted.

Jane configured a Simple Network Management Protocol (SNMP) listener to alert her to any events, so she receives the SNMP event that indicates that a HyperSwap occurred. Jane investigates the cause of the HyperSwap process and uses the z/OS console to identify the volume that triggered the HyperSwap process. Jane replaces the faulty disk controller. Then, to recover from the unplanned HyperSwap process, Jane issues the **Start H2->H1** command.

Global Mirror

Global Mirror is a method of asynchronous, remote data replication between two sites that are over 300 kilometers (km) apart. It maintains identical data in both the source and target, where the source is located in one storage system and the target is located in another storage system.

The data on the target is typically written a few seconds after the data is written to the source volumes. When a write is issued to the source copy, the change is propagated to the target copy, but subsequent changes are allowed to the source before the target verifies that it received the change. Because consistent copies of data are formed on the secondary site at set intervals, data loss is determined by the amount of time since the last consistency group was formed. If the system fails, Global Mirror might lose some data that was being transmitted when the failure occurs. Using Global Mirror, you can ensure that data is recoverable and consistent if a disaster occurs.

Global Mirror Single Direction

You can use a Global Mirror Single Direction session to run a Global Mirror replication process from only the primary site.

For ESS, DS6000, and DS8000 storage systems, each copy set in the single direction session consists of two host volumes and a journal volume. The following figure illustrates how a Global Mirror Single Direction session works on an ESS, DS6000, or DS8000 storage system.

For the following storage systems, each copy set in the Global Mirror Single Direction session consists of two host volumes:

- SAN Volume Controller
- Storwize V7000
- Storwize V7000 Unified

The following figure illustrates how a Global Mirror Single Direction session works on these storage systems.

Global Mirror Either Direction with Two-Site Practice (ESS, DS6000, and DS8000)

By using a Global Mirror Either Direction with Two-Site Practice session, you can run Global Mirror replication from either the primary or secondary site. It combines Global Mirror and FlashCopy to provide a point-in-time copy of the data on a remote site at a distance over 300 km away from your first site. By using this practice session, you can create volumes on both the primary and secondary site to practice what you might do if a disaster occurred, without affecting the disaster recovery capability.

Restriction: This replication method is available on only ESS, DS6000, and DS8000 storage systems.

The session consists of two host volumes, two intermediate volumes, and two journal volumes. The following figure illustrates how a Global Mirror Either Direction with Two-Site Practice session works.

Global Mirror Failover/Failback

Using Global Mirror Failover/Failback, your data exists on the second site that is more than 300 km away, and you can use failover or failback processing to switch the direction of the data flow. You can run your business from the secondary site.

For ESS, DS6000, and DS8000 storage systems, each copy set in the Global Mirror Failover/Failback session consists of two host volumes and a journal volume. The following figure illustrates how a Global Mirror Failover/Failback session works on an ESS, DS6000, or DS8000 storage system.

For the following storage systems, each copy set in the Global Mirror Failover/Failback session consists of two host volumes:

- SAN Volume Controller
- Storwize V7000
- Storwize V7000 Unified
- The XIV system

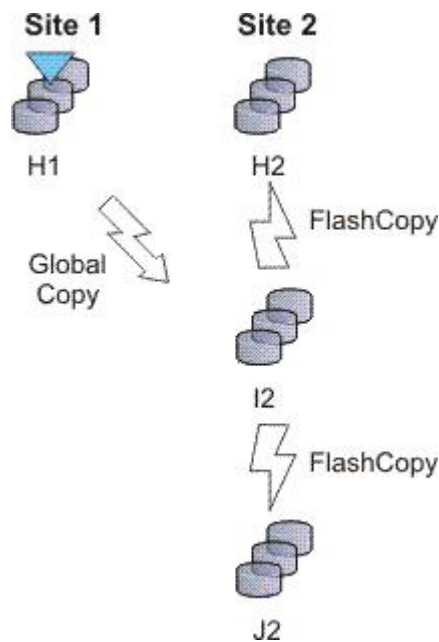

The following figure illustrates how a Global Mirror Failover/Failback session works on these storage systems.

Global Mirror Failover/Failback with Practice

A Global Mirror Failover/Failback with Practice session combines Global Mirror and FlashCopy features to provide a point-in-time copy of the data on a remote site at a distance over 300 KM away from your primary site. You can use this to practice what you might do if a disaster occurred, without affecting the disaster recovery capability.

For ESS, DS6000, and DS8000 storage systems, each copy set in the Global Mirror Failover/Failback with Practice session consists of two host volumes, an intermediate volume, and a journal volume. The following figure illustrates how a Global Mirror Failover/Failback with Practice session works on an ESS, DS6000, or DS8000 storage system.

For the following storage systems, each copy set in the Global Mirror failover/failback with Practice session consists of two host volumes and an intermediate volume:

- SAN Volume Controller
- Storwize V7000
- Storwize V7000 Unified

The following figure illustrates how a Global Mirror Failover/Failback with Practice session works on these storage systems.

Examples

Read the following scenarios for information on using Global Mirror for asynchronous, remote data replication between two sites.

Global Mirror Single Direction

Although Jane's FlashCopy and Metro Mirror copies were both planned, Jane realizes that sometimes a failure can occur, and she wants to ensure that the data is safe. Because Jane works in San Francisco, she wants her other site to be far away if a disaster occurs locally. Her other site is based in Houston. A minor earthquake occurs in San Francisco and power and communications both fails. Jane arranged for the data on customer accounts that recently opened or closed to be asynchronously copied in Houston, using Global Mirror. Jane risks losing the bytes of data that were being processed when the tremor disrupted the processing in San Francisco. However, she understands that it is minor inconvenience when weighed next to the value of backing up her data to an area that is not prone to earthquakes.

Global Mirror with Practice

Jane wants to run a Global Mirror with practice from San Francisco to Houston. She plans to verify her recovery procedure for the Houston site, but she cannot stop running the Global Mirror session while she takes time to practice a recovery. By using a Global Mirror with Practice session, Jane can practice her disaster recovery scenario in Houston while the Global Mirror session runs uninterrupted. When she practices running the applications at the Houston site, Jane is better prepared to recover the data if a disaster ever strikes the San Francisco site.

Global Mirror Either Direction with Two-Site Practice

Jane wants to run a Global Mirror with Practice from San Francisco to Houston. She plans to verify her recovery procedure for the Houston site, but she cannot stop running the Global Mirror session while she takes time to practice a recovery. By using a Global Mirror Either Direction with Two-Site Practice session, Jane can practice her disaster recovery scenario in Houston while the Global Mirror session runs uninterrupted. When she practices running the applications at the Houston site, Jane is better prepared to recover the data if a disaster ever strikes the San Francisco site.

Jane can use the Global Mirror Either Direction with Two-Site Practice session to run asynchronous consistent data replication from either the San Francisco site or the Houston site. She can practice the disaster-recovery tasks at the target site, regardless of the location of the current production

site. Jane's business can run a consistent Global Mirror session from its Houston site back to San Francisco while it runs a production site at Houston.

Setting up Global Mirror for Resource Groups on System Storage DS8000

If resource groups are defined on a System Storage DS8000, Global Mirror session IDs might be defined for some users. To determine which session IDs are valid, you must modify the `rmserver.properties` file and add the following property:

```
gm.master.sessionid.gm_role,session_name = xx
```

where `gm_role` is the role that has the master volume (for example, H1 in a Global Mirror failover/failback session), `session_name` is the name of the session that uses the session ID, and `xx` is the decimal number for the session ID.

Tip: System Storage DS8000 represents session IDs as a two-digit hexadecimal number. Use the decimal version of that number. For example, if you want a Global Mirror Failover/Failback session to use a session ID of 0F, the decimal number is 15, as shown in the following example:

```
gm.master.sessionid.H2.11194_wprac=15
```

Metro Global Mirror (ESS and DS8000)

Metro Global Mirror is a method of continuous, remote data replication that operates between three sites that are varying distances apart. Metro Global Mirror combines Metro Mirror synchronous copy and Global Mirror asynchronous copy into a single session, where the Metro Mirror target is the Global Mirror source.

This replication method is available on only TotalStorage Enterprise Storage Server Model 800 and System Storage DS8000 storage systems. You can select ESS storage systems in only the H1 volume role. All other volume roles must use DS8000 volumes.

You can use both ESS and DS8000 volumes in the H1 volume role. If ESS and DS8000 storage systems are both used in the H1 role, the DS8000 storage system performs Incremental Resync processing, and the ESS storage system performs a full copy operation. Because you cannot use the Incremental Resync function with ESS, a full copy is required when you change from H1->H2->H3 to H1>H3 and from H2->H1->H3 to H2->H3.

Attention: If you have Tivoli Storage Productivity Center for Replication for System z sessions that contain Metro Global Mirror relationships, ensure that the session does not contain system volumes (such as paging volumes) unless you select the **Manage H1-H2 with HyperSwap** or the **Enable Hardened Freeze** option for the session. By using these options, z/OS Input/Output Supervisor (IOS) manages freeze operations for the volumes in the session, which prevents Tivoli Storage Productivity Center for Replication from freezing the volumes and possibly freezing itself.

Metro Global Mirror maintains a consistent copy of data at the remote site, with minimal effect on applications at the local site. This remote mirroring function works in combination with FlashCopy to provide a disaster-recovery solution that includes the following features:

- Fast failover and failback
- Rapid reestablishment of three-site mirroring, without production outages

- Data currency at the remote site with minimal time lag at the local site, an average of only 3 - 5 seconds for many environments
- Quick resynchronization of mirrored sites using only incremental changes

If Tivoli Storage Productivity Center for Replication runs on a z/OS operating system, you can configure a Metro Global Mirror session to control the Metro Mirror relationship between the primary and secondary site by using the HyperSwap feature. With HyperSwap enabled, a failure on the primary storage system causes an automatic HyperSwap operation, which transparently redirects application I/O to the auxiliary storage system. The Global Mirror relationship continues to run uninterrupted throughout this process. With this configuration, you can achieve almost a zero data loss at larger distances.

Using synchronous mirroring, you can switch from local site H1 to remote site H2 during a planned or unplanned outage. It also provides continuous disaster recovery protection of the H2 and H3 sites. You do not have to configure H2, if a switch from site H1 occurs. With this configuration, you can reestablish H2->H1->H3 recoverability while production continues to run at site H2. Additionally, this setup can reduce the workload on site H1.

Important:

- If HyperSwap occurs by event when running a Metro Global Mirror with a HyperSwap session, a full copy of the data occurs to return to a full three-site configuration. If you issue a HyperSwap command when running a Metro Global Mirror with a HyperSwap session, a full copy does not occur. A full copy is required only for an unplanned HyperSwap or a HyperSwap initiated using the z/OS SETHS SWAP command.
- In Metro Global Mirror and Metro Global Mirror with Practice sessions, when the H1 is on an ESS storage system, you might risk filling up the space efficient journal volumes. Because incremental resynchronization is not available on the ESS storage system, full copies are performed in many of the transitions.

Metro Global Mirror

A Metro Global Mirror session with Practice combines Metro Mirror, Global Mirror, and FlashCopy across three sites to provide a point-in-time copy of the data on the third site.

The following figure illustrates how a Metro Global Mirror session works.

Metro Global Mirror with Practice

A Metro Global Mirror session with Practice combines Metro Mirror, Global Mirror, and FlashCopy across three sites to provide a point-in-time copy of the data on the third site. You can use this session to practice what you might do if a disaster occurred without losing your disaster recovery capability.

The session consists of three host volumes, an intermediate volume, and a journal volume. The following figure illustrates how a Metro Global Mirror with Practice session works.

Note: In Metro Global Mirror and Metro Global Mirror with Practice sessions, when the H1 is on an ESS storage system, you might risk filling up the space efficient journal volumes. Because incremental resynchronization is not available on the ESS storage system, full copies are performed in many of the transitions.

Examples

Read the following scenarios for information on using Metro Global Mirror for continuous, remote data replication between three sites.

Metro Global Mirror

Although Jane works in San Francisco, she wants to run the business from either Oakland, the secondary site, or Houston, the tertiary site. Jane can use Metro Global Mirror with Failover/Failback to switch the direction of the data flow, so that she can run the business from either Oakland or Houston. Using Metro Global Mirror, Jane has zero data loss at the secondary site and minimal data loss at the tertiary site.

Metro Global Mirror with Practice

Jane wants to run a Metro Global Mirror with Practice from San Francisco to Houston. She plans to verify her recovery procedure for the Houston site. However, she cannot stop running the Metro Global Mirror session while she takes time to practice a recovery. By using a Metro Global Mirror with Practice session, Jane can practice her disaster recovery scenario in Houston while the Metro Global Mirror session runs uninterrupted. When

she practices running the applications at the Houston site and is prepared to run the applications at the Oakland site, if necessary, Jane is prepared to recover data if a disaster occurs at the San Francisco site.

Jane can use Metro Global Mirror with Practice to switch the direction of the data flow, so that she can run the business from either Oakland or Houston. Using Metro Global Mirror, Jane has zero data loss at the secondary site and minimal data loss at the tertiary site.

Managing a session with HyperSwap and Open HyperSwap replication

HyperSwap and Open HyperSwap provide high availability of data if a primary disk storage system failure occurs. When a failure occurs in writing I/O to the primary storage system, the failure is detected by IOS, and IOS automatically swaps the I/O to the secondary site with no user interaction and minimal application effect.

Sessions that can be enabled for HyperSwap or Open HyperSwap:

You can create sessions that enable swapping, which provides a session with a highly available business continuity solution.

Sessions that can enable HyperSwap

The following session types can enable HyperSwap processing:

- Basic HyperSwap
- Metro Mirror with Failover/Failback
- Metro Global Mirror
- Metro Global Mirror with Practice

To enable HyperSwap processing, the following conditions must apply:

- The session is running on a Tivoli Storage Productivity Center for Replication server that is running on IBM z/OS.
- The volumes are only for TotalStorage Enterprise Storage Server, System Storage DS8000, and DS6000 systems.
- The volumes are count key data (CKD) volumes that are attached to the z/OS system.

Sessions that can enable Open HyperSwap

Only the Metro Mirror with Failover/Failback session type can enable Open HyperSwap processing.

To enable Open HyperSwap processing, the following conditions must apply:

- The volumes in the session are System Storage DS8000 5.1 or later volumes.
- The volumes in the session are fixed block and mounted to IBM AIX 5.3 or AIX 6.1 hosts with the following modules installed:
 - Subsystem Device Driver Path Control Module (SDDPCM) version 3.0.0.0 or later
 - Multi-Path Input/Output (MPIO) module (the version that is provided with AIX version 5.3 or 6.1)
- The connections between the AIX host systems and the Tivoli Storage Productivity Center for Replication server are established.

Setting up the environment for HyperSwap:

You must set up an environment in which you can run HyperSwap processing before you can enable HyperSwap for a IBM Tivoli Storage Productivity Center for Replication session.

Complete the following steps before you enable HyperSwap. For more information about these steps, see the IBM Tivoli Storage Productivity Center for Replication for System z Installation and Configuration Guide.

1. Install IBM Tivoli Storage Productivity Center for Replication for System z.
2. Set up the data store and configure other necessary system settings.
3. Ensure that all RESERVEs are converted to global enqueues (ENQs).
4. Ensure that all volumes in the session that you are enabling for HyperSwap are attached to the IBM z/OS system that runs Tivoli Storage Productivity Center for Replication.
5. Set up and start the IOSHSAPI and HSIB tasks.

Setting up the environment for Open HyperSwap:

You must set up an environment in which you can run Open HyperSwap processing before you can enable Open HyperSwap for a IBM Tivoli Storage Productivity Center for Replication session.

Complete the following steps before you enable Open HyperSwap.

1. Ensure that the IBM AIX hosts and IBM System Storage DS8000 meet the following hardware and software requirements:

AIX requirements

You can find the supported AIX version for each Tivoli Storage Productivity Center for Replication release in the support matrix at <http://www.ibm.com/support/docview.wss?uid=swg21386446>. Click the link for the applicable release under Agents, Servers, and GUI.

You must have the following AIX modules installed:

- Subsystem Device Driver Path Control Module (SDDPCM) version 3.0.0.0 or later
- Multi-Path Input/Output (MPIO) module (the version that is provided with AIX)

System Storage DS8000 hardware requirements

The Open HyperSwap function requires System Storage DS8000 5.1 or later.

You cannot use Open HyperSwap with High Availability Cluster Multi-Processing (HACMP™).

2. Create connections from Tivoli Storage Productivity Center for Replication to the AIX hosts by following the instructions at “Adding a host system connection” on page 695.
3. Assign copy set volumes from the storage device to the host by using the System Storage DS8000 command-line interface (CLI) or the graphical user interface (GUI).
4. Run the AIX `cfgmgr` command to discover the volumes that are assigned to the host.

Considerations for Open HyperSwap and the AIX host:

- A single session that has the Open HyperSwap function enabled can manage multiple hosts; however, each host can be associated with only one session. Multiple hosts can share the session.
- For AIX 5.3, a single host can manage a maximum of 1024 devices that are enabled for Open HyperSwap processing on the host. A maximum of eight logical paths can be configured for each copy set in the session. For AIX 6.1, a single host can manage a maximum of 1024 devices that are enabled for Open HyperSwap processing on the host. A maximum of 16 logical paths can be configured for each copy set in the session.
- If an application on the host opened a device, a Tivoli Storage Productivity Center for Replication session for that device cannot be ended. The **Terminate** command fails. To end the session, you must either close the application or remove the copy sets from the session. If you remove copy sets from the session, you must ensure that the application writes the data to the correct volume when the copy set relationship is restored.
- Open HyperSwap processing can fail on a subset of hosts for the session and continue to run on the remaining hosts for the same session. In this situation, you must determine the best action to take if the application is writing data to volumes on the source system and to volumes on the target system.
- To enable Open HyperSwap processing on the host, see the *IBM System Storage Multipath Subsystem Device Driver User's Guide*.

Configuring timers to support Open HyperSwap:

You can configure timeout values for the storage system, Tivoli Storage Productivity Center for Replication, and AIX hosts systems. These values can affect the operation of Open HyperSwap.

The following various timeout values can affect Open HyperSwap:

Storage system quiesce timeout value

This value is the time when the storage system starts a quiesce operation. When the timer value expires, I/O is resumed on the primary device. The default timeout value is 2 minutes, but the value can be set from 30 to 600 seconds. To set the quiesce timeout value, use the **chdev** command in the *IBM System Storage Multipath Subsystem Device Driver User's Guide*.

Storage system long busy timeout value

This value is the time in seconds that the logical subsystem (LSS) consistency group volume stays in the long busy state after a remote mirror and copy error is reported.

Timeout values for the applications that are on the host

The various applications that are running on the host have timeout values. The timeout values vary depending on the application.

Considerations for setting timers

Consider the following information for setting timers:

- If the host quiesce timer is set to a shorter value than the Tivoli Storage Productivity Center for Replication response timer, an I/O swap failure can occur. If a storage system triggers an unplanned failover and if the storage system quiesce timer expires before Tivoli Storage Productivity Center for Replication responds, the host attempts to write I/O to the primary volume

where the loss of access occurred. If the hardware condition that caused the loss of access continues, the write I/O operation fails again and an unplanned Open HyperSwap is not performed.

- If the host quiesce timer is set to a longer value than the Tivoli Storage Productivity Center for Replication response timer, an application timeout might occur if Open HyperSwap takes too long to complete.

Enabling a session for HyperSwap or Open HyperSwap:

Enabling HyperSwap or Open HyperSwap for a session provides business recovery and business continuity.

Ensure that you can use the HyperSwap or Open HyperSwap functions in your environment. See “Setting up the environment for HyperSwap” on page 101 or “Setting up the environment for Open HyperSwap” on page 101.

Enable a HyperSwap or Open HyperSwap session by completing the following steps:

1. In the Tivoli Storage Productivity Center for Replication navigation tree, select **Sessions**. Click the button next to the session that you want to enable.
2. From the **Select Action** menu, select **View/Modify Properties** and click **Go**. If you did not create the session, click **Create Session**. You can enable the HyperSwap or Open HyperSwap function on the Properties page
3. In **ESS / DS Metro Mirror Options**, select the appropriate HyperSwap or Open HyperSwap options:
 - **Manage H1-H2 with HyperSwap**. This option enables a session to manage the H1-H2 sequence using HyperSwap. If you select this option, select from the following additional options.
 - **Disable HyperSwap**. Select this option to prevent a HyperSwap from occurring by command or event.
 - **On Configuration Error**. Choose one of the following options:
 - **Partition the system(s) out of the sysplex**. Select this option to partition out of the sysplex when a new system is added to the sysplex and encounters an error in loading the configuration. A restart of your system is required if you select this option.
 - **Disable HyperSwap**. Select this option to prevent a HyperSwap from occurring by command or event.
 - **On Planned HyperSwap Error**. Choose one of the following options:
 - **Partition out the failing system(s) and continue swap processing on the remaining system(s)**. Select this option to partition out the failing system and continues the swap processing on any remaining systems.
 - **Disable HyperSwap after attempting backout**. Select this option to stop the HyperSwap action, and disable the HyperSwap commands or events.
 - **On Unplanned HyperSwap**. Choose one of the following options:
 - **Partition out the failing system(s) and continue swap processing on the remaining system(s)**. Select this option to partition out the failing systems and continues the HyperSwap processing on the remaining systems when a new system is added to the sysplex and HyperSwap does not complete. A restart of your system is required if you select this option.

- **Disable HyperSwap after attempting backout.** Select this option to stop the HyperSwap action, and disable the HyperSwap commands or events.
 - **Manage H1-H2 with Open HyperSwap.** If volumes are attached to an IBM AIX host, Tivoli Storage Productivity Center for Replication can manage the H1-H2 sequence of a Metro Mirror session using Open HyperSwap. If this option is selected, a failure on the host accessible volumes triggers a swap, which redirects application I/O to the secondary volumes. Only volumes that are currently attached to the host systems that are defined on the Tivoli Storage Productivity Center for Replication Host Systems panel are eligible for Open HyperSwap.
 - **Disable Open HyperSwap.** Select this option to prevent a swap from occurring by a command or event while keeping the configuration on the host system and all primary and secondary volumes coupled.
4. Click **OK** to apply the selected options.

Restarting an AIX Host System that is enabled for Open HyperSwap:

When an AIX host system is restarted, the host automatically opens any volumes for I/O that were open before the system was restarted. If Open HyperSwap was enabled for a set of volumes on the host system, the host must determine which storage system is the primary system before the host can allow the volumes to be opened.

If the Metro Mirror relationship for the set of volumes is in Prepared or Suspended state and the host has connectivity to both the primary and secondary storage systems, the host can determine through the hardware which storage system is the primary system. In this situation, the host automatically opens the volumes.

If the Metro Mirror relationship for the set of volumes is in Prepared state and the host has connectivity to only the secondary storage system, all I/O to the volumes might be blocked on the host system. The I/O might be blocked until the host can verify the primary volume in the relationship. The AIX varyonvg command fails to open the volumes for I/O to prevent the application from writing to an incorrect volume. If the host can determine which volume is the primary volume in the relationship and connectivity to the primary storage system is still lost, a HyperSwap event is triggered. This event causes all I/O to be automatically opened and directed to the secondary storage system.

If the Metro Mirror relationship for the set of volumes is in Target Available state or the host system does not have connectivity and is unable to determine which site is the primary site, all I/O to the volumes are blocked on the host system. The Target Available state occurs after a HyperSwap or a Recover command is issued for the session. The varyonvg command fails to open the volumes for I/O to prevent the application from writing to an incorrect volume.

Unblocking I/O on the host system after a host system restart

When any of the previous scenarios cause I/O to be blocked, manual actions might be necessary to remove the block.

If the relationships are in Target Available state on the hardware, issue the **Start** command to the session in the required direction of the relationship. This action defines the primary storage system for the host. The host system can allow the volumes to be opened for I/O processing.

If the relationships cannot be restarted, or the host cannot determine the primary storage system, it might be necessary to manually decouple the volumes on the host system.

To decouple the volumes, complete one of the following tasks:

- Stop the session or remove the copy set. This action requires a full copy when the relationships are restarted.
- Remove Object Data Manager (ODM) entries by using the following command:
`odmdelete -o Volume_Equivalency`

Restriction: This command deletes copy set information; use it only for this scenario.

Planned and unplanned swaps:

After a session is enabled for HyperSwap or Open HyperSwap processing and reaches Prepared state, Tivoli Storage Productivity Center for Replication loads the configuration of volumes that can be swapped to a z/OS or AIX operating system.

When the load is complete, the session can start a planned or unplanned swap. The H1-H2 role pair of the session shows a type of HS. An "H" is displayed over the connection in the dynamic image for that role pair, as shown in the following figure.

Metro Mirror Failover/Failback

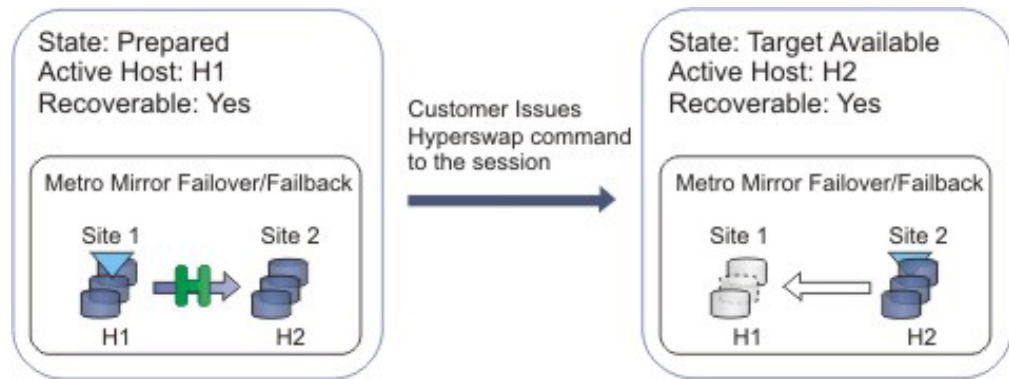

Completing a Planned Swap

When the session configuration is loaded on z/OS for HyperSwap or AIX for Open HyperSwap, the session is considered swap capable. There may be cases such as a planned maintenance or a migration from the primary storage, in which a planned swap might be required. When the session is in swap capable state, a planned swap can be completed by issuing the **HyperSwap** command for the session.

After you run a planned swap for z/OS HyperSwap and Open HyperSwap, the session transitions to Target Available state and all the H1-H2 pairs are in Target Available state. If the H1-H2 role pair was consistent at the time of the swap, the session has a status of Normal, which indicates that H1-H2 is consistent. If the H1-H2 role pair was not consistent at the time of the swap, the session has a status of SEVERE. The active host on the session is shown as H2.

All I/O is redirected to the H2 volumes. After a successful swap to site 2, you cannot enable the copy function to site 2. The only way to restart the copy processing is by issuing the **Start H2->H1** command. To have the volumes protected with high availability and disaster recovery again, correct the error that caused the swap to occur, and manually restart the session to begin copying data to the other site.

The following figure illustrates a planned swap operation.

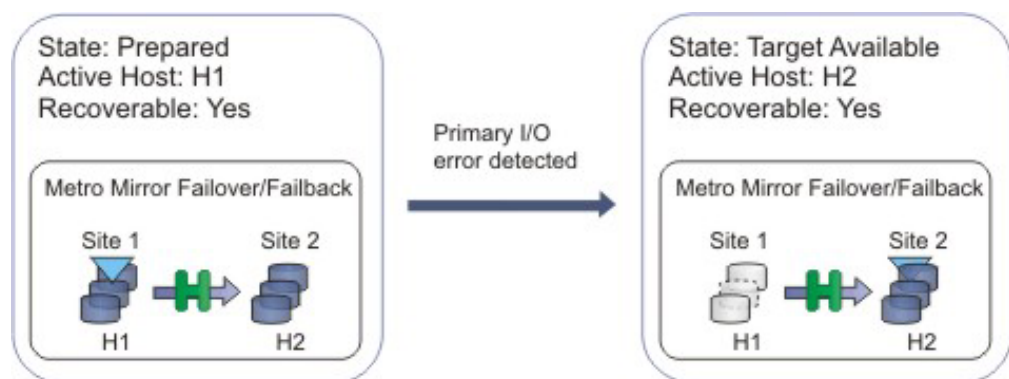

Unplanned swaps

When the session configuration is loaded on z/OS for HyperSwap processing or on AIX for Open HyperSwap processing, the session is considered swap capable. If a primary I/O error occurs, a swap occurs automatically. For HyperSwap, z/OS completes the swap and then alerts Tivoli Storage Productivity Center for Replication that a swap occurred. For Open HyperSwap, Tivoli Storage Productivity Center for Replication and the AIX host work together to complete the swap.

When an unplanned swap occurs for HyperSwap and Open HyperSwap, the session transitions to Target Available state and all the H1-H2 pairs are in Target Available state. If the H1-H2 role pair was consistent at the time of the swap, the session has a status of Normal and indicates that H1-H2 is consistent. If the H1-H2 role pair was not consistent at the time of the swap, the session might show a status of SEVERE. The active host on the session is shown as H2.

All I/O is redirected to the H2 volumes. After a successful swap to site 2, you cannot enable the copy function to site 2. Therefore, it is not possible to issue a **Start H1->H2** command. The only way to restart the copy processing is by issuing a **Start H2->H1** command. To have the volumes protected with high availability and disaster recovery again, correct the error that caused the swap to occur, and manually restart the session to begin copying data to the other site.

The following figure illustrates an unplanned swap.

Scenarios that require a full copy in Metro Global Mirror with HyperSwap sessions

You must run a full copy to return to the three-site configuration after a swap when the following conditions occur:

- If you run a Metro Global Mirror session with the HyperSwap function and you issue the **HyperSwap** command by using the z/OS HyperSwap API.
- If you run a Metro Global Mirror session with the HyperSwap function and an unplanned swap occurs.

Verifying a session for a planned or unplanned swap:

You can verify whether a session is capable of a planned or unplanned swap from the z/OS console on HyperSwap or the AIX host on Open HyperSwap.

Verify the status of HyperSwap from the z/OS console:

1. View the overall status of the HyperSwap session. Issue the `ds hs,status` command. For example:

```
15.03.06 SYSTEM1 d hs,status
15.03.06 SYSTEM1 STC00063 IOSHM0303I HyperSwap Status 531
Replication Session: SR_HS
HyperSwap enabled
New member configuration load failed: Disable
Planned swap recovery: Disable
Unplanned swap recovery: Disable
FreezeAll: No
Stop: No
```

2. Verify all the volumes in the configuration. Issue the `ds hs,config(detail,all)` command. For example:

```
15.03.51 SYSTEM1 d hs,config(detail,all)
15.03.51 SYSTEM1 STC00063 IOSHM0304I HyperSwap Configuration 534
Replication Session: SR_HS
Prim. SSID UA DEV# VOLSER Sec. SSID UA DEV# Status
06 02 00F42 8K3602 06 04 00FA2
06 01 00F41 8K3601 06 03 00FA1
06 00 00F40 8K3600 06 02 00FA0
```

Verify the status of Open HyperSwap from the AIX host:

1. View the session association and the path that the I/O is being routed to. The path is indicated by an asterisk. Issue the `pcmpath query device` command. For example:

```
host1> pcmpath query device 14
```

```
DEV#: 14 DEVICE NAME: hdisk14 TYPE: 2107900 ALGORITHM: Load Balance
SESSION NAME: session1
OS Direction: H1<-H2
```

```
=====
PRIMARY SERIAL: 25252520000
```

Path#	Adapter/Path Name	State	Mode	Select	Errors
0	fscsi0/path0	CLOSE	NORMAL	6091	0
1	fscsi0/path2	CLOSE	NORMAL	6300	0
2	fscsi1/path4	CLOSE	NORMAL	6294	0
3	fscsi1/path5	CLOSE	NORMAL	6187	0

```
SECONDARY SERIAL: 34343430000 *
```

Path#	Adapter/Path Name	State	Mode	Select	Errors
4	fscsi0/path1	CLOSE	NORMAL	59463	0

5	fscsi0/path3	CLOSE	NORMAL	59250	0
6	fscsi1/path6	CLOSE	NORMAL	59258	0
7	fscsi1/path7	CLOSE	NORMAL	59364	0

Temporarily disabling HyperSwap or Open HyperSwap:

In some situations, it might be necessary to temporarily disable the HyperSwap or Open HyperSwap function for a session.

You might want to disable HyperSwap or Open HyperSwap in the following circumstances:

- If you are performing maintenance on the system
- If one sysplex member cannot communicate with one or more volumes

Complete these steps to disable Open HyperSwap for a specific session:

1. In the Tivoli Storage Productivity Center for Replication navigation tree, select **Sessions**.
2. Select the sessions for which you want to disable the HyperSwap or Open HyperSwap function.
3. Select **View/Modify Properties** from the **Select Actions** list, and click **Go**.
4. Select **Disable HyperSwap** or **Disable Open HyperSwap**, and click **OK**.

Tip: On management servers that run on a z/OS operating system, you can disable the HyperSwap function from an MVS command prompt window by entering the **SETHS DISABLE** command.

Using active and standby Tivoli Storage Productivity Center for Replication servers with HyperSwap or Open HyperSwap:

You can set up an active and standby management server configuration with HyperSwap or Open HyperSwap.

Active and standby servers with HyperSwap

When the storage system is set up to connect through the z/OS interface, the connection information is sent to the standby server and a connection is attempted. The connection might fail if the standby server does not run on a z/OS operating system or does not have access to the same volumes. If the connection fails and the standby server resumes the processing, the standby server cannot manage the HyperSwap processing.

On the z/OS system, if the session configuration was successfully loaded before the HyperSwap processing, the z/OS system can manage the HyperSwap processing. If the z/OS system swaps the volumes but cannot communicate with the Tivoli Storage Productivity Center for Replication server, the session is set to Suspended or Severe state. To set the session to Target Available state, clear the **Manage H1-H2 with Hyperswap** option, and issue the **Recover** command for the session.

Active and standby servers with Open HyperSwap

When there is an active and standby management server configuration and a host system connection is added to the active server, a connection is attempted between the host system and the standby server. After AIX loads the session configuration, Open HyperSwap processing is possible only if there is communication between

AIX and the Tivoli Storage Productivity Center for Replication server. If a standby server resumes the processing and is unable to connect to the host system that manages the swap, the session cannot run Open HyperSwap processing. You must activate communication to the host system before the session can run Open HyperSwap processing.

Related tasks:

“Managing management servers” on page 674

This section provides information about how to set up active and standby management servers, restore a lost connection between the management servers, or perform a takeover on the standby management server.

Alerts

You can set up Tivoli Storage Productivity Center so that it examines the data that it collects about your storage infrastructure and writes an alert to a log when an event occurs. You also can specify that an action is initiated, such as sending an SNMP trap, sending an e-mail, or running a script when the event occurs.

Alerts that are triggered based on the data collected by monitoring jobs (for example, pings, scans, and probes) must be defined before the monitoring jobs are run. Alerts that are triggered based on an external source, such as an SNMP trap, must be defined after the SNMP server is configured properly.

You can define an alert in the following ways:

- As part of a data collection schedule
- As part of an alert definition

When an event occurs and triggers an alert, the alert is written to a log. You can also select one or more other ways to be notified of the event. These alert notifications include SNMP traps, IBM Tivoli Enterprise Console events, Tivoli Storage Productivity Center login notifications, operating-system event logs, or email.

Note: Alerts are not generated in a Tivoli Storage Productivity Center instance for actions that you perform from that instance. For example, if you start Tivoli Storage Productivity Center and use Disk Manager to assign or unassign volumes for a subsystem, you do not receive alerts for those volume changes in that instance. However, if you assign and unassign volumes outside of that Tivoli Storage Productivity Center instance, an alert is generated.

Triggering conditions for alerts

In general, the following types of conditions can trigger alerts:

- A data collection schedule failed to complete.
- A change occurred in the storage infrastructure.
- A performance threshold was violated.

The specific conditions that can trigger events vary, depending on the type of storage resource that is being monitored. See “Triggering conditions for alerts” on page 1489 for more information about triggering conditions.

Alert notifications and triggered actions

Notification methods, or triggered actions, define the method by which you are notified of an alert: SNMP Trap, Tivoli Enterprise Console Event, Login

Notification, Windows Event Log, UNIX Syslog, and email. Alerts are always written to the error log. Additionally, if a Data agent or Storage Resource agent is deployed on a monitored computer, you can run a script or start an IBM Tivoli Storage Manager job in response to the alert. See “Triggered actions for alerts” on page 1504 for more information about triggered actions.

Prerequisites for successfully using alerts

The following conditions must be met in order to successfully use alerts:

- Data collection schedules are configured and scheduled to run on a regular basis.
- If you want to be notified about an alert in some way other than an entry in the log file, such as using SNMP traps, Tivoli Enterprise Console events, or email, alert notification instructions must be configured before using the alert. See “Configuring alert destinations” on page 397).
- If an alert is triggered based on an SNMP trap from the monitored resource, you must properly configure the SNMP server of the monitor resource to enable Tivoli Storage Productivity Center to listen to SNMP traps. The default port number is 162, and the default community is public.

Default alerts

The following types of alerts are set for your system by default:

- New entity found
- Job failed

You can change the triggered actions and enable or disable these alerts, but you cannot delete them.

SAN Planner Overview

SAN Planner assists the user in end-to-end planning for fabrics, hosts, storage controllers, storage pools, volumes, paths, ports, zones, zone sets, storage resource groups (SRGs), and replication. You can implement a plan by using SAN Planner.

Supported Systems

You can use the following products with SAN Planner:

- TotalStorage Enterprise Storage Server
- System Storage DS8000
- System Storage DS6000
- SAN Volume Controller
- Storwize V3500
- Storwize V3700
- Storwize V7000
- Storwize V7000 Unified block level support
- The XIV system

SAN Planner supports the **Space Only** workload profile option for any other storage system.

Requirements for SAN Planner

For planning, IBM Tivoli Storage Productivity Center must be managing the host system, subsystem, and the fabric that interconnects them. If the host, subsystem, or fabric information is not collected by subsystem probes and fabric discovery, SAN Planner is not able to generate the plan or execute portions of the plan and issues an error message.

You can select host systems that do not have a Storage Resource agent installed, if the initiator ports for that host system are known to Tivoli Storage Productivity Center. The provisioning profile selected for these host systems can include only capacity and zone provisioning information. Path settings are not allowed for host systems with no Storage Resource agent, and the path planning option is unavailable in the SAN Planner wizard.

For volume or virtual disk creation, Tivoli Storage Productivity Center must be managing the subsystem. You must have run the subsystem probe either through an active CIM object manager (CIMOM) or native API connection as applicable for the subsystem.

For volume or virtual disk assignment, Tivoli Storage Productivity Center must be managing the host, fabric, and subsystem. The host and subsystem must be in the same fabric. If zoning changes are required, the SAN planner can be used to configure the zoning.

For fabric zoning configuration or fabric zone control operations, Tivoli Storage Productivity Center must manage the fabric. Depending on fabric type and agent capabilities, Tivoli Storage Productivity Center uses a CIM agent, inband agent, or Storage Resource Agent (SRA).

For a plan that requires a virtual disk to be assigned to a host, the virtual disk must have access to two nodes within an I/O group on the following storage systems:

- SAN Volume Controller
- Storwize V3500
- Storwize V3700
- Storwize V7000

These two nodes must be shared on the same fabric as the host.

A storage controller performance monitor must be run to select the **Workload Profile** options. For the following storage systems, it is required that the performance data is collected for all its back-end subsystems as well:

- SAN Volume Controller
- Storwize V3500
- Storwize V3700
- Storwize V7000

If a performance monitor has not been run, the **Space Only** workload profile option is allowed for planning based on available capacity only.

The IBM Subsystem Device Driver (SDD) installed on a host is required for multipath planning.

Note:

- The Linux SDD driver is no longer available. Starting with Red Hat Enterprise Linux Version 5 and SUSE Linux Enterprise Server Version 10, only the DM_Multipath is available. The DM_Multipath is supported by SAN Planner
- The SDD driver is no longer supported on HP, starting with HP-UX 11i v3 with Itanium. HP-UX 11i v3 provides a native multipathing feature which is supported by SAN Planner.
- If you are using the SAN planning tools which collect data from Oracle Solaris systems, the HBAs must be configured to use Solaris systems. This note applies to Storage Resource agents.

Run the following command on the Solaris system:

```
cfgadm -al
```

If the system displays this message:

```
fc-fabric connected unconfigured unknown
```

run this command:

```
cfgadm -c configure c#
```

where *c#* is your HBA controller ID. An example of an HBA controller ID is: c5.

You must reboot the Solaris system.

- The SAN Planner does not support Easy Tier[®] (mixed pools) as input to a plan for automated storage provisioning. These pools are not displayed when you select resources for planning or request a list of recommended pools.
- When creating a plan with multipath provisioning, do not include computers that have EMC Powerpath installed. For example, do not include EMC Clariion volumes in a plan with multipath provisioning.

For replication planning, you must add all the subsystems to be used in planning to IBM Tivoli Storage Productivity Center for Replication. You must also ensure that connectivity is established between the subsystems.

Creating a SAN plan

You can create a SAN plan by right-clicking the **IBM Tivoli Storage Productivity Center > Analytics > SAN Planner** node and selecting **Create Plan**. The planner wizard is started.

You can also create a SAN plan from the **IBM Tivoli Storage Productivity Center > Disk Manager > SAN Planner** node and selecting **Create Plan**. The planner wizard is started.

The type of plan that you select determines the content of the remaining pages in the wizard. The options are:

- **Provision storage only, including optional multipath and zone considerations**
Click to create a plan for provisioning new storage. The plan does not include provisioning for storage replication.
- **Provision storage with replication, including optional multipath and zone considerations on the source resources**
Click to create a plan for provisioning new storage and storage replication.
- **Provision replication to existing storage**
Click to create a plan for provisioning replication for existing storage (provision target volumes for existing source volumes).

- **Configure multipathing or zoning only**

Click to create a plan for provisioning multipathing and zoning for existing storage.

To print plan information from the interface, click **File > Print** on the Tivoli Storage

Productivity Center menu bar, or click on the toolbar.

Provision storage only, including optional multipath and zone considerations

Use this option to provision storage volumes or virtual disks with multipathing and zoning. The input resources for planning can be storage subsystems, volumes, hosts, or storage resource groups (SRGs). If you are provisioning storage for the following storage systems, you must select **Virtual Disks**:

- SAN Volume Controller
- Storwize V3500
- Storwize V3700
- Storwize V7000

An SRG is a set of entities managed by Tivoli Storage Productivity Center. These entities can be servers, switches, storage subsystems, fabrics, storage pools, and storage volumes. Using SRGs provides you with a means of separating your application data from your pool of unused resources. You can specify policies for provisioning (volume creation and selection, workload profiles, zoning, and multipathing configuration) and associate them with SRGs. These policies are used by SAN Planner to populate default settings.

You can use this option to plan and select appropriate storage controllers, storage pools, and storage volumes (when using unassigned volumes) that satisfy your inputs. This option enables you to select controller type preference, whether storage requests can be satisfied by multiple controller types, and the Redundant Array of Independent Disks (RAID) level. For the following storage systems, the RAID level represents the RAID level for the back-end controllers:

- SAN Volume Controller
- Storwize V3500
- Storwize V3700
- Storwize V7000

When creating new volumes on an extent pool, SAN Planner uses one of the following methods:

- If an encryption group is selected, SAN Planner creates volumes on pools that belong to the selected encryption group. Only pools that belong to that encryption group are used for planning. This option might not be enabled if the storage system does not support encryption.
- If an encryption group is not selected, SAN Planner uses the current performance utilization of storage resources to determine whether a new volume should be allocated on particular pool in a particular storage controller. If multiple storage pools from different controllers can potentially satisfy your provisioning request, then the SAN Planner uses the rated utilization of the pools (the sum of the previous provisioning performance requirements, which might be greater than the current utilization) to break the ties and select a candidate storage pool.

You can also select other options in the SAN Planner such as selecting a workload profile as an input to the SAN Planner's analysis, excluding solid-state drives from planning, or using thin provisioning for creating thin provisioned volumes based on the thin provisioning profile selected.

See the **Configure multipathing or zoning only** section for details on SAN Planner multipathing and zoning options.

Provision storage with replication, including optional multipath and zone considerations on the source resources

In addition to provisioning storage with multipathing and zoning options, when you select replication options in the wizard, SAN Planner provisions replication for your storage resources. Resilient resource planning is available only for devices which are supported by IBM Tivoli Storage Productivity Center for Replication.

Depending on the storage resources you are planning for, you can select from the following copy services session types:

- FlashCopy
- VDisk mirroring
- Synchronous Metro Mirror failover/failback
- Synchronous Metro Mirror failover/failback with practice
- Synchronous Metro Mirror single direction
- Asynchronous Global Mirror either direction with two-site practice
- Asynchronous Global Mirror failover/failback
- Asynchronous Global Mirror failover/failback with practice
- Asynchronous Global Mirror single direction
- Three-site Metro Global Mirror with practice
- Three-site Metro Global Mirror
- Snapshot

For example, if you are planning for the XIV system, you can only select from Snapshot, Metro Mirror, or Global Mirror session types. Practice sessions are not supported for the XIV system.

Provision replication to existing storage

This option extends existing replication sessions by adding more storage resources and protecting them. The new volumes are added to existing replication sessions. SAN Planner ensures that source volumes are added to the source side of a copy relationship and target volumes are added to the target side. For Snapshot copy sessions, SAN Planner does not provision or manage target volumes. The XIV system selects and manages the targets for Snapshot replication.

Configure multipathing or zoning only

SAN Planner enables you to set up multipath options. The supported multipath driver on a host is the IBM SDD.

Note:

- The Linux SDD driver is no longer available. Starting with Red Hat Enterprise Linux Version 5 and SUSE Linux Enterprise Server Version 10, only the DM_Multipath is available.

- The SDD driver is no longer supported on HP, starting with HP-UX 11i v3 with Itanium. HP-UX 11i v3 provides a native multipathing feature which is supported by SAN Planner.

SAN Planner enables system administrators and storage area network (SAN) administrators to plan and implement storage provisioning for hosts and storage systems with multipath support in fabrics managed by Tivoli Storage Productivity Center. Planning the provisioning of storage to hosts with multipath drivers requires knowing which storage systems are supported by the host multipath driver and the multipath modes that are supported by the driver and storage subsystem. Planning the paths between the hosts and storage controller requires designing paths between hosts and storage subsystems which are implemented through zones in the fabric.

SAN Planner is used for specifying multiple paths options between selected hosts and storage systems. There should be at least two paths available to a storage system and at least four paths available to SAN Volume Controller. Although not required, it is beneficial to have at least two host ports.

Path planning in SAN Planner does not directly interact with zone planning. The path planning option provides the path information which the zone planning option uses. Each path is represented by a host port WWPN, target port WWPN, and a Volume ID for the volume on the target that is mapped to the host port. These paths are created when the zone planning option is implemented.

SAN Planner specifies automatic zoning between ports on the selected hosts and subsystems in a fabric. All zoning is done with WWPN-based zoning. SAN Planner plans zoning configuration for new storage that is provisioned for use by a host. For example, the zoning option can be used when a new storage volume is created and assigned to a host. The zoning option can also be used with a volume that has already been created and is assigned to a host that requires more storage. In these cases, SAN Planner determines which host and storage need to be zoned together, which provides the zoning option with the exact set of ports that need to be zoned together. SAN Planner then uses the zoning inputs for the planning.

If the subsystem/host are within the same fabric and the zoning option is not checked, then existing zones or zone sets are used. If the zoning option is checked, a new zone or zone set is created.

To perform zoning, the host and subsystem being zoned by SAN Planner must be within the same fabric. For the case where the host and subsystem reside in more than one of the same fabrics, SAN Planner creates identical zones in all the fabrics.

The guidance policies used for zone planning are as follows:

- One zone per host bus adapter (HBA)
- One zone per host
- One zone per host port
- Auto zone: largest zone that satisfies the validation policies

The validation policies used for zone planning are as follows:

- Maximum number of zone members in a zone = N.
- No two controllers of different types in the same zone.
- Maximum number of zones in a fabric = N.

The second policy in the preceding list has a higher priority than the third policy.

Planner and user inputs interdependencies

The planner options depend on the inputs that you select. For example, selecting a host that does not have an agent installed limits the planning that can be done. The planning process reveals inconsistencies in your preferences. For example, it might not be possible to have your specified number of paths and have a different zone for each host. In such cases, the planner makes a best effort to satisfy your inputs. If the planner cannot satisfy conditions, it issues warnings. Errors discovered before plan execution display in the planner. You can adjust the inputs to correct the problem. Errors discovered during plan execution are in the job execution log.

If the selected Storage Resource group has a provisioning profile associated with it, the profile is selected in the Effective Provisioning Profile field. You can select a different profile from the list of available profiles.

Reporting

This section contains conceptual information about reporting.

Use the Reporting facilities in the different managers of IBM Tivoli Storage Productivity Center to view both overview and detailed information about your storage. The over 500 available reports are constructed from the statistical information accumulated in the repository and enable you to select exactly the computers, storage systems, switches, clusters, disks, file systems, hypervisors, users and even other Tivoli Storage Productivity Center servers upon which you want to report. You can view reports as tables of data or as graphical charts, which provides you with the flexibility to get a very detailed look at your information or a very high level overview.

You must collect information about your environment before you can use reports to view details about the storage resources in it. You can use monitoring jobs in Tivoli Storage Productivity Center such as probes, scans, pings, and Tivoli Storage Productivity Center server probes, and discovery jobs to gather comprehensive information and statistics about your storage resources.

Fabric and zones

Use the IBM Tivoli Storage Productivity Center to learn more about fabrics and zones.

Zones, zone aliases, and zone sets

Zones, zone aliases, and zone sets allow logical grouping of ports and storage devices within a storage area network. This section describes zoning concepts and elements.

In a storage area network a *zone* is a logical grouping of ports to form a virtual private storage network. Zones that belong to a single SAN can be grouped into a *zone set*, which can be activated or deactivated as a single entity across all switches in the fabric. A zone set can contain one or more zones, and a zone can be a member of more than one zone set. Using zoning, you can automatically or dynamically arrange fabric-connected devices into logical groups across a physical fabric.

Ports and devices in a zone are called *zone members*. A zone can contain one or more zone members. Ports that are members of a zone can communicate with each other, but they are isolated from ports in other zones. Devices, however, can belong to more than one zone. A *zone alias* is a collection of zone members. A zone alias can be added to one or more zones.

Note: In some cases, inactive zones might not have any zone members. Activating an inactive zone set that contains empty zones will fail if a switch does not support empty zones in active zone definitions.

Zone membership can be specified by:

- The N_Port_Name of the N_Port connected to the switch (also known as WWN zoning or port name zoning)
- The N_Port address identifier assigned during fabric login (also known as PortId or FCID zoning)
- The Node_Name associated with the N_Port
- The Domain identification (Domain_ID) and physical port ID of the Switch Port to which the N_Port is attached (also known as domain port zoning)
- An alias name

Zoning supports the use of aliases, which are meaningful names assigned to devices. An alias can also be a group of devices that are managed together to make zoning easier.

There are two types of zoning:

Hardware zoning (port zoning)

In hardware zoning (also called *port zoning*), the members of a zone are the physical ports on a fabric switch.

Software zoning (WWN zoning)

Software zoning uses the Simple Name Server (SNS) that runs inside a fabric switch. It is based on the node WWN or port WWN of the zone members to be included. Software zoning lets you create symbolic names for the zones and zone members.

A *default zone* is a group of devices that are not members of the active zone set. These can communicate with each other but not with members of any other zone. Default zoning is enabled by default. You can use a switch element manager to configure the Default Zone option to enable or disable the default zone independently of the active zone set.

Note:

1. If the default zone is disabled, devices that are not members of the active zone set cannot communicate.
2. If the default zone is disabled and no zone set is active, no devices can communicate.
3. If default zoning is enabled, deactivating the active zone set makes all devices members of the default zone. If default zoning is disabled, all communication stops.
4. If you activate one zone set while another zone set is active, the currently active zone set is deactivated.
5. If your EFC Manager manages multiple fabrics, ensure that you have the correct zone set for the fabric you are currently updating.

You can view zones in SANs using the topology viewer console. Fabric Manager lets you create, update, and delete zones, zone aliases, and zone sets in a SAN. In addition, you can do the following:

- Assign zones to zone sets
- Activate and deactivate zone sets
- View zone membership
- Add and remove zone members to and from a zone
- Add and remove zone members to and from a zone alias
- Assign zone aliases to zones

Note: Certain types of switches and the types of agents configured can affect the zoning operations that you can perform.

Zone configuration

When you configure zones, you can use Fabric Manager or the management application for the devices. The advantages of using Fabric Manager rather than the management applications of the devices are that Fabric Manager lets you perform zoning from a single interface, and you can use consistent, familiar methods to work with devices from multiple vendors.

Consider the following guidelines if you use Fabric Manager with zones:

- For Brocade fabrics, topology information is collected through CIM agents. If no CIM agents are configured, or if the fabric is a QLogic or Cisco fabric, have at least one Storage Resource agent attached to each fabric and as a member of an active zone for the complete topology display. In this way, you can manage your switches and a string is returned, provided by the vendor, that can be the worldwide name (WWN) or a vendor, model, and level type designation.
- For zone discovery and zone control for any fabrics with Brocade switches or vendor Brocade switches, you must have a SMI-S agent configured for the fabric.
- A zone set can be deleted while it contains zones. With QLogic switches, those zones are put into an orphan zone set. The zones can later be moved from an orphan set into other zone sets. The Fabric Manager zone configuration panels cannot display zones in an orphan zone set. However, the zones exist on the switch, and they can be configured using the tool from the switch vendor.
- You cannot add empty zones to inactive zone sets for switches. Activating an inactive zone set that contains empty zones can fail if a switch does not support empty zones in active zone definitions.

Note: Fabric probes through the Storage Resource agents do not detect orphan zones. These zones are not listed in the Zone Configuration window. However, the zones exist on the switch, and they can be configured using the tool from the switch vendor. However, Brocade orphan zones, which are discovered through Storage Management Initiative (SMI) agents, are listed in the Zone Configuration window and can be configured by the Fabric Manager. Brocade orphan zone aliases are listed in the Zone Configuration window and can be configured by the Fabric Manager.

Switch zoning capabilities

When you select a fabric in which to perform zoning operations, Fabric Manager determines the capabilities of the switches in the SAN and limits the zoning operations based on that information.

To see a list of supported switches and their capabilities, default values, ranges, and possible effects, go to <http://www.ibm.com/support/docview.wss?uid=swg27027300>.

Zoning for Cisco MDS 9000 devices:

Cisco switches support virtual SANs (VSANs), which is the logical partitioning of a fabric into multiple fabrics. The overall network is referred to as the physical infrastructure, and the logical fabrics are the VSANs. Fabric Manager provides basic zone discovery and zone control for the Cisco MDS 9000 series of devices using the FC-GS-3 protocol. This allows in-band zone control and defaults to the Cisco VSANs.

The following tasks are supported:

- Creating, deleting, and updating zones
- Creating, deleting, updating, activating, and deactivating zone sets

Fabric Manager supports these zone member types:

- N_Port WWN
- FC ID (the fibre channel ID of an N_port attached to the switch)

Unsupported zone and zone member types are displayed as non-standard on the topology display. Fabric Manager does not allow zone management of zones and zone sets that contain unsupported members.

Brocade switches in zones:

Brocade switches support some non-standard zones such as quick loop zones, fabric assist zones, and protocol zones. If the switch configurations have these zones already defined, Fabric Manager preserves them and does not modify them in any way. They are not displayed on the zone control interface. However, if they are part of a zone set that is active at some time, the devices that are part of such zones that are also online are displayed in the topology Zone View.

You can create, change, and delete non-standard zones by using the Brocade switch management application.

Note:

- A zone set displayed on the zone control interface might have no zones. This could mean that the zone set contains a non-standard zone on a Brocade switch.
- A zone set might have non-standard zones on a Brocade switch that are not displayed on the zone control interface.
- When creating a new zone using the same zone name as that of a non-standard zone that already exists on a Brocade switch, you might get a error that the zone already exists. Because the non-standard zone is not displayed on the zone control interface, you must verify this by using the switch management application.
- Tivoli Storage Productivity Center allows you to add empty zones to an inactive zone definition. Activation of a zone set containing empty zones may still fail if the switch does not support empty zones in active zone definitions.

Agents

The IBM Tivoli Storage Productivity Center uses agents to gather data: Common Information Model (CIM) agents, Storage Resource agents, and out-of-band Fabric agents.

Common Information Model agents

Common Information Model (CIM) agents enable communication between the storage device (storage subsystem, fabric switch, or tape library) and IBM Tivoli Storage Productivity Center. Each storage device that you want to manage must have a CIM agent either installed or embedded unless it is a device that uses Native API connection.

CIM agents are provided by the vendor of the storage subsystem, fabric switch, or tape library. Each vendor provides unique agent code for their family of storage devices. This code implements a Common Information Model Object Manager (CIMOM) that conforms to the Storage Management Initiative Specification (SMI-S) of the Storage Networking Industry Association (SNIA).

The CIM agent enables communication between the storage device and Tivoli Storage Productivity Center. Commands and responses are transmitted between Tivoli Storage Productivity Center and the CIM agent using an XML transport layer. The CIM agent to storage device layer uses a vendor-specific proprietary interface.

The CIM agent usually must be installed and configured, so that it can identify the storage devices with which it communicates. Some storage devices, such as Cisco fabric switches, contain embedded CIM agents and so do not require that CIM agents be installed, although Tivoli Storage Productivity Center must be configured to point directly to the storage devices that contain the embedded CIM agents.

CIM agents can be referred to as SMI-S providers, CIM proxy agents, and CIMOM agents. CIM agents can be embedded in the device or installed on a separate computer.

Note:

- Do not install multiple CIM agents on a single computer because of port conflicts.
- Do not install a CIM agent on the system where a Tivoli Storage Productivity Center server component is installed.

Storage Resource agents and Data agents

Use Storage Resource agents and Data agents to collect information about the storage resources (for example, servers, computers, workstations, HBAs, and so on) in your environment. You must deploy an agent on systems that you want Tivoli Storage Productivity Center to monitor.

Note: In Tivoli Storage Productivity Center v4.2 and later, you can deploy Storage Resource agents only. If you want to install a Data agent, you must own a previous version of the product. See the documentation for the previous version of the product for information about how to install a Data agent.

Agents gather the following information about storage resources:

- Asset information
- File and file system attributes

- Database application information
- Novell Directory Services (NDS) tree information (only supported by Data agents)
- Network attached storage (NAS) device information
- Topology information
- Zoning information

Agents also discover fabrics and perform zone control for Cisco and Qlogic fabrics.

Deployment guidelines and limitations for Storage Resource agents:

There are a number of guidelines and limitations that you must consider when managing the Storage Resource agents in your environment.

Use the following information when you deploy Storage Resource agents and migrate existing Data agents:

- Multiple Storage Resource agents that are probing or scanning the same storage resources
- Platforms that support Storage Resource agents deployments
- Product functions that are not available for storage devices monitored by Storage Resource agents
- Required authority for deploying Storage Resource agents
- Orphan zones
- Firewalls and Storage Resource agent deployments
- Multiple computers in a deployment
- Communication between the Tivoli Storage Productivity Center server and a Storage Resource agent
- Daemon and non-daemon services
- Authentication between the Tivoli Storage Productivity Center server and a Storage Resource agent
- Storage Resource agents on the same computer
- Time zones for computers monitored by Storage Resource agents
- UNIX systems using RSH protocol
- Deployments on Windows - NetBIOS setting
- Deployments on Windows - User Account Control (UAC) remote restrictions
- Additional information about Storage Resource agents

Multiple Storage Resource agents that are probing or scanning the same storage resources

If multiple Storage Resource agents are set up to probe or scan the same storage resources, the Storage Resource agent that was added to Tivoli Storage Productivity Center first is used for the probe or scan. Therefore, only data that is gathered by the first Storage Resource agent is shown.

Platforms that support Storage Resource agents for the same

For a list of platforms on which you can deploy Storage Resource agents, go to the Tivoli Storage Productivity Center support site at http://www.ibm.com/support/entry/portal/Overview/Software/Tivoli/Tivoli_Storage_Productivity_Center_Standard_Edition, click the **Documentation** link, and enter **Platform Support: Agents, Servers and GUI** in the **Search** box. Click the link to the document for the appropriate release.

Product functions that are not available for storage devices monitored by Storage Resource agents

Before you migrate an existing Data agent to a Storage Resource agent or deploy a new Storage Resource agent, make sure that the product functions you want to use on the monitored devices are available for those agents. The following functions are not available for storage devices that are monitored by Storage Resource agents:

- Certain relational database monitoring. For list of relational databases that can be monitored by Storage Resource agents, go to the Tivoli Storage Productivity Center support site at http://www.ibm.com/support/entry/portal/Overview/Software/Tivoli/Tivoli_Storage_Productivity_Center_Standard_Edition, click the **Documentation** link, and enter **Platform Support: Agents, Servers and GUI** in the **Search** box. Click the link to the document for the appropriate release.
- The changing of zone configurations and the reporting of HBA, fabric topology, or zoning information for fabrics connected to hosts running Linux on IBM System z hardware. These limitations also apply to Storage Resource agents on all guest operating systems for VMware configurations.

Required authorities for deploying and running Storage Resource agents

Before you can create deployment schedules and deploy Storage Resource agents on target computers, you must meet the following requirements:

- To create deployment schedules, you must be logged in to Tivoli Storage Productivity Center with a user ID that has the **Productivity Center Administrator** role. See the *IBM Tivoli Storage Productivity Center and IBM Tivoli Storage Productivity Center for Replication Installation and Configuration Guide* for more information about user roles.
- To deploy Storage Resource agents on target computers, you must provide a user ID that has administrative rights on those computers. You enter this ID when creating a deployment schedule. Tivoli Storage Productivity Center uses this ID to log on to the target computers and install and configure the necessary runtime files for the agents.

The user under which a Storage Resource agent (daemon or non-daemon) runs must have the following authorities on the target computers:

- On Linux or UNIX, the user must have root authority. By default, an agent runs under the user 'root'.
- On Windows, the user must have Administrator authority and be a member of the Administrators group. By default, a Storage Resource agent runs under the 'Local System' account.

Orphan zones

Storage Resource agents do not collect information about orphan zones. An orphan zone is a zone that does not belong to at least one zoneset.

Firewalls and Storage Resource agent deployments

Before you can deploy a Storage Resource agent on a computer, you must turn off the firewall on that computer. If you do not turn off the firewall, the deployment fails. To turn off the firewall on a Windows 2008 computer, complete the following steps:

1. On the desktop of the Windows 2008 computer, click **Start > Administrative Tools**.
2. Click **Windows Firewall with Advanced Security**.
3. Click **Windows Firewall Properties**.

4. Change the **Firewall state** field to **Off** on the following tabs: **Domain Profile, Private Profile, Public Profile**.
5. Click **OK** to accept the changes and exit.
6. Deploy a Storage Resource agent to the Windows 2008 computer.

Multiple computers in a deployment

You can define a deployment schedule to include multiple computers on which to install Storage Resource agents. The computers you include in a deployment schedule must share the same administrative user ID and password. IBM Tivoli Storage Productivity Center uses these user credentials to log on to the computers when installing Storage Resource agents. If the computers in a deployment schedule do not share the same administrative user credentials, you must create separate deployment jobs for them.

Note: When you deploy a Storage Resource agent to multiple computers, a globally unique identifier (GUID) is created for each computer (if one does not exist).

Communication between the Tivoli Storage Productivity Center server and a Storage Resource agent

The Tivoli Storage Productivity Center server connects to a monitored computer when a Storage Resource agent is deployed and whenever a data collection schedule runs against that agent.

During deployment, the server communicates with the target computer using one of the following protocols:

- Windows server message block protocol (SMB)
- Secure Shell protocol (SSH)
- Remote execution protocol (REXEC)
- Remote shell protocol (RSH)

After deployment, the type of communication between the server and agent on that computer depends on whether you deployed the agent as daemon service or non-daemon service. See the *IBM Tivoli Storage Productivity Center and IBM Tivoli Storage Productivity Center for Replication Installation and Configuration Guide* for more information about these protocols.

Daemon and non-daemon services

You can deploy a Storage Resource agent as a daemon or non-daemon service:

- A Storage Resource agent that is deployed as a daemon service runs in the background on the monitored computer and listens for requests from the Tivoli Storage Productivity Center server. Connectivity between the server and agent is established using SSL. The server and agent have their respective certificates and no additional information is required besides those certificates and the security that is provided by the SSL protocol.
- A Storage Resource agent deployed as a service on demand (non-daemon service) runs as a stand-alone executable file on the monitored computer. Communication from the server to the agent uses the same protocol that was used during the deployment of the agent. Communication from the agent to the server uses SSL.

Authentication between the Tivoli Storage Productivity Center server and a Storage Resource agent

Tivoli Storage Productivity Center requires the correct authentication information (user ID, password, port, certificate location, or passphrase) for monitored computers each time it communicates with Storage Resource agents on those computers. If the authentication information changes for a host computer on which a Storage Resource agent is deployed, the authentication information for that agent must be updated using the **Change Authentication** or **Update Storage Resource agent List** functions on the Data/Storage Resource agents panel located under the **Administrative Services > Data Sources** node in the navigation tree.

Storage Resource agents on the same computer

You cannot deploy a Storage Resource agent on a computer where a Storage Resource agent is already installed *and* pointing to the same Data server. You can deploy a Storage Resource agent on the same computer as another Storage Resource agent if those agents communicate with different Data servers and use different ports when listening for requests.

Time zones for computers monitored by Storage Resource agents

The time zones of computers that are monitored by Storage Resource agents are shown as Greenwich Mean Time (GMT) offsets in Tivoli Storage Productivity Center reports. For example, a computer in Los Angeles shows the following time zones in the By Computer report in Asset reporting:

(GMT-8:00) GMT-8:00

UNIX operating systems using Remote Shell protocol (RSH)

If RSH is configured to use a user ID and password, the connection fails. To successfully connect to a system using RSH, you must set up the `.rhosts` file (in the home directory of the account). RSH must be configured to accept a login from the system that is running your application.

Deployments on Windows operating systems - NetBIOS setting

If you want to install a Storage Resource agent on Windows targets, the **Enable NetBIOS over TCP/IP** option must be selected in the Control Panel settings for the computer's network connections properties. To set this option, click **Start > Settings > Control Panel > Network and Dial-Up Connections > <some_connection> > Properties > Internet Protocol (TCP/IP) > Advanced > WINS > Enable NetBIOS over TCP/IP**.

See the documentation for your firewall to determine if these ports are not blocked for inbound requests.

To determine if security policies are blocking the connection ports, click **Start > Settings > Control Panel > Administrative Tools**.

Depending on whether your policies are stored locally or in Active Directory, follow these directions:

Locally stored policies

For locally stored policies, click **Start > Settings > Control Panel > Administrative Tools > Local Security Policy > IP Security Policies on Local Computer**.

Policies stored in Active Directory

For policies stored in Active Directory, examine the IP security policies and edit or remove filters that block the ports:

- Click **Administrative Tools > Default Domain Security Settings > IP Security Policies on Active Directory**.

- Click **Administrative Tools > Default Domain Controller Security Settings > IP Security Policies on Active Directory**.

For all Windows systems, the Server service must be running to connect to a Windows system using the Windows protocol.

The following table lists the ports reserved for NetBIOS. Ensure that these ports are not blocked.

Port	Description
135	NetBIOS Remote procedure call. (Not currently used.)
137	NetBIOS name service.
138	NetBIOS datagram. (Not currently used.)
139	NetBIOS session (for file and print sharing).
445	CIFS (on Windows XP).

For Windows Server 2008, shares must be shared for the Guest or Everyone accounts, and password protected sharing must be disabled. To disable password protected sharing, follow these steps:

1. Click **Control Panel > Networking and Sharing Center**.
2. Click the down arrow next to **Password protected sharing**.
3. Click **Turn off password protected sharing**.
4. Click **Apply**. Exit from the Control Panel.

Deployments on Windows 2008 - User Account Control (UAC) remote restrictions

If you are planning to install Storage Resource agents remotely on a Windows 2008 operating system, you must disable the User Account Control (UAC) remote restrictions on the Windows operating system. User Account Control is a security component on Windows operating systems.

Note: This task contains steps that tell you how to modify the registry. Serious problems might occur if you modify the registry incorrectly. Therefore, make sure that you follow these steps carefully. For added protection, back up the registry before you modify it. Then you can restore the registry if problems occur. For information about how to back up and restore the registry, see <http://support.microsoft.com/kb/322756/>.

To disable UAC remote restrictions, follow these steps:

1. Click **Start > Run**. Enter **regedit** and click **OK**.
2. Locate and click the following registry subkey:
`HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies\System`
3. If the `LocalAccountTokenFilterPolicy` registry entry does not exist, follow these steps:
 - a. On the **Edit** menu, click **New > DWORD Value**.
 - b. Enter `LocalAccountTokenFilterPolicy` as the name for the DWORD value in the content pane. Click **Enter**.
 - c. Right-click `LocalAccountTokenFilterPolicy`, then click **Modify**.
 - d. In the Edit DWORD Value window, enter **1**, then click **OK**.

This value can be 0 or 1:

- 0** This value builds a filtered token. This value is the default value. The administrator credentials are removed.

- 1 This value builds an elevated token.
- e. Exit the registry editor.

Additional information about Storage Resource agents

See *Planning for Storage Resource agents* in the *IBM Tivoli Storage Productivity Center Installation and Configuration Guide* for more information about Storage Resource agents.

Storage Resource agents

Storage Resource agents collect information about the Storage Attached Network (SAN) fabrics. You must deploy agents on systems with host bus adapters (HBAs) that are connected to the SAN fabrics that you want to manage.

Agents communicate through the HBA and collect the following information:

- Attribute and topology information
- Host-level information, such as file system and volume mappings
- HBA information, including make, model, and driver versions
- Port state information
- Zoning information (for QLogic and Cisco fabrics)

You can deploy Storage Resource agents remotely from the Tivoli Storage Productivity Center server. Deploy a Storage Resource agent on *at least* one system that has an HBA that is connected to each switch that you want to manage; consider installing two Storage Resource agents for each switch to ensure redundancy.

Out-of-band fabric agents

Out-of-band fabric agents issue SNMP queries to the fabric switches and collect topology information.

Be sure that your out-of-band fabric agents point to each switch in the Storage Area Network (SAN) that you want to manage.

Out-of-band fabric agents are necessary for Virtual storage area network (VSAN) information for Cisco switches. For Brocade fabrics, if no SMI-S agent is configured, Out-of-band fabric agents are necessary for Zoning information for Brocade switches.

IBM Tivoli Storage Productivity Center only supports SNMP V1.

See the Planning > Planning for Fabric Manager > *Configuring Cisco switches* topic in the *Installation and Configuration Guide* for more information about using Out-of-band fabric agents and Cisco switches.

Tivoli Storage Productivity Center Monitoring Agent

The IBM Tivoli Storage Productivity Center Monitoring Agent can be used by the IBM Tivoli Enterprise Monitoring Server to monitor systems in your enterprise. This agent is an optional program you can install and use in your enterprise.

IBM Tivoli Monitoring monitors and manages system and network applications on a variety of operating systems, tracks the availability and performance of your enterprise system, and provides reports to track trends and troubleshoot problems. The Tivoli Storage Productivity Center Monitoring Agent participates in that environment.

For performance reasons, install the Tivoli Storage Productivity Center server on a separate system from the IBM Tivoli Monitoring server. You can install the Tivoli Storage Productivity Center Monitoring agent on any system you want to monitor.

Before using the Tivoli Storage Productivity Center Monitoring Agent, you must have IBM Tivoli Enterprise Monitoring Server installed. For information about the IBM Tivoli Enterprise Monitoring Server, see http://publib.boulder.ibm.com/infocenter/tivihelp/v15r1/index.jsp?topic=/com.ibm.itm.doc_6.2.1/welcome.htm.

For information about installing IBM Tivoli Monitoring, see the Quick Start Guide at <http://publib.boulder.ibm.com/infocenter/tivihelp/v15r1/index.jsp?topic=/com.ibm.itm.doc/GI11-8058-00.htm>.

To use the Tivoli Storage Productivity Center Monitoring Agent, install this agent on the system you want to monitor.

To see the type of reports displayed by the Tivoli Storage Productivity Center Monitoring Agent, see “Tivoli Storage Productivity Center Monitoring Agent reports” on page 1157.

Security

The IBM Tivoli Storage Productivity Center environment supports role-based security.

For role-based authorization, user groups that are contained in the authentication repository, which is either the local operating system or an LDAP-compliant directory, which depends on the choice of authentication mechanism that is made, during the Tivoli Storage Productivity Center installation, are associated with predefined roles. When a user ID is authenticated to Tivoli Storage Productivity Center through the GUI, CLI, or APIs, membership in a user group determines the authorization level.

Role-based authorization

Operating system groups or LDAP groups (for example, groups contained in your LDAP-compliant repository) are associated with predefined roles. When a user ID is authenticated to Tivoli Storage Productivity Center through the GUI, CLI, or APIs, membership in an operating system or LDAP group determines the authorization level of the user.

Table 25 shows the association between roles and authorization level.

If you select OS authentication for your Tivoli Storage Productivity Center installation, then you do not have to create any of the groups before installation. The Tivoli Storage Productivity Center superuser role automatically gets mapped to the Administrators group on the Windows operating system, to the system group on the AIX operating system, or to the root group on the Linux operating system.

Table 25. Roles and authorization levels

Role	Authorization level
Superuser	Has full access to all Tivoli Storage Productivity Center functions.
Productivity Center administrator	Has full access to operations in the Administration section of the GUI.

Table 25. Roles and authorization levels (continued)

Role	Authorization level
Disk administrator	Has full access to Tivoli Storage Productivity Center disk functions.
Disk operator	Has access to reports only for Tivoli Storage Productivity Center disk functions. These reports include information about tape devices.
Fabric administrator	Has full access to Tivoli Storage Productivity Center Fabric Manager functions.
Fabric operator	Has access to reports only for Tivoli Storage Productivity Center Fabric Manager functions.
Data administrator	Has full access to Tivoli Storage Productivity Center Data Manager functions.
Data operator	Has access to reports only Tivoli Storage Productivity Center Data Manager functions.
Tape administrator	Has full access to Tivoli Storage Productivity Center tape functions.
Tape operator	Has access to reports only for tape functions.

Notes:

1. If a user has multiple roles, the authorization level is a combination of the levels for each of the roles.
2. If a user is not a member of any of the roles listed, no access is granted to that user.
3. For enterprise-rollup reports, you need superuser or Tivoli Storage Productivity Center administrator authority to do the following actions:
 - Add, remove, or modify the Tivoli Storage Productivity Center subordinate server that the master server is monitoring.
 - Create or run probe jobs that include Tivoli Storage Productivity Center subordinate servers.

Any Tivoli Storage Productivity Center user can generate enterprise-rollup reports.
4. You need to assign the appropriate Tivoli Integrated Portal roles to other Tivoli Storage Productivity Center users and groups who are added later to the system.

SAN Volume Controller

This section contains information about the following SAN Volume Controller topics: managed disks (MDisks), managed-disk states, managed-disk groups, and virtual disks (VDisks).

Overview

SAN Volume Controller is a SAN appliance that attaches open-systems storage devices to supported open-systems hosts.

SAN Volume Controller provides symmetric virtualization by creating a pool of managed disks from the attached storage subsystems, which are then mapped to a set of virtual disks for use by attached host computer systems. System administrators can view and access a common pool of storage on the SAN, which enables them to use storage resources more efficiently and provides a common

base for advanced functions. The SAN Volume Controller performs the following functions for the SAN storage that it controls:

- Creates a single pool of storage
- Manages logical volumes
- Provides advanced functions for the SAN, such as large scalable cache, copy services, and space management

A "node" is a single storage engine. The storage engines are always installed in pairs with one or as many as four pairs of nodes which constitute a "cluster". Each node in a pair is configured to back up the other.

Each pair of nodes is known as an "I/O group". All I/O operations are cached on both nodes for resilience. To eliminate any single point of failure, each of the two nodes are protected by different uninterruptible power supplies. A node can be in only one I/O group.

Figure 5. A SAN Volume Controller node

I/O groups view the storage that is presented to the SAN by the back-end controllers as a number of disks, which are known as "managed disks". The application services do not see these managed disks. Instead, they see a number of logical disks, which are known as "virtual disks", that are presented to the SAN by the SAN Volume Controller. Each node must be in only one I/O group and provides access to the virtual disks in the I/O group.

The fabric contains two distinct zones: a host zone and a disk zone. In the host zone, the host systems can identify and address the nodes. You can have more than one host zone. Generally, you create one host zone per operating system type. In the disk zone, the nodes can identify the disk drives (storage subsystems). Host systems cannot operate on the disk drives directly; all data transfer occurs through the nodes. As shown in Figure 6 on page 130, several host systems can be connected to a SAN fabric. A cluster of SAN Volume Controllers is connected to the same fabric and presents virtual disks to the host systems. You configure these virtual disks by using the disks that are on the RAID controllers.

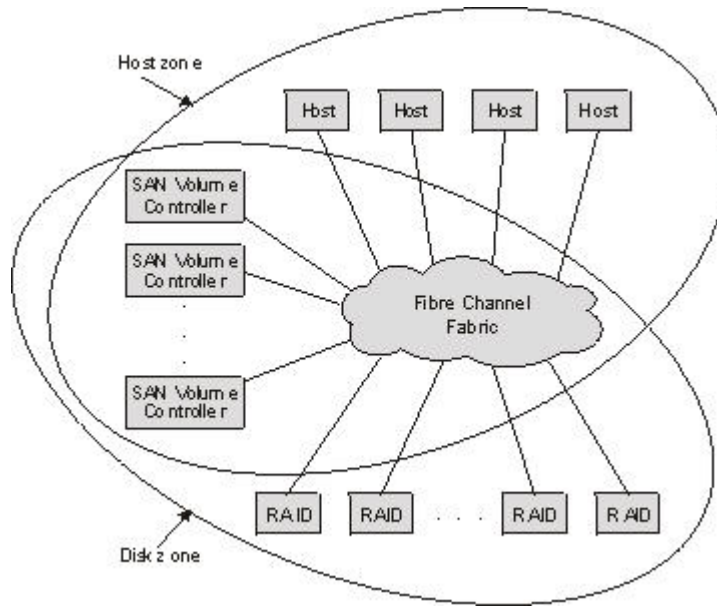

Figure 6. Example of a SAN Volume Controller in a fabric

Managed disks

A managed disk (MDisk) is a logical disk that a SAN Volume Controller has exported to the SAN fabric to which the nodes in the cluster are attached.

A managed disk might consist of multiple physical disks that are presented to the SAN as a single logical disk. A managed disk always provides usable blocks of physical storage to the cluster, even if it does not have a one-to-one correspondence with a physical disk.

Figure 7 shows physical disks and managed disks.

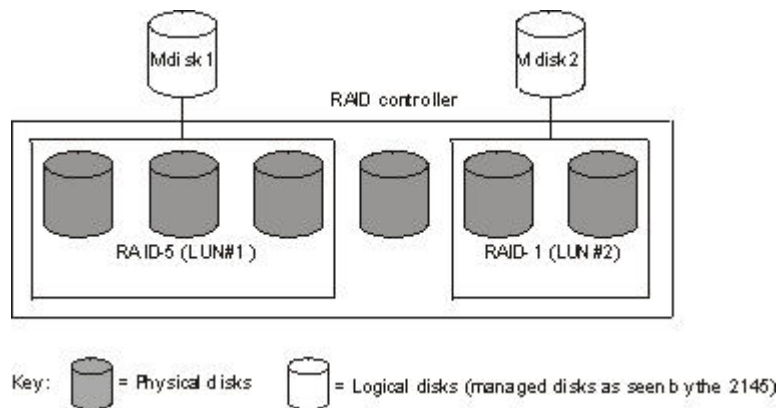

Figure 7. Physical disks and managed disks (MDisks)

Extents

Each MDisk is divided into chunks of equal size called *extents*. Extents are numbered sequentially (beginning at 0) from the start to the end of the managed disk. Extents are a unit of mapping the data between MDisks and virtual disks (VDisks).

The extent size is a property of managed-disk groups (MDisk groups). When a managed disk is added to a managed-disk group, the size of the extents that the MDisk will be broken into depends on the attribute of the managed-disk group to which it has been added.

Access modes

The access mode determines how the SAN Volume Controller cluster uses the MDisk. The possible modes are the following:

Unmanaged

The MDisk is not used by the cluster.

Managed

The MDisk is assigned to an MDisk group and provides extents that virtual disks (VDisks) can use.

Image The MDisk is assigned directly to a VDisk with a one-to-one mapping of extents between the MDisk and the VDisk.

Managed disk states

This topic describes the operational states of managed disks (MDisks).

Managed disks can be in the following states:

Online

The MDisk can be accessed by all online nodes. That is, all the nodes that are currently working members of the cluster can access this MDisk. The MDisk is online when the following conditions are met:

- All timeout error recovery procedures complete and report the disk as online.
- Volume inventory of the target ports correctly reported the MDisk.
- Discovery of this volume completed successfully.
- All of the managed disk target ports report this volume as available with no fault conditions.

Degraded

The MDisk cannot be accessed by all the online nodes. That is, one or more (but not all) of the nodes that are currently working members of the cluster cannot access this MDisk. The MDisk might be partially excluded; that is, some of the paths to the MDisk (but not all) have been excluded.

Excluded

The MDisk has been excluded from use by the cluster after repeated access errors.

Offline

The MDisk cannot be accessed by any of the online nodes. That is, all of the nodes that are currently working members of the cluster cannot access this MDisk. This state can be caused by a failure in the SAN, the storage subsystem, or one or more physical disks connected to the storage subsystem. The MDisk will only be reported as offline if all paths to the disk fail.

Attention: If your fabric is undergoing transient link breaks or you have been replacing cables or connections in your fabric, you might see one or more MDisks change to the degraded status. If an I/O operation was attempted during the link breaks and the same I/O failed several times, the MDisk will be partially excluded and change to a status of degraded. You must include the MDisk to resolve the problem.

Managed disk path Each managed disk will have an online path count, which is the number of nodes that have access to that managed disk; this represents a summary of the I/O path status between the cluster nodes and the particular storage device. The maximum path count is the maximum number of paths that have been detected by the cluster at any point in the past. Thus if the current path count is not equal to the maximum path count then the particular managed disk may be degraded. That is, one or more nodes may not see the managed disk on the fabric.

Managed disk groups

A SAN Volume Controller *MDisk group* is a collection of MDisks that jointly contain all the data for a specified set of virtual disks (VDisks).

All MDisks in a group are split into extents of the same size. VDisks are created from the extents that are available in the group. You can add MDisks to an MDisk group at any time in order to increase the number of extents that are available for new VDisks or to expand existing VDisks. You can add only MDisks that are in unmanaged mode. When MDisks are added to a group, their mode changes from unmanaged to managed.

Figure 8 shows an MDisk group containing four MDisks.

Figure 8. MDisk group

You can delete MDisks from a group under the following conditions:

- VDisks are not using any of the extents that are on the MDisk.
- Enough free extents are available elsewhere in the group to move any extents that are in use from this MDisk.

Attention: If you delete an MDisk group, you destroy all the VDisks that are made from the extents that are in the group. If the group is deleted, you cannot recover the mapping that existed between extents that are in the group and the extents that VDisks use. The MDisks that were in the group are returned to unmanaged mode and can be added to other groups. Because the deletion of a group can cause a loss of data, you must force the deletion if VDisks are associated with it.

Table 26 on page 133 describes the operational states of an MDisk group.

Table 26. Managed disk group states

Status	Description
Online	The MDisk group is online and available. All the MDisks in the group are available.
Degraded	The MDisk group is available; however, one or more nodes cannot access all the MDisks in the group.
Offline	The MDisk group is offline and unavailable. No nodes in the cluster can access the MDisks. The most likely cause is that one or more MDisks are offline or excluded.

Attention: If a single MDisk in an MDisk group is offline and therefore cannot be seen by any of the online nodes in the cluster, then the MDisk group of which this MDisk is a member goes offline. This causes *all* the VDIs that are being presented by this MDisk group to go offline. Care should be taken when creating MDisk groups to ensure an optimal configuration.

Consider the following guidelines when you create MDisk groups:

- If you are creating image-mode VDIs, do not put all of these VDIs into one MDisk group because a single MDisk failure results in all of these VDIs going offline. Allocate your image-mode VDIs between your MDisk groups.
- Ensure that all MDisks that are allocated to a single MDisk group are the same RAID type. This ensures that a single failure of a physical disk in the storage subsystem does not take the entire group offline. For example, if you have three RAID-5 arrays in one group and add a non-RAID disk to this group, then you lose access to all the data striped across the group if the non-RAID disk fails. Similarly, for performance reasons you should not mix RAID types. The performance of all VDIs will be reduced to the lowest performer in the group.
- If you intend to keep the virtual disk allocation within the storage exported by a storage subsystem, ensure that the MDisk group that corresponds with a single subsystem is presented by that subsystem. This also enables nondisruptive migration of data from one subsystem to another subsystem and simplifies the decommissioning process if you want to decommission a controller at a later time.

Extents

To track the space that is available, the SAN Volume Controller divides each MDisk in an MDisk group into chunks of equal size. These chunks are called *extents*, and are indexed internally. Extent sizes can be 16, 32, 64, 128, 256, or 512 MB.

You must specify the extent size when you create a new MDisk group. You cannot change the extent size later; it must remain constant throughout the lifetime of the MDisk group. MDisk groups can have different extent sizes. However, different extent sizes can place restrictions on the use of data migration. The choice of extent size affects the total amount of storage that can be managed by a cluster. Table 27 on page 134 shows the maximum amount of storage that can be managed by a cluster for each extent size. Because the SAN Volume Controller allocates a whole number of extents to each virtual disk that is created, using a larger extent size can increase the amount of wasted storage at the end of each virtual disk. Larger extent sizes also reduce the ability of the SAN Volume Controller to distribute

sequential I/O workloads across many managed disks. Therefore, larger extent sizes might reduce the performance benefits of virtualization.

Table 27. Capacities of the cluster given extent size

Extent size	Maximum storage capacity of cluster
16 MB	64 TB
32 MB	128 TB
64 MB	256 TB
128 MB	512 TB
256 MB	1 PB
512 MB	2 PB

Virtual disks

An SAN Volume Controller *VDisk* is a logical disk that the cluster presents to the storage area network (SAN).

Application servers on the SAN access *VDisks*, not managed disks (*MDisks*). *VDisks* are created from a set of extents in an *MDisk* group. There are three types of *VDisks*: striped, sequential, and image.

Types

You can create the following types of *VDisks*:

Striped

The striping is at extent level. One extent is allocated, in turn, from each managed disk that is in the group. For example, a managed disk group that has 10 *MDisks* takes one extent from each managed disk. The 11th extent is taken from the first managed disk, and so on. This procedure, known as a round-robin, is similar to RAID-0 striping.

You can also supply a list of *MDisks* to use as the stripe set. This list can contain two or more *MDisks* from the managed disk group. The round-robin procedure is used across the specified stripe set.

Attention: Care should be taken when specifying a stripe set if your *MDisk* group contains *MDisks* of unequal size. By default striped *VDisks* are striped across all *MDisks* in the group. If some of the *MDisks* are smaller than others, the extents on the smaller *MDisks* will be used up before the larger *MDisks* run out of extents. Manually specifying the stripe set in this case might result in the *VDisk* not being created.

Figure 9 on page 135 shows an example of a managed disk group containing three *MDisks*. This figure also shows a striped virtual disk created from the extents available in the group.

Figure 9. Managed disk groups and VDisks

Sequential

When selected, extents are allocated sequentially on one managed disk to create the virtual disk if enough consecutive free extents are available on the chosen managed disk.

Image Image-mode VDisks are special VDisks that have a direct relationship with one managed disk. If you have a managed disk that contains data that you want to merge into the cluster, you can create an image-mode virtual disk. When you create an image-mode virtual disk, a direct mapping is made between extents that are on the managed disk and extents that are on the virtual disk. The managed disk is not virtualized. In other words, the logical block address (LBA) x on the managed disk is the same as LBA x on the virtual disk.

When you create an image-mode VDisk, you must assign it to a managed disk group. An image-mode VDisk must be at least one extent in size. In other words, the minimum size of an image-mode VDisk is the extent size of the MDisk group to which it is assigned.

The extents are managed in the same way as other VDisks. When the extents have been created, you can move the data onto other MDisks that are in the group without losing access to the data. After you move one or more extents, the virtual disk becomes a real virtualized disk, and the mode of the managed disk changes from image to managed.

Attention: If you add an MDisk to an MDisk group as a managed disk, any data on the MDisk will be lost. Ensure that you create image-mode VDisks from the MDisks that contain data before you start adding any MDisks to groups.

MDisks that contain existing data have an initial mode of unmanaged, and the cluster cannot determine whether it contains partitions or data.

A virtual disk can have one of three states. The following list describes the different states of a virtual disk:

Online

The virtual disk is online and available if both nodes in the I/O group can access the virtual disk. A single node will only be able to access a VDisk if it can access all the MDisks in the MDisk group associated with the VDisk.

Offline

The VDisk is offline and unavailable if both nodes in the I/O group are missing or none of the nodes in the I/O group that are present can access the VDisk.

Degraded

The status of the virtual disk is degraded if one node in the I/O group is online and the other node is either missing or cannot access the virtual disk.

If you delete a virtual disk, you destroy access to the data that is on the virtual disk. The extents that were used in the virtual disk are returned to the pool of free extents that is in the managed disk group. The deletion might fail if the virtual disk is still mapped to hosts. The deletion might also fail if the virtual disk is still part of a FlashCopy or a Metro Mirror mapping. If the deletion fails, you can specify the force-delete flag to delete both the virtual disk and the associated mappings to hosts. Forcing the deletion will also delete the copy services relationship and mappings.

Chapter 3. Scenarios

This section contains scenarios which illustrate how to perform specific tasks using IBM Tivoli Storage Productivity Center.

The provided scenarios set out situations that can be solved using Tivoli Storage Productivity Center. When using these scenarios you should remember the following:

- The scenarios are intended to be step-by-step instructions that you follow to complete a specific job. Each scenario contains multiple tasks that must be followed in the order given.
- Specific values are given in the scenarios, such as user name, IP Address, probe name, and so forth. These are for illustration purposes only and you must replace them with values appropriate for your system.
- The scenarios do not provide in-depth conceptual information about the tasks. See the appropriate topics in the IBM Tivoli Storage Productivity Center Information Center for more information about the concepts behind the tasks.
- You will complete a scenario successfully if you follow the instructions correctly and your system performs as expected.

Monitoring and reporting on I/O utilization

This scenario involves monitoring a DS8000 and a DS4000 to determine what data can be moved to the less expensive storage media. Monitoring over time collects the necessary information for analysis. Trending reports, produced with IBM Tivoli Storage Productivity Center Reporter, display utilization information and can be used by management to make decisions about future storage needs.

You have a DS8000 and a DS4000. The DS8000 is nearly full but the DS4000 is only half full. You need to move workload onto the DS4000 as the demand for the DS8000 grows. You will monitor the utilization of volumes on each system to identify potential migration candidates. You will also gather this information over time to indicate trends. This trending information, in report format, will be used for future planning and will be presented to management who will make decisions based on the report.

To perform this scenario, complete the following steps:

Perform performance monitoring

1. **Configure the storage systems for monitoring by Tivoli Storage Productivity Center** This process is in two parts as Tivoli Storage Productivity Center uses native interfaces to connect to DS8000 storage systems while the DS4000 must be connected using a CIM object manager (CIMOM) connection. Use the Configure Devices wizard to configure the DS8000 system. For the DS4000 system, you can configure it manually by running a first discovery to locate the CIMOMs that are visible to the Device server with SLP. After configuring the CIMOM login information, run a second discovery to gather information about the DS4000 system. Run a CIMOM discovery every four hours. See “Discover storage subsystem, tape library, and fabric information with CIM agents” on page 334 for more information. Alternatively, you can configure the DS4000 system by using the Configure Devices wizard.

Configure the DS8000 system

- a. Use the Configure Devices wizard to enter connection information for the native interface of the DS8000 system. See “Configuring storage subsystems” on page 310 for details of how to use the Configure Devices wizard. You can use the wizard to include the DS8000 system automatically in a probe. If you want to monitor SAN Volume Controller systems or the XIV systems, you can also use the Configure Devices wizard to enter connection information for their native interfaces.

Configure the DS4000 system manually

- a. Expand **Administrative Services > Data Sources > CIMOM Agents** .
- b. For each CIMOM you use, click the magnifying glass to open the View and Edit window. Enter the name and password information. Check the **Test CIMOM connectivity before editing**.
- c. Click the **Save** icon. This action saves your information and performs a connectivity check. You must use this process for each SLP-discovered CIMOM you choose to use.
- d. Expand **Administrative Services > Discovery**, right-click on **CIMOM**, and click **Run Now**.
- e. In the **CIMOM Discovery job submitted** window, click OK.
- f. When the job has finished, you can view the list of discovered storage systems by expanding **Disk Manager > Storage Subsystems**.

Configure the DS4000 system using the Configure Devices wizard

- a. Use the Configure Devices wizard to enter connection information for the native interface of the DS8000 system. See “Configuring storage subsystems” on page 310 for details of how to use the Configure Devices wizard.
2. **Create a probe** Create the probe to run during off-hours.
 - a. Expand **Tivoli Storage Productivity Center > Monitoring > Probes**. Right-click **Probes** and select **Create Probe**.
 - b. In the **What to Probe** tab, move the DS6000 and the DS4000 from the **Available** list box to the **Current Selections** box.
 - c. In the **When to run** tab you will schedule when you want the probe to run. We strongly recommend that you run probes when nothing else is running.
 - 1) Choose to run the job repeatedly according to a schedule you specify.
 - 2) Select the current day, month, and year as the date when you want data collection to begin. Select 1:00 AM as the time the job should begin running.
 - 3) Select the days the job should run. Select all of them. A check mark will appear next to each day you have chosen.
 - d. In the **Alerts** tab accept the default (error log) as the means of notification if the job fails.
 - e. Click **Save**. The probe will run daily at 1:00 AM.
 3. **Create a storage-system performance monitor** Create a storage-system performance monitor to gather performance data and view the results in the log file.
 - a. Expand **Disk Manager > Monitoring**, right-click **Subsystem Performance Monitor** and select **Create Performance Monitor**.
 - b. In the Create Storage Subsystem Performance Monitor window, click the Storage Subsystems tab. Select the DS8000 and DS4000 you want to report

on and move them to the Current Selections field. Make sure these storage systems have been probed. If they have not been, data collection will fail.

- c. Click the Sampling and Scheduling tab. In the Sampling area, specify the length of the sampling window and how frequently the performance data is to be gathered, using the following values:
 - Interval length = 5 minutes
 - Duration = Indefinite
 - Scheduling = Begin immediately
- d. In the Alert tab, **Monitor Failed** is the only triggering condition. In the Triggered Actions area accept the default (error log) means of notification.
- e. Click **Save**. When prompted, type a name for the threshold and click **OK**. The name of the storage system performance monitor is displayed under the Subsystem Performance Monitors node. The performance monitor will take 3 hours to run, as set in step c. The status icon will indicate when the job has completed successfully.
- f. When the job has completed, a table is displayed listing the storage systems. To view the log file for each storage system, select the magnifying glass.

4. Tivoli Storage Productivity Center Reporter for Disk

This scenario uses Tivoli Storage Productivity Center Reporter for Disk to prepare a finished report automatically. Tivoli Storage Productivity Center Reporter is a free Java 2 Platform application that extracts storage system information and hourly performance statistics. The statistics are transcribed into a paper-style PDF file containing your storage server utilization, which is saved on the local machine.

If you do not have Tivoli Storage Productivity Center Reporter for Disk, complete the following steps. If you have installed Tivoli Storage Productivity Center Reporter for Disk, go to step 5.

- a. Go to the Tivoli Storage Productivity Center Reporter for Disk web page, <http://www-03.ibm.com/support/techdocs/atmastr.nsf/WebIndex/PRS2618>.
- b. Select **Download Tivoli Storage Productivity Center Reporter for Disk for Windows (60MB)**
- c. Follow steps to download Tivoli Storage Productivity Center Reporter.
- d. Run the Installer

5. Create your report with Tivoli Storage Productivity Center Reporter

- a. To start the program go to **Start > Programs > Tivoli Storage Productivity Center Reporter for Disk > Tivoli Storage Productivity Center Reporter for Disk**. Select **Start**. The Confirmation window will open.
- b. Enter the Hostname (or IP address), Port, UserID, and Password of the system that you want the report on. Click **Continue**. The Select Serial Number window will open. Tivoli Storage Productivity Center Reporter for Disk saves a list of the commands and the status of the commands you are using in the GUI. The commands and status of the commands are displayed in the Status window.
- c. If the probe of the selected systems was successful, the DS8000 and DS4000 storage systems will be listed in the Select Serial Number window. Select the DS8000 storage system. Click **Select**. You can only create a report for one storage system at a time.
- d. The Select Date Range window opens. Select the **Last 7 days** radio button. Click **Select**,

- e. The Customer Information window opens. This information will be included in the title information of the finished report. The first text field, **Company**, is required. This is the company name that will appear on the title page of the report. All other fields are optional. When finished, click **Continue**.
 - f. The IBM/Partner Information window opens. All fields are optional. Click **Continue**.
 - g. Select a file name and directory in which to save the generated report. The default directory is "My Documents" and the default file name is TPCReport.pdf. It is strongly recommended that you save the PDF file under a different name. Click **Save**.
 - h. The steps Tivoli Storage Productivity Center Reporter takes to create the report are shown in the status window. Once the report has been generated, the **Exit** button becomes available. Click **Exit**.
 - i. Go to "My Documents", find and double-click the PDF report.
The report includes the following information for storage systems, ports, arrays, and volumes:
 - General information
 - Performance summary
 - Statistics
 - Definitions
6. Using the DS8000 report, look at the Volume Performance Summary for volumes with low levels of I/O and throughput in Megabytes. These might be candidates for moving to the DS4000.

Printing

The report will have been saved as a PDF file using the latest Acrobat Reader on your system. If you only have the Reader of that version of Acrobat, you will be able to view the report, but you will be unable to print it. In this case take the following steps to print the report:

1. Open your complete version of Adobe Acrobat.
2. Select **File > Open** and navigate to the report.
3. Select **File > Print** to print the report.
4. Close the report. You will not be able to save the report as an earlier version of an Acrobat PDF file.

The following documents were referenced for this scenario:

- *IBM Tivoli Storage Productivity Center User's Guide GC32-1775*
- *Tivoli Storage Productivity Center Reporter for Disk Version 1.01 - Process and Report Overview*

Storage provisioning by using workflows

IBM Tivoli Storage Productivity Center and Tivoli Provisioning Manager Workflow automation can reduce provisioning time from hours to minutes and significantly simplify the task of provisioning new storage capacity. This automation is especially valuable when adding storage provisioning to existing automated server provisioning tasks, such as deploying operating systems, software, and network resources. This scenario shows you how to use Tivoli Provisioning Manager and Tivoli Storage Productivity Center Workflows to automate provisioning of SAN attached storage capacity to a server in a Microsoft Windows environment.

Tivoli Storage Productivity Center and Tivoli Provisioning Manager work together to provide automated storage provisioning for the data center.

Tivoli Provisioning Manager provides the means to automate common tasks in the data center that surround each of the four major pillars of provisioning:

- OS provisioning (Windows, Linux, AIX, Solaris, HP-UX, and so on)
- Software provisioning (DB2, WebSphere, Oracle, and many more)
- Network provisioning (provisioning VLANs, ACLs, IP addresses, activating, and deactivating switch ports, and so on)
- Storage provisioning (attaching SAN disks for use by the server)

Tivoli Provisioning Manager Workflows automate tasks, especially the tasks that are complex, repetitive, and prone to error by applying best practices for zoning, device configuration, and path selection automatically.

Tivoli Storage Productivity Center provides heterogeneous management functions for the SAN storage environment. Tivoli Storage Productivity Center Workflows provide status information about its SAN storage environment to Tivoli Provisioning Manager. They also allow Tivoli Provisioning Manager to modify the SAN through Tivoli Storage Productivity Center.

The following illustration shows the movement of workflow information between Tivoli Provisioning Manager and Tivoli Storage Productivity Center.

Restriction: You must ensure that each Tivoli Provisioning Manager manages only one Tivoli Storage Productivity Center server. If multiple Tivoli Storage Productivity Center servers are managed, and you run a probe on the second server, information on the first server is deleted.

Figure 10. High-level architecture

End-to-end provisioning of SAN storage is difficult due to the complexity of modern environments and inputs that must be considered. This scenario creates a Tivoli Provisioning Manager storage template used for end-to-end storage provisioning that can automate the process. After the storage template is created, it can be reused to automate end-to-end provisioning of SAN storage with a few mouse clicks.

Without workflows, you would need to complete the following individual steps in Tivoli Storage Productivity Center to provision storage:

- Add a volume (storage subsystem)
 - Select storage subsystem
 - Select or create new volume
 - Select host HBA ports (WWNs)
 - Select subsystem controller ports (WWNs)
 - Map volume to controller ports
 - Map volume to host HBA ports
- Set paths (SAN fabric switches)
 - Determine whether multiple paths are required
 - Create or update zones
 - Get active zone set
 - Add zone to zone set
 - Activate zone set
- Map the HBA Volumes to the operating system and file system (Host server)
 - Rediscover attached volumes
 - Configure multipathing drivers
 - Map volumes to OS devices
- Create volume and file system (Host server)
 - Create Windows volume
 - Create or extend NTFS file system

With workflows, after the template is created, these tasks are automated and condensed to the following tasks:

- Select the host that needs additional storage
 - Select the template name from the template list
 - Click OK.

To use workflows, the following prerequisites must be met:

- Tivoli Provisioning Manager v5.1 is installed and configured.
- Tivoli Storage Productivity Center v4.1 or later is installed and configured.
- The following two automation packages is downloaded, installed, and configured from the Open Process Automation Library (OPAL):
 - IBMTPC.tcdriver
 - WindowsNTFS.tcdriver

For more information about the prerequisites needed to use workflows, see the IBM white paper, *Tivoli Provisioning Manager and IBM Tivoli Storage Productivity Center-Storage Provisioning Configuration and Exercises*.

To create and use a storage template, complete the following steps:

1. To create the Tivoli Provisioning Manager workflow template, complete the following steps:
 - a. Select **Inventory > Manage Templates > Storage Templates** from the Tivoli Provisioning Manager navigation tree.

- b. Select **Edit** and click **Add Storage Template**. The **Create Storage Template** window opens.
- c. Enter **NTFS_SVC** as the name for the storage template. Click **Next**.
- d. Define the volume container settings. In the **Configure Volume Container Settings** window, enter the following information:
 - Type **NTFS** for the **Volume Container Name**.
 - Select **NTFS** as the **Storage Manager**.
 - Click **Add Volume Container Settings**.
 - Click **Next**.
- e. Define the physical volume settings
 - Scroll down to the **SAN Physical Volume Settings** and specify a SAN volume.
 - Type **SAN** in the **Name** field.
 - In the **Volume Container Settings** field, select **NTFS**.
 - Select **mdiskgrp0** as the appropriate storage pool from **Storage Pool/Storage Subsystem**.
 - Type **5G** as the value for **Consumable Size**.
 - Set the **Function Type** to **Generic**.
 - For the **RAID Level**, select **UNKNOWN**.
 - Click **Add SAN Setting** and click **Next**.
- f. Define the data path settings:
 - In the **Configure Data Path Settings** window, select **SAN** from the **SAN Physical Volume Setting** list box.
 - Click **Add Data Path Settings** and click **Next**.
- g. Define the logical volume settings:
 - In the **Configure Logical Volume Settings** window, type **TPMVolume** in the **Name** field.
 - Select **Simple** as the **Logical Volume Type**.
 - Select **NTFS** for the **Volume Container Settings**.
 - Specify **5G** for **Consumable Size**.
 - Set the **Function Type** to **Generic**.
 - Set the **RAID Level** to **UNKNOWN**.
 - Click **Add Logical Volume Settings** and click **Next**.
- h. Define file system settings:
 - In the **Configure File System Settings** window, select **TPMVolume** from the **Logical Volume Settings** list.
 - Type **H:** as the **Label**.
 - For the **File System Type**, select **NTFS** from the list.
 - Specify **5G** for **File System Size**.
 - Click **Add File System Settings** and click **Next**.
- i. File system mount settings are not used. In the **Configure Filesystem Mount Settings** window, click **Next**.
- j. Define disk partition settings:
 - In the **Configure Disk Partition Settings** window, set the **Partition Size** to **5G**.
 - From the **Physical Volume Settings** list, select **SAN**
 - From the **Logical Volume Settings** list, select **TPMVolume**.

- Click **Add Disk Partition Settings** and click **Next**.
- k. Verify the summary information. When you are done, click **Finish**.
- l. Verify that the **NTFS_SVC** template is displayed in the Tivoli Provisioning Manager GUI at **Inventory > Manage Templates > Storage Templates**.

This template allows any system administrator to complete end to end provisioning.

2. To provision, complete the following steps
 - a. From the **General** tab of a Windows computer in Tivoli Provisioning Manager, click **Edit** and select **Add Storage to Host**.
 - b. Select **NTFS_SVC** from the **Storage Template** list
 - c. Click **OK**.
 - d. Navigate to **Automation > Workflow Status** and track the status of the deployment request in the workflow status log until it completes successfully. It takes approximately 10 - 15 minutes to complete.

A new 5G volume is created on the SAN Volume Controller storage pool **mdiskgrp0**. This storage pool is assigned to your windows host and mounted and formatted as the drive letter **H** within a few minutes with consistent results and no user errors.

For more information about workflows, see the following publications:

- White paper: *Tivoli Provisioning Manager and Tivoli Storage Productivity Center - Storage Provisioning Configuration and Exercises*

Archive and delete files

This scenario shows you how to reclaim storage space by archiving and deleting files that meet criteria you define.

You are running out of available storage capacity and need to find stale data which can be archived and deleted in order to reclaim space and make it available to more pertinent data. Specifically, you are **TPCUser** and you want to find files on the **C:** file system of **computer1** that are larger than **5MB**, and have not been accessed in **365** days.

Steps include the following tasks:

- Running a probe (if needed)
- Defining the constraint
- Running a scan
- Generating a constraint violation report
- Running an archive/backup on selected files in the report

Before you can use the IBM Tivoli Storage Manager archive or backup functionality you must ensure the prerequisites listed in "Requesting an archive or backup" on page 478 have been met.

To create an archive job, complete the following steps:

1. Run a Probe

You may not need to complete this step if a successful probe has been recently completed. Check the most recent day and time a probe was run successfully at **IBM Tivoli Storage Productivity Center > Monitoring > Probes**. To do this, expand the probe name to see the date the last successful probe was run. In most cases the default probe is sufficient.

If you do need to run a probe, complete the following steps:

- a. Expand **IBM Tivoli Storage Productivity Center > Monitoring > Probes**, and select **Create Probe**. The **Create Probe** window opens.
- b. Enter a description for the probe.
- c. In the **What to Probe** tab, select the resources you want to probe, in this case **Computer Groups > TPCUser.Default Computer Group > computer1**.
- d. In the **When to Run** tab, accept the defaults: **Run Now** and **Local time in each time zone**.
- e. In the **Alerts** tab, accept the default. If the probe fails, a notification will be sent to the error log automatically.
- f. Click **Save** to save the probe. Enter **Archive Backup Probe** as the probe name and click **OK**. An entry for the probe appears under **IBM Tivoli Storage Productivity Center > Monitoring > Probes > TPCUser.Archive Backup Probe**.
- g. The probe will begin running immediately. The number of times this job has been run and the date and time will be listed under the probe name. To see the status of the job, right-click on the probe name and select **Update Job Status**.

2. Define Constraints

Define the criteria you are looking for with a constraint.

- a. Expand **Data Manager > Policy Management > Constraints**, right-click and select **Create Constraint**.
- b. In the **Description** field, enter a description of this constraint.
- c. In the **Filesystems** tab **Available** column, select **Filesystems > computer1 > C:** and move it to **Current Selections**.
- d. In the **File Types** tab, check **Forbid files matching these patterns**. All file types should be in the **Choose a file type** column. This will apply the constraint to all file types.
- e. In the **Users** tab, Check the **Forbid files owned by selected users**. All users should be listed in the **Available Users** column. This will apply the constraint to all users.
- f. In the **Options** tab, leave the default, **200**, in the text box in the **Violating File Limits** section. In the **Alerts on Files** section, select **number of days since last access greater than** and type **365**. Select **bigger than** and enter **5 MB**. Below the **Alerts on Files** section, **File Filter Text:** will list the values you picked in the **File Types**, **Users**, and **Options** tabs.
- g. In the **Alert** tab under **Triggering Conditions**, the only triggering condition is **Violating files consume more than**. Type **5** in the **Value** field. Select **Megabytes** from the **Value Units:** pull-down. Accept the default in **Triggered Actions**, which will send a message to the error log if the constraints you have defined are violated.
- h. Click the **Save** icon. Name the constraint **Archive File Constraint**. The constraint will be saved as **Data Manager > Policy Management > Constraints > TPCUser.Archive File Constraint**.

3. Run a Scan

Scan with the constraint violation you have created.

- a. Expand **Data Manager > Monitoring**, right-click **Scans** and select **Create Scan**. The **Create Scan** window opens.
- b. In the **Filesystems** tab, select **Filesystems > computer1 > C:/** from the **Available** column and move it to the **Current Selections** column.
- c. Do not select anything in the **Directory Groups** tab.
- d. In the **Profiles** tab, select all the profiles listed in the Available Profiles column and move them to both **Profiles to Apply to Filesystems** and **Profiles to Apply to Directories**.
- e. In the **When to Run** tab, select **Run Now** and **Local Time in each time zone**.
- f. In the **Alert** tab, **Scan Failed** is the only **Triggering Condition**. In the **Triggered Actions** area, select nothing to accept the default. If the job fails, a message will be sent to the log file automatically.
- g. Click the **Save** icon. Save the scan as **Archive Scan**. The scan is saved under **Data Manager > Monitoring > Scans > TPCUser.Archive Scan**. The scan starts to run immediately. Scans can take some time to complete depending on the number of storage assets scanned and the profiles used.

4. Generate a Constraint Violation Report

Generate a report listing files that met your constraint violation criteria.

- a. Expand **Data Manager > Reporting > Usage Violations > Constraint Violations** and click **By Constraint**. The **Constraint Violations: By Constraint** window opens to the **Selection** tab.
- b. In the **Report Filter Specifications** area, type **100** in the **Return maximum of text** field.
- c. In the **Report Filter Specifications** area, click **Selection**. The **Select Resources** pop-up opens listing the available constraints.
- d. Select **Archive File Constraint**. (You may have to de-select the other constraints.) Click **OK**.
- e. Select the columns you want to appear in the report. By default, all columns will be listed in **Included Columns**. If you want to remove columns from the report, select them and move them to **Available Columns**.
- f. Click **Generate Report**. The Constraint Violation Report is displayed on the monitor.
- g. The page will stay the same with the addition of a **Constraints** tab which shows the **Constraint Violations: By Constraint** report. Click the magnifying glass to drill down to the **Constraint Violations: By Filesystem** report. Click the magnifying glass again and the **Largest Files: By Filesystem** report opens. This report, the **Constraint Violation Report**, will be used to create an Archive/Backup job.

5. Run Archive/Backup on selected files in the report

Archive and backup files are automatically sent to the Tivoli Storage Manager server and are stored on that machine. Files are put into storage groups that are controlled through a Tivoli Storage Manager policy that the Tivoli Storage Manager server administrator usually creates.

- a. Select the files in the **Constraint Violation Report** that you want to archive or backup.
- b. Right-click on the selected files and select **Create a new archive\backup job**. The **Create New Archive/Backup Job** window opens.

- c. In the **Options** tab, choose **Archive**. In this scenario the purpose is to archive and delete files that violate the constraints, so select **Delete After Successful Archival**. If, for some reason, you did **not** want to delete the files after they have been archived, do not select **Delete After Successful Archival**. If the archive is not successful, the files will not be deleted.
- d. The files you have selected for archive/backup are shown in the **Files** tab.
- e. In the **When to Run** tab select **Run Now**. In the **How to handle time zones** section, select **Local time in each time zone**.
- f. In the **Alert** tab, in the **Triggering-Condition** area, the only triggering condition is **File Archive/Backup Failed**. Do not select anything in the **Triggered Actions** area to accept the default (a message sent to the error log).
- g. Click the **Save** icon. Enter the name **Archive Log** and click **OK**. The job log is saved at **Data Manager > Monitoring > Policy Management > Archive/Backup > TPCUser.Archive Log**.
- h. A notice telling you that the job has been submitted appears. Click **OK**.
- i. Expand the job name to see the status of this particular job. You can judge the status by the color coding. When the job has finished, click on the date and time to view the job log file.

Setting an archive/backup from the constraint

You can call archive backup when you set the constraint. However, if you set the delete option, it will automatically archive and delete **all** files that match the constraint criteria, which you probably do not want to do. At the very least you should not set archive/backup in the constraint the first time you run it.

To call for an archive/backup within a constraint, select **Archive/Backup** in the **Triggered Actions** area of the **Alert** tab in the **Create Constraint** window. Click **Define**. An **Archive/Backup Options** pop-up opens. Select **Delete After Successful Archival**. Go to the next tab and continue defining your constraint.

Related concepts:

“Requesting an archive or backup” on page 478

Request an IBM Tivoli Storage Manager archive and backup of the largest violating files identified by a constraint. Tivoli Storage Manager protects your data from hardware failures and other errors by storing backup and archive copies of data on auxiliary storage.

Related tasks:

Create and schedule a probe to job to gather information about your storage resources. You can define any number of probes to gather information about different storage resources at different times.

“Creating a file constraint” on page 472

Learn how to create a constraint that defines the acceptable and unacceptable file types, file sizes, and file owners for a computer or a set of computers in your environment.

“Defining an archive or backup in a constraint” on page 478

Learn how to request an IBM Tivoli Storage Manager archive and backup of the largest violating files identified by a constraint. Request a Tivoli Storage Manager archive and backup on the alert page of a constraint definition.

“Creating scans” on page 348

Create and schedule a scan to gather usage information about your storage resources. You can specify which file systems, computers, clusters, directories, databases, and other storage resources that you want to scan. You can define any number of scans to gather information about different storage resources at different times.

Create a profile with a filter

This scenario scans storage on a selected drive looking for the 100 largest media files, and summarizes space used by filesystem or directory and by owner.

There are a number of media files on computer1 that you suspect are taking up space that could be used for other purposes. You would like to search C:\ drive file systems and directories for the 100 largest files and create a report you can use to decide what action to take (contact the owner, archive and delete the files, and so forth). You will also publish this report to the web, where other people with permission levels greater to or equal to yours (TPCUser) can access it.

With this scenario, you perform the following tasks:

1. Create a profile to look for the largest media files
2. Create a filter within the profile
3. Create a new scan schedule using the profile
4. Create and run a batch report using the information gathered from the scan schedule
5. Save this report as an HTML file

For this scenario, complete the following steps:

1. **Create a new profile**
 - a. Expand **Data Manager > Monitoring**, right-click **Profiles** and select **Create Profile**.
 - b. The **Create Profiles** window opens. Enter a description for the profile.
 - c. In the **Statistics** tab, do the following:

- 1) Under **Summarize space usage by**, select **filesystem** or **directory** and **owner**.
 - 2) Under **Accumulate History**, select **Per Scan** and type **10** as the number of days to keep.
 - 3) Under **Gather statistics by length of time since**, select **creation**.
 - 4) Under **Gather the information on the**, select **largest files** and type **100** in the text field.
- d. In the **File Filters** tab, create the filter by doing the following:
- 1) Highlight **(All Files Selected)** and click **New Condition**. The **Create Condition** window opens.
 - 2) Select **NAME** and **Matches any of** from the pull-down lists.
 - 3) Select **In any Directory**.
 - 4) In the **match** field, enter the types of files you are looking for in either a comma-separated list or by pressing return after each entry. As you press return, the file type will be listed in the box underneath the text field. For this scenario the file types are ***.avi**, ***.au**, ***.mpeg3**, and ***.gif**. Click **OK**. The **Create Profile** window re-opens, reflecting your choices.
- e. Click the **Save** icon. Name the profile **Media Files Profile** and click **OK**. The profile will be saved as **Data Manager > Monitoring > Profiles > TPCUser.Media Files Profile**.
2. **Create the scan**
- a. Expand **Data Manager > Monitoring**, right-click **Scans** and select **Create Scan**.
 - b. The **Create Scans** window opens. Type a description of the scan.
 - c. In the **Filesystems** tab, select **C:/** as the file system to scan.
 - d. Do not select anything in the **Directory Groups** tab.
 - e. In the **Profiles** tab, select **TPCUser.Media Files Profile** from Available Profiles and move it to **Profiles to apply to Filesystems**.
 - f. In the **When to run** tab, choose **Run Now** and select **Local time in each time zone**.
 - g. In the **Alerts** tab, the only **Triggering Condition** is **Scan Fails**. In the **Triggered Actions** area, select nothing to accept the default. If the job fails, a notification will be sent to the error log automatically.
 - h. Click the **Save** icon. Name the scan **Media Files Scan** and click **OK**. The scan will be saved as **Data Manager > Monitoring > Scans > TPCUser.Media Files Scan** and the job will begin running immediately. This scan could take approximately 20 minutes to complete.
3. **Create the batch schedule**
- Once you have run a scan with the new profile, the data is in the database but you have to go get it with a custom-designed report or batch schedule.
- a. Expand **IBM Tivoli Storage Productivity Center > My Reports**, right-click **Batch Reports** and select **Create Batch Report**.
 - b. The **Create Batch Report** window opens. Enter a description for the report.
 - c. In the **Available** column in the **Report** tab, select **Usage > Files > Largest Files > by Computer** and move that to **Current Selections**.
 - d. In the **Selection** tab, select **TPCUser.Media Files Profile** from the available profiles. By default, all columns are included in **Included Columns**. If you do not want a column in your report, select it and move it to **Available Columns**.
 - e. In the **Options** tab, make the following selections:

- Under **Agent Computer Specification**, select **computer1**. This is the computer where the report will be run and the data stored. In most cases this is the Agent running on the Tivoli Storage Productivity Center server. If **computer1** is a Data Agent computer, you must accept the default report-destination path. If **computer1** is a V4.2 Storage Resource Agent or the Tivoli Storage Productivity Center server, you can accept the default path or you can specify a different path in the **Report destination** field. The default destination path varies depending on whether the computer is a Storage Resource Agent or the server.
 - Under **Report Type Specification**, select **HTML File**.
 - Select nothing under **Script**.
 - Under **Output File Specification**, enter the mask that will determine the output file name. It is recommended that you name the report something other than the default so that it can be easily identified by you and others. **{Report name}.{Report run date}** is recommended.
- f. In the **When to run** tab, choose **Run Now** and select **Local time in each time zone**.
 - g. In the **Alerts** tab, the only **Triggering Condition** is **Report Failed**. In the **Triggered Actions** area, select nothing to accept the default. If the job fails, a notification will be sent to the error log automatically.
 - h. Click the **Save** icon. Name the batch report **Largest Media Files** and click **OK**. The batch report criteria will be saved under **IBM Tivoli Storage Productivity Center > Reports > Batch Reports > TPCUser.Largest Media Files**. The job will begin running immediately. The job number, date, and time will be listed under **TPCUser.Largest Media Files**.
4. Batch reports can be saved to any computer running Tivoli Storage Productivity Center. Reports are saved to a default location for Data Agents. If the computer is a V4.2 Storage Resource Agent or the Tivoli Storage Productivity Center server, you can accept the default path or you can specify a different path when you select batch report options.

Related tasks:

“Creating a profile” on page 357

Create a profile for use within a scan.

“Creating scans” on page 348

Create and schedule a scan to gather usage information about your storage resources. You can specify which file systems, computers, clusters, directories, databases, and other storage resources that you want to scan. You can define any number of scans to gather information about different storage resources at different times.

“Creating batch reports” on page 1082

Create a batch report.

“Selecting batch report options” on page 1083

Define the agent computer that you want to run the batch report on and specify the format of the file to be saved.

Creating a performance threshold within an alert

You can monitor the performance of your enterprise by creating alerts with performance thresholds for storage subsystems and SAN switches. By defining alerts that are triggered by performance thresholds, you can get timely information about performance issues in your enterprise.

To properly monitor the performance of your storage subsystem you will need to create the appropriate data collection jobs and alert definitions. The performance monitors collect data from the devices they are monitoring and at each sample interval the data is compared to the performance thresholds you have set. If the thresholds are exceeded, a notification is generated and the actions you defined in an alert are performed.

Note: The term Alert can be used one of three ways. An IBM Tivoli Storage Productivity Center *Alert definition* is defined at **[Data | Disk | Tape] Manager > Alerting > [Type of Alert]**. Within the Alert definition there is an *Alert tab*. Within the Alert tab there is a *Triggering Condition* area which gives the condition that will result in an *Alert message*. Most Triggering Condition areas in the Alert tab have only one Triggering Condition, such as **Probe Failed**. However, in Disk Manager some of the triggering conditions have thresholds, which are condition boundaries you set. For example, **Total I/O Rate Threshold** requires two upper-threshold and two lower-threshold boundaries or values. Only if these boundaries are matched or exceeded will an Alert message be generated and sent by the method you chose in *Triggered Actions*.

In this scenario, you are defining a performance threshold alert to monitor a disk subsystem (**DS8000-21-7-1300271-IBM**), for the **Total I/O Rate Threshold** condition, and generating, viewing, and printing the results.

To complete this scenario, you need to perform the following tasks:

1. Create a storage subsystem performance monitor
2. Create a storage subsystem alert definition
3. Generate and view a report showing the collected storage subsystem data

Note: You must run probes against storage subsystems prior to successful performance monitoring of those subsystems.

1. Create a subsystem performance monitor

- a. Expand **Disk Manager > Monitoring**, right-click **Subsystem Performance Monitor** and select **Create Subsystem Performance Monitor**. The **Create Storage Subsystem Monitor** page opens to the **Storage Subsystem** tab.
- b. Select the disk you want to monitor from the **Available subsystems** column and move it to the **Selected subsystems** column. Although we do not do it here, you can select more than one subsystem at a time.
- c. Click the **Sampling and Scheduling** tab. In the **Sampling** area, set the interval for gathering data to **1 hour**. Select **Continuing gathering data for** and select a value of **1 month**. In the **Scheduling** area, select **Begin immediately**.

Note: You do not want to sample too frequently as it increases the size of the database repository significantly. Monitors should be set to run for long periods, such as weeks or indefinitely.

- d. Click the **Alert** tab. **Monitor Failed** is the only **Triggering Condition** available. In **Triggered Actions**, select nothing to accept the default. If the job fails, a message will be sent to the log file automatically.
 - e. Click the **Save** icon. Name the monitor **SS Monitor**. It will be listed at **Disk Manager > Monitoring > Subsystem Performance Monitors > TPCUser.SS Monitor**. The job will begin running immediately.
- 2. Create a storage subsystem performance alert**

- a. Expand **Disk Manager > Alerting**, right-click **Storage Subsystem Alerts** and select **Create Storage Subsystem Alert**. The **Create Storage Subsystem Alert** page opens.
- b. Click the **Alert** tab. Select **Total IO Rate Threshold** from the **Condition** drop down list in the **Triggering-Condition** area. Text fields will open for **Critical Stress**, **Warning Stress**, **Warning Idle**, and **Critical Idle**.

Note: The threshold values given in this scenario are examples and are **not** recommended values. They are for the purpose of illustration only. Your values will undoubtedly be different. Performance behavior varies tremendously between different devices and even different applications for different devices. We recommend monitoring your performance for several weeks and use this historical data to determine reasonable values for each threshold.

- In the **Critical Stress** field, type **3000** as the upper-threshold boundary for critical stress.
 - In the **Warning Stress** field, type **2200** as the upper-threshold boundary for warning stress.
 - Leave the **Warning Idle** field, the lower-threshold boundary for warning idle, blank.
 - Leave the **Critical Idle** field, the lower-threshold boundary for critical idle, blank.
- c. In the **Triggered-Actions** area, select **Email** to send an e-mail to a mail address you specify.
 - 1) When you select **Email** the **Email Recipients** text box becomes active.
 - 2) Click **Add** and type an e-mail address in the text box. You can type multiple e-mail addresses.
 - 3) Click **Edit e-mail** to customize the e-mail message. Note that errors sent to the error log are very generic, so you might want to be more descriptive in the text of the e-mail.
 - d. In the **Storage Subsystems** tab, select **Storage Subsystems > DS8000-21-7-1300271-IBM** in the **Available** column and move it to the **Current Selections** column.
 - e. To save the alert, click the **Save** icon. Name the alert **SS Alert**. It will be listed at **Disk Manager > Alerting > Storage Subsystem Alerts > TPCUser.SS Alert**. The conditions defined in the alert will be checked when the next probe runs against the subsystem.
3. **Generate and view a report**
- a. Expand **Disk Manager > Reporting > Storage Subsystem Performance**, and click **By Storage Subsystem**. The **Storage Subsystem Performance: By Storage Subsystem** window opens.
 - b. In the **Selection** tab, all performance metrics fields are selected by default. To remove a field from the report, click on the metric name in **Included Columns** and move it to **Available Columns**. In the **Report Filter Specifications** area enter the number of storage subsystems upon which you want a report in the **Return maximum of** text field.
 - c. Click the **Generate Report** button. A **Storage Subsystem** tab will open containing the report. There will be one line in the report for each storage subsystem.

- d. To save the report definition, click the **Save** icon. The **Save As** window opens. Name the report **SS Report** and click **OK**. The report will be saved at **IBM Tivoli Storage Productivity Center > My Reports > TPCUser's Reports > TPCUser.SS Report**.
- e. Click the **Print** icon to print the current page on the local machine. You can only print one screen at a time.

Note: You might want to monitor the **Total IO Rate Threshold** condition for the storage subsystem by using constraints instead of thresholds. The Triggering Condition for a constraint would be **Violating Files Consume More Than**. This will alert you if any file goes over the condition value you set. In the **Value** field, type **2200**, which is the value of Warning Stress. In **Value Units**, select **Megabytes** from the pull-down list. See “Archive and delete files” on page 144 for more information on creating constraints.

You can use the preceding steps, with some minor changes, to create performance monitors and alerts for certain types of switches that have been discovered by Tivoli Storage Productivity Center. Switch performance monitors, for example, are created in the Fabric Manager node:

- To create a switch performance monitor, expand **Fabric Manager > Monitoring > Switch Performance Monitors**
- To create a switch performance alert, expand **Fabric Manager > Alerting > Switch Performance Alerts**.

Related tasks:

“Creating storage subsystem performance monitor” on page 380

Create a subsystem performance monitor to gather performance data for storage systems.

“Creating storage system alerts” on page 394

You can use storage systems alerts to monitor systems for changes in configuration or status. When the condition is detected during a probe, an alert is generated. These alerts can be applied to storage subsystem groups and storage subsystems.

Related reference:

“Disk Manager reports” on page 1010

Use Disk Manager reports to view the relationships among the components of a storage subsystem and the storage capacity for a computer, filesystem, storage subsystem, volume, Array Sites, Ranks, and disk.

Determine application performance problems

This scenario provides a method for finding out why an application has stopped performing as expected.

A previously normal application has stopped performing well. You must find out what is impacting the application so that you can take steps to correct the situation. You suspect a storage system problem.

In this scenario, you perform the following tasks:

- Probe Storage Resource agents and Data agents
- Probe the Storage Systems and start the Performance Monitor running
- Create a **Storage Subsystem: By Filesystem/Logical Volume** report
- Create a **Storage Subsystem Performance: By Volume** report
- Create a **Storage Subsystem Performance: By Array** report

Tip: Ordinarily, you run probes and performance monitors on both storage systems and switches, because the problem might be in either place. However, in this scenario you are only gathering information about storage systems.

Prerequisites:

- The Storage Resource agents and Data agents must be installed on the monitored computers before you can complete the tasks in this scenario. These are usually installed as part of the IBM Tivoli Storage Productivity Center installation process.
- Storage Resource agents, Data agents, and Arrays must have already been probed.
- Storage systems such as IBM System Storage DS8000 Storage Manager, IBM System Storage SAN Volume Controller, and the XIV systems must be connected through native interfaces. For other storage systems, CIM object manager (CIMOM) connections must be added and discovered.

Substitutable values that are used in this scenario:

- Device path = M:\ (from application owner or server administrator)
- Computer = ODCCL163.odcclass.ibm.com (from Filesystem/Logical Volume report)
- Volume name = testvol-100 (id.1000)(from Filesystem/Logical Volume report)
- Storage system name = DS6000-1750-13AB44A-IBM (from Filesystem/Logical Volume report)
- Array = 1750.13AB24A-1 and A-2 (from the By Volume report, drill down to By Array report)

To track down application performance problems, collect information by running probes, performance monitors, and reports. Then use that information to determine actual performance and use values.

To perform this scenario, complete the following steps:

1. When the problem is reported, get computer information, device path information, and the application name from the application owner or the server administrator.
2. Probe the Storage Resource agents and Data agents.
 - a. Expand **IBM Tivoli Storage Productivity Center > Monitoring**. Right-click **Probes** and select **Create Probes**.
 - b. In the description field, type Probe for agents.
 - c. In the **What to Probe** page, expand 'Computers' in the **Available** box, select All Computers, and move that to **Current Selections**. This includes all Storage Resource agents and Data agents in the probe.
 - d. Click the **When to Run** tab and select **Run Repeatedly**, and set a regular time the probe is run. The following settings are up data collection for 2:00 AM every morning.
 - 1) Set the day in **Beginning at** a day ahead of the current day. If the day is February 21st, 2008, enter February 22, 2008, at 2:00 AM.
 - 2) Select **Repeat Every** and set **23 Hour(s)** to specify how often the probe is run. This setting allows time for the probe to shut down and start again.
In the **How to handle time zones** area, select **Use the timezone that the server runs in**, which uses the time zone where the Data server resides.
 - e. On the **Alert** page, **Probe Failed** is the only triggering condition that triggers an alert. In the **Triggered Actions** area, select **Windows Event Log** and set the **Event Type** to **Warning**.

- f. Click the **Save** icon. Type `AgentsProbe_1` as the probe name and click the **Save** button. The probe is listed in the navigation tree as **IBM Tivoli Storage Productivity Center > Monitoring > Probes > Administrator.AgentsProbe_1**.
 - g. To begin collecting data immediately, expand **IBM Tivoli Storage Productivity Center > Monitoring > Probes**, right-click **Administrator.AgentsProbe_1** and select **Run Now**. The status line for the probe is listed under **Administrator.AgentsProbe_1** by date and time.
A probe of the agents typically takes under a minute.
3. **Probe the Storage Systems.** Creating the Storage System probe is similar to creating the probe for the Storage Resource agents and Data Agents.
 - a. Expand **IBM Tivoli Storage Productivity Center > Monitoring**, right-click **Probes** and select **Create Probe**. In the **Description** field, type Probe for Storage Systems.
 - b. In the **What to Probe** tab Available area, expand **Storage Subsystems**. Select **All Storage Subsystems** and move it to Current Selections.
 - c. In the **When to Run** page, select **Run Repeatedly** beginning a day later than the current day at 3:00 AM.
 - d. Click the **Save** icon. Type `StorageSystemsProbe_1` as the probe name and click the **Save** button. The listing for the probe is displayed in the navigation tree as **IBM Tivoli Storage Productivity Center > Monitoring > Probes > Administrator.StorageSubsystemProbe_1**.
 - e. To collect initial data, right-click **Administrator.StorageSubsystemProbe_1** and select **Run Now**. Depending on the number and size of the storage systems to be probed, this probe might take up to 15 minutes.
 4. **Begin running the storage system Performance Manager.** If you have a current Performance Monitor running and you have added another storage system, you must start a new Performance Monitor.
 - a. Expand **Disk Manager > Monitoring**, right-click **Subsystem Performance Monitor** and select **Create Performance Monitor**. In the **Description** field, type System performance monitor.
 - b. Click the **Storage Subsystems** tab. All storage systems that have had probes created and completed are listed under **Available subsystems**. Select all the available systems and move them to **Selected subsystems**.
 - c. Click the **Sampling and Scheduling** tab. In the Sampling area specify how frequently data is to be gathered and the length of the sampling window.
 - 1) For the Interval Length, type 5 in the minutes field.
 - 2) For Duration, select **Continue indefinitely**.
 - 3) Select **Begin Immediately** in the **Scheduling** area.
 - d. Click the **Alert** tab.
 - 1) In the **Condition** area, **Monitor Failed** is the only triggering condition.
 - 2) In the **Triggered Actions** area, select **Windows Event Log** with a **Warning** event type.
 - e. Click the **Save** icon and enter `SSPerformanceMonitor_1` as the performance monitor name. Click **OK**. The name of the storage system performance monitor is displayed at **Disk Manager > Monitoring > Subsystem Performance Monitor > Administrator.SSPerformanceMonitor_1**.

Tip: Setting performance alerts is not necessary for this scenario, but at this point you can review the historical performance data for your environment. Then you can define performance alerts with values that you consider out

of the ordinary for your environment. You can set performance alerts for both storage systems and switches. After a performance alert is defined, future deviations will generate an alert and create an entry in the Performance Manager Constraint Violation report.

5. Gather information for at least two cycles (in this case, gather the information for at least 10 minutes). When information has been gathered, run the following reports to collect the data you can use to check performance.
 - **Disk Manager > Reporting > Storage Subsystems > Computer Views > By Filesystem/Logical Volume**
 - **Disk Manager > Reporting > Storage Subsystem Performance > By Volume**
 - **Disk Manager > Reporting > Storage Subsystem Performance > By Array**

The data from the reports is saved by date and time, but you might want to print copies of the reports for easier comparison.

- a. The **Storage Subsystem: By Filesystem/Logical Volume** report identifies the backend storage volumes associated with the file system. Variable values that are gathered from this report include values for computer, storage subsystem, and volume name.
 - 1) Run the report by expanding **Disk Manager > Reporting > Storage Subsystems > Computer Views** and click **By Filesystem/Logical Volume**.
 - 2) Click the **Selection** tab, and in the **Report Filter Specifications** area, select **Volumes to Relate Filesystems/Logical Volumes to** in the list.
 - 3) Click the **Selection** button, clear the listed computers, and select your Device Path (M:\). Click **OK** to return to the **Selection** tab. When you run the report, the information is limited to your device path.
 - 4) By default all columns are listed as **Included Columns**. If there are columns you do not want in the report, select them and move them to **Available Columns**. Do **not** to move the "volume name" columns to **Available Columns**.
 - 5) Click **Generate Report**.
- b. The **Storage Subsystem Performance: By Volume** report shows you the actual performance metrics that are associated with the volumes the problem file system resides on.
 - 1) Expand **Disk Manager > Reporting > Storage subsystem Performance** and click **By Volume**. By default all columns are listed as **Included Columns**. Do not move any of them to **Available Columns**.
 - 2) Click the **Selection** button. Click **Deselect All**, then find your system name (DS6000-1750-13AB24A-IBM) and component (the Volume Name - testvol-1000 (ID.1000)), and select that line. The information in the report is limited to that system and volume.
 - 3) Click **OK**. Click **Generate Report**.
- c. The **Storage Subsystem Performance: By Array** report shows the other volumes on the same array as the problem volume. It indicates whether the problem is specific to that one volume or if all of the volumes on the same array have a similar problem.

Note: Arrays are only supported on IBM TotalStorage Enterprise Storage Server, DS8000, and IBM System Storage DS6000systems.

- 1) Expand **Disk Manager > Reporting > Storage subsystem Performance** and click **By Array**.

- 2) In the **Report Filter Specifications** area, select **Display latest performance data (by sample)**.
 - 3) Click the Selection button. Click **Deselect All** then find your arrays (Component) (1750.13AB45A-1 and A-2) and select those lines. The information in the report is limited to those arrays.
 - 4) By default all columns are listed as **Included Columns**. Do not move any of them to **Available Columns**.
 - 5) Click **Generate Report**.
6. Parts of the information that you use to determine the problem is in all of the reports. Look for the following things:
- Look at the I/O rate and the response time together for a complete picture of the performance. Ideally, you want a high I/O rate and low response time.
 - If the I/O rate is high but the response time is slowing over time, look at the cache hits to see how well cache is performing and, therefore, how often the I/O must go to disk.
 - If the I/O rate is low, look at the data rate. When there is a large number of I/O requests with high transfer sizes, the data rates become more important than I/O rates. In this case, look at the data rates and transfer sizes together.
 - Look at all the volumes in the same array to determine the I/O rate and response times. To determine these values, drill up from a selected volume in the 'By Volume' report to view the arrays that the volume is a part of. Then drill down from the array to get a filtered 'By Volume' report of just the volumes on that array. Now compare the performance metrics against all the volumes in the same array. If all of them show the same performance problem, the performance bottleneck is the array. If only one volume has a performance problem, the performance bottleneck is somewhere else.
7. In this scenario, based on the I/O rates and the response times for the array over a time period, you determine that the array is being saturated with I/O and I/O should be off-loaded to other storage to improve performance.

Tip: You can also use Tivoli Storage Productivity Center to determine and project when more storage space is needed by monitoring I/O rates and response times over a time period.

Identifying performance hot spots

This scenario uses the Storage Optimizer to analyze storage systems to determine whether there are performance hot spots. This scenario also illustrates how to use the Storage Optimizer to get recommendations for improving storage system performance.

You want to analyze your two IBM System Storage DS8000 Storage Manager storage systems to determine whether there are performance hot spots. You want to identify the hot spots and get recommendations on how to improve storage system performance.

Prerequisites for using Storage Optimizer

- IBM Tivoli Storage Productivity Center Advanced Edition license
- One or more of these systems:
 - System Storage DS8000
 - System Storage DS6000
 - System Storage DS5000
 - System Storage DS4000
 - TotalStorage Enterprise Storage Server
 - SAN Volume Controller
 - Storwize V7000
- Performance monitoring data gathered for at least one week in advance of using Storage Optimizer. Providing a longer time interval for data collection increases the accuracy of the analysis and recommendations.

Monitoring the performance of your DS8000 systems

At least one week in advance, start performance monitoring for the DS8000 storage systems.

1. Use the Configure Devices wizard to enter connection information for the native interfaces of your DS8000 systems. For systems that connect through CIM object manager (CIMOM) connections, run a discovery for storage system CIMOMs.
2. Create a probe. See “Creating probes” on page 340.
3. Create a storage system performance monitor and allow it run for at least one week. See “Creating storage subsystem performance monitor” on page 380.

To identify performance hot spots, complete the following steps:

Part 1: Creating an analysis report that includes both DS8000 storage systems.

1. At least one week in advance, run a storage system performance monitor to collect performance data for both DS8000 systems.
2. Navigate to **IBM Tivoli Storage Productivity Center > Analytics**.
3. Right-click **Storage Optimizer** and select **Create Analysis**. The Create Analysis panel allows you to specify the storage systems that you want to analyze.
4. Under Create Analysis, enter "Analyze DS8000 systems" in the Description field.
5. Click **Add** in the Select Storage pane. The Optimizer Selection panel opens. This panel provides a topology view of the current storage network.
6. Select both of your DS8000 storage systems.

7. Click **OK** to return to the Storage Optimizer Create Analysis panel with the DS8000 systems displayed in the Select Storage pane.
8. Set the Performance Time Interval to start one week before the current date.
9. For How often to run, select **Run Now**.
10. Choose **File > Save** to save and submit the analysis report job.
11. When prompted to enter a name for the report job, enter "Analyze DS8000 systems" and click **OK**.
12. View the analysis report job status for "Analyze DS8000 systems" under the **Storage Optimizer** node in the navigation tree.

Part 2: Viewing the analysis report and identify hot spots

When the analysis report job "Analyze DS8000 systems" is complete (status is green), select it to view the analysis report for your DS8000 systems. The heat maps display color-coded cells that represent the projected utilization of both DS8000 systems, as measured against the required performance threshold of 80%. Each cell represents a storage pool.

1. From the list of components for **Heat Map based on**, choose Hard Disk to update the heat maps to display the analysis data for that component.
2. Move the performance threshold slider to see its affect on the heat maps.
3. Click the **Performance Tables** tab to display a tabular view of the data, if wanted.
4. In the Hard Disk heat map for one of your DS8000 systems, you notice a red cell, or "hot spot". Move your cursor over that cell to display the details for the storage pool named Pool 1. The details for Pool 1 indicate that it is exceeding the required performance threshold of 80%.

A green cell displays for Pool 2. The green color indicates that Pool 2 is performing at less than or equal to 25% of the established performance threshold.

You think that you might be able to improve the performance of Pool 1 by moving some of its volumes to Pool 2. You know that Pool 2 has some amount of available capacity.

Part 3: Creating an optimization report that includes recommendations on how to improve the performance of Pool 1.

1. In the analysis report, select the red cell which represents Pool 1.
2. Click >> next to **Source Entities** to move Pool 1 into the list of source entities.
3. Select the green cell which represents Pool 2.
4. Click >> next to **Target Entities** to move Pool 2 into the list of target entities.
5. Choose **File > Save** to save and submit the optimization report job.
6. When prompted to enter a name for the optimization report job, enter "Optimize DS8000 systems" and click **OK**.
7. Under **View Previously Run Optimization Reports**, click **Refresh Job Status** to update the report job status.

Part 4: Viewing the optimization report and recommendations.

When the optimization report job "Optimize DS8000 systems" is complete (job status is "Success"), click  to display the optimization report. The report includes a recommendation for how to improve the performance of Pool 1.

The heat maps in the optimization report display the performance utilization of Pool 1 and Pool 2 before and after implementing the recommendation. The heat maps show you that the red cell representing Pool 1 changes to green after implementing the recommendation. The heat maps also show you that the green cell representing Pool 2 changes to yellow after implementing the recommendation. This means that Pool 2 will be still be performing at less than or equal to 75% of the performance threshold after you implement the recommendation.

To view the effects on the before and after heat maps of implementing only some of the recommendations:

- Remove the check mark next to **Select all recommendations** and select a subset of the recommendations from the recommendations table.

To print the optimization report:

- Click the Print button in the optimization report.

The printed report includes additional information such as SVC sample scripts to help you implement the recommendations using the SAN Volume Controller command-line interface.

Related information:

See "Configuring storage subsystems" on page 310 for details of how to use the Configure Devices wizard to enter connection information for any of the storage systems that connect to Tivoli Storage Productivity Center using native interfaces. For more information, see "Discover storage subsystem, tape library, and fabric information with CIM agents" on page 334.

Retiring underutilized storage systems

This scenario illustrates how you can use the Storage Optimizer to create recommendations about retiring underutilized storage systems and migrating their data to other systems in your data center.

Your data center has seven IBM System Storage DS8000 Storage Manager storage systems in use. Using various IBM Tivoli Storage Productivity Center capacity reports, you determine that two of the systems are underutilized. You want to create a report that provides recommendations to help guide you in retiring the underutilized systems and migrating the data into your remaining five systems.

Prerequisites for using Storage Optimizer

- One or more of these supported systems:
 - System Storage DS8000
 - System Storage DS6000
 - System Storage DS5000
 - System Storage DS4000
 - TotalStorage Enterprise Storage Server
 - SAN Volume Controller
 - Storwize V7000

- Performance monitoring data gathered for at least one week in advance of using Storage Optimizer. Providing a longer time interval for data collection increases the accuracy of the analysis and recommendations.

Monitoring the performance of your DS8000 systems

At least one week in advance, start performance monitoring for the DS8000 storage systems.

1. Use the Configure Devices wizard to enter connection information for the native interfaces of your DS8000 systems. For systems that connect through CIM object manager (CIMOM) connections, run a discovery for storage system CIMOMs.
2. Create a probe. See “Creating probes” on page 340.
3. Create a storage system performance monitor and allow it run for at least one week. See “Creating storage subsystem performance monitor” on page 380.

To perform this scenario, complete the following steps:

Part 1: Creating an analysis report for the seven DS8000 storage systems in your data center.

1. At least one week in advance, run a storage system performance monitor to collect performance data for all DS8000 systems.
2. Navigate to **IBM Tivoli Storage Productivity Center > Analytics**.
3. Right-click **Storage Optimizer** and select **Create Analysis**. The Create Analysis panel allows you to specify the storage systems that you want to analyze.
4. Under Create Analysis, enter “Analyze DS8000 systems” in the Description field.
5. Click **Add** in the Select Storage pane. The Optimizer Selection panel opens. This panel provides a topology view of the current storage network.
6. Select all your DS8000 storage systems.
7. Click **OK** to return to the Storage Optimizer Create Analysis panel with the DS8000 systems displayed in the Select Storage pane.
8. Set the Performance Time Interval to start one week before the current date.
9. For How often to run, select **Run Now**.
10. Choose **File > Save** to save and submit the analysis report job.
11. When prompted to enter a name for the report job, enter “Analyze DS8000 systems” and click **OK**.
12. View the analysis report job status for “Analyze DS8000 systems” under the Storage Optimizer node in the navigation tree.

Part 2: Viewing the analysis report.

When the analysis report job “Analyze DS8000 systems” is complete (status is green), select it to view the analysis report for your DS8000 systems.

- For **Heat Map based on**, choose the **Space** option to view the heat maps in the analysis report based on disk space utilization. The heat maps confirm that most pools in systems 6 and 7 are performing at less than 75% of capacity.

Part 3: Creating an optimization report that includes recommendations on how to retire the underutilized systems 6 and 7 and migrate the data to your remaining five systems.

1. In the heat maps, select all pools for storage systems 6 and 7 using the **Select all pools for storage subsystem** check box.
2. Click >> next to **Source Entities** to move systems 6 and 7 into the list of source entities.
3. Click **Make retirement recommendations for the selected entity**.
4. In the heat maps, select all pools for storage systems 1 through 5 using the **Select all pools for storage subsystem** check box.
5. Click >> next to **Target Entities** to move systems 1 through 5 into the list of target entities.
6. Choose **File > Save** to save and submit the optimization report job.
7. When prompted to enter a name for the report job, enter "Retire DS8K" and click **OK**.
8. Under **View Previously Run Optimization Reports**, click **Refresh Job Status** to update the report job status.

Part 4: Viewing the optimization report and recommendations.

When the optimization report job "Retire DS8K" is complete (job status is

"Success"), click  to display the optimization report. If it is possible to retire systems 6 and 7, the report will include recommendations for retiring systems 6 and 7 and migrating the data into systems 1 through 5.

- For **Heat Map based on**, choose **Space** to view the before and after optimization heat maps based on disk space utilization.
- To view the effects on the before and after heat maps of implementing only some of the recommendations, remove the check mark next to **Select all recommendations** and select a subset of the recommendations from the recommendations table.

The before and after heat maps illustrate the effects of retiring systems 6 and 7 and migrating the data into systems 1 through 5. The heat maps also confirm that even after retiring systems 6 and 7, the remaining systems will still perform within the limits of the required performance threshold.

To print the optimization report:

- Click the Print button in the optimization report.

The printed report includes additional information such as SVC sample scripts to help you implement the recommendations using the SAN Volume Controller command-line interface.

Related information:

See "Configuring storage subsystems" on page 310 for details of how to use the Configure Devices wizard to enter connection information for any of the storage systems that connect to Tivoli Storage Productivity Center using native interfaces. For more information, see "Discover storage subsystem, tape library, and fabric information with CIM agents" on page 334.

Tivoli Storage Productivity Center for Replication scenarios

These scenarios illustrate how to perform specific replication tasks using IBM Tivoli Storage Productivity Center for Replication.

The provided scenarios set out situations that can be solved using IBM Tivoli Storage Productivity Center. When using these scenarios you should remember the following:

- The scenarios are intended to be step-by-step instructions that you follow to complete a specific task. Each scenario contains multiple steps that must be followed in the order given.
- Specific values such as user names, passwords, and IP Address are given in the scenarios only for illustration purposes. You must replace them with values appropriate for your environment.
- The scenarios do not provide in-depth conceptual information about the tasks.

Identifying and investigating a suspended Metro Mirror session

IBM Tivoli Storage Productivity Center and IBM Tivoli Storage Productivity Center for Replication work together to help meet your storage management needs and automate your replication management tasks. This scenario shows you how to use IBM Tivoli Storage Productivity Center to view and investigate a suspended Metro Mirror between two IBM DS8000 storage systems that was detected by IBM Tivoli Storage Productivity Center for Replication.

You want to use IBM Tivoli Storage Productivity Center to analyze alerts generated by events detected by IBM Tivoli Storage Productivity Center for Replication. You want to open a page in IBM Tivoli Storage Productivity Center for Replication from the IBM Tivoli Storage Productivity Center user interface.

Prerequisites:

- Two DS8000 storage systems.
- Use IBM Tivoli Storage Productivity Center for Replication to mirror a database application between the DS8000 storage systems.
- Set up IBM Tivoli Storage Productivity Center to monitor DS8000 storage systems. The general steps are as follows:
 1. Run a CIMOM discovery to identify the storage systems managed by CIMOMs in your environment. See information about discovering storage resources in the *IBM Tivoli Storage Productivity Center for Replication for System z User's Guide* for more information about how to discover storage systems.
 2. Create and schedule a probe to run against the storage systems. See information about collecting storage statistics (probes) in the *IBM Tivoli Storage Productivity Center for Replication for System z User's Guide* for more information about how to define probes.

IBM Tivoli Storage Productivity Center includes a predefined set of alerts that correspond to events detected by IBM Tivoli Storage Productivity Center for Replication. In this scenario, IBM Tivoli Storage Productivity Center for Replication detects that a Metro Mirror session just went into a suspended state. That event is communicated to IBM Tivoli Storage Productivity Center and recorded in the alert log. Use the alert log to view information about that alert and start the IBM Tivoli Storage Productivity Center for Replication user interface. Use IBM Tivoli Storage Productivity Center for Replication to determine that the paths between your DS8000 devices in a Metro Mirror session were removed and resolve the problem.

The following tasks are described in this scenario:

1. IBM Tivoli Storage Productivity Center: Set up notification methods for replication alerts.
2. IBM Tivoli Storage Productivity Center: Use the alert log to view information about a suspended Metro Mirror session that was detected by IBM Tivoli Storage Productivity Center for Replication.
3. IBM Tivoli Storage Productivity Center for Replication: Start IBM Tivoli Storage Productivity Center for Replication from the IBM Tivoli Storage Productivity Center user interface to access the Session Details panel for the alert and resolve the problem.

To use IBM Tivoli Storage Productivity Center and IBM Tivoli Storage Productivity Center for Replication to analyze storage events, complete the following steps:

1. IBM Tivoli Storage Productivity Center: Set up notification methods for replication alerts.
 - a. Start IBM Tivoli Storage Productivity Center.
 - b. In the navigation tree, expand **Replication Manager > Alerting** and select **Replication Alerts**.
 - c. Click **TPCUser.Replication Suspending Event**. The Edit Replication Alerts panel is displayed. Use this panel to determine how you are notified if IBM Tivoli Storage Productivity Center for Replication detects a suspending event in your storage environment.
 - d. In the **Triggered Actions** section, select the notification methods for the alert.

By default, all suspending events that are detected by IBM Tivoli Storage Productivity Center for Replication are recorded as entries in the Alert Log panel under **IBM Tivoli Storage Productivity Center > Alerting** . If you want to be notified using additional methods when the alert log is updated for a suspending event, select any of the following options:

- Select **SNMP Trap** to generate an SNMP trap message to any NMS, console, or terminal to indicate the triggering of a suspending alert.
- Select **TEC/OMNIBus Event** to send an alert to the Tivoli Event Console or OMNIBus.
- Select **Login Notification** to be notified of a suspending event when you log in to Tivoli Storage Productivity Center.
- Select **Windows Event Log** or **UNIX SYSLOG** to write the suspending alert to the operating system log file.
- Select **Run Script** to run a script when a suspending alert is triggered.
- Select **Email** to indicate the email addresses that receive notification when a suspending alert is triggered.

You are not required to select any of these options. Triggered alerts from IBM Tivoli Storage Productivity Center for Replication are automatically recorded in the alert log. These options are meant to provide you with additional methods for receiving alerts.

- e. Click the **Save** icon to save the alert definition. When IBM Tivoli Storage Productivity Center for Replication detects that a session has suspended, this alert is triggered, an entry is added to the IBM Tivoli Storage Productivity Center alert log, and any additional triggered actions are run.
2. IBM Tivoli Storage Productivity Center: Use the alert log to view information about a suspended Metro Mirror session.

This step occurs after IBM Tivoli Storage Productivity Center for Replication has detected a suspended session and triggered an alert in the IBM Tivoli Storage Productivity Center user interface.

- a. In the navigation tree, expand **IBM Tivoli Storage Productivity Center > Alerting** and select **Alerting Log**. A visual indicator is displayed next to each alert type under this node. In this scenario, a red, filled-in circle is displayed next to the **Replication** node to indicate that IBM Tivoli Storage Productivity Center has received an alert from IBM Tivoli Storage Productivity Center for Replication that is unresolved.
 - b. Click the **Replication** node. The content pane displays a table that contains a row for each alert received from IBM Tivoli Storage Productivity Center for Replication. The **Alert Type** column in this table indicates the type of alert that was triggered.
 - c. Click the magnifying glass icon next to the alert that displays **Suspending Event** in the **Alert Type** column. The Detail for Alert panel displays a description of the event that triggered the alert:

```
IWNR1958W [2009/03/04 15:11:49.250 EST] Session session_name has  
changed to the SEVERE status due to an unexpected error.
```
 - d. Click the back arrow in the tool bar to return to the Alert Log panel.
3. Start IBM Tivoli Storage Productivity Center for Replication from a suspended event alert in the alert log.

The Session Details page indicates that the session went suspended because the paths between the devices were dropped.

- a. On the **IBM Tivoli Storage Productivity Center > Alerting > Alerting Log** page, right-click the row for that represents the **Suspending Event** alert type. The menu that is displayed contains the actions that you can perform against the alert log entry. One of the actions is to start the IBM Tivoli Storage Productivity Center for Replication user interface.
- b. Click **Launch Replication Session Details** on the menu. The IBM Tivoli Storage Productivity Center for Replication user interface starts in a Web browser and displays the Session Details page. Use this page to view detailed information about the suspended event.

Single sign-on is an authentication process that enables you to enter one user ID and password to access multiple applications. Single sign-on integrates with the launch in context feature to enable you to move smoothly from the IBM Tivoli Storage Productivity Center user interface to a specific location in the IBM Tivoli Storage Productivity Center for Replication user interface without re-entering a user ID and password.

For example, this scenario shows how you can use single sign-on and launch in context to open a page in the IBM Tivoli Storage Productivity Center for Replication user interface based on a triggered alert in IBM Tivoli Storage Productivity Center.

- c. Use IBM Tivoli Storage Productivity Center for Replication to resolve the problem that triggered the alert.

You can use steps similar to the preceding ones to use IBM Tivoli Storage Productivity Center and IBM Tivoli Storage Productivity Center for Replication together to investigate and resolve different conditions and events that occur within your storage environment.

Performing planned maintenance scenarios

Scenarios for a planned outage consist of the removal of a unit from service to perform scheduled work on specific components for a predetermined duration.

Planned outage of local (H1), moving production to site 2 (H2) and optional return

In this scenario, your goal is to shut down the H1 box for maintenance, or for a planned power outage. As a result, you must move production to the H2 site, with the option of switching back to the H1 site after it is restored.

Follow these steps to carry out this scenario.

1. Start H1->H2->H3

Issue this command to begin Metro Global Mirror on your system when the production I/O is running on H1. The session will reach a Prepared state so there is a consistent point on Sites 2 and 3.

Note: Since the outage is a planned outage, stop production I/O to H1.

2. Suspend

This command creates the planned outage by suspending the Metro Mirror relationship between H1 and H2. When this step is complete, the session state should be suspended and recoverable.

3. Recover H2

This command makes H2 target-available. When the session state is Target Available, the production I/O can then be moved to write to the H2 volumes.

4. Start H2->H3

This command starts a Global Mirror session during the outage of H1. Production I/O can continue on H2. After the session reaches the Prepared state, a consistent copy of the data resides on Site 3, and can be used in the event of a disaster.

5. Start H2->H1->H3

Issue this command when H1 is available and ready to be brought back into the configuration. This command starts a Metro Global Mirror session with H1 and H2 roles reversed from the original configuration. Production I/O can continue on H2. After the session reaches the Prepared state, both Site 1 and Site 3 will have a consistent copy of the data.

Note: The following steps are the steps you must follow after you decide to switch production I/O to write on Site 1 again. Stop production I/O on H2 before continuing to the next step.

6. Suspend

This command suspends the Metro Mirror relationship between H2 and H1. When this step is complete, the session state should be suspended and recoverable.

7. Recover H1

This command makes H1 target-available. When the session state is target-available at H1, run production I/O to H1.

8. Start H1->H2->H3

This command returns the session to its original configuration, copying data from Site 1, to Site 2, to Site 3.

Planned outage on site 2 (H2) and return to three-site configuration

In this scenario, there is a planned outage expected on site 2. Disaster recovery capability is still needed so the copy will be setup between site 1 and site 3. After site 2 is brought back up, the session can then be brought back up to its original configuration.

Follow these steps to carry out this scenario:

1. Start H1->H2->H3

Run this command to begin Metro Global Mirror on your system when the production I/O is running on H1. After the session is in a Prepared state, both sites 2 and 3 will have a consistent copy of the data.

Note: Production I/O does not stop running to site 1 to perform the following steps.

2. Start H1->H3

This command starts a Global Mirror session between site 1 and site 3, during the outage of H2. Production I/O can continue on H1. After the session has reached a Prepared state, a consistent copy of the data will reside on Site 3.

Note:

- If running DS8000 devices on H1 with the correct level of microcode, and enough time has passed since the initial start of the session, the creation of the H1 to H3 pairs will *not* require a full copy.
- Data on Site 2 is no longer consistent at this point.
- After Site 2 is brought back up and is ready to hold a consistent copy of the data, go to the next step to return to the full three-site configuration. Production I/O never has to stop writing to H1 in this scenario.

3. Start H1->H2->H3

After the session reaches a Prepared state, site 2 and 3 will have a consistent copy of the data again.

Planned outage of local (H1) with production move to remote (H3)

In this scenario, there is a planned outage for Site 1 (H1). Site 2, however, does not have the resources to run production, so production will be moved to Site 3 during the outage at Site 1. When the outage is complete, production can then be moved back to Site 1 and resume the full three-site configuration.

Complete the following steps to carry out this scenario.

1. Start H1->H2->H3

Issue this command to begin Metro Global Mirror on your system when the production I/O is running on H1. Once the session is in a Prepared state, both sites 2 and 3 will have a consistent copy of the data.

Note: Because this is a planned outage at Site 1, stop production I/O to Site 1 (H1) before continuing to the next step.

2. Suspend

This command creates the planned outage by suspending the Metro Mirror relationship between H1->H2. When this step is complete, the session state should be suspended and recoverable.

3. Recover H3

This command makes H3 Target Available. When the session state is Target Available at H3, production I/O can be moved to H3.

Note: When Site 1 is ready to resume production, continue with the following steps. Production I/O can continue to be written to H3 through the following step.

4. **Start H3->H1->H2**

Issue this command when H1 and H2 are available and ready to be brought back into the configuration. Changes from production at the remote site (H3) flow from the local site (H1) to the intermediate site (H2). The H3-H1 and H1-H2 pairs are Global Copy. The session will remain in a preparing state.

Note: While the session is Preparing, you can decrease the amount of time that production I/O has to be stopped by waiting for progress on the H3-H1 role pair to be at or near 100%. The next step will drive H3-H1 to sync, which depending on the percentage of the copy that is complete, can take a significant amount of time. When you are ready to switch back to Site 1, stop production I/O on H3 before continuing to the next step.

5. **Suspend**

This command suspends Global Copy relationship between H3->H1 and H1->H2. When this step is complete, the session state should be suspended and recoverable.

6. **Recover H1**

This command makes H1 Target Available. When the session state is Target Available at H1, production can be switched back to H1.

7. **Start H1->H2->H3**

This command will resume copy from Site 1 back to sites 2 and 3. Once the session reaches a Prepared state, there will be a consistent copy on Site 2 and Site 3.

Planned outage of remote (H3) and returning

In this scenario, the remote site H3 has a planned outage, or consistency groups from the Global Mirror session need to be temporarily paused.

Complete the following steps to carry out this scenario.

1. **Start H1->H2->H3**

Issue this command to begin Metro Global Mirror on your system when the production I/O is running on H1. After the session is in a Prepared state, both sites 2 and 3 will have a consistent copy of the data.

Note: Production I/O to H1 can continue during the following steps.

2. **Suspend H2->H3**

Issue this command to suspend only the Global Mirror portion of the session. The Metro Mirror continues between H1 and H2. This causes the session state to be put into a SuspendedH2H3 state.

3. **Start H1->H2->H3**

This command restores the original configuration by restarting the Global Mirror portion of the session.

Recovering from a disaster scenarios

Scenarios for disaster recovery (or unplanned outages) describe the steps to recover from the loss of a complete site and restart operations after a disaster or disruption.

Unplanned outage of local (H1), production move to intermediate (H2)

In this scenario, there was an unplanned outage of the local site (H1), and production must be moved to Site 2 (H2) until Site 1 can be brought back up.

Complete the following steps to carry out this scenario.

Note: To ensure consistency in the event of a rolling disaster where the IBM Tivoli Storage Productivity Center for Replication server is lost on Site 1 before freezing all the copies in the session, enable the Metro Mirror heartbeat function.

1. Start H1->H2->H3

Issue this command to begin Metro Global Mirror on your system when the production I/O is running on H1. Once the session is in a Prepared state, both sites 2 and 3 will have a consistent copy of the data.

2. Unplanned outage of H1

This event causes an unplanned outage of H1, which causes the session to go suspended. It is recoverable if the session was in a Prepared state when the outage occurred. If the state was Preparing when the outage occurred, the session might be recoverable at Site 2 but will not be recoverable at Site 3.

3. RecoverH2

This command makes H2 Target Available. When the session state is Target Available at H2, production can be switched to H2.

4. Start H2->H3

This command starts a Global Mirror session from Site 2 to Site 3 during the outage of H1. Once the session reaches a Prepared state, consistent data should reside on Site 3.

Note: Do not perform the following step until Site 1 is back up and ready to receive a copy of the data that has been written to Site 2 during the outage.

5. Start H2->H1->H3

This command starts an MGM session with the H1 and H2 roles reversed from the original configuration. Production I/O can continue on H2. Wait for the session to go to the Prepared state, at which point there will be a consistent copy of the data on Site 1 and Site 3.

Note: The following steps can be used to return to the original configuration so that production I/O can be switched back to Site 1. Stop production I/O on H2 before continuing to the next step.

6. Suspend

This command suspends the Metro Mirror relationship between H2 and H1. When this step is complete, the session state should be suspended and recoverable.

7. RecoverH1

This command makes H1 Target Available. When the session state is Target Available at H1, production I/O can be switched back to H1.

8. Start H1->H2->H3

This command restores the original configuration. Once the session reaches a Prepared state, a consistent copy of the data will reside on Site 2 and Site 3.

Unplanned outage of Site 2 (H2)

In this scenario, an unplanned outage of Site 2 (H2) occurs. Disaster Recovery capability is still required, so a Global Mirror session must be set up between Site 1 (H1) and Site 3 (H3) while Site 2 is down.

Complete the following steps to carry out this scenario.

1. Start H1->H2->H3

Issue this command to begin Metro Global Mirror on your system when the production I/O is running on H1. Once the session is in a Prepared state, both sites 2 and 3 will have a consistent copy of the data

Note: Production I/O to H1 can continue during the following steps.

2. Unplanned outage of H2

This event causes an unplanned outage of H2, which causes the session to go suspended. It is recoverable if the session was in a Prepared state when the outage occurred. If the session state was Preparing, the session might be recoverable at Site 2 but would not be recoverable at Site 3.

3. Start H1->H3

This command starts a Global Mirror session between Site 1 and Site 3 during the outage of H2. Production I/O can continue on H1.

Note: If you are running DS8000 devices on H1 with the proper level of microcode, and enough time has passed since the initial start of the session, the creation of the H1 to H3 pairs will NOT require a full copy.

Once the session has reached a Prepared state, a consistent copy of the data will reside on Site 3.

Note: Data on Site 2 is no longer consistent at this point.

Note: After Site 2 has been successfully brought back up, perform the next step to return to the three-site configuration.

4. Start H1->H2->H3

Issue this command when H2 is ready to be brought back into the configuration. This command restores the original configuration. Production I/O can continue on H1. Once the session reaches a Prepared state, a consistent copy will reside on Site 2 and Site 3.

Unplanned outage of remote (H3)

In this scenario, an unplanned outage occurs on Site 3 (H3).

Complete the follow these steps to carry out this scenario.

1. Start H1->H2->H3

Issue this command to begin Metro Global Mirror on your system when the production I/O is running on H1. Once the session is in a Prepared state, both sites 2 and 3 will have a consistent copy of the data.

A failure of the remote site (H3) causes the session state to go from Prepared to SuspendedH2H3, with an error message that the connection to the H3 box has been lost.

Note: When the remote site (H3) is repaired and ready to return to the configuration, the session will remain SuspendedH2H3 and recoverable until step 2 is completed.

2. **Start H1->H2->H3**

Issue this command only when the remote site (H3) is repaired and ready to return to the configuration. With this command, your session returns to the original configuration by starting the Global Mirror portion back up.

Unplanned outage of local (H1) with production move to remote (H3)

In this scenario, there is an unplanned outage for Site 1 (H1). Site 2, however, does not have the resources to run production, so production will be moved to Site 3 during the outage at Site 1. When the outage is complete, production can then be moved back to Site 1 and resume the full three-site configuration.

Complete the following steps to carry out this scenario.

Note: To ensure consistency in the event of a rolling disaster where the IBM Tivoli Storage Productivity Center for Replication server might be lost on Site 1 before freezing all the copies in the session, enable the Metro Mirror heartbeat function.

1. **Start H1->H2->H3**

Issue this command to begin Metro Global Mirror on your system when the production I/O is running on H1. When the session is in a Prepared state, both sites 2 and 3 have a consistent copy of the data.

2. **Unplanned outage of H1 and H2**

This event causes an unplanned outage of H1 and H2 which causes the session to go suspended. It is recoverable if the session was in a Prepared state when the outage occurred. If the state was Preparing, the session might be recoverable at Site 2, but will not be recoverable at Site 3.

3. **Recover H3**

This command makes H3 Target Available. The session will be severe/Target Available. When the session state is Target Available at H3, production I/O can be moved to H3.

Note: Once Site 1 is brought back up, perform the following step to begin the process of returning production to Site 1.

4. **Start H3->H1->H2**

Issue this command when H1 and H2 are available and ready to be brought back into the configuration. Changes from production at the remote site (H3) flow from the local site (H1) to the intermediate site (H2). The H3-H1 and H1-H2 pairs are Global Copy. The session will in the preparing state.

Note: While the session is Preparing, you can decrease the amount of time that production I/O has to be stopped by waiting for the progress on the H3-H1 role pair to be at or near 100%. The next step will drive H3-H1 to sync, which depending on the percentage of the copy that is complete, can take a significant amount of time. When you are ready to switch back to Site 1, stop production I/O on H3 before continuing to next step.

5. **Suspend**

This command suspends the Global Copy relationship between H3>H1 and H1>H2. When this step is complete, the session state should be suspended and recoverable.

6. **Recover H1**

This command makes H1 Target Available. When the session state is Target Available at H1, run production I/O to H1.

7. **Start H1->H2->H3**

This command restores the original three-site configuration. Once the session reaches a Prepared state, a consistent copy of the data will reside on Site 2 and Site 3.

Practicing disaster recovery scenarios

This section provides scenarios for how to practice disaster recovery using a regular Metro Global Mirror session. You can follow these scenarios to practice disaster recovery while continuing to be disaster recovery-capable using only the Metro Mirror portion of the session. The Metro Global Mirror with Practice session is also available, which allows for practicing disaster recovery while maintaining full three-site disaster recovery capability.

Practice a recovery to H2 with production that is continuing on H1 in a normal configuration

In this scenario, your goal is to practice a recovery to H2 with production that is continuing on H1 in a normal configuration.

Follow these steps to carry out this scenario.

1. **Start H1->H2->H3**

Issue this command to begin a Metro Global Mirror session on your system when the production I/O is running on H1. Wait for the session to go to the prepared state.

You can continue to run production I/O to H1 during the following steps.

2. **Suspend**

This command creates the planned outage by suspending the Metro Mirror relationship between H1 and H2. When this step is complete, the session state should be suspended and recoverable.

Note: Stop running production I/O to H2 prior to issuing the Suspend command.

3. **Recover H2**

This command makes H2 target-available. When the session is target-available at H2, run practice I/O to H2.

4. **Start H1->H3**

Issue this command to ensure that any I/O that is written to site 1 is copied to site 3.

You can also use the Start H1->H3 command to practice for a disaster at the H2 site while still maintaining disaster recovery capability. When the H1->H3 role pair is in Global Mirror mode, you can recover the session at site 3 if a disaster occurs.

When you complete testing on H2, you can issue the Start H1->H2->H3 command to return to a three-site configuration without completing a full copy.

5. **Start H1->H2->H3**

Issue this command to restart the Metro Global Mirror session in the H1-H2-H3 configuration. Any changes from production at the local site (H1) flow from the remote site (H3) to the intermediate site (H2), which overwrites the test data on H2.

Table 28. Role-pair states at the completion of each step (participating and nonparticipating role pairs)

Steps	Role-pair states					
	H1-H2	H2-H3	H2-J3	H3-J3	H1-H3	H1-J3
1	Prepared	Preparing	Prepared	Target available	Non-participating	Non-participating
2	Suspended					
3						
4		Non-participating	Non-participating		Participating	Prepared
5	Prepared	Preparing	Prepared		Non-participating	Non-participating

Practice recovery to H1 with production that is continuing on H2

In this scenario, your goal is to practice a recovery to H1 with production that is continuing on H2.

Follow these steps to carry out this scenario.

1. Start H1->H2->H3

Issue this command to begin a Metro Global Mirror session on your system when the production I/O is running on H1. Wait for the session to go to the prepared state.

2. Suspend

This command creates the planned outage by suspending the Metro Mirror relationship between H1 and H2. When this step is complete, the session state should be suspended and recoverable.

Note: Stop running production I/O to H1 prior to issuing the Suspend command.

3. Recover H2

This command makes H2 target-available.

Note: Start running production I/O to H2.

4. Start H2->H1->H3

This command starts a Metro Global Mirror session with H1 and H2 roles reversed from the original configuration.

You can continue to run production I/O to H2 for the next two steps.

5. Suspend

This command creates the planned outage by suspending the Metro Mirror relationship between H1 and H2. When this step is complete, the session should be suspended and recoverable.

6. Recover H1

This command makes H1 target-available. When the session state is target-available at H1, run practice I/O to H1.

7. Start H2->H3

Issue this command to ensure that any I/O that is written to site 2 is copied to site 3.

You can also use the Start H2->H3 command to practice for a disaster at the H1 site while still maintaining disaster recovery capability. When the H2->H3 role pair is in Global Mirror mode, you can recover the session at site 3 if a disaster occurs.

When you complete testing on H1, you can issue the **Start H2->H1->H3** command to return to a three-site configuration without completing a full copy.

8. **Start H2->H1->H3**

Issue this command to restart the Metro Global Mirror session in the H2-H1-H3 configuration. Any changes from production at the local site (H2) flow from the remote site (H3) to the intermediate site (H1), which overwrites the test data on H1.

Table 29. Role-pair states at the completion of each step (participating and nonparticipating role pairs)

Steps	Role-pair states					
	H1-H2	H2-H3	H2-J3	H3-J3	H1-H3	H1-J3
1	Prepared	Preparing	Prepared	Target available	Non-participating	Non-participating
2	Suspended					
3						
4	Prepared	Non-participating	Non-participating		Preparing	Prepared
5	Suspended					
6						
7		Preparing	Prepared		Non-participating	Non-participating
8	Prepared	Non-participating	Non-participating		Preparing	Prepared

Practice at H3 for Metro Global Mirror

This topic describes how to practice at the remote site (H3) while running a Metro Global Mirror session.

To practice on the remote site, you first need to suspend the back-end. For example, if running in an H1->H2->H3 configuration, issue a **Suspend H2H3** command to pause the Global Mirror portion of the session while leaving the Metro Mirror portion of the session active. When the session is in a suspended state (that is, H2H3 is suspended while in an H1->H2->H3 configuration), you have the option to issue a **Recover H3** command.

The **Recover H3** command acts differently than other recover commands. In this case, the command acts only to make the remote site (H3) target-available and does not switch the application site to H3. The application site remains the original host site and the session acts as it does in a normal Metro Mirror Failover/Failback session.

While the session is in this mode, it remains capable of disaster recovery at Site 2 and will freeze all pairs to maintain consistency during an error. You can also suspend the session by command and recover to Site 2 if necessary. However, if recovering to Site 2 in this mode, it will not be possible to restart a full three-site solution. To get three sites back up and running, you need to copy back to H1 using the **Start H2->H1** command and then suspend and recover to H1. Once H1 is the application host again, you can issue the **Start H1->H2->H3** command to restart three-site support. If this is done, all data written to H3 during the practice is overwritten with the data that is on H1.

Overview of scenarios for practicing at H3 for Metro Global Mirror:

This topic provides an overview of the scenarios for practicing at H3 for Metro Global Mirror.

Note: For simplicity, the following scenarios are geared toward the configuration where the session is running H1->H2->H3. The same options apply when in the configuration is running H2->H1->H3.

There are two methods to set up a practice mode at the remote site, H3.

In the first method, you issue the following commands:

1. **Start H1->H2->H3**
2. **SuspendH2H3**
3. **RecoverH3**

When the session state is Target Available at H3, you can practice you disaster recovery steps on H3 while continuing to run the real production I/O to H1.

In the second method of setting up a practice mode, issue the following commands:

1. **Start H1->H2->H3**
2. **Suspend**
3. **RecoverH3**
4. **Start H1->H2**

When the session state is Target Available at H3, run practice I/O to H3. Continue running production I/O to H1.

The difference between the second method and the first method is that a **Suspend** command is issued instead of a **SuspendH2H3** command. When the session is in suspended mode (as opposed to suspended H2H3 mode), the session does not automatically go into practice mode. The application site switches to H3 and you must issue a **Start H1->H2** to enable the practice mode.

Practice scenario 1: While practicing, disaster occurs at Site 1, recover to Site 2:

This topic describes what to do in the event that a disaster occurs on Site 1 while practicing at Site 3.

If a disaster occurs at Site 1, the session immediately suspends itself. You then must complete the following steps:

1. Issue **RecoverH2**.
2. Move the production I/O to Site 2.
3. Issue **Start H2->H1** to make the session capable of disaster recovery again once Site 1 has been brought back up.

Practice scenario 2: While practicing, planned outage at Site 1, recover to Site 2:

This topic describes what to do if there is a planned outage on Site 1 while practicing at Site 3.

While practicing, if you want a planned outage with a switch to Site 2, complete the following steps:

1. Issue **Suspend**.

2. Issue **RecoverH2**.
3. Move the production I/O to Site 2.
4. Issue **Start H2->H1** to make the session capable of disaster recovery again once Site 1 has been brought back up.

Practice scenario 3: while practicing with production at site 2, move production back to site 1:

This topic describes an H3 practice scenario, with production running at site 2, followed by a move of production to site 1.

While practicing, if you moved the production to site 2, you need to move it back to site 1 before you can start three-site support. To move production back to site 1, do the following steps (assume the session is running H2->H1):

1. Issue **Suspend**.
2. Issue **Recover H1**.
3. Move the production I/O to site 1.
4. Issue **Start H1->H2** to make the session capable of disaster recovery again and move the production I/O to H3.
5. Issue **Start H1->H2->H3** when H3 is ready to receive a copy of the data at site 1. When this command completes, all writes that were done to H3 are overwritten by the data on site 1.

The following table shows the changing states of the role pairs after each step.

Table 30. Role-pair states at the completion of each step (participating and nonparticipating role pairs)

Steps	Role-pair states					
	H1-H2	H2-H3	H2-J3	H3-J3	H1-H3	H1-J3
1	Suspended	Nonparticipating				
2	Target Available					
4	Prepared	target-available			nonparticipating	
5		Preparing	Prepared	Target Available		

Chapter 4. Administering

Administer DB2 to back up the database and to start and stop the control center. Administer IBM Tivoli Storage Productivity Center to authorize users, start and use the console, which is the graphical user interface (GUI), start and stop services, and many other administrative tasks.

Starting Tivoli Storage Productivity Center

IBM Tivoli Storage Productivity Center provides two graphical user interface (GUI) applications for managing and monitoring the resources in a storage environment: a stand-alone GUI and a web-based GUI. You can start these GUIs on the Tivoli Storage Productivity Center server or on a remote system.

The stand-alone GUI and the web-based GUI provide different functions and offer different advantages. Start the one that is best suited to your current needs.

- The stand-alone GUI contains functions for monitoring the condition of storage resources, and all the tools for managing data, disk, fabric, tape, and replication. Start the stand-alone GUI if you must have the full administrative capabilities of Tivoli Storage Productivity Center. How you start the stand-alone GUI depends on whether the stand-alone GUI component is installed on your system.
- The web-based GUI provides quick access to pages that you can use to monitor the condition, capacity, and relationships of the resources within your storage environment. Start the web-based GUI if you are interested in monitoring your storage environment but do not require the full set of administrative tools available in the stand-alone GUI.

Starting the Tivoli Storage Productivity Center stand-alone GUI

The stand-alone GUI contains functions for monitoring the condition of storage resources, and all the tools for managing data, disk, fabric, tape, and replication.

How you start the stand-alone GUI depends on whether the stand-alone GUI component is installed on your system.

- On the Tivoli Storage Productivity Center server, or on a remote system where the stand-alone GUI component is installed, you start the stand-alone GUI by running a batch file or a shell script. For Windows operating systems, you run the batch file `tpc.bat`, which you can run from the Start menu. For AIX or Linux operating systems, you run the shell script `TPCD.sh`.
- If the stand-alone GUI component is not installed on a remote system, you use a Java Web start application to download and start the stand-alone GUI.

Starting the Tivoli Storage Productivity Center stand-alone GUI by using Java Web Start

Start the stand-alone Tivoli Storage Productivity Center GUI by using Java Web Start to interact remotely with Tivoli Storage Productivity Center running on the server.

Before you start Tivoli Storage Productivity Center, ensure that you are using a supported web browser. For a list of web browsers that you can use with Tivoli Storage Productivity Center, see the support matrix at <http://www.ibm.com/>

support/docview.wss?uid=swg21386446. In the **Agents, Servers and GUI** column, click the version of Tivoli Storage Productivity Center that is installed on your system. On the next page, click **Web Browsers** to find the web browsers that you can use.

On remote systems where the stand-alone GUI component is not installed, you can start the stand-alone Tivoli Storage Productivity Center GUI using Java Web Start. To start the stand-alone GUI by using Java Web Start, you click a web link that downloads a Java Network Launching Protocol (JNLP) file from the server. The JNLP file specifies all the files needed by the application. The Java Web Start Launcher on the remote system opens the JNLP file, downloads and caches all the required files, and starts the stand-alone GUI in a new window.

1. Start a web browser, and type the following address for the Java Web Start page.

```
http://hostname:port/ITSRM/app/welcome.html
```

In the preceding address, specify the following values:

hostname

The Tivoli Storage Productivity Center server. You can specify the *hostname* as an IP address or a Domain Name System (DNS) name. To verify your host name, ask your Tivoli Storage Productivity Center administrator.

port

The port number for the Device server. The default port number for connecting to the Device server using the HTTP protocol is 9550. However, this port number might be different for your site. For example, the port number might be different if the default port range was not accepted during installation. If the default port number does not work, ask your Tivoli Storage Productivity Center administrator for the correct port number.

2. The Tivoli Storage Productivity Center GUI requires an IBM Java Runtime Environment 1.6.0. Links are provided on the Java Web start page for you to download the IBM Java Runtime Environment 1.6.0 for Windows, Linux, or AIX. If an IBM Java Runtime Environment 1.6.0 is not already installed on the system, click the link to download the IBM Java Runtime Environment 1.6.0 for your operating system. On Windows, download a self-extracting executable. On Linux, download an RPM file. On AIX, download an executable JAR file. Install the JRE from the file that you downloaded before you start the stand-alone GUI. If you are prompted to install the JRE as the system JRE or to overwrite the current system JRE, click **No**.
3. From the Java Web Start page, click **TPC GUI (Java Web Start)**
The JNLP file is downloaded.

Important: Depending on your browser and operating system and their default settings for your browser and operating system) you might need to:

- Verify to your browser that the `tpcgui.jnlp` file is safe to download
- Indicate that JNLP files are to be opened by the Java Web Start Launcher

For more information, go to the Tivoli Storage Productivity Center information center at <http://publib.boulder.ibm.com/infocenter/tivihelp/v59r1/index.jsp> and search for *Cannot start the Tivoli Storage Productivity Center stand-alone GUI remotely*.

4. The stand-alone Tivoli Storage Productivity Center GUI opens in a separate window. To log on to Tivoli Storage Productivity Center, enter the following information and click **OK**.

- a. Enter your user ID and password.

Important: If you are logging on immediately after installation and, see “Overview of required user IDs for initial log on to the Tivoli Storage Productivity Center family of products” on page 183 for information on the user ID you must use.

- b. If the server field does not contain the address and port number of for the server, specify the following values for the *hostname* and *port*.

hostname

The Tivoli Storage Productivity Center server. You can specify the *hostname* as an IP address or a Domain Name System (DNS) name. To verify your host name, ask your Tivoli Storage Productivity Center administrator.

port

The port number for the Data server. The default port number for connecting to the Data server is 9549. However, this port number might be different for your site. For example, the port number might be different if the default port range was not accepted during installation.

Starting the Tivoli Storage Productivity Center stand-alone GUI on a system where the GUI component is installed

On the Tivoli Storage Productivity Center server, or on a remote system where the stand-alone GUI component is installed, you start the Tivoli Storage Productivity Center stand-alone GUI using the batch file `tpc.bat` on a Windows operating system or the shell script `TPCD.sh` on an AIX and Linux operating system.

A typical installation of Tivoli Storage Productivity Center on the server includes the stand-alone GUI component. A remote system can also have the stand-alone GUI component installed. On a system where the stand-alone GUI component is installed, use the following instructions for starting the stand-alone GUI. If you are on a remote system where the stand-alone GUI component is not installed, start the stand-alone GUI by using Java Web Start instead.

1. Start the Tivoli Storage Productivity Center GUI by using the Start menu or batch file on a Windows operating system or a shell script on an AIX or Linux operating system.

- On Windows, click **Start > Programs > IBM Tivoli Storage Productivity Center > TPC Stand-alone GUI**. This runs the Windows batch file `tpc.bat`. If you are on a remote system, the Start menu item for the stand-alone GUI might not be available. In this case, run the `tpc.bat` directly. The default location for the batch file is `C:\Program Files\IBM\TPC\gui\tpc.bat`.
- On AIX or Linux, type the following path and command at the command line.

```
/opt/IBM/TPC/gui/TPCD.sh
```

2. From the Tivoli Storage Productivity Center GUI logon window, log on to Tivoli Storage Productivity Center.

- a. Enter your user ID and password.
- b. If the server field does not contain the address of the server, enter the information in the format *hostname:port*. Specify the following values for the *hostname* and *port*:

hostname

The Tivoli Storage Productivity Center server. You can specify the *hostname* as an IP address or a Domain Name System (DNS) name.

port

The port number for the Data server. The default port number for connecting to the Data server is 9549. However, this port number might be different for your site. For example, the port number might be different if the default port range was not accepted during installation.

- c. Click **OK**.

Starting the Tivoli Storage Productivity Center web-based GUI

You can start the web-based Tivoli Storage Productivity Center GUI by opening a web browser and entering a web address for the Tivoli Storage Productivity Center logon page.

Before you start IBM Tivoli Storage Productivity Center, ensure that you are using a supported web browser. For a list of web browsers that you can use with Tivoli Storage Productivity Center, see the support matrix at <http://www.ibm.com/support/docview.wss?uid=swg21386446>. In the **Agents, Servers and GUI** column, click the version of Tivoli Storage Productivity Center that is installed on your system. On the next page, click **Web Browsers** to find the web browsers that you can use.

The web-based GUI provides quick access to pages that you can use to monitor the condition, capacity, and relationships of the resources within your storage environment. Start the web-based GUI if you are interested in monitoring your storage environment, but do not need the full set of administrative tools available in the stand-alone GUI.

1. On a server running the Windows operating system, click **Start > Programs > IBM Tivoli Storage Productivity Center > TPC Web-based GUI** to open a browser to the correct address. If you are not on a server running the Windows operating system, start a web browser and enter the following address in the address field:

`http://hostname:port/srm`

In the preceding address, specify the following values:

hostname

The Tivoli Storage Productivity Center server. You can specify the host name as an IP address or a Domain Name System (DNS) name.

port

The port number for Tivoli Storage Productivity Center. The default port number for connecting to Tivoli Storage Productivity Center by using the HTTP protocol is 9568. However, this port number might be different for your site. For example, the port number might be different if the default port range was not accepted during installation. If the default port number does not work, ask your Tivoli Storage Productivity Center administrator for the correct port number.

You might be redirected from the address that you enter to another address and port that provides secure access using the HTTPS protocol. This page is the Tivoli Storage Productivity Center logon page.

2. From the Tivoli Storage Productivity Center logon page, type your user name and password and click **Log in**. The web-based Tivoli Storage Productivity Center GUI opens in the browser.

Starting Tivoli Storage Productivity Center for Replication

You can start the IBM Tivoli Storage Productivity Center for Replication GUI by opening a web browser and entering a web address for the Tivoli Storage Productivity Center for Replication logon page.

Before you start Tivoli Storage Productivity Center for Replication, ensure that you are using a supported web browser. For a list of web browsers that you can use with Tivoli Storage Productivity Center, see the support matrix at <http://www.ibm.com/support/docview.wss?uid=swg21386446>. In the **Agents, Servers and GUI** column, click the version of Tivoli Storage Productivity Center that is installed on your system. On the next page, click **Web Browsers** to find the web browsers that you can use.

The Tivoli Storage Productivity Center for Replication GUI provides a single point of control to configure, manage, and monitor copy services. Whether you start it on the server or on a remote system, the GUI is web-based and is displayed in a browser.

1. On a server running the Windows operating system, click **Start > Programs > IBM Tivoli Storage Productivity Center > TPC Replication Manager GUI** to open a browser to the correct address. If you are not on a server running the Windows operating system, start a web browser and enter the following address in the address field. The address is case-sensitive.

`https://hostname:port/CSM`

In the preceding address, specify the following values:

hostname

The Tivoli Storage Productivity Center for Replication server. You can specify the host name as an IP address or a Domain Name System (DNS) name.

port

The port number for Tivoli Storage Productivity Center for Replication. The default port number for connecting to Tivoli Storage Productivity Center for Replication using the HTTPS protocol is 9559. However, this port number might be different for your site. For example:

- If you upgraded from Tivoli Storage Productivity Center for Replication version 3.3 or earlier, the default HTTPS port is 9443.
- If you upgraded from Tivoli Storage Productivity Center for Replication version 3.4 or later, the default HTTPS port is 3443.
- If you are using IBM WebSphere Application Server for z/OS, the default HTTPS port is 9443.
- If you are using IBM WebSphere Application Server OEM Edition for z/OS, the default HTTPS port is 32209.

You can also find the port number in the `install_root/eWAS/profiles/profile_name/properties/portdef.props` file. The default port for the HTTP protocol is defined by the `WC_defaulthost_secure` property within the file.

2. From the Tivoli Storage Productivity Center for Replication logon page, type your user name and password and click **Login**. The web-based Tivoli Storage Productivity Center for Replication GUI opens in the browser.

Starting the Tivoli Storage Productivity Center family of products through Tivoli Integrated Portal

You can start the Tivoli Storage Productivity Center stand-alone GUI, the Tivoli Storage Productivity Center web-based GUI, and the Tivoli Storage Productivity Center for Replication web-based GUI within IBM Tivoli Integrated Portal. Tivoli Integrated Portal provides the advantages of the single sign-on capability and launch-in-context integration.

Before you start Tivoli Storage Productivity Center, ensure that you are using a supported web browser. For a list of web browsers that you can use with Tivoli Storage Productivity Center, see the support matrix at <http://www.ibm.com/support/docview.wss?uid=swg21386446>. In the Agents, Servers and GUI column, click the version of Tivoli Storage Productivity Center that is installed on your system. On the next page, click Web Browsers to find the web browsers that you can use.

These instructions assume that you have previously started the Tivoli Storage Productivity Center stand-alone GUI, Tivoli Storage Productivity Center web-based GUI, or the Tivoli Storage Productivity Center for Replication web-based GUI outside of Tivoli Integrated Portal and that you already configured your system. For example, to start the stand-alone Tivoli Storage Productivity Center GUI by using Java Web Start, an IBM Java Runtime Environment 1.6.0 is required.

By logging on to Tivoli Integrated Portal, you eliminate the need to log on to Tivoli Storage Productivity Center or any other Tivoli application that uses the common portal framework. In addition to the convenience of single sign-on, Tivoli Integrated Portal provides launch-in-context integration. By using these functions, you can move between Tivoli Storage Productivity Center and another Tivoli application at specific points within the other application interface.

1. Start a web browser and enter the following address in the address field:
`http://hostname:port/ibm/console`

In the preceding address, specify the following values:

hostname

The Tivoli Integrated Portal server. You can specify the host name as an IP address or a Domain Name System (DNS) name.

port

The port number for Tivoli Integrated Portal. If you did not upgrade your system from an earlier version of the product, the default port number for connecting to Tivoli Integrated Portal using the HTTP protocol is 9568. However, this port number might be different for your site. For example, the port number might be different if you upgraded your system from an earlier version of the product or if the default port range was not accepted during installation. If the default port number does not work, see “Tivoli Integrated Portal port numbers” on page 232 for alternative default ports.

You might be redirected from the address you enter to another address and port that provides secure access using the HTTPS protocol. This page is the Tivoli Integrated Portal logon page.

2. From the Tivoli Integrated Portal logon page, type your Tivoli Storage Productivity Center ID and password and click **Log in**.
3. From the Tivoli Integrated Portal navigation tree, click **Tivoli Storage Productivity Center**.

4. From the Tivoli Storage Productivity Center portlets page, you can start the Tivoli Storage Productivity Center stand-alone GUI, the Tivoli Storage Productivity Center web-based GUI, or the Tivoli Storage Productivity Center for Replication web-based GUI. Select one of the following options:
 - **Start the stand-alone GUI for Tivoli Storage Productivity Center.**
 - **Start the web-based GUI for Tivoli Storage Productivity Center.**
 - **Start the web-based GUI for Tivoli Storage Productivity Center for Replication.**

Related tasks:

“Starting the Tivoli Storage Productivity Center stand-alone GUI by using Java Web Start” on page 177

Start the stand-alone Tivoli Storage Productivity Center GUI by using Java Web Start to interact remotely with Tivoli Storage Productivity Center running on the server.

“Starting the Tivoli Storage Productivity Center web-based GUI” on page 180

You can start the web-based Tivoli Storage Productivity Center GUI by opening a web browser and entering a web address for the Tivoli Storage Productivity Center logon page.

“Starting Tivoli Storage Productivity Center for Replication” on page 181

You can start the IBM Tivoli Storage Productivity Center for Replication GUI by opening a web browser and entering a web address for the Tivoli Storage Productivity Center for Replication logon page.

Overview of required user IDs for initial log on to the Tivoli Storage Productivity Center family of products

All the graphical user interfaces (GUIs) in the Tivoli Storage Productivity Center family require a user ID and password. If you are logging on to a GUI immediately after you installed the software, the user ID that you must use differs depending on the type of installation and the GUI interface.

Immediately after you install the software, you must use the user ID as described in the following tables. After you log on, you can assign roles for users in Tivoli Storage Productivity Center and Tivoli Storage Productivity Center for Replication. When users log on, their user roles determine their authorization level and the components that they can view in each GUI.

For example, if a user is in a group that is assigned to the Tivoli Storage Productivity Center Superuser role, the user has full access to all Tivoli Storage Productivity Center functions. However, if a user is in a group that is assigned to the Tape Administrator role, the user has access to only tape-related functions.

Required user ID for initial log on after installation on a single server when only the common user is defined

After you install the software on a single server, if you defined only the common user, and did not define a separate user for Tivoli Integrated Portal and Tivoli Common Reporting, the required user ID for initial log is the common user name that was defined for the installation of Tivoli Storage Productivity Center.

You must use this user ID to log on to Tivoli Storage Productivity Center stand-alone GUI, the Tivoli Storage Productivity Center web-based GUI, the Tivoli Storage Productivity Center for Replication web-based GUI, or the Tivoli Integrated Portal.

Required user ID for initial log on after installation on a single server when the common user and a separate user for Tivoli Integrated Portal and Tivoli Common Reporting are defined

After you install the software on a single server if you defined a common user and a separate user for Tivoli Integrated Portal and Tivoli Common Reporting, you must use the user ID as described in the following table.

Table 31. Required user ID for initial log on after installation on a single server when the common user and a separate user for Tivoli Integrated Portal and Tivoli Common Reporting are defined

To log on to:	Use this user ID:
Tivoli Storage Productivity Center stand-alone GUI	The common user name that was defined for the installation of Tivoli Storage Productivity Center
Tivoli Storage Productivity Center web-based GUI	The common user name that was defined for the installation of Tivoli Storage Productivity Center
Tivoli Storage Productivity Center for Replication web-based GUI	The common user name that was defined for the installation of Tivoli Storage Productivity Center
Tivoli Integrated Portal	The common user name that was defined for the installation of Tivoli Integrated Portal and Tivoli Common Reporting

Required user ID for initial log on after installation on multiple servers with a remote database schema

After you install the software on multiple servers with a remote database schema, you must use the user ID as described in the following table.

Table 32. Required user ID for initial log on after installation on multiple servers with a remote database schema

To log on to:	Use this user ID:
Tivoli Storage Productivity Center stand-alone GUI	The user name that was defined for the installation of Tivoli Storage Productivity Center
Tivoli Storage Productivity Center web-based GUI	The user name that was defined for the installation of Tivoli Storage Productivity Center
Tivoli Storage Productivity Center for Replication web-based GUI	The user name that was defined for the installation of Tivoli Storage Productivity Center
Tivoli Integrated Portal	The user name that was defined for the installation Tivoli Integrated Portal and Tivoli Common Reporting

Required user ID for initial log on after installation on multiple servers with remote Tivoli Integrated Portal and Tivoli Common Reporting

After you install the software on multiple servers with remote Tivoli Integrated Portal and Tivoli Common Reporting, you must use the user ID as described in the following table.

Table 33. Required user ID for initial log on after installation on multiple servers with remote Tivoli Integrated Portal and Tivoli Common Reporting

To log on to:	Use this user ID:
Tivoli Storage Productivity Center stand-alone GUI	The user name that was defined for the installation of Tivoli Storage Productivity Center. Because user authentication is conducted on the server where Tivoli Integrated Portal is installed, the user name and user group must exist in the operating system user and group registry on the Tivoli Integrated Portal server.
Tivoli Storage Productivity Center web-based GUI	The user name that was defined for the installation Tivoli Integrated Portal and Tivoli Common Reporting
Tivoli Storage Productivity Center for Replication web-based GUI	The user name that was defined for the installation of Tivoli Storage Productivity Center. The Tivoli Storage Productivity Center for Replication GUI detects only users and groups that are in the operating system user and group registry on the server where Tivoli Integrated Portal is installed. To provide access to a user or group in the Tivoli Storage Productivity Center for Replication GUI, the user or group must be in the operating system user and group registry on the Tivoli Integrated Portal server.
Tivoli Integrated Portal	The user name that was defined for the installation of Tivoli Integrated Portal and Tivoli Common Reporting

Administering DB2

Administer DB2 by backing up the IBM Tivoli Storage Productivity Center database, starting the control center, and starting and stopping DB2.

Backing up the Tivoli Storage Productivity Center database

IBM Tivoli Storage Productivity Center uses circular logs for the DB2 database. Therefore, only an offline database backup is supported. When an offline database backup is performed, the database connections are terminated. Therefore, the Tivoli Storage Productivity Center servers need to be stopped and then restarted.

1. Close the Tivoli Storage Productivity Center GUI.
2. Stop the Tivoli Storage Productivity Center servers.
3. Back up your database.
 - a. Open the DB2 Control Center.

- Important:** If you are using DB2 10.1, you must use the command-line interface.
- b. The Control Center View panel is displayed. Select **Basic** and click **OK**.
 - c. In the Control Center navigation tree, click **All Databases**.
 - d. Under the **All Databases** node, you see **TPCDB**. **TPCDB** is the IBM Tivoli Storage Productivity Center database. Highlight **TPCDB** and right-click it. Click **Backup**.
 - e. The Confirm the details of your database panel is displayed. Click **Next**.
 - f. The Specify where to store your backup image panel is displayed. For Media Type, enter **File System**. If you want to add a new folder, click **Add**.
 - g. On the Path Browser - LOCALHOST panel, click the **Create New Folder** icon. Enter the name of your new folder (for example, TPCbackup1). Click **OK**.
 - h. On the Specify where to store your backup image panel, you see your new folder listed (TPCbackup1). Click **Finish**. The database backup runs.
 - i. When the database backup is completed, you see a DB2 Message window indicating that the database backup completed successfully.
 - j. Close the DB2 Message window.
4. Restart the Tivoli Storage Productivity Center servers.

If you want to do an online backup of the database, you need to change the use of circular logs to linear logs. The use of linear logs can fill up the file system quickly if the database is not maintained properly. For information about how to change the use of circular logs to linear logs, see the DB2 Information Center. Click **Designing > Backups**.

Starting the Control Center

Start the DB2 Control Center on Linux or Windows operating systems. If you are using DB2 10.1, you must use the command line.

Important: If you are using DB2 10.1, you must use the command-line interface. Complete either of the following actions:

On Linux operating systems:

From a console window, run the **db2cc** command.

On Windows operating systems:

Click **Start > Programs > IBM DB2 > General Administration Tools > Control Center**.

Using the command line on UNIX and Linux

This topic describes how to use a command line to perform actions against a DB2 instance under UNIX or Linux.

If the DB2 Control Center is unavailable or you do not have access to a graphical user interface, you can use a command line to execute DB2 commands such as starting and stopping an instance.

Important: If you are using DB2 10.1, you must use the command-line interface.

To use a command line to perform actions against an instance of DB2, complete the following steps:

1. Log in with a user ID or name that has ROOT, SYSADM, SYSCTRL, or SYSMAINT authority on the instance; or log in as the instance owner.
2. Run the startup script:
 - For Bourne or Korn shell, type: **. HOME/sqllib/db2profile.**
 - For C shell, type: **source HOME/sqllib/db2cshrc.**

where HOME is the home directory of the instance you want to use.

3. To start the instance using the command line, type **db2start**.

Note: When you run commands to start the database manager instance, the DB2 database manager applies the command to the current instance.

4. To stop the instance using the command line, type **db2stop**.

Note: When you run commands to stop the database manager instance, the DB2 database manager applies the command to the current instance.

Manually starting DB2 on Windows

This topic describes how to manually start DB2 on Windows.

To start DB2 manually, complete the following steps:

1. Start the following Windows services:
 - DB2 - DB2-0
 - DB2DAS - DB2DAS00
 - DB2 JDBC Applet Server
 - DB2 License Server
 - DB2 Security Server
2. To open a DB2 command window, click **Start > Programs > IBM DB2 > Command Line Tools > Command Window**.
3. From the DB2 Command window, run the **db2start** command.

Manually stopping DB2 on Windows

This topic describes how to manually stop DB2 on Windows.

To stop DB2 manually, complete the following steps:

1. Stop the following Windows services:
 - DB2 Security Server
 - DB2 License Server
 - DB2 JDBC Applet Server
 - DB2DAS - DB2DAS00
 - DB2 - DB2-0

Note: When you stop the **DB2 Security Server** service, you are prompted to stop the Warehouse logger and Warehouse Serve; click **Yes**.

2. To open a DB2 command window, click **Start > Programs > IBM DB2 > Command Line Tools > Command Window**.
3. From the DB2 Command window, run the **db2stop** command.

To restart DB2, enter the **db2start** command from the DB2 Command window. Before you can issue the command, you must first start these services from the Windows Services panel:

DB2 - DB2-0
DB2DAS - DB2DAS00
DB2 JDBC Applet Server
DB2 License Server
DB2 Security Server

Monitoring DB2

The minimum user authority level needed for monitoring DB2 instances is a user with DB2 system maintenance authority (SYSMAINT).

To check and set SYSMAINT authority, follow these steps:

1. Run this command in the DB2 command prompt window to check to see if there is an operating system user group defined to have SYSMAINT authority:

```
db2 get dbm cfg
```

In the output file, look for this information:

```
SYSADM group name           (SYSADM_GROUP) =  
SYSCTRL group name         (SYSCTRL_GROUP) =  
SYSMAINT group name        (SYSMAINT_GROUP) =  
SYSMON group name          (SYSMON_GROUP) =
```

If the setup for the operating system group has not been done, you do not see a value set.

If the setup has been done, this example shows what you can expect to see:

```
SYSADM group name           (SYSADM_GROUP) =  
SYSCTRL group name         (SYSCTRL_GROUP) =  
SYSMAINT group name        (SYSMAINT_GROUP) = ADMINISTRATORS  
SYSMON group name          (SYSMON_GROUP) =
```

In this example, the "ADMINISTRATORS" group has SYSMAINT_GROUP authority.

2. If the setup has been done, add the user you want to use to the ADMINISTRATORS group using the operating system utilities or use a user that already belongs to the ADMINISTRATORS group.

If you want to give a user group "SYSMAINT_GROUP" authority, follow these steps:

- a. If a user (for example userA) belongs to an operating system group called db2monitor, here is an example of setting the db2monitor group with SYSMAINT authority. From the DB2 command prompt window, run the following command:

```
db2 update dbm cfg using SYSMAINT_GROUP db2monitor
```

- b. After issuing the **db2 update** command, restart DB2 by running the following command from the DB2 command prompt window or restarting the system:

```
db2 force application all
```

This command might need to be issued a few times to stop all the database connections.

- c. Run the following commands from the DB2 command prompt window:

```
db2stop  
db2start
```

- d. UserA can now monitor the DB2 database.

Adding a Tivoli Storage Productivity Center user group name to Tivoli Storage Productivity Center for Replication

To access Tivoli Storage Productivity Center for Replication using a user ID from the Tivoli Storage Productivity Center user group name, you must add the user group name to the Tivoli Storage Productivity Center for Replication administrative role. If you installed Tivoli Storage Productivity Center with LDAP authentication, you do not have to perform these steps.

Follow these steps:

1. Log in to Tivoli Storage Productivity Center as the Superuser.
2. Expand **Administrative Services > Configuration**. Left-click **Role-to-Group Mappings**. Locate the user group name that has the user ID you want for logging in to Tivoli Storage Productivity Center and Tivoli Storage Productivity Center for Replication.
3. Add the user group name to Tivoli Storage Productivity Center for Replication Administrator role by using the Add Access wizard. Open Tivoli Storage Productivity Center for Replication using a Tivoli Storage Productivity Center for Replication Administrator user ID.
4. Click **Add Access** on the Administration page.
5. Add the user group name to Tivoli Storage Productivity Center for Replication and complete the wizard.

Backing up and recovering all the Tivoli Storage Productivity Center for Replication

There are three backup methods for IBM Tivoli Storage Productivity Center for Replication. This section provides information about these methods.

The backup methods are:

- The first backup option is to use IBM Tivoli Storage Productivity Center for Replication's import and export function to save the configuration of each IBM Tivoli Storage Productivity Center for Replication session. You would export a IBM Tivoli Storage Productivity Center for Replication session to a CSV file. The CSV file can then be used to recover a IBM Tivoli Storage Productivity Center for Replication session.
- The second backup option is to use IBM Tivoli Storage Productivity Center for Replication's high availability function. This option allows IBM Tivoli Storage Productivity Center for Replication to have a real time backup server that can take over in the event of a disaster.
- The third backup option is to use the **mkbackup** command to create a backup copy of the embedded database repository. This option does not work for DB2 databases. Any user on DB2 (z/OS or IBM Tivoli Storage Productivity Center for Replication before version 4.2) will not be able to use the **mkbackup** command.

For information about the high availability function and configuring sessions and copy sets, go to the Information Center at <http://publib.boulder.ibm.com/infocenter/tivihelp/v59r1/index.jsp>.

Administering Tivoli Storage Productivity Center

Administer Tivoli Storage Productivity Center to authorize users, start the graphical user interfaces, manage services, change passwords, and many other administrative tasks.

Checking the Tivoli Storage Productivity Center version

Check the version of Tivoli Storage Productivity Center that is installed on your system.

To check the version of Tivoli Storage Productivity Center that you have installed, complete one of the following steps:

For Windows operating systems:

Search for the software tags in the C:\Program Files\IBM\TPC\properties\version directory.

Note: There is a base version tag and, if fix packs were installed, there are also fix pack tags.

For UNIX or Linux operating systems:

Open the version.txt file that is in the *usr or opt/IBM/TPC* directory.

This is an example of the information in the version.txt file:

```
TPC V5.1.0.0 Build 20120501-2311
```

Viewing and managing services

This topic describes viewing and managing services for Data server and Device server.

Data Server services

Data Server directs all monitoring operations. Data Server services include the various services that run in the IBM Tivoli Storage Productivity Center for Data Server component.

The Data Server is the control point for scheduling functions, configuration, event management, reporting, and GUI support. The Data Server directs all of the activities related to the monitoring performed on computers with agents installed and the reporting performed on the client GUI computers.

When you expand the Data Server node, five nodes appear which represent the running services within the server. Select any of the following nodes to display information on the server identification, run time statistics, requests processed, database information, and agent statistics:

Server The component that provides the functionality of the Data Server. The Server, sometimes called Data Server, provides monitoring functions for services, data, and facilities to the network.

Scheduler

The Scheduler is the process that receives requests to schedule operations, such as the running of scheduled pings, probes, and scans. It is a multithread background server process designed to handle the scheduling and launching of jobs, based on a simple timing scheme.

GUI The main graphical user interface that enables you to do monitoring

operations, such as generate reports, check the status of agents, create and run jobs, setup monitoring for the Data Server, and so forth.

Device

Converts general commands for peripheral devices and passes them between the Server and the device. Defines I/O devices to the operating system and then controls the operation of these devices.

Agent The process on the server that sends and receives requests from agents for information gathering or processing. Agents can perform specific operations, such as scans or probes, on a regular schedule.

With Data Server services you can perform the following tasks:

- View a Data Server service log
- Configure tracing on a service
- Shut down a service
- Restart a service that is inactive

Additionally, through the Server service you can do the following:

- Configure audit logging
- Broadcast name and port information

To view the status of the server and services, expand **Administrative Services > Services > Data Server**. A green box icon next to the name of a service (for example, **Scheduler**) means that the service is active and running normally. If the service is not currently active, a red circle icon is displayed next to the name.

Refresh the Data Server list

To refresh the Data Server list, complete the following steps:

1. In the Navigation Tree pane, expand **Administrative Services > Services**.
2. Right-click **Data Server**, and click **Refresh**.

Viewing Data Server information with the Server service:

The Server service directs all Data Server information. You can view information about the Server service, including the name and port, disk space, connections, requests, and agent information.

To view Data Server information, complete the following steps:

1. In the Navigation Tree pane, expand **Administrative Services > Services > Data Server**.
2. Click **Server**. In the content pane, the Server service page opens displaying the following information:

Server Displays the name of the server.

Port Displays the port number on which the server is listening to agents.

Start Time
Displays the date and time when the server was started.

Elapsed Time
Displays the elapsed time when the server was last updated.

VM Size
Displays the disk space allocated to the virtual memory size of the server.

Network Connections

Displays the number of networks to which the server is connected.

Maximum Connections

Displays the maximum number of networks to which the server can connect.

Pending Requests

Displays the number of outstanding requests waiting for server response.

Processed Requests

Displays the number of requests processed by the server.

Database

The following fields display information about the Data Manager's repository database.

JDBC URL

Displays the location of the JDBC file used to connect to the database.

JDBC Driver

Displays the name of the JDBC driver used to connect to the database.

DB Connections

Displays the number of connections to the database.

DB Pool Count

Displays the database pool count.

Agents

The following fields provide information about the status of Data Manager agents.

Total The number of agents that are installed.

Online

The number of agents that are currently online (communicating with the server).

Offline

The number of agents that are currently offline (not communicating with the server, but were shut down normally).

Unreachable

The number of agents that are 1) not communicating with the server, and 2) provided no information to the server that they were shutting down.

Upgrading

The number of agents that are currently in the process of upgrading to the same version as the server.

Upgrade Required

The number of agents that must be upgraded to the same version as the server.

Viewing information about Data Server services:

Select any of the Data Server services to display information on that services' identification, run time statistics, requests processed, database information, and agent statistics.

To display information about a service, complete the following steps:

1. In the Navigation Tree pane, expand **Administrative Services > Services > Data Server**.
2. Click one of the following services:
 - Scheduler**
Controls the running of scheduled pings, probes, and scans.
 - GUI** Enables you to generate report requests and to create and run jobs.
 - Device**
Converts commands for peripheral devices.
 - Agent** Sends and receives requests from agents.
3. In the content pane, the following information about the selected Data server service is displayed:

Service

Whether the service is active or down.

Pending Requests

Number of requests waiting to be processed by the scheduler for the current session.

Processed Requests

Number of requests processed by the scheduler for the current session.

Idle Threads

Number of threads waiting for a process request.

Viewing a Data Server service log:

Use the content of a service log file to troubleshoot any errors that might occur during startup, processing, or shutdown of the Data Server service.

To display a service log, complete the following steps:

1. In the Navigation Tree pane, expand **Administrative Services > Services > Data Server**.
2. Right-click the name of the service and click **View Log**. The service log will open in the content pane.

Service alerts, if any, are displayed in red.

Logs are searchable by search string. Enter the string in the field provided and click the up or down arrow to search.

Configuring audit logging for the Server:

Use audit logging to record a history of user actions. This function is available for the Server only.

To configure audit logging, complete the following steps:

1. In the Navigation Tree pane, expand **Administrative Services > Services > Data Server**.
2. Right-click the **Server** node and click **Configure Audit Logging**. The Server Audit Logging Configuration window opens.

3. In the Server Audit Logging Configuration window, check the **Enable Trace** check box to enable tracing for the server component. If this box is unchecked, tracing will not be performed.
4. Specify the audit logging options:

Maximum Number of Files

Select the maximum number of trace files that will be created. When the maximum number of files has been reached, tracing will rollover and start writing to the first file. (default is 5)

The value in this field also applies to the other services for which tracing is enabled.

Maximum File Size (kilobytes)

Select the maximum size of each log file. When the current trace file has reached its maximum capacity, tracing will continue to the next available trace file as defined in the Maximum Number of Files field. (default is 20 MB).

The value in this field also applies to the other services for which tracing is enabled.

5. Click **OK**.

Broadcasting the Data Server location:

Use broadcasting to inform agents of the Data Server location. Broadcasting is available with the Server service only.

Broadcasting informs agents of the server location

To broadcast the Data Server location, complete the following steps:

1. In the Navigation Tree pane, expand **Administrative Services > Services > Data Server**.
2. Right-click the **Server** node and click **Broadcast**.

Shutting down a Data Server service:

Shut down the active process or processes associated with a service (for example, processes on the server that receive requests from the scheduler). If you shut down a service, you must restart it before the server will resume receiving requests from it.

To shut down a running service, complete the following steps:

1. In the Navigation Tree pane, expand **Administrative Services > Services > Data Server**.
2. Right-click the name of the service and click **Shutdown**.
3. Select one of the following shutdown methods:

Normal

Let all running and scheduled processes complete and then shut down cleanly. During this shutdown process, new jobs are allowed to run if they were scheduled during the time that the shutdown is taking place. Once all jobs have completed and no more jobs are scheduled to start during the shutdown time, the service will be shut down.

Immediate

Let all running processes complete but not allow scheduled jobs to

start. During this shutdown process, new jobs are *not* allowed to start if they were scheduled during the time that the shutdown is taking place. Once all running jobs have completed, the service will be shut down.

Abort Stops whatever processes are currently running and then shuts down the service.

Starting a Data Server service:

Reactivate a service after it has been stopped. The start action is available only for services that are not running.

To start a service, complete the following steps:

1. In the Navigation Tree pane, expand **Administrative Services > Services > Data Server**.
2. Right-click the name of the service and click **Start**.

Configuring tracing:

Configure tracing for the Data server, agent, scheduler, Device server, and GUI by setting the debug level and log file characteristics. The level of information saved in a log file is determined by the tracing level. Tracing settings can only be changed by users with administrator authority.

To configure tracing for IBM Tivoli Storage Productivity Center, complete the following steps:

1. In the navigation tree pane, expand **Administrative Services > Services > Data Server**.
2. Right-click on one of the following components:
 - Server
 - Agent
 - Scheduler
 - Device
 - GUI

Click **Configure Tracing**.

3. In the Server Tracing Configuration window, check the **Enable Trace** check box. Specify additional tracing options:

Level Select the level of debugging you want to perform. Select one of the following debugging level:

DEBUG_MIN

Provides minimal information about errors. This option is the default value.

DEBUG_MID

Provides more information about errors.

DEBUG_MAX

Lists all debugging trace information.

Maximum number of files

Select the maximum number of trace files that is created. When the maximum number of files has been reached, tracing rolls over and start writing to the first file. (default is five)

The value in this field also applies to the other services for the Data server for which tracing is enabled.

Maximum File Size (kilobytes)

Select the maximum size of each log file. When the current trace file has reached its maximum capacity, tracing continues to the next available trace file as defined in the Maximum Number of Files field. (default is 20 MB).

4. Click **OK**.

Tracing can be turned off by clearing the **Enable Trace** option in the Server Tracing Configuration window.

Configuring tracing

Configure tracing for the Data server, agent, scheduler, Device server, and GUI by setting the debug level and log file characteristics. The level of information saved in a log file is determined by the tracing level. Tracing settings can only be changed by users with administrator authority.

To configure tracing for IBM Tivoli Storage Productivity Center, complete the following steps:

1. In the navigation tree pane, expand **Administrative Services > Services > Data Server**.
2. Right-click on one of the following components:
 - Server
 - Agent
 - Scheduler
 - Device
 - GUI

Click **Configure Tracing**.

3. In the Server Tracing Configuration window, check the **Enable Trace** check box. Specify additional tracing options:

Level Select the level of debugging you want to perform. Select one of the following debugging level:

DEBUG_MIN

Provides minimal information about errors. This option is the default value.

DEBUG_MID

Provides more information about errors.

DEBUG_MAX

Lists all debugging trace information.

Maximum number of files

Select the maximum number of trace files that is created. When the maximum number of files has been reached, tracing rolls over and start writing to the first file. (default is five)

The value in this field also applies to the other services for the Data server for which tracing is enabled.

Maximum File Size (kilobytes)

Select the maximum size of each log file. When the current trace file

has reached its maximum capacity, tracing continues to the next available trace file as defined in the Maximum Number of Files field. (default is 20 MB).

4. Click **OK**.

Tracing can be turned off by clearing the **Enable Trace** option in the Server Tracing Configuration window.

Device server services

A **Device server** node is present in the Navigation Tree pane only if a device server is deployed in IBM Tivoli Storage Productivity Center your environment.

In the Navigation Tree pane, expand **Administrative Services > Services > Device server** to display a list of the services associated with the Device server. The following services are displayed:

Device server

Detects all the operations of the Device server.

SAN Planner

Monitors the SAN planning tools.

Event Service that monitors external events.

Log Service for configuring logging and tracing.

Configuration Analysis and History

Monitors the SAN configuration tools.

Control

Service that provides control functions.

Fabric Manager

Service that provides fabric management functions.

Disk Manager

Service that provides storage subsystem management functions.

Inband Agent

Service that maintains the list of in-band Fabric agents.

Disk Monitor

Service that monitors the storage subsystems.

Out of Band Agent

Service that maintains the list of out-of-band Fabric agents.

Element Manager

Service that provides ability to manage element managers.

Performance

Service that monitors device performance.

Configuration

Service for configuring Device server properties.

Discovery

Service that provides discovery and probe functions.

Tape Manager

Service that provides tape management functions.

Message

Service that provides internal messaging functions.

Data Access functions

Service providing data access and control functions.

Data Server Monitor

Service that provides Data server monitoring functions.

Service Manager

Service that manages the other services.

Server Virtualization Management Service

Service providing server virtualization management functions.

Device server Monitor

Service that provides Device server monitoring functions.

A green box icon next to a service name means that the service is active and running normally. If the service is not currently active, a red circle icon displays next to the name.

Changing the Device server password:

This section provides information about changing the Device server password.

To change the password, follow this procedure:

1. In the Navigation Tree pane, expand **Administrative Services > Services > Device server**.
2. Right-click the Device server node and select **Change Password**.
3. In the Change Password window, type the name of the new password twice and click **OK**.

Displaying information about a Device server service

You can view service information including start time, version, and status.

To display information about a service, follow this procedure:

1. In the Navigation Tree pane, expand **Administrative Services > Services > Device server**.
2. Click the name of the service.

Viewing a Device server log

You can use the content of the log file to troubleshoot any errors that might occur during startup, processing or shut down. Service alerts, if any, are displayed in red.

To display the log of a service, follow this procedure:

1. In the Navigation Tree pane, expand **Administrative Services > Services > Device server**.
2. Right-click the name of the service and select **View Log**.

Starting and stopping the Tivoli Storage Productivity Center services

This section provides information about how to start and stop the IBM Tivoli Storage Productivity Center services.

Note: The IBM Tivoli Integrated Portal server starts automatically after you reboot the system or after a temporary power loss on Windows. The IBM Tivoli Integrated Portal server does not start automatically on AIX or Linux; you must manually start the server.

Stopping the IBM Tivoli Storage Productivity Center services

This topic describes how to stop the IBM Tivoli Storage Productivity Center services.

Stopping the services on Windows

To stop the services on Windows, click **Start > Control Panel > Administrative Tools > Services**. Stop the following services:

IBM WebSphere Application Server V8.0 - TPCDeviceServer

IBM Tivoli Storage Productivity Center - Data Server

IBM Storage Resource Agent - *directory*

where *directory* is where the Storage Resource agent is installed. The default directory is c:\Program Files\IBM\TPC\agent.

IBM WebSphere Application Server V8.0 - TPCReplicationServer

Tivoli Integrated Portal - V2.2_TIPProfile_Port_XXXXX

where XXXXX indicates the port specified during installation.

IBM Cognos Content Database

Stopping the services on Linux

To stop the services on Linux, go to a command prompt window and enter the following commands:

Data server

```
/TPC_install_directory/data/server/tpcdsrv1 stop
```

The default directory is /opt/IBM/TPC.

Device server

```
/TPC_install_directory/device/bin/linux/stopTPCF.sh
```

Storage Resource agent

```
/SRA_install_directory/agent/bin/agent.sh stop
```

The default directory is /opt/IBM/TPC.

IBM WebSphere Application Server V8.0 - TPCReplicationServer

```
/opt/IBM/TPC/ewas/profiles/ReplicationServerProfile/bin/stopServer.sh  
replicationServer
```

Tivoli Integrated Portal

```
/tcr_install_directory/bin/stopTCRserver.sh server1 user name password
```

The *tip_install_directory* default value is /opt/IBM/tipv2.

IBM Cognos Content Database service (Tivoli Common Reporting)

```
/tcr_install_directory/bin/stopTCRserver.sh server1 username  
password
```

The *tcr_install_directory* default value is /opt/IBM/tipv2Components/TCRComponent.

Remember: When you start the Tivoli Common Reporting server, the Tivoli Integrated Portal server also starts.

Stopping the services on AIX

To stop the services on AIX, go to the command prompt window and enter the following commands:

Data server

```
/TPC_install_directory/data/server/tpcdsrv1 stop
```

Device server

```
/TPC_install_directory/device/bin/aix/stopTPCF.sh
```

The default directory is /opt/IBM/TPC.

Storage Resource agent

```
/SRA_install_directory/agent/bin/agent.sh stop
```

The default directory is /opt/IBM/TPC.

IBM WebSphere Application Server V8.0 - TPCReplicationServer

```
/usr_or_opt/IBM/TPC/ewas/profiles/ReplicationServerProfile  
/bin/stopServer.sh replicationServer
```

Tivoli Integrated Portal

```
/tip_install_directory/profiles/TIPProfile/bin/stopServer.sh server1  
-username username -password password
```

IBM Cognos Content Database service (Tivoli Common Reporting)

Follow these steps:

1. Source the environment:

```
/tcr_install_directory/bin/stopTCRserver.sh server1 username password
```

2. Run this command:

```
/usr/ibm/common/acsi/bin/acsisrv.sh -stop
```

3. Wait for the operation to complete.

Starting the Tivoli Storage Productivity Center services

This topic describes how to start the Tivoli Storage Productivity Center services.

Starting the services on Windows

To start the services on Windows, click **Start > Control Panel > Administrative Tools > Services**. Start the following services:

IBM WebSphere Application Server V8.0 - TPCDeviceServer

IBM Tivoli Storage Productivity Center - Data Server

IBM Storage Resource Agent - *directory*

where *directory* is where the Storage Resource agent is installed. The default directory is c:\Program Files\IBM\TPC\agent.

IBM WebSphere Application Server V8.0 - TPCReplicationServer

Tivoli Integrated Portal - V2.2_TIPProfile_Port_XXXXX

where *XXXXX* indicates the port specified during installation.

IBM Cognos Content Database

Starting the services on Linux

To start the services on Linux, go to a command prompt window and enter the following commands:

Data server

```
/TPC_install_directory/data/server/tpcdsrv1 start
```

The default directory is /opt/IBM/TPC.

Device server

```
/TPC_install_directory/device/bin/linux/startTPCF.sh
```

The default directory is /opt/IBM/TPC.

Storage Resource agent

```
/SRA_install_directory/agent/bin/agent.sh start
```

The default directory is /opt/IBM/TPC.

IBM WebSphere Application Server V8.0 - TPCReplicationServer

```
/opt/IBM/TPC/ewas/profiles/ReplicationServerProfile/bin/startServer.sh  
replicationServer
```

Tivoli Integrated Portal

```
/tip_install_directory/profiles/TIPProfile/bin/startServer.sh server1  
tip_install_directory default value is /opt/IBM/tipv2
```

IBM Cognos Content Database service (Tivoli Common Reporting)

Run this command:

```
/tcr_install_directory/bin/startTCRserver.sh server1
```

where the *tcr_install_directory* default value is /opt/IBM/tipv2Components/TCRComponent.

Remember: When you start the Tivoli Common Reporting server, the Tivoli Integrated Portal server also starts.

Starting the services on AIX

To start the services on AIX, go to the command prompt window and enter the following commands:

Data server

```
/TPC_install_directory/data/server/tpcdsrv1 start
```

Device server

```
/TPC_install_directory/device/bin/aix/startTPCF.sh
```

The default directory is /opt/IBM/TPC.

Storage Resource agent

```
/SRA_install_directory/agent/bin/agent.sh start
```

The default directory is /opt/IBM/TPC.

IBM WebSphere Application Server V8.0 - TPCReplicationServer

```
great  
/opt/IBM/TPC/ewas/profiles/ReplicationServerProfile/bin/startServer.sh  
replicationServer
```

Tivoli Integrated Portal

```
/tip_install_directory/profiles/TIPProfile/bin/startServer.sh server1
```

where the *tip_install_directory* default value is /opt/IBM/tipv2.

IBM Cognos Content Database service (Tivoli Common Reporting)

Run this command:

```
/tcr_install_directory/bin/startTCRserver.sh server1
```

where the `tcr_install_directory` default value is `/opt/IBM/tipv2Components/TCRComponent`.

Remember: When you start the Tivoli Common Reporting server, the Tivoli Integrated Portal server also starts.

Starting and stopping the Tivoli Integrated Portal server

The IBM Tivoli Integrated Portal server starts automatically after you reboot the system or after a temporary power loss on Windows. The server does not start automatically on AIX or Linux; you must manually start Tivoli Integrated Portal and Tivoli Common Reporting. You can manually stop and start Tivoli Integrated Portal and Tivoli Common Reporting before beginning certain configuration tasks or as needed.

Perform the following steps at the command prompt:

1. Change to the following directory:

For Windows:

```
cd c:\program files\IBM\tipv2Components\TCRComponent\bin
```

For AIX or Linux:

```
cd /opt/IBM/tipv2Components/TCRComponent/bin
```

2. To stop Tivoli Integrated Portal and Tivoli Common Reporting, enter the following command:

For Windows:

```
stopTCRserver.cmd server1
```

For AIX or Linux:

```
stopTCRserver.sh server1
```

Wait for the operation to complete.

3. To start Tivoli Integrated Portal and Tivoli Common Reporting, enter the following command:

For Windows:

```
startTCRserver.cmd
```

For AIX or Linux:

```
startTCRserver.sh
```

Wait for the operation to complete.

Tip: For Windows, you can also stop and start the services by clicking **Start > Control Panel > Administrative Tools > Services**. Stop or start the following services:

- Tivoli Integrated Portal - V2.2_TIPProfile_Port_*port_number*, where *port_number* indicates the port specified during installation
- IBM Cognos Content Database

Checking Tivoli Storage Productivity Center status

This section provides information on checking the status of Tivoli Storage Productivity Center.

Checking the status of the Data Server

This topic describes how to check the status of the Data server.

To check the status of the Data Server, complete the following steps:

1. Open the IBM Tivoli Storage Productivity Center graphical user interface (GUI).

2. In the navigation tree, click **Administrative Services > Services > Data Server**. A status icon is displayed in the navigation tree for each service.

Checking the status of the Device server

This topic describes how to check the status of the Device server.

To check the status of the Device server, complete the following steps:

1. Open the IBM Tivoli Storage Productivity Center graphical user interface (GUI).
2. In the navigation tree, click **Administrative Services > Services > Device server**. A status icon is displayed in the navigation tree for each service.

Checking the status of agents

This topic describes how to check the status of the agents.

In the navigation tree, expand **Administrative Services > Data Sources**. Click on one of the following nodes:

- **CIMOM Agents**
- **Data/Storage Resource Agents**
- **Inband Fabric Agents**
- **Out of Band Fabric Agents**

In the content pane, a list of agents is displayed. If the agents are up and running, there will be a green health status icon in the State column. For CIMOM Agents, there will be a green health status icon in the Connection Status column.

If the status icon is red, you can view the log by selecting an agent and click **View Log** for Data, Native, and Inband Fabric. This action displays the log in the content pane. If the reason that an agent is down is a connectivity problem, you might not be able to get the log files. A given discovered CIMOM appears as a red (critical) icon status until you enter valid credentials.

Increasing memory allocation

If you run out of memory for the Data server, Device server, or agent, you might want to increase the memory allocated for these components. This section describes how to increase the memory allocated for these components on systems running AIX, Linux, and Windows.

Increasing the memory allocation for the Data server

If you run out of memory for the Data server, you might want to increase the memory allocated for the Data server. This section describes how to increase the memory allocated for the Data server on systems running AIX, Linux, and Windows.

Increasing the memory allocation for the Data server running on AIX:

This section describes how to increase the memory allocation for the Data server running on AIX.

To increase the memory allocated for the Data server running on AIX, complete the following steps:

1. Log in as a user with root authority.
2. To stop the Data Server, from the command prompt, run the following command:

```
/opt/IBM/TPC/data/server/tpcdsrv1 stop
```
3. Using a text editor, open the **tpcdsrv1** file.

4. Locate the following line:

```
exec $JAVAEXE -Dsun.net.inetaddr.ttl=300 -Xrs -Xmx XXXXm  
-cp $CLASSPATH com.tivoli.itsrm.server.Server &
```

where *XXXXm* is the memory allocated for the Data server. By default, this is 1024m (1024 MB).

5. Increase the memory allocated for the Data server. For example, to increase the memory to 1536 MB, change the line to read as follows:

```
exec $JAVAEXE -Dsun.net.inetaddr.ttl=300 -Xrs -Xmx1536m  
-cp $CLASSPATH com.tivoli.itsrm.server.Server &
```
6. Save the modified **tpcdsrv1** file.
7. To restart the Data server, run the following command:

```
/opt/IBM/TPC/data/server/tpcdsrv1 start
```

Increasing the memory allocation for the Data server running on UNIX or Linux:

This section describes how to increase the memory allocation for the Data server running on Linux.

To increase the memory allocated for the Data server running on HP-UX, Linux, or Sun Solaris, complete the following steps:

1. Log in as a user with root authority.
2. To stop the Data Server, from the command prompt, run the following command:

```
/opt/IBM/TPC/data/server/tpcdsrv1 stop
```
3. Using a text editor, open the **tpcdsrv1** file.
4. Locate the following line:

```
exec $JAVAEXE -Dsun.net.inetaddr.ttl=300 -Xrs -Xmxxxxx -cp  
$CLASSPATH com.tivoli.itsrm.server.Server &
```

where *xxxx* is the memory allocated for the Data server. By default, this is 1024m (1024 MB).

5. Increase the memory allocated for the Data server. For example, to increase the memory to 1536 MB, change the line to read as follows:

```
exec $JAVAEXE -Dsun.net.inetaddr.ttl=300 -Xrs -Xmx1536m -cp  
$CLASSPATH com.tivoli.itsrm.server.Server &
```
6. Save the modified **tpcdsrv1** file.
7. To restart the Data server, run the following command:

```
/opt/IBM/TPC/data/server/tpcdsrv1 start
```

Increasing memory allocation for Data server running on Windows:

This section describes how to increase the memory allocation for the Data server running on Windows.

To increase the amount of memory available to the server, complete the following steps:

1. Select **Start > Run**. The Run window is displayed.
2. Type **regedit** in the Open: field and click **OK**. The Registry Editor window is displayed.

3. Expand the **HKEY_LOCAL_MACHINE > SOFTWARE > IBM > TSRM** folder on the left-hand side of the Registry Editor window.
4. Right-click the **1** folder and select **New > String Value** from the pop-up menu.
5. Type **SRVJPARMS** as the name of the string.
6. Right-click the name of the string and select **Modify** from the pop-up menu.
7. Enter **-Xmx<###>m** in the Value data field, where **###** represents the number of megabytes for the server's maximum heap size. The default size is 256. Click **OK**. The largest possible value for the maximum heap size is 1536 megabytes. If the value is set to something larger than 1536, that value will be ignored and 1536 megabytes will be used as the maximum heap size.
8. Stop and restart the server to have the changes take effect. To stop the server, complete the following steps:
 - a. Go to **Start > Settings > Control Panel > Administrative Tools > Services**. The Services window is displayed.
 - b. Right-click on **IBM Tivoli Storage Productivity Center - Data Server** service and click **Stop** from the pop-up menu. To restart the server, complete the following steps:
 - 1) Go to **Start > Settings > Control Panel > Administrative Tools > Services**. The Services window is displayed.
 - 2) Right-click on **Tivoli Storage Productivity Center - Data Server** service and click **Start** from the pop-up menu.

Increasing the memory allocation for the Device server

This topic describes how to increase the memory allocated for the Device server.

1. Stop the Device server.
2. Open the `server.xml` file in a text editor. This file is located at

```
directory/ewas/profiles/DeviceServerProfile/config/cells/DeviceServerCell/nodes/DeviceServerNode/servers/deviceServer
```

where *directory* is where IBM Tivoli Storage Productivity Center is installed.
3. Search for `JVMArguments` and change the value of the `-Xmx1436m` parameter.
4. Save the modified `server.xml` file.
5. Restart the Device server.

Setting timeouts values for the Device server

If a probe or discovery of a storage subsystem times out before the operation completes, you can increase the timeout values for the Device server.

If a probe or discovery of a storage subsystem times out before the operation completes, you receive the following error message:

```
HWN021650E Encountered timeout while connecting to CIMOM IP:port.
Check the CIMOM or increase timeout value.
```

where *IP* is the IP address, and *port* is the port number. If you determine that the Common Information Model Object Manager (CIMOM) is not the cause of the problem, you can use the command-line interface (CLI) to increase the timeout values for the Device server.

For those storage systems that use native interfaces to connect to Tivoli Storage Productivity Center you see this error message:

```
HWN020103E The external process exceeded the timeout limit and was cancelled.
```

The following storage systems use native interfaces to connect to Tivoli Storage Productivity Center:

- System Storage DS8000
- SAN Volume Controller
- The XIV system
- Storwize V7000
- Storwize V7000 Unified
- IBM SONAS

1. Run the **getdscfg** command to determine the current values of the timeout properties. From the command prompt, enter the following command:

```
cli>tpctool getdscfg -user user -pwd password -url host:port
-property timeout_property
```

where:

- *user* is an IBM Tivoli Storage Productivity Center user ID.
- *password* is the password for the Tivoli Storage Productivity Center user ID.
- *host* is the host name or IP address, and *port* is a valid port number for the HTTP service of the Device server. The default value for *port* is usually 9550.
- *timeout_property* is one of the following strings:
 - http.timeout
 - CIMClientWrapper.Timeout
 - Probe.Timeout.Array
 - Probe.Timeout.InBand
 - Probe.Timeout.LMM
 - Discovery.Timeout
 - CIMOMManager.TestConnectionTimeout

Important: Timeout properties are displayed in milliseconds. If the value is 0 (zero), it means that there is no timeout.

For the storage systems that use the native interface, the *timeout_property* strings are:

- NAPI.Timeout.TestConnection
- NAPI.Timeout.Probe
- NAPI.Timeout.EventPoll
- *timeout_value* is the value for the timeout.

2. Run the **setdscfg** command to increase the timeout value. Run the following command:

```
cli>tpctool setdscfg -user user -pwd password -url host:port
-property timeout_property timeout_value
```

For more information about **tpctool**, see the *Tivoli Storage Productivity Center Command-Line Interface Reference*. You also can view help from the command line by issuing the command with the **-help** option.

Changing passwords

This section provides information about changing passwords.

If you installed IBM Tivoli Storage Productivity Center using the typical installation and used the same DB2 user ID and password for the items IBM Tivoli Storage Productivity Center requires, then when you change the DB2 password, you must also change the passwords for the items that the DB2 password applies to. For example, the DB2 administrative password might also apply to the following items:

- Database administration user ID and password (for the Data Server or Device server to connect to the database)
- Database user ID and password to create the database schema
- Host authentication password (for the Storage Resource agents to communicate with the Device server)
- Storage Resource agent service login user ID and password (for Windows only, if this user ID does not exist)
- WebSphere administration user ID and password (for the Device server to communicate with embedded WebSphere if the user ID does not exist). This is the case only if you select OS authentication during the IBM Tivoli Storage Productivity Center installation. If you chose LDAP authentication, then the WebSphere administration user ID and password are set to the LDAP TPC Administrator username and password.

Changing passwords by using the password tool

The password tool changes the passwords for DB2, Tivoli Storage Productivity Center, and IBM Tivoli Integrated Portal so that they can continue to authenticate to one another whenever you change a password.

Important: If you are logged on to Tivoli Storage Productivity Center by using a domain user account, which is also a member of the local administrator group, when you run the change password tool, passwords are not updated. If you run the tool by using a local OS user account, and an error occurs, complete these steps.

To run the password tool when you log in by using a domain user account, choose one of the following steps:

- Right-click the `changepasswords.bat` file and select **Run as administrator**.
- Complete the following steps:
 1. Select **Start > Administrative Tools > Local Security Policy**.
 2. On the Local Security Policy window, disable **User Account Control: Run all administrators in Admin Approval Mode**.
 3. Restart your computer.

Single server installation where components use the same logon credentials:

Use the password tool to change the password for DB2, Tivoli Storage Productivity Center, and IBM Tivoli Integrated Portal when they are installed on the same server, and use the same user name and password.

Before you use the password tool, ensure that you know the existing password or passwords that you want to change.

1. Complete the following steps:

For Windows operating systems where Tivoli Storage Productivity Center is configured for OS authentication:

- a. From the desktop, click **Start > Control Panel**.

- b. Double-click **User Accounts**.
- c. Click **Change your password**.
- d. Enter the current password, and then enter and confirm the new password. Click **Change password**. Close the User Accounts window.

For AIX or Linux operating systems where Tivoli Storage Productivity Center is configured for OS authentication:

Log in with the DB2 user ID, and run the `passwd` command.

Tip: To change other user credentials, run the `passwd username` command.

Tip: To find out how to change the LDAP user password, see your LDAP server documentation.

2. Open a command prompt window and change the directory to the following default directory:

On Windows operating systems:

`C:\Program Files\IBM\TPC\service`

On Linux or UNIX operating systems:

`/opt/IBM/TPC/service`

3. Start the password tool by running the following program:

On Windows operating systems:

`changepasswords.bat`

On Linux or AIX operating systems:

`changepasswords.sh`

4. From the "Choose the password to change" window, click **Change Tivoli Integrated Portal password** and click **OK**.
5. Complete the following steps:
 - a. Enter and confirm the new password, ensuring that it is the same as the new password that you entered in step 1.
 - b. Ensure that the **Restart servers** option is selected. Click **OK**.
 - c. In response to the following message, click **Yes**:
Are you sure you want to change the password?
 - d. When the process is completed, click **Back to Main**.
6. To change the password for Tivoli Storage Productivity Center, click **Change Tivoli Storage Productivity Center server and DB2 passwords** and click **OK**.
 - a. Enter and confirm the new password, ensuring that it is the same as the new password that you entered in step 1. Click **OK**.
 - b. In response to the following message, click **Yes**:
Are you sure you want to change the password?

Tip: After you click **Yes**, if the DB2 servers are already started, the following errors might be displayed in a command prompt window. Ignore them and continue with the procedure.

```
Changing DB2 User password for Data Server...
Changing DB2 User password for Device Server...
```

- c. When the process is completed, click **Back to Main**.

Tip: To verify that the password changes were completed successfully, review the `PWTool.log` file that is in the `TPC_installation_directory\`

service directory, where *TPC_installation_directory* is the directory where Tivoli Storage Productivity Center is installed.

7. Exit the password tool.

Related tasks:

“Single server installation where components use different logon credentials”

Use the password tool to change the passwords for DB2, Tivoli Storage Productivity Center, and IBM Tivoli Integrated Portal when they are installed on the same server, but use different user names and passwords.

“Multiple server installation where Tivoli Integrated Portal is remote” on page 211
Change the passwords for DB2, Tivoli Storage Productivity Center, and IBM Tivoli Integrated Portal when they are installed on two servers, with Tivoli Integrated Portal on server *A*, and DB2 and Tivoli Storage Productivity Center on server *B*.

“Multiple server installation where DB2 is remote” on page 213

Change the passwords for DB2, Tivoli Storage Productivity Center, and IBM Tivoli Integrated Portal when they are installed on two servers, with Tivoli Integrated Portal and Tivoli Storage Productivity Center on server *A*, and DB2 on server *B*.

Single server installation where components use different logon credentials:

Use the password tool to change the passwords for DB2, Tivoli Storage Productivity Center, and IBM Tivoli Integrated Portal when they are installed on the same server, but use different user names and passwords.

Before you use the password tool, ensure that you know the existing password or passwords that you want to change.

1. Complete the following steps:

On Windows operating systems where Tivoli Storage Productivity Center is configured for OS authentication:

- a. From the desktop, click **Start > Control Panel**.
- b. Double-click **User Accounts**.
- c. Click **Change your password**.
- d. Enter the current password, and then enter and confirm the new password. Click **Change password**. Close the User Accounts window.

On AIX or Linux operating systems where Tivoli Storage Productivity Center is configured for OS authentication:

When you are logged in with the DB2 user ID, run the **passwd** command. To change other user credentials, run the **passwd username** command.

Tip: To find out how to change the LDAP user password, refer to your LDAP server documentation.

2. Open a command prompt window and change the directory to the following default directory:

On Windows operating systems:

C:\Program Files\IBM\TPC\service

On Linux or UNIX operating systems:

/opt/IBM/TPC/service

3. Start the password tool by running the following program:

On Windows operating systems:

changepasswords.bat

On Linux or AIX operating systems:

changepasswords.sh

4. From the “Choose the password to change” window, click **Change Tivoli Integrated Portal password** and click **OK**.
5. To change the password, complete the following steps:
 - a. Enter and confirm the new password and click **OK**.
 - b. In response to the following message, click **Yes**:
Are you sure you want to change the password?
 - c. When the process is completed, click **Back to Main**.
6. To change the password for Tivoli Storage Productivity Center, click **Change Tivoli Storage Productivity Center server passwords** and click **OK**.
7. Complete the following steps:
 - a. Enter and confirm the new password and click **OK**.
 - b. In response to the following message, click **Yes**:
Are you sure you want to change the password?
 - c. When the process is completed, click **Back to Main**.
8. To change the password for DB2, click **Change DB2 password** and click **OK**.
9. Complete the following steps:
 - a. Enter and confirm the new password. Ensure that the **Restart servers** check box is selected and click **OK**.
 - b. In response to the following message, click **Yes**:
Are you sure you want to change the password?

Tip: After you click **Yes**, if the DB2 servers are already started, the following errors might be displayed in a command prompt window. Ignore them and continue with the procedure.

```
Changing DB2 User password for Data Server...  
Changing DB2 User password for Device Server...  
OpenServiceW failed, error code = 5  
OpenServiceW failed, error code = 5  
OpenServiceW failed, error code = 5  
OpenServiceW failed, error code = 5
```

- c. When the process is completed, click **Back to Main**.

Tip: To verify that the password changes were completed successfully, review the `PWTool.log` file that is in the `TPC_installation_directory\service directory`, where `TPC_installation_directory` is the directory where Tivoli Storage Productivity Center is installed.

Important: For Windows operating systems, if Tivoli Integrated Portal fails to stop and restart, restart your system manually.

Related tasks:

Change the passwords for DB2, Tivoli Storage Productivity Center, and IBM Tivoli Integrated Portal when they are installed on two servers, with Tivoli Integrated Portal on server *A*, and DB2 and Tivoli Storage Productivity Center on server *B*.

“Multiple server installation where DB2 is remote” on page 213

Change the passwords for DB2, Tivoli Storage Productivity Center, and IBM Tivoli Integrated Portal when they are installed on two servers, with Tivoli Integrated Portal and Tivoli Storage Productivity Center on server *A*, and DB2 on server *B*.

Multiple server installation where Tivoli Integrated Portal is remote:

Change the passwords for DB2, Tivoli Storage Productivity Center, and IBM Tivoli Integrated Portal when they are installed on two servers, with Tivoli Integrated Portal on server *A*, and DB2 and Tivoli Storage Productivity Center on server *B*.

Before you use the password tool, ensure that you know the existing password or passwords that you want to change.

1. On the server where DB2 and Tivoli Storage Productivity Center are installed, complete the following steps to change the DB2 and Tivoli Storage Productivity Center passwords:

On Windows operating systems where Tivoli Storage Productivity Center is configured for OS authentication:

- a. From the desktop, click **Start > Control Panel**.
- b. Double-click **User Accounts**.
- c. Click **Change your password**.
- d. Enter the current password, and then enter and confirm the new password. Click **Change password**. Close the User Accounts window.

For AIX or Linux operating systems where Tivoli Storage Productivity Center is configured for OS authentication:

When you are logged in with the DB2 user ID, run the **passwd** command. To change other user credentials, run the **passwd username** command.

Tip: To find out how to change the LDAP user password, refer to your LDAP server documentation.

2. On the server where Tivoli Integrated Portal is installed, complete the following tasks:

On Windows operating systems where Tivoli Storage Productivity Center is configured for OS authentication:

- a. From the desktop, click **Start > Control Panel**.
- b. Double-click **User Accounts**.
- c. Click **Change your password**.

- d. Enter the current password, and then enter and confirm the new password. The new password can be different from the password that you created in step 1. Click **Change password**. Close the User Accounts window.

For AIX or Linux operating systems where Tivoli Storage Productivity Center is configured for OS authentication:

When you are logged in with the DB2 user ID, run the **passwd** command. To change other user credentials, run the **passwd *username*** command.

3. On the same server, open a command prompt window and change the directory to the following default directory:

On Windows operating systems:

C:\Program Files\IBM\TPC\service

On Linux or UNIX operating systems:

/opt/IBM/TPC/service

4. Start the password tool by running the following program:

On Windows operating systems:

changepasswords.bat

On Linux or AIX operating systems:

changepasswords.sh

5. From the “Choose the password to change” window, click **Change Tivoli Integrated Portal password** and click **OK**.
6. Complete the following steps:
 - a. Enter and confirm the new password and click **OK**.
 - b. In response to the following message, click **Yes**:
Are you sure you want to change the password?
 - c. When the process is completed, click **Back to Main**.
7. On the same server, from the “Choose the password to change” window, click **Change DB2 password** and click **OK**.
8. Complete the following steps:
 - a. Enter and confirm the new password, ensuring that it is the same as the new password that you entered in step 1. Ensure that the **Restart servers** check box is selected and click **OK**.
 - b. In response to the following message, click **Yes**:
Are you sure you want to change the password?

Tip: After you click **Yes**, if the DB2 servers are already started, the following errors might be displayed in a command prompt window. Ignore them and continue with the procedure.

```
Changing DB2 User password for Data Server...
Changing DB2 User password for Device Server...
OpenServiceW failed, error code = 5
OpenServiceW failed, error code = 5
OpenServiceW failed, error code = 5
OpenServiceW failed, error code = 5
```

- c. When the process is completed, click **Back to Main**.
9. On the server where Tivoli Storage Productivity Center and DB2 are installed, from the “Choose the password to change” window, click **Change Tivoli Storage Productivity Center server passwords** and click **OK**.
10. Complete the following steps:

- a. Enter and confirm the new password, ensuring that it is the same as the new password that you entered in step 1. Click **OK**.
 - b. In response to the following message, click **Yes**:
Are you sure you want to change the password?
 - c. When the process is completed, click **Back to Main**.
11. On the same server, click **Change DB2 password** and click **OK**.
 12. Complete the following steps:
 - a. Enter and confirm the new password, ensuring that it is the same as the new password that you entered in step 1. Click **OK**.
 - b. In response to the following message, click **Yes**:
Are you sure you want to change the password?

Tip: After you click **Yes**, if the DB2 servers are already started, the following errors might be displayed in a command prompt window. Ignore them and continue with the procedure.

```
Changing DB2 User password for Data Server...
Changing DB2 User password for Device Server...
OpenServiceW failed, error code = 5
OpenServiceW failed, error code = 5
OpenServiceW failed, error code = 5
OpenServiceW failed, error code = 5
```

- c. When the process is completed, click **Back to Main**.
13. Exit the password tool.

Tip: To verify that the password changes were completed successfully, review the `PWTool.log` file that is in the `TPC_installation_directory\service` directory, where `TPC_installation_directory` is the directory where Tivoli Storage Productivity Center is installed.

Multiple server installation where DB2 is remote:

Change the passwords for DB2, Tivoli Storage Productivity Center, and IBM Tivoli Integrated Portal when they are installed on two servers, with Tivoli Integrated Portal and Tivoli Storage Productivity Center on server *A*, and DB2 on server *B*.

Before you use the password tool, ensure that you know the existing password or passwords that you want to change.

1. On the server where DB2 is installed, do the following steps:

For Windows operating systems where Tivoli Storage Productivity Center is configured for OS authentication:

- a. From the desktop, click **Start > Control Panel**.
- b. Double-click **User Accounts**.
- c. Click **Change your password**.
- d. Enter the current password, and then enter and confirm the new password. Click **Change password**. Close the User Accounts window.

For AIX or Linux operating systems where Tivoli Storage Productivity Center is configured for OS authentication:

When you are logged in with the DB2 user ID, run the **passwd** command. To change other user credentials, run the **passwd username** command.

Tip: To find out how to change the LDAP user password, refer to your LDAP server documentation.

2. On the server where Tivoli Integrated Portal and Tivoli Storage Productivity Center are installed, do the following steps:

For Windows operating systems where Tivoli Storage Productivity Center is configured for OS authentication:

- a. From the desktop, click **Start > Control Panel**.
- b. Double-click **User Accounts**.
- c. Click **Change your password**.
- d. Enter the current password, and then enter and confirm the new password. The new password can be different from the password that you created in step 1. Click **Change password**. Close the User Accounts window.

For AIX or Linux operating systems where Tivoli Storage Productivity Center is configured for OS authentication:

When you are logged in with the DB2 user ID, run the **passwd** command. To change other user credentials, run the **passwd username** command.

3. On the same server, open a command prompt window and change the directory to the following default directory:

On Windows operating systems:

C:\Program Files\IBM\TPC\service

On Linux or UNIX operating systems:

/opt/IBM/TPC/service

4. Start the password tool by running the following program:

On Windows operating systems:

changepasswords.bat

On Linux or AIX operating systems:

changepasswords.sh

5. From the “Choose the password to change” window, click **Change Tivoli Integrated Portal password** and click **OK**.

6. Complete the following steps:

- a. Enter and confirm the new password and click **OK**.
- b. In response to the following message, click **Yes**:
Are you sure you want to change the password?

- c. When the process is completed, click **Back to Main**.
7. On the same server, from the “Choose the password to change” window, click **Change Tivoli Storage Productivity Center server passwords** and click **OK**.
8. Complete the following steps:
 - a. Enter and confirm the new password, ensuring that it is the same as the new password that you entered in step 2. Click **OK**.
 - b. In response to the following message, click **Yes**:
Are you sure you want to change the password?
 - c. When the process is completed, click **Back to Main**.
9. On the server where DB2 is installed, from the “Choose the password to change” window, click **Change DB2 password** and click **OK**.
10. Complete the following steps:
 - a. Enter and confirm the new password, ensuring that it is the same as the new password that you entered in step 1. Ensure that the **Restart servers** check box is selected, and click **OK**.
 - b. In response to the following message, click **Yes**:
Are you sure you want to change the password?

Tip: After you click **Yes**, if the DB2 servers are already started, the following errors might be displayed in a command prompt window. Ignore them and continue with the procedure.

```
Changing DB2 User password for Data Server...
Changing DB2 User password for Device Server...
OpenServiceW failed, error code = 5
OpenServiceW failed, error code = 5
OpenServiceW failed, error code = 5
OpenServiceW failed, error code = 5
```

- c. When the process is completed, click **Back to Main**.
11. Click **Exit program**.
12. On the server where Tivoli Integrated Portal and Tivoli Storage Productivity Center are installed, from the “Choose the password to change” window, click **Change DB2 password**.
13. Complete the following steps:
 - a. Enter and confirm the new password, ensuring that it is the same as the new password that you entered in step 1. Ensure that the **Restart servers** check box is selected, and click **OK**.
 - b. In response to the following message, the following message, click **Yes**:
Are you sure you want to change the password?

Tip: After you click **Yes**, if the DB2 servers are already started, the following errors might be displayed in a command prompt window. Ignore them and continue with the procedure.

```
Changing DB2 User password for Data Server...
Changing DB2 User password for Device Server...
OpenServiceW failed, error code = 5
OpenServiceW failed, error code = 5
OpenServiceW failed, error code = 5
OpenServiceW failed, error code = 5
```

- c. When the process is completed, click **Back to Main**.
14. Exit the password tool.

Important: For the changes to take effect, you might have to manually restart the Data server, the Device server, or Tivoli Integrated Portal, or all three.

Tip: To verify that the password changes were completed successfully, review the `PWTool.log` file that is in the `TPC_installation_directory\service` directory, where `TPC_installation_directory` is the directory where Tivoli Storage Productivity Center is installed.

Related tasks:

Changing passwords by editing configuration files

Changing the DB2 user password for the Device server:

This section provides information about changing the DB2 user password for the Device server.

If you change the DB2 user password, follow these steps to change it for the Device server:

1. Go to the `TPC_installation_dir\cli` directory and run the following command:
`tpctool encrypt password`

This encrypts the password.

2. Copy the encrypted password to the following file: `TPC_installation_dir\device\conf\tsnmdbparms.properties` Replace this password:
`tivoli.sanmgmt.jdbc.dbPassword=<encrypted_password>`
3. Restart the Device server.

Changing the DB2 password for the Data Server:

This section provides information about changing the DB2 password for the Data Server.

To change the DB2 password, complete the following steps:

1. From a command prompt, change to the directory where the file `repository.config` resides in the IBM Tivoli Storage Productivity Center installation path. For example:
`c:\Program Files\IBM\TPC\data\config\` (Windows)
`/<usr or opt>/IBM/TPC/data/config/` (AIX or Linux)
2. Run the following command for the Data server. This assumes that the Tivoli Storage Productivity Center directory is in `C:\Program Files\IBM\TPC` for Windows.

```
"C:\Program Files\IBM\TPC\data\config>"program files"\
ibm\tpc\jre\bin\java -classpath "\program files\ibm\tpc\data\server\lib\
TSRMSrv.zip" com.tivoli.itsrm.repository.Transform
-p <new_password> repository.config
```

3. Stop and then restart the Data Server.
4. Start the Tivoli Storage Productivity Center GUI.

Checking for a fully qualified host name

IBM Tivoli Storage Productivity Center requires fully qualified host names. Some machines might be configured to return a short host name, such as **ddunham** instead of a fully qualified host name, such as **ddunham.myorg.mycompany.com**. This topic provides information on how to check for a fully qualified host name.

Checking for a fully qualified host name for Windows systems

This topic provides information on how to verify a fully qualified host name for Windows systems.

To verify a fully qualified host name, complete the following steps:

1. On the desktop, right-click **My Computer**.
2. Click **Properties**.
3. The System Properties panel is displayed.
4. On the Computer Name tab, click **Change**.
5. The Computer Name Changes panel is displayed. Enter your fully qualified host name in the Computer name field. Click **More**.
6. The DNS Suffix and NetBIOS Computer Name panel is displayed. Verify that the **Primary DNS suffix** field displays a domain name. Click **OK**.
7. Click **OK** on the Computer Name Changes panel.
8. Click **Apply** and close the System Properties panel.

Checking for a fully qualified host name for AIX systems

This topic provides information on how to verify a fully qualified host name for AIX.

The default domain name search order is as follows:

1. Domain Name System (DNS) server
2. Network Information Service (NIS)
3. Local /etc/hosts file.

If the /etc/resolv.conf file does not exist, the /etc/hosts file is used. If only the /etc/hosts file is used, the fully qualified computer name must be the first one that is listed after the IP address.

Verify that the /etc/resolv.conf file exists and contains the appropriate information, such as:

```
domain mydivision.mycompany.com
nameserver 123.123.123.123
```

If NIS is installed, the /etc/irs.conf file overrides the system default. It contains the following information:

```
hosts = bind,local
```

The /etc/netsvc.conf file, if it exists, overrides the /etc/irs.conf file and the system default. It contains the following information:

```
hosts = bind,local
```

If the NSORDER environment variable is set, it overrides all of the preceding files. It contains the following information:

```
export NSORDER=bind,local
```

Checking for a fully qualified host name for Linux systems

This topic provides information on how to verify a fully qualified host name for Linux.

Linux uses a resolver library to obtain the IP address corresponding to a host name. The `/etc/host.conf` file specifies how names are resolved. The entries in the `/etc/host.conf` file tell the resolver library what services to use, and in what order, to resolve names. Edit the `host.conf` file using the `vi` editor to add the following lines:

```
# Lookup names through DNS first then fall back to /etc/hosts.
order bind,hosts
# Machines with multiple IP addresses.
multi on
# Check for IP address spoofing.
nospoof on
```

The **order** option indicates the order of services. The sample entry specifies that the resolver library should first consult the name server to resolve a name and then check the `/etc/hosts` file. It is recommended to set the resolver library to first check the name server, `bind` file, and then the `hosts` file (`hosts`) for better performance and security on all your servers. You must have the DNS and BIND software installed for this configuration to work.

The **multi** option determines whether a host in the `/etc/hosts` file can have multiple IP addresses. Hosts that have more than one IP address are said to be multihomed, because the presence of multiple IP addresses implies that the host has several network interfaces.

The **nospoof** option takes care of not permitting spoofing on this machine. IP-Spoofing is a security exploit that works by tricking computers into a trust relationship that you are someone that you really are not. In this type of attack, a machine is set up to look like a legitimate server and then issue connections and other types of network activities to legitimize end systems, other servers, or large data repository systems. This option must be set ON for all types of servers.

Checking for a fully qualified host name for Oracle Solaris

This topic provides information about how to verify a fully qualified host name for Oracle Solaris systems.

Verify that the `/etc/resolv.conf` file exists and contains the appropriate information, such as:

```
domain mydivision.mycompany.com
nameserver 123.123.123.123
```

A short name is used if the `/etc/nsswitch.conf` file contains a line that begins as follows and if the `/etc/hosts` file contains the short name for the computer:

```
hosts: files
```

To correct this problem, follow these steps:

1. Change the line in the `/etc/nsswitch.conf` file to the following:

- ```
hosts: dns nis files
```
2. Enter the following command to stop the **inet** service:  
`/etc/init.d/inetsvc stop`
  3. Enter the following command to restart the **inet** service:  
`/etc/init.d/inetsvc start`

## Granting local administrative privileges to a domain account

For Windows users, the user account which the Storage Resource agent runs under requires local administrative rights. Because these rights are not necessarily guaranteed for domain users in a Windows domain environment, this topic provides information about how to grant local administrative rights for domain users. Using this procedure, you do not have to manually process each machine in the domain.

**Note:** These steps are for a Windows system that is a member of a Windows domain and not for the Windows Domain Primary Domain Controller.

To use Group Policy to grant local administrative privileges to a domain account, complete the following steps:

1. On the domain controller, go to **Administrative Tools > Active Directory Users and Computers** (you must be running with Domain Administrator privileges).
2. Right-click on the Organizational Unit (OU) upon which you want to apply the Group Policy. Click **Properties**.
3. The Group Policy Properties panel is displayed. Select the Group Policy tab and click **New** to create a Group Policy.
4. Designate a name for the new Group Policy. Select the new Group Policy and click **Edit**.
5. The Group Policy Object Editor panel is displayed. Go to **New Group Policy Object *your\_policy* > Computer Configuration > Windows Settings > Security Settings > Restricted Groups**. Right-click on **Restricted Groups**. Click **Add Group**.
6. For example, name the new group "Administrators." Under "Properties", add the user "Administrator", and the domain accounts or groups upon which you want the Group Policy in effect for. For example, you can add "TPC\tapeadmin", "TPC\tapegroup", and "TPC\TestGroup". Click **OK**.
7. Add these user rights to the domain account:
  - Act as part of the operating system
  - Log on as a service

In the Group Policy Object Editor, go to **New Group Policy Object *your\_policy* > Computer Configuration > Windows Settings > Security Settings > Local Policies > User Rights Assignments**. In the content pane, select "Log on as a service" and double-click. Add the domain user for whom you are granting user rights and click **OK**. Repeat this step for "Act as part of the operating system."

8. The group policy is now enforced for the Organizational Unit to include the domain accounts and groups specified under the local Administrators group on each computer in the Organizational Unit. In addition, the domain user has been granted the necessary rights. To verify the user rights, log in to a domain computer and open the Computer Management console. Select **Groups**, double-click the Administrators group, and verify the membership of the domain users.

## Importing SSL certificates for VMware

If your VMware uses SSL certificates, you must import the SSL certificates for VMware Virtual Infrastructure Data Source.

If your VMware uses SSL certificates, you must follow these steps before you can get data from the VMware Virtual Infrastructure. Complete the following steps:

1. Open a browser. Point the browser to the following:  
`https://ESX_server_IP_address/host`
2. You will see a list of Configuration files. Right-click on **ssl\_cert**. Save the file as `ESX_machine_name.crt`.

**Note:** Depending on your browser, you would save the file using **Save Target as** (for Internet Explorer) or **Save Link as** (for Firefox). Use this file to import the certificate.

3. The VirtualCenter Server uses a self-generated SSL certificate located in the following directory:

```
C:\Documents and Settings\All Users\Application Data\
VMware\VMware VirtualCenter\SSL\rui.crt
```

Install these certificates into a certificate store on the client machine. Copy the certificate file or files from the servers to a directory on the client machine.

Enter the **keytool** command:

```
TPC_installation_directory/jre/bin/keytool -import
-file certificate-filename
-alias server-name
-keystore vmware.jks
```

For example, run this command:

```
TPC_installation_directory/jre/bin/keytool -import
-file vc-server1.crt -alias vc-server1
-keystore vmware.jks
```

Enter a password for the keystore. Enter **yes** to import the certificate.

The truststore will be located in the Device server configuration directory:

```
TPC_installation_directory/device/conf
```

If the truststore was generated in another directory, it must be copied to `TPC_installation_directory/device/conf`. The truststore is called **vmware.jks**. The truststore will automatically be defined at service startup time as this property in the Device server JVM:

```
javax.net.ssl.trustStore System
```

4. Add a VMware data source using the URL, user name, and password for the service console.
5. Run a discovery job for the VMware data source.
6. Run a probe job for the VMware data source.
7. You will now be able to display VMware Virtual Infrastructure in reports and the topology viewer.

**Important:** For Linux: If you install Java when you install the operating system, the operating system version of the **keytool** command is installed. The operating system level of **keytool** might not be the correct version for Tivoli Storage Productivity Center to use. To create the `vmware.jks` file correctly, use the **keytool** located in `/opt/IBM/TPC/jre/bin`.

## SQL access to Tivoli Storage Productivity Center views

IBM Tivoli Storage Productivity Center stores the information collected by data collection schedules in its DB2 database repository. This information is organized into a set of accessible views. You can use Structured Query Language (SQL) to retrieve the information from these views to create custom reports or for use within other applications.

**Prerequisite:** See the *Planning* section in the Tivoli Storage Productivity Center Information Center for information about the requirements when retrieving data from views in the database repository.

A view is a logical table that consists of data that is generated by a query. A view is based on an underlying set of base tables in the database repository, and the data in a view is determined by a SELECT statement that is run on those base tables. The data collected Tivoli Storage Productivity Center is organized into the following sets of views that you can access in the database repository:

### Storage entity views

These views include detailed information about the properties of storage entities. For example, the name, disk space, and available disk space for a storage subsystem. Information about the following storage entities are available in views in the database repository:

- Storage entity views: Hosts, volume groups, disks, virtual disks, external storage volumes, disk paths, virtual disk paths, controllers, logical volumes, file systems, clusters, cluster resource groups, hypervisors, virtual machines, virtual machine disks, hypervisor volumes, host virtual files, hypervisor partitions, MAC addresses, files, file types, directories, exports, OS users, OS user groups, IP addresses, Windows domains, and Storage Resource agents.
- Host relationship views:
  - Logical volume to host disk
  - Logical volume to logical volume (Parent and child logical volume relationships)
  - Computer to storage entity (disk or logical volume)
  - Filesystem to logical volume

(for example, the relationship between a logical volume and a host disk)

- Database views: Database instances, database containers, database archive logs, database control files, database datafiles, database devices, database log files, database log groups, database segments, database tables, database tablespaces
- Storage subsystem views: Storage subsystems, storage virtualizers, storage pools, extents, volumes, disk drives, disk groups, element managers, nodes, backend disks, storage virtualizer I/O groups, volume paths, array sites, ranks
- Storage subsystem relationship views:
  - Disk drive to storage extent
  - Storage volume to storage extent
  - Volume to disk drive
  - Storage volume to backend disk
- NAS Filers
- Tape library views: Tape libraries, tape cartridges, tape drives, tape frames, tape I/O ports, tape media changers, tape media locations

- Fabric views: Fabrics, nodes, peripheral entities, port to port connections, switches, switch blades, zones, zone members, zone sets, zone aliases, FC ports, host bus adapters
- Fabric relationship views:
  - Blade to FC port
  - Node to HBA, Node to port
  - Peripheral entity to node
  - Switch to port
  - Zone to alias, Zone to zone member, Zone to node, Zone to member
  - Zone set to zone
  - Zone alias to node
  - Alias to member
  - Fabric to switch, Fabric to zoneset, Fabric to zone, Fabric to zone alias
- Performance management views (for example, metrics and threshold violations)

### **Entities defined by Tivoli Storage Productivity Center**

These views include information about entities that are defined by Tivoli Storage Productivity Center. These entities include Storage Resource agents, the alert log, the Tivoli Storage Productivity Center servers, scan profiles, external tools, monitoring groups, reporting groups, and storage resource groups.

### **Data sources**

These views include information about the data sources that are associated with Tivoli Storage Productivity Center. These data sources include Storage Resource agents, Tivoli Storage Productivity Center, CIMOM agents, Out of Band agents, and VMWare Virtual Infrastructure.

### **Aggregated views**

These views provide summary information for the database history, data in a database instance, and the Storage Resource agent file system.

### **Reporting views**

These views combine several different entities into one view, such as aggregate database and file system summary views, file size, time, and age distribution views, enterprise-wide statistics views, directory size views, and historical views of statistics for database summaries, ping jobs, user space usage, and files in user groups.

### **Rollup views**

These views include rollup report information from the master and subordinate Tivoli Storage Productivity Center servers, Storage Resource agents, host cluster data, computer group, host, database computer groups, fabric SAN assets, switch assets, storage subsystem group, storage subsystems, and Data Manager for Databases.

To view detailed descriptions of the views provided with Tivoli Storage Productivity Center, go to the Tivoli Storage Productivity Center support website.

This website contains the following documentation:

- Information about the TPCREPORT schema, including:
  - A list of the views that exist in the schema and descriptions of the columns with the views.

- A list of the views that contain performance data and descriptions of the performance metrics within those views.
- Diagrams that show the relationships between views.
- A diagram that traces the relationship between a computer and a storage subsystem disk and shows the views that contain information about the storage entities within that relationship.

### Accessing views in the database repository

Use SQL to access the views in Tivoli Storage Productivity Center database repository. You can do this using an SQL command line or an application capable of using SQL to retrieve information from views. This topic provides an example of how to create and view a report based on those views.

To retrieve information from the database repository you must have the proper authority to access the views. You must also collect information about your storage assets to populate those views with information. See the *Planning* section in the Tivoli Storage Productivity Center Information Center for more information.

To perform the steps described in this topic, you must install the correct version BIRT. You can download BIRT v2.2.1 from the following Web page: <http://www-01.ibm.com/software/brandcatalog/portal/opal/details?catalog.label=1TW10OT02>. You must use this version of BIRT when working with Tivoli Storage Productivity Center and Tivoli Common Reporting.

You can use a number of SQL and reporting tools for accessing and viewing the content of IBM Tivoli Storage Productivity Center's exposed views. For example, you can use the DB2 Command Line Processor to run SQL commands against the views.

This topic describes how to use BIRT to create a report package based on the views and how to import that package into Tivoli Common Reporting for viewing. Tivoli Common Reporting is installed with Tivoli Storage Productivity Center.

See the following web sites for more information about BIRT and Tivoli Common Reporting:

- BIRT overview information: <http://www.eclipse.org/birt/phoenix/intro/>
- Tivoli Common Reporting overview information: <http://www.ibm.com/developerworks/spaces/tcr>

Complete these steps to use BIRT and Tivoli Common Reporting to work with Tivoli Storage Productivity Center's views:

1. Install BIRT on a computer that has access to Tivoli Storage Productivity Center's database repository. The database repository is located on the computer where the Tivoli Storage Productivity Center server is installed.
2. Start the BIRT Designer tool.
3. Set the connection information for the Tivoli Storage Productivity Center database repository in Data Source section of the user interface.
4. Use the **Data Sets** section of the user interface to create a report based on SQL queries to the exposed views that are in the TPCREPORT schema. See <http://www.eclipse.org/birt/phoenix/intro/> for information on how to use BIRT to create a report. When writing queries against the views make sure to qualify the view names with the TPCREPORT schema (for example, TPCREPORT.STORAGESUBSYSTEM).

**Note:** BIRT limits the amount of views that are displayed to 100 by default. To change this, access the **Preferences** window for the Data Set Editor and enter a value greater than 275 in the **Maximum number of tables in each schema to display** field.

5. Define the layout of the report. Use BIRT to customize the appearance of a report, including customizing column names and creating charts, graphics, and aggregated totals for the data in the report. Use the preview function to view a snapshot of the report that you defined.
6. Create a report package (archive file) for the reports to import into Tivoli Common Reporting.
7. Import the report package into Tivoli Common Reporting.
  - a. Start Tivoli Integrated Portal. For information about starting Tivoli Integrated Portal, go to the Tivoli Storage Productivity Center information center. Search for **Starting the Tivoli Storage Productivity Center GUI from Tivoli Integrated Portal**.
  - b. Expand **Reporting** in the navigation tree and click **Common Reporting**.
  - c. Right-click **Report Sets** and select **Import Report Package**.
  - d. Select the report package you want to import and click **Import**. Click **Overwrite** in the **Advanced Options** section if the report package was previously imported. The name of the report package appears in the **Reports** section of the panel.
  - e. Right-click the report package and select **Views As > output\_type**, where *output\_type* represents the format of the generated report.
  - f. View the report.

## Repocopy tool

You can use the Repocopy tool to export all the tables in the IBM Tivoli Storage Productivity Center repository (Data Manager data) for purposes of debugging problems.

You can send the exported data to the IBM Support Center to help debug problems.

### **Note:**

- You must stop the Device server and Data server before running **repocopy**.
- You cannot import **repocopy** data into the IBM Tivoli Storage Productivity Center database if the migration tool has not been run against the database. When you upgrade the Device server, you must run the migration tool before importing **repocopy** data.

## Exporting repository data

Use the repocopy tool to export data from an existing repository into a comma delimited file.

To export repository data, follow these steps:

1. Go to the following default directory:

### **On Windows operating systems:**

c:\Program Files\IBM\TPC\data\server\tools

### **On Linux or UNIX operating systems:**

/opt/IBM/TPC/data/server/tools

2. Run the **repocopy.bat** or **repocopy.sh** command. A window opens prompting you for what you would like to do.
3. Select **Export data from repository tables** and click **Next**. The Options for Import/Export window is displayed.
4. In the Options for Import/Export window, enter information in the following fields:

**Directory for Export**

Enter the directory where the comma delimited file is saved.

**Delimiter**

Enter a delimiter for the delimited file format (comma is the default).

**Quote** Enter the symbol that contains string data (double quotation marks is the default).

IBM Tivoli Storage Productivity Center exports the data into the comma delimited file you specify, and place it in a file named *tablename.txt*. Click **Next**.

5. The Choices for DB2 Export window are displayed. You have the following choices:
  - Export Using DB2 native format
  - Export Using text files

Make a choice and click **Next**.

6. The Table Export Choices window opens. You have the following choices:
  - Export base tables (always)
  - Export Performance Manager tables
  - Export history tables used for IBM Tivoli Storage Productivity Center for Data history reports

Make a choice and click **Next**. The Connection Properties window opens.

Tivoli Storage Productivity Center reads the *server.config* file and determines your current repository and the information for accessing the database. The information detected in the *server.config* file is displayed in the Connection Properties window within the following fields:

- Database Types
- User name
- Password
- Driver Class
- Driver URL
- Database
- DB Creator
- Classpath

**Note:** If you want to export data from a different database from the one listed in the *server.config* file, you can select the database from the **Database Types** list box. Manually enter the database information.

7. Click **Finish**.
8. Tivoli Storage Productivity Center then connects to the database and displays the database and connection information. To begin the export process, click **Run**.

A window opens containing the export progress log. As you progress through the export process, messages are written to this progress log. You can keep track of the steps through the progress log.

**Note:** When you run the repocopy tool on a server that has a remote database, the repocopy tool displays a message. When the repocopy tool is used with a remote database, the DB2 shared library is unavailable for loading libTSRMinsudb.so. You can ignore this message. Click **OK** and continue.

## Importing repository data

Use the Repository Copy tool to import data from a comma delimited file. You must have previously exported data from an existing repository.

To import data into repository tables, follow these steps:

1. Stop the Device server and Data server.
2. Go to the following directory:
  - On Windows operating systems:**  
c:\Program Files\IBM\TPC\data\server\tools
  - On Linux or UNIX operating systems:**  
/opt/IBM/TPC/data/server/tools
3. Run the **repocopy.bat** or **repocopy.sh** command. A window is displayed prompting you for what you would like to do
4. Select **Import data into repository tables**, and then click **Next**. The Options for Import/Export window opens.
5. In the Options for Import/Export window, enter information in the following fields:

### Directory for Import

Enter the directory where the comma delimited files are stored.

### Delimiter

Enter a delimiter used for the delimited file format (comma is the default). You must use the same delimiter that was used in the exported file.

**Quote** Enter the symbol used to contain string data (double quotation marks is the default). You must use the same double quotation marks that were used in the exported file.

### Delete before inserting

Check this option if you want to delete any existing data in the repository tables before importing new data.

IBM Tivoli Storage Productivity Center imports the data from the comma delimited file that you specify. Click **Next**.

6. The Connection Properties window opens.
7. Enter the database and the access information of the database to which you want to import data. The Connection Properties window contains the following fields:
  - Database Types
  - User name
  - Password
  - Driver Class
  - Driver URL
  - Database

- DB Creator
- Classpath

Click **Finish**. Tivoli Storage Productivity Center then connects to the database and displays the database and connection information.

8. To begin the import process, click **Run**.

A window containing the import progress log opens. As you progress through the import, messages are written to this progress log. You can use the progress log to track the steps as they happen.

**Note:** When you run the repocopy tool on a server that has a remote database, the repocopy tool displays a message. When the repocopy tool is used with a remote database, the DB2 shared library is unavailable for loading `libTSRMinsudb.so`. You can ignore this message. Click **OK** and continue.

## Service tool: collecting information

The Service tool collects information from all installed IBM Tivoli Storage Productivity Center components. The tool detects system configuration, collects the applicable information, and creates a compressed file that can be sent to the IBM support center.

The Service tool collects the following information:

- Host name
- IP address and configuration information
- Operating system and version
- Java home, version, and class path
- Java Virtual Machine (JVM) implementation name and version
- Protocol statistics and current IBM Tivoli Storage Productivity Center / Internet Protocol network connections, including listening ports
- Diagnostic information regarding the system and its services
- Listing of all library files, for example, server and library, agent and library, and GUI library

When the Service tool is run on the system where the Data server or the Device server is installed, it also collects the following information:

- For the Data server, information about all of the graphical user interfaces (remote and local) that are associated with this Data server
- All applied e-fixes
- Installation logs
- Everything in the `log` directory, including subdirectories
- Everything in the `conf` directory
- Directory listing of the `lib` directory
- Everything in the `log` and `conf` directories underneath the `ewas` directory
- The version of DB2 (information from the `db2level` command)
- Information from the `ipconfig /all` command (Windows operating systems)
- Information from the `ipconfig -a` command (Linux and UNIX operating systems)
- Information from the `netstat -an` command

When the Service tool is run on the system where the database repository is installed, it also collects the following information:

- The DB2 support information (information from the db2support command)

When the Service tool is run on the system where Tivoli Integrated Portal and the TCR component is installed, it also collects the following information:

- Everything in the log and conf directories
- Logs for the deployment engine
- Listing of COI components installed
- InstallAnywhere logs for Tivoli Integrated Portal and TCR
- TCR COI related logs
- Tivoli Integrated Portal ewas configuration files

When the Service tool runs on the Storage Resource Agent computer, it collects the following information:

- All applied e-fixes
- Everything in the log directory (including subdirectories).
- Everything in the conf directory
- Directory listing of the lib directory
- Information from the **ipconfig /all** command (for Windows operating systems).
- Information from the **ifconfig -a** command (for UNIX and Linux operating systems).
- Information from the **netstat -an** command

By default, the service data is collected in the following directory:

**On Windows operating systems:**

*TPC\_installation\_directory\service\data*

**On UNIX and Linux operating systems:**

*TPC\_installation\_directory/service/data*

You can change the default directory. To do this, refer to the following topic: "Customizing the service tool from the command line" on page 230

**Tip:** You can run the Service tool on IBM Tivoli Storage Productivity Center regardless of whether you configured it on a single server or on a split server. The Service tool automatically recognizes the installed components and collects service data about them. To learn how to run the Service tool for servers, see the following topic: "Creating a compressed file about servers for the IBM Support Center."

**Restriction:** The Service tool does not collect service logs or other service information for Tivoli Storage Productivity Center for Replication. If you must collect the log and trace files for the Replication server, go to the information center. Go to **IBM Tivoli Storage Productivity Center > Troubleshooting > IBM Tivoli Storage Productivity Center for Replication > Logs**.

## **Creating a compressed file about servers for the IBM Support Center**

Run the Service tool for the Data server and the Device server to create a compressed file that can be sent to the IBM Support Center.

You must have administrator authority on Windows operating systems or root authority on UNIX and Linux operating systems.

To run the tool for the servers, follow these steps:

1. Log on to the system.
2. If you used the default directory, go to the following directory:
  - On Windows operating systems: C:\Program Files\IBM\TPC\service\.
  - On Linux or UNIX operating systems: /usr\_or\_opt/IBM/TPC/service/.
3. Run the following program:
  - On Windows operating systems:**  
service.bat
  - On Linux or UNIX operating systems:**  
service.sh

A compressed file, TPCServiceFiles.zip, is created in the following directory:

- On Windows operating systems**  
TPC\_installation\_directory\service\data
- On Linux or UNIX operating systems**  
TPC\_installation\_directory/service/data

**Tip:** You can customize the data that is collected by the Service tool. For more information, see “Customizing the service tool from the command line” on page 230

**Related tasks:**

“Creating a compressed file about Storage Resource Agents for the IBM Support Center”

Run the Service tool on Storage Resource Agents that were deployed by using the stand-alone GUI to create a compressed file that can be sent to the IBM Support Center.

**Creating a compressed file about Storage Resource Agents for the IBM Support Center**

Run the Service tool on Storage Resource Agents that were deployed by using the stand-alone GUI to create a compressed file that can be sent to the IBM Support Center.

You must have administrator authority on Windows operating systems or root authority on UNIX and Linux operating systems.

To run the Service tool on the Storage Resource agents, do the following steps:

1. Log on to the stand-alone GUI.
2. In the navigation tree, expand **Administrative Services > Data Sources > Data/Storage Resource Agents**.
3. In the content pane, select the agent. From the **Select Action** menu, click **Collect Service Data**.

The following compressed files are created:

- On Windows operating systems:**  
C:\Program Files\IBM\TPC\data\log\SRATraces\SRA\_computer\_name\TPCServiceInfo.zip
- On UNIX and Linux operating systems:**  
/opt/IBM/TPC/data/log/SRATraces/SRA\_computer\_name/TPCServiceInfo.zip

where *SRA\_computer\_name* represents the name of the computer on which the Storage Resource agent is located.

If the compressed file cannot be created, a message indicates that the job was unsuccessful.

For more information about the error, see the server log file or the services script information file. The files are in the following default locations:

#### **Server log file**

This file is on the system where IBM Tivoli Storage Productivity Center is installed:

##### **For Windows operating systems:**

c:\Program Files\IBM\TPC\data\log

##### **For UNIX or Linux operating systems**

/opt/IBM/TPC/data/log

#### **Services script information file**

This file is on the system where the Storage Resource agent is installed:

##### **For Windows operating systems:**

c:\Program Files\IBM\TPC\*SRA\_computer\_name*\services\TPCServiceInfo.log

##### **For UNIX or Linux operating systems:**

/opt/IBM/TPC/*SRA\_computer\_name*/services/TPCServiceInfo.log

**Tip:** You can customize the data that is collected by the Service tool. For more information, see “Customizing the service tool from the command line”

#### **Related tasks:**

“Creating a compressed file about servers for the IBM Support Center” on page 228

Run the Service tool for the Data server and the Device server to create a compressed file that can be sent to the IBM Support Center.

### **Customizing the service tool from the command line**

Using various parameters, you can use the service tool to collect data about specific IBM Tivoli Storage Productivity Center components, which you can then send to the IBM Support Center. You can also use the command line parameters to specify a location to place the data that is collected, specify whether the data should be compressed, or both.

### **Help and output command-line parameters**

To customize the data that is collected by the service tool, use the following command-line parameters:

#### **-output *directory\_path***

Places the files that contain the data that was collected in a directory that you specify. If you specify a directory that does not exist on your system, that directory is created. If you do not use the `-output directory_path` parameter, the files are placed in the default directory:

##### **On Windows operating systems:**

*TPC\_installation\_directory*\service\data

##### **On Linux or UNIX operating systems:**

*TPC\_installation\_directory*/service/data

**Restriction:** If you specify a directory, the directory path cannot contain spaces.

**-nozip**

When you use this parameter, separate directories are created for each Tivoli Storage Productivity Center component for which data was collected. You can then create compressed files for the files. In this way, you can control the size and content of each compressed file. To specify a directory other than the default directory, use the `-output directory_path` parameter.

**Tip:** You can specify more than one parameter, for example, `C:\Program Files\IBM\TPC\service>service -install -nozip`.

**Collecting data for specific Tivoli Storage Productivity Center components**

You can use the service tool to collect data about specific Tivoli Storage Productivity Center components.

The following list shows the parameters that are used to collect data for each component:

**-all**

Collects data about all Tivoli Storage Productivity Center components.

**-install**

Collects data about the installation component files.

**-data**

Collects data about the data server component files.

**-device**

Collects data about the device server component files.

**-repl**

Collects data about the replication server component files.

**-sra**

Collects data about the Storage Resource Agent component files.

**-db**

Collects data about DB2 files.

**-cli**

Collects data about command-line interface files.

**-gui**

Collects data about Tivoli Integrated Portal and other IBM Tivoli Storage Productivity Center web-based GUI files.

**-tcr**

Collects data about IBM Tivoli Common Reporting.

**Tip:** You can specify more than one parameter, for example, `C:\Program Files\IBM\TPC\service>service -tcr -install -gui`.

If you collect information about a particular component and you do not specify the **-nozip** parameter, you can identify the contents of a compressed service file from its name. For example, if you specify the **-tcr -install -gui** parameters but did not specify the **-nozip** parameter, a file named `TPCServiceFiles_tcr_install_gui.zip` is created.

**Attention:** An existing compressed file is overwritten when another file of the same name is created. For example, if you run C:\Program Files\IBM\TPC\service>service -db -gui, a file named TPCServiceFiles\_device\_db.zip is created. If you rerun the tool with the same component options, a new file named TPCServiceFiles\_device\_db.zip is created. This new file overwrites the previously created file unless you specify the **-nozip** parameter, or use the **-output** parameter to specify a different path.

If you specify the **-nozip** parameter, a subdirectory is created for the components that you specified in the parameter. If you did not specify a specific component, data is collected for all installed components, and the data is placed in files in the following directory:

**Windows operating systems:**

*TPC\_installation\_directory\service\data*

**UNIX or Linux operating systems:**

*TPC\_installation\_directory/service/data*

Files for particular components are then placed in a subdirectory that corresponds to that component. Common files, such as license.txt, are placed in the following directory:

**Windows operating systems:**

*TPC\_installation\_directory\service\data*

**UNIX or Linux operating systems:**

*TPC\_installation\_directory/service/data*

---

## Administering Tivoli Integrated Portal

This topic provides information on how to perform administrative tasks in Tivoli Integrated Portal that are reflected in Tivoli Storage Productivity Center.

### Tivoli Integrated Portal port numbers

Depending on how you installed Tivoli Storage Productivity Center, the default port numbers for Tivoli Integrated Portal can vary.

To find the default port numbers that are used in Tivoli Integrated Portal URLs, do the following steps:

**For a new installation of Tivoli Storage Productivity Center Version 5.1:**

1. Go to the following directory:

**On Windows operating systems:**

*C:\Program Files\IBM\tipv2\properties\*

**On Linux or UNIX operating systems:**

*/opt/IBM/tipv2/properties/*

2. Open the TIPPortDef.properties file.
3. Review the following entry:

**For http:// protocols:**

*WC\_defaulthost\_xxx*

**For https:// protocols:**

*WC\_defaulthost\_secure\_xxx*

**For an installation of Tivoli Storage Productivity Center Version 5.1 that was upgraded from an earlier version:**

1. Go to the following directory:

**On Windows operating systems:**

C:\Program Files\IBM\Tivoli\tipv2\properties\

**On Linux or UNIX operating systems:**

/opt/IBM/Tivoli/tipv2/properties/

2. Open the TIPPortDef.properties file.
3. Review the following entry:

**For http:// protocols:**

WC\_defaulthost\_xxxx

**For https:// protocols:**

WC\_defaulthost\_secure\_xxxx

### Port numbers for a new installation of Tivoli Storage Productivity Center Version 5.1

- If you installed Tivoli Storage Productivity Center Version 5.1 and used default Tivoli Integrated Portal port numbers, the port numbers are as follows:

**For http:// protocols:**

9568

**For example:**

`http://hostname:9568/ibm/console/logon.jsp`

**For https:// protocols:**

9569

**For example:**

`https://hostname:9569/ibm/console/logon.jsp`

- If you installed Tivoli Storage Productivity Center version 5.1 and used customized port numbers for Tivoli Integrated Portal, the URLs for a Tivoli Integrated Portal logon might appear as follows:

**For http:// protocols:**

**For example:**

`http://hostname:WC_defaulthost/ibm/console/logon.jsp`

**For https:// protocols:**

**For example:**

`https://hostname:WC_defaulthost_secure/ibm/console/logon.jsp`

### Port numbers for an upgraded installation of Tivoli Storage Productivity Center Version 4.2.2

- If you upgraded from Tivoli Storage Productivity Center Version 4.2.2 to Version 5.1, the default Tivoli Integrated Portal port numbers are as follows:

**For http:// protocols:**

16310

**For example:**

`http://hostname:16310/ibm/console/logon.jsp`

**For https:// protocols:**

16311

**For example:**

`https://hostname:16311/ibm/console/logon.jsp`

- If you used customized port numbers when you installed Tivoli Storage Productivity Center Version 4.2.2, upgraded to Version 5.1, and then used customized port numbers for Tivoli Integrated Portal, the URLs for a Tivoli Integrated Portal logon might appear as follows:

**For http:// protocols:**

`http://hostname:12345/ibm/console/logon.jsp`

**For https:// protocols:**

`https://hostname:12346/ibm/console/logon.jsp`

## Changing the user authentication configuration

The Tivoli Storage Productivity Center installation program establishes a default authentication configuration using the federated repositories feature of the WebSphere Application Server. If you want to change the user authentication configuration, follow these procedures.

Within the federated repositories framework, the Tivoli Storage Productivity Center installation program creates two repositories:

### File-based user repository

This repository contains the user "tpcFileRegistryUser" (This user password is the same as the common user password entered during the Tivoli Storage Productivity Center installation.)

### Operating system repository

In the federated repositories framework, the Tivoli Storage Productivity Center installation program creates two repositories on all the following Tivoli Storage Productivity Center IBM® WebSphere® Application Servers:

- Tivoli Integrated Portal server
- Device server
- Replication server

The Tivoli Integrated Portal server is used as the primary WebSphere Application Server for user authentication in Tivoli Storage Productivity Center. If the Tivoli Integrated Portal server is down, the Device Server and Replication Server are used as the back up WebSphere Application Servers to perform the user authentication and allow the authorized local OS users to log in to the Tivoli Storage Productivity Center stand-alone GUI and Tivoli Storage Productivity Center for Replication web-based GUI. You can add an LDAP repository as a post-install task. This configuration is completed on the Tivoli Integrated Portal server. The LDAP repository configuration settings are not propagated to the Device and Replication servers. So, if the Tivoli Integrated Portal server is down, then the authorized LDAP users cannot log in to Tivoli Storage Productivity Center stand-alone GUI and Tivoli Storage Productivity Center for Replication web-based GUI. The back up user authentication mechanism based on Device and Replication servers allows the authorized local OS users to log in to the Tivoli Storage Productivity Center stand-alone GUI and the Tivoli Storage Productivity Center for Replication web-based GUI.

This repository is referred to as the local OS repository and contains the users and groups that are managed by the local operating system. On computers that are members of a Windows domain, this local OS repository also contains the domain users and groups that are managed by the Windows domain, provided that the computer is correctly configured with the Windows domain.

Use of the Tivoli Storage Productivity Center single sign-on feature, especially with storage system element managers, is limited with this default authentication configuration. Storage system element managers do not support using the localOS repository or the file-based repository for single sign-on, even when the element manager is installed on the same system as Tivoli Storage Productivity Center.

The LDAP repositories supported by Tivoli Storage Productivity Center depend on the Tivoli Integrated Portal support. For more information about the LDAP repositories supported, see one of the following topics:

- For the Windows operating system: <http://www.ibm.com/support/docview.wss?rs=180&uid=swg27012421> .
- For the AIX operating system: <http://www.ibm.com/support/docview.wss?rs=180&uid=swg27012389>.
- For the Linux operating system: <http://www.ibm.com/support/docview.wss?rs=180&uid=swg27012415>.

Search for *LDAP Servers using Federated Repository Configuration*.

When you change the user authentication configuration (by adding or removing an LDAP repository within the federated repositories framework), you must first back up the existing Tivoli Integrated Portal WebSphere configuration files. The WebSphere backup files provide a restoration point in the event of a failure when performing these procedures. You must also back up the WebSphere configuration files after you add an LDAP repository to the user authentication configuration and want to later change the LDAP authentication settings.

The WebSphere Application Server cannot resolve duplicated users or groups if these users or groups are present in more than one repository in the federated repositories framework. For example, an Administrator user exists in both the local OS and LDAP repository. You must ensure that the duplicated users (or groups) are not used during the configuration or to manage Tivoli Storage Productivity Center.

The following topics describe how to select and configure each user authentication method.

### **Adding an LDAP repository to the federated repositories**

You can configure Tivoli Storage Productivity Center to communicate with an external Lightweight Directory Access Protocol (LDAP) repository such as IBM Tivoli Directory Server or Microsoft Active Directory. To add an LDAP repository to the federated repositories in Tivoli Storage Productivity Center, you must use Tivoli Integrated Portal.

If you installed Tivoli Storage Productivity Center on a correctly configured computer that is a member of a Windows domain, Active Directory users and groups also exist in the localOS repository. To determine whether the Active Directory users exist in the localOS repository, log on to Tivoli Integrated Portal and click **Users and Groups > Manage users**. You should not add the Active Directory repository if the Active Directory users exist. If you plan to add the Active Directory repository for performance reasons, you must remove the localOS repository from the federated repositories.

The WebSphere Application Server cannot resolve duplicated users or groups if these users or groups are present in more than one repository in the federated repositories framework. For example, an Administrator user exists in both the

localOS and LDAP repository. You must ensure that the duplicated users (or groups) are not used during the configuration or to manage Tivoli Storage Productivity Center.

To add an LDAP repository to the federated repositories in Tivoli Storage Productivity Center, complete the following steps. Contact your LDAP server administrator for assistance.

1. Back up the Tivoli Integrated Portal WebSphere Application Server configuration files. The WebSphere Application Server configuration backup files provide a restoration point in the event of a failure when you complete this procedure. This procedure uses the variable name *TIP\_installation\_directory* to indicate where Tivoli Integrated Portal is located.
  - a. Back up the WebSphere Application Server configuration files.  
For the AIX or Linux operating systems, run the following command:  

```
TIP_installation_directory/profiles/TIPProfile/bin/
backupConfig.sh
```

  
For the Windows operating systems, run the following command:  

```
TIP_installation_directory\profiles\TIPProfile\bin\
backupConfig.bat
```
  - b. Back up the `soap.client.props` file for Tivoli Integrated Portal.  
For the Windows operating systems, use the **copy** command to back up this file:  

```
TIP_installation_directory\profiles\TIPProfile\properties\
soap.client.props
```

  
For the AIX or Linux operating systems, use the **cp** command to back up this file:  

```
TIP_installation_directory/profiles/TIPProfile/properties/
soap.client.props
```
  - c. Back up the IBM Cognos 8.ear directory.  
For Windows operating systems, enter the **xcopy** command to back up this directory:  

```
TIP_installation_directory\profiles\TIPProfile\installedApps\
TIPCell\IBM Cognos 8.ear
```

  
For the AIX or Linux operating systems, enter the **cp** command to back up this directory:  

```
TIP_installation_directory/profiles/TIPProfile/installedApps/
TIPCell/IBM Cognos 8.ear
```
  - d. The WebSphere Application Server **backupConfig** command generates a compressed file: `WebSphereConfig_YYYY-DD-MM.zip`. When you run the **backupConfig** command, the Tivoli Integrated Portal server will shut down. The Tivoli Integrated Portal server must be restarted after the **backupConfig** command is finished.  
To start the Tivoli Integrated Portal server, follow these steps:
    - 1) For Windows operating systems, click **Start > Administrative Tools > Services**. On the Windows Services page, right-click **Tivoli Integrated Portal - V2.2\_TIPProfile\_Port\_xxxx** where *xxxx* indicates the port specified during installation and select **Start**.
    - 2) For AIX or Linux operating systems, open a command prompt window and enter the following command:  

```
TIP_installation_directory/profiles/TIPProfile/bin/
startServer.sh
```

2. To restore the WebSphere Application Server and IBM Cognos configuration, complete the following steps:

a. Restore the WebSphere configuration by running the `restoreConfig.sh` or `restoreConfig.bat` command. The **restoreConfig** command is located here:

- For Windows operating systems:

```
TIP_installation_directory\profiles\TIPProfile\bin\
restoreConfig.bat
```

- For AIX or Linux operating systems:

```
TIP_installation_directory/profiles/TIPProfile/bin/
restoreConfig.sh
```

b. Restore the IBM Cognos 8.ear directory that you backed up in step 1c. For the Windows operating systems, enter the **xcopy** command to replace the contents of this directory:

```
TIP_installation_directory\profiles\TIPProfile\installedApps\
TIPCell\IBM Cognos 8.ear
```

For the AIX or Linux operating systems, use the **cp** command to replace the contents of this directory:

```
TIP_installation_directory/profiles/TIPProfile/installedApps/
TIPCell/IBM Cognos 8.ear
```

3. Open an Internet Explorer or Mozilla Firefox web browser and enter the following information in the address bar:

```
http://hostname:port/ibm/console/logon.jsp
```

or

```
https://hostname:port/ibm/console/logon.jsp
```

Where *hostname* is the server that is running Tivoli Integrated Portal such as the server name or IP address and *port* is the port number for Tivoli Integrated Portal.

The port number differs depending on the protocol that you use (http or https) and the options that you selected during the installation of Tivoli Storage Productivity Center. For more information about port numbers, see “Tivoli Integrated Portal port numbers” on page 232.

You can also contact your Tivoli Storage Productivity Center administrator to verify the host name and port number.

4. On the Tivoli Integrated Portal logon page, log on using the appropriate user ID and password. Your user ID must have Tivoli Integrated Portal administrator authorization.

5. In the Tivoli Integrated Portal navigation tree, click **Settings > WebSphere Administrative Console**.

6. In the Tivoli Integrated Portal window, click **Launch WebSphere administrative console**.

7. In the WebSphere Application Server Administrative Console navigation tree, click **Security > Global security**.

8. On the Global security page, in the **User account repository** section, click the **Configure** button next to the **Available realm definitions** list.

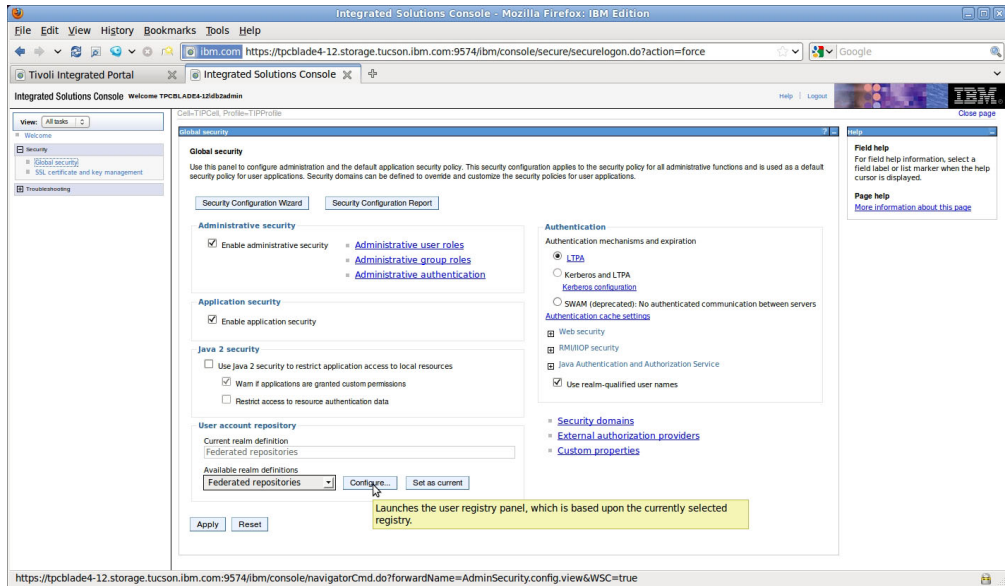

Figure 11. Global security page, configure federated repositories

9. On the Global security > Federated repositories page, under "Related Items," click **Manage repositories**.

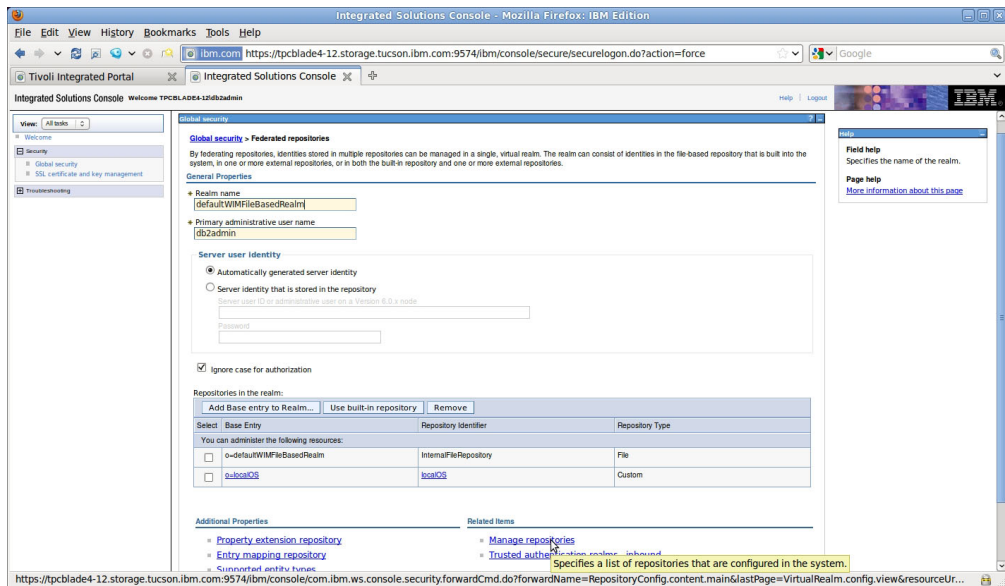

Figure 12. Federated repositories page, Manage repositories

In this window, you must ensure that the **Primary administrative user name** exists only in one repository. The WebSphere Application Server will not start if this user name exists in multiple repositories.

10. On the Global security > Federated repositories > Manage repositories page, add the LDAP repository that you want to use for authentication. Follow these steps:
  - a. Click **Add** to add a new repository.

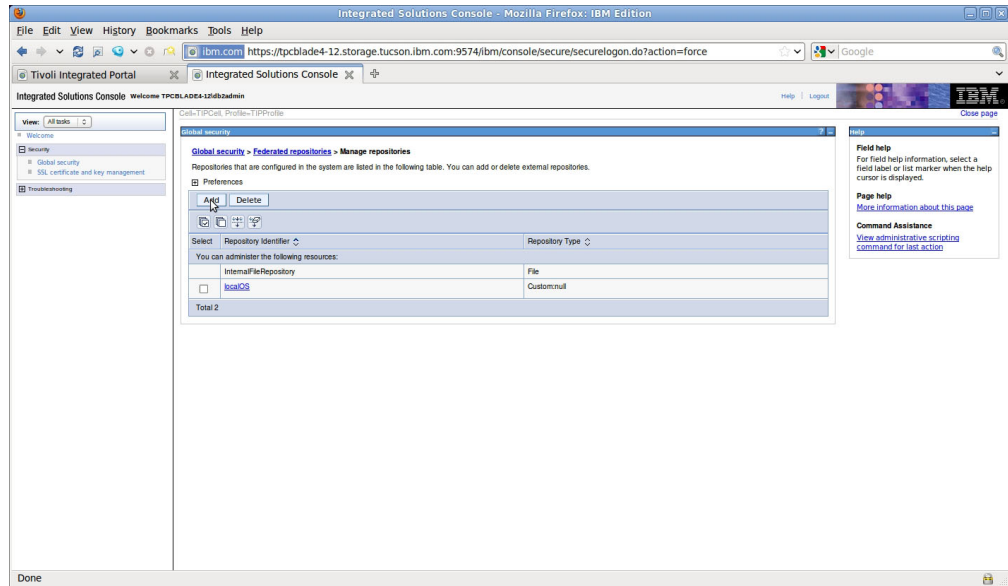

Figure 13. Manage repositories page, Add a new repository

- b. Enter the values for the following fields:

**Repository identifier**

A unique identifier for the LDAP repository. This identifier uniquely identifies the repository within the realm, for example, LDAP1.

**Directory type**

The type of LDAP server that you want to connect to.

**Primary host name**

The host name of the primary LDAP server. This host name is either an IP address or a domain name service (DNS) name.

**Port**

The LDAP server port. The default value is 389. You can specify a different port depending on your LDAP server configuration. If you do not know what port to use, contact your LDAP server administrator.

**Bind distinguished name**

The distinguished name (DN) for WebSphere Application Server to use when binding to the LDAP repository. If no name is specified, WebSphere Application Server binds anonymously. In most cases, bind DN and bind password are required. However, when an anonymous bind can satisfy all the required functions, bind DN and bind password are not required.

**Bind password**

The password for WebSphere Application Server to use when binding to the LDAP repository.

**Login properties**

The authentication properties that are used to log on to WebSphere Application Server. Type uid;cn in this field. This value enables WebSphere Application Server to use the property that is required for the directory type.

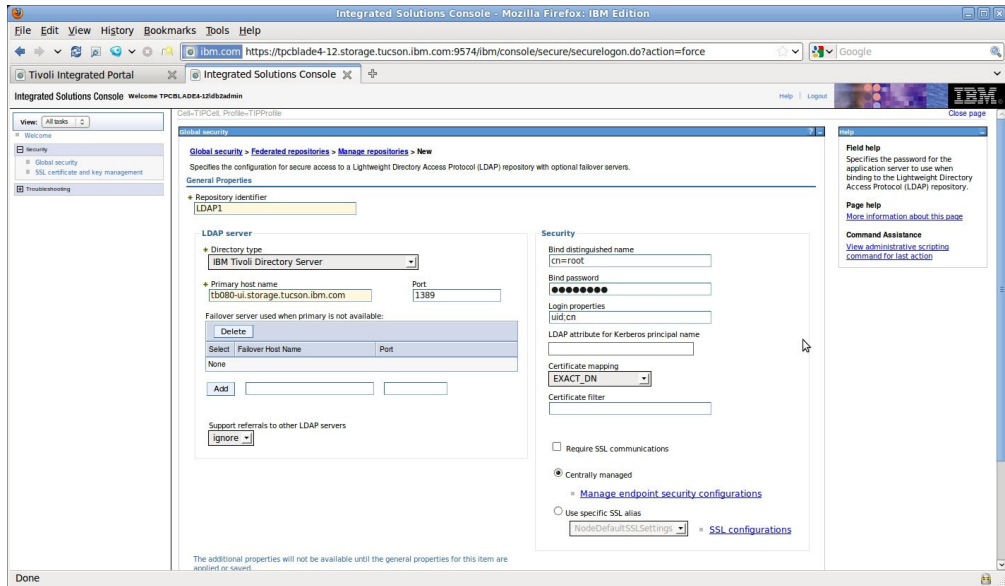

Figure 14. Manage repositories > New page

- c. Click **OK**.
- d. In the messages dialog box that is displayed on the Manage repositories page, click the **Save** link in **Save directly to the master configuration**.

**Important:** On the Global security > Federated repositories > Manage repositories page, do not delete the "localOS" repository.

- 11. From the Manage repositories page, return to the Global security > Federated repositories page.
- 12. Under "Repositories in the realm," click **Add Base entry to Realm**.

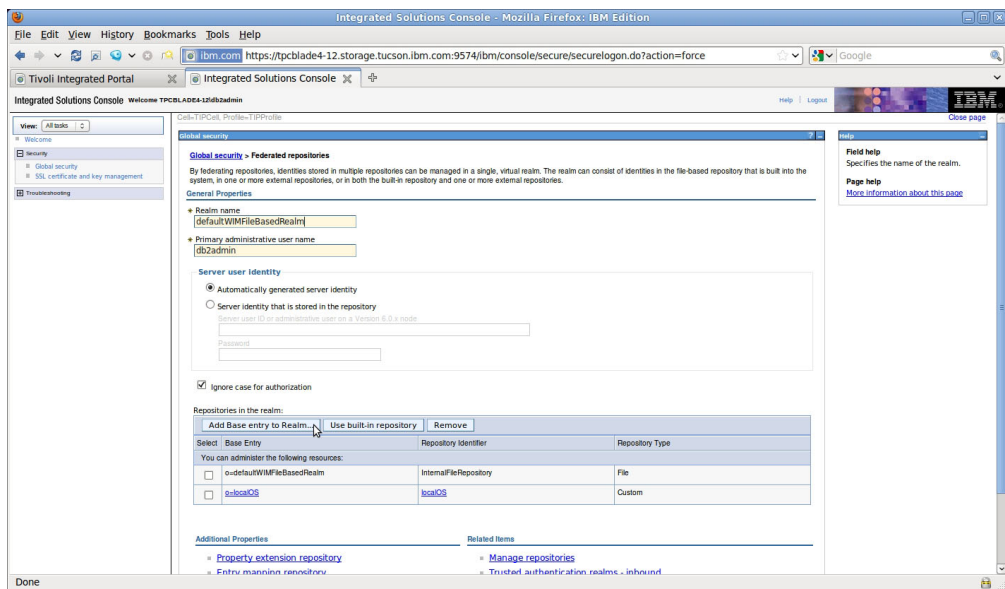

Figure 15. Global security > Federated repositories page, Add base entry to realm

- 13. If the Messages dialog box is displayed on the Repository reference page, click the **Save** link in **Save directly to the master configuration**.

14. On the Repository reference page, configure the following items:
- a. In the **Repository** list, select the repository that you created in step 10 on page 238.

- b. In the **Distinguished name of a base entry that uniquely identifies this set of entries in the realm** field, enter a DN for the repository. This DN maps to the DN of the base entry within the LDAP repository that you enter in the **Distinguished name of a base entry in this repository** field.

To avoid duplicate results during searches, the DN must uniquely identify the base entry in the repository. If multiple repositories are included in the realm and the repositories have the same base entry, use this field to define a DN that uniquely identifies each base entry. For example, repositories LDAP1 and LDAP2 might both use `o=ibm,c=us` as the base entry in the repository. Enter a DN in this field that distinguishes the base entries for each repository. For example: `o=ibm,c=us` for LDAP1 and `o=ibm2,c=us` for LDAP2.

- c. In the **Distinguished name of a base entry in this repository** field, enter the DN of the base entry in the LDAP repository that you want to map to the DN that you entered in the **Distinguished name of a base entry that uniquely identifies this set of entries in the realm** field. In most instances, the value is the same in both fields.

The value in this field indicates the starting point for searches in the LDAP directory server. For example, for a user with a DN of `cn=John Doe, ou=rochester, o=ibm, c=us`, you can specify the LDAP base entry as any of the following options:

- `ou=rochester, o=ibm, c=us`
- `o=ibm, c=us`
- `c=us`

**Important:** The DN value that is entered in this field must be broad enough to include both users and the groups that the users belong to. For example, if a user in `ou=rochester, o=ibm, c=us` is also a member of groups that are in `dc=stategroups, ou=rochester, o=ibm, c=us`, enter `o=ibm, c=us` in this field.

- d. Click **OK**.
- e. In the messages dialog box that is displayed, click the **Save** link in **Save directly to the master configuration**.

**Important:** In the **Repositories in the realm** table, do not remove the `InternalFileRepository` entry. Do not remove the `localOS` entry, unless you are planning to add an Active Directory repository to Tivoli Storage Productivity Center that is installed on a computer that is a member of a Windows domain and have verified that the Active Directory users exist in the localOS repository.

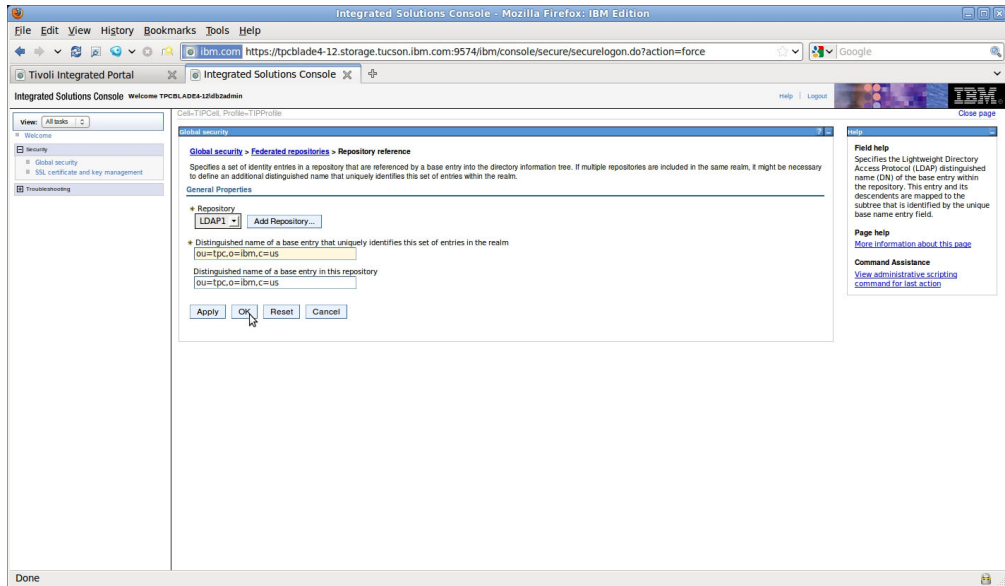

Figure 16. Global security > Federated repositories > Repository reference page, Add base entry to realm

15. Log out from the WebSphere Application Server Administrative Console.
16. Log out from the Tivoli Integrated Portal Administrative Console.
17. Stop and restart the Tivoli Integrated Portal server. For information about stopping and starting the Tivoli Integrated Portal server, see the Tivoli Storage Productivity Center information center. Search for *Starting and stopping the Tivoli Integrated Portal server*.

To verify that the LDAP federated repository is configured correctly, complete the following steps:

1. Log on to Tivoli Integrated Portal by using the same user ID and password from step 4 on page 237.
2. In the Tivoli Integrated Portal navigation tree, click **Users and Groups > Manage Users**.
3. In the Search by list, select **User ID**.
4. Click **Search** to search for users in the federated repositories. The list of users includes users from the local file repository, the operating system repository, and the LDAP repository.
5. In the Tivoli Integrated Portal navigation tree, click **Users and Groups > Manage Groups**.
6. In the Search by list, select **Group name**.
7. Click **Search** to search for groups in the federated repositories. The list of groups includes groups from the operating system repository and the LDAP repository.

**Important:** Before you establish the desired authorization configuration for Tivoli Integrated Portal, Tivoli Storage Productivity Center, and Tivoli Storage Productivity Center for Replication, you must ensure that there are no duplicated user names or group names within the local file repository, the operating system repository, and the LDAP repository.

After you have completed and verified the addition of an LDAP repository to the Tivoli Storage Productivity Center federated repositories authentication configuration, you must establish the desired authorization configuration for Tivoli Integrated Portal. Tivoli Integrated Portal administrators require the `iscadmins` and `administrator` roles. Operators viewing Tivoli Storage Productivity Center reports require the `tcrPortalOperator` role. For Tivoli Storage Productivity Center Version 5.1 single sign-on and launch in context features to work correctly, the LDAP user or group requires the following Tivoli Integrated Portal roles:

- administrator
- iscadmins
- tcrPortalOperator
- chartAdministrator
- monitor

For information about user roles and groups, go to the Tivoli Integrated Portal administrative console online help. On the Welcome page, open the online help by clicking `?`. On the Help welcome page, click **Using the Tivoli Integrated Portal > Users and Groups** in the navigation pane.

You should also assign Tivoli Storage Productivity Center roles to groups using the **Role-to-Group Mapping** node in the Tivoli Storage Productivity Center stand-alone GUI. You can map Tivoli Storage Productivity Center roles, such as Tape Operator or Fabric Administrator, to user groups that you create in your operating system repository and your LDAP repository. For information about the **Role-to-Group Mapping** node, go to the Tivoli Storage Productivity Center information center. Search for *Role-to-Group Mappings*.

For information about assigning roles to users and roles to groups for Tivoli Storage Productivity Center for Replication, go to the Tivoli Storage Productivity Center information center. Search for *Managing replication*. On the Managing replication page, click **Security**.

#### **Enabling secure communication between Tivoli Storage Productivity Center and the LDAP repository:**

You can use the Secure Socket Layer (SSL) protocol to secure the communication between Tivoli Storage Productivity Center and the LDAP repository that you are using for user authentication. The SSL protocol provides security and data integrity for communications over Transmission Control Protocol/Internet Protocol (TCP/IP) networks.

To enable SSL for LDAP communications, you must complete the following steps in Tivoli Integrated Portal:

1. Open an Internet Explorer or Firefox web browser. Enter the following information in the address bar: `https://hostname:port/ibm/console/logon.jsp` where *hostname* defines the server that is running Tivoli Integrated Portal such as the server name or IP address and *port* defines the port number for Tivoli Integrated Portal. To view information about Tivoli Integrated Portal port numbers, see “Tivoli Integrated Portal port numbers” on page 232. Contact your Tivoli Storage Productivity Center administrator if you must verify the host name and port number.
2. On the Tivoli Integrated Portal logon page, log on using the appropriate user ID and password. Your user ID must have Tivoli Integrated Portal administrator authorization.

3. In the Tivoli Integrated Portal navigation tree, click **Settings > WebSphere Administrative Console**.
4. In the Tivoli Integrated Portal content pane, click **Launch WebSphere administrative console**.
5. In the WebSphere Administrative Console navigation tree, click **Security > SSL certificate and key management**.
6. On the SSL certificate and key management page, in the "Related Items" section, click **Key stores and certificates**.
7. On the Key stores and certificates page, in the table, click **NodeDefaultTrustStore**.
8. On the NodeDefaultTrustStore page, in the "Additional Properties" section, click **Signer Certificates**.
9. On the Signer Certificates page, click **Retrieve from port**.
10. On the Retrieve from port page, enter the values for the following fields:
  - Host** The fully qualified host name and domain name of your LDAP-compliant repository.
  - Port** The port where the LDAP repository is listening for secure communications; this port is usually 636.

**SSL configuration for outbound connection**  
Accept the default value.

  - Alias** An alias name for the retrieved certificate.
11. Click **Retrieve signer information**.
12. When the signer information is displayed, click **OK**.
13. In the messages dialog box displayed on the Signer certificates page, click the **Save** link in **Save directly to the master configuration**.
14. In the WebSphere Administrative Console navigation tree, click **Security > Global security**.
15. On the Global security page, in the "User account repository" section, click the **Configure** button next to the "Available realm definitions" drop-down list.
16. On the Global security > Federated repositories page, under "Related Items," click **Manage repositories**.
17. On the Global security > Federated repositories > Manage repositories page, click the identifier for the LDAP repository for which you want to enable the SSL protocol.
18. On the configuration page for the LDAP repository, configure the following items:
  - a. In the Port field, enter the port where your LDAP repository is listening for secure communications; this port is usually 636.
  - b. Select **Require SSL communications**.

Click **OK**.
19. In the messages dialog box displayed on the Manage repositories page, click the **Save** link in **Save directly to the master configuration**.
20. Log out from the WebSphere Administrative Console.
21. Log out from the Tivoli Integrated Portal Administrative Console.
22. Stop and restart the Tivoli Integrated Portal server. For information about stopping and starting the Tivoli Integrated Portal server, see the Tivoli Storage Productivity Center information center. Search for *Starting and stopping the Tivoli Integrated Portal server*.

## Disabling secure communication between Tivoli Storage Productivity Center and the LDAP repository:

You can disable the Secure Socket Layer (SSL) protocol between the LDAP repository and the Tivoli Storage Productivity Center system at any time.

To disable the use of SSL, you must complete the following steps in Tivoli Integrated Portal:

1. Open an Internet Explorer or Firefox web browser. Enter the following information in the address bar: `https://hostname:port/ibm/console/logon.jsp` where *hostname* defines the server that is running Tivoli Integrated Portal such as the server name or IP address and *port* defines the port number for Tivoli Integrated Portal. To view information about Tivoli Integrated Portal port numbers, see "Tivoli Integrated Portal port numbers" on page 232. Contact your Tivoli Storage Productivity Center administrator if you must verify the host name and port number.
2. On the Tivoli Integrated Portal logon page, log on using the appropriate user ID and password. Your user ID must have Tivoli Integrated Portal administrator authorization.
3. In the Tivoli Integrated Portal navigation tree, click **Settings > WebSphere Administrative Console**.
4. In the Tivoli Integrated Portal content pane, click **Launch WebSphere administrative console**.
5. In the WebSphere Administrative Console navigation tree, click **Security > Global security**.
6. On the Global security page, in the "User account repository" section, click the **Configure** button next to the "Available realm definitions" drop-down list.
7. On the Global security > Federated repositories page, under "Related Items," click **Manage repositories**.
8. On the Global security > Federated repositories > Manage repositories page, click the identifier for the LDAP repository for which you want to disable the SSL protocol.
9. On the configuration page for the LDAP repository, configure the following items:
  - a. In the Port field, enter the port where your LDAP repository is listening for nonsecure communications; this port is usually 389.
  - b. Clear the **Require SSL communications** check box.Click **OK**.
10. In the messages dialog box displayed on the Manage repositories page, click the **Save** link in **Save directly to the master configuration**.
11. Log out from the WebSphere Administrative Console.
12. Log out from the Tivoli Integrated Portal Administrative Console.
13. Stop and restart the Tivoli Integrated Portal server. For information about stopping and starting the Tivoli Integrated Portal server, see the Tivoli Storage Productivity Center information center. Search for *Starting and stopping the Tivoli Integrated Portal server*.

## Removing an LDAP repository from the federated repositories

To remove an LDAP repository from the federated repositories, you must use Tivoli Integrated Portal.

If removing an LDAP repository from the federated repositories in Tivoli Storage Productivity Center leaves only the localOS repository and the file-based repository, so the use of the Tivoli Storage Productivity Center single sign-on feature is limited. Storage system element managers do not support using the localOS repository for single sign-on, even if the element manager is installed on the same system as Tivoli Storage Productivity Center. This procedure uses the variable name *TIP\_installation\_directory* to indicate where Tivoli Integrated Portal is located.

To remove an LDAP repository from the federated repositories, complete the following steps:

1. Back up the Tivoli Integrated Portal WebSphere configuration files. The WebSphere configuration backup files provide a restoration point in the event of a failure when you complete this procedure. This procedure uses the variable name *TIP\_installation\_directory* to indicate where Tivoli Integrated Portal is located.

- a. Back up the WebSphere configuration files.

For the AIX or Linux operating systems, run the following command:

```
TIP_installation_directory/profiles/TIPProfile/bin/
backupConfig.sh
```

For the Windows operating systems, run the following command:

```
TIP_installation_directory\profiles\TIPProfile\bin\
backupConfig.bat
```

- b. Back up the `soap.client.props` file for Tivoli Integrated Portal .

For the Windows operating systems, use the **copy** command to back up this file:

```
TIP_installation_directory\profiles\TIPProfile\properties\
soap.client.props
```

For the AIX or Linux operating systems, use the **cp** command to back up this file:

```
TIP_installation_directory/profiles/TIPProfile/properties/
soap.client.props
```

- c. Back up the IBM Cognos 8.ear directory.

- For Windows operating systems:

```
TIP_installation_directory\profiles\TIPProfile\installedApps\
TIPCell\IBM Cognos 8.ear
```

- For AIX or Linux operating systems:

```
TIP_installation_directory/profiles/TIPProfile/installedApps/
TIPCell/IBM Cognos 8.ear
```

- d. The WebSphere **backupConfig** command generates a compressed file: `WebSphereConfig_YYYY-DD-MM.zip`. When you run the **backupConfig** command, the Tivoli Integrated Portal server will shut down. The Tivoli Integrated Portal server must be restarted after the **backupConfig** command is finished.

To start the Tivoli Integrated Portal server, follow these steps:

- 1) For Windows operating systems, click **Start > Administrative Tools > Services**. On the Windows Services page, right-click **Tivoli Integrated Portal - V2.2\_TIPProfile\_Port\_xxxx** where *xxxx* indicates the port specified during installation. Select **Start**.
- 2) For AIX or Linux operating systems, open a command prompt window and enter the following command:

```
TIP_installation_directory/profiles/TIPProfile/bin/
startServer.sh
```

2. To restore the WebSphere Application Server and IBM Cognos configuration, complete the following steps:
  - a. Restore the WebSphere configuration by running the `restoreConfig.sh` or `restoreConfig.bat` command. The **restoreConfig** command is located here:
    - For Windows operating systems:

```
TIP_installation_directory/profiles/TIPProfile/bin/
restoreConfig.bat
```
    - For AIX or Linux operating systems:

```
TIP_installation_directory/profiles/TIPProfile/bin/
restoreConfig.sh
```
  - b. Restore the IBM Cognos 8.ear directory that you backed up in step 1c.
    - For the Windows operating systems, use the **xcopy** command to replace the contents of this directory:

```
TIP_installation_directory/profiles/TIPProfile
```
    - For the AIX or Linux operating systems, use the **cp** command to replace the contents of this directory:

```
TIP_installation_directory/profiles/TIPProfile/installedApps/
TIPCell/IBM Cognos 8.ear
```
3. Open an Internet Explorer or Mozilla Firefox web browser and type the following information in the address bar:

```
https://hostname:port/ibm/console/logon.jsp
```

Where *hostname* defines the server that is running Tivoli Integrated Portal such as the server name or IP address and *port* defines the port number for Tivoli Integrated Portal. If the default port range was accepted during the installation of Tivoli Integrated Portal, the port number is 9569. Contact your Tivoli Storage Productivity Center administrator if you must verify the host name and port number.

4. On the Tivoli Integrated Portal logon page, log on using the appropriate user ID and password. Your user ID must have administrator authorization.
5. In the Tivoli Integrated Portal navigation tree, click **Settings > WebSphere Administrative Console**.
6. In the Tivoli Integrated Portal content pane, click **Launch WebSphere administrative console**.

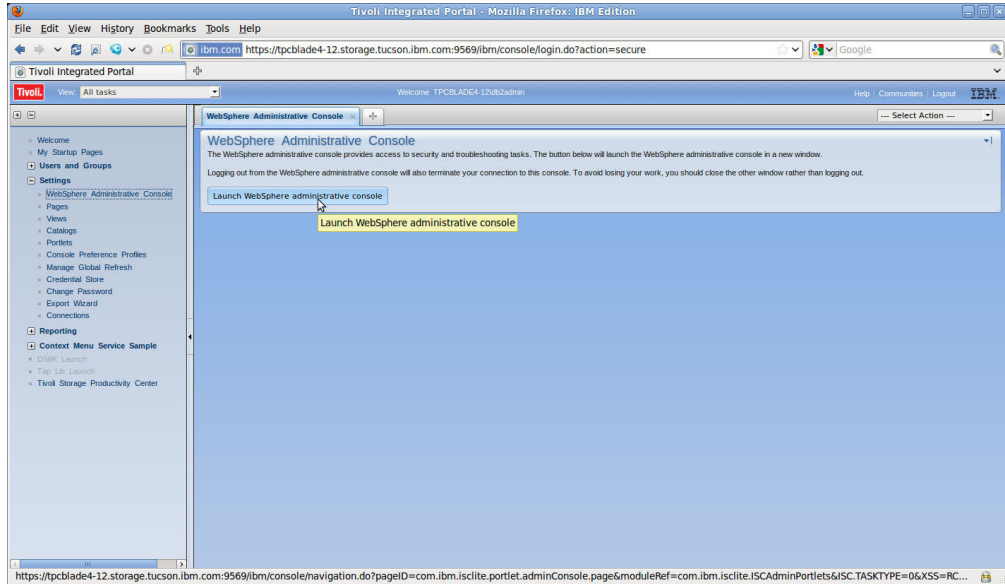

Figure 17. Launch the WebSphere administrative console

7. In the WebSphere Administrative Console navigation tree, click **Security** > **Global Security**.

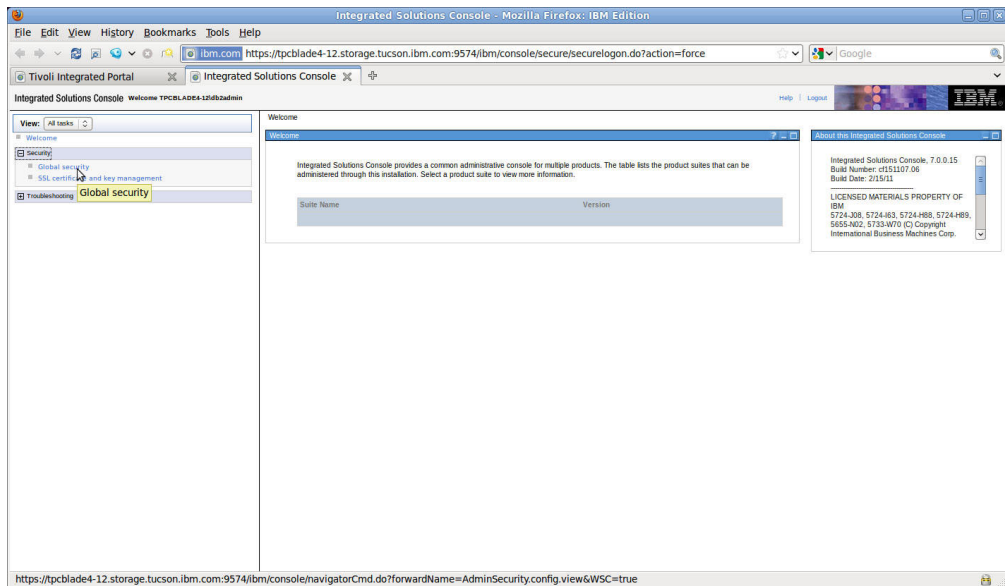

Figure 18. Opening the Global security page

8. On the Global security page, in the "User account repository" section, click **Configure** next to the "Available realm definitions" drop-down list.

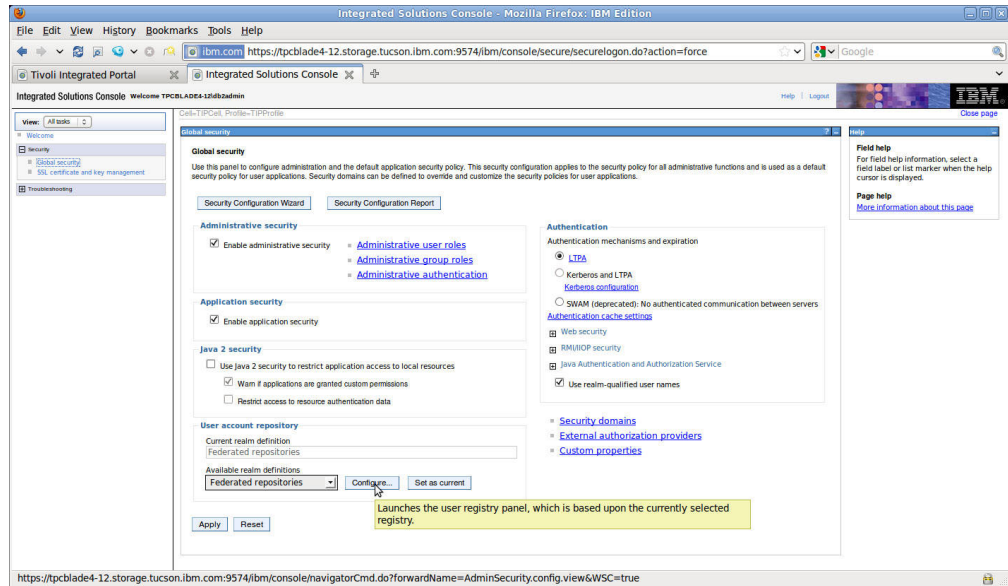

Figure 19. Configuring the available realm definitions

9. On the Global security > Federated repositories page, in the "Repositories in the realm" table, select the entry for the LDAP repository you previously added. Click **Remove**.

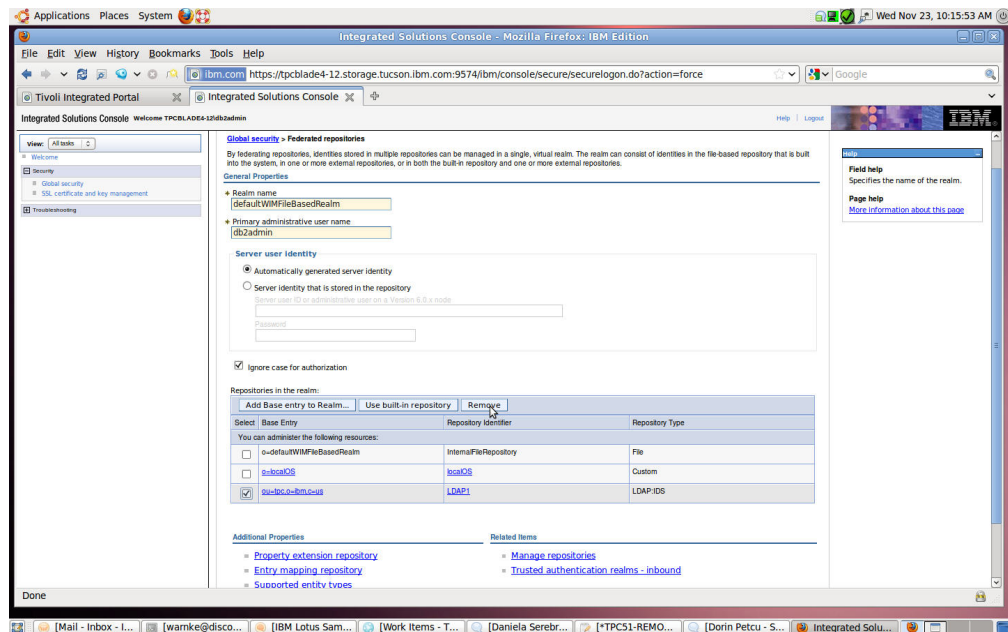

Figure 20. Removing the LDAP repository

10. In the message dialog box displayed on the Federated repositories page, click the **Save** link in **Save directly to the master configuration**.
11. On the Global security > Federated repositories page, under "Related items," click **Manage repositories**.

Figure 21. Managing the repositories

12. On the Global security > Federated repositories > Manage repositories page, select the entry for the LDAP repository that you previously added and click **Delete**.

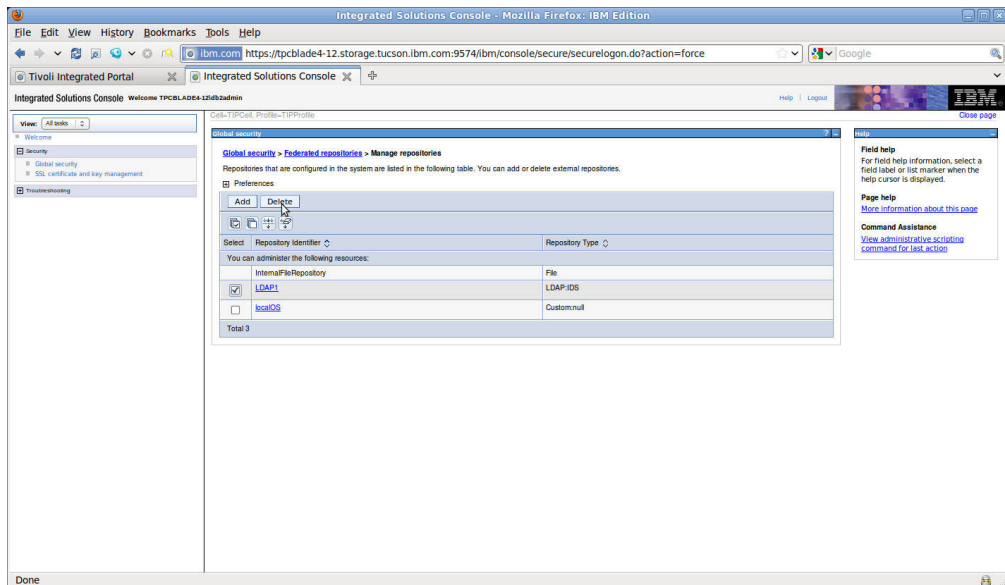

Figure 22. Deleting the LDAP repository

13. In the message dialog box displayed on the Manage repositories page, click the **Save** link in **Save directly to the master configuration**.
14. Log out from the WebSphere Administrative Console.
15. Log out from the Tivoli Integrated Portal Administrative Console.
16. Stop and restart the Tivoli Integrated Portal server. For information about stopping and starting the server, go to the Tivoli Storage Productivity Center information center. Search for *starting and stopping the Tivoli Integrated Portal server*.

**Important:** Before establishing the desired authorization configuration for Tivoli Integrated Portal, Tivoli Storage Productivity Center, and Tivoli Storage Productivity Center for Replication, you must ensure that there are no duplicated user names or group names within the local file-based repository and the localOS repository.

After you have completed the removal of the LDAP repository from the Tivoli Storage Productivity Center federated repositories authentication configuration, you should establish the desired authorization configuration for Tivoli Integrated Portal. Tivoli Integrated Portal administrators require the `iscadmins` and `administrator` roles. Operators viewing Tivoli Common Reporting reports require the `tcPortalOperator` role. For information about user roles and groups, go to the Tivoli Integrated Portal administrative console online help. On the Welcome page, open the online help by clicking `?`. On the help welcome page, click **Using the Tivoli Integrated Portal > Users and Groups** in the navigation pane.

You should also assign Tivoli Storage Productivity Center roles to groups using the **Role-to-Group Mapping** node in the Tivoli Storage Productivity Center stand-alone GUI. You can map Tivoli Storage Productivity Center roles, such as Tape Operator or Fabric Administrator, to user groups that you create in your local operating system repository. For information about the **Role-to-Group Mapping** node, go to the Tivoli Storage Productivity Center information center. Search for *Role-to-Group Mappings*.

For information about assigning roles to users and roles to groups for Tivoli Storage Productivity Center for Replication, go to the Tivoli Storage Productivity Center information center. Search for *Managing replication*. On the Managing replication page, click **Security**.

## Changing the LTPA token expiration for single sign-on

For single sign-on, the user authentication information is passed between applications using Lightweight Third-Party Authentication (LTPA) tokens. By default, the tokens expire after eight hours. You can change the LTPA token expiration time using the Tivoli Integrated Portal user interface.

To change the expiration time for the LTPA tokens, complete the following steps.

1. Start an Internet Explorer or Firefox web browser, and type the following information in the address bar: `https://hostname:port/ibm/console/logon.jsp` where *hostname* defines the server that is running Tivoli Integrated Portal, such as the server name or IP address, and *port* defines the port number for Tivoli Integrated Portal.

To view information about Tivoli Integrated Portal port numbers, see “Tivoli Integrated Portal port numbers” on page 232. Contact your Tivoli Storage Productivity Center administrator if you must verify the host name and port number.

2. On the Tivoli Integrated Portal logon page, log on using the appropriate user ID and password. Your user ID must have Tivoli Integrated Portal administrator authorization.
3. In the Tivoli Integrated Portal navigation tree, click **Settings > WebSphere Administrative Console**.
4. In the Tivoli Integrated Portal content pane, click **Launch WebSphere administrative console**.
5. In the WebSphere Administrative Console navigation tree, click **Security > Global security**.

6. On the Global security page, under "Authentication" and "Authentication mechanisms and expiration", ensure that the **LTPA** radio button is selected. Click the **LTPA** link.
7. On the Global security > LTPA page, under "LTPA Timeout", type the expiration time in minutes in the "LTPA Timeout value for forwarded credentials between servers" field. The default expiration time is 480 minutes (eight hours). The expiration time must be greater than the authentication cache timeout value. The authentication cache timeout value can be found by clicking the **Authentication cache settings** link in the "Authentication" section of the Global security page. The default authentication cache timeout value is 10 minutes. Click **OK**.
8. In the messages dialog box displayed on the Global security page, click the **Save** link in **Save directly to the master configuration**.
9. Log out from the WebSphere Administrative Console.
10. Log out from the Tivoli Integrated Portal Administrative Console.
11. Stop and restart the Tivoli Integrated Portal server. For information about stopping and starting the server, go to the Tivoli Storage Productivity Center information center. Search for *starting and stopping the Tivoli Integrated Portal server*.

---

## Administering data sources

Use the following topics for information about how to administer CIM agents, Storage Resource agents, out-of-band Fabric agents, storage systems, Tivoli Storage Productivity Center servers, and VMware VI data sources.

### Checking the health of your data sources

This topic provides information about checking the health of your data sources.

The storage systems that use the native interfaces (for example, DS8000, the XIV system, SAN Volume Controller, and Storwize V7000) do not use CIMOM agents. Once you successfully connect to the storage system, Tivoli Storage Productivity Center can display the status.

Expand **Administrative Services > Data Sources** and left-click the following nodes:

- **CIMOM Agents**
- **Data/Storage Resource Agents**
- **Inband Fabric Agents**
- **Out of Band Fabric Agents**
- **Storage Subsystems**
- **TPC Servers**
- **VMware VI Data Source**

A list of data sources is displayed in the content pane. If the agents are up and running, there is a green health status icon in the State column. For the CIMOM Agents and Storage Subsystems, a green health status icon is displayed in the Connection Status column.

### CIM agents

Common Information Model (CIM) agents provide a CIM interface for storage entities. IBM Tivoli Storage Productivity Center uses CIM agents to collect information about the entities that you want to monitor.

Storage entities include IBM TotalStorage Enterprise Storage Server, IBM System Storage DS4000, IBM System Storage DS5000 Storage Manager, IBM System Storage DS6000, tape, switch, and any SMI-S certified Common Information Model Object Manager (CIMOM).

CIM agents are not required for the following storage systems:

- System Storage DS8000
- SAN Volume Controller
- The XIV system
- Storwize V7000
- Storwize V7000 Unified
- IBM SONAS

Before you can monitor the entities that are managed by CIM agents, you must configure the agents in the Tivoli Storage Productivity Center user interface. Use either of the following methods to add a CIM agent:

- To automatically add a CIM agent and discover the entities that it manages, use the Configure Devices wizard. For more information, see “Adding resources for monitoring” on page 309.
- To manually add the CIM agent, use the **CIMOM Agents** node under **Administrative Services > Data Sources** in the navigation tree. For more information, see “Adding a CIM agent connection.”

After you manually add a CIM agent, you must run a discovery schedule to detect the entities that it manages. For more information about the discovery process, see “Discover storage subsystem, tape library, and fabric information with CIM agents” on page 334 and “Discover CIM agents automatically” on page 255.

### Adding a CIM agent connection

CIM agents provide a Common Information Model (CIM) interface for management applications. This topic discusses how to add a CIM agent connection.

You can add a CIM agent connection to Tivoli Storage Productivity Center by using the Configure Devices wizard or use the manual steps in this procedure.

To add a CIM agent connection using the Configure Devices wizard, see “Adding resources for monitoring” on page 309.

To add a CIM agent connection to Tivoli Storage Productivity Center manually, complete the following steps:

1. In the Navigation Tree pane, expand **Administrative Services > Data Sources** and click **CIMOM Agents**.
2. In the content pane, click **Add CIMOM**. The Add CIMOM window opens.
3. Specify information about the CIM agent:

**Host** The hostname of the computer on which the CIMOM is installed. For element managers, you can enter a host name, IPv4, or IPv6 address depending on what is supported within your environment:

- Enter an IPv4 address in the following format: **###.###.###.###**. For example: 192.168.1.65
- Enter an IPv6 address. The preferred IPv6 address representation is written as eight groups of four hexadecimal digits:

xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx, where each x is a hexadecimal digit representing 4 bits. For example: 2001:DB8:0000:1234:0000:0000:5678:ABCD. You can also specify IPv6 addresses using shortened formats that omit leading zeros 2001:DB8:0:1234:0:0:5678:ABCD or use double colons 2001:DB8:0000:1234::5678:ABCD in place of a series of zeros.

You can enter an IPv6 address for a CIMOM if the computer where IBM Tivoli Storage Productivity Center is installed is IPv6 or dual stack (IPv4 and IPv6) enabled.

**Port** The port on which the CIMOM is listening. By default this port is 5989 for a secure connection and 5988 for an unsecured connection. See the documentation for the appropriate SMI-S CIM Provider for more information about available ports.

**Username**

The user ID used for authentication, if required by the CIMOM.

**Password**

The password, if required by the CIMOM.

**Interoperability Namespace**

This namespace within the CIMOM allows for accessing the CIM Interop Schema (including the class instances of the Server Profile) and determines how IBM Tivoli Storage Productivity Center interacts with the CIMOM when retrieving information. For information about the namespace to use, see <http://www-01.ibm.com/support/docview.wss?uid=swg21386446>. Click the appropriate version for **Switches & Directors**.

To view a list of default namespaces for CIMOM agents for storage subsystems that is included with Tivoli Storage Productivity Center, open the following file in a text editor: *install\_directory/data/config/namespace.config*, where *install\_directory* represents the directory where the product is installed.

Check the documentation of the appropriate SMI-S CIM Provider or contact the storage system vendor to ensure that you use the most current namespaces.

**Protocol**

The version of the cim-xml protocol. Can be http or https.

**Display Name**

The name of the CIMOM, as specified by the CIMOM provider, to be displayed in the Tivoli Storage Productivity Center interface.

**Description**

An optional description of the CIMOM. This description can be any combination of alphanumeric characters.

**Test CIMOM connectivity before adding**

Select this option to have Tivoli Storage Productivity Center ensure that communication to the CIMOM is working properly before adding information about that CIMOM.

4. Click **Save**.

This procedure does not physically add a CIMOM, but adds the information you have given about the CIMOM to Tivoli Storage Productivity Center so that Tivoli Storage Productivity Center can communicate with the CIMOM.

## Discover CIM agents automatically

This topic discusses how to discover storage subsystem CIMOMs that are visible to the Device server using Service Location Protocol (SLP).

In many cases CIM agents can be automatically discovered using SLP. The criteria is that the CIM agent must be visible to the Device server.

To automatically discover all CIM agents that are visible to the Device server, complete the following steps:

1. In the navigation tree pane, expand **Administrative Services > Discovery** and click **CIMOM**.
  - a. Click the **Options** tab.
  - b. Enter the IP address or host name for the SLP directory agents for CIMOM discovery. Or select the **Scan local subnet** check box.
  - c. Click **File > Save** on the menu bar to save the information.
2. Right-click **CIMOM** and click **Run Now**.
3. After you submit a CIMOM discovery job, a message window is displayed with the text **CIMOM Discovery Job submitted**. Click **OK**. The job name is located in the navigation tree after **CIMOM**. While it is running, the CIMOM job has a blue circle outline by the job name.
4. To determine if the job has completed, right-click **CIMOM** and click **Update Job Status**. If the job has completed successfully, a green box is shown by the job name. If the job has completed but failed, a red circle is shown.

**Note:** The job returns as failed if one or more sub-jobs failed. Some CIMOMs might still have been discovered.

5. After the job completes, the discovered CIM agents are listed in the **CIMOM Agents** table. Expand **Administrative Services > Data Sources** and click **CIMOM Agents**.
6. For each CIM agent that you want to use, highlight the CIM agent and click the magnifying glass for the listing. You must select the CIM agents one at a time. The **CIMOM Agents** window is opened.
7. Enter additional information for the CIM agent, such as the user name and password, and select the **Test CIMOM connectivity before updating** check box.
8. Click **File > Save** on the menu bar to save the information and perform a connectivity check.

**Note:** This procedure does not physically add the CIM agent to your environment, but provides IBM Tivoli Storage Productivity Center with the information it needs to communicate with that CIM agent. This includes information that you have defined and CIM agents discovered using SLP.

## Viewing information about a CIM agent

Use panels and reports in IBM Tivoli Storage Productivity Center to view detailed information about a CIM agent.

Use the following reports to view information about a CIM agent:

- In the Navigation Tree pane, expand **IBM Tivoli Storage Productivity Center > Reporting > Data Source Reports > CIMOM Agents** and click **By CIMOM Agent** or **By Managed Device**. See “Data source reports - CIMOM agents” on page 1153 for more information about these reports.

- In the Navigation Tree pane, expand **Administrative Services > Data Sources** and click **CIMOM Agents**. A list of CIM agents appears in the content pane. Click the magnifying glass next to a CIM agent to view the following information about that agent:

**Service URL**

The service URL of the CIMOM containing the IP address of the CIMOM, the port on which the CIMOM is listening, and the protocol used for communication. This URL has a protocol [http|https], an IP or Hostname, and a port number. This field displays IPv4 and IPv6 addresses as appropriate.

**Display Name**

The name of the CIMOM as specified by the CIMOM provider that will appear in the IBM Tivoli Storage Productivity Center interface.

**Description**

The optional description that was entered on the Add CIMOM window.

**Username**

The CIMOM user ID used for authentication.

**Password**

The password for the CIMOM.

**Interoperability Namespace**

Enter the interoperability namespace of the CIMOM. This namespace within the CIMOM allows for accessing the CIM Interop Schema (including the class instances of the Server Profile) and determines how Tivoli Storage Productivity Center interacts with the CIMOM when retrieving information.

**Truststore Location**

The location (path on this computer) of a certificate file for certificate based authentication in the https protocol.

**User Interface Description**

The name of the Human Interface Service (if any) supported by this CIMOM.

**Software Level**

The software version level of the CIMOM agent.

**Protocol Version**

The version of the cim-xml protocol.

**Authentication Mechanism**

The authentication mechanism supported by the CIMOM. This field can contain the following values: Unknown, None, Other, Basic, Digest.

**Alias** The alias of the CIMOM.

**Service ID**

The service ID for the CIMOM.

**Protocol**

The communication protocol used for the CIMOM. Possible values are http and https.

**SLP Attributes**

The standard set of attributes for this CIMOM. The attributes are retrieved via SLP.

### **Connection Status**

The status of this CIMOM with respect to Tivoli Storage Productivity Center. Possible values are: SUCCESS, UNCONFIGURED, UNKNOWN, INVALID\_NAMESPACE, TIMEOUT, REFUSED, LOGIN\_FAILED, SSL\_HANDSHAKE\_ERROR, SSL\_REGISTRATION\_INVALID, CIMCLIENT\_ERROR

### **Status Timestamp**

The date/time when the Connection Status information was last collected.

### **Test CIMOM connectivity before updating**

If this box is checked Tivoli Storage Productivity Center ensures that communication to the CIMOM is working properly before making any changes.

## **Updating CIM agent user identification**

After a CIM agent has been added to the **CIMOM** node, you can update the user ID, password, and other information.

To update the CIM agent user identification, follow this procedure:

1. In the Navigation Tree window, expand **Administrative Services > Data Sources**. Left-click **CIMOM**.
2. In the content pane, click the magnifying glass icon for the agent for which you want to change information.
3. Information about the CIM agent is displayed in the Information window. The fields which can be updated are:

### **Display Name**

The name of the CIM agent, as specified by the CIMOM provider, that will appear in the IBM Tivoli Storage Productivity Center interface.

### **Description**

The optional description of the CIM agent that was entered on the Add CIMOM Agent window. Tivoli Storage Productivity Center

### **Username**

The user ID used for authentication, if required by the CIM agent.

### **Password**

The password for the CIM agent, if required by the CIM agent.

### **Interoperability Namespace**

This namespace within the CIM agent allows for accessing the CIM Interop Schema (including the class instances of the Server Profile) and determines how Tivoli Storage Productivity Center interacts with the CIM agent when retrieving information.

### **Test CIMOM connectivity before updating**

Check box. Check this box to have Tivoli Storage Productivity Center ensure that communication to the CIM agent is working properly before updating information about that CIM agent.

4. Save your changes by clicking the **Save** icon.
  - If you have selected **Test CIMOM connectivity before updating**, the CIMOM connectivity check will be run when you save the changes.
  - If **Test CIMOM connectivity before updating** is not selected, a discovery will be started immediately after you save the changes.

## Testing a CIM agent connection

Manually check to make sure that communication to the CIM agent is working properly.

To test a CIM agent connection, follow this procedure:

1. In the Navigation Tree, expand **Administrative Services > Data Sources**. Left-click **CIMOM**.
2. In the content pane, select a CIM agent. Click **Test CIMOM Connection**. a confirmation dialog appears: "Testing CIMOM connectivity can take up to several minutes in case of an incorrectly entered port number, network problems or an unpassed firewall. Would you like to continue anyway?" Select **yes** to perform the CIMOM connection test.
3. To close the Test CIMOM Connection window, click **OK**.

## Removing a CIM agent

You can remove a CIM agent from the navigation tree and the repository database. Data discovered by the CIM agent is not removed from the repository.

To remove a CIM agent, follow this procedure:

1. In the Navigation Tree pane, expand **Administrative Services > Data Sources**. Click **CIMOM Agents**.
2. In the content pane, select a CIM agent. Click **Remove CIMOM**.
3. The Remove CIMOM confirmation window opens. Click **Yes**. The CIM agent is immediately deleted from the list.

## Show managed devices for a CIM agent

You can display the managed devices for a CIM agent.

To show the managed devices for a CIM agent, follow these steps:

1. In the Navigation Tree pane, expand **Administrative Services > Data Sources**. Click **CIMOM Agents**.
2. In the content pane, select a CIM agent. Click **Show Managed Devices**.
3. The CIMOM Managed Devices window opens displaying the managed devices. Click **OK** to close the window.

## Collecting CIM agent logs

You can collect logs for certain IBM CIM agents using the command line interface.

**Remember:** Storage systems that use the native interfaces (for example, DS8000, the XIV system, SAN Volume Controller, and Storwize V7000) do not use CIM agents.

1. Change to the directory where the CIM agent is installed.
  - On Linux operating systems, DS3000, DS4000, DS5000, DS6000 are installed at `/opt/IBM/cimagent/cimom`
  - On Windows operating systems, DS3000, DS4000, DS5000, DS6000 are installed at `C:\Program Files\IBM\cimagent\cimom`
2. Run one of the following commands:

### On Linux operating systems

```
collectLogs.sh
```

### On Windows operating systems

```
collectLogs.bat
```

A **collectedLogs.zip** file is created.

**Important:** This file is overwritten if you run the script again.

### Verifying that a CIM agent is running

You can verify that a CIM agent is running from the command line interface.

To verify that a CIM agent is up and running, run the following command:

```
telnet <IP> <port>
```

Where <IP> is the IP address of the system where the CIM agent is installed, and <port> is the port number. By default, this is 5989 for a secure connection and 5988 for an unsecure connection.

## Storage Resource agents

This topic provides information about administering, configuring, and viewing information about Storage Resource agents.

See “Deployment guidelines and limitations for Storage Resource agents” on page 121 for information about deploying Storage Resource agents.

### Viewing information about an agent

View detailed information about a Storage Resource agent.

To view information about a Storage Resource agent from the Tivoli Storage Productivity Center GUI, complete the following steps:

1. In the navigation tree, click **Administrative Services > Data Sources**. Left-click **Data/Storage Resource Agents**.
2. In the content pane, click the magnifying glass icon for an agent under the list of agents. In the content pane, a notebook window opens. On the General page, the following information is displayed:

**Agent** Displays the name of an agent and indicates whether the agent is up or down.

**Port** Displays the port number on which an agent is listening for requests.

**Installation Location**

Displays where the agent is installed.

**Host Address**

Displays the host address of the computer on which an agent is running.

**Last update**

Displays the date and time when an agent was last updated.

**Time Zone**

Displays the current time zone for an agent.

**Connection Errors**

Displays any connection errors that occurred for an agent.

**Consecutive Errors**

Displays how many errors occurred consecutively.

**HBA Data**

Displays information about the HBA installed.

3. Click the **Details** tab to view more detailed information. The following information is displayed:

**Agent** Displays the name of the agent.

**Host** Displays the host name of the system on which the agent is running.

**Host ID**

Displays the identifier of the host computer in hexadecimal format. Tivoli Storage Productivity Center collects only Host ID information for Solaris systems. All other platforms display GUID information in the Host ID column.

**Start Time**

Displays the date and time that the agent was started.

**Elapsed Time**

Displays the time elapsed since the agent was last updated.

**VM Size**

Displays the size (in MB) of the disk space that is allotted to virtual memory for an agent. This value does not apply to Storage Resource agents. This size applies only to the size of the Java virtual machines for the agents.

**Manufacturer**

Displays the manufacturer of the system.

**OS Type**

Displays the operating system that is running on the system.

**CPU Architecture**

Displays the architecture of the system.

**Job Count**

Displays the number of jobs scheduled to run against the agent.

4. Click the **Jobs** tab to view information about the jobs scheduled to run on the managed system.

## Viewing an agent log file

The log file for a Storage Resource agent contains informational, warning, and error messages for the previous sessions of the agent. You can use the log file to troubleshoot errors that might occur when starting an agent, processing, or shutting down the agent.

The log file is located in the agent installation directory:

### Storage Resource agents

For Windows default: C:\Program Files\IBM\TPC\agent\log\  
<computer\_name>\agent.log.

For Linux or AIX (default): /opt/IBM/TPC/agent/log/  
<computer\_name>agent.log.

To view the log for a Storage Resource agent, complete the following steps:

1. In the navigation tree, click **Administrative Services > Data Sources**. Left-click **Data/Storage Resource Agents**.
2. In the content pane, select an agent and click **View Log**.

## Migrating a Data agent

Migrate a selected Data agent to a Storage Resource agent.

Tivoli Storage Productivity Center provides the following benefits when you migrate an existing Data agent or Inband Fabric agent to a Storage Resource agent:

- Storage Resource agents require less resources on a host computer than a Data agent or Fabric agent that is based on Common Agent Services. Additionally, you can deploy a Storage Resource agent as a daemon or non-daemon service.
- Reduced complexity when deploying agents. You can deploy Storage Resource agents directly from the Tivoli Storage Productivity Center user interface and they do not require you to install Agent Manager.
- Improved interface when deploying, upgrading, and administering agents. You can manage Storage Resource agents using the nodes in the **Administrative Services** section of the navigation tree. You can deploy and upgrade Storage Resource agents on schedules that you define.

To migrate a Storage Resource agent from the **Administrative Services > Data Sources** node in the user interface, complete the following steps:

1. In the navigation tree, expand **Administrative Services > Data Sources**. Left-click **Data/Storage Resource Agents**.
2. In the content pane, click **Migrate Agents**.
3. The Create Data/Fabric Agent Migration panel is displayed. Use this panel to schedule the migration of Data agents and Inband Fabric agents to Storage Resource agents.
4. Select **File > Save** to save the migration schedule. The agents on the computers that you specified are migrated according to the schedule that you defined.

The migration process deploys a Storage Resource agent on the target computer and then uninstalls the Data agent. The new Storage Resource agent retains the existing scheduled jobs that were defined for the Data agent. The scripts and batch reports for the Data agent are copied over to the Storage Resource agent. If for any reason the migration fails, Tivoli Storage Productivity Center restores the Data agent so that it can continue to monitor the target computer.

## Migrate Data/Fabric Agent

Define schedules to migrate existing Data agents or in-band Fabric agents to Storage Resource agents. The migration process deploys a Storage Resource agent on a target host and then uninstalls the existing agent.

Tivoli Storage Productivity Center provides the following benefits when you migrate an existing Data agent or in-band Fabric agent to a Storage Resource agent:

- Storage Resource agents require less resources on a host computer than a Data agent or Fabric agent that is based on Common Agent Services. Additionally, you can deploy a Storage Resource agent as a daemon or non-daemon service.
- Reduced complexity when deploying agents. You can deploy Storage Resource agents directly from the Tivoli Storage Productivity Center user interface and they do not require you to install Agent Manager.
- Improved interface when deploying, upgrading, and administering agents. You can manage Storage Resource agents using the nodes in the **Administrative Services** section of the navigation tree. You can deploy and upgrade Storage Resource agents on schedules that you define.

To migrate a Data agent or Fabric agent to a Storage Resource agent from the **Administrative Services > Configuration** node in the user interface, complete the following steps:

1. Use either of the following methods to access the panel for scheduling an agent migration:
  - Expand **Administrative Services > Data Sources** in the navigation tree. Left-click **Data/Storage Resource Agents**. In the topic pane, click **Migrate Agents**.
  - Expand **Administrative Services > Configuration** in the navigation tree. Right-click **Migrate Data/Fabric Agent** and select **Create Data/Fabric Agent Migration** from the menu.

The content pane displays a panel for defining a migration schedule.

2. Use the following pages on the panel to define information about the migration:

#### **Computers**

Use this page to select the computers and groups of computers that contain the Data and Fabric agents that you want to migrate to Storage Resource agents.

#### **When to Run**

Use this page to determine when the Data and Fabric agents in a schedule are migrated.

#### **Options**

Use this page to specify the runtime settings of a Storage Resource agent, the method for migrating an agent, and the login credentials for an agent. If you include multiple agents in a migration schedule, the settings that you define on this panel are applied to all those agent migrations.

**Alerts** Use this page to define the actions that occur if a Data/Fabric Agent Migration schedule fails.

3. Select **File > Save** to save the migration schedule. The agents on the computers that you specified are migrated according to the schedule that you defined.

The migration process deploys a Storage Resource agent on the target computer and then uninstalls the Data agent. The new Storage Resource agent retains the existing scheduled jobs that were defined for the Data agent. The scripts and batch reports for the Data agent are copied over to the Storage Resource agent.

## **Upgrading the Storage Resource agent by using the Data Sources node**

Use this information to upgrade a previous Storage Resource agent to the current release.

To upgrade a Storage Resource agent, follow these steps:

1. In the navigation tree, expand **Administrative Services > Data Sources**. Left-click **Data/Storage Resource Agents**.
2. In the topic pane, select one or more agents for which you want to upgrade. Click **Upgrade Agents**.
3. The Create Storage Resource Agent Upgrade page is displayed. Use this page to schedule an upgrade of the Storage Resource agent. You have the following tabs:

#### **Computers**

You can select Computer Groups or Computers.

#### **When to Run**

You can specify how often to run the job or how to handle time zones.

### Options

You can specify to force an upgrade for an agent, maintenance upgrade for an agent, or language pack to apply to an agent.

**Alerts** You can specify the triggering conditions and triggering actions.

Enter your information in the appropriate fields.

4. Save and run the job.

**Note:** The Storage Resource agent upgrade job delivers the software upgrade packages to the agent computer. The job log displays the status of the delivery. The actual status of the upgrade is found in the agent log on the agent computer. If the agent log indicates that the upgrade failed and the state of the Storage Resource agent remains in the “Upgrading agent software status”, try restarting the agent and running the upgrade job again.

## Storage Resource Agent Upgrades

You can configure IBM Tivoli Storage Productivity Center for a Storage Resource agent upgrade.

When you apply maintenance to Tivoli Storage Productivity Center, you can upgrade the Storage Resource agent now or upgrade the agent at a later time. To ensure that all your agents are at the current release level and to manage your network load, schedule upgrades on a regular basis.

To configure Tivoli Storage Productivity Center for a Storage Resource agent upgrade, complete the following steps:

1. In the navigation tree, expand **Administrative Services > Configuration > Storage Resource Agent Upgrades**.
2. Right-click on **Storage Resource Agent Upgrades**. Click **Create Storage Resource Agent Upgrade**.
3. The Create Storage Resource Agent Upgrade page is displayed in the topic pane. You have the following tabs:

### Computers

You can select Computer Groups or Computers.

### When to Run

You can specify how often to run the job or how to handle time zones.

### Options

You can specify to force an upgrade for an agent, maintenance upgrade for an agent, or language pack to apply to an agent.

**Alerts** You can specify the triggering conditions and triggering actions.

Enter your information in the appropriate fields.

4. Save and run the job.

## Configuring tracing for an agent

You can configure and enable tracing for a Storage Resource agent. This provides extensive logging of exception and trace messages; it can provide useful information for the IBM Support center.

You must have administrator authority to perform this procedure.

To configure tracing for a Storage Resource agent, complete the following steps:

1. In the navigation tree, click **Administrative Services > Data Sources** . Left-click **Data/Storage Resource Agents**.
2. In the topic pane, select a Storage Resource agent. Under the Select Action menu, click **Configure Tracing**. The Tracing Configuration window opens.
3. Select the **Enable Trace** check box.
4. Specify the tracing options:
  - a. In the **Level** field, select one of the following options:
    - DEBUG\_MIN**  
Minimum level of debugging
    - DEBUG\_MID**  
Medium level of debugging
    - DEBUG\_MAX**  
Maximum level of debugging
  - b. In the **Maximum Number of Files** field, specify the maximum number of trace files that are created. When this number is reached, the oldest file is overwritten. By default, this value is set to five.
  - c. In the **Maximum File Size (kilobytes)** field, specify the maximum size of each trace file.
5. Click **OK**. The settings are saved to the AgentTraceLog.config file

### Disabling an agent

You can disable a Storage Resource agent. Disabling the agent signifies that the Storage Resource agent is unavailable and the Data server should not contact that agent for any job processing.

You might want to disable a Storage Resource agent in the following situations:

- The agent computer is undergoing maintenance and is unavailable. This action prevents the server from flagging the agent as "down" if it cannot reach the agent. The amount of times that the server tries to contact the agent is defined by the **agentErrorLimit** parameter in the server.config file.
- The agent computer is busy with resource-intensive processing and you do not want to add any jobs to that processing load.

While disabled, the agent name in the user interface is outlined with a red circle with a line through it. The server does not attempt to contact the agent.

To disable a Storage Resource agent, complete the following steps:

1. In the navigation tree, click **Administrative Services > Data Sources > .** Left-click **Data/Storage Resource Agents**.
2. In the topic pane, select a Storage Resource agent. Under the Select Action menu, click **Disable**.

### Enabling an agent

You can enable an agent that is currently disabled. After it is enabled, the Data server resumes communication with that agent. This action is available for disabled agents only.

If the server cannot contact an agent, the server automatically flags the agent as "down". Click **Enable** to reestablish communication between the agent and server. The number of times the server tries to contact the agent is specified in the **agentErrorLimit** parameter in the server.config file. The default is 3.

The default directory for the `server.config` file is:

#### Windows

`C:\Program Files\IBM\TPC\Data\config`

#### Linux or UNIX

`/opt/IBM/TPC/Data/config`

**Tip:** Clicking **Check** also enables an agent that is disabled.

To enable an agent, complete the following steps:

1. In the navigation tree, click **Administrative Services > Data Sources**. Left-click **Data/Storage Resource Agents**.
2. In the content pane, select an agent. Under the Select Action menu, click **Enable**.

### Shutting down an agent

From the graphical user interface, you can shut down Storage Resource agents that are running as daemon processes.

An agent that is deployed as a daemon service runs in the background and listens for requests. An agent that is deployed as a non-daemon service runs as a stand-alone process. It is not necessary to shut down Storage Resource agents that are running as non-daemon processes.

To shut down an agent that is deployed as a daemon service, complete the following steps:

1. In the navigation tree, click **Administrative Services > Data Sources**. Left-click **Data/Storage Resource Agents**.
2. In the topic pane, select a Storage Resource agent. Under the **Select Action** menu, click **Shutdown**. This button is unavailable for Storage Resource agents that are deployed as non-daemons.
3. Select how you want an agent to shut down. You can select from the following options:

#### Normal

Shut down the agent software and let all running processes complete. The agent continues to accept new jobs that are submitted and is not shut down until the following conditions are met:

- All running processes are complete.
- There are no new jobs submitted.

#### Immediate

Shut down the agent software when the currently running processes complete. No new jobs are accepted by the agent and shutdown occurs immediately after the last job completes.

**Abort** Shut down the agent software and stop whatever processes are currently running.

For Storage Resource agents that are run as daemon processes, click **Start** on the Data/Storage Resource agent page to start those agents. See “Starting a Storage Resource agent” for more information about how to start Storage Resource agents.

### Starting a Storage Resource agent

You can start a Storage Resource agent if the daemon process for that Storage Resource agent is down.

You can only perform this task for Storage Resource agents running as a daemon service.

To start a Storage Resource agent, complete the following steps:

1. In the navigation tree, click **Administrative Services > Data Sources**. Left-click **Data/Storage Resource Agents**.
2. In the content pane, select a Storage Resource agent. Under the **Select Action** menu, click **Start**.
3. Enter the user ID and password that Tivoli Storage Productivity Center uses when logging in to the host computer for a Storage Resource agent agent and click **Ok**.

### **Checking whether an agent can communicate with the Data server**

You can check whether an agent can communicate with the Data server.

To check an agent, complete the following steps:

1. In the navigation tree, click **Administrative Services > Data Sources**. Left-click **Data/Storage Resource Agents**.
2. In the topic pane, select an agent and click **Check**.

This operation verifies that the Data server can communicate with the host system where the Storage Resource agent is deployed with the appropriate authentication information. After verifying that the Data server can communicate with the selected agent, the process checks for the existence of the runtime files for Storage Resource agents.

### **Changing authentication for a Storage Resource agent**

There are times when you might need to change the user ID, password, and certificate location for a Storage Resource agent.

To change the authentication for a Storage Resource agent, follow these steps:

1. In the navigation tree, expand **Administrative Services > Data Sources**. Left-click **Data/Storage Resource Agents**.
2. In the content pane, select one or more Storage Resource agents for which you want to change authentication information. Use ctrl + click or shift + click to select multiple agents.
3. Click **Change Authentication** from the **Select Action** menu.
4. In the Change Authentication window, enter the following information:

**User** Enter the user ID that IBM Tivoli Storage Productivity Center should use when logging on to the computer on which the Storage Resource agent is installed.

**Requirement:** This ID must have administrative or root privileges when installing a Storage Resource agent on a computer.

**Password**

Enter the password.

**Certificate Location**

Enter the fully qualified path of the certificate on the computer where the Data server is located. This file is used for certificate-based authentication. If you do not enter a value in this field the default location is used. When deploying Storage Resource agents, Tivoli Storage Productivity Center uses the Secure Shell (SSH) protocol to communicate with the target computer.

### Passphrase

Enter the passphrase for the certificate file. The passphrase was created when the certificate was generated.

Click **Save**.

### Related Tasks:

See **Planning > General Planning > Planning for Storage Resource agents** section in the *IBM Tivoli Storage Productivity Center Installation and Configuration Guide* for additional configuration information about certificates used after deployment.

## Adding Storage Resource agents

You can add Storage Resource agents to your system by scheduling a job or by adding an agent immediately.

To add a Storage Resource agent, complete the following steps:

1. In the navigation tree, click **Administrative Services > Configuration**. Right-click **Storage Resource Agent Deployments**. On the menu, click **Create Storage Resource Agent Deployments**.
2. The Create Storage Resource agent Deployments window opens displaying the Computers page. Enter the following information:

#### Header fields

##### Creator

Predefined creator name.

**Name** Predefined name.

##### Description (optional)

Enter a user-defined description name for the job.

##### Enabled

Check this box to enable Storage Resource agent deployments.

#### Add Host List

Click this button to enter names and logon credentials for the computers on which you want to deploy Storage Resource agents.

**Remember:** When you use an IPv6 address to add a server, the TPC Server must also have an IPv6 address. Both of these servers must be in the same domain name system (DNS).

You can enter information in one of the following ways:

- Click **Add Agents from MS Directory** to install Storage Resource agents on one or more Windows computers that are members of a Windows domain. Enter the domain controller name and login information about the displayed window. On the next window, select the domain and click **Get List of Domain Computers**. The host names of computers that you add by using this method are displayed in the **Remote Agent Machines** section of the window. In that section, you can also specify an installation location for each computer and indicate whether you are reinstalling a Storage Resource agent on a computer.
- Click this button to retrieve a list of computer names from a flat text file. The computers listed in the file are automatically added to the deployment schedule and displayed in the **Remote Agent Machines** section. In that section, you can also specify an installation location

for each computer and indicate whether you are reinstalling a Storage Resource agent on a computer.

The file that you retrieve must contain one host name or IP address per line. For example:

```
systemxyz.storage.usa.ibm.com
9.79.179.179
systemzyx.storage.usa.ibm.com
9.89.189.189
```

If Tivoli Storage Productivity Center discovers any syntax problems in the file, none of the host entries in the file are added to the deployment job.

- In the **Remote Agent Machines** section, enter the names or IP addresses of the computers where you want to deploy the Storage Resource agents. Specify the installation location for the Storage Resource agent runtime files. If you do not enter an installation location, the default location is used. The default installation directories are:
  - For Windows: C:\Program Files\IBM\TPC\agent
  - For Linux and UNIX: /opt/IBM/TPC/agent
- Select **Force** under the following circumstances:
  - If an earlier Storage Resource agent installation failed and there are damaged agent files on the computer that cause further installations to fail. If you select this option, Tivoli Storage Productivity Center attempts to overwrite the previous failed deployment on the computer with a new Storage Resource agent.
  - If you want an existing Storage Resource agent to communicate with an additional Tivoli Storage Productivity Center server. To do this, you must create the deployment job from the additional Tivoli Storage Productivity Center server to which you want the Storage Resource agent to communicate.

To install the Storage Resource agent to communicate with two different servers using the same location, follow the example in these steps:

- a. From server 1 (S1), install the Storage Resource agent to the location C:\Program Files\IBM\TPC\agent using port 9510.
- b. From server 2 (S2), install the Storage Resource agent in the same location using the same port 9510 and specify the **Force** option. This option is required when you install the Storage Resource agent in the same location.

If you want to install two Storage Resource agents on the same system, each with a different port, install the agents using different port numbers and different locations.

**Note:**

- You cannot change the communication type for a Storage Resource agent (daemon or non-daemon) when you select the **Force** option. Make sure to select the same communication type as the existing Storage Resource agent when you create a deployment job.
- If a Storage Resource agent exists on a target computer and you do not select **Force**, an error occurs during validation and the Storage Resource agent is not installed.

- Select **Initial Scan** to perform a file system scan on the computer where a Storage Resource agent is deployed. If this box is checked, the scan is run immediately after a Storage Resource agent is deployed.
- Click **Windows Services Information** to enter login information that Tivoli Storage Productivity Center uses to create a Windows service for the Storage Resource agent. Use the Windows Service Information window to select the local system account, enter information about an existing user account, or create a new local account. If you do not specify a Windows service account, the default itcauser account is created. This action is only available for agents that are deployed to Windows computers as daemon services. This button is disabled if Use Daemon Service for Runtime Operation is not selected.

Enter the following information:

**User** Enter the user ID that Tivoli Storage Productivity Center uses when logging in to the host computer to install a Storage Resource agent. The value in the field is applied to all the computers that appear in the **Remote Agent Machines** table.

**Attention:** This ID must have administrative or root privileges on the target computer.

**Password**

Enter the password for the user ID.

**Certificate Location**

Enter the fully qualified path of the certificate on the computer where the Data server is located. This file is used for certificate-based authentication. If you do not enter a value in this field the default location is used.

**Passphrase**

Enter the passphrase for the certificate file. The passphrase was created when the certificate was generated.

**Port** Enter the port number on which a Storage Resource agent listens for requests. The default is 9510.

**Tip:** This value is required if you run the Storage Resource agent as a daemon service.

**Use Daemon Service for Runtime Operation**

Select this option to run a Storage Resource agent on the monitored computer as a daemon service.

See Storage Resource agent Deployment Considerations for more information about deploying agents as daemon and non-daemon services.

**Restriction:** Do not select this option to run the Storage Resource agent as a stand-alone executable file on the monitored computer.

**Validate before Save**

Check this box to indicate that Tivoli Storage Productivity Center should attempt to communicate with the computers that

are added to the deployment job when you click **Save** on this page. If the validation fails for a computer, the agent is not installed on that computer.

#### **Edit Selected Entries**

Click this button to edit settings for the selected Storage Resource agents. This information includes user ID, password, certificate location, passphrase, and port. You must submit the deployment job for the changes to take effect.

#### **Remove**

Click this button to remove a Storage Resource agent from the deployment job.

**Tip:** This button does not remove the agent from Tivoli Storage Productivity Center if it is already installed; it only removes it from the deployment job.

3. Click the **When to run** tab to enter the following information:

#### **How often to run**

Specify a time to run:

- **Run now**
- **Run once at** (specify a date and time to run)

#### **How to handle time zones**

Specify a time zone to use:

- **Use the time zone that the server runs in**
- **Use this time zone** (select a time zone)

4. Click the **Alert** tab to specify the following information:

#### **Triggering-Condition**

The triggering condition you can specify is: Storage Resource agent Deployment Failed

#### **Triggered-Actions**

Choose from the following check boxes:

- **SNMP Trap**
- **TEC / OMNIBus Event**
- **Login Notification**
- **Windows Event Log**
- **Email**

Depending on what action you select, you might have other choices to make. For example, if you select the **Windows Event Log** check box, the **Event Type** field becomes active so that you can specify a severity for the event in the Windows event log.

5. Click **File > Save**.

For related tasks, see the *Planning > General Planning > Planning for Storage Resource agents* section in the *Tivoli Storage Productivity Center Installation and Configuration Guide* for additional configuration information about certificates used after deployment.

Check the `TPCD_#####.log` file in the Tivoli Storage Productivity Center installation directory to view the error messages related to failed validations. The following are the default locations for this log file:

- Windows: C:\Program Files\IBM\TPC\data\log
- UNIX/Linux: /opt/IBM/TPC/data/log

If multiple Storage Resource agents are set up to probe or scan the same storage resources, the Storage Resource agent that was added to Tivoli Storage Productivity Center first is used for the probe or scan. Therefore, only data that is gathered by the first Storage Resource agent is shown.

### Collecting service data

Collect service data about the selected Storage Resource agent. Service data includes diagnostic information such as logs, trace files, configuration information, and computer details. Use this data to troubleshoot any errors that might occur during startup, processing, or shutdown of a Storage Resource agent.

If the collection of service data is successful, Tivoli Storage Productivity Center displays a message that indicates where the resulting archive file (.zip) is stored. The archive file is stored in a directory on the same computer as the Tivoli Storage Productivity Center server. The file is located in the following default locations:

- Windows operating system: C:\Program Files\IBM\TPC\data\log\SRATraces\  
SRA\_computer\_name\TPCServiceInfo.zip
- UNIX or Linux operating system: /opt/IBM/TPC/data/log/SRATraces/  
SRA\_computer\_name/TPCServiceInfo.zip

*SRA\_computer\_name* represents the name of the computer on which the Storage Resource agent is deployed.

If the collection of service data fails, Tivoli Storage Productivity Center displays a message that indicates the job was unsuccessful. See the server log file or the services script output for more information about why the data collection failed. These files are located in the following default locations:

- Server log file (on the computer where the Tivoli Storage Productivity Center server is installed):
  - Windows operating system: c:\Program Files\IBM\TPC\data\log
  - UNIX or Linux operating system: /opt/IBM/TPC/data/log
- Services script output file (on the computer where the Storage Resource agent is deployed):
  - Windows operating system: C:\Program Files\IBM\TPC\agent\service\  
TPCServiceInfo.html
  - UNIX or Linux operating system: /opt/IBM/TPC/agent/service/  
TPCServiceInfo.html

where *SRA\_computer\_name* represents the name of the computer on which the Storage Resource agent is located.

To collect service data for a Storage Resource agent, complete the following steps:

1. In the navigation tree, click **Administrative Services > Data Sources**. Left-click **Data/Storage Resource agents**.
2. In the content pane, select a Storage Resource agent.
3. In the **Select Action** menu, click **Collect Service Data**.

### Enabling or disabling scripts for Storage Resource agents

You can enable or disable the running of scripts that are sent from the Tivoli Storage Productivity Center server to a Storage Resource agent. If enabled, a Storage Resource agent accepts and runs scripts that are sent from the server for

scheduling. If disabled, a Storage Resource agent does not accept scripts that are sent from the server and only runs scripts that are stored on the computer where the agent is deployed.

To enable or disable the running of scripts, complete the following steps:

1. In the navigation tree, expand **Administrative Services > Data Sources > Data/Storage Resource Agents**.
2. In the content pane under the Select Action menu, click **Enable Scripts** to enable the running of scripts. Click **Disable Scripts** to disable the running of scripts.

## Enabling or disabling the monitoring of fabrics by the Storage Resource agents

Enable or disable the monitoring of fabrics by the Storage Resource agent. By default a Storage Resource agent is enabled for fabric monitoring.

To enable or disable the monitoring of fabrics by the Storage Resource agent, complete the following steps:

1. In the navigation tree, expand **Administrative Services > Data Sources > Data/Storage Resource Agents**.
2. In the content pane under the Select Action menu, click **Enable Fabric** to enable the monitoring of fabrics. Click **Disable Fabric** to disable the monitoring of fabrics.

## Help command for Storage Resource agent

The **help** command for the Storage Resource agent provides information about the parameters for installing, uninstalling, and upgrading Storage Resource agents.

For information about the Storage Resource agent commands, run the **help** command. Follow these steps:

1. Go to the installation location for the Storage Resource agent:

```
cd <installation_location>
```

2. Run the following command:

```
bin/Agent -help
```

3. The output from the **help** command is as follows:

```
Usage:
Agent -INSTALL
 [-COMMTYPE DAEMON -AGENTPORT portnumber]
 [-FORCE]
 -INSTALLLOC pathname
 -SERVERIP address[,address,...]
 -SERVERPORT portnumber
 [-USERID username -PASSWORD password -CERT file -PASSPHRASE phrase]
```

```
Agent -UNINSTALL
 [-FORCE]
 -SERVERNAME servername
```

```
Agent -UPGRADE
 -INSTALLLOC pathname
```

For information about how to install the Storage Resource agent using commands, see the information about installing agents in the *Tivoli Storage Productivity Center Installation and Configuration Guide*.

For information about how to uninstall the Storage Resource agent using commands, see the information about uninstalling agents in the *Tivoli Storage Productivity Center Installation and Configuration Guide*.

For information about how to upgrade the Storage Resource agent using commands, see the information about upgrading agents in the *Tivoli Storage Productivity Center Installation and Configuration Guide*.

### Enabling and disabling NFS timeouts

You can enable or disable NFS timeouts for a Storage Resource agent when running scans on network file system (NFS) mounts. Enabling an agent for NFS timeouts prevents scans from locking up indefinitely when NFS mounts the agents are monitoring become unavailable.

This option determines the number of seconds a Storage Resource agent waits for a status system call on an NFS file system before it times out. The default wait time is 10 seconds.

**Note:** Enabling this option might decrease the performance of scans slightly. Disabling this option might increase the performance of scans slightly.

You might want to enable NFS timeouts when the NFS server is down or an NFS file system is stale. This condition can also occur when a scan is running for an agent and that agent is uninstalled.

The **FileSystemScanNFSTimeout** option is in the Data server configuration file (`server.config`). The default location of the `server.config` file is `c:\Program Files\IBM\TPC\config` for Windows and `/opt/IBM/TPC/config` for UNIX and Linux.

To enable or disable NFS timeouts, follow these steps:

1. In the navigation tree, click **Administrative Services > Data Sources**. Left-click **Data/Storage Resource Agents**.
2. In the content pane, select a Storage Resource agent.
3. To enable NFS timeouts for a Storage Resource agent, under the Select Action menu, click **Enable NFS Timeout**.
4. To disable NFS timeouts for a Storage Resource agent, under the Select Action menu, click **Disable NFS Timeout**.

### Deleting or uninstalling an agent using the GUI

You can delete or uninstall a Storage Resource agent and all the data that is collected by that agent from the database repository. The information that is collected by the agent is no longer available within Tivoli Storage Productivity Center reports. When you delete an agent, the agent is uninstalled and you can no longer activate the agent.

To delete or uninstall a Storage Resource agent:

1. In the navigation tree, click **Administrative Services > Data Sources**. Left-click **Data/Storage Resource Agents**.
2. In the content pane, select an agent and under the Select Action menu, click **Delete**.
3. In the confirmation dialog, select **Yes Delete the agent**.

## Exporting a Storage Resource agent list

You can export a Storage Resource agent list to a formatted flat file. This list is used to manage user authentication through a script file. This option is enabled for Storage Resource agents that use non-daemon based communication only.

This list contains the host name, installation location, user ID, encrypted password, and fully qualified certificate file for the selected Storage Resource agents. You can change the user authentication data such as user ID, password, and fully qualified certificate location.

When the file is created, the passwords for the agents are written as "\*\*\*\*\*" for security reasons. Before using this file with the **Update Storage Resource Agent List** action, you must enter an encrypted or non-encrypted password for each host. See the description of the **Update Storage Resource Agent List** action for more information about passwords.

Storage Resource agents can either be run as a daemon service or non-daemon service (on-demand service). If the agent is run as a non-daemon service, there is no agent process running on the managed host. Programs on the host system are run as needed.

To export a Storage Resource agent list, complete the following steps:

1. In the navigation tree, click **Administrative Services > Data Sources**. Left-click **Data/Storage Resource Agents**.
2. In the content pane, select a Storage Resource agent and click **Export Storage Resource Agent List** from the **Select Action** menu.

## Updating a Storage Resource agent list

The Storage Resource agent list file is used to manage user authentication through a script file. This list contains the host name, installation location, user ID, encrypted password, and fully qualified certificate file for the selected Storage Resource agents. The password is in encrypted format with @ENC@ appended to the encrypted password. You can change the user authentication data such as user ID, password, and fully-qualified certificate location.

To update a Storage Resource agent list, complete the following steps:

1. In the navigation tree, click **Administrative Services > Data Sources**. Left-click **Data/Storage Resource Agents**.
2. In the content pane, select the Storage Resource agents you want to update.
3. Under the Select Action menu, click **Update Storage Resource Agent List** to update information about the agent.
4. Edit the information in that file to match the changes that you want to make for the agent. You can update the logon credentials for the Storage Resource agents that are listed with the information in a file that you specify. The file must use the following format for the host names you want to update:

```
host_name|installation_location|user_ID|password
```

If the Data server cannot find any Storage Resource agent with a host name and location that you specify in the file, that entry is ignored and the error is logged.

Keep in mind the following considerations when including a password in the update file:

- For non-encrypted passwords: If you use "|" in the line for an agent, you must provide an "escape" character before it. The escape character is "\". For

example, if the password you want to include in an update file is "native|agent", use native\|agent in the update file.

If you use "\" in the line for an agent, you must provide an additional "\" as an escape character. For example, if the password is "native\agent", use native\\agent in the update file.

- For encrypted passwords:
  - To encrypt a password, start IBM Tivoli Storage Productivity Center's command-line tool (tpctool) from the \cli directory where Tivoli Storage Productivity Center is installed and run the following command: tpctool encrypt [password], where [password] represents the password you want to encrypt. This command will generate a text string that represents the encrypted version of the password. For example, output might appear like the following: iDroqToC070ubh5i4mxMHQ==. Copy this encrypted password to the correct location in the update file.
  - To include an encrypted password in an update file, you must add the following after the encrypted text: @ENC@. For example, an encrypted password in an update file might appear like this:  
iDroqToC070ubh5i4mxMHQ==@ENC@

**Note:**

- Do not include @ENC@ at the end of non-encrypted passwords.
- See the *IBM Tivoli Storage Productivity Center Command-Line Interface Reference* for more information about **tpctool**.

## Registering the Storage Resource agent with a different server

This topic provides information on how to register the Storage Resource agent with a different server.

To register the Storage Resource agent with a different server, complete the following steps:

1. You have a Storage Resource agent that is installed on Server A and you want the Storage Resource agent to also point to Server B.
2. From Server B, in the navigation tree, expand **Administrative Services > Configuration > Storage Resource Agent Deployments**. Right-click **Storage Resource Agent Deployments**.
3. Specify the same port and location with the **force** option.

**Note:** For an RXA Storage Resource agent, just specify the same location with the **force** option.

4. Run the deployment job. The Storage Resource agent now points to Server A and Server B. If you no longer want the Storage Resource agent to point to Server A, just go to the GUI on Server A and delete the Storage Resource agent.

## Manually changing the Windows service logon

Change the Windows service logon for a Storage Resource agent.

To change the Windows service logon for a Storage Resource agent, complete the following steps:

1. On the Windows desktop, go to **Start > Settings > Control Panel > Administrative Tools > Services**.
2. On the Services window, right-click **IBM Tivoli Storage Resource agent - 'C:\Program Files\IBM\TPC\'**.
3. Select **Properties**.

4. Click the **Log On** tab.
5. Change the values for **This account**, **Password**, and **Confirm password** to the login credentials that you want to use. If your Tivoli Storage Productivity Center server is part of a Windows domain, change this logon to <domain>\<account>. For example: mydomain\myaccount.

**Important:** The Storage Resource agent requires that the domain account has local administrator privileges and the "Log on as a service" and "Act as part of the operating system" user rights.

6. Click **Apply** and then **OK** to save your changes.

## Managing the daemon Storage Resource agent service

Use this information to start and stop the daemon Storage Resource agent service for the Virtual I/O Server.

### Starting and stopping the daemon Storage Resource agent service

To start or stop the daemon service, follow these steps:

1. Log in to the Virtual I/O Server using the **padmin** user ID.
2. Run the following command to set up the AIX environment:  
oem\_setup\_env
3. Change to the base directory where the Storage Resource agent is located. For example:
  - To stop the service, run this command:  
/SRA\_install\_directory/agent/bin/agent.sh stop
  - To start the service, run this command:  
/SRA\_install\_directory/agent/bin/agent.sh start

## Deployment guidelines and limitations for Storage Resource agents

There are a number of guidelines and limitations that you must consider when managing the Storage Resource agents in your environment.

Use the following information when you deploy Storage Resource agents and migrate existing Data agents:

- Multiple Storage Resource agents that are probing or scanning the same storage resources
- Platforms that support Storage Resource agents deployments
- Product functions that are not available for storage devices monitored by Storage Resource agents
- Required authority for deploying Storage Resource agents
- Orphan zones
- Firewalls and Storage Resource agent deployments
- Multiple computers in a deployment
- Communication between the Tivoli Storage Productivity Center server and a Storage Resource agent
- Daemon and non-daemon services
- Authentication between the Tivoli Storage Productivity Center server and a Storage Resource agent
- Storage Resource agents on the same computer
- Time zones for computers monitored by Storage Resource agents

- UNIX systems using RSH protocol
- Deployments on Windows - NetBIOS setting
- Deployments on Windows - User Account Control (UAC) remote restrictions
- Additional information about Storage Resource agents

#### **Multiple Storage Resource agents that are probing or scanning the same storage resources**

If multiple Storage Resource agents are set up to probe or scan the same storage resources, the Storage Resource agent that was added to Tivoli Storage Productivity Center first is used for the probe or scan. Therefore, only data that is gathered by the first Storage Resource agent is shown.

#### **Platforms that support Storage Resource agents for the same**

For a list of platforms on which you can deploy Storage Resource agents, go to the Tivoli Storage Productivity Center support site at [http://www.ibm.com/support/entry/portal/Overview/Software/Tivoli/Tivoli\\_Storage\\_Productivity\\_Center\\_Standard\\_Edition](http://www.ibm.com/support/entry/portal/Overview/Software/Tivoli/Tivoli_Storage_Productivity_Center_Standard_Edition), click the **Documentation** link, and enter **Platform Support: Agents, Servers and GUI** in the **Search** box. Click the link to the document for the appropriate release.

#### **Product functions that are not available for storage devices monitored by Storage Resource agents**

Before you migrate an existing Data agent to a Storage Resource agent or deploy a new Storage Resource agent, make sure that the product functions you want to use on the monitored devices are available for those agents. The following functions are not available for storage devices that are monitored by Storage Resource agents:

- Certain relational database monitoring. For list of relational databases that can be monitored by Storage Resource agents, go to the Tivoli Storage Productivity Center support site at [http://www.ibm.com/support/entry/portal/Overview/Software/Tivoli/Tivoli\\_Storage\\_Productivity\\_Center\\_Standard\\_Edition](http://www.ibm.com/support/entry/portal/Overview/Software/Tivoli/Tivoli_Storage_Productivity_Center_Standard_Edition), click the **Documentation** link, and enter **Platform Support: Agents, Servers and GUI** in the **Search** box. Click the link to the document for the appropriate release.
- The changing of zone configurations and the reporting of HBA, fabric topology, or zoning information for fabrics connected to hosts running Linux on IBM System z hardware. These limitations also apply to Storage Resource agents on all guest operating systems for VMware configurations.

#### **Required authorities for deploying and running Storage Resource agents**

Before you can create deployment schedules and deploy Storage Resource agents on target computers, you must meet the following requirements:

- To create deployment schedules, you must be logged in to Tivoli Storage Productivity Center with a user ID that has the **Productivity Center Administrator** role. See the *IBM Tivoli Storage Productivity Center and IBM Tivoli Storage Productivity Center for Replication Installation and Configuration Guide* for more information about user roles.
- To deploy Storage Resource agents on target computers, you must provide a user ID that has administrative rights on those computers. You enter this ID when creating a deployment schedule. Tivoli Storage Productivity Center uses this ID to log on to the target computers and install and configure the necessary runtime files for the agents.

The user under which a Storage Resource agent (daemon or non-daemon) runs must have the following authorities on the target computers:

- On Linux or UNIX, the user must have root authority. By default, an agent runs under the user 'root'.
- On Windows, the user must have Administrator authority and be a member of the Administrators group. By default, a Storage Resource agent runs under the 'Local System' account.

### Orphan zones

Storage Resource agents do not collect information about orphan zones. An orphan zone is a zone that does not belong to at least one zoneset.

### Firewalls and Storage Resource agent deployments

Before you can deploy a Storage Resource agent on a computer, you must turn off the firewall on that computer. If you do not turn off the firewall, the deployment fails. To turn off the firewall on a Windows 2008 computer, complete the following steps:

1. On the desktop of the Windows 2008 computer, click **Start > Administrative Tools**.
2. Click **Windows Firewall with Advanced Security**.
3. Click **Windows Firewall Properties**.
4. Change the **Firewall state** field to **Off** on the following tabs: **Domain Profile, Private Profile, Public Profile**.
5. Click **OK** to accept the changes and exit.
6. Deploy a Storage Resource agent to the Windows 2008 computer.

### Multiple computers in a deployment

You can define a deployment schedule to include multiple computers on which to install Storage Resource agents. The computers you include in a deployment schedule must share the same administrative user ID and password. IBM Tivoli Storage Productivity Center uses these user credentials to log on to the computers when installing Storage Resource agents. If the computers in a deployment schedule do not share the same administrative user credentials, you must create separate deployment jobs for them.

**Note:** When you deploy a Storage Resource agent to multiple computers, a globally unique identifier (GUID) is created for each computer (if one does not exist).

### Communication between the Tivoli Storage Productivity Center server and a Storage Resource agent

The Tivoli Storage Productivity Center server connects to a monitored computer when a Storage Resource agent is deployed and whenever a data collection schedule runs against that agent.

During deployment, the server communicates with the target computer using one of the following protocols:

- Windows server message block protocol (SMB)
- Secure Shell protocol (SSH)
- Remote execution protocol (REXEC)
- Remote shell protocol (RSH)

After deployment, the type of communication between the server and agent on that computer depends on whether you deployed the agent as daemon service or non-daemon service. See the *IBM Tivoli Storage*

*Productivity Center and IBM Tivoli Storage Productivity Center for Replication Installation and Configuration Guide* for more information about these protocols.

### **Daemon and non-daemon services**

You can deploy a Storage Resource agent as a daemon or non-daemon service:

- A Storage Resource agent that is deployed as a daemon service runs in the background on the monitored computer and listens for requests from the Tivoli Storage Productivity Center server. Connectivity between the server and agent is established using SSL. The server and agent have their respective certificates and no additional information is required besides those certificates and the security that is provided by the SSL protocol.
- A Storage Resource agent deployed as a service on demand (non-daemon service) runs as a stand-alone executable file on the monitored computer. Communication from the server to the agent uses the same protocol that was used during the deployment of the agent. Communication from the agent to the server uses SSL.

### **Authentication between the Tivoli Storage Productivity Center server and a Storage Resource agent**

Tivoli Storage Productivity Center requires the correct authentication information (user ID, password, port, certificate location, or passphrase) for monitored computers each time it communicates with Storage Resource agents on those computers. If the authentication information changes for a host computer on which a Storage Resource agent is deployed, the authentication information for that agent must be updated using the **Change Authentication** or **Update Storage Resource agent List** functions on the Data/Storage Resource agents panel located under the **Administrative Services > Data Sources** node in the navigation tree.

### **Storage Resource agents on the same computer**

You cannot deploy a Storage Resource agent on a computer where a Storage Resource agent is already installed *and* pointing to the same Data server. You can deploy a Storage Resource agent on the same computer as another Storage Resource agent if those agents communicate with different Data servers and use different ports when listening for requests.

### **Time zones for computers monitored by Storage Resource agents**

The time zones of computers that are monitored by Storage Resource agents are shown as Greenwich Mean Time (GMT) offsets in Tivoli Storage Productivity Center reports. For example, a computer in Los Angeles shows the following time zones in the By Computer report in Asset reporting:

(GMT-8:00) GMT-8:00

### **UNIX operating systems using Remote Shell protocol (RSH)**

If RSH is configured to use a user ID and password, the connection fails. To successfully connect to a system using RSH, you must set up the `.rhosts` file (in the home directory of the account). RSH must be configured to accept a login from the system that is running your application.

### **Deployments on Windows operating systems - NetBIOS setting**

If you want to install a Storage Resource agent on Windows targets, the **Enable NetBIOS over TCP/IP** option must be selected in the Control Panel settings for the computer's network connections properties. To set this option, click **Start > Settings > Control Panel > Network and Dial-Up**

**Connections > <some\_connection> > Properties > Internet Protocol (TCP/IP) > Advanced > WINS > Enable NetBIOS over TCP/IP.**

See the documentation for your firewall to determine if these ports are not blocked for inbound requests.

To determine if security policies are blocking the connection ports, click **Start > Settings > Control Panel > Administrative Tools.**

Depending on whether your policies are stored locally or in Active Directory, follow these directions:

#### **Locally stored policies**

For locally stored policies, click **Start > Settings > Control Panel > Administrative Tools > Local Security Policy > IP Security Policies on Local Computer.**

#### **Policies stored in Active Directory**

For policies stored in Active Directory, examine the IP security policies and edit or remove filters that block the ports:

- Click **Administrative Tools > Default Domain Security Settings > IP Security Policies on Active Directory.**
- Click **Administrative Tools > Default Domain Controller Security Settings > IP Security Policies on Active Directory.**

For all Windows systems, the Server service must be running to connect to a Windows system using the Windows protocol.

The following table lists the ports reserved for NetBIOS. Ensure that these ports are not blocked.

| <b>Port</b> | <b>Description</b>                                   |
|-------------|------------------------------------------------------|
| 135         | NetBIOS Remote procedure call. (Not currently used.) |
| 137         | NetBIOS name service.                                |
| 138         | NetBIOS datagram. (Not currently used.)              |
| 139         | NetBIOS session (for file and print sharing).        |
| 445         | CIFS (on Windows XP).                                |

For Windows Server 2008, shares must be shared for the Guest or Everyone accounts, and password protected sharing must be disabled. To disable password protected sharing, follow these steps:

1. Click **Control Panel > Networking and Sharing Center.**
2. Click the down arrow next to **Password protected sharing.**
3. Click **Turn off password protected sharing.**
4. Click **Apply.** Exit from the Control Panel.

#### **Deployments on Windows 2008 - User Account Control (UAC) remote restrictions**

If you are planning to install Storage Resource agents remotely on a Windows 2008 operating system, you must disable the User Account Control (UAC) remote restrictions on the Windows operating system. User Account Control is a security component on Windows operating systems.

**Note:** This task contains steps that tell you how to modify the registry. Serious problems might occur if you modify the registry incorrectly. Therefore, make sure that you follow these steps carefully. For added protection, back up the registry before you modify it. Then you can restore

the registry if problems occur. For information about how to back up and restore the registry, see <http://support.microsoft.com/kb/322756/>.

To disable UAC remote restrictions, follow these steps:

1. Click **Start > Run**. Enter **regedit** and click **OK**.
2. Locate and click the following registry subkey:  
HKEY\_LOCAL\_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\  
Policies\System
3. If the LocalAccountTokenFilterPolicy registry entry does not exist, follow these steps:
  - a. On the **Edit** menu, click **New > DWORD Value**.
  - b. Enter **LocalAccountTokenFilterPolicy** as the name for the DWORD value in the content pane. Click **Enter**.
  - c. Right-click **LocalAccountTokenFilterPolicy**, then click **Modify**.
  - d. In the Edit DWORD Value window, enter **1**, then click **OK**.  
This value can be 0 or 1:
    - 0 This value builds a filtered token. This value is the default value. The administrator credentials are removed.
    - 1 This value builds an elevated token.
  - e. Exit the registry editor.

#### **Additional information about Storage Resource agents**

See *Planning for Storage Resource agents* in the *IBM Tivoli Storage Productivity Center Installation and Configuration Guide* for more information about Storage Resource agents.

## **In-band Fabric agents**

In-band Fabric agents are no longer installed or supported by Tivoli Storage Productivity Center. You can migrate in-band Fabric agents to Storage Resource agents.

For information about the supported agent types for switch performance management and fabric zone configuration, see “Supported Fabric Agent Types” on page 1476.

### **Deleting an in-band Fabric agent**

You can delete an in-band Fabric agent from the navigation tree and the database. Data discovered by the agent is removed from the database repository. This action is available for inactive agents only. You must first stop the agent before deleting the information for the agent. The agent is not uninstalled from IBM Tivoli Storage Productivity Center.

To remove information for an in-band Fabric agent, follow this procedure:

1. In the navigation tree, expand **Administrative Services > Data Sources**.  
Left-click **Inband Fabric Agents**.
2. In the content pane, select the agent and click **Delete**.

### **Migrating an in-band Fabric agent**

Migrate a selected in-band Fabric agent to a Storage Resource agent.

The migration process deploys a Storage Resource agent on the target computer and then uninstalls the in-band Fabric agent. Before the migration, Tivoli Storage

Productivity Center must shut down the Fabric agent. The agent is not shut down until 1) all running processes are complete, and 2) there are no new schedules submitted for the agent.

## Out-of-band Fabric agents

Out-of-band agents are used by Fabric Manager for out-of-band SAN operations.

For information about the supported agent types for switch performance management and fabric zone configuration, see “Supported Fabric Agent Types” on page 1476.

### Displaying information about an out-of-band agent

You can view information about an out-of-band agent including the IP address, status, and SNMP community.

To display information about an out-of-band agent, follow this procedure:

1. In the navigation tree, expand **Administrative Services > Data Sources**. Click **Out of Band Fabric Agents**.
2. In the content pane, click the icon to the left of the agent for which you want information. In the content pane, a notebook window opens. On the General Information page, the following information is displayed:

**Status** The status of the agent.

**Host Name**

The host name of the system on which the agent is installed.

**IP Address**

The IP address of the system on which the agent is installed. This column displays Internet Protocol Version 4 (IPv4) and Internet Protocol Version 6 (IPv6) addresses as appropriate.

**SNMP Community Read**

The name of the Simple Network Management Protocol (SNMP) community to which the agent belongs. The SNMP community name acts as a password that is shared by one or more SNMP hosts. The community name is used to authenticate messages being received by this SNMP host. This field is optional and might be blank if the SNMP community has not been set.

**Note:** The default SNMP community is public. If the community name is not the correct community name for your environment, the out-of-band agent might not be able to properly perform scans.

**SNMP Community Write**

The community string for SNMP writes. Tivoli Storage Productivity Center uses the write community string to refresh information for the Out of Band Fabric Agent. The default is private. This value is used for Cisco switches only.

### Updating out-of-band agent information

After an out-of-band agent has been added, you can update the SNMP community information.

To update information for an out-of-band agent, follow this procedure:

1. In the Navigation Tree pane, expand **Administrative Services > Data Sources**. Left-click **Out of Band Fabric Agents**.

2. In the content pane, click on the icon by the agent.
3. In the content pane, a notebook window opens. On the General page, update the following information:

#### **SNMP Community Read**

Enter the name of the Simple Network Management Protocol (SNMP) community to which the agent belongs. The SNMP community name acts as a password that is shared by one or more SNMP hosts. The community name is used to authenticate messages being received by this SNMP host. This field is optional.

**Note:** The default SNMP community is public. If this is not the correct community name for your environment, the out-of-band agent might not be able to properly perform scans.

#### **SNMP Community Write**

Enter the community string for SNMP writes. Tivoli Storage Productivity Center uses the write community string to refresh information for the Out of Band Fabric Agent. The default is private. This value is used for Cisco switches only.

### **Checking the out-of-band agent connection**

You can check to determine if an out-of-band agent is running.

To check the agent connection, follow this procedure:

1. In the Navigation Tree pane, expand **Administrative Services > Data Sources**. Left-click **Out of Band Fabric Agents**.
2. In the content pane, select an agent and click **Check**. The status of the agent is displayed in the Agent Status window. If updates are required, they are automatically installed.

### **Adding an out-of-band Fabric agent**

This topic provides information about adding an out-of-band Fabric agent.

You can add an out-of-band Fabric agent with the Configure Devices wizard or by using the manual steps in this procedure. To add an out-of-band Fabric agent with the Configure Devices wizard, see “Adding resources for monitoring” on page 309.

To add an out-of-band Fabric agent manually, complete the following steps:

1. In the navigation tree, expand **Administrative Services > Data Sources**. Left-click **Out of Band Fabric Agents**.
2. In the content pane, click **Add**.
3. In the Add Out of Band Fabric Agent window, complete the host name, SNMP community read (optional), and SNMP community write (optional) fields. Click **OK**.

### **Deleting an out-of-band agent**

You can remove an out-of-band agent from the navigation tree and the database. Data discovered by the agent is not removed from the database repository.

To remove an out-of-band agent, follow this procedure:

1. In the navigation tree, expand **Administrative Services > Data Sources**. Left-click **Out of Band Fabric**.
2. In the content pane, select an agent and click **Delete**.

## Tivoli Storage Productivity Center servers

Use the **Administrative Services > Data Sources > IBM Tivoli Storage Productivity Center Servers >** function to manage the relationships between a *master* Tivoli Storage Productivity Center server and its *subordinate* Tivoli Storage Productivity Center servers.

By creating master and subordinate relationships between Tivoli Storage Productivity Center servers, you can then use a single interface to generate reports based on data and metrics collected by multiple servers in a storage environment:

- A **master** server is a server that performs normal monitoring and reporting of storage resources like a standard server, but also gathers the storage information (using Tivoli Storage Productivity Center server probes) that was collected by subordinate servers.
- A **subordinate** server is a server that monitors and reports on storage resources like a standard server, but also communicates with the master server during Tivoli Storage Productivity Center server probes. During these probes, the master server collects the storage information gathered by a subordinate server's agents and stores that information in its own database repository.

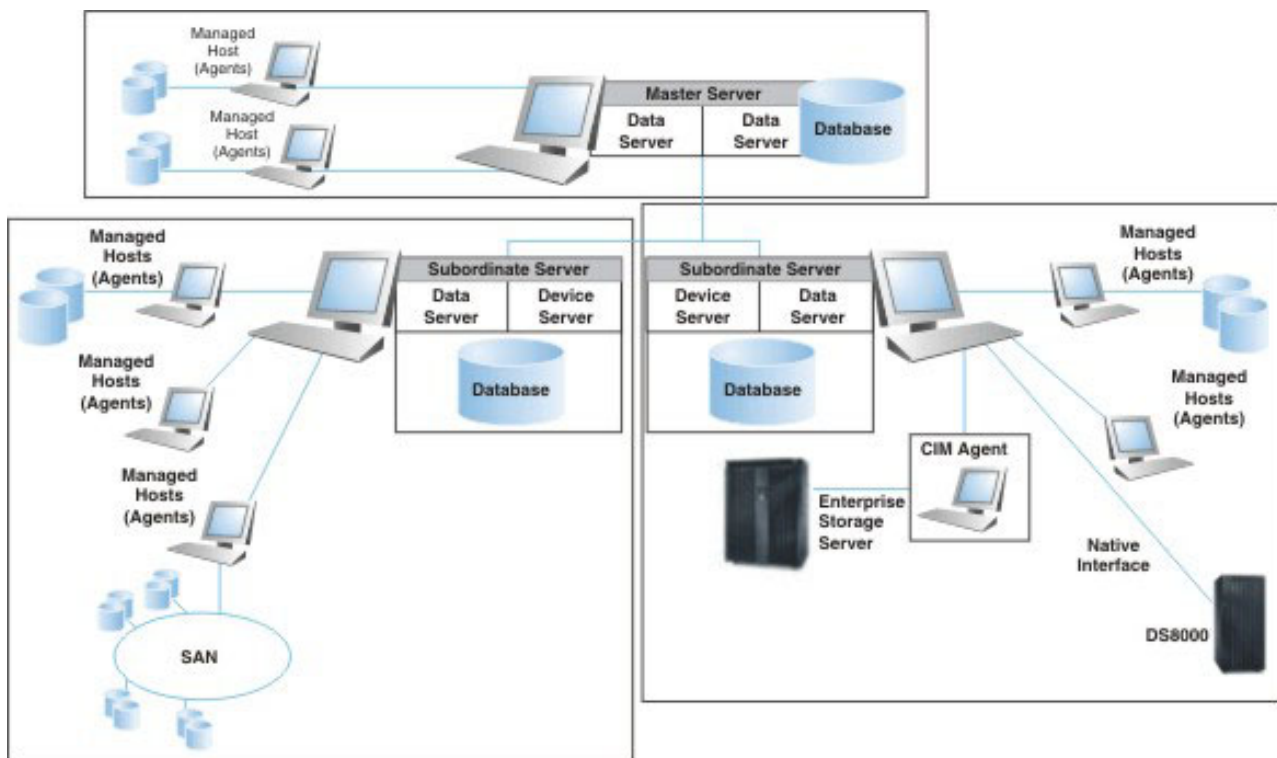

Figure 23. Master and subordinate server architecture

The rollup reports that reflect the storage information collected by the master server from subordinate servers are available in the **Tivoli Storage Productivity Center > Rollup Reports** node. This node is available in the navigation tree for the master server.

If the master server is on an IPv6-only server, it can communicate with existing subordinate servers under the following conditions:

- The subordinate servers are upgraded to Tivoli Storage Productivity Center V5.1 or higher and

- The IPv6 protocol is enabled on the machines where they are located.

Before you can configure and manage subordinate servers, keep in mind the following items:

- The master server must be up and running.
- You must be log on to the user interface as an Tivoli Storage Productivity Center administrator or superuser
- We recommend that the master server monitor no more than 500 unique data sources. This number includes subordinate servers, Storage Resource agents, CIMOM agents, and VM servers (VMWare).
- We recommend that each subordinate server monitors no more than 1200 unique data sources. This number includes Storage Resource agents, CIMOM agents, and VM servers (VMWare). After this threshold is met for a server, a new server is deployed and all new agents point to it.
- After upgrading to Tivoli Storage Productivity Center 5.1, you must run probes against the monitored storage assets for the master server to have information about those assets displayed in **Tivoli Storage Productivity Center > Reporting > Rollup Reports**.
- After you remove a data source (agent) from a subordinate server or a storage entity that it monitors, the master server continues to display information about that agent or storage resource in rollup reports for a specified amount of time. You can specify how quickly that information is removed by accessing the Administrative Services > Configuration > Removed Resource Retention panel and changing the settings for **TPC servers**. Additionally, if a master server is unable to contact a subordinate server for the number of days defined in the **TPC Servers** setting on the Removed Resource Retention panel, that server is removed from the subordinate server as well as information about the storage entities it was monitoring.
- A host might appear more than once in a rollup report and its data is counted multiple times in report totals. Multiple entries for a host might occur if the following conditions are true:
  - An agent is removed from a host, the GUID (globally unique identifier) for the host is changed, and then an agent is redeployed on the host.
  - The amount of time that information about a host is retained is longer than the time it took to remove the original agent and change the GUID for the host.

For example, if the number of days to retain information about a host is 14 days, and then you 1) remove the agent on the host, 2) change the GUID of the host, and 3) redeploy an agent on that host all in less than 14 days, duplicate entries for the host appears in rollup reports. After 14 days have passed, the entry for the host before the GUID change is removed from the database and only one entry appears for the host in rollup reports.

You can specify how quickly information is removed by changing the settings for **TPC servers** on the Administrative Services > Configuration > Removed Resource Retention panel.

## Adding an Tivoli Storage Productivity Center Server

Learn how to add an Tivoli Storage Productivity Center server as a subordinate sever.

Keep in mind the following when adding a Tivoli Storage Productivity Center server as a subordinate server:

- How subordinate servers are configured to monitor storage entities within your environment can determine if fragmentation occurs within rollup reports. See Rollup reports - Fragmentation for more information.
- Tivoli Storage Productivity Center servers must be at version 3.3 or greater to be added as a subordinate server.
- We recommend that the master server monitor no more than 500 unique data sources. This number includes subordinate servers, Storage Resource agents, CIMOM agents, and VM servers (VMWare).
- We recommend that each subordinate server monitors no more than 1200 unique data sources. This number includes Storage Resource agents, CIMOM agents, and VM servers (VMWare). After this threshold is met for a server, a new server is deployed and all new agents point to it.
- If the master server is located on an IPv6-only server, it can communicate with existing subordinate servers under the following conditions:
  - The subordinate servers are upgraded to Tivoli Storage Productivity Center V4.1 or higher and
  - The IPv6 protocol is enabled on the machines where they are located.

To add a server as a subordinate server, follow this procedure:

1. In the Navigation Tree pane, expand **Administrative Services > Data Sources > Tivoli Storage Productivity Center Servers**.
2. In the content pane, click **Add Tivoli Storage Productivity Center Server**.
3. In the Add Tivoli Storage Productivity Center Server window, enter the following information:

**Host Name**

Enter the host name of the machine on which the subordinate server is installed.

**Host Device server Port**

Enter the port with which the subordinate server's Device server is listening for requests. The default port for Tivoli Storage Productivity Center servers is 9550.

**Host Authentication Password**

Enter the password for the subordinate Tivoli Storage Productivity Center server. This host authentication password is entered when installing Tivoli Storage Productivity Center. Contact your system administrator or the person who installed Tivoli Storage Productivity Center to determine this password.

**Display Name (optional)**

Enter a name for the subordinate server.

**Description (optional)**

Enter a description for the subordinate server.

**Test Tivoli Storage Productivity Center Server Connectivity before adding**

Select this check box to have the master server connect and log into the subordinate server using the information provided on this window. This test is performed when you click **Save**.

4. Click **Save** to add the server as a subordinate server.
  - If you selected **Test Tivoli Storage Productivity Center Server Connectivity before adding**, IBM Tivoli Storage Productivity Center attempts to connect to the subordinate server using the information provided on this window.

- If you did not select **Test Tivoli Storage Productivity Center Server Connectivity before adding**, the subordinate server is automatically added as a subordinate server but has a connection status of **Unknown** on the **Administrative Services > Data Sources > Tivoli Storage Productivity Center Servers** window.

**Note:** If the login information for a subordinate server is incorrect, an error occurs and an associated error message dialog box is displayed.

## Viewing subordinate server details

Learn how to view information about the subordinate servers that have been associated with a master server.

After you add a subordinate server to a master server, basic information about that server appears on the **Administrative Services > Data Sources > TPC Servers** window. To view additional information about a subordinate server on the TPC Servers window, follow this procedure:

1. In the navigation tree, expand **Administrative Services > Data Sources > TPC Servers**.
2. In the content pane, double-click a server row or click the icon next to a server for more detailed information about that server. Information about a subordinate server appears on the **Administrative Services > Data Sources > TPC Servers > TPC Server Details** window.

## Testing the connection to subordinate servers

Learn how to test the connection from a master server to its associated subordinate servers.

After you add a subordinate server to a master server, basic information about that server appears on the **Administrative Services > Data Sources > TPC Servers** window. To verify that the master server can use the information provided to connect to subordinate server, follow this procedure:

1. In the navigation tree, expand **Administrative Services > Data Sources > TPC Servers**.
2. In the content pane, highlight the row for a subordinate server and click **Test TPC Server Connection** to test its connection to the master server. A message window will appear with the results of the tested connection. The information that appears in the **Connection Status** field will be updated to reflect its status.

## Removing subordinate servers

Learn how to remove a subordinate server from its association with a master server.

Use the **Administrative Services > Data Sources > TPC Servers** window to remove a subordinate server from a master server. Removing a subordinate server removes subordinate server information from:

- The master server database repository
- All rollup reports
- The **TPC Servers** list on the **Administrative Services > Data Sources > TPC Servers** window

To remove a subordinate server, follow this procedure:

1. In the navigation tree, expand **Administrative Services > Data Sources > TPC Servers**.

2. In the content pane, highlight the row of a subordinate server and click **Remove TPC Server**. A confirmation window appears.
3. Click **Yes** to confirm the removal of the subordinate server.

## Modifying subordinate server information

Learn how to modify information about the subordinate servers that have been associated with a master server.

After you add a subordinate server to a master server, basic information about that server appears on the **Administrative Services > Data Sources > TPC Servers** window. You can edit the information for a subordinate server by modifying its Display Name, Description, and Host Authentication Password. To view modify information about a subordinate server on the TPC Servers window, follow this procedure:

1. In the navigation tree, expand **Administrative Services > Data Sources > TPC Servers**.
2. In the content pane, double-click a server row or click the icon next to a server to edit information about that server. Information about a subordinate server appears on **Administrative Services > Data Sources > TPC Servers > TPC Server Details**.
3. Edit the information in the following fields:

### Host Authentication Password

Enter the password for the subordinate IBM Tivoli Storage Productivity Center server.

### Display Name (optional)

Enter a name for the subordinate server.

### Description (optional)

Enter a description for the subordinate server.

### Test TPC Server Connectivity before adding

Select this check box to have the master server connect and log into the subordinate server using the information provided on this window. This test is performed when you click **Save**.

4. Select **File > Save** . If successful, the TPC Servers window appears and any new values for **Display Name** and **Description** are shown for a subordinate server.

## Rollup reports - fragmentation

Fragmentation occurs when related storage entities are being monitored by different subordinate IBM Tivoli Storage Productivity Center servers.

The following example shows when fragmentation can occur using subordinate servers and rollup reports:

- **Example:** Host A is assigned a volume from storage subsystem 1. Host A is being monitored only by one Tivoli Storage Productivity Center subordinate server (Server 1) and storage subsystem 1 is being monitored by another subordinate server (Server 2). Server 1 and Server 2 are subordinate servers to the master server (Server 3).

**Reason for fragmentation:** In this example, the host and subsystem are fragmented because they are not being monitored by the same Tivoli Storage Productivity Center server. This will cause the **Correlated Volume Space** value in the rollup reports for storage subsystems and volumes to be incorrect.

To prevent fragmentation when using master and subordinate server relationships to generate rollup reports, we recommend the following:

- Do not monitor a storage subsystem and the hosts to which its volumes are assigned with different subordinate servers that are associated with the same master server.
- Do not monitor a fabric and its related switches with different subordinate servers that are associated with the same master server.
- If an agent machine is using storage from a subsystem, then both the agent and subsystem should be monitored by the same subordinate server.
- Configure all the subordinate servers to discover all the storage subsystems within your environment. Note that if a subordinate server is monitoring a subsystem with an agent other than the agent that is using storage on that subsystem, the value for the **Correlated Volume Space** column in rollup reports will be incorrect. For example:
  - Host A has storage from Subsystem 1
  - Subordinate server B is Monitoring Host A and Subsystem 1
  - Subordinate server C is Monitoring Subsystem 1 and probed the subsystem more recently than server B.
  - The master server is monitoring subordinate servers B and server C.

The master server will report the storage subsystem data from server C. Because the master server does not know about Host A, the value for the **Correlated Volume Space** column will be incorrect.

## Storage systems

This topic provides information about administering, configuring, and viewing information about monitored storage systems in your IBM Tivoli Storage Productivity Center environment.

You can add many different types of storage systems to your Tivoli Storage Productivity Center environment. Use the native storage system interfaces provided to connect to the following storage systems:

- DS8000
- SAN Volume Controller
- Storwize V7000
- IBM Storwize V7000 Unified
- The XIV system
- IBM SONAS

For other storage systems, use the Common Interface Model (CIM) agent interfaces.

### Adding a storage system

Learn how to add a storage system to your IBM Tivoli Storage Productivity Center environment.

Tivoli Storage Productivity Center provides multiple ways to add a storage system to your environment. Use the Configure Devices wizard to guide you through the steps for adding a storage subsystem using its native interface or a CIMOM, or manually add a CIMOM and discover the storage subsystem that it manages. See “Configuring storage subsystems” on page 310 for details of how to use the Configure Devices wizard.

To add a storage subsystem, use any of the following methods:

- If you want to add a new storage subsystem to Tivoli Storage Productivity Center using its native interface, use the Configure Devices wizard. The wizard guides you through the steps for adding a storage subsystem and running a discovery. To use this method, you can click the Configure Devices icon in the toolbar or you can complete the following steps:
  1. In the navigation tree, expand **Administrative Services > Data Sources > Storage Subsystems**.
  2. Click **Add**. This action launches the Configure Devices wizard. See “Configuring storage subsystems” on page 310 for details of how to use the Configure Devices wizard.
- If you want to add a CIMOM to Tivoli Storage Productivity Center and discover the storage subsystem that it manages, use the Configure Devices wizard. The wizard guides you through the steps for adding a CIMOM and running a discovery. To use this method, you can click the Configure Devices icon in the toolbar or you can complete the following steps:
  1. In the navigation tree, expand **Administrative Services > Data Sources > Storage Subsystems**.
  2. Click **Add**. This action launches the Configure Devices wizard. See “Configuring storage subsystems” on page 310 for details of how to use the Configure Devices wizard.
- If you want to manually add a new CIMOM to Tivoli Storage Productivity Center and then manually discover the storage subsystem that it manages, use the following steps:
  1. In the navigation tree, expand **Administrative Services > Data Sources** and click **CIMOM Agents**.
  2. In the content pane, click **Add CIMOM**. The Add CIMOM window opens. See “Adding a CIM agent connection” on page 253 for details of how to add the CIMOM.
  3. To discover the storage subsystem that a CIMOM manages, in the navigation tree pane, expand **Administrative Services > Discovery** and click **CIMOM**. See “Discover storage subsystem, tape library, and fabric information with CIM agents” on page 334 for details about how to discover the storage subsystems managed by the CIMOMs that you manually added.

## Viewing storage system details

Learn how to view information about monitored storage systems in your IBM Tivoli Storage Productivity Center.

After you add storage systems, basic information about those systems appears on the **Administrative Services > Data Sources > Storage Subsystems** panel. To view information about a storage system on the Storage Subsystems panel, follow this procedure:

1. In the navigation tree, expand **Administrative Services > Data Sources > Storage Subsystems**.
2. In the content pane, you can view basic information about the storage systems in the Storage Subsystems area.

### Magnifying glass icon

The function of this icon depends on the value that is in the Credential Status column:

- If the value is **Present**, click the icon to view and modify more detailed information about the system.

- If the value is **Missing**, click the icon to start the Configure Devices wizard and provide the configuration information for the storage system.
- If the value is **Required**, click the icon to open the subsystem credentials update dialog box.

**Name** The name of the storage system.

**Label** A user-defined name of the system.

**Type** The type of storage system.

**IP Address**

The IP address of the storage system.

**Credential Status**

The status of the credentials that are used to connect to the storage system. Possible values are:

- **Present** (the credentials are available).
- **Missing** (no credentials are available because the system had been discovered using the automated discovery process. To add the required credentials, click the  icon to open the Configure Devices wizard. Follow the steps in the wizard.
- **Required** (the system must be updated from CIM object manager [CIMOM] to native interface connection). To update the connection method, click the  icon to open the Update Subsystem Credentials dialog box.

**Connection Status**

The status of the connection between Tivoli Storage Productivity Center and the storage system.

**Data Source IP Address**

The IP address of the entity that Tivoli Storage Productivity Center uses to connect to the storage system. If Tivoli Storage Productivity Center uses the native interface of a system for connection, this IP address is the same as the address in the **IP Address** field. If Tivoli Storage Productivity Center uses a CIMOM for connection, the data source IP address is the address for the CIMOM.

## Modifying XIV system details

Learn how to modify information for an IBM XIV Storage System device that connects to IBM Tivoli Storage Productivity Center.

After you add an XIV system device, basic information about that system appears on the **Administrative Services > Data Sources > Storage Subsystems** panel. To modify information about the XIV system device on the Storage Subsystems panel, follow this procedure:

1. In the navigation tree, expand **Administrative Services > Data Sources > Storage Subsystems**.
2. In the content panel, double-click a storage subsystem row or click the icon next to a row to edit information about that storage subsystem. Information about the storage subsystem appears on the Storage Subsystems Details window.
3. You can edit the information in the following fields:

**Username**

Displays the user name for the device.

**Password**

Displays the password for the device.

The information in the following fields cannot be edited:

**Storage Subsystem**

Displays the name of the device.

**IP Address**

Displays the IP address or host name for the device.

4. Select **File > Save**. If successful, the Storage Subsystems window appears and any new values for the storage subsystem are shown.

## Modifying SAN Volume Controller or Storwize V7000 storage system details

Learn how to modify information about SAN Volume Controller or Storwize V7000 storage systems that connect to IBM Tivoli Storage Productivity Center.

After you add a SAN Volume Controller or Storwize V7000 device, basic information about that system appears on the **Administrative Services > Data Sources > Storage Subsystems** panel. To modify information about a SAN Volume Controller on the Storage Subsystems panel, follow this procedure:

1. In the navigation tree, expand **Administrative Services > Data Sources > Storage Subsystems**.
2. In the content panel, double-click a storage subsystem row or click the icon next to a row to edit information about that storage subsystem. Information about the storage subsystem appears on the Storage Subsystems Details window.
3. You can edit the information in the fields that are specified in bold in the window:

**Software Version**

Displays the version of the SAN Volume Controller or Storwize V7000 device.

**Storage Subsystem**

Displays the name of the device.

**IP Address**

Displays the IP address or host name for the device.

**Select Key**

Lists the actions that are available for the public Secure Shell (SSH) key:

- **Use existing uploaded key**. This action is the default. If you select this action, the **Admin Username** and **Admin Password** fields are optional.
- **Upload new key**. If you select this action, the **Admin Username** and **Admin Password** are required.

**Admin Username**

If you selected **Upload new key** in the **Select Key** list, enter the name of a user that has the administrator role for the SAN Volume Controller or Storwize V7000 cluster that contains the device. If you selected **Use existing uploaded key**, this field is optional.

**Admin Password**

Enter the password for the user that you entered in the **Admin Username** field.

**Username**

Enter an authorized user for the device. This field is active if you have selected **Upload new key** in the **Select Key** list and have entered a user name and password in the **Admin Username** and **Admin Password** fields. To search for a user, click **Select User**. You must enter a valid administrator name and password to retrieve a list of users.

**Private SSH Key**

Displays the path for the private SSH key. If you want to change this path, enter a new path or click the **Browse** button to search for a new path.

**Passphrase (optional)**

Displays the passphrase for the SSH key pair.

4. Select **File > Save**. If successful, the Storage Subsystems window appears and any new values for the storage subsystem are shown.

**Modifying Storwize V7000 Unified storage system details**

After you add a Storwize V7000 Unified storage system, information about the system is displayed in the Storage Subsystems Details page. You can modify the information that is in the available fields that are on this page.

Storwize V7000 Unified is composed of Storwize V7000 and Storwize V7000 File Module. You can connect to only Storwize V7000 or to both Storwize V7000 and Storwize V7000 File Module. Storwize V7000 provides block-level data and Storwize V7000 File Module provides file-level data.

To modify information about a Storwize V7000 Unified storage system, follow this procedure:

1. In the navigation tree, expand **Administrative Services > Data Sources > Storage Subsystems**.
2. On the Storage Subsystems page, double-click a storage subsystem row to edit information about that storage subsystem. The following information about the storage subsystem is displayed:

**Storwize V7000****Storage Subsystem**

Displays the name of the storage system.

**IP Address**

Enter the IP address or host name of the Storwize V7000 storage system. You can enter an IPv4 or IPv6 address, for example:

- 127.0.0.1
- [2001:DB8:0:0:0:0:0:0/32]

**Select Key**

An SSH key is required to access Storwize V7000. Select one of the following actions for the SSH key:

- **Upload new key:** Select this option to upload a new key. Public key content is extracted from the private key that is provided in the **Private SSH Key** field and is uploaded to

the Storwize V7000 cluster. If you select this action, the **Administrator User Name** and **Administrator Password** fields are required.

- **Use existing uploaded key:** Select this option if you want to use a public key that was already uploaded by using a method other than through Tivoli Storage Productivity Center, such as the Storwize V7000 web interface. Enter the location of the private key file that corresponds to the public key in the **Private SSH Key** field. The **Administrator User Name** and **Administrator Password** fields are not required if you select this option.

#### **Administrator User Name**

If you selected **Upload new key** in the **Select Key** list, enter the name of a user that has the Security Administrator role for the Storwize V7000 cluster that contains the storage system. Tivoli Storage Productivity Center uses this value during the setup process to contact the cluster and configure the SSH keys for the user. This user must belong to the Security Administrator role, which has privileges to modify other user accounts. Otherwise, Tivoli Storage Productivity Center cannot configure the SSH keys.

If you selected **Use existing uploaded key**, this field is optional.

#### **Administrator Password**

Enter the password for the user name that you entered in the **Administrator User Name** field.

If you selected **Use existing uploaded key**, this field is optional.

#### **User Name**

Enter an authorized user name for the storage system. Tivoli Storage Productivity Center uses this value to monitor and configure the storage system. If the user name does not exist, it is created. This user name must belong to the Administrator role.

This field is active if you selected **Upload new key** in the **Select Key** list and entered a user name and password in the **Administrator User Name** and **Administrator Password** fields.

**Important:** If you upload a new key for the existing Storwize V7000 user by using Tivoli Storage Productivity Center, that new key overrides the existing key for the user name. If you have another application that is using that user name (for example Tivoli Storage Productivity Center for Replication), the application cannot log on to Storwize V7000 because the key associated with the user is overwritten.

If this situation occurs, create a user ID specifically for Tivoli Storage Productivity Center or Tivoli Storage Productivity Center for Replication on the Storwize V7000 cluster. Add the Storwize V7000 storage system to Tivoli Storage Productivity Center for Replication using the new user ID and password (or change the user ID and password while the storage system is in the disconnected state).

### Select User

Select a user name from the list. The names are defined on Storwize V7000.

### Private SSH Key

By default, the private key entry includes `${device.conf}\tpc_svc.pem`, which represents the Tivoli Storage Productivity Center default key `tpc_svc.pem`. The `tpc_svc.pem` key is in the `conf` directory where the Device server is installed. If you want to use your own key, the key must exist on the system where you are running the Tivoli Storage Productivity Center user interface. The key is uploaded to the Tivoli Storage Productivity Center server system. To identify a new key, click **Browse**.

The private SSH key must be in OpenSSH format or in PuTTY (.ppk) format that is not password protected. If you have a password protected PuTTY .ppk key, use the PuTTYgen utility on a Windows operating system to convert that key to OpenSSH format by following these steps:

- a. Start the PuTTYgen utility.
- b. Load the .ppk file by clicking **File > Load private key**.
- c. From the menu bar, click **Conversion > Export OpenSSH key conversion**.

This action saves the key in OpenSSH format.

### Passphrase (Optional)

Enter the passphrase for the private SSH key. The passphrase protects your private SSH key file. If you do not have a passphrase, leave this field blank.

### Storwize V7000 File Module (Optional)

If this check box *was not* selected when the storage system was added, you can select the check box to connect to the Storwize V7000 File Module. If this check box *was* selected when the storage system was added, you cannot clear the box.

Depending on the configuration of Storwize V7000 Unified, the information that is required to connect to this system can be the same as or different from the information for Storwize V7000. The fields and field descriptions are the same as the fields in the Storwize V7000 pane with the following exceptions:

- The **IP Address** field is not displayed because the IP address is retrieved automatically.
- The **Select Key** list contains the option **Use user password** in addition to the **Upload new key** and **Use existing uploaded key** options. If you select **Use user password**, the **User Password** field is enabled and you can use a user name and password to connect to the file module.

If you select **Use user password**, the **Administrator User Name** and **Administrator Password** fields are optional.

- The **User Name** field is always required.
- The private SSH key must be in OpenSSH format. The PuTTY format is not supported. You can use the PuTTYgen utility to convert the key to the OpenSSH format.

3. Click **File** > **Save** on the menu bar. If the modifications are successful, the Storage Subsystems page is displayed and any new values for the storage subsystem are shown.

## Modifying System Storage DS8000 details

Learn how to modify information about a IBM System Storage DS8000 device that connects to IBM Tivoli Storage Productivity Center.

After you add a System Storage DS8000 device, basic information about that system appears on the **Administrative Services** > **Data Sources** > **Storage Subsystems** panel. To modify information about a System Storage DS8000 device on the Storage Subsystems panel, follow this procedure:

1. In the navigation tree, expand **Administrative Services** > **Data Sources** > **Storage Subsystems**.
2. In the content panel, double-click a storage subsystem row or click the icon next to a row to edit information about that storage subsystem. Information about the storage subsystem appears on the Storage Subsystems Details window.
3. You can edit the information in the fields that are specified in bold in the window:

### **Storage Subsystem**

Displays the name of the System Storage DS8000 device.

### **HMC Address**

Displays the IP address or host name for the Hardware Management Console (HMC) that is used to manage the device.

### **HMC2 Address (optional)**

Displays the IP address or host name for a second HMC that is used to manage the device.

### **Username**

Displays the user name for the device.

### **Password**

Displays the password for the device.

4. Select **File** > **Save**. If successful, the Storage Subsystems window appears and any new values for **Username** and **Password** for the storage subsystem are shown.

## Modifying other storage system details

Learn how to modify information about the storage systems that connect to IBM Tivoli Storage Productivity Center using CIM object managers (CIMOMs).

After you add a CIMOM, basic information about that CIMOM appears on the **Administrative Services** > **Data Sources** > **Storage Subsystems** panel. To modify information about a CIMOM on the Storage Subsystems panel, follow this procedure:

1. In the navigation tree, expand **Administrative Services** > **Data Sources** > **Storage Subsystems**.
2. In the content panel, double-click a storage subsystems row or click the icon next to a row to display a table of the CIMOMs that the storage subsystem is registered with.

### **Service URL**

Displays the service Web address of the CIMOM. This Web address contains the IP address of the CIMOM, the port on which the CIMOM

is listening, and the protocol used for communication. This Web address has a protocol (http | https), an IP address (IPv4 or IPv6), and a port number. For example: IPv4: https://127.0.0.1:5989 IPv6: https://2001:DB8:0:0:0:0:0:0:5989.

#### **Connection Status**

Displays the status of the connection between Tivoli Storage Productivity Center and the CIMOM.

#### **Interoperability Namespace**

Displays the interoperability namespace of the CIMOM. This namespace within the CIMOM allows the CIM Interop Schema (including the class instances of the Server Profile) to be accessed. The namespace also determines how Tivoli Storage Productivity Center interacts with the CIMOM when retrieving information. For a NetApp CIMOM, the value is /interop.

#### **Display Name**

Displays the name of the CIMOM as specified by the CIMOM provider.

#### **Description (optional)**

Displays the description that was entered on the Add CIMOM Agent window.

3. In the content panel, double-click a CIMOM row or click the icon next to a row to display details for the CIMOM. The connection information that you enter for a CIMOM is like the information that you enter on the Add CIMOM Agent panel. See “Adding a CIM agent connection” on page 253 for descriptions of the fields on this panel.
4. Select **File > Save**. If successful, the View and Edit CIMOM window appears and any new values for the CIMOM are shown.

### **Testing the connection to a storage system**

Learn how to test the connection from IBM Tivoli Storage Productivity Center to a storage system.

You must have Administrator privileges to perform this action.

After you add a storage system to Tivoli Storage Productivity Center, basic information about that system appears on the **Administrative Services > Data Sources > Storage Subsystems** panel. To verify that Tivoli Storage Productivity Center can use the information provided to connect to the storage system, follow this procedure:

1. In the navigation tree, expand **Administrative Services > Data Sources > Storage Subsystems**.
2. In the content panel, highlight the row for a storage system and click **Test Connection** to test its connection to Tivoli Storage Productivity Center. The results of the test are displayed in the Test Subsystem Connection dialog box.
3. Click **OK** to close the dialog box. The **Connection Status** field is updated to reflect the status.

### **Removing a storage system**

Learn how to remove the connection between a storage system and IBM Tivoli Storage Productivity Center.

You must have Administrator privileges to perform this action.

Use the **Administrative Services > Data Sources > Storage Subsystems** panel to remove a storage system. Removing a storage system will:

- Remove the storage system information from master server database repository
- Remove the storage system information from all rollup reports
- Remove the storage system from the **Storage Subsystems** table

To remove a storage system, follow this procedure:

1. In the navigation tree, expand **Administrative Services > Data Sources > Storage Subsystems**.
2. In the content panel, select a storage system and click **Remove**. A dialog box appears.
3. Click **Yes** to confirm the removal of the connection between the storage system and Tivoli Storage Productivity Center.

## VMware data source

VMware Virtual Infrastructure data sources are used by IBM Tivoli Storage Productivity Center to collect information from the hypervisors and virtual machines within them.

When you add a VMware data source in IBM Tivoli Storage Productivity Center, you need a user ID that has permission to browse through the data stores on VMware. IBM Tivoli Storage Productivity Center needs to browse through the data stores to collect information from the ESX Servers. However the "Read Only" role as defined by VMware does not allow IBM Tivoli Storage Productivity Center to browse the data stores. You can use the "Virtual Machine Power User" role as a choice if you do not want to use the Administrator role, or you can create a custom role with the required permissions.

To check what user role you have for VMware, follow these steps:

1. Connect a VI client to the ESX Server or VirtualCenter (whichever is used as the data source). Click the ESX Server and go to the **Summary** tab. Select a data source, right-click the data source and select **Browse**, to confirm that the browse permission is working correctly.
2. Connect the VI client to the data source with the admin role, go to the **Permission** tab and determine if the role name is used for the user.
3. Open the **Permissions** view, select that role, then right-click and select the **Edit** role. See what permissions are checked. Expand the check groups to find the specific ones.

For more information about VMware user roles, see: [http://www.vmware.com/pdf/vi3\\_vc\\_roles.pdf](http://www.vmware.com/pdf/vi3_vc_roles.pdf).

### Adding a VMware VI Data Source

This topic provides information about adding a VMware Virtual Infrastructure data source.

To add a VMware VI data source, follow this procedure:

1. In the Navigation Tree pane, expand **Administrative Services > Data Sources > VMware VI Data Source**.
2. In the content pane, click **Add VMware VI Data Source**.
3. In the Add VMware VI Data Source window, enter the following information:

**Host Name**

The host name for the VMware data source (ESX Server or VirtualCenter).

**Protocol**

This is http or https. If you use https, you must have first imported the SSL certificate into IBM Tivoli Storage Productivity Center. For information about how to import the SSL certificate, see the *IBM Tivoli Storage Productivity Center and IBM Tivoli Storage Productivity Center for Replication Installation and Configuration Guide Version 4 Release 1*. The protocol must match the same protocol that is set for the ESX Server or VirtualCenter.

**Port** The port used by the VMware data source.

**Username**

The user name for the VMware data source.

**Password**

The password for the VMware data source.

**Password Confirm**

The password is confirmed for the VMware data source.

**Display Name**

The name displayed in reports for the VMware data source.

**Description**

The description for the VMware data source.

**Test VMware VI Data Source connectivity before adding**

Check this box to check the connectivity for the VMware data source.

4. Click **Save**.

**Updating VMware data source information**

After a VMware data source has been added, you can update the administrator name or password for the VMware data source.

To update information for a VMware data source, follow this procedure:

1. In the navigation tree, expand **Administrative Services > Data Sources > VMware VI Data Source**.
2. In the content pane, click on the icon by the VMware data source you wish to change.
3. In the content pane, a notebook window opens. Make the appropriate changes.

**Displaying information about a VMware data source**

You can view information about a VMware data source including its host name, protocol, port, and type.

To display information about a VMware data source, follow this procedure:

1. In the navigation tree, expand **Administrative Services > Data Sources > VMware VI Data Source**.
2. In the content pane, click on the magnifying glass icon for the VMware data source for which you want information for. In the content pane, a notebook window opens. The following information is displayed:

**Host Name**

The IP address of the data source.

**Protocol**

This is http or https.

**Port** The port used by the VMware data source.

**Type** Virtual Center.

**Administrator Name**

The name of the administrator for the VMware data source.

**Password**

The password for the VMware data source.

**Password Confirm**

Confirm the password for the VMware data source.

**Display Name**

The name displayed for the VMware data source.

**Description**

Description for the VMware data source.

**Software Level**

The software level for the VMware data source.

**ConnectionStatus**

The connection status to the VMware data source.

**Status Timestamp****Test VMware VI Data Source connectivity before updating**

Check this box to check the connectivity to the VMware data source.

**Show managed devices for VMware**

You can view information about the managed devices for VMware.

To show the managed devices for VMware, follow this procedure:

1. In the navigation tree, expand **Administrative Services > Data Sources > VMware VI Data Source**.
2. In the content pane, click **Show Managed Devices**.
3. A pop-up window displays the VMware managed devices. Click **OK** to close the window.

**Deleting a VMware VI Data Source**

This topic provides information about deleting a VMware Virtual Infrastructure data source.

To delete a VMware VI data source, follow this procedure:

1. In the Navigation Tree pane, expand **Administrative Services > Data Sources > VMware VI Data Source**.
2. In the content pane, click **Remove VMware VI Data Source**.
3. In the confirmation dialog window to remove a VMware data source, click **OK**.

---

## Managing schedules, jobs, and runs

Use the Job Management panel to view and manage all the schedules, runs, and jobs related to the storage devices that are monitored by IBM Tivoli Storage Productivity Center.

Specifically, you can use the Job Management panel to perform the following tasks:

- View information about all schedules, runs, and jobs in one central location. In previous versions of the product, this information was available only through nodes under each schedule type in the navigation tree.
- Identify all the schedules that include a particular storage device.
- Identify all the schedules, runs, and jobs that are encountering problems when executing.
- Ensure that a storage device is fully monitored by Tivoli Storage Productivity Center.
- Edit, rename, delete, and run schedules. You must be logged in as the user who created a schedule to perform some of these actions.

Use either of the following methods to access the Job Management panel:

- Click the job management icon  in the toolbar.
- Open the definition of a schedule and click the **View Job History** button to view the runs and jobs related to the schedule. For example, in the navigation tree, click **IBM Tivoli Storage Productivity Center > Monitoring > Probes > TPCUser.Default Probe** to view the probe definition panel and click **View Job History**.

The following terms are used on this panel:

- **Schedule:** A schedule is a definition of a monitoring task that collects data about storage resources. Monitoring tasks include scans, probes, pings, quotas, discovery, and performance monitors. For example, define a probe schedule to collect data about storage subsystems; define a scan schedule to collect file-level information about hosts.
- **Run:** A run is a single invocation of a schedule.
- **Job:** A job is a unit of work within a run for a schedule. One run might have multiple jobs. For example, a subsystem probe schedule has one job created per subsystem for which it collects data.

The Job Management panel is divided into the following sections:

#### Filters section

Use this section to perform the following tasks:

- Determine the type of storage entities whose schedules are displayed on the panel.
- View recommendations for storage entities that are not fully monitored by Tivoli Storage Productivity Center.

Filtering the contents of this panel based on entity type is optional. You select **Show All** from the **Entity Type** menu to display all the schedules defined in Tivoli Storage Productivity Center.

#### Schedules section

Use this section to manage the schedules related to the entities you selected in the **Filters** section. You can perform the following actions for each schedule:

- View and edit the definition of a schedule.
- Run a schedule immediately.
- Rename a schedule.
- Delete a schedule.
- Display schedules that have a certain status, such as Success, Running, or Failed.

- View basic information about a schedule, including the ID of the user who created it, description, job type (for example, ping, probe, or scan), the last time the schedule was run, and the next time the schedule is run.

### **Jobs for Selected Schedule section**

Use this section to manage each run of a schedule and the jobs associated with a run. You can perform the following tasks for jobs and runs:

- View the status of a run and the date and time when it was executed.
- View information about the jobs associated with each run, including the name of the computer on which a job was run, the type of the monitored device, and the status of the job.
- View the log files for one or more jobs at a time.
- Display jobs that have started or completed within a specified length of time. For example, display jobs that have completed in the last two weeks.
- Display jobs that have a certain status, such as Success, Running, or Failed.

Click and drag the horizontal lines on the panel to resize each section. Click the names of columns in the **Schedules** and **Jobs for Selected Schedule** sections to sort the contents of lists based on the clicked column.

## **Filters**

### **Refresh All**

Click this button to update all the lists that are displayed on the panel.

### **Entity Type**

Select the type of storage entity whose related schedule information you want to view. By default all schedules are displayed when you first access this panel. When you select a specific entity type, the following actions take place:

- The schedules, runs, and jobs related to the entity type are displayed in the appropriate sections on the panel.
- The names of the devices that belong to that entity type are displayed in the **Entity Name** list box.
- The text that is displayed above the **Show Recommendations** button indicates if the devices are fully monitored.

You can select from the following entity types in the **Entity Type** menu:

### **Show All**

(default) View all the schedules defined in Tivoli Storage Productivity Center.

### **Storage Subsystem**

View the schedules for storage subsystems that are monitored by Tivoli Storage Productivity Center.

**Fabric** View the schedules for fabrics that are monitored by Tivoli Storage Productivity Center.

### **Computer**

View the schedules for computers that are monitored by Tivoli Storage Productivity Center.

**Switch**

View the schedules for switches that are monitored by Tivoli Storage Productivity Center.

**Tape Library**

View the schedules for tape libraries that are monitored by Tivoli Storage Productivity Center.

**Monitoring Group**

View the schedules that contain monitoring groups.

**Storage Resource Group**

View the schedules for all the devices contained within a particular storage resource group.

**Entity Name Filter**

Enter text to filter the names of entities that are displayed in the **Entity Name** list box. You can enter a combination of letters, numbers, dashes, underscores, and spaces. The filter text is not case sensitive. You can also enter the following wildcard characters:

- Use an asterisk (\*) to represent zero or more unknown characters of any value. For example, enter **DS8\*** to display devices of the selected type that begin with **DS** in their names, such as DS6000-A12-IBM, DS8000-B34-IBM, and DS5000-B35-IBM.
- Use a question mark to represent a single unknown character of any value. For example, enter **D?000-B3?-IBM** to include devices such as DS8000-B34-IBM, DS8000-B36-IBM, and DS5000-B35-IBM in the **Entity Name** list box.

**Text that is displayed above the Show Recommendations button**

Warning text is displayed above the **Show Recommendations** button if the devices selected in the **Entity Name** list box are not fully monitored.

A device is considered not fully monitored if it is not included in all data collection schedules that are available in the licensed edition of Tivoli Storage Productivity Center that is installed. For example, if using the Advanced edition of Tivoli Storage Productivity Center to monitor a host, that host must appear in the following schedule definitions to be considered fully monitored: ping, probe, and scan. If using the Disk edition of Tivoli Storage Productivity Center to monitor a storage subsystem, that storage subsystem must appear in the following schedule definitions to be considered fully monitored: probe.

If a device is considered not fully monitored, click **Show Recommendations** to view a list of recommended actions you can take to address the warning.

**Show Recommendations**

Click this button to view recommended actions for a selected device that is not fully monitored. From the Recommendations panel, you can perform the following tasks:

- View the schedules that are recommended for a device.
- Click the **Take Action** button to create the recommended schedule for a device.

**Schedules****View Detail**

View the definition of a schedule that is selected in the schedule list. The

schedule definition panel opens when you click this button. Use this panel to view and edit the definition of a schedule.

#### **Run Now**

Run the selected schedule immediately. This option is only available if the job is not currently running.

#### **Refresh**

Update the status of the schedule that is selected in the schedule list. The process to refresh the status of a schedule might take a few moments based on the current server load and network speed.

#### **action drop down menu**

Use the options in this menu to perform actions against the selected schedule. The menu includes **View Detail**, **Run Now**, **Stop Now** (for performance monitor schedules) and the following actions:

##### **Rename**

Rename a schedule. You must be the owner of a schedule or the Tivoli Storage Productivity Center superuser to perform this action. This action is not available for the default schedules that are owned by TPCUser.

**Delete** Delete a schedule. When you delete a schedule, all the runs and jobs associated with the schedule are also deleted. You must be the owner of a schedule or the Tivoli Storage Productivity Center superuser to perform this action. This action is not available for the default schedules that are owned by TPCUser.

#### **Only show schedules with status**

Filter the schedules that appear in the schedules list based on their status. For example, use this menu to indicate that only schedules with a status of **Running** are displayed in the schedules list. The default setting displays all schedules.

You can filter schedules using the following statuses:

- Show All
- Show All Unsuccessful
- Success
- Running
- Warnings
- Failed
- The job is waiting
- The job is running

Tivoli Storage Productivity Center automatically updates the schedules list if you change the value selected in this menu.

#### **schedules list**

Use this list to view the schedules for the storage entities that are selected in the **Filters** section of the panel. The schedules that are displayed must also meet the filter selected in the **Only show schedules with status** menu. Click the name of a column to sort the contents of this list based on that column.

Some jobs that run in Tivoli Storage Productivity Center do not have a schedule associated with them. For example, jobs that are run through the command-line interface (CLI) do not have a schedule defined for them. To ensure that these job types are displayed on the Job Management panel, a

new schedule called **CLI and Event Driven Jobs** was created. Select this schedule to view the runs and jobs that do not have user-created schedules associated with them. The job log files for the CLI and Event Driven Jobs schedule are automatically retained for 90 days and then deleted.

The following information is displayed for each schedule:

**Creator**

The ID of the Tivoli Storage Productivity Center user who created the schedule.

**Name** The name of a schedule.

**Description**

The description of a schedule.

**Job Type**

The type of the schedule, such as Probe, Ping, Scan, Aggregator Job, CIMOM Discovery, or Subsystem Performance Monitor.

**Last Run Finished**

The data and time when the most recent run of a schedule completed. This column is blank if the schedule has never been run.

**Last Run Status**

The status of the most recent run of a schedule.

**Next Run**

The date and time when the next run of the schedule is planned. The value **On Demand** is displayed for schedules that are defined with the **Run Now** option. The value **Never** is displayed for schedules that are defined with the **Run Once** option and have already run.

**row number**

Appears in the lower right corner of the schedules list and indicates the number of rows in the schedules list. One row is displayed for each schedule. Use the horizontal lines on the panel to resize the section and increase or decrease the number of rows that are displayed.

## Jobs for Selected Schedule

**View Log File(s)**

View the log files of jobs that are selected in the runs list. Use the Shift + click and Ctrl + click keyboard shortcuts to select multiple jobs. You can view up to 10 logs at one time. The Log File Viewer panel opens when you click this button or when you double-click a row for a job. Use this panel to view all the processing performed by the Tivoli Storage Productivity Center server and agents for jobs.

**Note:** The number of job log files that are retained for a schedule is determined by the values defined on the Log File and Cached Batch Report Retention panel under **Administrative Services > Configuration**. However, for CLI and Event Driven Jobs schedules, job log files are automatically retained for 90 days.

**Show Jobs, in the last**

Use these fields to determine the runs that are displayed for the selected schedule. Use the following conditions in the filter:

- Select **Started** or **Completed** from the **Show Jobs** menu to display runs based on whether they started or completed in the time frame specified on the **last** field.
- Specify a time frame for started or completed runs by entering a number in the **last field** and selecting a unit of measurement from the menu.

For example, select **Started**, enter **4**, and select **weeks** to display the runs for a schedule that have started within the last four weeks. Tivoli Storage Productivity Center automatically updates the runs list if you change the value selected in these fields.

#### Only show jobs with status

Determine the runs that are displayed in the runs list based on their status. For example, use this menu to indicate that only runs with a status of **Completed with warning(s)** are displayed. The default setting displays all runs for the selected schedule.

You can filter the display of runs using the following statuses:

- Show All
- Show All Unsuccessful
- The job is waiting
- Running
- The job is running
- Completed successfully
- Running with warning(s)
- Completed with warning(s)
- Completed with error(s)
- System error occurred
- The agent did not respond (to a request from the server)
- The agent is being upgraded
- The agent is not licensed
- Agent not found
- Agent could not be reached
- The job delay limit was exceeded.
- The agent disconnected
- Host was shutdown or recycled
- Cluster resource group unreachable: no IP
- Scripts are disabled for this agent
- Script was not found or has an invalid extension
- The agent disk space is low

Tivoli Storage Productivity Center automatically updates the runs list if you change the value selected in this menu.

#### runs list

Use this list to view the runs and jobs of the schedule selected in the **Schedules** section of the panel. This list displays runs based on the criteria specified in the **Show jobs** and **in the last** fields.

Click the + symbol next to an entry in the **Run** field to view the jobs associated with a run. Click the name of a column to sort the contents of this list based on that column.

The following information is displayed for each run or job:

**Run Status**

The status of a run.

**Run** The run number assigned to a run and the date and time when the run was started.

**Computer**

(jobs only) The name of the computer where a job is executed. For database probes, this column displays the name of the Storage Resource agent that is performing the probe. For storage subsystem probes, this column displays **localhost** because the probe is performed by the Tivoli Storage Productivity Center server.

**Device**

(jobs only) The name of the device to which a job applies. This column is blank if the job is not related to a specific device.

**Status** (jobs only) The status of a job.

**Start Time**

(jobs only) The date and time when a job started.

**Finish Time**

(jobs only) The data and time when a job completed.

**Log File Name**

(jobs only) The name of the log file for a job. Click the **View Log File** to view the contents of a job log.

**row number**

Appears in the lower right corner of the runs list and indicates the number of rows in the runs list. One row is displayed for each run. You can expand each run row to view the jobs related to that run. Use the horizontal lines on the panel to resize the section and increase or decrease the number of rows that are displayed.

## Job Management - Recommendations

Use this window to view and apply the recommendations for storage resources that are not fully monitored by Tivoli Storage Productivity Center.

A resource is not fully monitored if it is not included in all the data collection schedules that are available in the licensed edition of Tivoli Storage Productivity Center that is installed. For example, when you use the IBM Tivoli Storage Productivity Center Advanced license to monitor a host, that host must be included a ping, probe, and scan to be considered fully monitored. If you use IBM Storage Productivity Center Select Edition to monitor a storage subsystem, that storage subsystem must be included in a probe to be fully monitored.

**Recommendation Severity**

Indicates whether a recommendation is a warning or only informational.

- A warning message indicates an action that you can take to more fully use Tivoli Storage Productivity Center to monitor a resource. For example, when you use a probe schedule in the IBM Tivoli Storage Productivity Center Advanced license to collect data about a storage system, a warning message is displayed. This message recommends that you also include the storage subsystem in a performance monitor schedule. You can then use the data that is collected by performance monitor to identify the bottlenecks in storage usage and performance for the storage subsystem.

- An informational message is a recommendation to upgrade Tivoli Storage Productivity Center to an edition that includes more monitoring functions. For example, when you use probe schedules in IBM Storage Productivity Center Select Edition to collect data about a fabric, an informational message is displayed. This message indicates that if you upgrade to IBM Tivoli Storage Productivity Center Advanced, performance data can be collected about the fabric.

For warning messages, select the corresponding row and click **Take Action** to take the recommended action.

**Entity** Displays the name of a storage resource to which the recommendation applies.

**Recommendation**

Indicates the recommended actions for a storage entity. One row is displayed per recommendation. Click **Take Action** to resolve recommendations that have a warning severity.

If multiple recommendations are displayed for a resource, sometimes completing one of the recommended actions might resolve the other recommendations. For example, consider if these two recommendations are displayed for a fabric:

- In order to collect information about resource configuration, define a probe schedule for fabric {0}
- To enable zone control, add a data source that is capable of zone control for fabric {0}

If you click **Take Action** for the first recommendation and include the fabric in a probe, the second recommendation is also resolved. Both recommendations are then automatically removed from the **Recommendation** list

**Take Action**

Take the recommended action for a warning. When you click the **Take Action** button, the corresponding panel for the action is displayed. For example, if the recommended action is to include a storage subsystem in a performance monitor, the panel is displayed.

**Cancel**

Exit the window without taking any actions.

---

## Chapter 5. Managing resources in the stand-alone GUI

You can use the stand-alone GUI to manage and monitor the resources and storage infrastructure in an enterprise environment. This interface provides all the tools to manage data, disk, fabric, tape, and replication.

Tivoli Storage Productivity Center also provides a web-based GUI for monitoring resources. Each GUI provides different functions for managing your storage. To view a comparison of the functions that are available in each GUI, see “Available functions and report information in the interfaces” on page 21.

### Related concepts:

Chapter 6, “Managing resources in the web-based GUI,” on page 625

You can use the web-based GUI to monitor the condition, capacity, and relationships of the monitored resources within your storage environment.

---

## Adding resources for monitoring

Use the Configure Devices wizard to add resources for monitoring by IBM Tivoli Storage Productivity Center. The wizard guides you through the steps for configuring a resource as a data source, running a discovery, including devices in groups, specifying alerts, and setting up data collection.

In previous versions of IBM Tivoli Storage Productivity Center, setting up a storage device for monitoring required completing tasks in different locations of the user interface, and each type of device required different steps. In Tivoli Storage Productivity Center v4.2 and later, all the tasks for setting up and configuring a device are included in the Configure Devices wizard.

Use the wizard to configure the following device types for monitoring:

- Storage subsystems
- Fabrics and switches
- Computers
- Tape libraries

You can add multiple devices of the same type in a single session of the wizard. For example, you can add an IBM DS8000, IBM XIV, IBM SAN Volume Controller, IBM Storwize V7000, IBM Storwize V7000 Unified, IBM SONAS, and storage subsystems that are associated with CIM agents by using a single session of the wizard. You cannot configure multiple devices of different types at the same time. For example, you cannot add a storage subsystem and a fabric in a single session of the wizard.

**Note:** The Configure Devices wizard queries all schedules to identify whether a resource is already included in a probe. If a probe was defined for a global entity such as **All Computers** or **All Storage subsystems**, the Configure Devices wizard does not display a resource of that type as an entity that requires configuration.

The pages in the wizard are divided into two sections:

**Steps** Displays the steps for completing in the wizard. An icon is displayed next to the current step. The wizard includes the following steps for configuring a device:

1. Select the device type that you want to configure.
2. Select the specific devices that you want to configure.
3. Determine how data is collected from the devices.
4. Review your selections and run the wizard.
5. Review the results of the wizard.

How you access the wizard determines on what step you begin. For example, if you click the **Configure Devices** icon in the toolbar or select the **Configure Devices** node in the navigation tree, you start by selecting the device type that you want to configure. If you click the **Add Storage Subsystem** button on the **Disk Manager > Storage Subsystems** panel, you begin by entering connection information about the storage systems that you want to configure.

#### Options

Displays the options and fields that you must select and complete for each step.

#### Related reference:

“Alerts and schedules associated with monitoring groups and templates” on page 1469

Use alerts to notify you when conditions for storage devices are detected by a data collection schedule. Include storage devices in monitoring groups or templates to automatically associate alerts and schedules with those devices.

## Configuring storage subsystems

Use the Configure Devices wizard to add storage systems for monitoring by Tivoli Storage Productivity Center. Storage subsystems that you configure are automatically included in probe schedules and associated with alert conditions.

You can configure more than one storage system at a time by using the Configure Devices wizard. All the storage systems that you configure by using the wizard share probe schedule and alert conditions.

Depending on the type of storage system that you want to configure, you must define connection information for its native interface or associated CIMOM. Enter information in the wizard about the native interfaces for the following storage systems:

- System Storage DS8000
- SAN Volume Controller
- The XIV system
- Storwize V3500
- Storwize V3700
- Storwize V7000
- Storwize V7000 Unified
- IBM SONAS

For all other storage systems, you must enter information about the CIM agents that manage them.

To configure storage systems to be monitored by Tivoli Storage Productivity Center, complete the following steps:

1. Select one of the following ways to access the wizard:

- To configure existing storage systems, click the **Configure Devices** icon on the toolbar. You cannot configure existing storage systems if they are already included in a probe schedule.

If you select this method, you must also complete the following steps:

- a. On the Select Device Type page, select **Storage Subsystem**.
  - b. Click **Configure existing storage subsystems**. The page displays the storage systems that are known to Tivoli Storage Productivity Center. Continue to next step.
- To only add storage systems, select one of the following methods and proceed to step 4:
    - In the navigation tree, expand **Disk Manager > Storage Subsystems** and click **Add Storage Subsystem**.
    - In the navigation tree, expand **IBM Tivoli Storage Productivity Center > Configuration Utility > Services > Storage Subsystem Interfaces** and click **Add**.
2. Select the existing storage systems that you want to configure. Storage systems that are already included in probe schedules are not displayed.  
If the Credentials column indicates Missing or New Credentials Required for the storage systems that you select, you must update the storage system connection properties before you continue.
  3. Specify connection properties for each storage system that you want to configure, and continue to step 6.
  4. Configure the storage system or CIMOM connections. Tivoli Storage Productivity Center uses this information to connect to a storage system or CIMOM.  
Enter information for a storage system or CIMOM, and then click **Add**. Repeat steps 1 - 3 to configure multiple storage systems or CIMOMs in the same session of the wizard.  
Tivoli Storage Productivity Center discovers the storage systems that are managed by each of the CIMOM connections that you entered.
  5. Select the storage systems that you want to configure. Any storage systems that were added in previous steps are automatically selected. Clear storage systems that you do not want to configure.
  6. Specify how data is collected for storage systems by including them in a monitoring group or template. Use monitoring groups and templates to determine when data is collected and what alert conditions are checked for the storage systems that you are configuring.
    - Select a monitoring group if you want to manage a collection of storage systems in the same manner. By default, the monitoring group that you select is associated with an existing probe schedule and set of alerts. When you select the group, its data collection schedule and alerts are automatically applied to all the storage systems that you are configuring. After you complete the wizard, the storage systems remain in the group and you can use that group in other parts of the user interface, such as in reports.

**Tip:** Tivoli Storage Productivity Center provides a number of default monitoring groups for storage systems. If you want to include a storage system in a user-defined group rather than in a default group, that group must be associated with a data collection schedule. If the user-defined group is not associated with a data collection schedule, it is not displayed in the list of monitoring groups from which you can select.

- Select a template if you want to create a unique probe schedule and set of alerts for a storage system rather than using the settings of an existing group.

The option that you select in this step determines the next step in the wizard.

- If you select a monitoring group, the following actions occur:
  - The storage systems are automatically included in a probe schedule to which the group is associated. For example, if you select Subsystem Basic Group, the storage systems are included in the Subsystem Basic Probe schedule. The Subsystem Basic Probe schedule runs one time per week on Tuesday at 1:00 am.
  - A set of alert conditions is applied to the storage systems in a group. When any of these conditions are detected during data collection, an alert is triggered. The group that you select determines the alerts that are associated with the storage systems. For example, if you select Subsystem Basic Group, 14 alert conditions are automatically checked for the storage systems.
  - The storage systems are included in the group. You can use that group in other parts of the user interface, such as in reports.
- If you select a monitoring template, the following actions occur:
  - The storage systems are automatically included in a probe schedule that is created for the template. For example, if you select the Basic Subsystem Monitoring template, the storage systems are automatically included in a new probe that runs one time per week on Tuesday. The probe is created after the wizard is completed. Tivoli Storage Productivity Center determines the time when the probe is run based on server load to ensure optimal performance.
  - A set of alert conditions is applied to storage systems in the template. When any of these conditions are detected during data collection, an alert is triggered. The template that you select determines the alerts that are associated with the storage systems. For example, if you select to the Basic Subsystem Monitoring template, 14 alert conditions are automatically checked for the storage systems.
  - You must enter a prefix for the probe schedule and alerts that are created for the template. This prefix is used to identify the probe and alerts in the user interface. For example, if you select the Basic Subsystem Monitoring template and enter the prefix "ABC", a probe schedule named "*user ID*.ABCssBasicProbe" and alerts such as "*user ID*.ABCPool Discovered (Basic)" are created, where *user ID* represents the ID of the user that is logged on to Tivoli Storage Productivity Center.

The new probe and alerts are displayed under the corresponding node in the navigation tree for you to view and edit. For example, a probe schedule that is created from a template in the wizard is displayed under the **IBM Tivoli Storage Productivity Center > Monitoring > Probes** node; new storage system alerts is displayed under the **Disk Manager > Alerting** node.

See Alerts and schedules associated with monitoring groups and templates for a list of groups and templates with their associated schedules and alerts.

7. On the summary page of the wizard, review the selections that you made.

View the results of the device configuration and close the wizard. The devices that you configured are probed.

## Configure storage subsystem connections page

Use this page in the Configure Devices wizard to enter or update connection properties for the storage systems and CIMOMs that you are configuring. Tivoli Storage Productivity Center uses this information to collect data about the storage systems.

Use the Configure storage system connections page to enter or update connection properties for the following storage entities. Depending on the type of storage system that you want to configure, you must define connection information for its native interface or associated CIMOM.

The entity that is selected from the **Device Type** list determines the information that Tivoli Storage Productivity Center requires to connect to that entity. The following sections describe the fields for each entity.

**Requirement:** If you are adding or updating connection properties for a SAN Volume Controller, Storwize V3500, Storwize V3700, or Storwize V7000 storage system, select **IBM SAN Volume Controller / IBM Storwize V7000** in the **Device Type** list. If you are adding or updating connection properties for a Storwize V7000 Unified storage system, select **IBM Storwize V7000 Unified**.

### IBM DS8000

Enter or update the following information to have Tivoli Storage Productivity Center connect to a System Storage DS8000 storage system.

#### HMC Address

Enter the IP address or host name for the Hardware Management Console (HMC) that is used to manage the System Storage DS8000 storage system.

#### HMC2 Address (Optional)

Enter the IP address or host name for a second HMC that is used to manage the storage system.

#### Username

Enter the user name for logging in to the System Storage DS8000 element manager. The default user name is `admin`.

**Note:** This user name is the same as the ESSNI user name.

#### Password

Enter the password for the user name.

### IBM XIV

Enter or update the following information to have Tivoli Storage Productivity Center connect to the XIV system.

#### IP Address

Enter the IP address or host name for the XIV system that you want to configure.

#### Username

Enter the user name for the XIV system.

#### Password

Enter the password for the user name.

## IBM SAN Volume Controller / IBM Storwize V7000

Enter or update the following information to have Tivoli Storage Productivity Center connect to a SAN Volume Controller, Storwize V3500, Storwize V3700, or Storwize V7000 storage system.

### Software Version

Enter the version of the SAN Volume Controller, Storwize V3500, Storwize V3700, or Storwize V7000 software that you want to configure.

### IP Address

Enter the IP address or host name of the storage system. You can enter an IPv4 or IPv6 address, for example:

- 127.0.0.1
- [2001:DB8:0:0:0:0:0/32]

### Select Key

A Secure Shell (SSH) key is required to access the storage system. Select one of the following actions for the SSH key:

- **Upload new key:** Select this option to upload a new key. Public key content is extracted from the private key that is provided in the **Private SSH Key** field and is uploaded to the storage system cluster. If you select this option, the **Administrator User Name** and **Administrator Password** fields are required.
- **Use existing uploaded key:** Select this option if you want to use a public key that was already uploaded by using a method other than through Tivoli Storage Productivity Center, such as the storage system web interface. Enter the location of the private key file that corresponds to the public key in the **Private SSH Key** field. The **Administrator User Name** and **Administrator Password** fields are not required if you select this option.

### Administrator User Name

If you selected **Upload new key** in the **Select Key** list, enter the name of a user that has the Security Administrator role for the cluster that contains the storage system. Tivoli Storage Productivity Center uses this value during the setup process to contact the cluster and configure the SSH keys for the user. This user name must have privileges to modify other user accounts (Security Administrator role); otherwise, Tivoli Storage Productivity Center cannot configure the SSH keys.

If you selected the **Use existing uploaded key** option, this field is optional.

**Note:** The **Administrator User Name** applies to only SVC5.x+; it does not apply to SVC 4.x.

### Administrator Password

Enter the password for the user name that you entered in the **Administrator User Name** field.

### User Name

Enter an authorized user name for the storage system. Tivoli Storage Productivity Center uses this value when monitoring and configuring the storage system. If the user name does not exist it is created. This user name must be assigned the Administrator role.

This field is active if you selected **Upload new key** in the **Select Key** list and entered a user name and password in the **Administrator User Name** and **Administrator Password** fields.

**Important:** If you upload a new key for the existing storage system user by using Tivoli Storage Productivity Center, that new key overrides the existing key for the user. If you have another application that is using that user (for example Tivoli Storage Productivity Center for Replication), the application cannot log on to the storage system because the key associated with the user is overwritten.

If you have this situation, create a user ID specifically for Tivoli Storage Productivity Center or Tivoli Storage Productivity Center for Replication on the storage system cluster. Add the storage system to Tivoli Storage Productivity Center for Replication using the new user ID and password (or change the user ID and password while the storage system is in the disconnected state).

#### Select User

Click this button to select from a list of existing users that are defined on the storage system.

#### Private SSH Key

By default, the private key entry includes `${device.conf}\tpc_svc.pem`, which represents the Tivoli Storage Productivity Center default key `tpc_svc.pem`. The `tpc_svc.pem` key is in the `conf` directory where the Device server is installed. If you want to use your own key, the key must exist on the system where you are running the Tivoli Storage Productivity Center user interface. The key is uploaded to the Tivoli Storage Productivity Center server system. To identify a new key, click **Browse**.

The private SSH key must be in OpenSSH format or in PuTTY (.ppk) format that is not password protected. If you have a password protected PuTTY .ppk key, use the PuTTYgen utility on a Windows operating system to convert that key to OpenSSH format by following these steps:

1. Start the PuTTYgen utility.
2. Load the .ppk file by clicking **File > Load private key**.
3. From the menu bar, click **Conversion > Export OpenSSH key conversion**.

This action saves the key in OpenSSH format.

#### Passphrase (Optional)

Enter the passphrase for the private SSH key. The passphrase protects your private SSH key file. If you do not have a passphrase, leave this field blank.

#### Storwize V7000 Unified

Enter or update the following information to have Tivoli Storage Productivity Center connect to a Storwize V7000 Unified storage system.

Storwize V7000 Unified is composed of Storwize V7000 and Storwize V7000 File Module. You can connect to only Storwize V7000 or to both Storwize V7000 and Storwize V7000 File Module. Storwize V7000 provides block-level data and Storwize V7000 File Module provides file-level data.

#### Storwize V7000

Use the information in this section to connect Storwize V7000.

#### IP Address

Enter the IP address or host name of the Storwize V7000 storage system. You can enter an IPv4 or IPv6 address, for example:

- 127.0.0.1
- [2001:DB8:0:0:0:0:0/32]

### Select Key

An SSH key is required to access Storwize V7000. Select one of the following actions for the SSH key:

- **Upload new key:** Select this option to upload a new key. Public key content is extracted from the private key that is provided in the **Private SSH Key** field and is uploaded to the Storwize V7000 cluster. If you select this action, the **Administrator User Name** and **Administrator Password** fields are required.
- **Use existing uploaded key:** Select this option if you want to use a public key that was already uploaded by using a method other than through Tivoli Storage Productivity Center, such as the Storwize V7000 web interface. Enter the location of the private key file that corresponds to the public key in the **Private SSH Key** field. The **Administrator User Name** and **Administrator Password** fields are not required if you select this option.

### Administrator User Name

If you selected **Upload new key** in the **Select Key** list, enter the name of a user that has the Security Administrator role for the Storwize V7000 cluster that contains the storage system. Tivoli Storage Productivity Center uses this value during the setup process to contact the cluster and configure the SSH keys for the user. This user must belong to the Security Administrator role, which has privileges to modify other user accounts. Otherwise, Tivoli Storage Productivity Center cannot configure the SSH keys.

If you selected **Use existing uploaded key**, this field is optional.

### Administrator Password

Enter the password for the user name that you entered in the **Administrator User Name** field.

If you selected **Use existing uploaded key**, this field is optional.

### User Name

Enter an authorized user name for the storage system. Tivoli Storage Productivity Center uses this value to monitor and configure the storage system. If the user name does not exist, it is created. This user name must belong to the Administrator role.

This field is active if you selected **Upload new key** in the **Select Key** list and entered a user name and password in the **Administrator User Name** and **Administrator Password** fields.

**Important:** If you upload a new key for the existing Storwize V7000 user by using Tivoli Storage Productivity Center, that new key overrides the existing key for the user name. If you have another application that is using that user name (for example Tivoli Storage Productivity Center for Replication), the application cannot log on to Storwize V7000 because the key associated with the user is overwritten.

If this situation occurs, create a user ID specifically for Tivoli Storage Productivity Center or Tivoli Storage Productivity Center for Replication on the Storwize V7000 cluster. Add the Storwize V7000 storage system to Tivoli Storage Productivity Center for

Replication using the new user ID and password (or change the user ID and password while the storage system is in the disconnected state).

#### Select User

Select a user name from the list. The names are defined on Storwize V7000.

#### Private SSH Key

By default, the private key entry includes `${device.conf}\tpc_svc.pem`, which represents the Tivoli Storage Productivity Center default key `tpc_svc.pem`. The `tpc_svc.pem` key is in the `conf` directory where the Device server is installed. If you want to use your own key, the key must exist on the system where you are running the Tivoli Storage Productivity Center user interface. The key is uploaded to the Tivoli Storage Productivity Center server system. To identify a new key, click **Browse**.

The private SSH key must be in OpenSSH format or in PuTTY (.ppk) format that is not password protected. If you have a password protected PuTTY .ppk key, use the PuTTYgen utility on a Windows operating system to convert that key to OpenSSH format by following these steps:

1. Start the PuTTYgen utility.
2. Load the .ppk file by clicking **File > Load private key**.
3. From the menu bar, click **Conversion > Export OpenSSH key conversion**.

This action saves the key in OpenSSH format.

#### Passphrase (Optional)

Enter the passphrase for the private SSH key. The passphrase protects your private SSH key file. If you do not have a passphrase, leave this field blank.

#### Storwize V7000 File Module (Optional)

To connect to the Storwize V7000 Unified system, select the check box.

Depending on the configuration of Storwize V7000 Unified, the information that is required to connect to this system can be the same as or different from the information for Storwize V7000. The fields and field descriptions are the same as the fields in the Storwize V7000 pane with the following exceptions:

- The **IP Address** field is not displayed because the IP address is retrieved automatically.
- The **Select Key** list contains the option **Use user password** in addition to the **Upload new key** and **Use existing uploaded key** options. If you select **Use user password**, the **User Password** field is enabled and you can use a user name and password to connect to the file module.  
If you select **Use user password**, the **Administrator User Name** and **Administrator Password** fields are optional.
- The **User Name** field is always required.
- The private SSH key must be in OpenSSH format. The PuTTY format is not supported. You can use the PuTTYgen utility to convert the key to the OpenSSH format.

## IBM SONAS

Enter or update the following information so that Tivoli Storage Productivity Center can connect to an IBM SONAS system.

### IP Address

Enter the IP address or host name of the IBM SONAS system. You can enter an IPv4 or IPv6 address, for example:

- 127.0.0.1
- 2001:DB8:0:0:0:0:0/32

### Select Key

You must use a Secure Shell (SSH) key to access the storage system. Select one of the following actions for the SSH key:

- **Upload new key:** Select this option to upload a new key. Public key content is extracted from the private key that is provided in the **Private SSH Key** field and is uploaded to the IBM SONAS system. If you select this action, you must specify a value for the **Administrator User Name** and **Administrator Password** fields.
- **Use existing uploaded key:** Select this option if you want to use a public key that was already uploaded by using a method outside of Tivoli Storage Productivity Center, such as the IBM SONAS system web interface. Enter the location of the private key file that corresponds to the public key in the **Private SSH Key** field. You do not have to specify a value in the **Administrator User Name** and **Administrator Password** fields.
- **Use user password:** Select this option if you want to use a user name and password to connect to the file module. If you select this option, the **User Password** field is enabled and you can use a user name and password to connect to the file module.

If you select **Use user password**, the **User Password** field is enabled and the **Administrator User Name** and **Administrator Password** fields are optional.

### Administrator User Name

If you selected **Upload new key** in the **Select Key** list, enter the name of a user that has the Security Administrator role for the IBM SONAS system. Tivoli Storage Productivity Center uses this value during the setup process to contact the system and configure the SSH keys for the user. This user name must have privileges to modify other user accounts (Security Administrator role); otherwise, Tivoli Storage Productivity Center cannot configure the SSH keys.

If you selected **Use existing uploaded key**, this field is optional.

### Administrator Password

Enter the password for the user name that you entered in the **Administrator User Name** field.

### User Name

Enter an authorized user name for the storage system. Tivoli Storage Productivity Center uses this value when it configures and monitors the storage system. If the user name does not exist it is created. This user name must have the Administrator role.

This field is active if you selected **Upload new key** in the **Select Key** list and entered a user name and password in the **Administrator User Name** and **Administrator Password** fields.

### Select User

Select from a list of existing user names that are defined on the IBM SONAS system.

### Private SSH Key

By default, the private key entry includes `${device.conf}\tpc_svc.pem`, which represents the Tivoli Storage Productivity Center default key `tpc_svc.pem`. The `tpc_svc.pem` key is in the `conf` directory where the Device server is installed. If you want to use your own key, the key must exist on the system where you are running the Tivoli Storage Productivity Center user interface. The key is uploaded to the Tivoli Storage Productivity Center server system. To identify a new key, click **Browse**.

The private SSH key must be in OpenSSH format or in PuTTY (.ppk) format that is not password protected. If you have a password protected PuTTY .ppk key, use the PuTTYgen utility on a Windows operating system to convert that key to OpenSSH format by following these steps:

1. Start the PuTTYgen utility.
2. Load the .ppk file by clicking **File > Load private key**.
3. From the menu bar, click **Conversion > Export OpenSSH key conversion**.

This action saves the key in OpenSSH format.

### Passphrase (Optional)

Enter the passphrase for the private SSH key. The passphrase protects the private SSH key file. If you do not have a passphrase, leave this field blank.

### User Password

Enter the password for the user name that you entered in the **User Name** field.

### Other (CIMOM)

Enter or update connection properties for a CIMOM. Tivoli Storage Productivity Center uses this information to discover the storage systems that are managed by a CIMOM. You can then configure those storage systems as part of the wizard session.

The connection information that you enter for a CIMOM is similar to the information that you enter when adding a CIMOM on the Add CIMOM page. See "Adding a CIM agent connection" on page 253 for descriptions of the fields on this page.

### Discovered Storage Systems

After you run a discovery job, a table is displayed on the "Configure storage subsystem connections" page. This table provides information about the storage systems that were discovered for the selected storage system type.

You can remove the connection to a storage system by clicking the row for the system in the table, and then clicking **Remove**.

## Configure fabrics and switches

Use the Configure Devices wizard to add fabrics and switches for monitoring by Tivoli Storage Productivity Center. Fabrics and switches that you configure in the wizard are automatically included in probe schedules and associated with alert conditions.

You can use the wizard to configure the following fabric and switch types for monitoring:

- Brocade
- Cisco
- QLogic

You can configure one or more fabrics in a single session of the Configure Devices wizard. All the fabrics and switches that you configure in a single pass share a probe schedule and alert conditions.

To configure fabrics and switches, complete the following steps:

1. Access the wizard:
  - If you want to add new or configure existing fabrics and switches, click the configure devices icon in the toolbar or select the **Configure Devices** node in the navigation tree. If you use this method, you must also complete the following steps:
    - a. Select **Fabrics/Switches** on the Select Device Type page.
    - b. Determine whether to add new fabrics or configure existing fabrics that are known to Tivoli Storage Productivity Center.
      - To add fabrics and switches, select **Add and configure new fabrics** and go to step 3.
      - To configure existing fabrics and switches, select **Configure existing fabrics**. The page displays the fabrics that are known to Tivoli Storage Productivity Center. Go to step 2.
  - If you only want to add new fabrics and switches, go to **Fabric Manager > Fabrics** and click **Add Fabric**. Go to step 3.
2. Select the existing fabrics that you want to configure. Fabrics that are already included in probe schedules are not displayed. Go to step 6 after you select the fabrics that you want to configure.
3. Configure CIMOM or agent connections. The fields for entering connection information for a fabric changes based on the type of fabric you are adding. Tivoli Storage Productivity Center uses the information that you enter in this step to connect to a fabric or CIMOM. Click **Add** to configure multiple fabrics in a session of the wizard.

**Note:** Depending on the type of fabric you are adding, the wizard recommends whether to enter CIMOM or agent information. For example, if you are configuring a Brocade fabric, the recommended way to administer it is with a CIMOM. If a CIMOM is not available, enter connection information for an out of band fabric agent.
4. Discover the fabrics that are managed by the CIMOMs that you entered in the previous step. Tivoli Storage Productivity Center collects initial configuration information for these entities.
5. Select the fabrics that you want to configure for monitoring. Any fabrics that were added in previous steps are automatically selected. Clear the check box for the fabrics that you do not want to configure.

6. Specify how data is collected for fabrics by including them in a monitoring group or template. Use monitoring groups and templates to determine when data is collected and what alert conditions are checked for the fabrics that you are configuring.
  - Select a monitoring group if you want to manage a collection of fabrics in the same manner. Each monitoring group that you can select is associated with an existing probe schedule and set of alerts. When you select a group, its data collection schedule and alerts are automatically applied to all the fabrics that you are configuring. After you complete the wizard, the fabrics remain in the group and you can use that group in other parts of the user interface, such as in reports.

**Tip:** Tivoli Storage Productivity Center provides a number of default monitoring groups for fabrics. If you want to include a fabric in a user-defined group rather than in a default group, that group must be associated with a data collection schedule. If the user-defined group is not associated with a data collection schedule, it is not displayed in the list of monitoring groups from which you can select.

- Select a template if you want to create a unique probe schedule and set of alerts for a fabric rather than using the settings of an existing group.

The option that you select in this step determines the field and pages that appear next in the wizard.

- If you select a monitoring group, the following actions occur:
  - The fabrics are automatically included in a probe schedule to which the group is associated. For example, if you select Fabric Basic Group, the fabrics are included in the Fabric Basic Probe schedule. The Fabric Basic Probe schedule runs two times per week on Monday and Wednesday at 3:00 am.
  - A set of alert conditions is applied to the fabrics in a group. When any of these conditions are detected during data collection, an alert is triggered. The group that you select determines the alerts that are associated with the fabrics. For example, if you select Fabric Basic Group, nine alert conditions are automatically checked for the fabrics.
  - The fabrics are included in the group. You can use that group in other parts of the user interface, such as in reports.
- If you select a monitoring template, the following actions occur:
  - The fabrics are automatically included in a probe schedule that is created for a template. For example, if you select the Basic Fabric Monitoring template, the fabrics are automatically included in a new probe that runs two times per week on Monday and Wednesday. The probe is created after the wizard is completed. Tivoli Storage Productivity Center determines the time when the probe is run based on server load to ensure optimal performance.
  - A set of alert conditions is applied to the fabrics in a template. When any of these conditions are detected during data collection, an alert is triggered. The template that you select determines the alerts that are associated with the fabrics. For example, if you select the Basic Fabric Monitoring template, nine alert conditions are automatically checked for the fabrics.
  - You must enter a prefix for the probe schedule and alerts that are based on a template. This prefix is used to identify the probe and alerts in the user interface. For example, if you select the Basic Fabric Monitoring template and enter the prefix "ABC", a probe schedule named "*user*

*ID.ABCfabBasicProbe*" and alerts such as "*user ID.ABCFabric State Change (Basic)*" are created, where *user ID* represents the ID of the user that is logged on to Tivoli Storage Productivity Center.

The new probe and alerts are displayed under the corresponding node in the navigation tree for you to view and edit. For example, a probe schedule created from a template in the wizard appears under the **Tivoli Storage Productivity Center > Monitoring > Probes** node; new storage system alerts appear under the **Fabric Manager > Alerting** node.

See Alerts and schedules associated with monitoring groups and templates for a list of groups and templates with their associated schedules and alerts.

7. On the summary page of the wizard, review the selections that you made.

View the results of the device configuration and close the wizard. The devices that you configured are probed.

## Configure computers

Use the Configure Devices wizard to add computers for monitoring by Tivoli Storage Productivity Center. Computers that you configure in the wizard are automatically included in probe and ping schedules and associated with alert conditions.

Use the Configure Devices wizard to configure computers that meet the following conditions:

- A Storage Resource agent was deployed on the computer.
- The computer is not included in an existing probe schedule. Devices that are included in existing probe schedules are not displayed in the Configure Devices wizard because they are considered to be already configured for monitoring.

**Important:** When computers are added to Tivoli Storage Productivity Center, they are automatically included in the default computer group, and that group is included in the default probe schedule (TPCUser.Default Probe). Because the computers are included in TPCUser.Default Probe, they are considered to be configured for monitoring and are not displayed in the wizard.

To use the Configure Devices wizard to configure computers that were included in TPCUser.Default Probe, move them into a group that is not associated with an existing probe schedule. To move them into a new group, complete the following steps:

1. In the navigation tree, go to **Data Manager > Monitoring > Groups > Computer**.
2. Right click **Computer** and select **Create Computer Group**.
3. Select the computers that you want to configure in the Configure Devices wizard and click the right arrow icon to move them into the new group.
4. Click the save icon in the toolbar to save the group. Do not associate this group with a probe schedule.
5. Start the Configure Devices wizard to the configure computers. The computers in the new group are displayed in the wizard.

You can configure one or more computers in a single session of the Configure Devices wizard. All the computers that you configure in a single session share a probe schedule, ping schedule, and alert conditions.

To configure computers, complete the following steps:

1. Click the configure devices icon in the toolbar or select the **Configure Devices** node in the navigation tree.
2. Select **Computers** on the Select Device Type page.
3. Select the computers that you want to configure. Computers that are already included in an existing probe schedule are not displayed.
4. Specify how data is collected for computers by including them in a monitoring group or template. Use monitoring groups and templates to determine when data is collected and what alert conditions are checked for the computers that you are configuring.
  - Select a monitoring group if you want to manage a collection of computers in the same manner. Each monitoring group that you can select is associated with existing probe and ping schedules and a set of alerts. When you select a group, its data collection schedules and alerts are automatically applied to all the computers that you are configuring. After you complete the wizard, the computers remain in the group and you can use that group in other parts of the user interface, such as in reports.

**Tip:** Tivoli Storage Productivity Center provides a number of default monitoring groups for computers. If you want to include a computer in a user-defined group rather than in a default group, that group must be associated with a data collection schedule. If the user-defined group is not associated with a data collection schedule, it is not displayed in the list of monitoring groups from which you can select.

- Select a template if you want to create a unique probe schedule, ping schedule, and set of alerts for a computer rather than using the settings of an existing group.

The option that you select in this step determines the field and pages that appear next in the wizard.

- If you select a monitoring group, the following actions occur:
  - The computers are automatically included in probe and ping schedules to which the group is associated. For example, if you select Computer Basic Group, the computers are included in the Computer Basic Probe and Computer Basic Ping schedules. The Computer Basic Probe schedule runs two times per week on Monday and Wednesday at 3:00 am. The Computer Basic Ping schedule runs every 3 hours.
  - A set of alert conditions is applied to the computers in a group. When any of these conditions are detected during data collection, an alert is triggered. The group that you select determines the alerts that are associated with the computers. For example, if you select Computer Basic Group, seven alert conditions are automatically checked for the computers.
  - The computers are included in the group. You can use that group in other parts of the user interface, such as in reports.
- If you select a monitoring template, the following actions occur:
  - The computers are automatically included in a probe and ping schedule that are created for the template. For example, if you select the Basic Computer Monitoring template, the computers are automatically included in a new probe that runs two times per week on Monday and Wednesday and a ping that runs every three hours. The probe and ping are created after the wizard is completed. Tivoli Storage Productivity Center determines the time when the probe is run based on server load to ensure optimal performance.

- A set of alert conditions is applied to the computers in a template. When any of these conditions are detected during data collection, an alert is triggered. The template that you select determines the alerts that are associated with the computers. For example, if you select to the Basic Computer Monitoring template, seven alert conditions are automatically checked for the computers.
- You must enter a prefix for the probe schedules, ping schedules, and alerts that are based on a template. This prefix is used to identify these definitions in the user interface. For example, if you select the Standard Computer Monitoring template and enter the prefix "ABC", the following definitions are created in the user interface after the wizard is completed:
  - A probe schedule named "*user ID*.ABCcompStandardProbe"
  - A ping schedule named "*user ID*.ABCcompStandardPing"
  - Seven alerts that follow this naming convention: *user ID*.ABCStatus Change Online (Standard)

Where *user ID* represents the ID of the user that is logged in to Tivoli Storage Productivity Center.

The new schedule definitions and alerts are displayed under the corresponding node in the navigation tree for you to view and edit. For example, a probe schedule that is created from a template in the wizard is displayed under the **Tivoli Storage Productivity Center > Monitoring > Probes** node; a ping schedule is displayed under the **Data Manager > Monitoring > Pings** node; new storage system alerts appear under the **Data Manager > Alerting** node.

See Alerts and schedules associated with monitoring groups and templates for a list of groups and templates with their associated schedules and alerts.

5. Review the selections that you made in the wizard. The Review user selections page includes the following information:
  - A list of devices that you are configuring.
  - The name of the monitoring group that you selected. This value is not displayed if you selected a template.
  - The name of the probe and ping schedules that are created based on the template you selected. This value is not displayed if you selected a monitoring group.
  - Information about the schedules that are created for a template.
  - The names of the alerts that are created based on the template you selected. This value is not displayed if you selected a monitoring group.

View the results of the device configuration and close the wizard. The devices that you configured are probed.

## Configure tape libraries

Use the Configure Devices wizard to add tape libraries for monitoring by IBM Tivoli Storage Productivity Center. Tape libraries that you configure in the wizard are automatically included in probe schedules.

You can configure one or more tape libraries in a single session of the wizard. All the tape libraries that you configure in a single session share a probe schedule.

To configure tape libraries, complete the following steps:

1. Access the wizard:

- If you want to add new or configure existing tape libraries, click the configure devices icon in the toolbar or select the **Configure Devices** node in the navigation tree. If you use this method, you must also complete the following steps:
    - a. Select **Tape Libraries** on the Select Device Type page.
    - b. Determine whether to add new tape libraries or configure existing tape libraries that are known to Tivoli Storage Productivity Center.
      - To add tape libraries, select **Add and configure new tape libraries** and go to step 3.
      - To configure existing tape libraries, select **Configure existing tape libraries**. The page displays the tape libraries that are known to Tivoli Storage Productivity Center. Go to step 2.
  - If you want to only add new tape libraries, go to **Tape Manager > Tape Libraries** and click **Add Tape Library**. Go to step 3.
2. Select the existing tape libraries that you want to configure. Tape libraries that are already included in probe schedules are not displayed. Go to step 6 after you select the tape libraries that you want to configure.
  3. Configure CIMOM connections for tape libraries. Tivoli Storage Productivity Center uses the information that you enter in this step to connect to a CIMOM. Click **Add** to configure multiple CIMOMs in a session of the wizard.  
The connection information that you enter for a CIMOM is like the information that you enter on the Add CIMOM panel.
  4. Discover the tape libraries that are managed by the CIMOMs you entered in the previous step. Tivoli Storage Productivity Center uses the information that you enter in this step to connect to a CIMOM. Click **Add** to configure multiple CIMOMs in a session of the wizard.
  5. Select the tape libraries that you want to configure for monitoring. Any tape libraries that were added in previous steps are automatically selected. Clear tape libraries that you do not want to configure.
  6. Specify how data is collected for tape libraries by including them in a monitoring group or template. Use monitoring groups and templates to determine when data is collected for the tape libraries that you are configuring.
    - Select a monitoring group if you want to manage a collection of tape libraries in the same manner. Each monitoring group that you can select is associated with an existing probe schedule. When you select a group, its data collection schedule is automatically applied to all the tape libraries that you are configuring. After you complete the wizard, the tape libraries remain in the group and you can use that group in other parts of the user interface, such as in reports.

**Tip:** Tivoli Storage Productivity Center provides a number of default monitoring groups for tape libraries. If you want to include a tape library in a user-defined group rather than in a default group, that group must be associated with a data collection schedule. If the user-defined group is not associated with a data collection schedule, it is not displayed in the list of monitoring groups from which you can select.

- Select a template if you want to create a unique probe schedule for a tape library rather than using the settings of an existing group.

The option that you select in this step determines the field and pages that appear next in the wizard.

- If you select a monitoring group, the following actions occur:

- The tape libraries are automatically included in a probe schedule to which the group is associated. For example, if you select Tape Basic Group, the tape libraries are included in the Tape Basic Probe schedule. The Tape Basic Probe schedule runs one time per week on Sunday at 4:00 am.
- The tape libraries are included in the group. You can use that group in other parts of the user interface, such as in reports.
- If you select a monitoring template, the following actions occur:
  - The tape libraries are automatically included in a probe schedule that is created for a template. For example, if you select the Basic Tape Monitoring template, the tape libraries are automatically included in a new probe that runs one time per week on Sunday. The probe is created after the wizard is completed. Tivoli Storage Productivity Center determines the time when the probe is run based on server load to ensure optimal performance.
  - You must enter a prefix for the probe schedule and alerts that are based on a template. This prefix is used to identify the probe and alerts in the user interface. For example, if you select the Basic Tape Monitoring template and enter the prefix "ABC", a probe schedule named "*user ID*.ABCtapeBasicProbe" is created, where *user ID* represents the ID of the user that is logged in to Tivoli Storage Productivity Center.

The new probe is displayed under the corresponding node in the navigation tree for you to view and edit. For example, a probe schedule created from a template in the wizard appears under the **Tivoli Storage Productivity Center > Monitoring > Probes** node.

See Alerts and schedules associated with monitoring groups and templates for a list of groups and templates with their associated schedules and alerts.

7. On the summary page of the wizard, review the selections that you made.

View the results of the device configuration and close the wizard. The devices that you configured are probed.

---

## Discovering storage resources

Run discovery schedules to collect information about the storage resources in your environment.

The process of finding storage resources within an enterprise, including detection of network topology, is called discovery. Use discovery schedules in Tivoli Storage Productivity Center to collect basic information about the storage resources in your environment, including computers, CIMOMs, storage systems, fabrics and switches, filers, clusters, and tape libraries. You must run discovery schedules before you can collect more detailed information about storage resources using other data collection schedules, such as probes, scans, and pings.

You are not required to run discovery schedules for storage resources that meet either of the following conditions:

- Storage resources that use native interfaces to connect to the Tivoli Storage Productivity Center.
- Storage resources that are configured using the Configure Devices wizard.

## Discovery overview

Use the discovery process to find new CIM agents, Out of Band Fabrics, Windows Domains, NAS filers, SAN File Systems, and other resources in your environment.

The discovery types in Tivoli Storage Productivity Center are summarized in the following table. Additionally the table summarizes the types of information that each discovery provides.

*Table 34. Discovery types, their data sources, and top-level entities that are discovered*

| Type of discovery                        | Data source                               | Top-level resources                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CIMOM                                    | CIM Agent                                 | <ul style="list-style-type: none"> <li>• Fabric (switches)</li> <li>• Storage systems</li> <li>• Tape subsystems</li> </ul>                                                                                                                                                                                                                                                                                              |
| Storage system                           | The native interface for a storage system | Tivoli Storage Productivity Center can communicate with certain storage systems without requiring a CIM agent.                                                                                                                                                                                                                                                                                                           |
| Out-of-band                              | SNMP agents on the switches               | Fabric (switches). A fabric discovery gets all the fabric information switches that were added as out-of-band agents. All information is collected by using the SNMP protocol to send queries across the IP network to the management information bases (MIBs) supported on the switch.                                                                                                                                  |
| Storage Resource agent                   | Storage Resource agent                    | <p>Fabric (switches). If you deployed Storage Resource agents on the computers that are attached to the fabric, you are not required to complete a specific discovery step for these Storage Resource agent. The fabric is automatically discovered.</p> <p><b>Note:</b> In Tivoli Storage Productivity Center v4.2 and later, you can deploy Storage Resource agents only. Inband fabric agents are no longer used.</p> |
| Windows domain, NAS, and SAN File System | Data agent or Storage Resource agent      | <ul style="list-style-type: none"> <li>• Computers</li> <li>• Filers</li> <li>• Clusters</li> <li>• Names or agents</li> </ul>                                                                                                                                                                                                                                                                                           |
| VMWare VI                                | VMWare VI data source                     | The data source can be a hypervisor (ESX Server or VirtualCenter).                                                                                                                                                                                                                                                                                                                                                       |

Generally, discovery provides information only about the existence of a resource. Use probes and scans to obtain detailed information about a specific resource after it was discovered.

For a Windows domain, Tivoli Storage Productivity Center runs a discovery only on the first Windows system on the domain; not all the systems on the domain.

## CIMOM discovery

This topic describes how the IBM Tivoli Storage Productivity Center manages and monitors disk, switch, and tape devices through Common Information Model Object Managers (CIMOMs).

**Note:** CIMOM can be referred to by a variety of names, such as CIM agents or SMIS agents. A CIM agent consists of a CIMOM and an SMIS provider for the managed device.

CIM agents on the same subnet as the Tivoli Storage Productivity Center Device server are automatically discovered with CIMOM discovery. If CIM agents are not in the same subnet, they can be discovered using a Service Location Protocol (SLP) Directory Agent (DA) or they can be added manually. If you do not want Tivoli Storage Productivity Center to discover CIM agents in the local subnet, clear the Scan local subnet box in the CIMOM discovery Options panel. To include SLP Directory Agents in the discovery, add the IP address of the DA in the CIMOM discovery Options panel and click **Add**. CIMOM discovery has several purposes. It can scan the local subnet to find CIM agents and contact CIM agents that have been added through the dialog. After it has found a CIM agent, it attempts to log in and discover the storage entities being managed by the CIM agent. If a CIM agent is discovered but requires login information, you need to enter it in the View and Edit CIMOM panel and then rerun the discovery to collect the information for the storage entities. The amount of time CIMOM discovery takes depends on the number of CIM agents, the number of storage entities, and whether you are scanning the local subnet.

CIMOM discovery can be run on a schedule. How often you run it depends on how dynamic your environment is. It must be run to detect a new subsystem. CIMOM discovery also performs basic health checks of the CIM agent and subsystem.

For Tivoli Storage Productivity Center to successfully communicate with the CIM agents, the CIMOM service must be accessible through the IP network. The TCP/IP network configuration on the host where Tivoli Storage Productivity Center is installed must include in its list of domain names, all the domains that contain storage devices that are discoverable by Tivoli Storage Productivity Center.

The CIM agents are installed outside of Tivoli Storage Productivity Center. Contact your device vendor for information about installing the CIM agent.

## SLP registration with slptool

This topic describes how IBM Tivoli Storage Productivity Center uses Service Location Protocol (SLP) discovery.

SLP discovery requires that all of the CIMOMs that Disk Manager discovers are registered using the SLP. However, for CIMOMs outside of the IP subnet, you need to use an SLP DA and register the CIMOM using **slptool**. In a non-multicast network environment, you must use the **slptool** as SLP can only discover CIMOMs that are registered in its IP subnet. When you use **slptool**, ensure that the **CIM\_InteropSchemaNamespace** and **Namespace** attributes are specified.

For example, enter the following command:

```
slptool register service:wbem:https://<myhost.com>:<port>
```

Where *myhost.com* is the name of the machine hosting the CIMOM, and *port* is the port number of the service, for example 5989.

**Note:** `slptool` is installed with a CIMOM. Run the command from the machine hosting the CIMOM.

### **SMI-S discovery**

This topic describes how the IBM Tivoli Storage Productivity Center can discover storage devices that comply with the Storage Management Initiative Specification (SMI-S).

SMI-S-compliant CIM Agents are discovered using the Service Location Protocol (SLP). The Tivoli Storage Productivity Center server software performs SLP discovery on the network. The SLP User Agent (UA) looks for all registered services with a service type of **service:wbem**.

The Tivoli Storage Productivity Center performs the following discovery tasks:

- Locates individual storage devices
- Retrieves vital characteristics for those storage devices
- Populates the internal Tivoli Storage Productivity Center databases with the discovered information

### **Device server and discovery on a SAN**

Storage Management Initiative (SMI) agents, out-of-band Simple Network Management Protocol (SNMP) agents, and Storage Resource agents can be used to discover and probe switches and fabrics. When multiple agents are available, Tivoli Storage Productivity Center creates a list of the agents. The first agent on the list is started first. If an agent fails, the next agent on the list is started.

Host and device information is gathered by Storage Resource agents. Topology information is gathered using SMI (Brocade switches only), out-of-band, or Storage Resource agents. The topology discovery operations of all agent types provide a similar level of information. However, zone information is available only through certain agent types for certain vendors. See Table 35 on page 330 for details.

For Brocade fabrics, the preferred type of agent is the SMI agent. The SMI agent provides most fabric functions and the other agent types can be added for redundancy. However, Storage Resource agents are required to gather host bus adapter (HBA) information.

For QLogic and Cisco fabrics, a combination of different agent types is required to enable all functions. If Storage Resource agents are not used, the devices and hosts are displayed as entities of unknown type. You can change the icon and labels of the unknown entities to something more appropriate for your enterprise.

If you want to use out-of-band fabric agents, you must configure the switches to send SNMP traps to the the Device server. A similar configuration is not required for CIM indications for SMI agents because they are automatically subscribed to after a CIMOM discovery. However, in some environments, manual configuration of certain settings might be required. SNMP traps and CIM indications determine when to start an automatic rediscovery operation

The following table shows the actions that trigger data collection and the data that is collected depending on the type of agent that is used.

Table 35. Information collected by agent

| Action that triggers data collection                                                                                                                                          | Storage Resource agent                                                                                                                                                                                                                                                                 | Out-of-band fabric agent (SNMP)                                                                                                                                                                            | SMI agent (Brocade)                                                                                                                                                                                                                                                                                                  | SMI agent (Cisco and QLogic)                                                                                                                                         |

| CIM indication received from fabric SMI agent                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                        |                                 | <p>Performs a mini-probe to collect information that is relevant to the indication received, or sets entities as missing. Might do one of the following actions:</p> <ul style="list-style-type: none"> <li>Retrieves switches and fabrics, or</li> <li>Retrieves zoning data, or</li> <li>Retrieves switch port status and connection to node, or</li> <li>Retrieves switch blade status and all port connections for the blade, or</li> <li>Sets fabric, switch, blades, connections, or nodes as missing</li> </ul> |                              |
| <p>1. The Storage Resource agent has two distinct functions:</p> <ul style="list-style-type: none"> <li><b>Discovery</b><br/>When a discovery job is run, Tivoli Storage Productivity Center gathers information about the fabrics, fabric to switch relationships, and other key attributes about the switches in the fabrics.</li> <li><b>Probe</b><br/>When a probe job is run, Tivoli Storage Productivity Center gathers additional details for topology and zoning information.</li> </ul> <p>If you deploy a Storage Resource agent and a fabric probe job is not run, the connections from the Storage Resource agents to the switches are not displayed, and all the Fibre Channel (FC) ports are reported as unused</p> |                        |                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                              |

## SMI agents

In general, it is most beneficial to use SMI agents as the primary agent type for Brocade fabrics. See Table 35 on page 330 for the fabric information that is gathered by SMI agents. The use of SMI agents enables support for fabrics composed of switches from Brocade.

The following SMI agent profiles and their respective subprofiles are supported:

Table 36. Supported SMI agent profiles and subprofiles

| Profile | Subprofile                                                                                                                                                              |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fabric  | <ul style="list-style-type: none"> <li>• Zone Control</li> <li>• Enhanced Zoning and Enhanced Zoning Control</li> </ul>                                                 |
| Switch  | <ul style="list-style-type: none"> <li>• Blades</li> <li>• Access Points</li> <li>• Multiple Computer System</li> <li>• Physical Package</li> <li>• Software</li> </ul> |

The level of support depends on the subprofiles registered with the SMI agent. For example, zone control support requires that the SMI agent has the Zone Control subprofile registered with it.

SMI agents also notify the Device server of changes on the fabric, such as changes to the topology or to the zoning. This notification is done through CIM indications. The CIM indications are subscribed to for a SMI agent through the CIMOM discovery job. Some extra configuration might be required set up CIM indications for environments with systems that have multiple IP addresses.

The CIM indications send specific details of a change on the fabric to the Device server. Rather than recollect the complete topology and zoning information for every CIM indication received, the Device server analyzes the CIM indication. In most cases, the Device server either sends a small set of post-indication discovery requests to the SMI agent to collect information pertinent to that event, or sets certain devices as missing without any post-indication requests made to the SMI agent. For CIM Indications that represent a zoning change, the complete zoning information is recollected from the SMI agent.

### Other agents

Although the SMI agents provide the most benefits, the use of multiple agent types also has advantages, such as redundant collection of information if one type of agent fails. Also, some types of agents provide certain features the other agents do not. However, the use of multiple agent types can increase network traffic and management load on the switches.

See Table 35 on page 330 for a list of the different types of jobs that collect data for the fabrics. You can use this table to determine which agent types to use for your fabric.

Out-of-band agents and Storage Resource agents provide the same information, such as a change that occurred in the SAN, by indicating that a discovery operation should be performed. The agents notify the Device server when something happened in the SAN and then a discovery is done to identify the changes.

The fabric agents that are running on the managed hosts detect Storage Resource agent events.

The the Device server out-of-band change agent detects the SNMP traps. For the Device server to receive the SNMP traps, configure the device, such as a switch, to send traps to the Device server.

The SNMP traps that are sent by the devices and by the Device server can be sent to the IBM Tivoli Storage Productivity Center graphical user interface (GUI). The events can be displayed in the event browser, or they can be sent to another trap console for monitoring. You then can provide error recovery or other advanced processing, such as paging.

### **Fabric discovery**

This topic describes how the Fabric Manager uses SNMP queries to discover information about selected fabric switches.

Management Information Base (MIB) information is collected from those switches. Out-of-band agents are configured for the Device server and contacted from the server through SNMP.

## **Discovering computers in the Windows domain, NAS, and SAN File System**

This topic describes how a NAS discovery finds SAN File System clusters.

When you run a discovery to find Windows computers on a domain, it discovers only new Windows computers. For IBM Tivoli Storage Productivity Center to recognize a non-Windows computer, you must install an agent on that computer.

For a Windows domain, Tivoli Storage Productivity Center only performs a discovery on the first Windows system on the domain; not all the systems on the domain.

A NAS discovery finds NAS Filers, and a SAN File System discovery finds the SAN File System clusters.

For information about configuring your system for NAS and SAN File System discovery, see the section about the Manual NAS/NetWare Server Entry node in the *IBM Tivoli Storage Productivity Center and IBM Tivoli Storage Productivity Center for Replication Installation and Configuration Guide*.

### **Discovering Windows computers that do not have agents**

Use discovery schedules to detect Windows computers that do not have Storage Resource agents deployed on them.

To discover Windows computers that do not have agents in your Windows domain, complete the following steps:

1. In the navigation tree, expand **Administrative Services > Discovery**.
2. Right-click **Windows Domain, NAS, and SAN FS** and click **Run Now**.
3. When you identify the computers, you can deploy Storage Resource agent on the computers to get detailed information about the computers and file systems. Computers that are discovered by Tivoli Storage Productivity Center, but do not have Storage Resource agents deployed on them, are displayed on the Data Manager > Reporting > System-wide > Unmanaged Computers report.

### **Discovering VMware VI data sources**

This topic describes how you can discover VMware VI data sources.

To display information about VMware VI data sources, complete the following steps:

1. In the Navigation Tree pane, expand **Administrative Services > Discovery > VMware VI Data Source**.
2. Right-click **VMware VI Data Source**. Click **Run Now**.

## Discovering computers

This topic describes how Tivoli Storage Productivity Center gathers information from the computers that are discovered.

You must install Storage Resource agents directly on the computer it manages so that you can gather information about that computer. To gather information from the agents, you create ping, probe, and scan jobs. A scan job discovers the largest amount of information but is the most time-consuming and intensive job.

When an agent shuts down and Tivoli Storage Productivity Center detects that the agent is no longer responding, the agent is put into the missing state (represented by a black circle  ) to indicate that it is not detectable. Tivoli Storage Productivity Center also does a heartbeat ping to the agents every 30 minutes. If this ping detects the host while the agent is not running, the host is put into the warning state (represented by a warning status icon  ) to indicate that the host is responding but the agent is not.

If Tivoli Storage Productivity Center can no longer communicate with an agent, the agent is marked as missing (a black circle  ). Information about the host continues to be displayed until the host is removed from the database. To remove the host from the database, you must uninstall the Storage Resource agent.

## Discover storage subsystem, tape library, and fabric information with CIM agents

This topic describes how you can discover storage subsystems, tape libraries, and fabrics in your environment using CIM agents.

CIM agents can be referred to by various names, such as CIMOM (CIM Object Manager) or SMIS agent. A CIM agent consists of a CIMOM and an SMI-S provider for the managed device. CIMOM discovery performs basic health checks of the CIMOMs. Even if you do not expect the number of CIMOMs to vary, be sure to schedule a CIMOM discovery often enough to be kept informed about your environment.

To automatically discover CIMOMs that are visible to the Device server with SLP, follow the instructions in “Discover CIM agents automatically” on page 255.

To add and discover CIMOMs manually, follow the instructions in “Adding a CIM agent connection” on page 253.

When your CIMOMs are manually added you must perform a CIMOM discovery to gather information about the CIMOMs so that IBM Tivoli Storage Productivity Center can communicate with them.

You are not required to run discovery jobs for storage resources that connect to Tivoli Storage Productivity Center using native interfaces:

- DS8000
- SAN Volume Controller

- Storwize V7000
- IBM Storwize V7000 Unified
- The XIV system
- IBM SONAS

To discover CIMOM information for any CIMOMs that you manually added, complete the following steps:

1. Expand **Administrative Services > Data Sources > CIMOM Agents**. CIMOMs are listed in the CIMOM Agents table along with their connection status. For each automatically discovered CIMOM you want to use, click the magnifying glass by the CIMOM name in the table. The View and Edit window for that CIMOM opens. Enter missing information, such as user name and password, for that CIMOM. Also make sure that you check the **Test CIMOM connectivity before updating** box. Click **File > Save** on the menu bar. This action saves your information and performs a connectivity check based on the information you entered. You must repeat this process for each SLP-discovered CIMOM you choose to use.
2. Expand **Administrative Services > Discovery > CIMOM**. The **Edit CIMOM** page opens in the content pane.
3. Optional: Click the **Options** tab. Enter the IP addresses or host names for the directory agents to be discovered.

**Note:** If you do not want to discover every CIMOM in the local subnet of your system, clear the Scan Local Subnet check box. If you clear this box the CIMOM discovery runs only on those CIMOMs already listed under **Administrative Services > Data Sources > CIMOM Agents**. If you chose not to clear this box CIMOM discovery searches for and discover all the CIMOMs in your subnet which might take a long time.

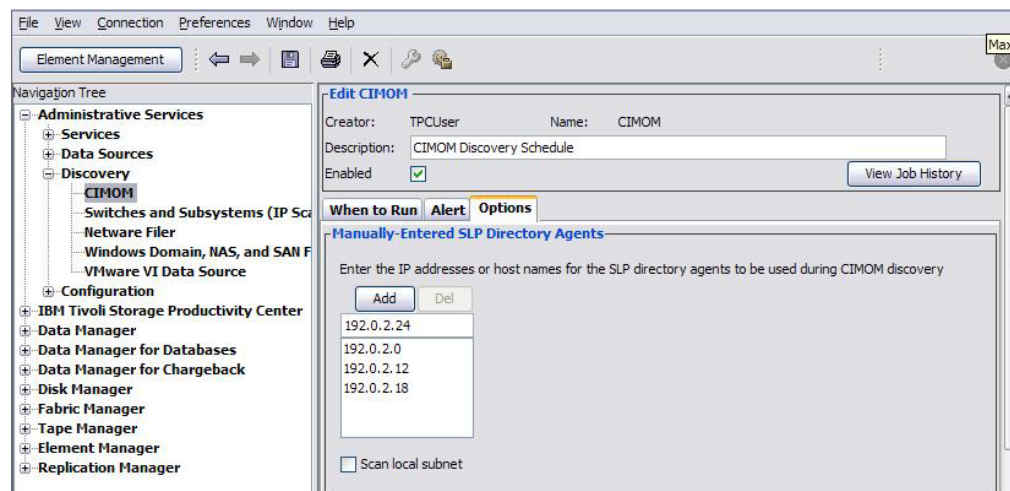

Figure 24. Editing the CIMOM discovery job (Options tab)

4. Click the **When to Run** tab and indicate how often and when to run this discovery job.
5. Click **File > Save** to save the job.

Figure 25. Editing the CIMOM discovery job (When to Run tab)

6. After you set the parameters for a CIMOM discovery, perform the discovery to gather information about all the CIMOMs you entered in the Options page. Expand **Administrative Services > Discovery**. Right-click on **CIMOM** and click **Run Now**.
7. Click the Job Management icon (📁) in the toolbar to view the status of the discovery.
8. When the discovery finishes, view the list of discovered storage subsystems or tape libraries by expanding either **Disk Manager** and click **Storage Subsystems**, or **Tape Manager** and click **Tape Libraries**.

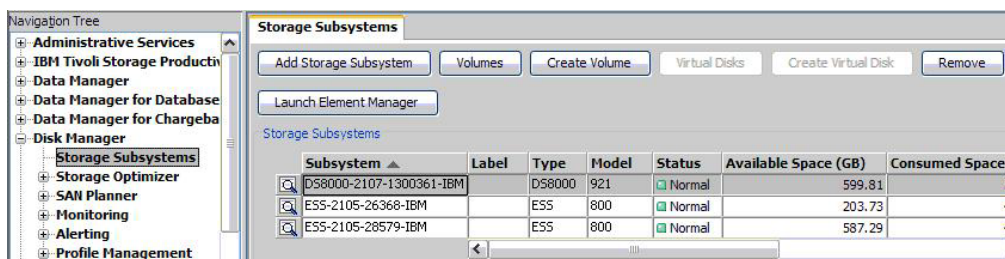

Figure 26. Checking storage subsystems

## Discovering fabrics with Storage Resource agents

When you deploy Storage Resource agents to computers, the agents automatically run discovery and provide information about the fabrics or switches to which the computers are attached. You do not need to run a specific discovery step for the fabrics connected to computers on which Storage Resource agent are deployed.

For example, if you have QLogic switches and have Storage Resource agents deployed on the computers that are attached to these switches, the switches are automatically discovered when you deploy the Storage Resource agents.

Discovering fabrics with the Storage Resource agent provides the following information:

- Fabric WWN, information about fabric-to-switch relationships, and key attributes
- Host and device information (collected from Storage Resource agents only), including HBA information
- Basic information to identify the host and devices in the fabric

After a discovery is run, you can run probes to collect topology and zoning information for the fabrics.

The vendors of fabric switches can help you determine whether to use CIM agents or Storage Resource agents to discover and monitor fabrics. For example, for Brocade switches, use CIM agents to collect all fabric data and enable performance monitoring and zone control. Use Storage Resource agents to collect information about HBAs. For Cisco and QLogic switches, you must have one or more Storage Resource agents on the fabric to collect full topology and zoning information, and to enable the zone control functions.

See the *Planning for Fabric Manager* section in the *Tivoli Storage Productivity Center Information Center* or *Installation and Configuration Guide* for more information about using CIM and Storage Resource agents to collect information about fabrics.

## Discovering storage subsystems and switches

Use the Switches and Subsystems (IP Scan) discovery schedule to find switches and storage systems in your environment. This discovery schedule searches for devices with a range of IP addresses that you specify.

Keep in mind the following considerations before running this discovery schedule:

- Switches and storage systems that require a CIM object manager (CIMOM) are not discovered using an IP scan. Use CIMOM discovery to discover these devices.
- Before a switch can be discovered, you must have an out-of-band fabric agent installed on the computer where the switch is installed or have the agent installed on a computer that has access to the switch.
- Before you can discover storage devices, ensure that port 7 (ECHO port) is open on the devices, and Internet Control Message Protocol (ICMP) is available. If you run Internet Protocol Version 6 (IPv6), it can take up to 30 seconds to discover the storage devices.
- If no CIM Agents for your Brocade switches are configured, you must discover out-of-band Fabric agents to get zone information for the Brocade switches.

To edit a discovery schedule for scanning a range of IP addresses, complete these steps:

1. In the navigation tree, expand **Administrative Services > Discovery**.
2. Click **Switches and Subsystems (IP Scan)**. The Edit Switches and Subsystems (IP Scan) panel is displayed.
3. Click **Options** to display the Options page.

4. Specify the IP address ranges that you want to scan in the **From** and **To** fields. You can enter an IPv4 or IPv6 address depending on what is supported within your environment:
  - Enter IPv4 addresses in the following format: ###.###.###.###. For example, if you enter **192.168.1.68** in the **From** field and **192.168.1.254** in the **To** field, Tivoli Storage Productivity Center scans IP addresses that fall in the range between 192.168.x.68 and 192.168.x.254.
  - Enter IPv6 addresses according to the standards in your environment. The preferred IPv6 address representation is written as eight groups of four hexadecimal digits: xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx, where each x is a hexadecimal digit representing 4 bits. For example: 2001:DB8:0000:1234:0000:0000:5678:ABCD. You can also specify IPv6 addresses using shortened formats that omit leading zeros 2001:DB8:0:1234:0:0:5678:ABCD or use double colons 2001:DB8:0000:1234::5678:ABCD in place of a series of zeros. For example, if you enter **2001:DB8::0** in the **From** field and **2001:DB8::FF** in the **To** field, Tivoli Storage Productivity Center scans the IP addresses that fall in the range between 2001:DB8:x:0 to 2001:DB8:x:FF. The address range that you specify determines how long an SNMP scan takes to run. For example, if the range includes over 256 addresses, the scan might take some time to complete. A warning message is displayed if you indicate a range that includes between 257 and 4096 (0xFFF) addresses. This warning message notifies you that the scan requires significant time to run as more addresses are included. Keep in mind that the scan range you enter cannot exceed 4096 (0xFFF) addresses.
 

**Note:** It takes about 5 minutes to search a subnet. For out of band fabric discovery to work, the FC Management MIB and FE MIB must be enabled on the switch.
5. On the **When to Run** page, determine when and how often to run the discovery.
6. On the **Alert** page, specify any alerts to trigger if the discovery schedule fails to run.
7. Click **File > Save** to save the discovery. The discovery runs according to the schedule that you defined on the **When to Run** page.

### Gathering switch performance data

This topic describes how to gather performance data from a switch to evaluate the switches that are in your environment.

To complete the discovery process for switch performance functions, a SMI agent must be enabled for your switch.

- For some switches, if you have the prerequisite firmware, you must enable the SMI agent (also referred to as an embedded SMI agent).
- For other switch vendors, you must install the SMI agent on any host computer and configure the agent to run providers for one or more switches. An SMI agent that is installed on a host is referred to as an external SMI agent.

Contact your switch vendor for information about how to enable the embedded SMI agent or to install the external CIM agent. For the SMI agents that are supported by IBM Tivoli Storage Productivity Center, see the support matrix at [http://www.ibm.com/support/docview.wss?rs=40&q1=switch&uid=swg21384219&loc=en\\_US&cs=utf-8&lang=en](http://www.ibm.com/support/docview.wss?rs=40&q1=switch&uid=swg21384219&loc=en_US&cs=utf-8&lang=en).

To gather switch performance data, complete the following steps:

1. Run a CIMOM discovery for a switch SMI agent.
2. Run a Fabric Probe for the Fabric that the switch is a part of.

For information about creating a switch performance monitor, see “Creating a switch performance monitor” on page 378.

---

## Collecting data

Create data collection jobs to gather information about the storage resources in your environment. There are different data collection jobs within IBM Tivoli Storage Productivity Center depending on the type of information is collected and from which types of resources the information is retrieved: discovery, probes, Tivoli Storage Productivity Center Server probes, scans, and pings.

### Collecting storage statistics

Use probes to collect statistics about the monitored storage resources in your environment, such as computers, storage systems, fabrics, volumes, disk controllers, hard disks, and file systems. Probe jobs can also discover information about new or removed disks and file systems. You can view the information collected by probes in Asset, Capacity, Storage Subsystems, and System reports.

You can define any number of probes to collect statistics for different storage resources at different times.

- From the **IBM Tivoli Storage Productivity Center** node, you can collect statistics on computers, disk controllers, hard disks, clusters, fabrics, storage subsystems, volumes, tape libraries, and file systems.

**Important:** Probes collect Common Internet File System (CIFS) and Network File System (NFS) exports (shares) of a network-attached storage (NAS) server that are on the computer. On Windows operating systems, the export must be mounted while running as the local system user or from a service that is running under the local system account so that it is visible to all logon sessions.

One way to map a drive as the local system user is to run the **net use** command from a psexec command window. The psexec command window is available as part of the Sysinternals command-line tools for Windows operating systems. The user that is used to make the connection, as specified by the **net use** user parameter, must belong to the Administrator group on the NAS server.

**Important:** For file system probes, the default behavior of the probe is to discard export paths that are not at the root of the file system. This behavior prevents a situation in which the product counts information twice on a file system. If you want to collect data for all file systems regardless of their location, add the **saveNonRoot=1** parameter to the [server] section of the TPCD.config file. Restart the Data server after you have saved the updated the file. The TPCD.config file is located in the *TPC\_installation\_directory/data/config* directory where *TPC\_installation\_directory* is where Tivoli Storage Productivity Center is installed.

- From the **Data Manager for Databases** node you can itemize and create an inventory of the files, instance, logs, and objects that make up your enterprise's monitored RDBMSs.

The login ID that Data Manager for Databases uses to log in to Microsoft SQL Server instances that you want to probe must have "Permit" access. For

information about how to set the logins for Microsoft SQL Server instances, see the *IBM Tivoli Storage Productivity Center and IBM Tivoli Storage Productivity Center for Replication Installation and Configuration Guide*.

To ensure the accuracy and consistency of the data that appears in the reports, run regularly scheduled probes against the hosts that use/import volumes and the storage systems upon which you want to report. You should run probes against storage systems after you run probes against any hosts.

## Creating probes

Create and schedule a probe to job to gather information about your storage resources. You can define any number of probes to gather information about different storage resources at different times.

To create a probe, complete the following steps:

1. Expand **IBM Tivoli Storage Productivity Center > Monitoring > Probes**. For Data Manager for Databases, expand **Data Manager for Databases > Monitoring > Probes**.
2. Right-click **Probes** A menu is displayed.
3. Select **Create Probe**.
4. In the **What to Probe** or **Instance** page, perform the following steps:
  - a. In the **Available** list box, highlight the resources you want to probe.
  - b. Click . The resources are moved to **Current Selections** list box. Use  to move resources to the **Available** list box.
5. In the **When to Run** page, schedule when you want the probe to run. You have the following options:
  - Run the job immediately
  - Run the job once at a specified time and date. Use the list boxes to specify the month, day, year, and the hour, minute, and AM or PM.
  - Run the job repeatedly according to a schedule you specify. You can perform the following tasks:
    - Specify the month, day, year, and the hour, minute, and AM or PM when the job is to run.
    - Indicate how often the job runs. You can use the list boxes to specify the number of minutes, hours, days, weeks, or months.
    - Indicate which days on which run the job. A check mark is displayed next to the days you select.

Use the fields in the **How to handle timezones** section to indicate the time zone that Data Manager for Databases uses when scheduling and running the action. For example, if you selected to run the job at 9:00 AM, you can use the fields in this section to run it at:

- 9:00 AM of the time zone where the server resides
- 9:00 AM of a specific time zone, such as 9:00 AM CST or 9:00 GMT. For example, if you select 9:00 AM CST, the job will run at 7:00 AM on a Storage Resource agent or Data agent located in the PST time zone.

### Use the timezone that the server runs in

Select this option to use the time zone of the location where the Data server resides.

### Use this timezone

Select this option to indicate a specific time zone for when to run the

job. When you select this option, a drop-down list is activated. Select the timezone from this drop-down list.

6. In the **Alert** page, set the following options:
  - The condition that triggers an alert. The default setting is **Probe Failed**. No other conditions are currently available.
  - The notification method of an alert: SNMP Trap, IBM Tivoli Enterprise Console Event, Login Notification, Windows Event Log, UNIX Syslog, running a script, and email. If you select SNMP Trap, Tivoli Enterprise Console Event, or email for the method by which you are notified of an alert, you must define a destination for the method on the **Administrative Services** → **Configuration** → **Alert Dispositions** window.
7. Click  to save the probe. You must save the probe before Tivoli Storage Productivity Center can collect data about storage resources.
8. Enter a name for the probe and click **OK**. An entry for the probe is displayed under the **Probes** node in the navigation tree. The probe is run at the date and time specified in the schedule definition.
9. Use the Job Management panel to manage view information about the runs and jobs that are related to the probe. For example, use the Job Management panel to view the status of a run for a schedule, the date and time when it was run, and the log files of the jobs associated with the run.

**Related reference:**

“Managing schedules, jobs, and runs” on page 300

Use the Job Management panel to view and manage all the schedules, runs, and jobs related to the storage devices that are monitored by IBM Tivoli Storage Productivity Center.

## Editing probes

Change the settings in an existing probe job.

To edit an existing probe, complete the following steps:

1. Expand **IBM Tivoli Storage Productivity Center** > **Monitoring** > **Probes**. For Data Manager for Databases, expand **Data Manager for Databases** > **Monitoring** > **Probes**.
2. Click the name of the probe you want to edit. The content pane displays information about that job.
3. Edit the probe definition.
4. Click  to save the updated probe definition.

## Creating fabric probes

Use probes to collect statistics about fabrics and fabric groups.

After you have defined your fabric groups, you can use Fabric Manager to run probes against fabrics and fabric groups to collect information.

To run probes against fabrics, complete the following steps:

1. Expand **IBM Tivoli Storage Productivity Center** → **Monitoring**, right-click **Probes**, and select **Create Probe**.
2. In the **What to Probe** tab enter a description for the probe, and from the **Available** column, select the fabrics and fabric groups to be probed. Move them to the **Current Selections** column by clicking .

3. In the **When to Run** tab specify when the probe is to begin. You can begin the probe immediately, schedule it to begin at a later time, and specify whether to run the probe repeatedly.
4. In the **Alert** tab specify the action to be taken if the probe fails. See “Running scripts with alerts” on page 495 for a description of these triggered actions.
5. Click  to save the probe. You must save the probe before Tivoli Storage Productivity Center can collect data about storage resources.
6. Enter a name for the probe and click **OK**. An entry for the probe is displayed under the **Probes** node in the navigation tree. The probe is run at the date and time specified in the schedule definition.
7. Use the Job Management panel to manage view information about the runs and jobs that are related to the probe. For example, use the Job Management panel to view the status of a run for a schedule, the date and time when it was run, and the log files of the jobs associated with the run.

**Related reference:**

“Managing schedules, jobs, and runs” on page 300

Use the Job Management panel to view and manage all the schedules, runs, and jobs related to the storage devices that are monitored by IBM Tivoli Storage Productivity Center.

## Creating tape library probes

Probes collect data from the tape libraries that have been discovered.

You can create tape library probes that collect information from all your tape libraries, or a subset. Probes can be scheduled to run immediately, or at a scheduled point in time. The data that probes collect is put into the database and is displayed in various places throughout the product, such as the topology viewer and the **Tape Manager > Tape Libraries** node.

To create a tape library probe:

1. Expand **IBM Tivoli Storage Productivity Center > Monitoring > Probes** and select **Create Probe**
2. Enter the information in the three tabbed pages:
  - **What to Probe** - select the tape libraries and tape library groups to include in this probe
  - **When to Probe** - specify the scheduling information for this probe
  - **Alert** - specify the triggering condition that will cause an alert to be generated for this probe, and the actions taken when an alert is generated
3. Click  to save the probe. You must save the probe before Tivoli Storage Productivity Center can collect data about storage resources.
4. Enter a name for the probe and click **OK**. An entry for the probe is displayed under the **Probes** node in the navigation tree. The probe is run at the date and time specified in the schedule definition.
5. Use the Job Management panel to manage view information about the runs and jobs that are related to the probe. For example, use the Job Management panel to view the status of a run for a schedule, the date and time when it was run, and the log files of the jobs associated with the run.

There are some special situations to note when creating and running probes of tape libraries:

- Do not include more than three tape libraries in the same probe if they are all registered with the same IBM SMI-S Agent for Tape. Doing so can increase the load on the SMI-S agent and can increase the possibility of timeouts. To avoid timeouts, create multiple probes with different start times, and split the libraries up among the probes.
- After the list of tape libraries that are registered with the IBM SMI-S Agent for Tape has been altered, a condition can occur in which not all of the tape cartridges are returned to the CIM client, in this case, Tivoli Storage Productivity Center. To resolve this situation, restart the IBM SMI-S Agent for Tape. For instructions, see the documentation for the SMI-S Agent.
- When the probe of a tape library successfully completes, some of the buttons in the Tape Libraries GUI panel might be disabled. To enable the buttons, close and then redisplay the panel.

**Related reference:**

“Managing schedules, jobs, and runs” on page 300

Use the Job Management panel to view and manage all the schedules, runs, and jobs related to the storage devices that are monitored by IBM Tivoli Storage Productivity Center.

**Locating a tape cartridge:**

View a list of all the cartridges for each discovered tape library.

Tape libraries can contain many cartridges (sometimes called tape volumes), and it can be difficult to find a particular tape cartridge among all the cartridges for a particular tape drive. IBM Tivoli Storage Productivity Center simplifies this task by listing all the cartridges for each discovered tape library. To find a particular tape cartridge:

1. Expand the **Tape Manager** node and click **Tape Libraries**.
2. Select a tape library from the list of discovered tape libraries.
3. Click **Cartridges**.
4. Click the **Label** column header to sort the list of cartridges by label.
5. Scroll through the list of cartridges to find the one you are looking for.
6. The **Location** column will indicate exactly where the tape is located in the library.

**Note:** You can also sort by other columns by clicking on the column headers. For example, if you know that the cartridge you are looking for is dual sided, you can sort the list by that criterion. This can make finding a particular cartridge much easier, especially for libraries that have many cartridges.

**Creating a VMware VI probe**

Probes collect data from the VMware VI data sources that have been discovered.

To create a VMware probe, complete the following steps:

1. In the Navigation Tree pane, expand **IBM Tivoli Storage Productivity Center > Monitoring > Probes**.
2. Right-click on **Probes** and click **Create Probes**.
3. Enter the information in the three tabbed pages:

**What to Probe**

Enter a description for the probe and from the **Available** column, select

**Hypervisors** to include in the group to be probed. Click >> to move the group to the **Current Selections** column.

**When to Run**

Specify when the probe is to begin. You can begin the probe immediately, schedule it to begin at a later time, and specify if it should be run repeatedly.

**Alert** Specify the triggering condition that will cause an alert to be generated for this probe, and the actions that should be taken when an alert is generated.

4. To save the probe, click **Save**.
5. In the **Save As** window, enter the probe name and click **OK**.

## Collecting storage statistics from Tivoli Storage Productivity Center servers

Schedule probes from the master server for Tivoli Storage Productivity Center to collect storage information that has been gathered by subordinate servers. The information gathered by probes of subordinate servers is displayed in the **Tivoli Storage Productivity Center > Rollup Reports** node in the navigation tree of the master server. You can define server probes by selecting **TPC Server Probe** in the navigation tree.

A subordinate server is a server that monitors and reports on storage resources like a standard server, but also communicates with the master server during TPC server probes. During these probes, the master server collects the storage information gathered by a subordinate server's agents and stores that information in its own database repository.

**Note:** If the same storage entity is managed by multiple subordinate servers, rollup reports reflect the storage information from the subordinate server that most recently probed that entity.

Before you run TPC server probes:

1. Associate subordinate servers with the master server on the **Administrative Services > Data Sources > TPC Servers** window. See “Adding an Tivoli Storage Productivity Center Server” on page 285 for information on how to associate subordinate servers with a master server.
2. Run discoveries, probes, and scans on the subordinate servers to gather information about their locally-managed entities.

The information collected by TPC server probes from subordinate servers includes:

- Asset information: detailed statistics about agents (Tivoli Storage Productivity Center), computers, storage subsystems, disk and volume groups, disks, filesystems, logical volumes, volumes, and fabrics.
- Database asset information: detailed statistics about the RDBMSs in your environment, including Oracle, SQL Server, Sybase, and UDB.
- Capacity information: storage metrics related to the disk capacity, filesystem capacity, filesystem used space, and filesystem freespace of the storage entities in your environment.
- Database capacity information: storage metrics related to the storage capacity of the RDBMSs in your environment, including Oracle, SQL Server, Sybase, and UDB.

Additional storage information collected by a subordinate server and used within such Tivoli Storage Productivity Center functions as the topology viewer, data path explorer, volume provisioning, volume performance, and SAN Planner is available for only that subordinate server. That information is not collected by the master server, and thus not rolled up into the reports available through the master server.

Also, the Tivoli Storage Productivity Center functions within the master server use the storage information collected by only the master server.

## Creating Tivoli Storage Productivity Center server probes

Use Tivoli Storage Productivity Center server probes from the master server to collect storage information that has been gathered by subordinate servers.

To create a Tivoli Storage Productivity Center server probe, complete the following steps:

1. Expand **IBM Tivoli Storage Productivity Center > Monitoring > TPC Server Probes**.
2. Right-click **TPC Server Probes** and select **Create TPC Server Probes** from the menu.
3. Enter a brief description of the probe in the **Description** field.
4. In the **What to Probe** page, perform the following steps:
  - a. In the **Available** list box, highlight the Tivoli Storage Productivity Center servers you want to probe. You can do any of the following: 1. Select the **All TPC Servers** item to automatically include all subordinate servers in the probe. 2. Select the name of a specific subordinate server and all its related storage entities that you want to probe. 3. Select the specific entities on a subordinate server that you want to probe. For example, you can expand the node for a subordinate server and select the specific entities for which you want to collect data: All Resources, Clusters, Computer Groups, Computers (including Hypervisors), Database Instances, Fabrics, RDBMS Computer Groups, Storage Subsystem Groups, and Storage Subsystems.
  - b. Click  to include highlighted Tivoli Storage Productivity Center servers or storage entities in the probe. The entities that you selected are moved to **Current Selections** list box.
5. In the **When to Run** page, schedule when you want the probe to run. You have the following options:
  - Run the job immediately
  - Run the job once at a specified time and date. Use the list boxes to specify the month, day year, and the hour, minute, and AM/PM.
  - Run the job repeatedly according to a schedule you specify. You can perform the following tasks:
    - Specify the month, day, year, and the hour, minute, and AM or PM when the job is to run.
    - Indicate how often the job runs. Use the list boxes to specify the number of minutes, hours, days, weeks, or months.
    - Indicate which days on which run the job. A check mark is displayed next to the days you select.

Use the fields in the **How to handle timezones** section to indicate the time zone that Data Manager for Databases uses when scheduling and running the action. For example, if you selected to run the job at 9:00 AM, you can use the fields in this section to run it at:

- 9:00 AM of the time zone where the server resides

- 9:00 AM of a specific time zone, such as 9:00 AM CST or 9:00 GMT. For example, if you select 9:00 AM CST, the job will run at 7:00 AM on a Storage Resource agent or Data agent located in the PST time zone.

#### Use the timezone that the server runs in

Select this option to use the time zone of the location where the Data server resides.

#### Use this timezone

Select this option to indicate a specific time zone for when to run the job. When you select this option, a drop-down list is activated. Select the timezone from this drop-down list.

6. In the **Alert** page, set the following options:
  - The condition that triggers an alert. The default setting is **Probe Failed**. No other conditions are currently available.
  - The notification method of an alert: SNMP Trap, IBM Tivoli Enterprise Console Event, Login Notification, Windows Event Log, UNIX Syslog, running a script, and email. If you select SNMP Trap, Tivoli Enterprise Console Event, or email for the method by which you are notified of an alert, you must define a destination for the method on the **Administrative Services** → **Configuration** → **Alert Dispositions** window.
7. Click  to save the probe. You must save the probe before Tivoli Storage Productivity Center can collect data about storage resources.
8. Enter a name for the probe and click **OK**. An entry for the probe is displayed under the **TPC Server Probes** node in the navigation tree. The probe is run at the date and time specified in the schedule definition.
9. Use the Job Management panel to manage view information about the runs and jobs that are related to the probe. For example, use the Job Management panel to view the status of a run for a schedule, the date and time when it was run, and the log files of the jobs associated with the run.

#### Related reference:

“Managing schedules, jobs, and runs” on page 300

Use the Job Management panel to view and manage all the schedules, runs, and jobs related to the storage devices that are monitored by IBM Tivoli Storage Productivity Center.

## Editing TPC Server probes

Learn how to edit the definition of a TPC server probe.

To edit an existing TPC server probe, complete the following steps:

1. Expand **IBM Tivoli Storage Productivity Center** > **Monitoring** > **TPC Server Probes**.
2. Click the name of the TPC server probe you want to edit. The content pane displays information about that probe.
3. Edit the values on the What to PROBE, When to Run, and Alert pages to change the TPC server probe definition.
4. Click  to save the updated TPC server probe definition.

## Managing the runs and jobs for TPC Server Probes

View information about the runs, jobs, and log files for TPC Server Probes.

Tivoli Storage Productivity Center creates a run each time a TPC Server Probe schedule collects data from subordinate servers. A job is a unit of work within a run for a schedule. Use the Job Management panel to manage TPC Server Probe schedules and view information about the related runs and jobs. Specifically, use this panel to perform the following tasks for schedules:

- View or edit the definition of a schedule.
- Run a schedule immediately.
- Rename or delete a schedule.
- View basic information about a schedule, including the ID of the user who created it, description, the last time the schedule was run, and the next time the schedule is run.

Use the Job Management panel to perform the following tasks for the runs and jobs related to TPC Server Probe schedules:

- View the status of a run and the date and time when it was executed.
- View information about the jobs associated with each run, including the name of the computer on which a job was run, the type of the monitored device, and the status of the job.
- View the log files for one or more jobs at a time.
- Display jobs that have started or completed within a specified length of time. For example, display jobs that have completed in the last two weeks.
- Display jobs that have a certain status, such as Success, Running, or Failed.

To access the Job Management panel for a TPC Server Probe schedule, complete the following steps:

1. In the navigation tree, expand **IBM Tivoli Storage Productivity Center > Monitoring > TPC Server Probes**.
2. Select the probe schedule whose runs and jobs you want to manage. The content pane displays information about the schedule.
3. In the content pane, click **View Job History**. The Job Management panel is displayed and the selected schedule is highlighted in the **Schedules** section. View the entries in the **Jobs for Selected Schedules** section to manage the jobs and runs for the schedule.

You can also access the Job Management panel at any time by clicking the related icon () in the toolbar. Use the **Filters** section on the Job Management panel to display the TPC Server Probe schedule that you want to manage. See “Managing schedules, jobs, and runs” on page 300 for more information.

## Collecting storage usage and trending information

Use scans to collect statistics about the usage and trending of storage consumption of storage resources in your environment. You can view the information collected by scans in reports and use it as part of a quota analysis.

Use a Storage Resource agent to collect information for a scan. The Storage Resource agent must be deployed on the storage resources that you want to monitor. By running scans and generating the results of those scans in reports, you can complete the following tasks:

- View when files were created, accessed, and modified and by what group or user
- Map storage resources to the consumers of those resources

- Generate historical views of storage consumption and utilization that show usage trends over time. System administrators can use these views to project and plan for future storage consumption.
- Collect detailed RDBMS space usage reports at the table, index, and user levels
- Gather individual user space usage at the table space, database, instance, computer, and network wide levels
- Collect detailed space usage information about monitored tables and their associated indexes. For example, when you scan UDB tables, this information includes many of the calculated REORGCHK values. These include Used Page %, Used Space %, and Cluster Ratio.
- Historically track database, table space, and user usage and use that data to forecast and display future usage
- Gather information for quotas that can be created to trigger alerts (and create reports) when users exceed a specified amount of space usage
- (UDB only) Perform (optionally) runstats on all tables involved in the scan process
- Assign costs to space used at the user level when combined with Data Manager for Chargeback

**Note:**

1. A licensed agent must be installed on a computer that contains instances against which you want to run a scan. You must run a probe against an instance before you can select any table spaces against which you want to run a scan.
2. The login ID that Data Manager uses to log in to Microsoft SQL Server instances that you want to scan must have "Permit" access.

**Creating scans**

Create and schedule a scan to gather usage information about your storage resources. You can specify which file systems, computers, clusters, directories, databases, and other storage resources that you want to scan. You can define any number of scans to gather information about different storage resources at different times.

To create a scan, complete the following steps:

1. Expand **Data Manager > Monitoring > Scans**. For Data Manager for Databases, expand **Data Manager for Databases > Monitoring > Scans**.
2. Right-click the **Scans** node and select **Create Scan**.
3. For Data Manager, define the following scan properties:
  - The computers and file systems whose storage usage and consumption you want to monitor. For more information, see “Including storage resources in a scan” on page 349.
  - The directory groups to scan. For more information, see “Selecting directory groups to scan” on page 350.
  - The profiles to use during a scan. For more information, see “Using profiles in a scan” on page 352.
  - The schedule when you want a scan to run. For more information, see “When to run the scan” on page 353.
  - An alert to notify you if the scan fails. For more information, see “Defining alert values for a scan” on page 354.
4. For Data Manager for Databases, define the following scan properties:

- The databases, table spaces, instances, and computers whose storage usage and consumption you want to scan. For more information, see “Selecting databases, tablespaces to scan” on page 351.
  - The table groups you want to scan. For more information, see “Select the table groups to scan” on page 351.
  - The profiles to use during a scan. For more information, see “Using profiles in a scan” on page 352.
  - The schedule when you want a scan to run. For more information, see “When to run the scan” on page 353.
  - The options for Oracle and UDB. For more information, see “Specify options for Oracle and UDB” on page 353.
  - An alert to notify you if the scan fails. For more information, see “Defining alert values for a scan” on page 354.
5. Click  to save the scan. You must save the scan before Tivoli Storage Productivity Center can collect data about storage resources.
  6. Enter a name for the scan and click **OK**. An entry for the scan is displayed under the **Scans** node in the navigation tree. The scan is run at the date and time specified in the schedule definition.
  7. Use the Job Management panel to manage view information about the runs and jobs that are related to the scan. For example, use the Job Management panel to view the status of a run for a schedule, the date and time when it was run, and the log files of the jobs associated with the run.

**Related reference:**

“Managing schedules, jobs, and runs” on page 300

Use the Job Management panel to view and manage all the schedules, runs, and jobs related to the storage devices that are monitored by IBM Tivoli Storage Productivity Center.

**Including storage resources in a scan:**

In a scan, include the computers, computer groups, file systems, file system groups, and clusters whose storage usage and consumption that you want to monitor.

Use the **Filesystems** page to select the storage resources that you want to scan. Include clusters, individual file systems and computers, or file system and computer groups (that have been predefined using the “Working with groups of resources” on page 374 facility).

The **Current Selections** list box shows the storage resources that have been selected for the scan. The **Available** list box shows which storage resources are still available for selection in the scan.

**Note:** A cluster name is displayed next to individual computers that are members of a PowerHA or Microsoft Cluster Server cluster. Cluster resource groups are identified with a special icon. Clusters displayed in the **Available** list box cannot be expanded to show member nodes. You can move a cluster to the **Current Selections** list box to view and, if necessary, exclude member nodes.

**To include storage resources in a scan:**

1. Highlight the file systems, file system groups, computer groups, computers, and clusters you want to include in the scan in the **Available** list box.

**Note:** Before you can include file systems in a scan, you must probe the computers that contain those file systems. If you do not probe a computer before you define a scan, the file systems on that computer are unavailable for the scan.

2. Click . The storage resources that you selected are displayed in the **Current Selections** list box.

**To remove storage resources from a scan:**

- Highlight the file systems, file system groups, computer groups, computers, and clusters that you want to remove and click . This action removes the storage resources from the **Current Selections** list box and moves them to the **Available** list box.

**To exclude one or more file systems or computers from a selected cluster or group:**

Perform the following steps if you want to exclude specific file systems or computers from a cluster or group that you included in a scan:

1. Double click the cluster or group name in the **Current Selections** list box.
2. Right click on the file systems or computers that you want to exclude. A pop-up menu is displayed.
3. Select **Exclude**. This action creates an **Excludes** section in the **Current Selections** list box that displays the names of the file systems or computers that you have excluded from a scan. This action is useful when you want to select a group or cluster for scanning, but you want to exclude a few file systems or computers from that monitoring.

**Selecting directory groups to scan:**

This topic describes how to select the directory groups that you want to scan.

Use the Directory Groups tab to select the groups of directories that you want to scan. Including directory groups within a scan enables you to monitor and gather information about specific directories across a number of machines.

The **Selected Directory Groups** list box shows what directory groups have been included in the scan. The **Available Directory Groups** list box shows the groups that are still available for selection. You can select directory groups that have been predefined using the groups facility.

**To select a directory group:**

1. Highlight the desired directory group in the **Available Directory Groups** list box.
2. Click . The group you selected appears in the **Selected Directory Groups** list box.

**To remove a directory group from a scan:**

- Highlight the groups you want to remove and click . This will remove the groups from the **Selected Directory Groups** list box and move them to the **Available Directory Groups** list box.

### To create a new directory group:

- Click **New Directory Group**. The **New Directory Group** window opens, enabling you to create a new group. See “Creating directory groups” on page 375 for more information on how to create a directory group.

### Selecting databases, tablespaces to scan:

This topic describes how to select the databases and tablespaces that you want to scan.

Use the Database-Tablespaces page to select what databases, tablespaces, instances, and computers whose storage usage and consumption you want to monitor. You can include single or groups of databases, tablespaces, and computers against which to run the scan.

The **Current Selections** list box shows the databases, tablespaces, tablespace groups, computers, and computer groups that have been selected for the job. The **Available** list box shows what items are still available for selection.

### To include a database, tablespace, computer, instance, or group in a scan:

1. Highlight the desired databases, tablespaces, computers, instances, or groups in the **Available** list box.
2. Click . The databases, tablespaces, computers, instances, or groups you selected appear in the **Current Selections** list box.

For example, if you select a computer to include in a scan, that job will scan all the databases and/or tablespaces on all the instances that reside on that computer.

### To remove a database, tablespace, computer, instance, or group from a scan:

- Highlight the items you want to remove and click . This will remove the databases, tablespaces, computers, instances, or groups from the **Current Selections** list box and move them to the **Available** list box.

### Select the table groups to scan:

Select the table groups that you want to scan.

Use this page to select the table groups you want to scan. A table group represents a group of defined tables. By choosing a table group on this window, you can perform more detailed scans of tables that might not appear within other Data Manager for Databases reports (such as the Largest Table or Monitored Tables reports).

**Note:** Before you can view detailed information about tables in an RDBMS, you must have 1) defined a table group that contains the tables about which you want to view storage information and 2) scheduled and run a scan against that table group.

The **Selected Table Groups** list box shows the table groups that have been selected for the job. The **Available Table Groups** list box shows the table groups that are still available for selection.

### To include a table group in a scan:

1. Highlight the desired group in the **Available Table Groups** list box.
2. Click . The group you selected appears in the **Selected Table Groups** list box.

**To remove a table group from a scan:**

- Highlight the groups you want to remove and click . This will remove the groups from the **Selected Table Groups** list box and move them to the **Available Table Groups** list box.

**To create a new table group:**

- Click **New Table Group**. The **New Table Group** window opens, enabling you to create a new group.

**Using profiles in a scan:**

Select the profile to use as part of a scan. Profiles enable you to control what files are scanned and what statistics are gathered.

Use the **Profiles** page to select which profiles to use during a scan. Using profiles is a powerful method for determining the statistics you want to gather during scans. Keep in mind that the more profiles you include within a scan, the longer the scan will take to gather the statistics specified by those profiles.

**To include profiles in a scan:**

1. Highlight the desired profiles in the **Available Profiles** list box.
2. Click the  for the **Profiles to apply to Filesystems** list box to apply the selected profiles to file systems; click the  for the **Profiles to apply to Directories** list box to apply the selected profile(s) to directories. The profiles you selected appear in the either the **Profiles to apply to Filesystems** or **Profiles to apply to Directories** list box

**Note:** To collect statistics according to Data Manager default settings, select all of the default profiles.

**To remove profiles from a scan:**

- Highlight the profiles you want to remove and click the corresponding . This will move the selected profiles to the **Available Profiles** list box.

**To create a new profile:**

- Click **New Profile**. The **Statistics** tab on the **Create Profile** window is displayed, enabling you to create a new profile. See “Using profiles” on page 355 for more information.

**Related concepts:**

“Using profiles” on page 355

Use profiles to specify what statistical information is gathered and to fine tune and control what files are scanned during a scan. You can also use profiles with some reports to determine what statistics are displayed.

**When to run the scan:**

Schedule when and how often to run a scan.

You have the following options for determining when to run a scan:

- Run the job immediately
- Run the job once at a specified time and date. Use the list boxes to specify the month, day, year, and the hour, minute, and AM or PM.
- Run the job repeatedly according to a schedule you specify. You can:
  - use the list boxes to specify the month, day, year, and the hour, minute, and AM or PM when the job should begin running.
  - indicate how often the job should run. You can use the list boxes to specify the number of minute(s), hour(s), day(s), week(s), or month(s).
  - select which days you wish to run the job.

Use the fields in the **How to handle timezones** section to indicate the time zone that Data Manager should use when scheduling and running the scan. For example, if you selected to run the job at 9:00 AM, you can use the fields in this section to run it at:

- 9:00 AM of the time zone where the server resides
- 9:00 AM of a specific time zone, such as 9:00 AM CST or 9:00 GMT. For example, if you select 9:00 AM CST, the job will run at 7:00 AM on an agent located in the PST time zone.

**Use the timezone that the server runs in.** Select this option to use the time zone of the location where the Data server resides.

**Use this timezone.** Select this option to indicate a specific time zone for when to run the job. When you select this option, a list box is activated. Select a timezone from the list box.

**Specify options for Oracle and UDB:**

Specify options for Oracle and UDB when defining a scan.

Use the Options page to do the following:

- Determine if the job should scan the freelist chains associated with the segments in your Oracle environment. Free list chains represent the pages allocated to a segment that have enough free space for additional rows. Note that checking this option will increase the time required by the scan to complete.
- Set the number of pages Data Manager for Databases should scan on a chain before stopping.
- Determine if the job should gather segment extent data for locally-managed tablespaces.
- Run the DB2 utility runstats against the tables being scanned. Checking this box will enable Data Manager for Databases to collect the most up-to-date storage statistics about tables from the DB2 catalog. Note that checking this option will

increase the time required by the scan to complete, but will ensure that table and user statistics are up-to-date in UDB/DB2 databases. Alerts based on table and user stats will not function until runstats is run.

### Defining alert values for a scan:

This topic describes how to set an alert that will be triggered if the scan job fails.

Use the Alert page to can define an alert to notify you if a scan fails and how to notify you. You can choose to be notified by SNMP trap, IBM Tivoli Enterprise Console event, login notification, Windows event log, UNIX Syslog, running a script, and e-mail. If you select SNMP trap, Tivoli Enterprise Console event, or e-mail, you must also define a destination (for example, an e-mail address). Define this destination by expanding **Administrative Services > Configuration > Alert Dispositions**.

To define an alert for a scan, complete the following steps:

1. Click the **Alert** tab; the Alert page opens.
2. In the **Triggering Condition** area, select Scan Failed. This indicates that an alert will be triggered if the scan fails to run.
3. In the **Triggered Actions** area, select the actions that occur as a result of the triggering condition You can choose from the following actions:

#### **SNMP trap**

An SNMP trap is sent to any NMS, console, or terminal when the condition occurs.

#### **TEC / OMNibus Event**

A IBM Tivoli Enterprise Console event is sent when the condition occurs. The Tivoli Enterprise Console administrator can write correlation and automation rules to analyze Tivoli Storage Productivity Center events according to the event definitions specified in the tivoliSRM.baroc file (provided with the product). It also performs responses such as sending further notification, creating or updating trouble tickets, running programs, and so on.

#### **Login notification**

The alert is sent to a Tivoli Storage Productivity Center user. The user receives the alert upon logging in to Tivoli Storage Productivity Center. In the **Login ID** field, type the user ID.

#### **Login ID**

The ID of the user who receives alert notification upon logging in to the system.

#### **Windows Event Log, UNIX Syslog**

The ID of the user who receives alert notification upon logging in to the system.

#### **Event Type (Windows Event Log only)**

The type of event that is recorded to the OS log.

#### **Facility (UNIX Syslog only)**

The location where the UNIX Syslog is sent. You can select User or Local.

#### **Level (UNIX Syslog only)**

The level of UNIX Syslog event. You can select Informational, Notice, Warning, Error, Critical, or Alert.

### Run script

A script is run when the condition occurs. Click **Define** to specify the script that is run when the triggering condition occurs. The parameters listed in the **Specify Script** window are passed to the script when the alert is triggered

**Email** An email is sent. Click **Add** or **Delete** to edit the list of email addresses to which an email is sent. Click **Edit email** to change the actual email message.

4. Click **File** > **Save** to save the scan.
5. Enter a name for the scan and click **OK**. An entry for the scan appears under the **Scans** node.

### Editing scans

Change the settings in an existing scan job.

To edit an existing scan, complete the following steps:

1. Expand **Data Manager** > **Monitoring** > **Scans**. For Data Manager for Databases, expand **Data Manager for Databases** > **Monitoring** > **Scans**.
2. Click the name of the scan you want to edit. The content pane displays information about that job.
3. Edit the scan definition by changing the values that appear on the following pages:
  - Filesystems. Use this page to edit the computers and file systems whose storage usage and consumption you want to monitor as part of a scan.
  - Directory Groups. Use this page to edit the groups of directories that you want to scan.
  - Databases-Tablespaces. Use this page to edit the databases, tablespaces, instances, and computers whose storage usage and consumption you want to monitor as part of a scan.
  - Table Groups. Use this page to edit the table groups that you want to scan. A table group represents a group of defined tables.
  - Profiles. Use this page to edit which profiles are used during a scan. Using profiles is a powerful method for determining the statistics you want to gather during scans.
  - When to Run. Use this page to edit when a scan is run.
  - Options (Oracle and UDB only). Use this page to edit the scan options for Oracle or UDB.
  - Alert. Use this page to edit how you are notified if a scan fails.
4. Click  to save the updated scan definition.

### Using profiles

Use profiles to specify what statistical information is gathered and to fine tune and control what files are scanned during a scan. You can also use profiles with some reports to determine what statistics are displayed.

Until you begin creating your own profiles, you can use the default profiles that are supplied with IBM Tivoli Storage Productivity Center. Each of these default profiles allows you to select a specific statistic that you want to gather. If you want to scan a computer or filesystem, and want to gather all of the statistical information available, simply select all of the default profiles when you create your scan job.

See “Default profiles” for more information about default profiles.

### **Default profiles:**

Default Profiles are provided for your use with IBM Tivoli Storage Productivity Center. Each default profile represents a specific statistic that you can gather (which is included in the name of the profile for convenient identification).

If you want to scan a computer or filesystem and gather all of the statistical information available, select all of the default profiles when you create your scan. TPCUser is shown as the creator of the default profiles, and TPCUser is the prefix name for each of the profiles. The following list identifies the default Data Manager profiles and describes their functions.

#### **By Access**

Gathers statistics by length of time since last access of files.

#### **By Creation**

Gather storage statistics by the length of time since the creation of files. This profile applies to scans run against Windows computers only. Scans with this profile do not gather any creation time data from non-Windows computers.

#### **By Mod Not Backed Up**

Gathers statistics by length of time since last modification, only for files not backed up since modification. (Windows operating systems only)

#### **By Modification**

Gathers statistics by length of time since last modification of files.

#### **Size Distribution**

Gathers information on the size distribution of files.

#### **Largest Directories**

Gathers statistics on the *n* largest directories. (20 is the default amount.)

#### **Largest Files**

Gathers statistics on the *n* largest files. (20 is the default amount.)

#### **Largest Orphans**

Gathers statistics on the *n* largest orphan files. (20 is the default amount.)

#### **Most At Risk**

Windows operating systems only: Gathers statistics on the *n* files that have been modified the longest time ago and have not yet been backed up since they were modified. (20 is the default amount.)

#### **Oldest Orphans**

Gathers statistics on the *n* oldest orphan files. (20 is the default amount.)

#### **Most Obsolete Files**

Gathers statistics on the *n* most obsolete files (i.e., files that have not been accessed or modified for the longest period of time). (20 is the default amount.)

#### **Summary By File Type**

Summarizes space usage by file types (for example, .exe., .dll, .doc, .mp3, etc.).

#### **Summary By Filesystem/Directory**

Summarizes space usage by file system or directory.

**Summary By Group**

Summarizes space usage by OS Group.

**Summary By Owner**

Summarizes space usage by Owner.

**Temporary Files**

Gathers statistics on the non-OS files not accessed in the last year and orphan files.

**Wasted Space**

Gathers statistics on the non-OS files not accessed in the last year and orphaned files.

The following list identifies the default Data Manager for Databases profiles and describes their functions.

**DB User Space**

Gathers statistics about the user space usage within a database or tablespace.

**Largest Tables**

Gathers statistics on the  $n$  largest tables. (20 is the default amount)

**Segment Most Extents**

Gathers statistics on the  $n$  segments with the most extents. (20 is the default amount)

**Segment Most Unused Space**

Gathers statistics on the  $n$  segments with the most empty used space. (20 is the default amount). Empty used space represents the space allocated to a segment that is currently empty/not being used. Gathering this information can help you discover space that can be reclaimed and allocated to other objects. Specifically, use this Profile to:

- find objects that are over-allocated (not using all their associated free space)
- find the free space that exists in excess of a table's high-water mark (the high water mark is the highest block that was written for a table)
- find segments that have the largest amount of blocks that are not filled

**Summary**

Summarizes space usage by database or tablespace, such as how many segments are in a tablespace (Oracle only), how many of those segments are tables (Oracle only), indexes, etc.

**Creating a profile:**

Create a profile for use within a scan.

To create a profile perform the following steps:

1. Expand **Data Manager > Monitoring**. For Data Manager for Databases, expand **Data Manager for Databases > Monitoring**.
2. Perform one of the following actions:
  - Select **Create Profile** from the pop-up menu.
  - Click **New Profile** from the **Profiles** tab of the Create scan window.

Use the Create Profile window to specify exactly what level of detail to collect when running a scan. The more information that you specify, the more reports

that you will be able to run against the information that you collect during the scan. Statistics are tied to a specific profile.

3. The **Statistics** tab on the **Create Profile** window is displayed.
4. Select statistics you want the scan to collect. Statistics are tied to a specific profile.  
See “Default profiles” on page 356 for more information about statistics.
5. If you want to further limit specific files to be scanned, select the **File Filters** tab. You can define exclusive conditions that filter what files are analyzed during the scan.  
See the “Creating file filters” on page 360 section for more information on using this tab.
6. The first time you view a new profile, this window is blank except for the text **All files selected**. That is the default and indicates that information will be collected for all files. To create your first group or condition, simply right-click **All files selected** and choose to create a new group or condition.
7. In the **File Filters** page, the default condition **All files selected** is displayed. Right-click **All files selected** and select **New Condition** from the pop-up menu. You can also specify groups for these conditions, by selecting **New Group**.

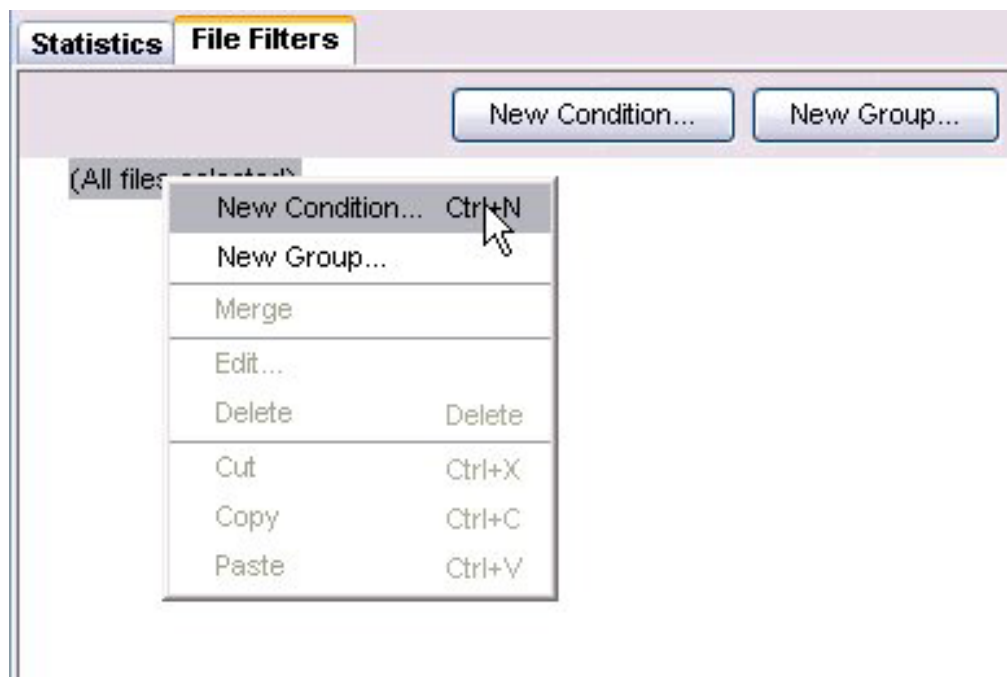

Figure 27. File Filters tab, pop-up menu

8. In the preceding figure, **New Condition** is selected. The **Create Condition** window opens, enabling you to define your file conditions. You can create conditions based on access time, creation time, file name or group, modification time, file attributes, size, type, owner, or length.

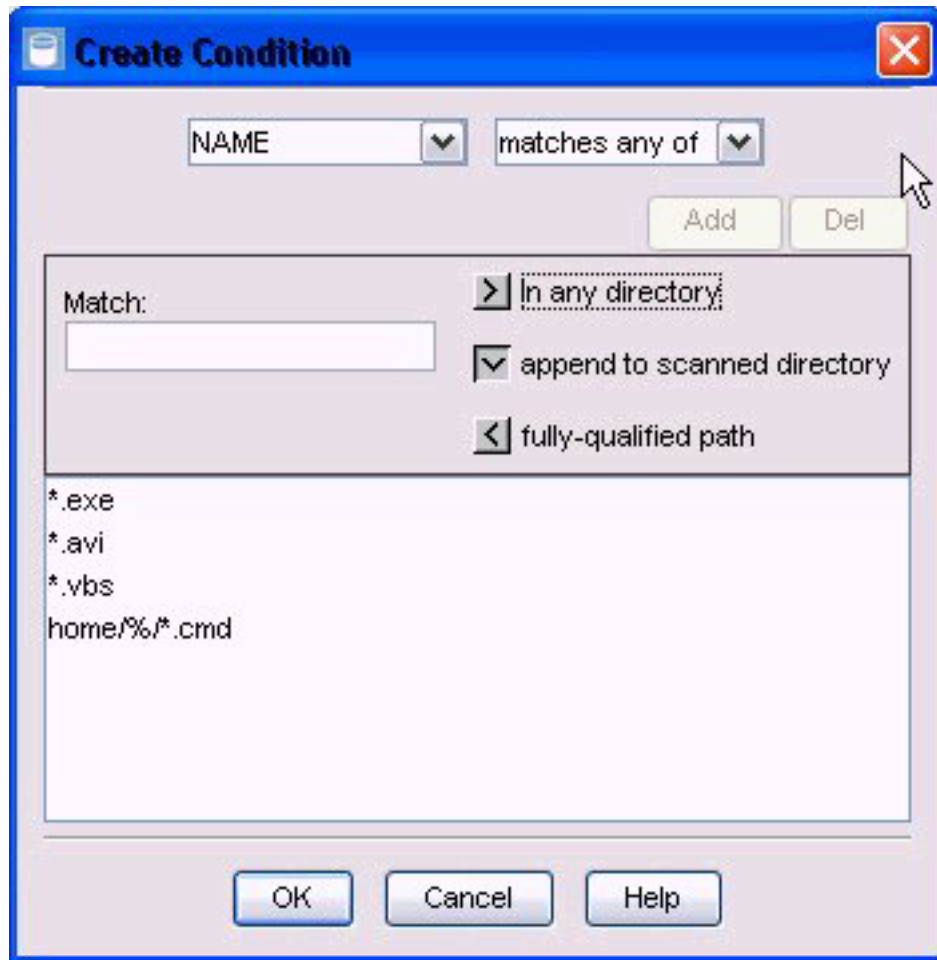

Figure 28. Create Condition window

9. Press **OK** after defining each condition.
10. If you are defining more than one condition, the **Create Group** dialog box displays to help you associate the conditions you created:

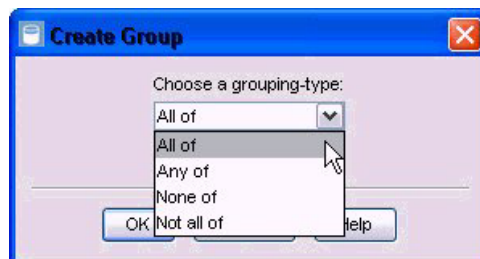

Figure 29. Create Group Window

11. Select how you want to associate the conditions you have defined. See “Associating conditions with groups” on page 365 for more information on creating groups.
12. The condition is displayed in the **File Filter** window.

Figure 30. File Filter window

13. Click  to save the profile.
14. Enter a name for the profile and click **OK**. An entry for the profile appears as a node under the **Profiles** node.

*Creating file filters:*

Use file filters as part of a profile to further define the files that you want to include or exclude in a scan. Filters limit the files on which you are gathering data during the scan based on criteria that you define.

In the following example, a group (All of) has been created with three conditions:

- The first controls the type of files to collect information on (MP3, GIF, AVI, and JPG files).
- The second specifies that the files must have been created within the last year.
- The third limits the profile to analyzing only files greater than 500 KB.

To create file filters within profile, complete the following steps:

1. To edit the file filters in an existing profile, expand **Data Manager > Monitoring > Profiles** and select an existing profile in the navigation tree. To create a new profile and add file filters, expand **Data Manager > Monitoring**, right-click **Profiles**, and select **Create Profile**.
2. Click the **File Filters** tab.
3. The first time you view a new profile, this window is blank except for **All files selected**. Selecting all files is the default and indicates that information is collected for all files. To create your first group or condition, right-click **All files selected** and choose to create a new group or condition.
4. In the File Filters page, the default condition **All files selected** is displayed. Right-click **All files selected** and select **New Condition**. You can also specify groups for these conditions by selecting **New Group**.

The **Create Condition** window opens, enabling you to define your file conditions. You can create conditions based on access time, creation time, file name or group, modification time, file attributes, size, type, owner, or length.

5. Press **OK** after defining each condition. See “Defining a filter condition” for more information on creating groups.

Each condition is displayed in the **File Filter** window.

If you are defining more than one condition, the **Create Group** dialog box helps you associate the conditions you create.

6. Associate the conditions you have defined.

See “Associating conditions with groups” on page 365 for more information on creating groups.

*Defining a filter condition:*

Define a condition for a filter.

On the File Filters page, right-click **All files selected** and select **New Condition**. The Create Condition window opens.

The first drop down list displays file criteria that you can select to define your condition. You can define file criteria based on access time, creation time, file name or group, modification time, file attributes, size, type, owner, or length. Depending on the criteria you choose to define, the second drop down list and window fields change dynamically to help you set parameters for the selected criteria. The following table describes the file criteria you can select for your file filter.

| Condition            | Description                                                                                                                                                                                                                   | Method for filtering the files                                                                                                   | Condition Modifiers                                                                                                                                                                                      |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Last Accessed</b> | Use this condition to limit files based on the last time they were accessed. For example, you can define a filter that includes files that were last accessed between 12:01 on January 1, 2005 and 11:59 on January 30, 2005. | <ul style="list-style-type: none"> <li>• later than</li> <li>• earlier than</li> <li>• between</li> <li>• not between</li> </ul> | <ul style="list-style-type: none"> <li>• Length of time before scan: enter the years, weeks, days, hours, or minutes before a scan</li> <li>• Timestamp - select files based on the timestamp</li> </ul> |
| <b>Created</b>       | Use this condition to limit files based on when they were created. For example, you can define a filter that includes files that were created between 12:01 on January 1, 2005 and 11:59 on January 30, 2005.                 | <ul style="list-style-type: none"> <li>• later than</li> <li>• earlier than</li> <li>• between</li> <li>• not between</li> </ul> | <ul style="list-style-type: none"> <li>• Length of time before scan: enter the years, weeks, days, hours, or minutes before a scan</li> <li>• Timestamp: select files based on the timestamp</li> </ul>  |

| Condition            | Description                                                                                                                                                                                                       | Method for filtering the files                                                                                                                                                                                                                         | Condition Modifiers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>          | Use this condition to limit files based on their name. For example, you can define a filters that include files that end in *.html, or include files that end in .cmd and appear within a specified subdirectory. | <ul style="list-style-type: none"> <li>• matches any of</li> <li>• matches none of</li> <li>• matches</li> <li>• does not match</li> </ul>                                                                                                             | <p>Enter the file name upon which you want the condition to be based. For example, you can specify, *.exe, *.mp3, *.avi. in the <b>Match</b> field. See "Using wildcards in file filters" on page 366 for information about how to use wildcards (*, %, etc.) in this field.</p> <p>Select the location where the file name will be searched during the scan:</p> <ul style="list-style-type: none"> <li>• <b>In any directory.</b> During a scan, Data Manager will look for the file name in any directory. In this condition, the search string will occur at the end of the full directory path.</li> <li>• <b>Append to scanned directory.</b> This option enables you to restrict what directory to scan. Data Manager will look for the file type in the specified file system root directory or in a monitored directory in a directory group tied to a scan. In this option, you must first specify what directory groups you want scanned in the <b>Directory Groups</b> tab of the <b>Scan</b> window. See "Selecting directory groups to scan" on page 350 for more information.</li> <li>• <b>Fully-qualified path.</b> Enter the fully-qualified path when you enter the file type in the <b>Match</b> field. During a scan, Data Manager will look for the file type in the exact path you specify here. This is useful when you want to exclude system directories and files in a Most Obsolete Files report.</li> </ul> |
| <b>Group</b>         | Use this condition to limit files based on the OS group to which those files belong.                                                                                                                              | <ul style="list-style-type: none"> <li>• matches any of</li> <li>• matches none of</li> <li>• between</li> <li>• not between</li> <li>• matches</li> <li>• does not match</li> <li>• &gt;=</li> <li>• &lt;</li> <li>• &gt;</li> <li>• &lt;=</li> </ul> | Name of the OS group                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Attributes</b> | Use this condition to limit files based on file attributes such as read only, system, temporary, etc. | <ul style="list-style-type: none"> <li>• include any of</li> <li>• include none of</li> <li>• include all of</li> <li>• don't include all of</li> </ul> | <p>Select the file attribute upon which you want the condition to be based. You can select:</p> <ul style="list-style-type: none"> <li>• Read only: Users cannot write to the file.</li> <li>• Hidden: A file that cannot be seen by users during a normal directory listing.</li> <li>• System: A file used by the operating system that cannot normally be viewed by users.</li> <li>• Archive: A file that has been backed-up and the archive bit is turned off. An Archive bit signifies that the file has been changed since it was last archived.</li> <li>• Normal: A file with no special attributes set to it.</li> <li>• Temporary: (Windows only) A temporary or backup copy of a file.</li> <li>• Sparse: A file with a special kind of compression that does not take up a lot of CPU time. The logical size of the file looks bigger than is actually allocated. It contains some blank pages which are not on disk.</li> <li>• Reparse Point: New NTFS file system objects that have a definable attribute containing user-controlled data and are used to extend functionality in the input/output (I/O) Subsystem.</li> <li>• Compressed: A file to which a compression algorithm was applied. This file takes up less space on disk, but it will be slower to read.</li> <li>• Offline: A file that was migrated to tape.</li> <li>• Not Content Indexed: A file that is not indexed--the Windows indexing service was told that this is not a file that should be searched through for text strings.</li> <li>• Encrypted: A file that was saved with a password (is password-protected).</li> <li>• Orphaned: (for Windows, UNIX, and Linux) The user who owns the file is no longer present in the system database.</li> </ul> |

| Condition                        | Description                                                          | Method for filtering the files                                                                                                                                                                                                                         | Condition Modifiers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Attributes</b><br>(continued) |                                                                      |                                                                                                                                                                                                                                                        | <ul style="list-style-type: none"> <li>Block Device: (UNIX/Linux only) A disk device file (not a real file).</li> <li>Executable: A file that you can run or execute.</li> <li>Sticky: A special type of executable file that is read into memory when it is first run and never released. Use Scans to find these types of files and set them to "unsticky".</li> <li>SETGID: (UNIX/Linux only, for executable files) When a file is run, its group changes to the group of the file. For example, if a user belongs to User group and runs a file from a different group (e.g., Root), then the user's group will be changed to Root while running the file (for security purposes).</li> <li>SETUID: (UNIX/Linux only, for executable files) When a file is run, the user's effective user will be changed when the file is run. For example, if a file is SETUID =Root, a users effective user ID becomes Root when running the file. This is considered a security hole by UNIX Administrators, so you can define a Profile to search for files that have a SETUID = Root.</li> </ul> |
| <b>Size</b>                      | Use this condition to limit files based on their physical file size. | <ul style="list-style-type: none"> <li>• between</li> <li>• not between</li> <li>• &gt;=</li> <li>• &lt;</li> <li>• &gt;</li> <li>• &lt;=</li> </ul>                                                                                                   | <ul style="list-style-type: none"> <li>• KB (kilobytes)</li> <li>• MB (megabytes)</li> <li>• GB (gigabytes)</li> <li>• TB (terabytes)</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Type</b>                      | Use this condition to limit files based on pre-defined file types.   | <ul style="list-style-type: none"> <li>• in</li> <li>• not in</li> <li>• =</li> <li>• &lt;</li> <li>• &gt;</li> </ul>                                                                                                                                  | <ul style="list-style-type: none"> <li>• Link</li> <li>• Directory</li> <li>• Fifo</li> <li>• Socket</li> <li>• Device</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Owner</b>                     | Use this condition to limit files based on their owner.              | <ul style="list-style-type: none"> <li>• matches any of</li> <li>• matches none of</li> <li>• between</li> <li>• not between</li> <li>• matches</li> <li>• does not match</li> <li>• &gt;=</li> <li>• &lt;</li> <li>• &gt;</li> <li>• &lt;=</li> </ul> | Enter the name of the owner upon which you want the condition to be based in the <b>Entry</b> field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Condition | Description                                                                        | Method for filtering the files                                                                                                                       | Condition Modifiers                                                                                                                                                                                                                               |
|-----------|------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Length    | Use this condition to limit files based on the logical size of the files contents. | <ul style="list-style-type: none"> <li>• between</li> <li>• not between</li> <li>• &gt;=</li> <li>• &lt;</li> <li>• &gt;</li> <li>• &lt;=</li> </ul> | Enter the file length range. You can qualify both values by selecting from one of the following: <ul style="list-style-type: none"> <li>• KB (kilobytes)</li> <li>• MB (megabytes)</li> <li>• GB (gigabytes)</li> <li>• TB (terabytes)</li> </ul> |

*Associating conditions with groups:*

Associate multiple conditions in a group or groups.

Groups can further define your file filter by including or excluding certain files based on specific criteria.

1. Create a new group using one of the following options.
  - In the **File Filters** tab, right-click a condition and select **New Group** from the pop-up menu.  
The **Create Group** dialog box is displayed.
  - Create each file condition for your file filter.  
As you create a new file condition, the **Create Group** dialog box is displayed.
2. Select the grouping for the file conditions you created. The grouped condition is displayed in the **File Filters** tab.

Select one of the following groups.

| Group             | Description                                                                                                                                         |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>All of</b>     | All inclusive. All the conditions must be met.<br><br>For example: <ul style="list-style-type: none"> <li>• <i>a and b and c</i></li> </ul>         |
| <b>Any of</b>     | Any one or more of the following conditions will be met.<br><br>For example: <ul style="list-style-type: none"> <li>• <i>a or b or c</i></li> </ul> |
| <b>None of</b>    | None of the conditions are met.<br><br>For example: <ul style="list-style-type: none"> <li>• <i>not (a or b or c)</i></li> </ul>                    |
| <b>Not all of</b> | All of the following conditions are not met.<br><br>For example: <ul style="list-style-type: none"> <li>• <i>not (a and b and c)</i></li> </ul>     |

For example, say you want to create a file filter with the following conditions:

- Name in (\*.gif, \*.jpg)
- Size > 1 MB
- Attribute is Read Only

How you group the conditions produces different results. The following table shows the different results depending on the group you select:

| File                   | Group        | Result  |
|------------------------|--------------|---------|
| A.gif 500KB read only  | • All of     | • False |
|                        | • Any of     | • True  |
|                        | • None of    | • False |
|                        | • Not all of | • True  |
| B.jpg 2 MB read only   | • All of     | • True  |
|                        | • Any of     | • True  |
|                        | • None of    | • False |
|                        | • Not all of | • False |
| C.gif 2 MB read/write  | • All of     | • False |
|                        | • Any of     | • True  |
|                        | • None of    | • False |
|                        | • Not all of | • True  |
| D.txt 500KB read/write | • All of     | • False |
|                        | • Any of     | • False |
|                        | • None of    | • True  |
|                        | • Not all of | • True  |

#### Using wildcards in file filters:

Use wildcard characters within the conditions of file filters to perform pattern matching of file names. A wildcard is a special symbol that represents one or more characters.

You can use wildcards in File Filter conditions to identify multiple files and directories with a single specification. The following table describes the wildcards that are available in Data Manager:

| Wildcard Character | Description                                                                                                                                                            | Examples                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| *                  | Use the asterisk (*) to represent unknown characters in file names. It can act as a wildcard for zero or more characters of any value within a directory or file name. | <ul style="list-style-type: none"> <li>• <b>s*</b> refers to all files that begin with <b>s</b></li> <li>• <b>*.exe</b> refers to all files that have <b>.exe</b> as an extension</li> <li>• <b>/user/*</b> refers to all files under the <b>/user</b> directory</li> </ul>                                                                                                               |
| %                  | Use the percent (%) character to specify a wildcard for a directories within the path of a file. It can act as a wildcard for zero or more directories within a path.  | <ul style="list-style-type: none"> <li>• <b>/home/%/*cmd</b> will match all files with the extension <b>.cmd</b> and located in any of the subdirectories under the <b>/home</b> directory</li> <li>• <b>/usr/%/*</b> will match all files and subdirectories under the <b>/usr</b> directory (for example, <b>/usr/files/c</b>, <b>/usr/c</b>, <b>/usr/files/documents/c</b>)</li> </ul> |

| Wildcard Character | Description                                                                                                                                                            | Examples                                                                                                                                                                                                                                                                                                         |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ?                  | Use the question mark (?) to represent a character within a file name or directory name. It can be used as a wildcard for a character within a directory or file name. | <ul style="list-style-type: none"> <li>• <code>/home/usr?/</code> will match directories like: <code>/home/usr1/</code>, <code>/home/usr2/</code>, etc.</li> <li>• <code>/usr/temp/temp??.tmp</code> will match files like <code>/usr/temp/temp01.tmp</code>, <code>/usr/temp/temp02.tmp</code>, etc.</li> </ul> |

Data Manager supports standard UNIX shell path name expansion wildcarding within file filter conditions. See the appropriate UNIX man pages for more information about the wildcards that you can use.

## Determining the availability of storage resources

Use pings to collect information about the availability of the storage resources in your environment. You can view the information collected by pings in Availability and System reports.

Pings enable you to monitor and report on the availability of your storage from a network point of view or from a computer uptime perspective. See the percentage of off-network time due to network problems or system downtime. Define any number of pings that each check the availability of a unique storage resource.

### Creating pings

Create pings to collect information about the availability of the storage resources in your environment. You can define any number of pings to gather information about different storage resources at different times.

To create a ping, complete the following steps:

1. Expand **Data Manager > Monitoring > Pings**.
2. Right-click **Pings**. A menu is displayed.
3. Select **Create Ping**.
4. Select the computers whose availability you want to check. "Select computers to ping" on page 368.
5. Schedule when you want a ping to run. "When to run the ping" on page 368.
6. Specify how often you want the server to write out the ping results to the database repository for viewing in reports. "Specify ping options" on page 369.
7. Click  to save the ping. You must save the ping before Tivoli Storage Productivity Center can collect data about storage resources.
8. Enter a name for the ping and click **OK**. An entry for the ping is displayed under the **Pings** node in the navigation tree. The ping is run at the date and time specified in the schedule definition.
9. Use the Job Management panel to manage view information about the runs and jobs that are related to the ping. For example, use the Job Management panel to view the status of a run for a schedule, the date and time when it was run, and the log files of the jobs associated with the run.

**Related reference:**

“Managing schedules, jobs, and runs” on page 300

Use the Job Management panel to view and manage all the schedules, runs, and jobs related to the storage devices that are monitored by IBM Tivoli Storage Productivity Center.

**Select computers to ping:**

Select the computers and clusters that you want to ping.

Use the **Computers** page to select the computers and clusters whose availability statistics you want to collect. The **Available** list box shows the computers, computer groups, or clusters that are currently being monitored and available for inclusion in the ping. After you include storage resources in the ping it is removed from this list and moved to the **Current Selections** list box. The **Current Selections** list box shows the computers, computer groups, or clusters that have been selected for the ping.

**Note:** A cluster name is displayed next to individual computers that are members of a PowerHA or Microsoft Cluster Server cluster. Cluster resource groups are identified with a special icon. Clusters displayed in the **Available** list box cannot be expanded to show member nodes. You can move a cluster to the **Current Selections** list box to view and, if necessary, exclude member nodes.

You can include individual computers, computer groups, or clusters against which to run a ping. See “Working with groups of resources” on page 374 for information about groups.

**To include storage resources in a ping:**

1. In the **Available** list box, highlight the computers, computer groups, and clusters that you want to include in the ping.
2. Click . The storage resource that you selected is moved to the **Current Selections** list box.

**To remove storage resources from a ping:**

- Highlight the computers, computer groups, and clusters that you want to remove and click . The storage resource is removed from the ping and moved from the **Current Selections** list box to the **Available** list box.

**To exclude one or more computers from a selected computer group or cluster:**

1. Double click the group or name of the cluster in the **Current Selections** list box.
2. Right click the computers that you want to exclude. A menu is displayed.
3. Select **Exclude**. An **Excludes** section is created in the **Current Selections** list box that displays the names of the computers that you have excluded from the ping.

**When to run the ping:**

Schedule when and how often to run a ping.

You have the following options for determining when to run a ping:

- Run the job immediately
- Run the job once at a specified time and date. Use the list boxes to specify the month, day, year, and the hour, minute, and AM or PM.

- Run the job repeatedly according to a schedule you specify. You can do the following:
  - Use the list boxes to specify the month, day, year, and the hour, minute, and AM or PM when the job should begin running.
  - Indicate how often the job should run. Use the list boxes to specify the number of minutes, hours, days, weeks, or months.
  - Select which days you wish to run the job.

Use the fields in the **How to handle timezones** section to indicate the time zone that Data Manager should use when scheduling and running the ping. For example, if you selected to run the job at 9:00 AM, you can use the fields in this section to run it at:

- 9:00 AM of the time zone where the server resides
- 9:00 AM of a specific time zone, such as 9:00 AM CST or 9:00 GMT. For example, if you select 9:00 AM CST, the job will run at 7:00 AM on an agent located in the PST time zone.

**Use the timezone that the server runs in.** Select this option to use the time zone of the location where the Data server resides.

**Use this timezone.** Select this option to indicate a specific time zone for when to run the job. Select the timezone from the list provided.

#### **Specify ping options:**

Determine how often the results of pings are written from memory and stored in the database repository.

For greater efficiency, the server temporarily stores ping results in memory. The unit of time you specify in the **Options** tab determines how often these results are externalized to the repository.

You can specify a unit of time in a number of pings, minutes, hours or days.

#### **Define alert values for a ping:**

Set an alert that will be triggered if the ping job fails.

Use the Alert page to define an alert to notify you if a computer that a ping is trying to check is unreachable for a certain amount of time. You can choose to be notified by SNMP trap, IBM Tivoli Enterprise Console event, login notification, Windows event log, UNIX Syslog, running a script, and e-mail. If you select SNMP trap, Tivoli Enterprise Console event, or e-mail, you must also define a destination (for example, an e-mail address). Define this destination by expanding **Administrative Services > Configuration > Alert Dispositions**.

To define an alert for a ping, complete the following steps:

1. Click the **Alerts** tab; the Alert page opens.
2. Define the conditions that will trigger the alert. The default setting is **Computer Is Unreachable More Than**. No other alerting conditions are currently available. Enter the **Value** and **Value Units**. These values specify how many pings occur before an error is generated. By default, **Value Units** is set to **Times**.

3. In the **Triggered Actions** area, select the actions that occur as a result of the triggering condition. You can choose from the following actions:

**SNMP trap**

An SNMP trap is sent to any NMS, console, or terminal when the condition occurs.

**TEC / OMNIBus Event**

A IBM Tivoli Enterprise Console event is sent when the condition occurs. The Tivoli Enterprise Console administrator can write correlation and automation rules to analyze Tivoli Storage Productivity Center events according to the event definitions specified in the tivoliSRM.baroc file (provided with the product). It also performs responses such as sending further notification, creating or updating trouble tickets, running programs, and so on.

**Login notification**

The alert is sent to a Tivoli Storage Productivity Center user. The user receives the alert upon logging in to Tivoli Storage Productivity Center. In the **Login ID** field, type the user ID.

**Login ID**

The ID of the user who receives alert notification upon logging in to the system.

**Windows Event Log, UNIX Syslog**

The ID of the user who receives alert notification upon logging in to the system.

**Event Type (Windows Event Log only)**

The type of event that is recorded to the OS log.

**Facility (UNIX Syslog only)**

The location where the UNIX Syslog is sent. You can select User or Local.

**Level (UNIX Syslog only)**

The level of UNIX Syslog event. You can select Informational, Notice, Warning, Error, Critical, or Alert.

**Run script**

A script is run when the condition occurs. Click **Define** to specify the script that is run when the triggering condition occurs. The parameters listed in the **Specify Script** window are passed to the script when the alert is triggered.

**Email** An email is sent. Click **Add** or **Delete** to edit the list of email addresses to which an email is sent. Click **Edit email** to change the actual email message.

4. Click **File > Save** to save the ping.
5. Enter a name for the ping and click **OK**. An entry for the ping appears under the **Pings** node.

## Editing pings

Change the settings in an existing ping job.

To edit an existing ping, complete the following steps:

1. Expand **Data Manager > Monitoring > Pings**.
2. Click the name of the ping you want to edit. The content pane displays information about that job.

3. Edit the ping definition by changing the values that appear on the following pages:
  - **Computers.** Use this page to edit the computers, computer groups, and clusters whose availability you want to monitor as part of a ping.
  - **When to Run.** Use this page to edit when a ping is run.
  - **Options** Use this page to edit how often the results of pings are written from memory and stored in the database repository.
  - **Alert.** Use this page to edit how long a storage entity is unreachable before you are notified that the ping has failed.
4. Click  to save the updated ping definition.

## Data collection groups

Groups enable you to define a set of related resources such as a computer, fabric, or storage subsystem once and save these selections as a named group for future use in scans, pings, and probes, making data collection more efficient. For example, you can create a group that contains a number of related computers. You can then reference that group within a monitoring job when you want to collect data about all those computers at the same time.

Each type of group is represented by a node under the **Monitoring > Groups** and **IBM Tivoli Storage Productivity Center > Monitoring > Probes** sections. You can expand the tree for each type of group to see what groups exist for that type. Resources can belong to only one group at a time. For example, if a computer already belongs to a computer group and you attempt to add it to a different computer group, the system removes it from the first computer group before adding it to the new computer group (this includes removing it from the default group if it had never been previously assigned to a user defined group). This is to prevent a resource from being counted twice statistically.

Additionally, you can use Data Manager for Chargeback to create invoices for these groups. When implementing your chargeback system, it is recommended that you group the IT resources within your organization into functional groups. Accurately identifying the types and locations of your stored data and resources is the first step in implementing an effective and equitable chargeback policy. Defining groups with Data Manager enables you to classify your data and resources into billable entities, which in turn provides information on who is using what storage. This enables you to bill specific groups according to their usage of storage space.

The following table lists and describes the types of groups that you can create.

| Group Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Data Manager</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Computer</b>     | <p>A logical grouping of related computers. A computer can belong to one computer group only. A computer will automatically be removed from a group if you add it to another group. You can use computer groups to monitor computers that are related to each other or belong to a common group such as a department, location, territory, and so on.</p> <p>Examples of computer groups include Sales, Accounting, Development, IT, West, East, Midwest, NAS Filers, Remote Servers</p> |

| Group Type                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Filesystem                        | <p>A grouping of file systems across multiple computers. A file system can belong to one file system group only. A file system will automatically be removed from a group if you add it to another group.</p> <p>Here is an example of file system groups: C:\, D:\, /boot, /home, /usr</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Directory                         | <p>A grouping of directories across multiple computers. You can include a directory in multiple directory groups.</p> <p>Examples of directory groups include:</p> <p>WindowsTempDir Included Computer Name:Directory -<br/> a:\machine1\winnt\temp, b:\machine2\winnt\temp,<br/> c:\machine3\winnt\temp</p> <p><b>Note:</b> To monitor directories from the IBM Tivoli Storage SAN File Systems, you must create a directory group and add the desired directories as follows:</p> <pre data-bbox="670 745 1242 772">/ &lt;SAN File System cluster name&gt; / &lt;directory name&gt;</pre> <p>where &lt;SAN File System cluster name&gt; represents the name of the SAN File System cluster that contains the directory that you want to add and &lt;directory name&gt; represents the name of the directory you want to add (for example, /IBM/myFilesetName/myDirectoryName, /IBM/myDirectoryName).</p> |
| User                              | <p>A grouping of related users. A user can belong to one user group only. A user will automatically be removed from a group if you add it to another group. Users that were discovered by Tivoli Storage Productivity Center can be included in a user group.</p> <p><b>Note:</b> The user groups that you define in Data Manager for Databases will also be available in Data Manager, and vice versa.</p> <p>Examples of user groups include Administrators, Developers, Marketing staff, HR staff</p>                                                                                                                                                                                                                                                                                                                                                                                                   |
| OS User Group                     | <p>A grouping of OS user groups that were defined outside of Tivoli Storage Productivity Center at the operating system level. OS user groups are the operating system groups that Tivoli Storage Productivity Center finds that own files and directories in the environment.</p> <p>Examples of OS user groups include Windows, Linux, UNIX</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Data Manager for Databases</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Databases-<br>Tablespaces | <p>A grouping of RDBMS databases or tablespaces. You can use database-tablespace groups to monitor entire databases or tablespaces (depending on the RDBMS) across multiple instances. A database or tablespace will automatically be removed from a group if you add it to another group. A database or tablespace can belong to one database-tablespace group only.</p> <p>Examples of database-tablespace groups include DB2 databases, system tablespaces</p>                                        |
| Table                     | A grouping of related RDBMS tables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| User                      | <p>A grouping of related users. A user can belong to one user group only. A user will automatically be removed from a group if you add it to another group. Users that were discovered by Tivoli Storage Productivity Center can be included in a user group.</p> <p><b>Note:</b> The user groups that you define in Data Manager for Databases will also be available in Data Manager, and vice versa.</p> <p>Examples of user groups include Administrators, Developers, Marketing staff, HR staff</p> |
| <b>Disk Manager</b>       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Storage Subsystem         | A storage subsystem group can contain subsystems and SAN Volume Controllers.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Fabric Manager</b>     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Fabric                    | A grouping of fabrics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Tape Manager</b>       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Tape Libraries            | A grouping of tape libraries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Default groups

Default groups for each storage resource are also provided within each group type node. As IBM Tivoli Storage Productivity Center discovers these resources within your enterprise through discovery, probes, and scans, the resources are automatically added to the corresponding default groups.

The following table lists the names of the default groups for each group type.

| Manager                     | Group Type                | Default Group Name               |
|-----------------------------|---------------------------|----------------------------------|
| Data Manager                | Computer                  | TPCUser.Default Computer Group   |
|                             | Filesystem                | TPCUser.Default FS Group         |
|                             | Directory                 | n/a                              |
|                             | User                      | TPCUser.Default User Group       |
|                             | OS User Group             | TPCUser.Default OSGroup Group    |
| Data Manager -<br>Databases | Computer                  | TPCUser.Default Computer Group   |
|                             | Databases-<br>Tablespaces | TPCUser.Default Tablespace Group |
|                             | Table                     | n/a                              |
|                             | User                      | TPCUser.Default User Group       |

| Manager        | Group Type         | Default Group Name                      |
|----------------|--------------------|-----------------------------------------|
| Disk Manager   | Storage Subsystems | TPCUser.Default Storage Subsystem Group |
| Fabric Manager | Fabrics            | TPCUser.Default Fabric Group            |
| Tape Manager   | Tape Library       | TPCUser.Default Tape Group              |

## Working with groups of resources

Create resource groups to logically arrange resources and to permit actions against the entire group.

### Creating a group

You can create named groups that represent a set of resources, such as computers, databases, table spaces, tables, and users, to later use in pings, scans, and probes.

To create a new group, perform the following steps.

1. Expand **Monitoring > Groups**. For example, **Data Manager > Monitoring > Groups**.
2. Right-click the type of group you want to create and select **Create group type**, where *group type* represents the group you want to create, such as a **Create Computer Group**, **Create Filesystem Group**, or **Create Table Group**.
3. In the Create *group type* Groups page, select the resources in the **Available** column that you want to include in the group. Hold down the Ctrl key as you click to select multiple resources.

**Note:** For computer and file system groups in Data Manager, a **Group By Cluster** check box is displayed. When this option is not selected, the **Available** pane displays a cluster name next to any clustered computers and cluster resource groups. When this option is selected, any computer or cluster resource group that belongs to a PowerHA or MSCS cluster is grouped under its cluster name. Cluster resource groups are identified with a special icon along with the name of the current host node. All other computers will be grouped under **Non-Clustered Computers**.

4. Click  to move the selected resources to the **Current Selections** column.  
Click  to move resources from the **Current Selections** column and move them to the **Available** column.
5. Optional: Type a description of the group in the **Description** field.
6. Click the save icon in the menu bar to save the group.
7. Type a descriptive name for the group and click **OK**.

### Creating tape library groups

Create groups of tape libraries that have similar attributes to make it easier to perform storage management tasks on the grouped libraries.

1. Expand the **Tape Manager > Monitoring > Groups** node and right-click **Tape Library**.
2. Select **Create Tape Library Groups**.
3. In the Create Tape Library Groups page, select the libraries in the **Available** column to include the libraries in the group.  
Hold down **Ctrl** to click multiple libraries.
4. Click  to move selected libraries to the **Current Selections** column.

- Optional: Enter a description of the tape library group in the **Description** field.
- Click  to type a descriptive name for the group in the **Save As** dialog. Then click **OK** to save the group.

The new tape library group is listed under the **Tape Library** node in the navigation tree.

## Grouping fabrics

You can group fabrics to run reporting jobs against all the fabrics in the group. A fabric can belong to multiple groups at a time.

For more information on groups, see “Data collection groups” on page 371.

To create a fabric group, complete the following steps:

- Expand **Fabric Manager > Monitoring > Groups**, right-click on **Fabric**, and select **Create Fabric Group**.
- Enter a description for the group, and from the **Available** column, select the fabrics to be added to the group. Move them to the **Current Selections** column by clicking .
- To save the group, click **File > Save**.
- In the **Save As** window, enter the group name and click **OK**.

## Editing groups

When you update the resources that are included within a group, those updates are automatically picked up by the jobs that reference that group.

To edit an existing group, perform the following steps.

- Expand **Monitoring > Groups**. For example, to edit groups within Disk Manager, expand **Disk Manager > Monitoring > Groups > Storage Subsystem**.
- Expand a group type to view the list of groups defined for that type. For example, to view storage subsystem groups, expand the **Storage Subsystem** node under Disk Manager.
- Click the name of the group you want to edit. Details for the selected group are displayed in the Create *group type* Groups page, where group type is the type of group (for example, Directory or Computer).
- Edit the values defined for the group as desired. Click  to move the selected resources to the **Current Selections** column. Click  to move resources from the **Current Selections** column and move them to the **Available** column.
- Click the save icon in the menu bar to save the group.

## Creating directory groups

Create and use directory groups within scans to monitor and gather information about specific directories within filesystems across a number of machines.

**Note:** IBM Tivoli Storage SAN File Systems information: To monitor directories from the SAN File System, you must create a directory group and add the desired directories as follows:

```
/<IBM Tivoli Storage SAN File Systems cluster name>/<directory name>
```

where:

- *<IBM Tivoli Storage SAN File Systems cluster name>* represents the name of the IBM Tivoli Storage SAN File Systems cluster that contains the directory you want to add
- *<directory name>* represents the name of the directory you want to add

Examples:

- /IBM/myFilesetName/myDirectoryName
- /IBM/myFilesetName
- /IBM/myDirectoryName

To create a directory group, perform the following steps.

1. Expand **Data Manager > Monitoring > Groups > Directory** or click **Create Directory Group** from the **Directory Groups** tab of the Scan window. The Create Directory Group window opens.
2. Use the New Directory window to edit or add directories to a directory group.

| Field                              | Description                                                                                                                                                                                                                                                                     |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Creator</b>                     | Displays the creator of the group.                                                                                                                                                                                                                                              |
| <b>Name</b>                        | Displays the name of the group you are adding or editing. This name can be helpful in determining the content of the group. For example, a directory group named UnixUserHomes might consist of the /home directory on all the UNIX and Linux computers within an organization. |
| <b>Description</b>                 | A description of the group you are adding or editing.                                                                                                                                                                                                                           |
| <b>New Computer, New Directory</b> | Click these buttons to add a directory or computer to the group.                                                                                                                                                                                                                |

#### Viewing directory groups:

When adding directories to a group, you can determine how you want to view groups of directories. You can choose either of the following options:

- **Directories by computer.** Use this option to display the directories in the directory group according to the computer on which they exist.
  1. Expand Data Manager.
  2. Expand Monitoring.
  3. Expand Groups.
  4. Expand Directory.
  5. Double-click a directory object.
  6. In the content pane, under View, select Directories by Computer which is the default setting.

**Note:** You might need to try more than one directory object to find one with data.

- **Computers by directory.** Use this option to display the computers in the group according to the directories included in the directory group.
  1. Expand Data Manager.
  2. Expand Monitoring.
  3. Expand Groups.
  4. Expand Directory.
  5. Double-click a directory object.

6. In the content pane, under View, select Computers by Directory.

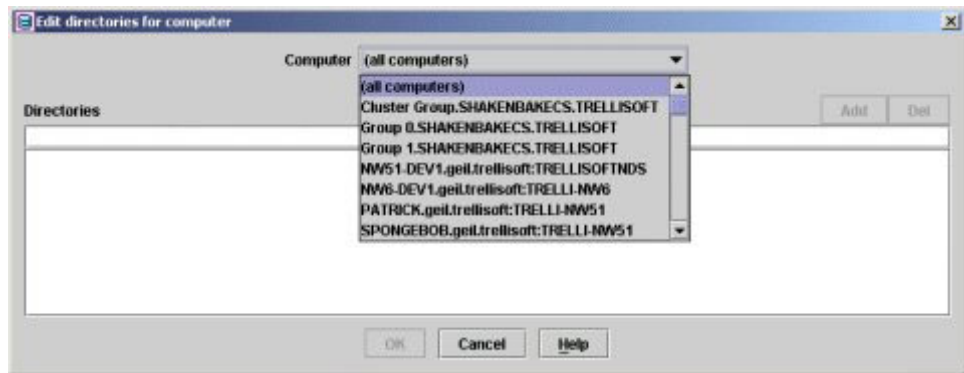

**Note:** You might need to try more than one directory object to find one with data.

**Tip:** Choosing these different buttons enables you to add directories to a directory group in different ways. For example, if you want to monitor or receive alerts on different directories on multiple computers, choose the Directories by Computer option. If you want to monitor or receive alerts on the same directory across multiple computers, choose the Computers by Directory option.

#### Adding new directories by computer:

If you want to add new directories to a directory group by first selecting the computers on which they exist, perform the following steps:

1. Select **directories by computer** on the Create Directory Group window.
2. Click **New computer**. The Edit Directories for Computer window opens. This window enables you to select the computer for which you want to monitor specific directories, and enter the directories for the selected computer.

3. Click the **Computer** list box.
4. Select the computer for which you want to monitor specific directories.
5. Enter the directory you want to add to the group in the **Directories** field. For example: c:\or /home/\*.
6. Click **Add**. The directory is added to the list box.
7. Click **OK** when you are done adding directories. The New Directory Group window opens. The computer you added will be displayed as a node in the display area, with the specified directories under the node.

#### Adding new computers by directory:

If you want to add new directories to a directory group by first specifying the directory and then selecting the computers on which they exist, perform the following steps:

1. Select **computers by directory** on the Create Directory Group window.
2. Click **New computer**. The Edit Computers for Directory window opens. This window enables you to enter the directories you want to add to the directory group and specify which computers contain those directories.
3. Enter the directory you want to add to the group in the **Directory** field. For example: c:\, /home/\*, \user\\*, \windows\temp\, /usr/\*.

4. Select the computers you want to include in the group and click . The computer will be displayed in the **Current Selections** column. Select the **All computers** option to include all computers that contain the directory in the Directory Group.
5. Click **OK**. The New Directory Group window opens. The directory you added will be displayed as a node in the display area, with the selected computers under the node.

---

## Collecting performance data

Use the tasks in this section to collect performance data about your storage subsystems, fabric switches, and tape libraries.

### Monitoring switch performance

You can monitor the performance of those switches in your fabrics from which you can collect performance data.

#### Creating a switch performance monitor

You can monitor the performance of selected fabric switches. Fabric Manager can collect performance data for the switches and generate reports from the results of those monitors.

Report data is collected on data rates, operations rates, switch port errors, and other performance statistics. For information about generating those reports, see “Creating switch performance reports” on page 1023.

**Note:** A fabric probe is now required after a CIMOM discovery before a switch performance monitor job can be run.

To create a switch performance monitor, complete the following steps:

1. Expand **Fabric Manager > Monitoring**, right-click **Switch Performance Monitors**, and select **Create Switch Performance Monitors**.
2. In the **Switches** tab, enter a description for the performance monitor, and from the **Available** column, select the switches to be added to the monitor definition.

Move them to the **Current Selections** column by clicking .

**Note:** Only those switches from which Fabric Manager can collect performance data are listed in the **Available** column. If a switch is added to a performance monitor, it is no longer listed as an available switch.

3. In the **Sampling and Scheduling** tab, specify an interval for the performance averages, the duration of the data collections, and a schedule for the monitor. You can begin the monitor immediately, schedule it to begin at a later time, and specify whether to run the monitor repeatedly.
4. In the **Alert** tab, specify the action to be taken if the monitor fails. See “Running scripts with alerts” on page 495 for a description of these triggered actions.
5. Click  to save the performance monitor. You must save the monitor before Tivoli Storage Productivity Center can collect data about storage resources.

6. Enter a name for the performance monitor and click **OK**. An entry for the monitor is displayed under the **Switch Performance Monitors** node in the navigation tree. The monitor is run at the date and time specified in the schedule definition.
7. Use the Job Management panel to manage view information about the runs and jobs that are related to the performance monitor. For example, use the Job Management panel to view the status of a run for a schedule, the date and time when it was run, and the log files of the jobs associated with the run.

### Editing a switch performance monitor

Edit a saved switch performance monitor to change settings, such as which switches to include in the collection.

1. Expand **Fabric Manager > Monitoring > Switch Performance Monitors**. There will be a node for each saved monitor definition.
2. Click the name of the monitor you want to edit.
3. Edit the monitor definition.
4. To save the edited monitor, click **Save**.

## Monitoring storage-subsystem performance

Discover, probe, define performance thresholds, and view performance data and alerts to monitor a storage system.

1. Configure the storage system for monitoring by IBM Tivoli Storage Productivity Center. Use one of the following methods based on the storage system connects with Tivoli Storage Productivity Center:
  - To monitor any of the following storage systems, use the Configure Devices wizard to enter connection information for their native interfaces:
    - System Storage DS8000
    - SAN Volume Controller
    - The XIV system
    - Storwize V7000
    - Storwize V7000 Unified
    - IBM SONAS
  - To monitor storage systems that use CIM object manager (CIMOM) connections, there are a number of ways to enter the connection information into Tivoli Storage Productivity Center. If the CIMOM is in the same subnet as the Device server, it can be discovered through Service Location Protocol (SLP). You can manually add the CIMOM to Tivoli Storage Productivity Center by expanding the **Administrative Services > Data Sources** node and clicking **CIMOM Agents**. See Adding a CIM agent manually for details of how to add the CIMOM. Alternatively, you can also use the Configure Devices wizard to enter the CIMOM information.
2. Discover the storage system.
 

Discovery gets general information about the devices that affiliated with the CIMOMs. These devices are switches and other storage systems such as IBM System Storage DS5000 and other DS series systems, and IBM TotalStorage Enterprise Storage Server. You can run discovery for CIMOMs by expanding the **Administrative Services > Discovery > CIMOM** node. Alternatively, you can also use the Configure Devices wizard to run discovery for CIMOMs.

The discovery step is not required for the storage systems that are connected to Tivoli Storage Productivity Center using native interfaces.
3. Probe the storage system.

Probes collect information about logical devices, such as volumes and virtual disks, that are associated with the storage system. Probes also collect information about hosts that are mapped to the logical devices.

If you use the Configure Devices wizard, storage subsystems are included automatically in probes. To create probes manually, expand **IBM Tivoli Storage Productivity Center > Monitoring > Probes**. For Data Manager for Databases, expand **Data Manager for Databases > Monitoring > Probes**.

4. Define storage-system performance thresholds.

Thresholds draw your attention to exceptions to normally expected values in the data that you collect.

5. Collect storage-system performance data.

Collect performance data for an individual storage system.

6. View storage system performance data.

**Related information:**

For details of how to use the Configure Devices wizard to enter connection information for any of the storage systems that connect to Tivoli Storage Productivity Center using native interfaces, see “Configuring storage subsystems” on page 310.

## Creating storage subsystem performance monitor

Create a subsystem performance monitor to gather performance data for storage systems.

**Note:** If you schedule a performance monitor to collect data about a storage subsystem at the same time you plan to create many volumes on that subsystem, the performance of the volume creation job and the general performance of the associated CIMOM might decrease. Consider scheduling a performance monitoring job at a different time than when you plan to create many volumes on a subsystem.

Complete the following steps to collect performance data for a storage system:

1. In the navigation tree pane, expand **Disk Manager → Monitoring**.
2. Right-click **Subsystem Performance Monitor** and click **Create Performance Monitor**.

The Create Storage Subsystem Performance Monitor window opens in the content pane.

3. Optional: In the **Description** field, type a description of the threshold.
4. Click the **Storage Subsystems** tab. The Storage Subsystems page is displayed and all storage subsystems that have been discovered are listed.
5. In the **Available subsystems** field, click storage subsystems to select them for collection. Then click  .

The selected storage subsystems are displayed in the **Current selections** field.

6. Verify that you have created and run a probe for each selected storage subsystem, as described in “Creating probes” on page 340.

Storage-subsystem reports use data gathered by probes, including data on storage assets in the enterprise, such as computers, storage subsystems, disk controllers, hard disks, and file systems. Data collection fails if a selected system has not yet been probed.

7. Click the **Sampling and Scheduling** tab. The **Sampling and Scheduling** page is displayed.

8. In the **Sampling** area, specify the length of the sampling window and how frequently the performance data is gathered.
  - a. In the **Interval length** field, select the length of the sampling window.

The interval length is the number of minutes over which performance data is averaged. For example, if you select 15 minutes, all performance-data samples gathered from the storage subsystem represent an average of the performance of the subsystem over the previous 15 minute interval.
  - b. In the **Duration** field, specify how long the monitoring task will run.

You can specify that the task runs indefinitely or specify the length of time that the performance data is gathered.
  - c. In the **Scheduling** area, click either **Begin immediately** or **Schedule to begin later**.

If you click **Schedule to begin later**, specify the date and time that you want the data collection to start. You also can specify that the data collection recurs, how frequently it recurs, and whether certain days of the week are excluded.

**Important:** When you specify a start time for using performance monitor data in a plan, a report, or an optimization plan, the start time might not coincide with the start of a performance monitor data collection interval. If the requested start time is after the start of a data collection interval and the duration of the data collection interval is long enough so that it ends at or after the requested start time, Tivoli Storage Productivity Center includes all data from the collection interval that began before the requested start time. This might include data collected before the start time that you specified. This processing ensures that the maximum amount of available performance data is utilized. For example, if a performance monitor collects data every 20 minutes starting at 01:00, but you request performance data starting at 1:15, Tivoli Storage Productivity Center still analyzes performance data starting at 01:00 that has a duration of 20 minutes.

9. Click the **Alert** tab. The **Alert** page is displayed. In the **Condition** area **Monitor Failed** is the triggering condition.
10. In the **Triggered Actions** area, select actions to trigger when the data collection task fails.

You can select from the following check boxes:

- **SNMP Trap**
- **TEC / OMNIBUS Event**
- **Login Notification**
- **Windows Event Log**
- **Run Script**
- **Email**

Depending on what action you select, you might have other choices to make. Suppose that you select the **Windows Event Log** check box, for example. The **Event Type** field becomes activate to specify a severity for the event in the Windows event log.

11. Click **File** → **Save**. You must save the performance monitor before Tivoli Storage Productivity Center can collect data about storage resources.
12. Enter a name for the performance monitor and click **OK**.

An entry for the monitor is displayed under the **Subsystem Performance Monitors** node in the navigation tree. The monitor is run at the date and time specified in the schedule definition.

13. After the monitoring job completes, expand the name of the storage-subsystem performance monitor.

The following information is displayed:

- A status icon that indicates whether the task completed successfully
- Number of times that the task ran
- Date that the task ran
- Time that the task began

14. To view additional information, click the task information.

In the content pane, the following additional information is displayed:

- Time that the task finished
- Number of jobs in the task
- Number of jobs that failed

A table contains information about the storage subsystems in the data collection.

15. In the table, click a storage subsystem, and then click  to display the contents of the log file.
16. Use the Job Management panel to manage view information about the runs and jobs that are related to the monitor. For example, use the Job Management panel to view the status of a run for a schedule, the date and time when it was run, and the log files of the jobs associated with the run.

## Example log file

The following example is a log file for a SAN Volume Controller:

```
Job log file: <Location of log file>
<date><time>HWNPM21131 The performance monitor for device
<name> (<IP address>:<?>) is starting in an active state
<date><time>HWNPM21151 Monitor Policy:name="svcProbe",
creator="administrator", description=""
<date><time>HWNPM21161 Monitor Policy:retention period:
sample data=14 days,hourly data=30 days,daily data=90 days
<date><time>HWNPM21171 Monitor Policy:interval length=900 secs,
frequency=900 secs, duration=1 hours
<date><time>HWNPM21181 Threshold Policy:name=
"Default Threshold Policy for SVC",creator="System",
description="Current default performance threshold policy for
SAN Volume Controller"
<date><time>HWNPM21191 Threshold Policy:retention period:
exception data=14 days
<date><time>HWNPM21201 Threshold Policy:threshold name=
Total I/O Rate Threshold,enabled=no,boundaries=-1,-1,-1,-1 ops/sec
<date><time>HWNPM21201 Threshold Policy:threshold name=
Total Data Rate Threshold,enabled=no,boundaries=-1,-1,-1,-1 MB/sec
<date><time>HWNPM21201 Threshold Policy:threshold name=
Total Backend I/O Rate Threshold,enabled=no,boundaries=3,2,1,0 ops/sec
<date><time>HWNPM21201 Threshold Policy:threshold name=
Total Backend Data Rate Threshold,enabled=yes,boundaries=3,2,1,0 MB/sec
<date><time>HWNPM21201 Threshold Policy:threshold name=
Overall Backend Response Time Threshold,enabled=yes,
boundaries=-1,-1,-1,-1 ms/sec
<date><time>HWNPM02001 This operation (startPerfCollection())
on Performance Manager was successful.
<date><time>HWNPM22001 Successfully retrieved the configuration
data for the storage system.
Found 1 I/O Groups,2MDisk Groups,25MDisks, and 1 VDisk
<date><time>HWNPM21231 Performance data was collected and processed
successfully.
27 performance data records were inserted into the database.
<date><time>HWNPM21231 Performance data was collected and processed
successfully.
54 performance data records were inserted into the database.
<date><time>HWNPM21261 The performance monitor for device
<name> (<IP address>:<?>) is stopping because its
intended duration has elapsed.
```

Descriptions of variables in the log file include:

- <date> is the date, for example, 1/23/06.
- <time> is the time, for example, 12:45:20 PM.
- <name> is the device ID of the storage subsystem, for example, SVC-2145-RedC3-IBM.
- <IP address> is the IP address of the storage subsystem, for example, 9.47.97.159.

This log also provides the following information:

- The monitoring task was targeted against a single SAN Volume Controller, SVC-2145-RedC3-IBM.
- The name of the monitoring task is **svcProbe**, and it was created by a user with an ID **administrator**.
- The retention period for exception data.
- The user had provided the following values for the task: interval length: sampling window of 900 seconds (15 minutes) and duration of one hour.

- The monitoring task successfully retrieved the configuration data from the SAN Volume Controller. The task associated the following logical entities with the SAN Volume Controller:
  - One I/O group
  - Two managed-disk groups (MDisk groups)
  - 25 managed disks (MDisks)
  - One virtual disk (VDisk)
- The monitoring task successfully collected and processed data for two performance metrics. A total of 81 performance records were written to the database.
- The monitoring task stopped when its duration (one hour) had elapsed.

## Editing a storage-subsystem performance monitor

Edit a storage-subsystem performance monitor.

Complete the following steps to edit storage subsystem performance monitor:

1. In the left-hand pane, expand Disk Manager > **Monitoring** > **Subsystem Performance Monitors**. The list of existing subsystem performance monitors is displayed.
2. Click the monitor that you want to edit. The Edit Subsystem Performance Monitor window opens.  
The Create Storage Subsystem Performance Monitor window opens in the right-hand pane.
3. Make any necessary changes.
4. Click **File** → **Save**.

## Monitoring tape libraries

Monitor the performance of tape libraries to be aware of events that occur, and to respond to alerts.

1. Create one or more tape library groups, as described in “Creating tape library groups” on page 374.
2. Create a probe job to collect data about your tape libraries and library groups, as described in “Creating tape library probes” on page 342.
3. View alerts that are generated by your tape libraries, as described in “Viewing alert logs” on page 405.

## Viewing performance data

View collected performance data and recognized threshold exceptions in various user-friendly formats to stay aware of usage trends and exceptions.

Display data in a tabular format (actual values of the collected metrics), a graphical format (primarily as line-graphs), or export the data to a file. Select whether recent data, historical data, or information about threshold exceptions (constraint violations) is displayed.

Select a device or a device component, select a particular metric, and specify a time range to plot the data over the time range.

Use constraint violation reports to view a list of any threshold exceptions that occurred during a particular time range. Bar graphs of exceptions are commonly used to show the total number of threshold violations.

## Viewing storage-subsystem performance data

View collected storage-subsystem performance data and recognized threshold exceptions to stay aware of storage-subsystem usage trends and exceptions.

1. In the navigation tree, expand **Disk Manager** → **Reporting** → **Storage Subsystem Performance**.

A list of reports is displayed under **Storage Subsystem Performance node**.

The following reports generate information concerning SAN Volume Controller models:

- By Storage Subsystem
- By Controller
- By I/O Group
- By Module/Node
- By Array
- By Managed Disk Group
- By Volume
- By Managed Disk
- By Port
- Constraint Violations

2. Click **By I/O Group** to view information about I/O groups.

In the content pane, the Selection page is displayed. By default, all applicable performance metrics are selected for inclusion in the report.

3. Select the data or performance metrics that you want to exclude from the report in the **Included Columns** field. See “Performance metrics” on page 1519 for a list of performance metrics.

a. Click the items that you want to exclude from the report.

- b. Click .

Excluded items are displayed in the **Available Columns** field.

- c. Select a metric and click either  or  to change the order of the selected metric in the report.

4. Type the number of I/O groups to include in the report, in the **Return maximum of** field.

Limit the number of I/O groups to reduce the amount of performance information in the report. By default, this value is set to 2500.

5. Click **Selection** to open the Select Resources window.
6. Select check boxes to select I/O groups for the report, then click **OK**.
7. Click **Filter** to open the Edit Filter window.
8. Specify filter conditions for the report.
9. Click **Generate Report**.

An I/O Group page opens and the report is displayed.

10. Optional: View the report in chart format.

- a. Click , to specify charting options, then click **OK**.

b. Click **Customize this chart** to further customize the chart.

11. Optional: Click  and type a name to save the report settings for future use.

The report is saved under the **IBM Tivoli Storage Productivity Center** node.

### Viewing tape library information

View collected tape library data to stay aware of discovered tape libraries and usage information.

- Click **Tape Manager**. Left-click **Tape Libraries**. In the content pane, the Tape Libraries page is displayed, which lists the discovered tape libraries.

Select a library from the table and then click one of the buttons to see further details about that library. For example, select a library and click **Drives** to open a page that lists all the drives for that library.

You can also right-click a library in the **Tape Libraries** table and select **View Details**.

- Use the **View Details** feature in the topology viewer, as described in “Working with tape libraries in the topology viewer” on page 541.

---

## Working with alerts

Create an alert, configure how the alert is publicized, or edit, delete, disable, rename, or view an alert.

### Related reference:

“Performance thresholds” on page 1508

Performance thresholds are triggering conditions which are used to monitor a component with user-defined values.

## Creating alerts

You can define alerts so that IBM Tivoli Storage Productivity Center notifies you when a specified event occurs. The specific triggering conditions that you can use depend on the type of storage resource that you are monitoring.

**Note:** Alerts are not generated in a Tivoli Storage Productivity Center instance for actions that you perform from that instance. For example, if you start Tivoli Storage Productivity Center and use Disk Manager to assign or unassign volumes for a subsystem, you will not receive alerts for those volume changes in that instance. However, if you assign and unassign volumes outside of that Tivoli Storage Productivity Center instance, an alert is generated.

### Related reference:

“Performance thresholds” on page 1508

Performance thresholds are triggering conditions which are used to monitor a component with user-defined values.

### Creating computer alerts

You can use these alerts to monitor computers for changes in configuration or status. When a condition is detected during a probe, an alert is generated. Computer alerts can be applied to computers, computer groups, and clusters.

If necessary, complete the following prerequisites before you begin the task:

- If you want a script to be run after an event has triggered an alert, you must create the script before you create the alert.
- If you want to use Simple Network Management Protocol (SNMP) traps, IBM Tivoli Enterprise Console events, or email as an alert notification, you must

specify disposition values in the Alert Dispositions window. Expand **Administrative Services > Configuration > Alert Disposition**.

To create a computer alert, complete the following steps:

1. In the Navigation Tree pane, expand **Data Manager > Alerting**.
2. Right-click **Computer Alert** and click **Create Alert**. The Create Alert window opens and the Alert page is displayed.
3. Select the **Enabled** check box.
4. In the **Description** field, type a brief description of the job.
5. In the **Triggering-Condition** area, specify the event that will trigger the alert:
  - a. In the **Condition** field, select the triggering condition.
  - b. In the **Value** field, type a numeric value. Depending on the triggering condition that you selected, this field might be unavailable.
  - c. In the **Value Units** field, select the unit of measurement. Depending on the triggering condition that you selected, this field might be unavailable.
6. In the **Triggered-Actions** pane, select the actions that occur as a result of the triggering condition. For an explanation of triggered actions, see “Triggered actions for alerts” on page 1504.
7. Click the **Computer** tab; the Computers page opens.
8. Select the resources to which you want the alert to apply:
  - a. In the **Available** field, click the resources.
  - b. Click . The resources are moved to the **Current Selections** field.
9. Save the alert:
  - a. Click **File > Save**.
  - b. In the Save As window, type a name for the alert in the **Specify Alert name** field and click **OK**. The alert is displayed in the navigation tree.

## Creating file system alerts

You can use these alerts to monitor file systems for available free space, changes in configuration, or a file system being removed or unmounted. When the condition is detected during a scan, a probe, or upon an SNMP event, an alert is generated.

If necessary, complete the following prerequisites before you begin the task:

- If you want a script to be run after an event has triggered an alert, you must create the script before you create the alert.
- If you want to use Simple Network Management Protocol (SNMP) traps, IBM Tivoli Enterprise Console events, or email as an alert notification, you must specify disposition values in the Alert Dispositions window. Expand **Administrative Services > Configuration > Alert Disposition**.

File system alerts can be applied to file systems, file system groups, computers, computer groups, storage systems, storage system groups, and clusters. To create a file system alert, complete the following steps:

1. In the navigation tree, expand **Data Manager > Alerting**.
2. Right-click **Filesystem Alert**, and then click **Create Alert**. The Create Alert panel opens and the Alert page is displayed.
3. Select the **Enabled** check box.
4. In the **Description** field, type a brief description of the job.
5. In the **Triggering-Condition** area, specify the event that will trigger the alert:

- a. In the **Condition** field, select the triggering condition.
  - b. In the **Value** field, type a numeric value. Depending on the triggering condition that you selected, this field might be unavailable.
  - c. In the **Value Units** field, select the unit of measurement. Depending on the triggering condition that you selected, this field might be unavailable.
6. In the **Triggered-Actions** pane, select the actions that occur as a result of the triggering condition. For an explanation of triggered actions, see “Triggered actions for alerts” on page 1504.
  7. Click the **Filesystems** tab; the Filesystems window opens.
  8. Select the resources to which you want the alert to apply:
    - a. In the **Available** field, click the resources.
    - b. Click . The resources are moved to the **Current Selections** field.
  9. Save the alert:
    - a. Click **File > Save**.
    - b. In the Save As window, type a name for the alert in the **Specify Alert name** field and click **OK**. The alert is displayed in the navigation tree.

## Creating directory alerts

You can use these alerts to be notified when either a directory is not found or a directory consumes more than a specified amount of storage space. When a condition is detected during a scan, an alert is generated. These alerts can be applied to directories only.

Before you can create a directory alert, you must have completed the following prerequisites:

- If you want a script to be run after an event has triggered an alert, you must create the script before you create the alert.
- If you want to use Simple Network Management Protocol (SNMP) traps, IBM Tivoli Enterprise Console events, or email as an alert notification, you must specify disposition values in the Alert Dispositions window. Expand **Administrative Services > Configuration > Alert Disposition**.
- Directories must be grouped into a directory group before they can be included in an alert.

To create a directory alert, complete the following steps:

1. In the Navigation Tree pane, expand **Data Manager > Alerting**
2. Right-click **Directory Alert** and click **Create Alert**. The Create Alert window opens and the Alert page is displayed.
3. Select the **Enabled** check box.
4. In the **Description** field, type a brief description of the job.
5. In the **Triggering-Condition** area, specify the event that will trigger the alert:
  - a. In the **Condition** field, select the triggering condition.
  - b. In the **Value** field, type a numeric value. Depending on the triggering condition that you selected, this field might be unavailable.
  - c. In the **Value Units** field, select the unit of measurement. Depending on the triggering condition that you selected, this field might be unavailable.
6. In the **Triggered-Actions** pane, select the actions that occur as a result of the triggering condition. For an explanation of triggered actions, see “Triggered actions for alerts” on page 1504.
7. Click the **Directories** tab; the Directories windows opens.

8. Select the resources to which you want the alert to apply:
  - a. In the **Available** field, click the resources.
  - b. Click . The resources are moved to the **Current Selections** field.
9. Save the alert:
  - a. Click **File > Save**.
  - b. In the Save As window, type a name for the alert in the **Specify Alert name** field and click **OK**. The alert is displayed in the navigation tree.

### Creating hypervisor alerts

Define hypervisor alerts to be notified when certain conditions are detected on monitored hypervisors.

If necessary, complete the following prerequisites before you begin the task:

- If you want a script to be run after an event has triggered an alert, you must create the script before you create the alert.
- If you want to use Simple Network Management Protocol (SNMP) traps, IBM Tivoli Enterprise Console events, or email as an alert notification, you must specify disposition values in the Alert Dispositions window. Expand **Administrative Services > Configuration > Alert Disposition**.

To create a hypervisor alert, complete the following steps:

1. In the navigation tree, expand **Data Manager > Alerting**.
2. Right-click **Hypervisor Alert** and click **Create Alert**.
3. Select the **Enabled** check box.
4. In the **Description** field, type a brief description of the job.
5. In the **Triggering-Condition** area, specify the event that will trigger the alert:
  - a. In the **Condition** field, select the triggering condition.
  - b. In the **Value** field, type a numeric value. Depending on the triggering condition that you selected, this field might be unavailable.
  - c. In the **Value Units** field, select the unit of measurement. Depending on the triggering condition that you selected, this field might be unavailable.
6. In the **Triggered-Actions** pane, select the actions that occur as a result of the triggering condition. For an explanation of triggered actions, see “Triggered actions for alerts” on page 1504.
7. Click the **Hypervisors** tab to view a list of monitored hypervisors.
8. Select the resources to which you want the alert to apply:
  - a. In the **Available** field, click the resources.
  - b. Click . The resources are moved to the **Current Selections** field.
9. Save the alert:
  - a. Click **File > Save**.
  - b. In the Save As window, type a name for the alert in the **Specify Alert name** field and click **OK**. The alert is displayed in the navigation tree.

### Creating other NAS alerts

You can use other network-attached storage (NAS) alerts to monitor systems that include NAS and are not included in other alert types. When a change in configuration or status is detected during a probe or from an SNMP event, an alert is generated.

If necessary, complete the following prerequisites before you begin the task:

- If you want a script to be run after an event has triggered an alert, you must create the script before you create the alert.
- If you want to use Simple Network Management Protocol (SNMP) traps, IBM Tivoli Enterprise Console events, or email as an alert notification, you must specify disposition values in the Alert Dispositions window. Expand **Administrative Services > Configuration > Alert Disposition**.

Other NAS alerts can be applied to NAS clusters, nodes, storage systems, and storage system groups. To create a NAS alert, complete the following steps:

1. In the navigation tree, expand **Data Manager > Alerting**.
2. Right-click **Other NAS Alerts**, and then click **Create Alert**. The Create Alert panel opens and the Alert page is displayed.
3. Select the **Enabled** check box.
4. In the **Description** field, type a brief description of the job.
5. In the **Triggering-Condition** area, specify the event that will trigger the alert:
  - a. In the **Condition** field, select the triggering condition.
  - b. In the **Value** field, type a numeric value. Depending on the triggering condition that you selected, this field might be unavailable.
  - c. In the **Value Units** field, select the unit of measurement. Depending on the triggering condition that you selected, this field might be unavailable.
6. In the **Triggered-Actions** pane, select the actions that occur as a result of the triggering condition. For an explanation of triggered actions, see “Triggered actions for alerts” on page 1504.
7. Click the **NAS** tab; the NAS page opens.
8. Select the resources to which you want the alert to apply:
  - a. In the **Available** field, click the resources.
  - b. Click . The resources are moved to the **Current Selections** field.
9. Save the alert:
  - a. Click **File > Save**.
  - b. In the Save As window, type a name for the alert in the **Specify Alert name** field and click **OK**. The alert is displayed in the navigation tree.

## Creating instance alerts

You can use these alerts to monitor instances for changes. When the condition is detected during a probe, an alert is generated. These alerts can be applied to instances, computers, and computer groups.

If necessary, complete the following prerequisites before you begin the task:

- If you want a script to be run after an event has triggered an alert, you must create the script before you create the alert.
- If you want to use Simple Network Management Protocol (SNMP) traps, IBM Tivoli Enterprise Console events, or email as an alert notification, you must specify disposition values in the Alert Dispositions window. Expand **Administrative Services > Configuration > Alert Disposition**.

To create an instance alert, complete the following steps:

1. From the Navigation Tree pane, expand **Data Manager for Databases > Alerting**.

2. Right-click **Instance Alerts** and click **Create Alert..** The Create Alert window opens and the Alert page is displayed.
3. Select the **Enabled** check box.
4. In the **Description** field, type a brief description of the job.
5. In the **Triggering Condition** area, specify the event that will trigger the alert:
  - a. In the **Rdbms Type** field, select the type of database application. You can choose **All Rdbms, Oracle, SQL\Server, Sybase, or UDB.**
  - b. In the **Condition** field, select the triggering condition.
  - c. In the **Value** field, type a numeric value. Depending on the triggering condition that you selected, this field might be unavailable.
  - d. In the **Value Units** field, select the unit of measurement. Depending on the triggering condition that you selected, this field might be unavailable.
6. In the **Triggered-Actions** pane, select the actions that occur as a result of the triggering condition. For an explanation of triggered actions, see “Triggered actions for alerts” on page 1504.
7. Click the **Instances** tab; the **Instances** window opens.
8. Select the resources to which you want the alert to apply:
  - a. In the **Available** field, click the resources.
  - b. Click . The resources are moved to the **Current Selections** field.
9. Save the alert:
  - a. Click **File > Save.**
  - b. In the Save As window, type a name for the alert in the **Specify Alert name** field and click **OK.** The alert is displayed in the navigation tree.

### Creating database and tablespace alerts

You can use these alerts to monitor database and tablespaces for changes. When a scans or probes are run, events are recognized and alerts triggered. These alerts can be applied to databases, database groups, table spaces, table space groups, instances, computers, and computer groups.

If necessary, complete the following prerequisites before you begin the task:

- If you want a script to be run after an event has triggered an alert, you must create the script before you create the alert.
- If you want to use Simple Network Management Protocol (SNMP) traps, IBM Tivoli Enterprise Console events, or email as an alert notification, you must specify disposition values in the Alert Dispositions window. Expand **Administrative Services > Configuration > Alert Disposition.**

**Note:** (DB2 only) Alerts triggered by table and user statistics will not function until the **runstats** utility is run. This utility ensures that table and user statistics are up-to-date. When you define a scan job for DB2 databases, select the **Perform runstats on all tables being scanned** check box on the **Options** page.

**Note:** (DB2 only) When the following conditions apply, an alert is not generated:

- The triggering condition selected is Database-Tablespace Free Space Less Than.
- The storage entities selected are DB2 databases.
- The table spaces affected by the triggering condition are System Managed Space (SMS) tablespaces.

The alert is not triggered because IBM Tivoli Storage Productivity Center considers SMS containers to be directories on a file system

To create a database-table space alert, complete the following steps:

1. From the Navigation Tree pane, expand **Data Manager for Databases > Alerting**.
2. Right-click **Database-Tablespace Alerts** and click **Create Alert..** The Create Alert window opens and the Alert page is displayed.
3. Select the **Enabled** check box.
4. In the **Description** field, type a brief description of the job.
5. In the **Triggering Condition** area, specify the event that will trigger the alert:
  - a. In the **Rdbms Type** field, select the type of database application. You can choose **All Rdbms**, **Oracle**, **SQL\Server**, **Sybase**, or **UDB**.
  - b. In the **Condition** field, select the triggering condition.
  - c. In the **Value** field, type a numeric value. Depending on the triggering condition that you selected, this field might be unavailable.
  - d. In the **Value Units** field, select the unit of measurement. Depending on the triggering condition that you selected, this field might be unavailable.
6. In the **Triggered-Actions** pane, select the actions that occur as a result of the triggering condition. For an explanation of triggered actions, see “Triggered actions for alerts” on page 1504.
7. Click the **Databases-Tablespaces** tab; the **Databases-Tablespaces** window opens.
8. Select the resources to which you want the alert to apply:
  - a. In the **Available** field, click the resources.
  - b. Click . The resources are moved to the **Current Selections** field.
9. Save the alert:
  - a. Click **File > Save**.
  - b. In the Save As window, type a name for the alert in the **Specify Alert name** field and click **OK**. The alert is displayed in the navigation tree.

## Creating table alerts

You can use these alerts to monitor tables for certain conditions. When the condition is detected during a scan, an alert is generated. These alerts can be applied to table groups and tables only.

- If you want a script to be run after an event has triggered an alert, you must create the script before you create the alert.
- If you want to use Simple Network Management Protocol (SNMP) traps, IBM Tivoli Enterprise Console events, or email as an alert notification, you must specify disposition values in the Alert Dispositions window. Expand **Administrative Services > Configuration > Alert Disposition**.
- Tables must be grouped into a table group before they can be included in an alert.

To create a table alert, complete the following steps:

1. From the Navigation Tree pane, expand **Data Manager for Databases > Alerting**.
2. Right-click **Table Alerts** and click **Create Alert..** The Create Alert window opens and the Alert page is displayed.
3. Select the **Enabled** check box.
4. In the **Description** field, type a brief description of the job.
5. In the **Triggering Condition** area, specify the event that will trigger the alert:

- a. In the **Rdbms Type** field, select the type of database application. You can choose **All Rdbms**, **Oracle**, **SQL\Server**, **Sybase**, or **UDB**.
  - b. In the **Condition** field, select the triggering condition.
  - c. In the **Value** field, type a numeric value. Depending on the triggering condition that you selected, this field might be unavailable.
  - d. In the **Value Units** field, select the unit of measurement. Depending on the triggering condition that you selected, this field might be unavailable.
6. In the **Triggered-Actions** pane, select the actions that occur as a result of the triggering condition. For an explanation of triggered actions, see “Triggered actions for alerts” on page 1504.
  7. Click the **Tables** tab; the **Tables** window opens.
  8. Select the resources to which you want the alert to apply:
    - a. In the **Available** field, click the resources.
    - b. Click . The resources are moved to the **Current Selections** field.
  9. Save the alert:
    - a. Click **File > Save**.
    - b. In the Save As window, type a name for the alert in the **Specify Alert name** field and click **OK**. The alert is displayed in the navigation tree.

### Creating fabric alerts

You can use these alerts to monitor fabrics for changes. When the condition is detected during a probe, an alert is generated. These alerts can be applied to fabrics, zones, and zone sets.

If necessary, complete the following prerequisites before you begin the task:

- If you want a script to be run after an event has triggered an alert, you must create the script before you create the alert.
  - If you want to use Simple Network Management Protocol (SNMP) traps, IBM Tivoli Enterprise Console events, or email as an alert notification, you must specify disposition values in the Alert Dispositions window. Expand **Administrative Services > Configuration > Alert Disposition**.
1. In the Navigation Tree pane, expand **Fabric Manager > Alerting**.
  2. Right-click **Fabric Alert** and click **Create Fabric Alerts**. The Create Fabric Alerts window opens and the Alert page is displayed.
  3. Select the **Enabled** check box.
  4. In the **Description** field, type a brief description of the job.
  5. In the **Triggering Condition** area, specify the event that will trigger the alert.
  6. In the **Triggered-Actions** pane, select the actions that occur as a result of the triggering condition. For an explanation of triggered actions, see “Triggered actions for alerts” on page 1504.
  7. Click the **Fabrics** tab; the Fabrics page opens.
  8. Select the resources to which you want the alert to apply:
    - a. In the **Available** field, click the resources.
    - b. Click . The resources are moved to the **Current Selections** field.
  9. Save the alert:
    - a. Click **File > Save**.
    - b. In the Save As window, type a name for the alert in the **Specify Alert name** field and click **OK**. The alert is displayed in the navigation tree.

## Creating storage system alerts

You can use storage systems alerts to monitor systems for changes in configuration or status. When the condition is detected during a probe, an alert is generated. These alerts can be applied to storage subsystem groups and storage subsystems.

If necessary, complete the following prerequisites before you begin the task:

- If you want a script to be run after an event has triggered an alert, you must create the script before you create the alert.
- If you want to use Simple Network Management Protocol (SNMP) traps, IBM Tivoli Enterprise Console events, or email as an alert notification, you must specify disposition values in the Alert Dispositions window. Expand **Administrative Services > Configuration > Alert Disposition**.

To create a storage subsystem alert, complete the following steps:

1. Expand the **Disk Manager > Alerting** node in the navigation tree.
2. Right-click **Storage Subsystem Alerts**, and click **Create Storage Subsystem Alert**. The Create Storage Subsystem Alert window is opened.
3. In the **Description** field, type a brief description of the job.
4. Select the **Enabled** check box.
5. In the **Triggering Condition** pane, specify the event that will trigger the alert:
  - a. In the **Condition** field, select the triggering condition. See “Triggering conditions for alerts” on page 1489 for a list of triggering conditions that are available for each alert type.
  - b. If you selected a performance threshold, specify the thresholds:
    - 1) In the **Critical Stress** field, type the upper-threshold boundary. When this boundary is exceeded, a critical condition is recognized.
    - 2) In the **Warning Stress** field, type the upper-threshold boundary. When this boundary is exceeded, a warning condition is recognized.
    - 3) In the **Warning Idle** field, type the lower-threshold boundary. When the value falls under this boundary, a warning condition is recognized.
    - 4) In the **Critical Idle** field, type the lower-threshold boundary. When the value falls under this boundary, a critical condition is recognized.

For more information about thresholds, see “Performance thresholds” on page 1508.
6. In the **Alert Suppression** pane, choose the condition under which alerts are triggered, and then choose how to manage repeating alerts. For an explanation of the options in this pane, see “Alert suppression actions” on page 1504.
7. In the **Triggered-Actions** pane, select the actions that occur as a result of the triggering condition. For an explanation of triggered actions, see “Triggered actions for alerts” on page 1504.
8. Click the **Storage Subsystems** tab. The Storage Subsystems page is displayed.
9. Select the storage systems and storage system groups to which you want the alert to apply:
  - a. In the **Available** field, click the storage entities.
  - b. Click . The storage entities are moved to the **Current Selections** field.
10. Save the alert:
  - a. Click **File > Save**.

- b. In the Save As window, type a name for the alert in the **Specify Alert name** field and click **OK**. The alert is displayed in the navigation tree.

## Creating switch alerts

You can use these alerts to monitor switches for changes in configuration or status. When the condition is detected during a probe, an alert is generated. These alerts can only be applied to switches.

If necessary, complete the following prerequisites before you begin the task:

- If you want a script to be run after an event has triggered an alert, you must create the script before you create the alert.
- If you want to use Simple Network Management Protocol (SNMP) traps, IBM Tivoli Enterprise Console events, or email as an alert notification, you must specify disposition values in the Alert Dispositions window. Expand **Administrative Services > Configuration > Alert Disposition**.

To create a switch alert, complete the following steps:

1. In the Navigation Tree pane, expand **Fabric Manager > Alerting**.
2. Right-click **Switch Alerts** and click **Create Switch Alerts**. The Create Switch Alerts page opens and the Alert page is displayed.
3. Select the **Enabled** check box.
4. In the **Description** field, type a brief description of the job.
5. In the **Triggering Condition** pane, specify the event that will trigger the alert:
  - a. In the **Condition** field, select the triggering condition. See “Triggering conditions for alerts” on page 1489 for a list of triggering conditions that are available for each alert type.
  - b. If you selected a performance threshold, specify the thresholds:
    - 1) In the **Critical Stress** field, type the upper-threshold boundary. When this boundary is exceeded, a critical condition is recognized.
    - 2) In the **Warning Stress** field, type the upper-threshold boundary. When this boundary is exceeded, a warning condition is recognized.
    - 3) In the **Warning Idle** field, type the lower-threshold boundary. When the value falls under this boundary, a warning condition is recognized.
    - 4) In the **Critical Idle** field, type the lower-threshold boundary. When the value falls under this boundary, a critical condition is recognized.

For more information about thresholds, see “Performance thresholds” on page 1508.
6. In the **Alert Suppression** pane, choose the condition under which alerts are triggered, and then choose how to manage repeating alerts. For an explanation of the options in this pane, see “Alert suppression actions” on page 1504.
7. In the **Triggered-Actions** pane, select the actions that occur as a result of the triggering condition. For an explanation of triggered actions, see “Triggered actions for alerts” on page 1504.
8. Click the **Switches** tab. The Switches page is displayed.

**Note:** If you selected a performance threshold as the triggering condition, only those switches for which performance data can be collected are listed.

9. Select the storage entities to which you want the alert to apply:
  - a. In the **Available** field, click the storage entities.

- b. Click . The storage entities are moved to the **Current Selections** field.

**Note:** You can select one or more switches from the **Switches** category. For device triggering conditions only, you can select one or more fabrics from the **Switches In Fabric** category. Selecting fabrics will include all switches in those fabrics. You can also select from both categories.

10. Save the alert:
  - a. Click **File > Save**.
  - b. In the Save As window, type a name for the alert in the **Specify Alert name** field and click **OK**. The alert is displayed in the navigation tree.

### Creating endpoint device alerts

You can use these alerts to monitor endpoint devices. When the condition is detected during a probe, an alert is generated. These alerts can be applied to endpoint devices only.

If necessary, complete the following prerequisites before you begin the task:

- If you want a script to be run after an event has triggered an alert, you must create the script before you create the alert.
- If you want to use Simple Network Management Protocol (SNMP) traps, IBM Tivoli Enterprise Console events, or email as an alert notification, you must specify disposition values in the Alert Dispositions window. Expand **Administrative Services > Configuration > Alert Disposition**.

To create an endpoint device alert, complete the following steps:

1. In the Navigation Tree pane, expand **Fabric Manager > Alerting**.
2. Right-click **Endpoint Device Alerts** and click **Create Endpoint Device Alerts**. The Create Endpoint Device Alerts window opens and the Alert page is displayed.
3. Select the **Enabled** check box.
4. In the **Description** field, type a brief description of the job.
5. In the **Triggering Condition** area, specify the event that will trigger the alert.
6. In the **Triggered-Actions** pane, select the actions that occur as a result of the triggering condition. For an explanation of triggered actions, see “Triggered actions for alerts” on page 1504.
7. Click the **Endpoint Devices** tab; the Endpoint Devices page opens.
8. Select the resources to which you want the alert to apply:
  - a. In the **Available** field, click the resources.
  - b. Click . The resources are moved to the **Current Selections** field.
9. Save the alert:
  - a. Click **File > Save**.
  - b. In the Save As window, type a name for the alert in the **Specify Alert name** field and click **OK**. The alert is displayed in the navigation tree.

### Database connection alerts

Database connection alerts notify the Tivoli Storage Productivity Center administrator when the database connection used by the Tivoli Storage Productivity Center server is lost unexpectedly and when the database connection is restored.

If necessary, complete the following prerequisites before you begin the task:

- If you want a script to be run after an event has triggered an alert, you must create the script before you create the alert.
- If you want to use Simple Network Management Protocol (SNMP) traps, IBM Tivoli Enterprise Console events, or email as an alert notification, you must specify disposition values in the Alert Dispositions window. Expand **Administrative Services > Configuration > Alert Disposition**.

The database connection alerts are always enabled and configured to add the alert to the alert log and send an e-mail to the data administrator.

The database connection alerts are:

- DB connection failed
- DB connection successful

You cannot create, configure, delete, disable, edit, or rename these alerts. You can, however, change the destination for the database connection alerts. Expand **Administrative Services > Configuration**. Left-click **Alert Disposition**. In the content pane, under Email, you can change all of the fields.

## Configuring alert destinations

Entries in the Alert Disposition window define destination host addresses for SNMP, IBM Tivoli Enterprise Console, and email.

If you want to send SNMP traps, IBM Tivoli Enterprise Console events, or email when an alert is triggered, you must configure IBM Tivoli Storage Productivity Center with the alert destinations and email settings.

To configure alert dispositions, complete the following steps:

1. In the Navigation Tree pane, expand **Administrative Services > Configuration**.
2. Click **Alert Disposition**. The Edit Alert Disposition window opens.
3. In the **SNMP** area, specify the information about where SNMP traps are sent:
  - a. In the **Community** field, type the name of the SNMP community. By default, this is set to public.
  - b. In the **Host** field, type the fully qualified name of the system that you have configured to receive SNMP traps.
  - c. In the **Port** field, type the port number to which Tivoli Storage Productivity Center will direct SNMP traps. By default, this is set to 162.
  - d. If you want to configure a second SNMP destination, type the required information in the fields in the **SNMP Destination 2** area.
4. In the **TEC** area, specify information about where Tivoli Enterprise Console events are sent:
  - a. In the **Server** field, type the fully qualified name of the Tivoli Enterprise Console server.
  - b. In the **Port** field, type the port number to which Tivoli Storage Productivity Center will direct Tivoli Enterprise Console events. By default, this is set to 5529.
5. In the **Email** area, configure email settings:
  - a. In the **Mail Server** field, type the name of the mail server.
  - b. In the **Mail Port** field, type the port number for the SMTP server.

- c. In the **Default Domain field**, type the domain, for example, MyCompany.com.
  - d. In the **Return to field**, type the email address to which undeliverable mail is sent.
  - e. In the **Reply to field**, type the email address to which email is sent when someone replies to an email notification about an alert. (It is a best practice to specify the email address of an Tivoli Storage Productivity Center administrator.)
  - f. In the **Data Administrator field**, type the email address of the Data Administrator.
6. In the **Alert Log Disposition field**, select the length of time to keep entries in the alert logs. The default is 90 days.

## Deleting alerts

To ensure that the list of alerts in the navigation tree is up-to-date, you can delete alerts that you no longer want to implement.

To delete an alert, complete the following steps:

1. In the navigation tree, complete one of the following actions:

| Alert type                     | Action                                                                                  |
|--------------------------------|-----------------------------------------------------------------------------------------|
| For computer alerts            | Expand <b>Data Manager &gt; Alerting &gt; Computer Alerts.</b>                          |
| For file system alerts         | Expand <b>Data Manager &gt; Alerting &gt; Filesystem Alerts.</b>                        |
| For directory alerts           | Expand <b>Data Manager &gt; Alerting &gt; Directory Alerts.</b>                         |
| For hypervisor alerts          | Expand <b>Data Manager &gt; Alerting &gt; Hypervisor Alerts</b>                         |
| For other NAS alerts           | Expand <b>Data Manager &gt; Alerting &gt; Other NAS Alerts</b>                          |
| For instance alerts            | Expand <b>Data Manager for Databases &gt; Alerting &gt; Instance Alerts.</b>            |
| For database-tablespace alerts | Expand <b>Data Manager for Databases &gt; Alerting &gt; Database-Tablespace Alerts.</b> |
| For table alerts               | Expand <b>Data Manager for Databases &gt; Alerting &gt; Table Alerts.</b>               |
| For storage subsystem alerts   | Expand <b>Disk Manager &gt; Alerting &gt; Storage Subsystem Alerts.</b>                 |
| For fabric alerts              | Expand <b>Fabric Manager &gt; Alerting &gt; Fabric Alerts.</b>                          |
| For switch alerts              | Expand <b>Fabric Manager &gt; Alerting &gt; Switch Alerts.</b>                          |
| For endpoint device alerts     | Expand <b>Fabric Manager &gt; Alerting &gt; Endpoint Device Alerts.</b>                 |

The list of existing alerts is displayed.

2. Right-click the alert and click **Delete**. The Delete Alert window opens.

**Tip:** If **Delete** is not available, you do not have authority to delete the alert.

3. Click **Yes**.

## Disabling an alert

You can disable an alert. This retains the alert definition but prevents the alert from being run.

To disable an alert, complete the following steps:

1. In the Navigation Tree pane, complete one of the following actions:

**For computer alerts**

Expand **Data Manager > Alerting > Computer Alerts**.

**For file system alerts**

Expand **Data Manager > Alerting > Filesystem Alerts**.

**For directory alerts**

Expand **Data Manager > Alerting > Directory Alerts**.

**For hypervisor alerts**

Expand **Data Manager > Alerting > Hypervisor Alerts**.

**For other NAS alerts**

Expand **Data Manager > Alerting > Other NAS Alerts**.

**For instance alerts**

Expand **Data Manager for Databases > Alerting > Instance Alerts**.

**For database-tablespace alerts**

Expand **Data Manager for Databases > Alerting > Database-Tablespace Alerts**.

**For table alerts**

Expand **Data Manager for Databases > Alerting > Table Alerts**.

**For storage subsystem alerts**

Expand **Disk Manager > Alerting > Storage Subsystem Alerts**.

**For fabric alerts**

Expand **Fabric Manager > Alerting > Fabric Alerts**.

**For switch alerts**

Expand **Fabric Manager > Alerting > Switch Alerts**.

**For endpoint device alerts**

Expand **Fabric Manager > Alerting > Endpoint Device Alerts**.

The list of existing alerts is displayed.

2. Click the alert that you want to disable. The Edit Alert page opens.
3. Clear the **Enabled** check box.
4. Click **File > Save**.

## Editing alerts

You can edit an alert if you want to change the triggering condition, triggered action, or the storage resources against which it is deployed.

To edit an alert, complete the following steps:

1. In the navigation tree, complete one of the following actions:

---

| Alert type | Action |
|------------|--------|
|------------|--------|

---

|                                |                                                                                         |
|--------------------------------|-----------------------------------------------------------------------------------------|
| For computer alerts            | Expand <b>Data Manager &gt; Alerting &gt; Computer Alerts.</b>                          |
| For file system alerts         | Expand <b>Data Manager &gt; Alerting &gt; Filesystem Alerts.</b>                        |
| For directory alerts           | Expand <b>Data Manager &gt; Alerting &gt; Directory Alerts.</b>                         |
| For hypervisor alerts          | Expand <b>Data Manager &gt; Alerting &gt; Hypervisor Alerts</b>                         |
| For other NAS alerts           | Expand <b>Data Manager &gt; Alerting &gt; Other NAS Alerts</b>                          |
| For instance alerts            | Expand <b>Data Manager for Databases &gt; Alerting &gt; Instance Alerts.</b>            |
| For database-tablespace alerts | Expand <b>Data Manager for Databases &gt; Alerting &gt; Database-Tablespace Alerts.</b> |
| For table alerts               | Expand <b>Data Manager for Databases &gt; Alerting &gt; Table Alerts.</b>               |
| For storage subsystem alerts   | Expand <b>Disk Manager &gt; Alerting &gt; Storage Subsystem Alerts.</b>                 |
| For fabric alerts              | Expand <b>Fabric Manager &gt; Alerting &gt; Fabric Alerts.</b>                          |
| For switch alerts              | Expand <b>Fabric Manager &gt; Alerting &gt; Switch Alerts.</b>                          |
| For endpoint device alerts     | Expand <b>Fabric Manager &gt; Alerting &gt; Endpoint Device Alerts.</b>                 |

The list of existing alerts is displayed.

2. Click the alert that you want to edit. The Edit Alert page opens.
3. Make any necessary changes.
4. Click **File > Save.**

**Tip:** Some alerts are shown automatically when a client application is registered to receive alerts from Tivoli Storage Productivity Center. You can identify these alerts by the keyword *Pre-defined* in their names. You can hide these alerts from view in the GUI. For more information, see the IBM Tivoli Storage Productivity Center Problem Determination Guide.

## Renaming alerts

You can rename alerts. This might be useful if the original name is ambiguous or lacks clarity.

To rename an alert, complete the following steps:

1. In the navigation tree, complete one of the following actions:

| Alert type             | Action                                                           |
|------------------------|------------------------------------------------------------------|
| For computer alerts    | Expand <b>Data Manager &gt; Alerting &gt; Computer Alerts.</b>   |
| For file system alerts | Expand <b>Data Manager &gt; Alerting &gt; Filesystem Alerts.</b> |
| For directory alerts   | Expand <b>Data Manager &gt; Alerting &gt; Directory Alerts.</b>  |

|                                |                                                                                         |
|--------------------------------|-----------------------------------------------------------------------------------------|
| For hypervisor alerts          | Expand <b>Data Manager &gt; Alerting &gt; Hypervisor Alerts</b>                         |
| For other NAS alerts           | Expand <b>Data Manager &gt; Alerting &gt; Other NAS Alerts</b>                          |
| For instance alerts            | Expand <b>Data Manager for Databases &gt; Alerting &gt; Instance Alerts.</b>            |
| For database-tablespace alerts | Expand <b>Data Manager for Databases &gt; Alerting &gt; Database-Tablespace Alerts.</b> |
| For table alerts               | Expand <b>Data Manager for Databases &gt; Alerting &gt; Table Alerts.</b>               |
| For storage subsystem alerts   | Expand <b>Disk Manager &gt; Alerting &gt; Storage Subsystem Alerts.</b>                 |
| For fabric alerts              | Expand <b>Fabric Manager &gt; Alerting &gt; Fabric Alerts.</b>                          |
| For switch alerts              | Expand <b>Fabric Manager &gt; Alerting &gt; Switch Alerts.</b>                          |
| For endpoint device alerts     | Expand <b>Fabric Manager &gt; Alerting &gt; Endpoint Device Alerts.</b>                 |

The list of existing alerts is displayed.

2. Right-click the alert, and click **Rename**. The Rename Alert window opens.
3. Type the new name, and click **OK**.

## Viewing alerts

View alerts that are detected on monitored resources.

To view an alert, choose one of the following methods:

### Alert log

In the navigation tree, click **IBM Tivoli Storage Productivity Center > Alerting > Alert Log**. The nodes that contain alerts are highlighted in red and are preceded by a red circle. Depending on the node that you select, the page displays all alerts or only the alerts for the resource that you selected. You can filter the alerts that are displayed on a page by selecting an option from the **View** menu. For example, on the **All Alerts** page, select **Storage Subsystem Alerts** from the **View** menu to view only the alerts that were detected on storage subsystems. Figure 31 on page 402 shows the All Alerts panel.

|  | Computer                  | Obj. Type              | Object                  | Alert Type                 | First Triggered         |
|--|---------------------------|------------------------|-------------------------|----------------------------|-------------------------|
|  | (N/A)                     | Configuration Analysis | db2admin.sqz5d3         | Policy Violation           | Apr 23, 2007 9:30:32 AM |
|  | (N/A)                     | Configuration Analysis | db2admin.sqz5d3         | Policy Violation           | Apr 23, 2007 9:30:32 AM |
|  | (N/A)                     | Discovery              | TPCUser.CIMOM Discovery | Job Failed                 | Apr 23, 2007 3:39:59 AM |

|  | (N/A)                     | Discovery              | TPCUser.CIMOM Discovery | Job Failed                 | Apr 21, 2007 3:41:52 AM |
|  | bubs.sanjose.ibm.com      | (N/A)                  |                         | Performance monitor failed | Apr 20, 2007 1:31:06 PM |

Figure 31. Alert History page

To view details about each alert, click or double-click . The Detail for Alert page displays more information (see Figure 32). You can obtain similar information about any alert if you click **Topology** to access the topology viewer. Details are available on the alert overlay in the graphical view and the Alert tab in the table view. The following figure shows the Detail for Alert panel. This panel shows the name of the job, number of the run, type of alert, state of the alert, timestamp, name of the alert creator, name of the alert, and text about the alert

**Detail for Alert**

**Configuration Analysis** db2admin.sqz5d3  
**Run** 1  
**Alert Type** Policy Violation  
**State** Active  
**Timestamp** Apr 23, 2007 9:30:32 AM  
**Alert Creator** TPCUser  
**Alert Name** Default Configuration Analysis Alert  
**Alert Text** ALR0077W: Policy 1 got violated 14 times during the run number 1 of Analyze db2admin.sqz5d3.

The configuration analysis policy violation details can be viewed in the Alert overlay within the topology viewer.

[Topology](#)

Figure 32. Detail for Alert page

### Alert overlay

The alert overlay represents various types of alerts. You can enable or disable the alert overlay in the graphical view of the topology viewer by right-clicking a blank space in the background of the graphical view, clicking **Global Settings** from the menu, and clicking **Alert** under Active overlays (see Figure 33 on page 403). After you make your selection, click **OK**.

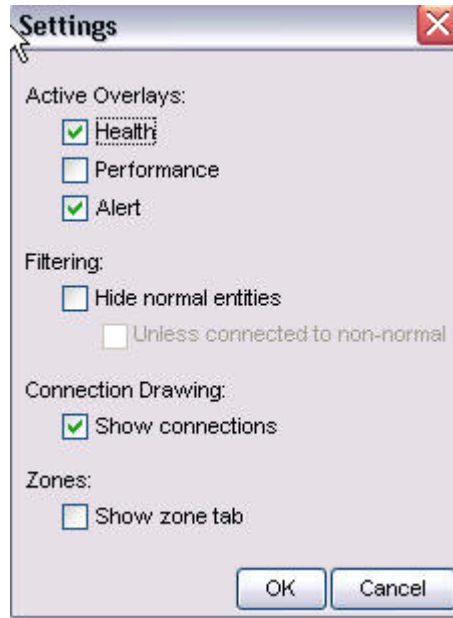

Figure 33. Enabling or disabling the alert overlay. In this example, the alert overlay is enabled.

When the alert overlay is active, entities that have alerts associated with them display a red alert overlay icon  by the pinning icon. The icon also shown in the title bar of groups and tabs. The alert overlay is disabled on the Configuration History panel.

The alert overlay provides rollup, similar to pinning. If alerts are inside a collapsed group, the number of alerts within that group are aggregated and indicated in the collapsed group with an alert icon. All alerts are aggregated into one count, independent of type or entity involved. Hover over the alert icon for a tab or group to determine the total number of alerts that are rolled up into that icon and the time stamp of the newest alert.

In the topology viewer, right-click an entity with an alert icon to display a menu. Click **Show Alerts in Tabular View** to move to the Alert tab and to highlight alerts that are associated with that entity in the table view (see Figure 34 on page 404). When you select an alert under the Alert tab, entities that are associated with that alert are highlighted in purple in the graphical view. Such an action might highlight more than one entity in the topology viewer.

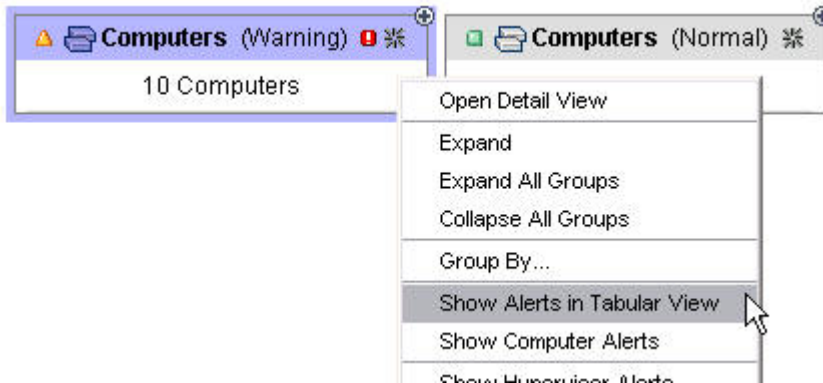

Figure 34. The menu to view alerts in the table view

External alerts do not display in the alert overlay. These alerts are usually Common Information Model (CIM) indications that cannot be tied to specific resources. To view the list of external alerts, click **IBM Tivoli Storage Productivity Center > Alerting > Alert Log > External**.

### Alert tab

The Alert tab is in the table view of the topology viewer (see Figure 35). Click this tab to view a hierarchical list of all current alerts that are associated with entities shown in the topology. For configuration analysis alerts, the highest level provides information about which policy was violated during a particular analyzer run. The next level indicates the number of times that the policy was violated. This list contains one node for each policy violation. The Alert tab lists the policy violations that contain at least one of the affected entities that are displayed in the graphical view. The remaining policy violations are filtered. The only exception is the Overview panel where the Alert tab lists all of the Tivoli Storage Productivity Center alerts. Click each violation to view a list of affected entities. Parent (enclosing) entities display in a separate column.

| Action: Expand All Groups |                          | Locate                  |                                                            |                          |
|---------------------------|--------------------------|-------------------------|------------------------------------------------------------|--------------------------|
| Computer                  |                          | Alert                   |                                                            |                          |
| ...                       | Condition                | △ Last Triggered        | Enclosing Entity                                           | Affected Entity          |
| ⊖                         | <b>Policy 1 Violated</b> | Apr 23, 2007 9:30:32 AM |                                                            |                          |
| ⊖                         | <b>Violation 1</b>       |                         |                                                            |                          |
|                           | Violation 1              |                         | Fabric (200000000000B000)                                  | Zone Set (ZS1-FAB2-TAPE) |
|                           | Violation 1              |                         | Computer (hydrogen.almaden.ibm...FCPort (A00000000000A003) |                          |
| ⊕                         | <b>Violation 2</b>       |                         |                                                            |                          |
| ⊕                         | <b>Violation 3</b>       |                         |                                                            |                          |
| ⊕                         | <b>Policy 2 Violated</b> | Apr 23, 2007 9:30:32 AM |                                                            |                          |

Figure 35. Viewing alerts by using the Alert tab in the table view. Expand the levels to view information about each violation.

For information about fixing policy violations, see “Resolving policy violations” on page 418. You can resort the alert list by clicking the headers in the table. To find resources that are associated with an alert in the graphical view, click the alert in the table to highlight (in purple) the associated resources.

## Viewing alert logs

Use the alert log to view and manage the alert conditions that were detected on the monitored resources in your environment. The alert log contains entries for all alert conditions so that you can monitor and address critical storage events from a central location.

There are two alert logs that are available in the stand-alone GUI. The type of alert determines where information about the alert is shown:

- For alerts generated by Data Manager for Databases, expand **Data Manager for Databases > Alerting > Alert Log**. You can view:
  - All alerts or alerts organized by RDBMS such as by Oracle, SQL Server, Sybase, and UDB. If you do not have a license for a specific RDBMS, no nodes for that RDBMS are displayed under the **Alert Log** node.
  - Alerts by type (such as by Instance, Database-Tablespace, Table, User)
  - Alerts directed to you (the user currently logged on to the UI component)
- For alerts generated by all other components, expand **IBM Tivoli Storage Productivity Center > Alerting > Alert Log**. The alert types that are displayed depend on the Tivoli Storage Productivity Center license type. The following is a list of the possible alert types that are displayed under **Alert Log**:
  - All
  - Alerts Directed to <user-id> - Alerts directed to the user logged on to the interface.
  - Authentication Configuration
  - Replication
  - Storage Subsystem
  - Computer
  - Disk
  - Filesystem
  - Directory
  - User
  - OS User Group
  - Fabric
  - Switch
  - Endpoint Device
  - External
  - Tape Library
  - Configuration Analysis
  - Hypervisor

For alert types that are not displayed for certain license types, see “Product licenses for Tivoli Storage Productivity Center” on page 14

Each alert node has an icon next to it that indicates its status:

- Red-outlined circle: a negative alert occurred, such as job failed, new disk defect.
- Green-outlined box: a neutral alert was detected, such as a new disk detected.

When you click an alert node, the alert log window opens a table that contains

information for all the alerts for that node. Click  on a row to drill down for more information.

The following table describes the buttons on the Alert Log window:

| Button     | Description                                                                                                                                                                                            |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Clear      | Clear the selected alerts. When you click this button, the icon for the alert changes to indicate that the alert was cleared. The alert continues to be displayed in the alert log.                    |
| Delete     | Delete the selected alerts from the alert log.                                                                                                                                                         |
| Clear ALL  | Clear all of the alerts in the report. When you click this button, the icon for all the alerts changes to indicate that the alerts were cleared. The alerts continue to be displayed in the alert log. |
| Delete ALL | Delete all of the alerts in the current report from the alert log.                                                                                                                                     |
| Refresh    | Regenerate the report you are viewing to pick up any newly generated alerts that were triggered since you last generated the report.                                                                   |

**Tip:** Some alerts are shown automatically when a client application is registered to receive alerts from Tivoli Storage Productivity Center. You can identify these alerts by the keyword *Pre-defined* in their names. You can hide these alerts from view in the GUI. For more information, see the IBM Tivoli Storage Productivity Center Problem Determination Guide.

**Restriction:** For database tables, the values in the **Resource Type** and **Resource Name** columns are set to N/A for the following alerts:

- Total Table Size Greater Than
- Chained Row Count Greater Than

## Viewing tape library alerts

View discovered alert conditions in the tape libraries. Alerts are based on the CIM\_AlertIndication specification of SMI-S.

To view these alerts, expand **IBM Tivoli Storage Productivity Center > Alerting > Alert Log** and click the **Tape Library** node.

---

## Checking storage configurations

This section introduces methods that a system administrator can use to assess changes that have occurred in SAN configurations over time and to check whether SAN configurations comply with predefined policies.

### Using configuration history

Capture and analyze historical data that identifies possible problems with a storage area network (SAN) configuration.

**Note:** The configuration history feature is available only with the IBM Tivoli Storage Productivity Center Advanced Edition.

The configuration history feature takes and displays snapshots of changes that occurred in your SAN configuration over a period that you specify. After you set the time period (how often to take snapshots and how long to store them), in a page similar to the topology viewer you can manipulate a snapshot selection panel to show changes that occurred between two or more points in the time period. System administrators can use the configuration history feature to:

### **Correlate performance statistics with configuration changes**

For example, during the collection of performance statistics (including volume performance statistics) on an TotalStorage Enterprise Storage Server system you might delete a volume. While no new statistics are reported on that volume, the Tivoli Storage Productivity Center Performance Manager would have already collected partial statistical information before the volume was deleted. At the end of the data collection task, reporting of the partially collected statistics on the (now) deleted volume would require access to its properties which would not be available. The configuration history feature, with its ability to take and store snapshots of the configuration of a system, could provide access to the properties of the volume.

### **Analyze end-to-end performance**

You want to know why performance changed on volume A during the last 24 hours. To learn why, it is useful to know what changes were made to the configuration of the storage subsystem that might affect the performance of the volume, even if performance statistics were not recorded on some of those elements. For example, even if performance statistics on a per-rank basis are not collected, but the number of volumes that are allocated on a rank is increased from 1 to 100 over time, access to that configuration history information helps with analyzing the degraded performance of the volume over time.

### **Aid in planning and provisioning**

The availability of configuration history can enhance the quality of both provisioning and planning. For example, historical data is useful when you use the Tivoli Storage Productivity Center Volume Performance Advisor to provision a volume or when you use the Tivoli Storage Productivity Center Integrated Host, Security and Subsystem Planner to plan tasks.

To use the configuration history feature, complete the following steps:

1. In the Navigation tree pane, expand **Administrative Services > Configuration > Configuration History Settings**. The Configuration History Settings page displays for you to indicate how often to capture SAN configuration data and how long to retain it.
2. Perform the following to collect historical data:
  - a. In the **Create snapshot every** field, click the check box to enable this option and type how often (in hours) you want the system to take snapshot views of the configuration.
  - b. In the **Delete snapshots older than** field, click the check box to enable this option and type how long (in days) you want the snapshots to be stored.
  - c. The page displays the total number of snapshots in the database and the date and time of when the latest snapshot was taken. To refresh this information, click **Update**.
  - d. To optionally create and title a snapshot on demand, in the **Title this snapshot** field type a name for the on-demand snapshot and click **Create Snapshot Now**. If you do not want to title the on-demand snapshot, click **Create Snapshot Now**.
  - e. To return to the default settings (the default settings are create snapshots every 12 hours and delete snapshots older than 14 days), click **Reset to defaults**.
  - f. To save your settings, click **File > Save**.
3. In the Navigation tree pane, expand **Tivoli Storage Productivity Center > Analytics > Configuration History**, and click **Configuration History**. The

software loads the snapshot data for the length of time that you specified. The Configuration History page (a variation of the topology viewer) displays the configuration entities and a floating snapshot selection panel. In the panel, you can define the periods against which the configuration is compared to determine whether changes occurred.

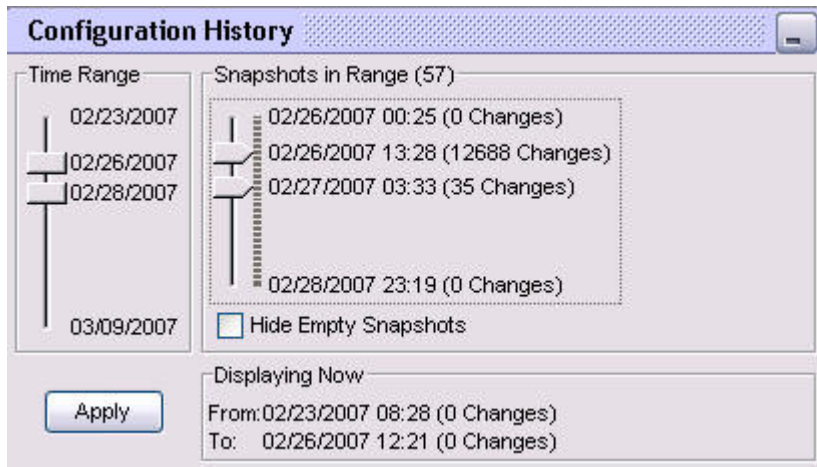

Figure 36. Snapshot selection panel. Use the thumb sliders to establish the time interval that you want to examine.

4. To define the time periods that you want to compare, complete the following steps:
  - a. Using the mouse, drag the two “thumbs” in the **Time Range** slider to establish the time interval. The Time Range slider covers the range of time from the oldest snapshot in the system to the current time. It indicates the date as *mm/dd/yyyy*, where *mm* equals the month, *dd* equals the day, and *yyyy* equals the year.
  - b. Drag the two thumbs in the **Snapshots in Range** slider to indicate the two snapshots to compare. With the Snapshots in Range slider, you can select any two snapshots from the time interval that is specified by the Time Range slider. The value in parentheses for the Snapshots in Range slider indicates the total snapshots in the currently selected time range. The Snapshots in Range slider has one tick mark for each snapshot from the time interval that you specified in the Time Range slider. Each snapshot in the Snapshots in Range slider is represented as time stamp *mm/dd/yyyy hh:mm*, where the first *mm* equals the month, *dd* equals the day, *yyyy* equals the year, *hh* equals the hour, and the second *mm* equals the minute. The value in parentheses for each snapshot indicates the number of changes that occurred between the current and the previous snapshot. Snapshots with zero changes are called empty snapshots. If you provided a title when you created an on-demand snapshot, the title displays after the time stamp. If you want to remove empty snapshots, click the check box to display a check mark in **Hide Empty Snapshots**. The **Displaying Now** box indicates the two snapshots that are currently active.
  - c. Click **Apply**.
5. Determine the changes that occurred to the entities by examining the icons and the colors that are associated with them in the graphical and table views: For information about viewing the changes, see “Viewing configuration changes in the graphical view” on page 409 and “Viewing configuration changes in the table view” on page 411.

One single snapshot selection panel applies for all Configuration History views that are open at the same time. Any change that you make in this panel is applied to all of the Configuration History views.

**Important:** If you manually deleted a missing entity from the Tivoli Storage Productivity Center, the configuration history feature rediscovers and displays the entity in the configuration history viewer as both Missing and in a Normal state. For example, Entity A (with ID 12) is missing and you decide to manually delete it by selecting the **Remove From Database** option from the pop-up menu for Entity A in the topology viewer or configuration history viewer. Later, the Tivoli Storage Productivity Center rediscovers Entity A and assigns it a new ID (ID 22). The configuration history feature treats the same Entity A (with ID 12 and ID 22) as two different entities and displays them in both Missing and Normal states in the configuration history viewer. This scenario can also occur if a missing entity is removed by the Tivoli Storage Productivity Center removed resource retention function and is rediscovered by the Tivoli Storage Productivity Center again at a later time.

**Important:** Name changes for volumes, storage pools, and managed disks are not highlighted as being changed in the Configuration History topology viewer.

### Viewing configuration changes in the graphical view

This section describes how to determine the changes that have occurred to a configuration over time by examining the icons and colors of the change overlay in the graphical view of the Configuration History page.

In the Configuration History page, a *change overlay* presents icons and colors that indicate changes in the configuration between the time that a snapshot was taken and the time that a later snapshot was taken:

- The icons display next to the name of the entity in the graphical view and in the change status column of the table view.
- The colors display as background colors for entities in the graphical view and for affected rows in the table view.

Table 37 describes the icons and colors of the change overlay.

Table 37. Icons and colors of the change overlay

| Change overlay icon                                                                                      | Change overlay color indicator | Description                                                                                                              |
|----------------------------------------------------------------------------------------------------------|--------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <br>Yellow pencil     | Blue background                | Entity changed between the time that the snapshot was taken and the time that a later snapshot was taken.                |
| <br>Light gray circle | Dark gray background           | Entity did not change between the time that the snapshot was taken and the time that a later snapshot was taken.         |
| <br>Green cross       | Green background               | Entity was created or added between the time that the snapshot was taken and the time that a later snapshot was taken.   |
| <br>Red minus sign    | Red background                 | Entity was deleted or removed between the time that the snapshot was taken and the time that a later snapshot was taken. |
| Not applicable                                                                                           | Light gray background          | Entity did not exist at the time that the snapshot was taken or at the time that a later snapshot was taken.             |

Figure 37. Icons and colors of the change overlay. In the graphical view, the pencil icon next to the switches and storage entities and the blue background color indicate that change occurred to these entities. The pencil icon and blue background also appears for these entities in the table view. In the snapshot selection panel, use the Time Range and Snapshots in Range sliders to determine when the change occurred.

To distinguish them from tabs in the topology viewer page, tabs in the Configuration History page (Overview, Computers, Fabrics, Storage, and Other) have a light gray background and are outlined in orange. The minimap in the Configuration History page uses the following colors to indicate the aggregated change status of groups:

- **Blue** - One or more entities in the group have changed. Note that the addition or removal of an entity is considered a change.
- **Gray** - All of the entities in the group are unchanged.

Entities in the graphical view may be *active* (they existed at one or both snapshots) or *inactive* (not yet created or deleted). *Active entities* act like they normally do in the topology viewer; when you select them all relevant information also appears in the table view. You can adjust a grouping of active entities, but you may not perform actions that change the database, such as pinning. *Inactive entities* do not exist in the selected snapshots, but exist in the other snapshots. They are shown in a light gray background and do not have a change icon associated with them. Inactive entities display to keep the topology layout stable and to make it easier to

follow what has changed (instead of having the entities flicker in and out of existence when you change the snapshot selection). Inactive entities are not listed in the table view.

An entity that is moved from one group to another group appears only once in the new group in the graphical view. For example, if the health status of a computer has changed from Normal to Warning, the Configuration History page displays the computer as changed in the Warning health group (and no longer displays the computer in the Normal health group).

**Note:** In the Configuration History view, the performance and alert overlays are disabled and the minimap's shortcut to the Data Path Explorer is not available.

### Viewing configuration changes in the table view

This section describes how to determine the changes that have occurred to a configuration over time by examining the icons and colors of the change overlay in the table view of the Configuration History page.

In the table view, a changed cell or tab is color coded. The change overlay uses the same colors and icons for the table view as for the graphical view (see Table 37 on page 409). The changed cell or tab displays both the old and new values as **Old Value > New Value**. To display a summary of change for the entire row, hover over the changed row. The summary displays the title of the column. It also displays the old and new value for each cell or tab that changed. For example, if a group contains one new entity but everything else in the group is unchanged, the group as a whole displays as “changed.” If you click the group, the one new entity displays as “created” and all other entities display as “unchanged.”

The Change column in the table view also indicates changed entities.

An object that is moved from one group to another group appears only once in the new group in the graphical view. For example, if the health status of a computer has changed from Normal to Warning, the Configuration History page displays the computer as changed in the Warning health group (and no longer displays the computer in the Normal health group).

## Using configuration analysis

This topic describes how system administrators can determine whether an existing SAN configuration complies with predefined best practices (policies).

**Note:** The configuration analysis feature is available only with the IBM Tivoli Storage Productivity Center Advanced Edition.

The configuration analysis feature allows a system administrator to select up to 16 policies and to specify the name of a target SAN (or zone set) for the analysis. The analysis tool reads the specified SAN data and the policy information for the specified policies from the IBM Tivoli Storage Productivity Center database. It outputs the policy violations as Tivoli Storage Productivity Center alerts. To view an alert, you can use one of three methods:

- Click the alert in the Configuration Analysis alert log
- Click the alert overlay icon () next to the affected entity
- Click the Alert tab in the table view of the topology viewer

System administrators can use configuration analysis to learn of any best-practices violations their actions might have caused. For example, in provisioning a new

storage subsystem, an administrator might inadvertently violate a zoning-related policy. If the zoning-related configuration changes persist in the database, configuration analysis can detect this policy violation.

To perform configuration analysis, complete the following steps:

1. Ensure that you have previously run discovery and probe jobs for the computers, fabrics, switches, storage, and other objects of interest.
2. Ensure that the Tivoli Storage Productivity Center Data Server and Device server are running. To do so, in the navigation tree pane, expand the following:
  - **Administrative Services > Services > Data Server > Server**
  - **Administrative Services > Services > Device Server > Device server**
3. Ensure that the following Tivoli Storage Productivity Center agents are installed and configured.

**Tip:** The agent information that is required to evaluate a policy for violations must be collected and stored in the Tivoli Storage Productivity Center database.

- You can have a combination of in-band or Storage Resource agent, out-of-band agent, and CIMOM fabric agents to collect all fabric topology information. This information includes switches, interconnections, and zoning, and is required to evaluate all configuration analysis policies.
  - You can have CIMOM agents for storage subsystems, which collect the storage subsystem information. This information includes subsystem details, storage volumes, storage ports, and storage volumes to hosts mappings, and is required to evaluate configuration analysis policies 2, 3, 5, 7 and 11. CIMOMs are not required to communicate with storage systems that use native interfaces. Tivoli Storage Productivity Center uses native interfaces to connect to the following storage systems:
    - DS8000
    - SAN Volume Controller
    - Storwize V7000
    - IBM Storwize V7000 Unified
    - The XIV system
    - IBM SONAS
  - Data agents or Storage Resource agents to collect the host information (operating system type and version). This information is needed for the evaluation of configuration analysis policies 3 and 9.
  - In-band Fabric agents or Storage Resource agents to collect the attribute information from the host information (HBA and host port details). This information is needed for the evaluation of configuration analysis policies 2, 3, 4, 8 and 9.
  - CIMOM agents for Tape to collect the tape information. This information is needed for the evaluation of configuration analysis policy 2.
4. In the navigation tree pane, expand **IBM Tivoli Storage Productivity Center > Analytics**.
  5. Right-click **Configuration Analysis**. A selection list displays.
  6. Click **Create Analyzer**. The Create Analyzer window opens (see Figure 38 on page 413).

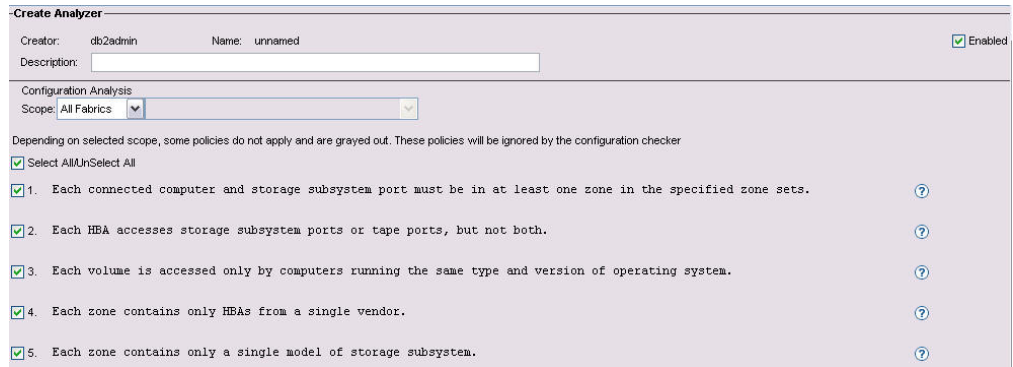

Figure 38. The Create Analyzer window. The figure shows a partial view of the window. Use the Create Analyzer window to select the scope and the policies of the configuration analysis.

7. To define the analysis, do the following steps:
  - a. Select the check box for **Enabled**.
  - b. In the **Description** field, type a brief description of the analysis job.
  - c. To specify the scope of the SAN data to be checked, make a selection from the **Configuration Analysis Scope** list. Choices include:
    - All Fabrics
    - One fabric
    - One Zoneset

If you select One fabric or One Zoneset, an adjacent list displays for you to click a specific fabric or zone set.
  - d. Check the SAN data against up to 16 policies by performing one of the following:
    - Choose all of the policies by selecting the **Select All/Unselect All** check box.
    - Choose one or more individual policies by selecting the check box for each policy.

**Note:** For Policies 12 and 13, type values up to a maximum of 9999.

The policies are described in the following list. You can also access each explanation by clicking  for that policy.

**Each connected computer and storage subsystem port must be in at least one zone in the specified zone sets.**

Determines whether an administrator forgot to zone a connected port. Putting connected ports into zones is useful for security and performance reasons. Ports are usually grouped into zones based on applications, server operating systems, or HBA vendors. The Fabric scope is not supported by this policy.

**Each HBA accesses storage subsystem ports or tape ports, but not both.**

Determines whether an HBA accesses both storage subsystem and tape ports. Because HBA buffer management is configured differently for storage subsystems and tape, it is not desirable to use the same HBA for both disk and tape traffic. The Fabric and Zone Set scopes are not supported by this policy because an HBA can be connected to multiple fabrics.

**Each volume is accessed only by computers running the same type and version of operating system.**

Determines whether computers that run different operating systems access the same storage volumes. Use of the same volumes by computers that run different operating systems may corrupt the data that is stored on the volumes. This applies, regardless of whether the computers are in the same zone.

**Each zone contains only HBAs from a single vendor.**

Determines whether HBAs from different vendor types are in their own zone. Receiving a registered state change notification (RSCN) may cause an HBA to lose a zoned device, preventing the HBA from seeing or communicating with other devices in the zone. To avoid losing a zoned device, keep HBAs from different vendor types in their own zone.

**Each zone contains only a single model of storage subsystem.**

Determines whether different storage subsystems are in the same zone. While no technical problem is associated with storage subsystems from different vendors and of different models being in the same zone, an administrator may find them more difficult to organize. When similar storage systems are in the same zone, an administrator can easily group them for different applications.

**Each zone is part of a zone set.**

Determines the presence of orphan zones. Orphan zones are not associated with any zone set. They are not useful because their definitions are not used and they take up switch resources.

**Each host must be zoned so that it can access all of its assigned volumes.**

Determines whether the zones that were configured by the storage administrator allow each computer to access all of the storage volumes that are assigned to it. The administrator specifies the storage subsystem ports through which the computer port accesses volumes, but may forget to configure zones that enable the ports to communicate during volume assignment. This policy also determines whether zoning makes assigned volumes inaccessible to the computer ports. The Fabric scope is not supported by this policy.

**Each computer has only HBAs of the same model and firmware version.**

Checks whether there is only one type of HBA in each computer. Using only one type of HBA minimizes configuration problems. The policy also checks whether firmware upgrades have been done properly for all HBAs in a computer. The Zone Set scope is not supported by this policy.

**For each host type and operating system, every HBA of a given model must have the same firmware version.**

Determines whether all firmware upgrades have been done for the HBAs in the operating system. The Zone Set scope is not supported by this policy.

**Every SAN switch of a given model must have the same firmware version.**

Determines whether firmware upgrades have been done for all switches of the same type. For example, if you have four identical models of SAN switches from the same vendor and you perform a firmware upgrade on one, it is best to perform the upgrade on all of the others. The Zone set scope is not supported by this policy.

**Every storage subsystem of a given model must have the same firmware version.**

Determines whether firmware upgrades have been done for all storage subsystems of the same type. For example, if you have four identical storage subsystems from the same vendor and you perform a firmware upgrade on one, it is best to perform the upgrade on all of the others. The Zone Set scope is not supported by this policy.

**Each fabric may have a maximum of x zones.**

Checks whether the number of zone definitions in the fabric is larger than the number that you entered. In large fabrics, too large a number of zone definitions can become a problem. Fabric zone definitions are controlled by one of the switches in that fabric, and limiting their number ensures that the switch's zoning tables do not run out of space. The Zone Set scope is not supported by this policy. You can enter up to a maximum of 9999 zones.

**Each zone may have a maximum of x zone members.**

Checks whether the number of zone members in a zone is larger than the number that you entered. In large fabrics, too large a number of zone members can become a problem. Fabric zone members are controlled by one of the switches in that fabric, and limiting their number ensures that the switch's zoning tables do not run out of space. You can enter up to a maximum of 9999 zones.

**Replication Plan is intact with respect to the SRG(s) and the replication session associated during planning through SAN Planner.**

Determines whether SRGs that have associated resiliency profiles are intact with respect to their members and their replication relationships.

**All the source volumes involved in Metro Mirror Failover/Failback sessions are conforming to 1:4 primary to secondary LSS for a failback direction scenario.**

Metro Mirror (Failover/Failback) can be directional, and up to 4 LSS secondaries can be connected to a primary LSS.

**Inter/intra site connectivity is valid for replication plan deployments.**

Checks whether connectivity either direct or through fiber channel fabric exists for resiliency session deployments.

8. To specify how often to run the analysis, scroll to **Scheduling**.
9. In the **How often to run** area, schedule how often you want the job to run. Choose from the following actions:

**Run Now**

Run the job immediately.

**Run Once at**

Run the job once at a specified date and time. Use the list boxes to specify the month, day, and year. Type the hour and minutes over the existing defaults. Click AM or PM.

**Note:** The Tivoli Storage Productivity Center framework that starts the Tivoli Storage Productivity Center jobs finds all jobs in an interval between one minute to the scheduled time and the scheduled start time. This ensures that if many jobs are planned to run at a certain time, they will not all start after the scheduled start time.

### Run Repeatedly

Run the job repeatedly according to a schedule that you specify:

- Indicate when to begin the job. Use the list boxes to specify the month, day, and year. Type the hour and minutes over the existing defaults. Click AM or PM.
  - Indicate how often to run the job. Select one of the following:
    - In the **Repeat Every** field, click the desired number of minutes, hours, days, weeks, or months.
    - In the **Run on these days** field, click to display a check mark next to the desired days.
10. In the **How to handle time zones** area, indicate the time zone to be used when scheduling and running the policy. Click one of the following:

#### Use the time zone that the server runs in

Select this option to use the time zone of the location where the Data server resides.

#### Use this time zone

Select this option to indicate a specific time zone for when to run the job. From the list box, select the time zone.

11. From the menu bar, select **File > Save**. The Save As pop-up opens.
12. Type a name for the analyzer and click **OK**. The Notice pop-up displays **Analyzer submitted**.
13. Click **OK** to begin the job. To display the newly named analyzer job in the Navigation tree pane, expand **IBM Tivoli Storage Productivity Center > Analytics > Configuration Analysis**. The format of the name is *creator.analyzer*, where *creator* is the name that is displayed on the Create Analyzer window and *analyzer* is name that you assigned in step 12 (for example *db2admin.analyzer2*).
14. Expand the job to view information about the run. The information includes the number of times that the job was run, and the date and time of the run. The color of the type indicates the status:
- Blue indicates that the run is in progress.
  - Green indicates that the run is finished.
- To refresh the status, right-click the job and click **Update Job Status**.
15. Click the run to view information about it. On a page titled with the name of the job and run number, the following information is displayed:

**Run** Number of the run

**Status** The status of the run (Success or Failed), not whether policy violations occurred

#### Start Time

The time at which the run started

#### Finish Time

The time at which the run ended

**# Jobs** The number of jobs

#### # failed

The number of jobs that failed

#### Computer

The IP address of the computer on which the job was run

**Status** The status of the run

**Start Time**

The time at which the run started

**Finish Time**

The time at which the run ended

**Log File Name**

The complete path name of the log file

16. To view whether a policy violation occurred, click . The Job log file page displays the following information:
- Scope of the run (all fabrics, one fabric, or one zone set)
  - Policies that were checked
  - Total violations
  - Breakdown of violations per policy
  - Whether the run completed successfully or the errors it encountered

**Note:** To avoid overloading the Topology Viewer, the analysis job stores and displays the first 50 policy violations only. You must resolve these violations and run the job again to view any remaining violations, or you can change this policy violation limit by using the **setdscfg** command. The attribute to set is **MaxPolicyViolationsStored**.

17. To view one or more alerts generated by policy violations, in the Navigation tree expand **IBM Tivoli Storage Productivity Center > Alerting > Alert Log > Configuration Analysis**. The Alert History - All Policy Violations page displays a log of job runs that generated alerts for policy violations. A policy violation alert is generated for each policy that was violated during a run. A policy might be violated several times, but only one alert is generated. The text in the alert indicates the number of times the policy was violated. The Alert History - All Policy Violations page includes the following information:

| Column                                                                              | Description                                                                                                          |
|-------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
|  | When clicked, this provides details about the alert.                                                                 |
|  | When clicked, this makes the Clear and Delete buttons active. When double-clicked, provides details about the alert. |
| Computer                                                                            | Not applicable (N/A)                                                                                                 |
| Configuration Analysis                                                              | The name of the configuration analysis job                                                                           |
| Alert Type                                                                          | The type of alert generated during the run                                                                           |
| First Triggered                                                                     | The date and time of when the first alert was generated                                                              |
| Last Triggered                                                                      | The date and time of when the last alert was generated                                                               |
| # Times                                                                             | The number of times that an alert was generated for a run                                                            |
| Alert Creator                                                                       | The userid of the person who created the run                                                                         |
| Alert Name                                                                          | The official name of the alert                                                                                       |
| Script                                                                              | Not applicable (N/A)                                                                                                 |

For more information about the alert log, see “Viewing alert logs” on page 405.

18. To view details about each alert, in the Alert History - All Policy Violations page click the run that you want, then click  or double-click . The Detail for Alert page displays the following information:

| Field                  | Description                                                                                                                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Configuration Analysis | The name and scope of the analyzer job.                                                                                                                                                                                                                                                                                                |
| Run                    | The number of run in which the alert occurred.                                                                                                                                                                                                                                                                                         |
| Alert Type             | The type of alert (Policy Violation).                                                                                                                                                                                                                                                                                                  |
| State                  | The status of the alert. An <i>active</i> (unresolved) state displays a red exclamation mark  ; an <i>acknowledged</i> (resolved) state displays a green check mark  |
| Timestamp              | The date and time that the alert was created. Expressed as the month, day, year, hour, minute, second, and AM or PM.                                                                                                                                                                                                                   |
| Alert Creator          | The userid of the person who created the analyzer job.                                                                                                                                                                                                                                                                                 |
| Alert Name             | The name of the alert.                                                                                                                                                                                                                                                                                                                 |
| Alert Text             | A description of the policy that was violated and the number of times that it was violated during that analyzer run.                                                                                                                                                                                                                   |

You can also use the topology viewer to view alerts about policy violations. To launch the viewer, click **Topology**. For more information, see “Viewing alerts” on page 401.

### Resolving policy violations

When you click the Alert tab in the topology viewer and expand the entries in the table view, information displays about each configuration analysis policy violation. To verify and fix the policy violation, use the information in the following table.

| Configuration Analysis Policy                                                                                         | Enclosing Entity              | Affected Entity | How to Verify and Fix the Policy Violation                                                                                                                                         |
|-----------------------------------------------------------------------------------------------------------------------|-------------------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Policy 1. Each connected computer and storage subsystem port must be in at least one zone in the specified zone sets. | Computer, Subsystem, or Other | Port            | In the zone tab within the L2:Fabric view, verify that the port is not a member of the zone set. Fix the violation by adding the port to the appropriate zone within the zone set. |
|                                                                                                                       | Fabric                        | Zone set        |                                                                                                                                                                                    |

| Configuration Analysis Policy                                                                              | Enclosing Entity  | Affected Entity | How to Verify and Fix the Policy Violation                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------------------------------------|-------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Policy 2. Each HBA accesses storage subsystem ports or tape ports, but not both.                           | Computer          | HBA             | In the zone tab within the L2:Computer view, verify that HBA ports are accessing both the disk and tape subsystems. Fix the violation by configuring the computer access to disk and tape in two separate zone sets, and ensuring that only one of these is active at a given time.                                                |
| Policy 3. Each volume is accessed only by computers running the same type and version of operating system. | Subsystem         | Volume          | In L1:Computers view, one can see that the computers accessing the volume do not have the same OS type and version. This violation can be fixed by mapping or assigning the volume only to the computers with same OS type and version.                                                                                            |
|                                                                                                            | Computer          | Port            |                                                                                                                                                                                                                                                                                                                                    |
|                                                                                                            | Computer          | Port            |                                                                                                                                                                                                                                                                                                                                    |
| Policy 4. Each zone contains only HBAs from a single vendor.                                               | Fabric            | Zone            | In the zone tab within the L2:Fabric view, find the computers in the zone. Open the respective L2:Computer views and select the HBA tab in the table view to view the vendor of the HBAs on those computers. Fix the violation by editing the zone definition and ensuring that all the HBAs in the zone are from the same vendor. |
| Policy 5. Each zone contains only a single model of storage subsystem.                                     | Fabric            | Zone            | In the L2:Fabric view, verify that the models of the subsystems in the zone are different. Fix the violation by editing the zone definition and ensuring that all the subsystems in the zone have the same model.                                                                                                                  |
|                                                                                                            | Subsystem         | Port            |                                                                                                                                                                                                                                                                                                                                    |
| Policy 6. Each zone is part of a zone set.                                                                 | Fabric            | Zone            | In the zone tab within the L2:Fabric view, verify that the zone does not belong to any of the zone sets and is listed under Orphan Zones. Fix the violation by adding the zone to a zone set or by deleting the zone.                                                                                                              |
| Policy 7. Each host must be zoned so that it can access all of its assigned volumes.                       | Computer or Other | Port            | None of the zones in the L2:Computer or L2:Subsystem views has both the computer and subsystem port. Fix the violation by adding or editing the zone definition, and by ensuring that both the computer and subsystem port are in the same zone.                                                                                   |
|                                                                                                            | Subsystem         | Port            |                                                                                                                                                                                                                                                                                                                                    |
|                                                                                                            | Subsystem         | Volume          |                                                                                                                                                                                                                                                                                                                                    |
| Policy 8. Each computer has only HBAs of the same model and firmware version.                              | Computer          | Computer        | Open the L2:Computer view and select the HBA tab in the table view to verify that the model and firmware version for the HBAs on that computer are different. Fix the violation by installing the HBAs of the same model or upgrading the firmware version of the HBA on that computer.                                            |

| Configuration Analysis Policy                                                                                                                | Enclosing Entity             | Affected Entity     | How to Verify and Fix the Policy Violation                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Policy 9. For each host type and operating system, every HBA of a given model must have the same firmware version.                           | Computer                     | HBA                 | Open the respective L2:Computer views and select the HBA tab in the table view to verify that the firmware and driver version for the HBAs on those computers are different. Fix the violation by upgrading the firmware and driver versions of the HBAs on those computers.                                                                  |
|                                                                                                                                              | Computer                     | HBA                 |                                                                                                                                                                                                                                                                                                                                               |
| Policy 10. Every SAN switch of a given model must have the same firmware version.                                                            | Switch                       | Switch              | Open the L1:Switches view and select the switch tab to verify that the firmware versions on those switches are different. Fix the violation by upgrading the firmware versions on those switches.                                                                                                                                             |
|                                                                                                                                              | Switch                       | Switch              |                                                                                                                                                                                                                                                                                                                                               |
| Policy 11. Every storage subsystem of a given model must have the same firmware version.                                                     | Subsystem                    | Subsystem           | Open the L1:Subsystems view and select the subsystem tab to verify that the firmware versions on those subsystems are different. Fix the violation by upgrading the firmware versions on those subsystems.                                                                                                                                    |
|                                                                                                                                              | Subsystem                    | Subsystem           |                                                                                                                                                                                                                                                                                                                                               |
| Policy 12. Each fabric may have a maximum of $x$ zones.                                                                                      | Fabric                       | Fabric              | In the zone tab within the L2:Fabric view, verify that the number of zones present in the fabric is greater than $x$ (the value entered by the user in this policy). Fix the violation by reducing the number of zones to a value less than $x$ .                                                                                             |
| Policy 13. Each zone may have a maximum of $x$ zone members.                                                                                 | Fabric                       | Zone                | Search for the zone in the zone tab in the L2:Fabric view. Verify that the number of zone members present in that zone is greater than $x$ (the value entered by the user in this policy). Fix the violation by reducing the number of zone members to a value less than $x$ .                                                                |
| Policy 14. Replication Plan is intact with respect to the SRG(s) and the replication session associated during planning through SAN Planner. | Storage Resource Group (SRG) | Replication session | In the alert tab in the L0:Storage Resource Groups view, verify that the numbers of source and target volumes in the SRG are not equal or that the volumes are not in a replication relationship. Fix the violation by running the SAN Planner again and provisioning additional volumes or provisioning resiliency for the existing volumes. |
|                                                                                                                                              | SRG                          | Volume              |                                                                                                                                                                                                                                                                                                                                               |

| Configuration Analysis Policy                                                                                                                                           | Enclosing Entity | Affected Entity         | How to Verify and Fix the Policy Violation                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Policy 15. All the source volumes involved in Metro Mirror Failover/Failback sessions are conforming to 1:4 primary to secondary LSS for a failback direction scenario. | SRG              | Logical Subsystem (LSS) | IBM Tivoli Storage Productivity Center does not have an LSS view, but in the L2:Storage view, you can verify the details of the LSSs responsible for the violation. This violation only occurs if the copy session is created incorrectly in IBM Tivoli Storage Productivity Center for Replication. Fix the violation by changing the session details in Tivoli Storage Productivity Center for Replication to conform with the policy. |
| Policy 16. Inter/intra site connectivity is valid for replication plan deployments.                                                                                     | SRG              | Replication session     | In the alert tab in the L0:Storage Resource Groups view, verify that there is no connectivity between source and target volumes. Fix the violation by manually providing a common fibre channel fabric or direct connection.                                                                                                                                                                                                             |

## Planning and modifying storage configurations

This section describes SAN Planner and how to use it to plan and modify changes to the system configuration.

### Configuring a provisioning plan by using SAN Planner

Use SAN Planner to select configuration information for a provisioning plan and to modify a configuration.

You must run a fabric, disk, and data discovery, and system and fabric configuration probes on the storage controllers that you want to use for planning purposes. You must also run a performance monitor on the storage controllers. You can use the following storage products with SAN Planner:

- TotalStorage Enterprise Storage Server
- System Storage DS6000
- System Storage DS8000
- SAN Volume Controller
- Storwize V7000
- Storwize V7000 Unified
- The XIV system

For other storage products, SAN Planner works with the **Space Only** workload profile.

To obtain host information that is used in volume assignments, you must use a Storage Resource agent. To obtain fabric information, you can do so from another Storage Resource agent in the same fabric, from an out-of-band agent, or through the CIM object manager (CIMOM) that manages the switch. If you do not run a Storage Resource agent, and the storage controller does not have information about the host operating system, an asterisk is displayed next to the host port. The

operating system imposes limits on the number of volumes that you can access. Ensure that you do not exceed these limits.

1. Expand the **IBM Tivoli Storage Productivity Center > Analytics or Disk Manager** node in the navigation tree.
2. Right-click **SAN Planner** and select **Create Plan**. The SAN Planner wizard is displayed. The wizard provides the interface for user input to put together a plan for volume, path, zone, and replication planning. It also provides configuration recommendations based on the current storage configurations and the user inputs.

**Note:** Clicking a saved plan (located under the **SAN Planner** node in the navigation tree) opens the wizard with the Edit Plan *TPCuserid.plan\_name* pane instead of the Create Plan pane, where *TPCuserid* is the Tivoli Storage Productivity Center user ID and *plan\_name* is the name the plan was given when it was previously saved.

3. To move to the next page in the wizard, click **Next**.

### **SAN Planner wizard: Selecting the planning task**

Select the type of storage provisioning plan that you want to create. The type of plan that you select determines the content of the remaining pages in the SAN Planner Wizard.

1. Select the type of provisioning plan from the following options:

**Provision storage only, including optional multipath and zone considerations**

Click to create a plan for provisioning new storage. The plan does not include provisioning for storage replication.

**Provision storage with replication, including optional multipath and zone considerations on the source resources**

Click to create a plan for provisioning new storage and storage replication.

**Provision replication to existing storage**

Click to create a plan for provisioning replication for existing storage (provision target volumes for existing source volumes).

**Configure multipathing or zoning only**

Click to create a plan for provisioning multipathing and zoning for existing storage.

2. To move to the next page in the wizard, click **Next**.

### **SAN Planner wizard: Selecting the provision plan details**

Select the type of storage that you want to provision: volumes or virtual disks. You can also select whether you want to include multipath and zoning provisioning in the SAN plan.

1. To specify the type of storage that you want to provision, click **Volumes** or **Virtual Disks**. If you are provisioning storage for IBM System Storage SAN Volume Controller, you must select **Virtual Disks**.
2. Click **Include multipath planning in the plan** to enable multipath provisioning later in the wizard. This option is unavailable if you selected **Provision replication to existing storage** on the previous page of the wizard.
3. Click **Include fabric rezoning for host planning in the plan** to enable zoning provisioning later in the wizard. This option is unavailable if you selected **Provision replication to existing storage** on the previous page of the wizard.
4. To move to the next page in the wizard, click **Next**.

## SAN Planner wizard: Specifying the plan content

Select the input resources that you want to use in your Storage Area Network (SAN) plan. Input resources can be storage systems, volumes, hosts, or a storage resource group (SRG).

If you plan to use an SRG, you can select the SRG when you add the input resources at the top of this page, or you can select a candidate SRG from the **Use a candidate SRG** at the bottom of this page.

A candidate SRG is an SRG grouping storage resources together. By providing an SRG as a candidate SRG to SAN Planner, you are instructing SAN Planner to consider storage resources from this SRG when doing the capacity planning. Using a candidate SRG provides you with a means of separating your application data from your pool of unused resources.

You can create SRGs using the Storage Resource Group Management panel.

1. To specify the type of storage that you want to provision, click **Add**. The Topology Viewer in the Planner Selection window is opened. The Topology Viewer provides a topology view of the current system configuration.
2. Double-click the box title for a storage item in the topology viewer to expand the storage view into the L0 level view of the available systems. Before selecting systems, you might want to view the relationship between the systems and switch connectivity. To view relationships, double-click a specific system at the L0 Storage tab view. The L1 Subsystems view is opened, which displays the Subsystems and the Connectivity (Switches) boxes. Double-clicking a specific system displays the L2 view of that system and everything the system is connected to.
3. In the L0, L1 or L2 view, first expand the system using the + or – buttons in the upper right corner of the icon for the system. Then you must click the system itself to activate the >> button to include the system in the plan. Click each SAN Planner supported element in the same manner, that you want to include in the SAN plan. To select multiple elements, press and hold the **Ctrl** key and click each element icon.
4. Click  to move the selected elements into the **Selected Elements** pane.

### Tips:

- The **Selected Elements** pane lists the storage resource groups, fabrics, computers, storage systems, pools, and volumes that are selected. When using the **Selected Elements** pane, the subsystem selections are not required to be in the same fabric. The **Fabrics** section lists the fabrics (by WWN) and the corresponding selected systems and selected hosts within each fabric. If a system has been configured in different fabrics, it is listed multiple times. The **Subsystems** section contains the selected storage systems. The number of fabrics to which the system belongs is shown next to each system. Selected pools are listed under their storage systems. Selected volumes are listed under their pools. The **Computers** section lists the selected hosts and the number of fabrics the host belongs to. The hosts are used in path planning and zone planning if **Include multipath planning in the plan** and **Include fabric rezoning for host planning in the plan** are selected in the Select Planning Tasks page.
- To remove an element from the **Selected Elements** pane, select the element and click **Remove**.

5. Click **OK** to save your selections and return to the Specify Plan Content page where the storage elements that you selected are displayed. If an SRG is selected as an input resource, the name of the associated provisioning profile, if any, is displayed.
6. To use a candidate SRG as a pool of storage resources from which to provision new storage, click **Use a candidate SRG**. Select the SRG that you want to use from the **Candidate SRG** list. If you select a candidate SRG, existing unassigned volumes belonging to the candidate SRG are used or new volumes are created from a candidate SRG. The name of the candidate SRG is displayed. Unassigned volumes in the SRGs selected as input resources in the **Selected Elements** pane are not used and new volumes are not created from the input SRG.
7. If you have selected a candidate SRG, click **View SRG** to view the SRG details.
8. To move to the next page in the wizard, click **Next**.

**Related tasks:**

“Working with storage resource groups” on page 491

Use storage resource groups to organize logically related storage entities into named groups. For example, a storage resource group that represents a business critical email application might include all the hosts that participate in the email application cluster, the storage subsystems that provide storage to the application, and the switches and fabrics through which the application’s data is configured to travel.

**SAN Planner wizard: Specifying selected volume assignments for input resources**

Select how the SAN Planner uses any individual unassigned volumes contained in the plan input resources.

If one or more of the volumes in your plan input resources is assigned to hosts, but not all of them are, then you can decide how to assign them.

1. Select the type of volume assignment for your input resources from the following options:

**Use these volumes as candidates for capacity planning**

Click to use the unassigned volumes as candidates for provisioning storage on the Specify Capacity Plan page.

**Assign these volumes to the hosts and skip capacity planning**

Click to omit the Specify Capacity Plan page and continue on with the next steps in the planner. You can view the volume assignment on the Review User Selections page.

**Ignore these volumes in the capacity planning**

Click to remove the volumes from consideration in the plan. If there are no storage pools or storage systems in the input resources, then no capacity planning can be done.

2. To move to the next page in the wizard, click **Next**.

**SAN Planner wizard: Specifying selected volume assignments for an SRG**

Select how the SAN Planner uses any unassigned volumes contained in a candidate storage resource group (SRG).

If one or more of the volumes in your plan candidate SRG is assigned to hosts, but not all of them are, then you can decide how to assign them.

1. Select the type of volume assignment for your candidate SRG from the following options:

**Assign these volumes to the hosts**

Click to assign the volumes to all the hosts and continue to the Specify Capacity Plan page. You can view the volume assignment on the Review User Selections page.

**Ignore these volumes in the capacity planning**

Click to remove the volumes from consideration in the plan and continue to the Specify Capacity Plan page.

2. To move to the next page in the wizard, click **Next**.

### **SAN Planner wizard: Specifying capacity plan**

Create and configure new storage volumes or virtual disks specified in your SAN plan.

- If you want to select any predefined workload profile other than **Space only**, you must have run a performance monitor on the storage controller.
- If you want to select a user-defined workload profile, you must first create a workload profile using the Workload Profiles panel.

Some of the field names that are displayed on the Specify Capacity Plan page differ depending on the type of storage (volumes or virtual disks) that you selected on the Select Provision Plan Details page.

1. In the **Total Capacity** field, enter the total capacity of the volumes or virtual disks that are to be used for provisioning storage in GB. The Topology Viewer in the Planner Selection window is opened. The Topology Viewer provides a topology view of the current system configuration.
2. In the **Number of Volumes** or **Number of Virtual Disks** field, enter the number of volumes or virtual disks that you want to create.
3. In the **RAID level** field, select an Array of Independent Disks (RAID) level for the volume or virtual disk.
4. In the **Volume Name Prefix** or **Virtual Disk Name Prefix** field, enter the prefix to be used in the volume or virtual disk name. If the prefix is longer than 14 characters, a warning prompt is displayed. On the plan recommendation page, if the SAN Planner determines that the prefix length exceeds the naming limitation of the storage system, you are prompted to change the prefix. The following values represent the maximum volume name length for IBM storage systems. The maximum volume name length includes the prefix that you enter + the volume name.

*Table 38. Maximum volume name lengths for storage systems*

| Storage system                        | Maximum volume name length (in characters)* |
|---------------------------------------|---------------------------------------------|
| ESS                                   | 8                                           |
| DS4000, DS5000                        | 30                                          |
| DS6000, DS8000                        | 16                                          |
| XIV                                   | 63                                          |
| SAN Volume Controller 5.1 and earlier | 15                                          |
| SAN Volume Controller 6.1             | 60                                          |

Table 38. Maximum volume name lengths for storage systems (continued)

| Storage system                                                                                                                                                                                                                                                                              | Maximum volume name length (in characters)* |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| <p><b>Note:</b> Tivoli Storage Productivity Center adds one or more characters to the volume name depending upon how many volumes you are creating. For example, if 1-9 volumes are created, one character is added; if 10-99 volumes are created, two characters are added, and so on.</p> |                                             |

5. In the **Workload Profile** field, select a workload profile for the volume or virtual disk. All predefined profiles other than Space only are supported by IBM System Storage DS8000, IBM System Storage DS6000, SAN Volume Controller, and IBM TotalStorage Enterprise Storage Server only.
6. For **The recommended provisioning will be based on the performance data collected between** section, enter a **Start Date** and **End Date** for the collection of performance data that you want to use in planning.
7. Click **Use unassigned volumes not involved in copy relationship** if you want to use existing unassigned volumes. Unassigned volumes that are in a copy relationship are excluded. Exception: The following unassigned volumes are excluded regardless of their copy relationship:
  - Unassigned volumes on IBM storage systems that have copy relationships that were not created in IBM Tivoli Storage Productivity Center or IBM Tivoli Storage Productivity Center for Replication.
8. To move to the next page in the wizard, click **Next**.

### **SAN Planner wizard: Specifying advanced capacity plan**

Select additional options for creating and configuring new storage volumes or virtual disks specified in your SAN plan.

1. To create thin volumes or virtual disks for IBM System Storage SAN Volume Controller, IBM System Storage DS8000, or IBM XIV Storage System, select one of the predefined profiles from the **Thin Provisioning Profile** field. You can also create a profile in the Thin Provisioning Profiles panel. The predefined options are as follows:

#### **Ignore thin provisioning**

A thin provisioning profile is not used.

#### **Standard**

This profile sets the over allocation limit for a pool at 200%. This percentage sets the virtual capacity at up to two times the real capacity.

#### **Conservative**

This profile sets the over allocation limit for a pool at 150%. This percentage sets the virtual capacity at up to one and a half times the real capacity.

#### **Aggressive**

This profile sets the over allocation limit for a pool at 300%. This percentage sets the virtual capacity at up to three times the real capacity.

2. To specify whether you want to use or exclude solid-state disks from provisioning, click one of the following options from the **Solid State Disks** field:

#### **Use Solid State Disks**

Click to use only solid-state disks for provisioning.

#### **Do not use Solid State Disks**

Click to exclude solid-state disks from provisioning,

3. To create new volumes on extent pools that belong to an encryption group, select a value from the **Encryption Group** list. If there are no encryption groups available, **<none selected>** is displayed in this box.
4. Click **Show Recommended Pools** to show the pools to be used for provisioning. The recommended pools are displayed under the corresponding storage systems in the **The following resources are selected for planning** box.
5. Optional: To remove pools from the provisioning process, select a pool or pools from the **The following resources are selected for planning** box and click **Remove Pool**.
6. To move to the next page in the wizard, click **Next**.

**Related tasks:**

“Thin provisioning profiles” on page 550

Learn how to create, modify, and delete thin provisioning profiles.

### **SAN Planner wizard: Specifying path plan**

Set multipath options for provisioning in your SAN plan.

The supported multipath driver on a host is the IBM Subsystem Device Driver (SDD). For Linux-based hosts starting with Red Hat Enterprise Linux Version 5 and SUSE Linux Enterprise Server Version 10, only the DM\_Multipath driver is available. The SDD driver is no longer supported on HP, starting with HP-UX 11i v3 with Itanium®. HP-UX 11i v3 provides a native multipathing feature which is supported by SAN Planner.

1. To specify how the driver uses the paths between the host and the storage system, select one of the following options from the **Multipath Option** field:

**Load Balancing**

Sends input/output on all paths.

**Round Robin**

Sends input/output on one path until a time interval that is set in an SDD setting at the host expires, then switches to another path.

**Fail-Over**

Sends input/output on one path until a failure occurs, then switches to another path.

On HP-UX 11i v3 with Itanium®, the multipath options used by the SAN Planner are as follows:

**Load Balancing**

If you select this option for HP-UX 11i v3, the option implemented is Least Command Load. This option selects the path with the least number of pending I/O requests for the next I/O operation.

**Round Robin**

On HP-UX 11i v3, this policy distributes the I/O load equally across all active paths irrespective of the current load on each path.

**Fail-Over**

If you select this option for HP-UX 11i v3, the policy implemented is Preferred Path. For this policy, you specify a path to an optimized controller. This path is preferred for I/O transfers. The preferred path must be set manually.

2. Select the **Specify number of paths** check box and enter the number of paths that you want to configure between the host and storage system. If you do not specify the number of paths in this field, the default is two paths (**<auto>**)

3. To use the paths from host to storage systems through a minimum of two fabrics, select **Use fully redundant paths (requires at least 2 fabrics)**.
4. To move to the next page in the wizard, click **Next**.

### **SAN Planner wizard: Specifying zone plan**

Use SAN Planner to specify zoning between ports on the hosts and systems in a fabric.

The supported multipath driver on a host is the IBM Subsystem Device Driver (SDD). For Linux-based hosts starting with Red Hat Enterprise Linux Version 5 and SUSE Linux Enterprise Server Version 10, only the DM\_Multipath driver is available. The SDD driver is no longer supported on HP, starting with HP-UX 11i v3 with Itanium®. HP-UX 11i v3 provides a native multipathing feature which is supported by SAN Planner.

1. To specify how the zones are created, select one of the following options from the **Automatically Create Zone** field:

**<auto-zone>**

The plan generates using the maximum number of zones without grouping the data paths based on hosts, host ports, or host bus adapters (HBAs).

**...for each host**

Creates a zone for each host.

**...for each HBA**

Creates a zone for each host bus adapter.

**...for each port**

Creates a zone for each port.

2. Optional: Select the **Specify maximum number of zones** check box and enter the maximum number of zones that you want to create between the host and storage system.
3. Optional: Select the **Maximum zone members per zone** check box and enter the maximum number of zone members for each zone.
4. Optional: If you do not want two controllers with different types to be used in the same zone, select the **No two controllers with different types should be used in the same zone** check box.
5. Optional: If you want to apply updates to the active zone set, select the **Use active zone set** check box. This action applies changes to the inactive zone set that has the same name as the active zone set and then the zone set is activated. Before using this option, ensure that the zones and zone members in the active zone set matches the zones and zone members in the inactive zone set with the same name.
6. Optional: If you want to append a zone prefix to each zone name, select the **Append zone name prefix** check box and enter a prefix.
7. To move to the next page in the wizard, click **Next**.

### **SAN Planner wizard: Selecting replication sessions**

Create a replication session for the storage being provisioned, or, if one is available, use an existing replication session.

This task is available if you have selected either **Provision storage with replication, including optional multipath and zone considerations on the source resources** or **Provision replication to existing storage provisioning plans** on the Select Planning Task page.

1. To create a replication session for the storage being provisioned, click **Create a new replication session for the storage being protected**.
2. If an existing replication session is available, click **Use an existing replication session for the storage being protected** and select the session that you want. An existing session is listed here only if the input contains a storage resource group and that storage resource group has a replication session associated with it.
3. To move to the next page in the wizard, click **Next**.

### **SAN Planner wizard: Specifying replication session properties**

Provide a name for the replication session and select the type of session to create.

This task is available if you have selected either **Provision storage with replication, including optional multipath and zone considerations on the source resources** or **Provision replication to existing storage** provisioning plans on the Select Planning Task page.

1. In the **Session Name** field, enter a name for the replication session.
2. Select a value from the **Session Type** list that displays those replication session types applicable to the kind of planning you have chosen. For example, if you selected **Volumes** on the Select Provision Plan Details page, only the session types pertaining to volume planning are shown. To filter the **Session Type** list, select a value from the **Filter by Copy Technology** list. The value that you select here combined with the value in the **Location** list determines the replication sessions that are shown in the **Session Type** list. The options are:

#### **No filtering**

No filtering is performed.

#### **Point-in-time Copy**

The replication session FlashCopy is displayed in the **Session Type** list.

#### **Continuous Copy**

The replication sessions that are displayed in the **Session Type** list perform continuous replication and depend on the value in the **Location** list.

3. Select a location for the target volumes or virtual disks from the **Location** list. This list is disabled if you selected **No filtering** or **Point-in-time Copy** for filtering. The options are: **Same Region**, **Across Regions**, and **Same and Across Regions**
4. Select the **Use practice volume** check box to include a practice volume in the plan. If you want to practice what you would do in the event of a disaster, without interrupting current data replication, you can use a practice volume. Practice volumes are available in Metro Mirror, Global Mirror, and Metro Global Mirror replication sessions.
5. Click the replication session type that you want to create. The copy type that is associated with the session determines the actions that can be performed against all copy sets in the session, the number of volumes or virtual disks in each copy set, and the role that each volume or virtual disk plays. The options are:
  - FlashCopy
  - VDisk Mirroring
  - Metro Mirror Failover/Failback
  - Metro Mirror Failover/Failback with Practice
  - Metro Mirror Single Direction

- Global Mirror Either Direction with Two Site Practice
- Global Mirror Failover/Failback
- Global Mirror Failover/Failback with Practice
- Global Mirror Single Direction
- Metro Global Mirror with Practice
- Metro Global Mirror

When you select a session type, a session image is displayed. The image is a visual aid to help you create your session. It shows how many roles there are in the session, and how the roles are distributed between the sites. The arrows indicate the type of copy between roles:

- Straight arrows = synchronous Metro Mirror copies
- Zigzag arrows = asynchronous Global Copy relationships
- Lightning bolts = FlashCopy relationships

**Note:** For Global Mirror sessions on IBM(r) System Storage(tm) devices, SAN Planner might report a successful creation and start of the session, but the actual session start might take much longer. Verify the session using IBM Tivoli Storage Productivity Center for Replication.

6. From the **Copy Synchronization Rate**, select the rate that data is copied from the source virtual disk to the target virtual disk. This check box is enabled only if **VDisk Mirroring** is selected in the **Session Type** list.
7. To move to the next page in the wizard, click **Next**.

### **SAN Planner wizard: Specifying a secondary location**

Specify a secondary location for creating target volumes and virtual disks. You can use an existing storage resource group (SRG), create an SRG, or use a candidate SRG. You can also select a provisioning profile for the secondary SRG.

This task is available if you have selected either **Provision storage with replication, including optional multipath and zone considerations on the source resources** or **Provision replication to existing storage** provisioning plans on the Select Planning Task page. If you did not specify an SRG in the input for the source volumes in the Specifying the Plan Content page, the secondary SRG inputs are disabled here. The list of SRGs displayed contains SRGs that are not part of any existing replication sessions. If all SRGs are part of replication sessions, these input fields are disabled.

1. To specify a secondary location, select from the following options:

#### **Secondary Candidate SRG**

Click to select the candidate SRG that you want to use. Click **View SRG** to view the candidate SRG. The secondary candidate SRG is used as the secondary source for the volume creation.

#### **Create a new storage resource group**

Click to create an SRG. Enter the name for the SRG in the **Name** field. This secondary SRG is where the replication target volume will be placed after the replication plan is executed.

#### **Use existing storage resource group**

Click to use an existing SRG. Select the SRG and click **View SRG** to view. This secondary SRG is where the replication target volume will be placed after the replication plan is executed.

2. To select a provisioning profile for the secondary SRG, select from the following options:

#### **Use the source storage resource group profile**

Click to select the provisioning profile that is associated with the source SRG.

#### **Use existing provisioning profile**

Click to use the existing provisioning profile.

3. To move to the next page in the wizard, click **Next**.

### **SAN Planner wizard: Specifying a tertiary location**

Specify a tertiary location for creating target volumes and virtual disks. You can use an existing storage resource group (SRG), create an SRG, or use a candidate SRG. You can also select a provisioning profile for the tertiary SRG.

This task is available if you have selected either **Provision storage with replication, including optional multipath and zone considerations on the source resources** or **Provision replication to existing storage** provisioning plans on the Select Planning Task page, and Metro Global Mirror session as the replication session type. If you did not specify an SRG in the input for the source volumes in the Specifying the Plan Content page, the tertiary SRG inputs are disabled here. The list of SRGs displayed contains SRGs that are not part of any existing replication sessions. If all SRGs are part of replication sessions, these input fields are disabled.

1. To specify a tertiary location, select from the following options:

#### **Tertiary Candidate SRG**

Click to select the candidate SRG that you want to use. Click **View SRG** to view the candidate SRG. The tertiary candidate SRG is used as the tertiary source for the volume creation.

#### **Create a new storage resource group**

Click to create an SRG. Enter the name for the SRG in the **Name** field. This tertiary SRG is where the replication target volume will be placed after the replication plan is executed.

#### **Use existing storage resource group**

Click to use an existing SRG. Select the SRG and click **View SRG** to view. This tertiary SRG is where the replication target volume will be placed after the replication plan is executed.

2. To select a provisioning profile for the tertiary SRG, select from the following options:

#### **Use the source storage resource group profile**

Click to select the provisioning profile that is associated with the source SRG.

#### **Use existing provisioning profile**

Click to use the existing provisioning profile.

3. To move to the next page in the wizard, click **Next**.

### **SAN Planner wizard: Reviewing user selections**

Review your selections in the SAN Planner wizard.

Review your selections in the wizard. If you want to change any settings, click **Back**, and make your changes. Click **Next** to generate the plan. The Getting Recommendation dialog box is displayed while the settings in the wizard are validated and the planning is performed. If the process runs without errors, the Execute Plan page is opened showing the recommended storage configuration plan. If an error occurs, a message that explains the error is displayed.

## SAN Planner wizard: Executing the plan

View the SAN Planner recommended storage configuration. Execute the plan as a job.

1. In the "Plan involves the following changes" pane, review the configuration changes that the SAN Planner job can make.
2. Click **Show Plan Topology** to look at a more detailed view of the planned storage configuration.
3. To accept the configuration changes, click one of the following options to specify when you want the job to run:

### Run now

Click to run the job immediately.

### Run Once at

Click to specify a date and time to run the job and select the appropriate date and time.

4. To specify the time zone that you want to use, click one of the following options:

### Use the time zone that the server runs in

Click to use the time zone where the IBM Tivoli Storage Productivity Center server runs.

### Use this time zone

Select the time zone from the list.

5. Click **Execute Plan** to save the plan and run the job. The job is run at the date, time, and time zone specified by the **When to run** and **How to handle time zones** settings. The plan is saved under the **SAN Planner** node in the Tivoli Storage Productivity Center navigation tree.

**Note:** For Global Mirror sessions on IBM(r) System Storage(tm) devices, SAN Planner might report a successful creation and start of the session, but the actual session start might take much longer. Verify the session using IBM Tivoli Storage Productivity Center for Replication.

## SAN Planner wizard: Editing the plan

Use the Edit panel to edit the plan that was created using the SAN Planner wizard or to change the run time configuration for a plan.

1. Expand the **Disk Manager** node in the navigation tree. Right-click **SAN Planner** and select a saved plan to open the wizard with the Edit Plan *TPCuserid.plan\_name* panel, where *TPCuserid* is the Tivoli Storage Productivity Center user ID and *plan\_name* is the name the plan was given when it was previously saved.
2. Click **View Job History** to view a detailed history of job runs for the plan. The Job Management panel is displayed.
3. In the **Plan involves the following changes** pane, review the configuration changes that the SAN Planner job can make.
4. Click **Show Plan Topology** to look at a more detailed view of the planned storage configuration.
5. In the **When to run pane** pane, click one of the following options to specify when you want the job to run. This pane is disabled if **Run now** is selected for the plan.

### Run now

Click to run the job immediately.

**Run Once at**

Click to specify a date and time to run the job and select the appropriate date and time.

6. To specify the time zone that you want to use, click one of the following options in the **How to handle timezones** pane. This pane is disabled if **Run now** is selected for the plan.

**Use the time zone that the server runs in**

Click to use the time zone where the IBM Tivoli Storage Productivity Center server runs.

**Use this time zone**

Select the time zone from the list.

7. Click **Open Plan Wizard** to open the SAN Planner wizard where you can view or edit the contents of the plan.
8. Click **Save** to save the changes to the plan that you have made on this panel. This option is disabled if the **When to run** and **How to handle time zone** panes are disabled.
9. Click **Execute Plan** to run the plan immediately. This option is disabled if the **When to run** and **How to handle time zone** panes are disabled. settings.
10. Click **Cancel** to cancel the edits that you have made on this panel.

## Working with storage resource group sessions

This topic describes viewing and deleting replication sessions that are created in the SAN Planner wizard for a storage resource group.

You can delete the replication session from IBM Tivoli Storage Productivity Center and optionally also from IBM Tivoli Storage Productivity Center for Replication.

1. In the navigation tree pane, expand **Replication Manager > Storage Resource Group Sessions**. A table of the currently defined storage resource group sessions is displayed in the content pane.
2. To select a storage resource group session to delete, click a row in the table. You can use Ctrl+click and Shift+click to select multiple sessions simultaneously.
3. Click **Delete Storage Resource Group Session**. Tivoli Storage Productivity Center does not automatically delete the replication session from Tivoli Storage Productivity Center for Replication. A dialog box opens enabling you to specify how you want to delete the session. You can select from the following options:
  - Click **Yes** to remove the selected replication session from the Tivoli Storage Productivity Center database and the Tivoli Storage Productivity Center for Replication database.
  - Click **No** to remove the selected replication session from the Tivoli Storage Productivity Center database only.
  - Click **Cancel** to close the dialog box without deleting the selected replication session from the Tivoli Storage Productivity Center database or Tivoli Storage Productivity Center for Replication database.

---

## Optimizing storage configurations

Use the Storage Optimizer to analyze storage subsystems to identify performance bottlenecks and to help you improve subsystem performance. You can also use the report for migration and consolidation recommendations. You can optimize the tiered storage of your system by using the recommendations of the tiering policy analysis to efficiently manage the different storage tiers.

### Storage Optimizer overview

The Storage Optimizer uses data in the IBM Tivoli Storage Productivity Center database to analyze your storage subsystems to identify performance bottlenecks, and recommend changes to improve performance. This topic lists the supported subsystems and describes the general steps for using Storage Optimizer.

The Storage Optimizer helps you develop storage migration or storage consolidation plans, and helps you plan for the growth of your storage infrastructure. For example, you can use the Storage Optimizer to create a weekly report that provides details on the performance of your storage subsystems and makes recommendations for how to improve performance.

**Note:** The Storage Optimizer does not actually perform any migrations or modify subsystem configurations. Its primary purpose is to provide you with a performance analysis and optimization recommendations that you can choose to implement at your discretion.

**Important:** Storage Optimizer does not take into account any established replication relationships or sessions. Follow migration recommendations with care to ensure continuity of all replication relationships.

To use the Storage Optimizer, you must have an IBM Tivoli Storage Productivity Center Advanced license.

The following IBM storage subsystems or applications are supported:

- DS8000
- DS6000
- DS5000
- DS4000
- TotalStorage Enterprise Storage Server
- SAN Volume Controller
- Storwize V7000
- IBM Storwize V7000 Unified block level support
- The XIV system
- IBM SONAS

Before running Storage Optimizer, you must set up performance monitors to collect performance data at least once a day for all storage subsystems that you want Storage Optimizer to analyze. You must also collect performance monitoring data for the back-end subsystems for SAN Volume Controller or Storwize V7000. The performance data for the subsystems produce the most accurate Storage Optimizer analysis.

The analysis is less accurate if there are any gaps in the data collection for the time interval being analyzed. It is recommended that you collect at least one week's

worth of performance monitoring data before using Storage Optimizer. Providing a longer time interval for data collection increases the accuracy of the Storage Optimizer analysis and recommendations. For more information, see “Creating storage subsystem performance monitor” on page 380.

You must provide the Storage Optimizer with the following input:

- Configuration and performance data that you collect for the supported storage subsystems before running the Storage Optimizer
- One or more selected storage subsystems that you specify as input to the Storage Optimizer.
- Connected fabric topology and zoning information is used in the analysis if it is available.

The Storage Optimizer produces the following output:

- An analysis report that displays performance heat maps and tables that graphically illustrate the performance utilization of the storage subsystems that you specified as input.
- An optimization report that provides migration and consolidation recommendations for improving performance.

The Storage Optimizer produces more accurate results if you provide both the required and optional input data requested by the Storage Optimizer, and if you collect storage subsystem performance monitoring data over a longer time interval before using the Storage Optimizer.

**Note:** Since running the Storage Optimizer is a processor-intensive task for the IBM Tivoli Storage Productivity Center server, schedule a time to run the Storage Optimizer when processor demand on the IBM Tivoli Storage Productivity Center server is expected to be at a minimum.

The general steps for using the Storage Optimizer are as follows:

1. In the Create Analysis window, enter information in the required fields and choose **File > Save** to submit the analysis report job. For more information, see “Creating an analysis report” on page 436.
2. Review the Storage Optimizer analysis report. For more information, see “Viewing an analysis report” on page 437.
3. Create an optimization report based on this analysis. For more information, see “Creating an optimization report” on page 439.
4. View the optimization report. For more information, see “Viewing an optimization report” on page 440.
5. At your discretion, implement the recommendations suggested in the optimization report, or rerun the analysis using different inputs.

## Using the Storage Optimizer

This topic describes how to use the Storage Optimizer to analyze storage subsystem performance and create an optimization report that includes recommendations to improve performance.

Before running Storage Optimizer, you must set up performance monitors and collect performance monitoring data for all storage subsystems that you want Storage Optimizer to analyze. Storage Optimizer analyzes performance monitoring data for the time interval you specify. The analysis will be less accurate if there are any gaps in the data collection for the time interval being analyzed. For best

results, collect at least one week's worth of performance monitoring data before using Storage Optimizer. Providing a longer time interval for data collection will increase the accuracy of the Storage Optimizer analysis and recommendations. See "Creating storage subsystem performance monitor" on page 380 for more information.

**Tip:** The Storage Optimizer does not make any modifications to subsystem configurations. Its primary purpose is to provide you with a performance analysis and optimization recommendations that you can choose to implement at your discretion.

## Creating an analysis report

Creating a performance analysis report is the first step in using Storage Optimizer.

When you specify a start time for using performance monitor data in an optimization plan, the start time might not coincide with the start of a performance monitor data collection interval. If the requested start time is after the start of a data collection interval and the duration of the data collection interval is long enough so that it ends at or after the requested start time, Tivoli Storage Productivity Center includes all data from the collection interval that began before the requested start time. This might include data collected before the start time that you specified. This processing ensures that the maximum amount of available performance data is utilized. For example, if a performance monitor collects data every 20 minutes starting at 01:00, but you request performance data starting at 1:15, Tivoli Storage Productivity Center still analyzes performance data starting at 01:00 that has a duration of 20 minutes.

To create the analysis, complete the following steps:

1. Navigate to one of the following nodes:
  - **IBM Tivoli Storage Productivity Center > Analytics > Storage Optimizer**
  - **Disk Manager > Storage Optimizer.**
2. Right-click **Storage Optimizer** and select **Create Analysis** to open the Create Analysis panel. Use this panel to specify the storage subsystems that you want to analyze.
3. Optional: In the **Create Analysis** panel, enter a short description of the analysis job in the **Description** field.
4. The **Select Storage** pane lists the storage subsystems that you want to include in the analysis. Use the **Add** button to add elements to the plan:
  - a. Click **Add**. The **Optimizer Selection** panel opens. This provides a topology view of the current system configuration. Select the storage subsystems that you want to include in the analysis.

**Tip:** The Topology Viewer pane displays the configuration from which selections are made. The Select Elements pane displays the selections that will be used in the analysis.

**Note:** When using the Select Elements pane, the subsystem selections do not need to be in the same fabric.

- b. Double-click the Storage box title to expand the storage view into the L0 level view of the available subsystems.
- c. Click an element to select it. To select multiple elements, press and hold the **CTRL** key and click on each element icon.

- d. Click >> to move the selected elements into the **Select Elements** pane. If you decide to remove the selected elements from the **Select Elements** pane, click <<.
  - e. When you are satisfied with all your selections, click **OK**. You return to the Storage Optimizer Create Analysis panel with the selections displayed in the **Select Storage** pane.
5. Optional: select an element to remove it by clicking **Remove**.
  6. In the **Performance Time Interval** section, for **Data Type**, choose Daily to get average performance data for each 24 hour period, or choose Sample/Hourly to analyze a specific time period each day. Select the **Start Date** and **End Date** to define the date interval that the Storage Optimizer uses to extract performance monitoring data from the IBM Tivoli Storage Productivity Center database. Performance monitoring data must exist in the database for the entire interval you specify. The default date interval is the start and end date of the current date. If you choose Sample/Hourly, specify the **Start Time** and **End Time** of the daily time period that you want to analyze. For example, if you choose Sample/Hourly with November 1 as the start date, November 15 as the end date, and 6 PM as the start time and 8 PM as the end time, then data will be analyzed between 6 PM and 8 PM only for days between November 1 and November 15.
  7. Click **Run Now** to begin the analysis as soon as you save the analysis job using **File > Save**. Alternatively, click **Run Once at** to begin the analysis at a time you specify. When you save the analysis job using **File > Save**, the analysis job appears under the **Storage Optimizer** node in the navigation tree, but the job status is not displayed until the job has started running.
  8. For **How to handle time zones**, specify which time zone to use.
  9. Click **File > Save** to save and submit the analysis report job. After the analysis report job starts, you can view the analysis job status under the **Storage Optimizer** node in the navigation tree.
  10. When the analysis report job is complete, select it to view the analysis report.

## Viewing an analysis report

The analysis report displays a performance analysis for storage systems, and lets you generate an optimization report that lists storage migration and consolidation recommendations. You can experiment with different migration and consolidation scenarios to help you achieve the desired performance improvements for your storage infrastructure.

To view the analysis report:

1. Navigate to one of the following nodes:
  - **IBM Tivoli Storage Productivity Center > Analytics > Storage Optimizer**
  - **Disk Manager > Storage Optimizer**.
2. Expand the **Storage Optimizer** node and select a completed (green) analysis job to display the analysis report. By default, the heat maps display the performance utilization of all components.
3. To display the performance utilization for a specific component, select the component from the **Heat map based on** list.
4. Drag the **Performance Threshold** slider to change the performance threshold for all the selected subsystems. The heat maps are automatically updated to reflect changes in the performance threshold. This allows you to see the performance threshold at which different subsystems or components become bottlenecked.

There is one heat map for each storage subsystem included in the analysis. The heat map uses different colors to represent the actual performance of a storage subsystem, as measured against the default performance threshold of 80%. If you change the performance threshold, the heat maps are automatically updated to display the changes.

Each cell represents a storage pool. If there aren't enough storage pools to fill an entire row, the remaining cells in that row will be gray. Select a cell to display more information about that storage pool. Right-click a cell and choose **show optimizer view** to display performance metrics for volumes in the selected pool.

Green, blue, yellow, orange, and red cells indicate storage pool performance as follows:

**Green** storage pools that are performing at less than or equal to 25% of the performance threshold.

**Blue** storage pools that are performing at less than or equal to 50% of the performance threshold.

**Yellow** storage pools that are performing at less than or equal to 75% of the performance threshold.

**Orange** storage pools that are performing at less than or equal to 100% of the performance threshold.

**Red** storage pools that exceed the performance threshold.

The Performance tables represent the same information that is displayed in each heat map, but in more detail. There is one table for each storage subsystem. Each row represents a storage pool. You can sort the table by clicking a column. Column descriptions are as follows:

**Pool Name**  
the name of the storage pool.

**Utilization**  
the aggregated performance utilization of all components, as measured against the performance threshold.

**Host Adaptor**  
the performance utilization of the host adapter ports on the storage subsystem.

**Hard Disk**  
the performance utilization of the disk arrays.

**Controller**  
processor and memory performance utilization.

**Device Adapter**  
the performance utilization of the device adapter which connects the controller to the disk arrays.

**Space** The physical disk space utilization.

## Creating an optimization report

You can create an optimization report that lists storage migration and consolidation recommendations. You can experiment with different migration and consolidation scenarios to help you achieve the desired performance improvements for your storage infrastructure.

To create the optimization report, follow these steps:

1. Navigate to one of the following nodes:
  - **IBM Tivoli Storage Productivity Center > Analytics > Storage Optimizer**
  - **Disk ManagerStorage Optimizer.**
2. Select a completed analysis job to display the analysis report.
3. To include a storage pool or storage subsystem as a source entity that you want to migrate or consolidate to improve performance:
  - a. In the heat map or table, select a storage pool or storage subsystem. Select **Select all pools for storage subsystem** to select all storage pools in a storage subsystem so that you can include them as source entities.
  - b. Click >> for **Source Entities** to add the selected item to the source entities. The same storage pool cannot be added as both a source and target entity.
  - c. For the list of source entities, if you select **Make retirement recommendations for the selected entity**, the optimization report will make retirement recommendations for all source entities.
  - d. To remove an item from the list of source entities, select it and click <<.

**Note:** The values in the optimization report are estimates and could be influenced by data activity on the selected entity

The Storage Optimizer does not support Easy Tier (mixed pools) as source in a migration or consolidation plan. However, Easy Tier pools are displayed in the Performance Heat Maps and Performance Tables when you create an optimization report. These pools are marked with the text **E.T.** and cannot be selected.

4. To include a storage pool or storage subsystem as a target entity that you want to keep after storage migration and consolidation:
  - a. In the heat map or table, select a storage pool or storage subsystem. Select **Select all pools for storage subsystem** to select all storage pools in a storage subsystem so that you can include them as target entities.
  - b. Click >> for **Target Entities** to add the selected item to the target entities. The same storage pool cannot be added as both a source and target entity.
  - c. To remove an item from the list of target entities, select it and click <<.

When the Storage Optimizer considers potential pools as targets of a migration, it takes into consideration whether the source and target pools have the same RAID level, format (CKD or FB), and whether or not the potential target has enough available capacity. The Storage Optimizer does not support Easy Tier (mixed pools) as target entities in a migration or consolidation plan.

5. Choose when to run the optimization report using one of the following options:
  - **Run Now:** creates the optimization report as soon as you save your report settings by clicking **File > Save**. After the report job begins, you can view the report and job status under the **View Previously Run Optimization Reports** pane.

- **Run Once at:** begins the report job at a specified date and time. When you save the report job by clicking **File > Save**, the report job is displayed under the **View Previously Run Optimization Reports** pane, but the job status will not appear until the job has started running.
6. Drag the **Performance Threshold** slider to change the performance threshold for the selected subsystems and pools. The heat maps are automatically updated to reflect changes in the performance threshold. This allows you to see the performance threshold at which different subsystems and pools become bottlenecked. Keep in mind that if you select the **Make retirement recommendations for the selected entity** option, the threshold you choose using the **Performance Threshold** slider determines if the move to the target subsystem will keep the target subsystem under the chosen threshold.
  7. Click **File > Save** to save and submit the optimization report job.
  8. To update the job status for all optimization reports, click **Refresh Job Status**.
  9. To view a completed optimization report, click  .
  10. To see how the optimization recommendations change if you use a different performance threshold, select a different performance threshold and run another optimization report. You can continue creating optimization reports using different performance thresholds until you achieve the expected performance improvements.

## Viewing an optimization report

The optimization report displays a storage migration and consolidation report that lists recommendations for improving storage subsystem performance.

The Storage Optimizer does not actually perform any migrations or make any modifications to subsystem configurations. Its primary purpose is to provide you with recommendations that you can choose to implement at your discretion.

**Important:** Storage Optimizer does not take into account any established replication relationships or sessions. Migration recommendations should be followed with care to ensure continuity of all replication relationships.

To view the optimization report:

1. Navigate to one of the following nodes:
  - **IBM Tivoli Storage Productivity Center > Analytics > Storage Optimizer**
  - **Disk ManagerStorage Optimizer**.
2. Select a completed analysis job.
3. Optional: Under the **View Previously Run Optimization Reports** pane, click **Refresh Job Status** to update the job status for all optimization reports.
4. Click  to open an optimization report.
5. To view the results of implementing only some of the recommendations, remove the check mark next to **Select all recommendations** and select a subset of the recommendations from the table of recommendations. Only the selected recommendations will be included in the printed report.
6. To display the performance utilization for a specific component, select the component next to **Heat map based on**.
7. To print the report, click the **Print** button in the optimization report. If a PDF printer driver is installed, you can print the report to a PDF file. Alternatively,

you can print the report to a printer. The printed report includes an explanation of each recommendation, and sample migration scripts for the SAN Volume Controller.

The optimization recommendations include the following information:

**Recommendation number**

The sequential number associated with the recommendation.

**Source subsystem**

The name of the source subsystem.

**Target subsystem**

The name of the target subsystem.

**Source volume**

The name of the source volume.

**Target volume**

The name of the target volume.

**Source pool**

The name of the source pool.

**Target pool**

The name of the target pool.

**Reason**

The reason why the storage pool utilization has exceeded the performance threshold.

**Port information**

The recommendation on which ports need to be configured on the target subsystem for the target volume. This information only appears in the printed report.

**Zone information**

The recommended zoning changes necessary so that the target volume is visible to the host. This information only appears in the printed report.

**SVC pseudoscript**

The sample migration script that serves as a guide to the commands that you must enter using the SAN Volume Controller command-line interface. This information only appears in the printed report.

After you implement the recommendations, if you want to verify that you have achieved the expected performance improvements, you must first collect more performance monitoring data before running the Storage Optimizer again.

## Deleting analysis jobs

You can delete analysis job definitions or individual analysis jobs if you no longer need them.

To delete an analysis job definition or job run:

1. Navigate to one of the following nodes:
  - **IBM Tivoli Storage Productivity Center > Analytics > Storage Optimizer**
  - **Disk ManagerStorage Optimizer> Disk Manager.**
2. Expand the **Storage Optimizer** node.
3. Right-click an analysis job definition or an analysis job.
4. Click **Delete**.

Keep in mind that deleting an analysis job definition also deletes all analysis jobs and optimization reports that are associated with that job definition. If you delete an analysis job, all optimization reports associated with that job are also deleted.

## Deleting an optimization report

You can delete optimization reports if you no longer need them.

To delete an optimization report job:

1. Navigate to one of the following nodes:
  - **IBM Tivoli Storage Productivity Center > Analytics > Storage Optimizer**
  - **Disk ManagerStorage Optimizer.**
2. Expand the **Storage Optimizer** node.
3. Select a completed analysis job to display the list of optimization reports that are associated with that analysis job.
4. Under **View Previously Run Optimization Reports**, right-click a completed report and choose **Delete**.

## Retrieving an optimization report job definition

You can retrieve the report job definition that was used to generate an optimization report.

To retrieve the optimization report job definition associated with an optimization report:

1. Navigate to one of the following nodes:
  - **IBM Tivoli Storage Productivity Center > Analytics > Storage Optimizer**
  - **Disk ManagerStorage Optimizer.**
2. Expand the **Storage Optimizer** node.
3. Select a completed analysis job to display the list of optimization reports that are associated with that analysis job under **View Previously Run Optimization Reports**.
4. Right-click an optimization report and choose **Retrieve**.

The **Generate Optimization Report** pane displays the inputs that were used to create the selected optimization report.

## Understanding zoning recommendations

This topic describes the zoning recommendations provided by Storage Optimizer in the printed optimization report.

**Note:** Storage Optimizer only provides zoning recommendations in the printed optimization report. The report lists the zoning recommendations for all volumes under each volume.

Where possible, Storage Optimizer provides zoning recommendations for each migration recommendation. The zoning recommendations will be to put the target subsystem's port(s) into the same zones as that of the source subsystem's ports, regardless of which zones the host is also a member of.

For example, suppose you want Storage Optimizer to provide zoning recommendations using the following source and target subsystems.

Source subsystem A includes the following:

- Port 1 (member of zones: host1\_zone, host2\_zone, host3\_zone)

- Port 2 (member of zones: host4\_zone, host5\_zone, host6\_zone)
- Volume X (mapped to host1 using Port 1)
- Volume Y (mapped to host4 using Port 2)

Target subsystem B includes the following:

- Port 1
- Port 2

Suppose that Storage Optimizer recommends migrating Volume X from Source subsystem A to Target subsystem B. The zoning recommendations that accompany this migration recommendation will be to add Target subsystem B's Port 1 to zones host1\_zone, host2\_zone, and host3\_zone.

## Optimizing tiered storage

You can optimize the tiered storage of your system by defining storage tiering policies that specify criteria that determine when volumes should be moved from one storage pool to another. Using the recommendations of the tiering policy analysis, you can ensure that the different storage tiers are efficiently managed.

You can optimize the tiered storage on SAN Volume Controller, Storwize V7000, and Storwize V7000 Unified storage systems.

For example, you might have three different storage tiers with the first tier having the highest performance capacity and being the most expensive storage. You can manage each storage tier, especially the high performing storage, to meet the performance and access goals of your system. To help you achieve this goal, you can use the CLI tiering policy commands.

By creating storage tiering policies and running the tiering policy analysis, you can use the analysis information to ensure that storage volumes are in the appropriate storage tier. The tiering policy analysis compares recent performance data and file system usage data with policy conditions that you specify for the tiering policies. This comparison determines whether volumes are in an incorrect storage tier.

The tiering policy analysis recommends the appropriate storage pools to which volumes should be migrated. You can then move the volumes to the appropriate storage tier. For example, you might want to move infrequently accessed volumes from a high-performance storage tier to a lower-performance storage tier, which is, correspondingly, less expensive. The tiering policy analysis does not migrate the volumes.

In addition, you can use the Volume Migration Recommendation Report to help you analyze tiering policies and to improve your storage utilization.

### Related reference:

“Volume Migration Recommendation Report” on page 1306

The Volume Migration Recommendation Report, shows the volumes that comply with the criteria for migrating volumes to a pool in another storage resource group. Use the report to identify volumes that might require migration based on the conditions that are set in tiering policies.

## Storage tiering policies

You can define storage tiering policies and specify criteria for volumes to be migrated from one storage resource group to another. Using the information that is

provided by the tiering policy analysis, you can optimize the usage of the different storage tiers by ensuring that volumes are moved to the correct tier.

Use CLI commands to specify storage tiering policies. For example, in a typical scenario, you create, analyze, and modify tiering policies:

- Create a tiering policy that is associated with specific storage resource groups by using the **mktp** command.
- Add conditions to the tiering policy by using the **addtpcondition** command.
- Evaluate tiering policies by using the **analyzetsp** command, which recommends which storage entities to migrate.
- Change the attributes of the tiering policy by using the **modifytsp** command.
- Modify the conditions of the tiering policy by using the **rmtptconditions** command and then the **addtpcondition** command.
- Verify the changes to the tiering policy by using the **lstp** command.
- Retrieve the results of the most recent tiering policy analysis by using the **gettprec** command.
- Remove the tiering policy by using the **rmtpt** command.

You add conditions to a tiering policy that are used during the tiering policy analysis to determine which storage entities to recommend for migration. For example, you can add any of the following conditions:

- Specify that the candidate volumes should be moved by using the **force** condition type.
- Exclude volumes from consideration by subsequent policies for being moved by using the **ignore** condition type.
- Compare the percentage of files with last accessed times that are less or greater than an age that you specify to a percentage you specify by using the **age** condition type.
- Compare the measured I/O rate per GB of a volume to the I/O rate that you specify by using the **iodensity** condition type.

The tiering policy analysis does not migrate volumes; it recommends which volumes to migrate based on the tiering policy conditions that you specify.

Volumes must meet the qualifying criteria before they can be recommended for migration, for example:

- The volumes must be in an online storage pool.
- There must be online storage pools in the destination storage resource groups that are on the same storage system and that have sufficient space.
- Both the current and destination storage pools must be in a non-error state.

When there are no suitable destination pools, the tiering policy analysis cannot make recommendations. Therefore, it is possible that only some or none of the volumes in the source storage resource group are recommended if the destination storage resource group does not have sufficient space.

You can also use the Volume Migration Recommendation Report to help you analyze tiering policies. This report provides migration recommendations by tiering policy.

**Related concepts:**

“Optimizing tiered storage” on page 443

You can optimize the tiered storage of your system by defining storage tiering policies that specify criteria that determine when volumes should be moved from one storage pool to another. Using the recommendations of the tiering policy analysis, you can ensure that the different storage tiers are efficiently managed.

**Related reference:**

“Volume Migration Recommendation Report” on page 1306

The Volume Migration Recommendation Report, shows the volumes that comply with the criteria for migrating volumes to a pool in another storage resource group. Use the report to identify volumes that might require migration based on the conditions that are set in tiering policies.

---

## Enforcing storage policies

Enforcing policies for storage usage can be critical to ensuring the proper and most cost-effective use of storage devices. Policies are enforced when conditions that you defined are detected by a monitoring job. Use quotas, constraints, and scheduled actions to manage and enforce your storage policies.

Use the **Policy Management** node in Data Manager and Data Manager for Databases to manage and enforce storage policies.

For example, if you want to enforce a policy that limits the amount of space a group of users can consume on the network, use a Data Manager quota. That quota will be triggered: 1) after a scan is run and 2) the scan detected that a group of users is consuming more storage space than was indicated in the quota.

The following table describes the jobs you can use to enforce policies for storage usage in your environment:

*Table 39. Descriptions of policy types and their triggering conditions*

| Policy Type / Manager                                                                                                                                                                                                             | What can I do with this job?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | What conditions can trigger an alert?                                                                                                                                                                                                                                       |

## Setting storage usage quotas

Use quotas to set limits on the amount of storage space that a user or group of users can consume. You can use Data Manager and Data Manager for Databases to set quotas at the file system, computer, network, database, table space, and instance levels.

Use quotas to set limits on the amount of storage that a user or a group of users can consume.

The following steps provide an overview of how quotas work:

1. A scan gathers extensive information about the storage resources within an enterprise. This information is stored in the database repository.
2. When a quota job runs, it checks the information in the repository to determine whether any quota violations exist.
3. If there are any violations, an alert is triggered and the appropriate action is taken.

**Note:** Because the information that is analyzed by quotas is provided by scans, schedule the quota to run after the scan to collect information. This ensures that quotas are using the latest information about an enterprise to determine violations.

You can define two different kinds of quotas: User and OS User Group.

### User Quota

Select users and groups of users for a quota that are defined in Data Manager or Data Manager for Databases

### OS User Group Quota

Select OS User Groups for a quota. OS User Groups are groups of users that are defined in the operating system outside of Data Manager. You can create Groups that contain many OS User Groups. When you create a quota of this type, you can select individual OS User Groups and groups that consist of multiple OS User Groups.

By providing you with the ability to define quotas at different levels, you can control precisely how much storage a user or user group can consume on specific file systems, computers, network, databases, table spaces, and instances:

### File system

Set storage usage limits on specific file systems and groups of file systems that are monitored by Data Manager. You are alerted if a user or group of users exceeds the storage usage limit that is defined for the specific file system or groups of file systems in the quota.

### Computer

Set storage usage limits on specific computers and groups of computers that are monitored by Data Manager. You are alerted if a user or group of users exceeds the storage usage limit that is defined for the specific computers or groups of computers in the quota.

### Database-Tablespace

Set storage usage limits on specific databases, table spaces, groups of databases, and groups of table spaces that are monitored by Data Manager for Databases. You are alerted if a user or group of users exceeds the storage usage limit that is defined for those storage resources in the quota.

### Instance

Set storage usage limits on specific instances, computers, and groups of

computers that are monitored by Data Manager for Databases. You are alerted if a user or group of users exceeds the storage usage limit that you defined for the specific instances, computers, and groups of computers in the quota.

### Network

Set network-level storage usage limits for multiple computers, groups of computers, file systems, databases, and table spaces within your network that are monitored by Data Manager and Data Manager for Databases.

## Creating a network-wide quota

Learn how to create a quota that generates an alert when a user or group of users consumes more than a specified amount of storage space across the filesystems and computers on a network.

To create a network-wide quota, complete the following steps:

1. In the Navigation tree pane, expand **Data Manager > Policy Management > Quotas**.
2. Expand the **User** or **OS User Group** node depending upon which entity you want to apply a quota.
3. Select the level at which you want to apply the quota by right-clicking **Network**.
4. Select **Create Quota** from the pop-up menu. The Create Quota window opens.
5. In the **Description** field, type a brief description of the quota.
6. Select a profile from the **Profile** selection list to control which storage usage statistics are used when checking for quota violations. You can select any of the GROUP\_BY\_OWNER type profiles shown. Make sure that the selected profile is used in scans of all the filesystems chosen on the **Filesystems** tab. This ensures that the quota is fairly enforced for all users.
7. Select users or user groups against which you want to apply the quota:
  - a. In the **Available** field, click the users or groups of users against which you want to apply the quota.
  - b. Click . The users or groups are moved to the **Current Selections** field.
8. Click the **Filesystems** tab; the Filesystems page opens.
9. Select filesystems, filesystem groups, computers, and computers groups on which you want to limit the storage usage of users and user groups.
  - a. In the **Available** field, click the storage resources to which you want to apply the quota. The groups displayed in this field were created using **Data Manager > Monitoring > Groups**.
  - b. Click . The resources are moved to the **Current Selections** field.
10. Click the **When to Run** tab; the When to Run page opens.
11. In the **How often to run** area, schedule how often you want the quota to be checked. You can choose from the following actions:

#### Run Now

Check the quota immediately.

#### Run Once at

Check the quota once at a specified time and date. You can use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM.

**Note:** The Tivoli Storage Productivity Center framework that starts the Tivoli Storage Productivity Center jobs finds all jobs in an interval between one minute to the scheduled time and the scheduled start time. This ensures that if many jobs are planned to run at a certain time, they will not all start after the scheduled start time.

### Run Repeatedly

Check the quota repeatedly according to a schedule you specify. You can:

- Use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM when the job should begin running.
- Indicate how often the job should run. You can use the drop-down lists to specify the number of minutes, hours, days, weeks, or months.
- Indicate which days on which run the job. A check mark is displayed next to the days you select.

12. In the **How to Handle Time Zones** area, indicate the time zone to be used when scheduling and running the policy. For example, if you selected to run the job at 9:00 AM, you can use the fields in this section to run it at:
  - a. 9:00 AM of the time zone where the Data server resides
  - b. 9:00 AM of a specific time zone, such as 9:00 AM CST or 9:00 GMT. For example, if you select 9:00 AM CST, the job will run at 7:00 AM on an agent located in the PST time zone.

### Use the timezone that the server runs in

Select this option to use the time zone of the location where the Data server resides.

### Use this timezone

Select this option to indicate a specific time zone for when to run the job. When you select this option, a drop-down list is activated. Select the timezone from this drop-down list.

13. Click the **Alert** tab; the Alert page opens.
14. In the **Triggering Condition** area, specify the event that will trigger the alert:
  - a. In the **Condition** field, the default setting is **User Consumes More Than *n***, where *n* represents a value that you define in the **Value** field. No other conditions are available.
  - b. In the **Value** field, type a numeric value that represents the storage usage limit for the quota. If the storage entities selected for the quota (for example, users and user groups) exceed this limit, the quota is triggered.
  - c. In the **Value Units** field, select the unit of measurement: kilobytes, megabytes, or gigabytes.
15. In the **Triggered Actions** area, select the actions that occur as a result of the triggering condition You can choose from the following actions:

### SNMP trap

An SNMP trap is sent to any NMS, console, or terminal when the condition occurs.

### TEC / OMNIBus Event

A IBM Tivoli Enterprise Console event is sent when the condition occurs. The Tivoli Enterprise Console administrator can write correlation and automation rules to analyze Tivoli Storage Productivity Center events according to the event definitions specified in the tivoliSRM.baroc file (provided with the product). It also

performs responses such as sending further notification, creating or updating trouble tickets, running programs, and so on.

**Login notification**

The alert is sent to a Tivoli Storage Productivity Center user. The user receives the alert upon logging in to Tivoli Storage Productivity Center. In the **Login ID** field, type the user ID.

**Login ID**

The ID of the user who receives alert notification upon logging in to the system.

**Windows Event Log, UNIX Syslog**

The ID of the user who receives alert notification upon logging in to the system.

**Event Type (Windows Event Log only)**

The type of event that is recorded to the OS log.

**Facility (UNIX Syslog only)**

The location where the UNIX Syslog is sent. You can select User or Local.

**Level (UNIX Syslog only)**

The level of UNIX Syslog event. You can select Informational, Notice, Warning, Error, Critical, or Alert.

**Run script**

A script is run when the condition occurs. Click **Define** to specify the script that is run when the triggering condition occurs. The parameters listed in the **Specify Script** window are passed to the script when the alert is triggered

**Email** An email is sent. Click **Add** or **Delete** to edit the list of email addresses to which an email is sent. Click **Edit email** to change the actual email message.

16. Save the quota:
  - a. Click **File > Save**. The Save As window opens.
  - b. In the **Specify Quota name** field, type a name for the quota and click **OK**. The quota is displayed in the navigation tree pane

## Creating a network-wide quota for databases

Learn how to create a quota that generates an alert when a user or group of users consumes more than a specified amount of RDBMS storage space across the databases, tablespaces, groups of database-tablespaces, computers, and groups of computers on a network.

To create a network-wide quota, complete the following steps:

1. In the Navigation tree pane, expand **Data Manager for Databases > Policy Management > Quotas**.
2. Select the level at which you want to apply the quota by right-clicking **Network**.
3. Select **Create Quota** from the pop-up menu. The Create Quota window opens.
4. In the **Description** field, type a brief description of the quota.
5. Select a profile from the **Profile** selection list to control which storage usage statistics are used when checking for quota violations. You can select any of the GROUP\_BY\_OWNER type profiles shown. Make sure that the selected

profile is used in scans of all the databases and tablespaces chosen on the **Databases-Tablespaces** tab. This ensures that the quota is fairly enforced for all users.

6. Select users or user groups against which you want to apply the quota:
  - a. In the **Available** field, click the users or groups of users against which you want to apply the quota.
  - b. Click . The users or groups are moved to the **Current Selections** field.
7. Click the **Databases-Tablespaces** tab; the Databases-Tablespaces page opens.
8. Select the databases, tablespaces, database-tablespaces groups, computers, and computer groups on which you want to limit the storage usage of users and user groups.
  - a. In the **Available** field, click the storage resources to which you want to apply the quota. The groups displayed in this field were created using **Data Manager for Databases > Monitoring > Groups**.
  - b. Click . The resources are moved to the **Current Selections** field.
9. Click the **When to Run** tab; the When to Run page opens.
10. In the **How often to run** area, schedule how often you want the quota to be checked. You can choose from the following actions:

#### **Run Now**

Check the quota immediately.

#### **Run Once at**

Check the quota once at a specified time and date. You can use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM.

**Note:** The Tivoli Storage Productivity Center framework that starts the Tivoli Storage Productivity Center jobs finds all jobs in an interval between one minute to the scheduled time and the scheduled start time. This ensures that if many jobs are planned to run at a certain time, they will not all start after the scheduled start time.

#### **Run Repeatedly**

Check the quota repeatedly according to a schedule you specify. You can:

- Use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM when the job should begin running.
- Indicate how often the job should run. You can use the drop-down lists to specify the number of minutes, hours, days, weeks, or months.
- Indicate which days on which run the job. A check mark is displayed next to the days you select.

11. In the **How to Handle Time Zones** area, indicate the time zone to be used when scheduling and running the policy. For example, if you selected to run the job at 9:00 AM, you can use the fields in this section to run it at:
  - a. 9:00 AM of the time zone where the Data server resides
  - b. 9:00 AM of a specific time zone, such as 9:00 AM CST or 9:00 GMT. For example, if you select 9:00 AM CST, the job will run at 7:00 AM on an agent located in the PST time zone.

**Use the timezone that the server runs in**

Select this option to use the time zone of the location where the Data server resides.

**Use this timezone**

Select this option to indicate a specific time zone for when to run the job. When you select this option, a drop-down list is activated. Select the timezone from this drop-down list.

12. Click the **Alert** tab; the Alert page opens.
13. In the **Triggering Condition** area, specify the event that will trigger the alert:
  - a. In the **Condition** field, the default setting is **User Consumes More Than *n***, where *n* represents a value that you define in the **Value** field. No other conditions are available.
  - b. In the **Value** field, type a numeric value that represents the storage usage limit for the quota. If the storage entities selected for the quota (for example, users and user groups) exceed this limit, the quota is triggered.
  - c. In the **Value Units** field, select the unit of measurement: kilobytes, megabytes, or gigabytes.
14. In the **Triggered Actions** area, select the actions that occur as a result of the triggering condition. You can choose from the following actions:

**SNMP trap**

An SNMP trap is sent to any NMS, console, or terminal when the condition occurs.

**TEC / OMNIbus Event**

A IBM Tivoli Enterprise Console event is sent when the condition occurs. The Tivoli Enterprise Console administrator can write correlation and automation rules to analyze Tivoli Storage Productivity Center events according to the event definitions specified in the tivoliSRM.baroc file (provided with the product). It also performs responses such as sending further notification, creating or updating trouble tickets, running programs, and so on.

**Login notification**

The alert is sent to a Tivoli Storage Productivity Center user. The user receives the alert upon logging in to Tivoli Storage Productivity Center. In the **Login ID** field, type the user ID.

**Login ID**

The ID of the user who receives alert notification upon logging in to the system.

**Windows Event Log, UNIX Syslog**

The ID of the user who receives alert notification upon logging in to the system.

**Event Type (Windows Event Log only)**

The type of event that is recorded to the OS log.

**Facility (UNIX Syslog only)**

The location where the UNIX Syslog is sent. You can select User or Local.

**Level (UNIX Syslog only)**

The level of UNIX Syslog event. You can select Informational, Notice, Warning, Error, Critical, or Alert.

### Run script

A script is run when the condition occurs. Click **Define** to specify the script that is run when the triggering condition occurs. The parameters listed in the **Specify Script** window are passed to the script when the alert is triggered

**Email** An email is sent. Click **Add** or **Delete** to edit the list of email addresses to which an email is sent. Click **Edit email** to change the actual email message.

15. Save the quota:
  - a. Click **File > Save**. The Save As window opens.
  - b. In the **Specify Quota name** field, type a name for the quota and click **OK**. The quota is displayed in the navigation tree pane

### Creating a computer quota

Learn how to create a quota that generates an alert when a user or group of users consumes more than a specified amount of storage space across computers and groups of computers.

To create a computer quota, complete the following steps:

1. In the Navigation tree pane, expand **Data Manager > Policy Management > Quotas**.
2. In the **Description** field, type a brief description of the job.
3. Expand the **User** or **OS User Group** node depending upon which entity you want to apply a quota.
4. Select the level at which you want to apply the quota by right-clicking **Computer**.
5. Select **Create Quota** from the pop-up menu. The Create Quota window opens.
6. In the **Description** field, type a brief description of the quota.
7. Select a profile from the **Profile** selection list to control which storage usage statistics are used when checking for quota violations. You can select any of the GROUP\_BY\_OWNER type profiles shown.
8. Select users or user groups against which you want to apply the quota:
  - a. In the **Available** field, click the users or groups of users against which you want to apply the quota.
  - b. Click . The users or groups are moved to the **Current Selections** field.
9. Click the **Computers** tab; the Computers page opens.
10. Select computers and computers groups on which you want to limit the storage usage of users and user groups.
  - a. In the **Available** field, click the computers and computers groups to which you want to apply the quota. The groups displayed in this field were created using **Data Manager > Monitoring > Groups**.
  - b. Click . The resources are moved to the **Current Selections** field.
11. Click the **When to Run** tab; the When to Run page opens.
12. In the **How often to run** area, schedule how often you want the quota to be checked You can choose from the following actions:

### Run Now

Check the quota immediately.

### Run Once at

Check the quota once at a specified time and date. You can use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM.

**Note:** The Tivoli Storage Productivity Center framework that starts the Tivoli Storage Productivity Center jobs finds all jobs in an interval between one minute to the scheduled time and the scheduled start time. This ensures that if many jobs are planned to run at a certain time, they will not all start after the scheduled start time.

### Run Repeatedly

Check the quota repeatedly according to a schedule you specify. You can:

- Use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM when the job should begin running.
  - Indicate how often the job should run. You can use the drop-down lists to specify the number of minutes, hours, days, weeks, or months.
  - Indicate which days on which run the job. A check mark is displayed next to the days you select.
13. In the **How to Handle Time Zones** area, indicate the time zone to be used when scheduling and running the policy. For example, if you selected to run the job at 9:00 AM, you can use the fields in this section to run it at:
- a. 9:00 AM of the time zone where the Data server resides
  - b. 9:00 AM of a specific time zone, such as 9:00 AM CST or 9:00 GMT. For example, if you select 9:00 AM CST, the job will run at 7:00 AM on an agent located in the PST time zone.

### Use the timezone that the server runs in

Select this option to use the time zone of the location where the Data server resides.

### Use this timezone

Select this option to indicate a specific time zone for when to run the job. When you select this option, a drop-down list is activated. Select the timezone from this drop-down list.

14. Click the **Alert** tab; the Alert page opens.
15. In the **Triggering Condition** area, specify the event that will trigger the alert:
- a. In the **Condition** field, the default setting is **User Consumes More Than *n***, where *n* represents a value that you define in the **Value** field. No other conditions are available.
  - b. In the **Value** field, type a numeric value that represents the storage usage limit for the quota. If the storage entities selected for the quota (for example, users and user groups) exceed this limit, the quota is triggered.
  - c. In the **Value Units** field, select the unit of measurement: kilobytes, megabytes, or gigabytes.
16. In the **Triggered Actions** area, select the actions that occur as a result of the triggering condition You can choose from the following actions:

### SNMP trap

An SNMP trap is sent to any NMS, console, or terminal when the condition occurs.

### **TEC / OMNIbus Event**

A IBM Tivoli Enterprise Console event is sent when the condition occurs. The Tivoli Enterprise Console administrator can write correlation and automation rules to analyze Tivoli Storage Productivity Center events according to the event definitions specified in the tivoliSRM.baroc file (provided with the product). It also performs responses such as sending further notification, creating or updating trouble tickets, running programs, and so on.

### **Login notification**

The alert is sent to a Tivoli Storage Productivity Center user. The user receives the alert upon logging in to Tivoli Storage Productivity Center. In the **Login ID** field, type the user ID.

### **Login ID**

The ID of the user who receives alert notification upon logging in to the system.

### **Windows Event Log, UNIX Syslog**

The ID of the user who receives alert notification upon logging in to the system.

### **Event Type (Windows Event Log only)**

The type of event that is recorded to the OS log.

### **Facility (UNIX Syslog only)**

The location where the UNIX Syslog is sent. You can select User or Local.

### **Level (UNIX Syslog only)**

The level of UNIX Syslog event. You can select Informational, Notice, Warning, Error, Critical, or Alert.

### **Run script**

A script is run when the condition occurs. Click **Define** to specify the script that is run when the triggering condition occurs. The parameters listed in the **Specify Script** window are passed to the script when the alert is triggered.

**Email** An email is sent. Click **Add** or **Delete** to edit the list of email addresses to which an email is sent. Click **Edit email** to change the actual email message.

17. Save the quota:
  - a. Click **File > Save**. The Save As window opens.
  - b. In the **Specify Quota name** field, type a name for the quota and click **OK**. The quota is displayed in the navigation tree pane.

## **Creating a filesystem quota**

Learn how to create a quota that generates an alert when a user or group of users consumes more than a specified amount of storage space across filesystems, groups of filesystems, computers, and groups of computers.

To create a filesystem quota, complete the following steps:

1. In the Navigation tree pane, expand **Data Manager > Policy Management > Quotas**.
2. Expand the **User** or **OS User Group** node depending upon which entity you want to apply a quota.
3. Select the level at which you want to apply the quota by right-clicking **Filesystem**.

4. Select **Create Quota** from the pop-up menu. The Create Quota window opens.
5. In the **Description** field, type a brief description of the job.
6. Select a profile from the **Profile** selection list to control which storage usage statistics are used when checking for quota violations. You can select any of the GROUP\_BY\_OWNER type profiles shown. Make sure that the selected profile is used in scans of all the filesystems chosen on the **Filesystems** tab. This ensures that the quota is fairly enforced for all users.
7. Select users or user groups against which you want to apply the quota:
  - a. In the **Available** field, click the users or groups of users against which you want to apply the quota.
  - b. Click . The users or groups are moved to the **Current Selections** field.
8. Click the **Filesystems** tab; the Filesystems page opens.
9. Select filesystems, filesystems, computers, and computer groups on which you want to limit the storage usage of users and user groups.
  - a. In the **Available** field, click the storage resources to which you want to apply the quota. The groups displayed in this field were created using **Data Manager > Monitoring > Groups**.
  - b. Click . The resources are moved to the **Current Selections** field.
10. Click the **When to Run** tab; the When to Run page opens.
11. In the **How often to run** area, schedule how often you want the quota to be checked. You can choose from the following actions:

**Run Now**

Check the quota immediately.

**Run Once at**

Check the quota once at a specified time and date. You can use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM.

**Note:** The Tivoli Storage Productivity Center framework that starts the Tivoli Storage Productivity Center jobs finds all jobs in an interval between one minute to the scheduled time and the scheduled start time. This ensures that if many jobs are planned to run at a certain time, they will not all start after the scheduled start time.

**Run Repeatedly**

Check the quota repeatedly according to a schedule you specify. You can:

- Use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM when the job should begin running.
- Indicate how often the job should run. You can use the drop-down lists to specify the number of minutes, hours, days, weeks, or months.
- Indicate which days on which run the job. A check mark is displayed next to the days you select.

12. In the **How to Handle Time Zones** area, indicate the time zone to be used when scheduling and running the policy. For example, if you selected to run the job at 9:00 AM, you can use the fields in this section to run it at:
  - a. 9:00 AM of the time zone where the Data server resides

- b. 9:00 AM of a specific time zone, such as 9:00 AM CST or 9:00 GMT. For example, if you select 9:00 AM CST, the job will run at 7:00 AM on an agent located in the PST time zone.

**Use the timezone that the server runs in**

Select this option to use the time zone of the location where the Data server resides.

**Use this timezone**

Select this option to indicate a specific time zone for when to run the job. When you select this option, a drop-down list is activated. Select the timezone from this drop-down list.

- 13. Click the **Alert** tab; the Alert page opens.
- 14. In the **Triggering Condition** area, specify the event that will trigger the alert:
  - a. In the **Condition** field, the default setting is **User Consumes More Than *n***, where *n* represents a value that you define in the **Value** field. No other conditions are available.
  - b. In the **Value** field, type a numeric value that represents the storage usage limit for the quota. If the storage entities selected for the quota (for example, users and user groups) exceed this limit, the quota is triggered.
  - c. In the **Value Units** field, select the unit of measurement: kilobytes, megabytes, or gigabytes.
- 15. In the **Triggered Actions** area, select the actions that occur as a result of the triggering condition You can choose from the following actions:

**SNMP trap**

An SNMP trap is sent to any NMS, console, or terminal when the condition occurs.

**TEC / OMNIbus Event**

A IBM Tivoli Enterprise Console event is sent when the condition occurs. The Tivoli Enterprise Console administrator can write correlation and automation rules to analyze Tivoli Storage Productivity Center events according to the event definitions specified in the tivoliSRM.baroc file (provided with the product). It also performs responses such as sending further notification, creating or updating trouble tickets, running programs, and so on.

**Login notification**

The alert is sent to a Tivoli Storage Productivity Center user. The user receives the alert upon logging in to Tivoli Storage Productivity Center. In the **Login ID** field, type the user ID.

**Login ID**

The ID of the user who receives alert notification upon logging in to the system.

**Windows Event Log, UNIX Syslog**

The ID of the user who receives alert notification upon logging in to the system.

**Event Type (Windows Event Log only)**

The type of event that is recorded to the OS log.

**Facility (UNIX Syslog only)**

The location where the UNIX Syslog is sent. You can select User or Local.

### Level (UNIX Syslog only)

The level of UNIX Syslog event. You can select Informational, Notice, Warning, Error, Critical, or Alert.

### Run script

A script is run when the condition occurs. Click **Define** to specify the script that is run when the triggering condition occurs. The parameters listed in the **Specify Script** window are passed to the script when the alert is triggered

**Email** An email is sent. Click **Add** or **Delete** to edit the list of email addresses to which an email is sent. Click **Edit email** to change the actual email message.

16. Save the quota:
  - a. Click **File > Save**. The Save As window opens.
  - b. In the **Specify Quota name** field, type a name for the quota and click **OK**. The quota is displayed in the navigation tree pane

## Creating an instance quota

Learn how to create a quota that generates an alert when a user or group of users consumes more than a specified amount of RDBMS storage space across instances, computers, and groups of computers.

To create an instance quota, complete the following steps:

1. In the Navigation tree pane, expand **Data Manager for Databases > Policy Management > Quotas**.
2. Select the level at which you want to apply the quota by right-clicking **Instance**.
3. Select **Create Quota** from the pop-up menu. The Create Quota window opens.
4. In the **Description** field, type a brief description of the quota.
5. Select a profile from the **Profile** selection list to control which storage usage statistics are used when checking for quota violations. You can select any of the GROUP\_BY\_OWNER type profiles shown.
6. Select users or user groups against which you want to apply the quota:
  - a. In the **Available** field, click the users or groups of users against which you want to apply the quota.
  - b. Click . The users or groups are moved to the **Current Selections** field.
7. Click the **Instances** tab; the Instances page opens.
8. Select the instances, computers, and computer groups on which you want to limit the storage usage of users and user groups.
  - a. In the **Available** field, click the storage resources to which you want to apply the quota. The groups displayed in this field were created using **Data Manager for Databases > Monitoring > Groups**.
  - b. Click . The resources are moved to the **Current Selections** field.
9. Click the **When to Run** tab; the When to Run page opens.
10. In the **How often to run** area, schedule how often you want the quota to be checked. You can choose from the following actions:

### Run Now

Check the quota immediately.

### Run Once at

Check the quota once at a specified time and date. You can use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM.

**Note:** The Tivoli Storage Productivity Center framework that starts the Tivoli Storage Productivity Center jobs finds all jobs in an interval between one minute to the scheduled time and the scheduled start time. This ensures that if many jobs are planned to run at a certain time, they will not all start after the scheduled start time.

### Run Repeatedly

Check the quota repeatedly according to a schedule you specify. You can:

- Use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM when the job should begin running.
- Indicate how often the job should run. You can use the drop-down lists to specify the number of minutes, hours, days, weeks, or months.
- Indicate which days on which run the job. A check mark is displayed next to the days you select.

11. In the **How to Handle Time Zones** area, indicate the time zone to be used when scheduling and running the policy. For example, if you selected to run the job at 9:00 AM, you can use the fields in this section to run it at:
  - a. 9:00 AM of the time zone where the Data server resides
  - b. 9:00 AM of a specific time zone, such as 9:00 AM CST or 9:00 GMT. For example, if you select 9:00 AM CST, the job will run at 7:00 AM on an agent located in the PST time zone.

### Use the timezone that the server runs in

Select this option to use the time zone of the location where the Data server resides.

### Use this timezone

Select this option to indicate a specific time zone for when to run the job. When you select this option, a drop-down list is activated. Select the timezone from this drop-down list.

12. Click the **Alert** tab; the Alert page opens.
13. In the **Triggering Condition** area, specify the event that will trigger the alert:
  - a. In the **Condition** field, the default setting is **User Consumes More Than *n***, where *n* represents a value that you define in the **Value** field. No other conditions are available.
  - b. In the **Value** field, type a numeric value that represents the storage usage limit for the quota. If the storage entities selected for the quota (for example, users and user groups) exceed this limit, the quota is triggered.
  - c. In the **Value Units** field, select the unit of measurement: kilobytes, megabytes, or gigabytes.
14. In the **Triggered Actions** area, select the actions that occur as a result of the triggering condition You can choose from the following actions:

### SNMP trap

An SNMP trap is sent to any NMS, console, or terminal when the condition occurs.

### **TEC / OMNIbus Event**

A IBM Tivoli Enterprise Console event is sent when the condition occurs. The Tivoli Enterprise Console administrator can write correlation and automation rules to analyze Tivoli Storage Productivity Center events according to the event definitions specified in the tivoliSRM.baroc file (provided with the product). It also performs responses such as sending further notification, creating or updating trouble tickets, running programs, and so on.

### **Login notification**

The alert is sent to a Tivoli Storage Productivity Center user. The user receives the alert upon logging in to Tivoli Storage Productivity Center. In the **Login ID** field, type the user ID.

### **Login ID**

The ID of the user who receives alert notification upon logging in to the system.

### **Windows Event Log, UNIX Syslog**

The ID of the user who receives alert notification upon logging in to the system.

### **Event Type (Windows Event Log only)**

The type of event that is recorded to the OS log.

### **Facility (UNIX Syslog only)**

The location where the UNIX Syslog is sent. You can select User or Local.

### **Level (UNIX Syslog only)**

The level of UNIX Syslog event. You can select Informational, Notice, Warning, Error, Critical, or Alert.

### **Run script**

A script is run when the condition occurs. Click **Define** to specify the script that is run when the triggering condition occurs. The parameters listed in the **Specify Script** window are passed to the script when the alert is triggered.

**Email** An email is sent. Click **Add** or **Delete** to edit the list of email addresses to which an email is sent. Click **Edit email** to change the actual email message.

15. Save the quota:
  - a. Click **File > Save**. The Save As window opens.
  - b. In the **Specify Quota name** field, type a name for the quota and click **OK**. The quota is displayed in the navigation tree pane.

## **Creating a database-tablespace quota**

Learn how to create a quota that generates an alert when a user or group of users consumes more than a specified amount of RDBMS storage space across databases, tablespaces, groups of databases, and groups of tablespaces.

To create a databases-tablespaces quota, complete the following steps:

1. In the Navigation tree pane, expand **Data Manager for Databases > Policy Management > Quotas**.
2. Select the level at which you want to apply the quota by right-clicking **Databases-Tablespaces**.
3. Select **Create Quota** from the pop-up menu. The Create Quota window opens.

4. In the **Description** field, type a brief description of the quota.
5. Select a profile from the **Profile** selection list to control which storage usage statistics are used when checking for quota violations. You can select any of the GROUP\_BY\_OWNER type profiles shown. Make sure that the selected profile is used in scans of all the databases and tablespaces chosen on the **Databases-Tablespaces** tab. This ensures that the quota is fairly enforced for all users.
6. Select users or user groups against which you want to apply the quota:
  - a. In the **Available** field, click the users or groups of users against which you want to apply the quota.
  - b. Click . The users or groups are moved to the **Current Selections** field.
7. Click the **Databases-Tablespaces** tab; the Databases-Tablespaces page opens.
8. Select the databases, tablespaces, database-tablespaces groups, computers, and computer groups on which you want to limit the storage usage of users and user groups.
  - a. In the **Available** field, click the storage resources to which you want to apply the quota. The groups displayed in this field were created using **Data Manager for Databases > Monitoring > Groups**.
  - b. Click . The resources are moved to the **Current Selections** field.
9. Click the **When to Run** tab; the When to Run page opens.
10. In the **How often to run** area, schedule how often you want the quota to be checked. You can choose from the following actions:

**Run Now**

Check the quota immediately.

**Run Once at**

Check the quota once at a specified time and date. You can use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM.

**Note:** The Tivoli Storage Productivity Center framework that starts the Tivoli Storage Productivity Center jobs finds all jobs in an interval between one minute to the scheduled time and the scheduled start time. This ensures that if many jobs are planned to run at a certain time, they will not all start after the scheduled start time.

**Run Repeatedly**

Check the quota repeatedly according to a schedule you specify. You can:

- Use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM when the job should begin running.
- Indicate how often the job should run. You can use the drop-down lists to specify the number of minutes, hours, days, weeks, or months.
- Indicate which days on which run the job. A check mark is displayed next to the days you select.

11. In the **How to Handle Time Zones** area, indicate the time zone to be used when scheduling and running the policy. For example, if you selected to run the job at 9:00 AM, you can use the fields in this section to run it at:
  - a. 9:00 AM of the time zone where the Data server resides

- b. 9:00 AM of a specific time zone, such as 9:00 AM CST or 9:00 GMT. For example, if you select 9:00 AM CST, the job will run at 7:00 AM on an agent located in the PST time zone.

**Use the timezone that the server runs in**

Select this option to use the time zone of the location where the Data server resides.

**Use this timezone**

Select this option to indicate a specific time zone for when to run the job. When you select this option, a drop-down list is activated. Select the timezone from this drop-down list.

12. Click the **Alert** tab; the Alert page opens.
13. In the **Triggering Condition** area, specify the event that will trigger the alert:
  - a. In the **Condition** field, the default setting is **User Consumes More Than *n***, where *n* represents a value that you define in the **Value** field. No other conditions are available.
  - b. In the **Value** field, type a numeric value that represents the storage usage limit for the quota. If the storage entities selected for the quota (for example, users and user groups) exceed this limit, the quota is triggered.
  - c. In the **Value Units** field, select the unit of measurement: kilobytes, megabytes, or gigabytes.
14. In the **Triggered Actions** area, select the actions that occur as a result of the triggering condition You can choose from the following actions:

**SNMP trap**

An SNMP trap is sent to any NMS, console, or terminal when the condition occurs.

**TEC / OMNIbus Event**

A IBM Tivoli Enterprise Console event is sent when the condition occurs. The Tivoli Enterprise Console administrator can write correlation and automation rules to analyze Tivoli Storage Productivity Center events according to the event definitions specified in the tivoliSRM.baroc file (provided with the product). It also performs responses such as sending further notification, creating or updating trouble tickets, running programs, and so on.

**Login notification**

The alert is sent to a Tivoli Storage Productivity Center user. The user receives the alert upon logging in to Tivoli Storage Productivity Center. In the **Login ID** field, type the user ID.

**Login ID**

The ID of the user who receives alert notification upon logging in to the system.

**Windows Event Log, UNIX Syslog**

The ID of the user who receives alert notification upon logging in to the system.

**Event Type (Windows Event Log only)**

The type of event that is recorded to the OS log.

**Facility (UNIX Syslog only)**

The location where the UNIX Syslog is sent. You can select User or Local.

### Level (UNIX Syslog only)

The level of UNIX Syslog event. You can select Informational, Notice, Warning, Error, Critical, or Alert.

### Run script

A script is run when the condition occurs. Click **Define** to specify the script that is run when the triggering condition occurs. The parameters listed in the **Specify Script** window are passed to the script when the alert is triggered

**Email** An email is sent. Click **Add** or **Delete** to edit the list of email addresses to which an email is sent. Click **Edit email** to change the actual email message.

15. Save the quota:
  - a. Click **File > Save**. The Save As window opens.
  - b. In the **Specify Quota name** field, type a name for the quota and click **OK**. The quota is displayed in the navigation tree pane

## Editing a storage usage quota

Learn how to change the settings for a quota, including the users or user groups to which the quota applies, the resources on which the quota is set, and the amount set as the limit for storage usage.

To edit a quota, complete the following steps:

1. In the Navigation tree pane, expand **Data Manager > Policy Management > Quotas**.
2. Expand the **User** or **OS User Group** node depending upon the type of quota you want to edit.
3. Expand the level of the quota you want to edit. For example, if you want to edit a computer quota, expand the **Computer** node.
4. Select the quota you want to edit. Information about the quota you want to edit appears in the right-hand content pane.
5. In the **Description** field, type a brief description of the quota.
6. Select a profile from the **Profile** selection list to control which storage usage statistics are used when checking for quota violations. You can select any of the GROUP\_BY\_OWNER type profiles shown.
7. Select additional users or user groups against which you want to apply the quota:
  - a. In the **Available** field, click the users or groups of users against which you want to apply the quota. The groups displayed in this field were created using **Data Manager > Monitoring > Groups**
  - b. Click . The users or groups are moved to the **Current Selections** field.
8. Remove users or user groups previously included in the quota:
  - a. In the **Current Selections** field, click the users or groups of users that you want to remove from the quota.
  - b. Click . The users or groups are moved back to the **Available** field.
9. Click the **Computers** or **Filesystems** tab depending on quota you are editing; the Computers or Filesystems page opens.

10. Select additional filesystems, filesystem groups, computers, or computers groups on which you want to limit the storage usage of users and user groups.
  - a. In the **Available** field, click the storage resources to which you want to apply the quota. The groups displayed in this field were created using **Data Manager > Monitoring > Groups**.
  - b. Click . The resources are moved to the **Current Selections** field.
11. Remove any filesystems, filesystem groups, computers, or computers groups that you do not want included in the quota.
  - a. In the **Current Selections** field, click the storage resources to remove.
  - b. Click . The resources are moved to the **Current Selections** field.
12. Click the **When to Run** tab; the When to Run page opens.
13. In the **How often to run** area, schedule how often you want the quota to be checked. You can choose from the following actions:

#### **Run Now**

Check the quota immediately.

#### **Run Once at**

Check the quota once at a specified time and date. You can use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM.

**Note:** The Tivoli Storage Productivity Center framework that starts the Tivoli Storage Productivity Center jobs finds all jobs in an interval between one minute to the scheduled time and the scheduled start time. This ensures that if many jobs are planned to run at a certain time, they will not all start after the scheduled start time.

#### **Run Repeatedly**

Check the quota repeatedly according to a schedule you specify. You can:

- Use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM when the job should begin running.
- Indicate how often the job should run. You can use the drop-down lists to specify the number of minutes, hours, days, weeks, or months.
- Indicate which days on which run the job. A check mark is displayed next to the days you select.

14. In the **How to Handle Time Zones** area, indicate the time zone to be used when scheduling and running the policy. For example, if you selected to run the job at 9:00 AM, you can use the fields in this section to run it at:
  - a. 9:00 AM of the time zone where the Data server resides
  - b. 9:00 AM of a specific time zone, such as 9:00 AM CST or 9:00 GMT. For example, if you select 9:00 AM CST, the job will run at 7:00 AM on an agent located in the PST time zone.

#### **Use the timezone that the server runs in**

Select this option to use the time zone of the location where the Data server resides.

#### **Use this timezone**

Select this option to indicate a specific time zone for when to run the

job. When you select this option, a drop-down list is activated. Select the timezone from this drop-down list.

15. Click the **Alert** tab; the Alert page opens.
16. In the **Triggering Condition** area, specify the event that will trigger the alert:
  - a. In the **Condition** field, the default setting is **User Consumes More Than *n***, where *n* represents a value that you define in the **Value** field. No other conditions are available.
  - b. In the **Value** field, type a numeric value that represents the storage usage limit for the quota. If the storage entities selected for the quota (for example, users and user groups) exceed this limit, the quota is triggered.
  - c. In the **Value Units** field, select the unit of measurement: kilobytes, megabytes, or gigabytes.
17. Click **File > Save** to save your changes.

### Editing a storage usage quota for databases

Learn how to change the settings for a quota, including the users or user groups to which the quota applies, the resources on which the quota is set, and the amount set as the limit for storage usage.

To edit a quota, complete the following steps:

1. In the Navigation tree pane, expand **Data Manager for Databases > Policy Management > Quotas**.
2. Expand the level of the quota you want to edit. For example, if you want to edit a instance quota, expand the **Instance** node.
3. Click the quota you want to edit. Information about the quota you want to edit appears in the right-hand content pane.
4. In the **Description** field, type a brief description of the quota.
5. Select a profile from the **Profile** selection list to control which storage usage statistics are used when checking for quota violations. You can select any of the GROUP\_BY\_OWNER type profiles shown.
6. Select additional users or user groups against which you want to apply the quota:
  - a. In the **Available** field, click the users or groups of users against which you want to apply the quota. The groups displayed in this field were created using **Data Manager > Monitoring > Groups**
  - b. Click . The users or groups are moved to the **Current Selections** field.
7. Remove users or user groups previously included in the quota:
  - a. In the **Current Selections** field, click the users or groups of users that you want to remove from the quota.
  - b. Click . The users or groups are moved back to the **Available** field.
8. Click the **Databases-Tablespaces** or **Instances** tab depending on quota you are editing; the Databases-Tablespaces or Instances page opens.
9. Select additional databases, tablespaces, instances, computers, or computers groups on which you want to limit the storage usage of users and user groups.
  - a. In the **Available** field, click the storage resources to which you want to apply the quota. The groups displayed in this field were created using **Data Manager for Databases > Monitoring > Groups**.

- b. Click . The resources are moved to the **Current Selections** field.
10. Remove any databases, tablespaces, instances, computers, or computers groups that you do not want included in the quota.
  - a. In the **Current Selections** field, click the storage resources to remove.
    - b. Click . The resources are moved to the **Current Selections** field.
11. Click the **When to Run** tab; the When to Run page opens.
12. In the **How often to run** area, schedule how often you want the quota to be checked. You can choose from the following actions:

#### Run Now

Check the quota immediately.

#### Run Once at

Check the quota once at a specified time and date. You can use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM.

**Note:** The Tivoli Storage Productivity Center framework that starts the Tivoli Storage Productivity Center jobs finds all jobs in an interval between one minute to the scheduled time and the scheduled start time. This ensures that if many jobs are planned to run at a certain time, they will not all start after the scheduled start time.

#### Run Repeatedly

Check the quota repeatedly according to a schedule you specify. You can:

- Use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM when the job should begin running.
- Indicate how often the job should run. You can use the drop-down lists to specify the number of minutes, hours, days, weeks, or months.
- Indicate which days on which run the job. A check mark is displayed next to the days you select.

13. In the **How to Handle Time Zones** area, indicate the time zone to be used when scheduling and running the policy. For example, if you selected to run the job at 9:00 AM, you can use the fields in this section to run it at:
  - a. 9:00 AM of the time zone where the Data server resides
  - b. 9:00 AM of a specific time zone, such as 9:00 AM CST or 9:00 GMT. For example, if you select 9:00 AM CST, the job will run at 7:00 AM on an agent located in the PST time zone.

#### Use the timezone that the server runs in

Select this option to use the time zone of the location where the Data server resides.

#### Use this timezone

Select this option to indicate a specific time zone for when to run the job. When you select this option, a drop-down list is activated. Select the timezone from this drop-down list.

14. Click the **Alert** tab; the Alert page opens.
15. In the **Triggering Condition** area, specify the event that will trigger the alert:
  - a. In the **Condition** field, the default setting is **User Consumes More Than *n***, where *n* represents a value that you define in the **Value** field. No other conditions are available.

- b. In the **Value** field, type a numeric value that represents the storage usage limit for the quota. If the storage entities selected for the quota (for example, users and user groups) exceed this limit, the quota is triggered.
  - c. In the **Value Units** field, select the unit of measurement: kilobytes, megabytes, or gigabytes.
16. Click **File** > **Save** to save your changes.

## Storage usage for Network Appliance quotas

Use Network Appliance quotas to import quotas from Network Appliance file servers and determine how and when you will be alerted to the hard limits defined in those quotas.

**Restriction:** You can only import quotas if the NetApp device is configured as a file server. It is not available if the NetApp device was added only as a CIMOM.

You can use the NAS support within IBM Tivoli Storage Productivity Center to work with quotas defined using the software provided with Network Appliance (NetApp) File Servers. Using the **Network Appliance** node under **Policy Management**, you can do the following:

- Use the **Schedules** node to define a Data Manager quota that will import NetApp quotas and alert you to when those quotas are close to being exceeded.
- Use the **Imported User Quotas** node to view the definitions of User quotas stored on the NetApp file servers against which you ran a Data Manager quota (defined in the **Schedules** node).
- Use the **Imported OS User Group Quotas** node to view the definitions of OS User Group quotas stored on the NetApp file servers against which you ran a Data Manager quota (defined in the **Schedules** node).

For example, you can define to be alerted when:

- A user or user group is close to reaching the hard limit defined within the corresponding NetApp Quota
- The space consumed on a QTree is approaching the hard limit defined within the corresponding NetApp Quota

Specifically, the Data Manager NAS component enables you to work with the following types of Network Appliance quotas:

- Quotas that limit the space that QTree directories can consume on a volume
- Quotas that limit the space consumed by specific users on a volume
- Quotas that limit the space consumed by specific user groups on a volume

### Quick Steps for Working with Network Appliance quotas

The following describes the general steps you must perform to work with Network Appliance Quotas:

1. Run a Data Manager scan against the Network Appliance file servers whose quotas you want to check. This ensures that Data Manager is using the latest statistics when determining quota violations.
2. Expand **Policy Management** > **Network Appliance Quotas**.
3. Right click the **Schedules** node and select **Create NetApp Quota Job** to define a quota job. The NetApp Quota window appears.
4. Use the tabs in the NetApp Quota window to specify:
  - the Network Appliance file servers whose quotas you want to import

- when and how often to run the quota
  - the condition (% of hard limit) that will trigger an alert for the Network Appliance quotas and how you will be notified of that alert. For example, if you enter 90% for the alert condition, Data Manager will notify you whenever any of the quotas you are importing are within 10% of being violated.
5. Run the quota job from the **Schedules** node to import the Network Appliance quota definitions from the target NAS filer. When quotas are imported, the following occurs:
    - any User or OS User Group quotas violations are shown in the Quota Violation reports
    - any directory quota (Qtree) violations and definitions are displayed in **Alert Log >> Directory**.

## Creating a Network Appliance storage usage quota

Learn how to create a Network Appliance storage usage quota that imports Network Appliance quotas from filers and alert you to violations of those quotas.

Complete the following steps to:

- define the NetApp filers whose quotas you want to import
  - determine when and how often to run the quota that checks for user-defined violations (% of hard limit) of NetApp Quotas
  - specify the condition (% of hard limit) that will trigger an alert violation for a quota and how you will be notified of that alert
1. In the Navigation tree pane, expand **Data Manager > Policy Management > Network Appliance Quotas**.
  2. Right click the **Schedules** node.
  3. Select **New NetApp Quota Job** from the pop-up menu. The content pane displays the What to PROBE page.
  4. In the **Description** field, type a brief description of the quota.
  5. Select the NetApp filers against which you want to run the quota job:
    - a. In the **Available** field, click the NetApp filers or NetApp filer groups against which you want to apply the quota.
    - b. Click . The NetApp filers or NetApp filer groups are moved to the **Current Selections** field.
  6. Click the **When to Run** tab; the When to Run page opens.
  7. In the **How often to run** area, schedule how often you want the quota to be checked You can choose from the following actions:

### Run Now

Check the quota immediately.

### Run Once at

Check the quota once at a specified time and date. You can use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM.

**Note:** The Tivoli Storage Productivity Center framework that starts the Tivoli Storage Productivity Center jobs finds all jobs in an interval between one minute to the scheduled time and the scheduled start time. This ensures that if many jobs are planned to run at a certain time, they will not all start after the scheduled start time.

### Run Repeatedly

Check the quota repeatedly according to a schedule you specify. You can:

- Use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM when the job should begin running.
  - Indicate how often the job should run. You can use the drop-down lists to specify the number of minutes, hours, days, weeks, or months.
  - Indicate which days on which run the job. A check mark is displayed next to the days you select.
8. In the **How to Handle Time Zones** area, indicate the time zone to be used when scheduling and running the policy. For example, if you selected to run the job at 9:00 AM, you can use the fields in this section to run it at:
- a. 9:00 AM of the time zone where the Data server resides
  - b. 9:00 AM of a specific time zone, such as 9:00 AM CST or 9:00 GMT. For example, if you select 9:00 AM CST, the job will run at 7:00 AM on an agent located in the PST time zone.

### Use the timezone that the server runs in

Select this option to use the time zone of the location where the Data server resides.

### Use this timezone

Select this option to indicate a specific time zone for when to run the job. When you select this option, a drop-down list is activated. Select the timezone from this drop-down list.

9. Click the **Alert** tab; the Alert page opens.
10. In the **Triggering Condition** area, specify the event that will trigger the alert:
- a. In the **Condition** field, the default setting is **User Consumes More Than *n***, where *n* represents a value that you define in the **Value** field. No other conditions are available.
  - b. In the **Value** field, enter the value that represents the percentage of a NetApp's hard limit at which the alert is triggered. The hard limit represents the most amount of space a user or directory (Qtree) can consume on a NAS filer. For example, if the hard limit defined within a NetApp Quota for a user group is 150 MB, and you enter **90** in the **Value** field, the Data Manager quota will report a violation when that user group consumes 135 or more megabytes.
  - c. In the **Value Units** field, the only value units available is the % of Hard Limit.
11. In the **Triggered Actions** area, select the actions that occur as a result of the triggering condition You can choose from the following actions:

### SNMP trap

An SNMP trap is sent to any NMS, console, or terminal when the condition occurs.

### TEC / OMNIbus Event

A IBM Tivoli Enterprise Console event is sent when the condition occurs. The Tivoli Enterprise Console administrator can write correlation and automation rules to analyze Tivoli Storage Productivity Center events according to the event definitions specified in the tivoliSRM.baroc file (provided with the product). It also performs responses such as sending further notification, creating or updating trouble tickets, running programs, and so on.

**Login notification**

The alert is sent to a Tivoli Storage Productivity Center user. The user receives the alert upon logging in to Tivoli Storage Productivity Center. In the **Login ID** field, type the user ID.

**Login ID**

The ID of the user who receives alert notification upon logging in to the system.

**Windows Event Log, UNIX Syslog**

The ID of the user who receives alert notification upon logging in to the system.

**Event Type (Windows Event Log only)**

The type of event that is recorded to the OS log.

**Facility (UNIX Syslog only)**

The location where the UNIX Syslog is sent. You can select User or Local.

**Level (UNIX Syslog only)**

The level of UNIX Syslog event. You can select Informational, Notice, Warning, Error, Critical, or Alert.

**Run script**

A script is run when the condition occurs. Click **Define** to specify the script that is run when the triggering condition occurs. The parameters listed in the **Specify Script** window are passed to the script when the alert is triggered

**Email** An email is sent. Click **Add** or **Delete** to edit the list of email addresses to which an email is sent. Click **Edit email** to change the actual email message.

12. Save the quota:
  - a. Click **File > Save**. The Save As window opens.
  - b. In the **Specify NetApp Quota job name** field, type a name for the quota and click **OK**. The quota is displayed in the Navigation Tree pane

**Viewing user quotas imported from Network Appliance filers**

Learn how to view the definitions of user quotas stored on the NetApp filers against which you ran a Data Manager quota.

Before you can import Network Appliance user quotas and view them through **Data Manager > Policy Management > Network Appliance Quotas > Imported User Quotas**, you must:

1. Run a scan against the Network Appliance filers whose user quotas you want to import.
2. Use **Policy Management > Network Appliance Quotas > Schedules** to define and run a quota checking job against the NetApp filers whose user quotas you want to import.

Complete the following steps to view imported Network Appliance user quotas:

1. In the Navigation tree pane, expand **Data Manager > Policy Management > Network Appliance Quotas > Imported User Quotas**.
2. Click the NetApp Quota whose definition you want to view. The content pane displays information about the NetApp user quota.
3. In the Users page of the Edit *quota\_name* window, view the following information about imported Network Appliance user quotas:

### Hard Limit

The hard limit for used space defined within the NetApp quota.

### Current Selections

The users against which the NetApp quota applies.

4. In the Filesystems page of the Edit *quota\_name* window, view the filesystems to which the NetApp Quota applies.

## Viewing OS user quotas imported from Network Appliance filers

Learn how to view the definitions of OS User Quotas stored on the NetApp filers against which you ran a Data Manager quota.

Before you can import Network Appliance OS user quotas and view them through **Data Manager > Policy Management > Network Appliance Quotas > Imported OS User Group Quotas**, you must:

1. Run a scan against the Network Appliance filers whose OS user quotas you want to import.
2. Use **Policy Management > Network Appliance Quotas > Schedules** to define and run a quota checking job against the NetApp filers whose OS user quotas you want to import.

Complete the following steps to view imported Network Appliance OS user quotas:

1. In the Navigation tree pane, expand **Data Manager > Policy Management > Network Appliance Quotas > Imported OS User Quotas**.
2. Click the NetApp Quota whose definition you want to view. The content pane displays information about the NetApp OS user quota.
3. In the OS Users page of the Edit *quota\_name* window, view the following information about imported Network Appliance OS user quotas:

### Hard Limit

The hard limit for used space defined within the NetApp quota.

### Current Selections

The OS users against which the NetApp quota applies.

4. In the Filesystems page of the Edit *quota\_name* window, view the filesystems to which the NetApp Quota applies.

## Viewing directory (QTree) quotas and violations

Learn how to view the definitions of user quotas stored on the Network Appliance filers against which you ran a Data Manager quota.

Before you can view QTree quotas and violations, perform the following steps:

1. Use **Policy Management > Network Appliance Quotas > Schedules** to define and run a quota checking job against the Network Appliance filers containing the QTree quotas you want to import.
2. Create and run a scan job that includes the following objects:
  - the NetApp filers containing the QTrees whose quotas you want to import
  - the directory group named TPCUser.NetApp QTree Group
3. Use **Policy Management > Network Appliance Quotas > Schedules** to rerun the quota checking job you defined in step 1.

Complete the following steps to view a QTree quota violation and definition:

1. In the Navigation tree pane, expand **Alerting > Alert Log**.

2. Click the **Directory** node. The Alert History — All Directories window appears. This window lists all the alerts triggered by directory and QTree quota violations.
3. To view details about a violation you can do either of the following:
  - Double click the entry representing the QTree violation to view details about that violation and the QTree quota definition.
  - Right click the entry representing the QTree violation and select **Edit Definition** from the pop-up menu to view the QTree quota definition.

**Note:** You cannot edit a QTree quota definition using Data Manager. To edit a QTree quota definition you must use the software provided with your Network Appliance filer.

## Setting file constraints

Use constraints to define the acceptable and unacceptable file types, file sizes, and file owners for a NAS filer or a set of NAS filers in your environment. You can also use constraints to request an IBM Tivoli Storage Manager archive and backup of the largest violating files identified by a constraint.

### Creating a file constraint

Learn how to create a constraint that defines the acceptable and unacceptable file types, file sizes, and file owners for a computer or a set of computers in your environment.

To create a constraint, complete the following steps:

1. In the Navigation tree pane, expand **Data Manager > Policy Management**.
2. Right-click **Constraints**, and click **Create Constraint**. The Create Constraint window opens.
3. In the **Description** field, type a brief description of the job.
4. Select file systems, file system groups, computers, and computer groups against which to apply the constraint:
  - a. In the **Available** field, click the storage resources against which you want to apply the constraint. Select individual filesystems and computers, as well as file system and computer groups that you have previously defined using the group facility. Note that cluster resource groups in a PowerHA or MSCS clustered environment are listed as computers.
  - b. Click . The storage resources are moved to the **Current Selections** field.
5. Click the **File Types** tab; the File Types page opens. Use this page to select the file types that you want to allow or forbid.
6. Click one of the following:
 

**Forbid file matching these patterns**  
Do *not* allow files of the specified type on the storage resources selected on the Filesystems page.

**Allow ONLY file matching these patterns**  
Allow files *only* of the specified type on the storage resources selected on the Filesystems page.
7. Click the file types that you would like to allow or forbid in the **Choose a file type** list box. The file types listed in this box are predefined in the system.
  - a. In the **Choose a file type:** field, click the file types that you would like to allow or forbid.

- b. Click . The file types are moved to the **Forbidden files** field.
- 8. Optionally, create a custom file type:
  - a. Enter the pattern in the **Or enter a pattern** field.
  - b. Click . The file type is moved to the **Forbidden files** field.
- 9. Click the **Users** tab; the Users page opens. Use this page to allow or forbid files owned by specific users
- 10. Click one of the following:

**Forbid file owned by selected users**

Do *not* allow files owned by the specified users.

**Allow ONLY file owned by the specified owner**

Allow files owned by the specified users only.

- 11. Select the users whose files you want to allow or forbid:
  - a. In the **Available Users** field, click the users you want to include.
  - b. Click . The users are moved to the **Forbidden Users** field.
- 12. Click the **Options** tab; the Options page opens. Use this page to define alerts for files based on characteristics other than file type and file owner, and to view a where clause that will be used as a filter for locating files that violate the constraint definition. This page contains the following information:

**Violating File Limits**

Indicate the maximum number of violating filenames that should be kept per agent.

**number of days since last access greater than**

Click this box and enter a length of time (in days) in which files have not been accessed. When a constraint job locates a file that has not been accessed in the length of time you indicated in this field, an alert is triggered.

**bigger than ##**

Check this box and enter a file size that should trigger an alert. When a constraint job locates a file of the size (or greater) that you indicated in this field, an alert is triggered. Select the unit of measurement for the value you entered in the list box. The valid choices are: bytes, **KB** (kilobytes)**MB** (megabytes), **GB** (gigabytes), and **TB** (terabytes).

**set-UID root**

Check this box trigger alerts on files that have the SET-UID root bit on (because this can be a security consideration).

**not backed up (Windows only) and number of days since last modification greater than**

Click this box and enter the number of days since a file was last modified and not backed up. When the constraint job locates a file that was modified and not backed up in the amount of days that you indicate in this field, an alert is triggered.

**File Filter text**

This section displays a *where* clause that will be used as a filter for locating files that violate the Constraint definition. The choices you make on this tab and the choices you made on the Users and File Types pages are reflected in the content of this *where* clause. To edit

the *where* clause filter text, click **Edit Filter**. This will allow you to create new where conditions and groupings using the where clause interface.

13. Click the **Alert** tab; the Alert page opens. Use the Alert tab to define the alerting criteria for a constraint.
14. In the **Triggering Condition** area, specify the event that will trigger the constraint alert:
  - a. In the **Condition** field, the default setting is **User Consumes More Than *n***, where *n* represents a value that you define in the **Value** field. No other conditions are available.
  - b. In the **Value** field, type a numeric value that represents the amount of space a file must consume to violate the constraint.
  - c. In the **Value Units** field, select the unit of measurement: kilobytes, megabytes, or gigabytes.

Once Data Manager has found enough files that violate the condition (i.e., that exceed the total size amount you specified in this section), the constraint is considered violated and the alert is triggered. When the alert is triggered, the actions that you specify in the **Triggered Actions** section are taken.

15. In the **Triggered Actions** area, select the actions that occur as a result of the triggering condition. You can choose from the following actions:

**SNMP trap**

An SNMP trap is sent to any NMS, console, or terminal when the condition occurs.

**TEC / OMNIbus Event**

A IBM Tivoli Enterprise Console event is sent when the condition occurs. The Tivoli Enterprise Console administrator can write correlation and automation rules to analyze Tivoli Storage Productivity Center events according to the event definitions specified in the tivoliSRM.baroc file (provided with the product). It also performs responses such as sending further notification, creating or updating trouble tickets, running programs, and so on.

**Login notification**

The alert is sent to a Tivoli Storage Productivity Center user. The user receives the alert upon logging in to Tivoli Storage Productivity Center. In the **Login ID** field, type the user ID.

**Login ID**

The ID of the user who receives alert notification upon logging in to the system.

**Windows Event Log, UNIX Syslog**

The ID of the user who receives alert notification upon logging in to the system.

**Event Type (Windows Event Log only)**

The type of event that is recorded to the OS log.

**Facility (UNIX Syslog only)**

The location where the UNIX Syslog is sent. You can select User or Local.

**Level (UNIX Syslog only)**

The level of UNIX Syslog event. You can select Informational, Notice, Warning, Error, Critical, or Alert.

### Run script

A script is run when the condition occurs. Click **Define** to specify the script that is run when the triggering condition occurs. The parameters listed in the **Specify Script** window are passed to the script when the alert is triggered

**Email** An email is sent. Click **Add** or **Delete** to edit the list of email addresses to which an email is sent. Click **Edit email** to change the actual email message.

16. Save the constraint:

- a. Click **File > Save**. The Save As window opens.
- b. In the **Specify Constraint name** field, type a name for the constraint and click **OK**. The constraint is displayed in the navigation tree pane. The constraint is automatically checked whenever an appropriate scan job is run.

### Editing a constraint

Edit a constraint to: change the acceptable and unacceptable file types, file sizes, and file owners, add or remove users and user groups to which the constraint applies, edit the constraint options, and change the alert settings.

To edit a constraint, complete the following steps:

1. In the Navigation tree pane, expand **Data Manager > Policy Management > Constraints**.
2. Click the constraint you want to edit. Information about the constraint you want to edit appears in the content pane.
3. Add or remove the filesystems, filesystem groups, computers, and computer groups against which to apply the constraint:
  - a. In the **Available** field, click the storage resources that you want add. Click . The users or groups are moved to the **Current Selections** field.
  - b. In the **Current Selections** field, click the storage resources that you want remove from the constraint. Click . The users or groups are moved to the **Available** field.
4. Click the **File Types** tab; the File Types page opens. Use this page to edit the file types that you want to allow or forbid.
5. Click one of the following:

#### Forbid file matching these patterns

Do *not* allow files of the specified type on the storage resources selected on the Filesystems page.

#### Allow ONLY file matching these patterns

Allow files *only* of the specified type on the storage resources selected on the Filesystems page.

6. Click the file types that you would like to allow or forbid in the **Choose a file type** list box. The file types listed in this box are predefined in the system.
  - a. In the **Choose a file type:** field, click the file types that you would like to allow or forbid.
  - b. Click . The file types are moved to the **Forbidden files** field.
7. Optionally, create a custom file type:
  - a. Enter the pattern in the **Or enter a pattern** field.

- b. Click . The file type is moved to the **Forbidden files** field.
8. Click the **Users** tab; the Users page opens. Use this page to allow or forbid files owned by specific users
9. Click one of the following:
  - Forbid file owned by selected users**  
Do *not* allow files owned by the specified users.
  - Allow ONLY file owned by the specified owner**  
Allow files owned by the specified users only.
10. Select the users whose files you want to allow or forbid:
  - a. In the **Available Users** field, click the users you want to include.
  - b. Click . The users are moved to the **Forbidden Users** field.
11. Click the **Options** tab; the Options page opens. Use this page to edit alerts for files based on characteristics other than file type and file owner, and to view a where clause that will be used as a filter for locating files that violate the constraint definition. This page contains the following information:
  - Violating File Limits**  
Indicate the maximum number of violating filenames that should be kept per agent.
  - number of days since last access greater than**  
Click this box and enter a length of time (in days) in which files have not been accessed. When a constraint job locates a file that has not been accessed in the length of time you indicated in this field, an alert is triggered.
  - bigger than ##**  
Check this box and enter a file size that should trigger an alert. When a constraint job locates a file of the size (or greater) that you indicated in this field, an alert is triggered. Select the unit of measurement for the value you entered in the list box. The valid choices are: bytes, **KB** (kilobytes), **MB** (megabytes), **GB** (gigabytes), and **TB** (terabytes).
  - set-UID root**  
Check this box trigger alerts on files that have the SET-UID root bit on (because this can be a security consideration).
  - not backed up (Windows only) and number of days since last modification greater than**  
Click this box and enter the number of days since a file was last modified and not backed up. When the constraint job locates a file that was modified and not backed up in the amount of days that you indicate in this field, an alert is triggered.
  - File Filter text**  
This section displays a *where* clause that will be used as a filter for locating files that violate the Constraint definition. The choices you make on this tab and the choices you made on the Users and File Types pages are reflected in the content of this *where* clause. To edit the *where* clause filter text, click **Edit Filter**. This will allow you to create new where conditions and groupings using the where clause interface.
12. Click the **Alert** tab; the Alert page opens. Use the Alert tab to define the alerting criteria for a constraint.

13. In the **Triggering Condition** area, specify the event that will trigger the constraint alert:
  - a. In the **Condition** field, the default setting is **User Consumes More Than *n***, where *n* represents a value that you define in the **Value** field. No other conditions are available.
  - b. In the **Value** field, type a numeric value that represents the amount of space a file must consume to violate the constraint.
  - c. In the **Value Units** field, select the unit of measurement: kilobytes, megabytes, or gigabytes.

Once Data Manager has found enough files that violate the condition (i.e., that exceed the total size amount you specified in this section), the constraint is considered violated and the alert is triggered. When the alert is triggered, the actions that you specify in the **Triggered Actions** section are taken.

14. In the **Triggered Actions** area, select the actions that occur as a result of the triggering condition. You can choose from the following actions:

**SNMP trap**

An SNMP trap is sent to any NMS, console, or terminal when the condition occurs.

**TEC / OMNIbus Event**

A IBM Tivoli Enterprise Console event is sent when the condition occurs. The Tivoli Enterprise Console administrator can write correlation and automation rules to analyze Tivoli Storage Productivity Center events according to the event definitions specified in the tivoliSRM.baroc file (provided with the product). It also performs responses such as sending further notification, creating or updating trouble tickets, running programs, and so on.

**Login notification**

The alert is sent to a Tivoli Storage Productivity Center user. The user receives the alert upon logging in to Tivoli Storage Productivity Center. In the **Login ID** field, type the user ID.

**Login ID**

The ID of the user who receives alert notification upon logging in to the system.

**Windows Event Log, UNIX Syslog**

The ID of the user who receives alert notification upon logging in to the system.

**Event Type (Windows Event Log only)**

The type of event that is recorded to the OS log.

**Facility (UNIX Syslog only)**

The location where the UNIX Syslog is sent. You can select User or Local.

**Level (UNIX Syslog only)**

The level of UNIX Syslog event. You can select Informational, Notice, Warning, Error, Critical, or Alert.

**Run script**

A script is run when the condition occurs. Click **Define** to specify the script that is run when the triggering condition occurs. The parameters listed in the **Specify Script** window are passed to the script when the alert is triggered.

**Email** An email is sent. Click **Add** or **Delete** to edit the list of email addresses to which an email is sent. Click **Edit email** to change the actual email message.

15. Click **File** > **Save** to save your changes.

### **Requesting an archive or backup**

Request an IBM Tivoli Storage Manager archive and backup of the largest violating files identified by a constraint. Tivoli Storage Manager protects your data from hardware failures and other errors by storing backup and archive copies of data on auxiliary storage.

Data Manager provides a method within the alerting function of a constraint where you can automatically start a Tivoli Storage Manager archive or backup to run against the files that violate that constraint. For example, you can do the following actions:

- Define a constraint to identify the .vbs files within your organization that are larger than 2 megabytes. Other file types include .avi, .dll, .doc, .exe, .gif, .jpg, .mp3, .rtf, .txt, .wsh, and .zip. You can also define a pattern to use when identifying files that need to be archived or backed up.
- Define a constraint that runs Tivoli Storage Manager to archive and then delete those files

### **Before you begin**

Before you can use the Tivoli Storage Manager archive and backup functions with Data Manager constraints, you must ensure that the following conditions are met:

- Your user ID has Administrator authority within Tivoli Storage Productivity Center.
- Tivoli Storage Manager client software is installed on each of the hosts where a Data agent or Storage Resource agent is used to perform archive and backup functions.
- (For SAN attached storage only) Tivoli Storage Manager client software must be installed on a host computer where a Data agent or Storage Resource agent is configured to act as the scanning agent for NAS storage.
- A Tivoli Storage Manager client must be configured to run without a password. This condition is typically done by either including the password in the client options (dsm.opt) file, or using the options `PASSWORDACCESS = GENERATE` in the client options file.
- The Tivoli Storage Manager client must be version 5.1 or higher

### **Defining an archive or backup in a constraint:**

Learn how to request an IBM Tivoli Storage Manager archive and backup of the largest violating files identified by a constraint. Request a Tivoli Storage Manager archive and backup on the alert page of a constraint definition.

### **Create a new constraint:**

1. In the Navigation tree pane, expand **Data Manager** > **Policy Management**.
2. Right-click **Constraints**, and click **Create Constraint**. The Create Constraint window opens.
3. Select filesystems, filesystem groups, computers, and computer groups against which to apply the constraint:

- a. In the **Available** field, click the storage resources against which you want to apply the constraint. Select individual filesystems and computers, as well as file system and computer groups that you have previously defined using the group facility. Note that cluster resource groups in a PowerHA or MSCS clustered environment are listed as computers.
  - b. Click . The users or groups are moved to the **Current Selections** field.
4. Click the **File Types** tab; the File Types page opens. Use this page to select the file types that you want to allow or forbid.
  5. Click one of the following:

**Forbid file matching these patterns**

Do *not* allow files of the specified type on the storage resources selected on the Filesystems page.

**Allow ONLY file matching these patterns**

Allow files *only* of the specified type on the storage resources selected on the Filesystems page.

6. Click the file types that you would like to allow or forbid in the **Choose a file type** list box. The file types listed in this box are predefined in the system.
  - a. In the **Choose a file type:** field, click the file types that you would like to allow or forbid.
  - b. Click . The file types are moved to the **Forbidden files** field.
7. Optionally, create a custom file type:
  - a. Enter the pattern in the **Or enter a pattern** field.
  - b. Click . The file type is moved to the **Forbidden files** field.
8. Click the **Users** tab; the Users page opens. Use this page to allow or forbid files owned by specific users
9. Click one of the following:

**Forbid file owned by selected users**

Do *not* allow files owned by the specified users.

**Allow ONLY file owned by the specified owner**

Allow files owned by the specified users only.

10. Select the users whose files you want to allow or forbid:
  - a. In the **Available Users** field, click the users you want to include.
  - b. Click . The users are moved to the **Forbidden Users** field.
11. Click the **Options** tab; the Options page opens. Use this page to define alerts for files based on characteristics other than file type and file owner, and to view a where clause that will be used as a filter for locating files that violate the constraint definition. This page contains the following information:

**Violating File Limits**

Indicate the maximum number of violating filenames that should be kept per agent.

**number of days since last access greater than**

Click this box and enter a length of time (in days) in which files have not been accessed. When a constraint job locates a file that has not been accessed in the length of time you indicated in this field, an alert is triggered.

**bigger than ##**

Check this box and enter a file size that should trigger an alert. When a constraint job locates a file of the size (or greater) that you indicated in this field, an alert is triggered. Select the unit of measurement for the value you entered in the list box. The valid choices are: bytes, **KB** (kilobytes), **MB** (megabytes), **GB** (gigabytes), and **TB** (terabytes).

**set-UID root**

Check this box trigger alerts on files that have the SET-UID root bit on (because this can be a security consideration).

**not backed up (Windows only) and number of days since last modification greater than**

Click this box and enter the number of days since a file was last modified and not backed up. When the constraint job locates a file that was modified and not backed up in the amount of days that you indicate in this field, an alert is triggered.

**File Filter text**

This section displays a *where* clause that will be used as a filter for locating files that violate the Constraint definition. The choices you make on this tab and the choices you made on the Users and File Types pages are reflected in the content of this *where* clause. To edit the *where* clause filter text, click **Edit Filter**. This will allow you to create new where conditions and groupings using the where clause interface.

12. Click the **Alert** tab; the Alert page opens. Use the Alert tab to define the alerting criteria for a constraint.
13. In the **Triggering Condition** area, specify the event that will trigger the constraint alert:
  - a. In the **Condition** field, the default setting is **User Consumes More Than *n***, where *n* represents a value that you define in the **Value** field. No other conditions are available.
  - b. In the **Value** field, type a numeric value that represents the amount of space a file must consume to violate the constraint.
  - c. In the **Value Units** field, select the unit of measurement: kilobytes, megabytes, or gigabytes.

Once Data Manager has found enough files that violate the condition (i.e., that exceed the total size amount you specified in this section), the constraint is considered violated and the alert is triggered. When the alert is triggered, the actions that you specify in the **Triggered Actions** section are taken.

14. In the **Triggered Actions** area, select **Archive/Backup** and click **Define**. The Archive / Backup Options window appears. Click one of the following:

**Archive**

Perform an archive on the files that violate a constraint. Archives are copies of data from online storage copies to offline storage. If you select the Archive option, you can also check the **Delete After Successful Archival** box to automatically delete the files that violated the constraint after the files have been successfully archived.

**Selective Backup**

Perform a selective backup of the files that violate a constraint. A selective backup enables you to back up specified files. These files are

not excluded in the include-exclude list and meet the requirement for serialization in the backup copy group of the management class assigned to each file.

### **Incremental Backup**

Perform an incremental backup of the files that violate a constraint. An incremental backup enables you to back up new or changed files or directories from a client domain or from specified directories or files. These directories or files are not excluded in the include-exclude list and meet the requirements for frequency, mode, and serialization as defined by a backup copy group of the management class assigned to each file.

### **Tivoli Storage Manager Command Options**

Enter additional that will be passed on to the Tivoli Storage Manager `dsmc` command. You can enter up to 512 bytes of text.

15. Save the constraint:
  - a. Click **File > Save**. The Save As window opens.
  - b. In the **Specify Constraint name** field, type a name for the constraint and click **OK**. The constraint is displayed in the navigation tree pane. The constraint is automatically checked whenever an appropriate scan job is run.

See the *IBM Tivoli Storage Manager Client User's Guide* for more information about each of the TSM actions you can select when defining triggered actions for a constraint.

## **Scheduling script-based actions**

Use scheduled actions to run user-defined scripts against selected computers and computer groups.

You can access the scheduled actions facility using either Data Manager or Data Manager for Chargeback. The actions that you schedule to run are based on user-defined scripts, allowing you to use any third-party tools for actions, such as recovery or provisioning. You can schedule scripts to run:

- Immediately
- Once at a specified time and date
- Repeatedly according to a schedule you specify

Select the option you want and then edit the time and date information accordingly. You can also select the time zone for the schedule you specify. You can either select the time zone that the Data server is in or any other time zone.

**Note:** Scheduled actions should not be confused with triggered actions. Triggered actions enable you to run scripts based upon conditions and alerts that are detected within your storage environment. Scheduled actions enable you to run scripts according to the schedule that you define, without having to associate the script with an alert.

### **Running scripts using scheduled actions**

Use the scheduled action facility to run a script according to a schedule that you define. The scheduled action facility is available in Data Manager and Data Manager for Databases.

Use scheduled actions to run scripts against selected computers and computer groups. The scheduled actions facility is script-based, so you can use any third-party tools for actions, such as recovery, or provisioning. You can schedule scripts to run:

- Immediately
- Once at a specified time and date
- Repeatedly according to a schedule you specify

Scheduled actions are different from triggered actions. Use triggered actions to run scripts based upon conditions and alerts that are detected within your storage environment. Use scheduled actions to run scripts according to the schedule that you define, without having to associate the script with an alert.

To create a scheduled action, complete the following steps:

1. In the Navigation tree pane, expand **Data Manager > Policy Management > Scheduled Actions** or **Data Manager for Databases > Policy Management > Scheduled Actions**.
2. Right-click **Scripts**, and click **Create Script**. The Create Script panel opens.
3. In the **Description** field, type a brief description of the job.
4. Select computers and computer groups against which to run the action:
  - a. In the **Available** field, click the computers and computer groups against which you want to run the action. You can select individual computers as well as computer groups that you have previously defined using the group facility. Cluster resource groups in a PowerHA or MSCS clustered environment are listed as computers.
  - b. Click . The computers and computer groups are moved to the **Current Selections** field.
5. Click the **Script Options** tab; the Script Options page opens. Use this page to select the script that you want to run against the selected computers and computer groups.
6. Select a script from **Script Name**. The scripts that appear in **Script Name** are stored in the `\<TPC_installation_directory>\scripts` directory on the Data server. The default installation directory where scripts are located is:
  - Windows: C:\Program Files\IBM\TPC\data\scripts
  - UNIX, Linux: /opt/IBM/TPC/data/scripts or /usr/IBM/TPC/data/scripts

**Note:** The scripts that appear in the Script Name list are stored on the computer where the Data server component is located. If you want to run a script that is stored on a Storage Resource agent or Data agent, you must type the name of that script in the Script Name field.

7. Click the **When to Run** tab; the When to Run page opens. Use the When to Run page to specify when the scheduled action is run.
8. In the **How often to run** area, schedule how often you want to run the script associated with the action. You can choose from the following options:

#### **Run Now**

Run the script immediately.

#### **Run Once at**

Run the script once at a specified time and date. You can use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM.

**Note:** The Tivoli Storage Productivity Center framework that starts the Tivoli Storage Productivity Center jobs finds all jobs in an interval between one minute to the scheduled time and the scheduled start time. This process ensures that if many jobs are planned to run at a certain time, they will not all start after the scheduled start time.

### Run Repeatedly

Run the script repeatedly according to a schedule you specify. You can:

- Use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM when the job should begin running.
  - Indicate how often the job should run. You can use the drop-down lists to specify the number of minutes, hours, days, weeks, or months.
  - Indicate which days on which run the job. A check mark is displayed next to the days that you select.
9. In the **How to Handle Time Zones** area, indicate the time zone to be used when scheduling and running the policy. For example, if you selected to run the job at 9:00 AM, you can use the fields in this section to run it at:
    - a. 9:00 AM of the time zone where the Data server resides
    - b. 9:00 AM of a specific time zone, such as 9:00 AM CST or 9:00 GMT. For example, if you select 9:00 AM CST, the job will run at 7:00 AM on an agent located in the PST time zone.

### Use the timezone that the server runs in

Select this option to use the time zone of the location where the Data server resides.

### Use this timezone

Select this option to indicate a specific time zone for when to run the job. When you select this option, a drop-down list is activated. Select the timezone from this drop-down list.

10. Click the **Alert** tab; the Alert page opens. Use the Alert page to define the alerting criteria for a scheduled action.
11. In the **Triggering Condition** area, the only condition is **Script Failed**. An alert is automatically triggered if the scheduled action fails to run.
12. In the **Triggered-Actions** pane, select the actions that occur as a result of the triggering condition. For an explanation of triggered actions, see “Triggered actions for alerts” on page 1504.
13. Save the scheduled action:
  - a. Click **File > Save**. The Save As window opens.
  - b. In the **Specify Script name** field, type a name for the job and click **OK**. The scheduled action is displayed in the navigation tree pane.

## Editing a scheduled action

Edit a scheduled action to change: the computers and groups against which the action is run, the script that is run, when the script is run, and the alerting conditions if the action fails to run.

To edit a scheduled action, complete the following steps:

1. In the Navigation tree pane, expand **Data Manager > Policy Management > Scheduled Actions > Scripts** or **Data Manager for Databases > Policy Management > Scheduled Actions > Scripts**.

2. Select the scheduled action that you want to edit. Information about the action appears in the right-hand content pane.
3. In the **Description** field, type a brief description of the job.
4. Select computers and computer groups against which to run the action:
  - a. In the **Available** field, click the computers and computer groups against which you want to run the action. Select individual computers, as well as computer groups that you have previously defined using the group facility. Note that cluster resource groups in a PowerHA or MSCS clustered environment are listed as computers.
  - b. Click . The computers and computer groups are moved to the **Current Selections** field.
5. Click the **Script Options** tab; the Script Options page opens. Use this page to change the script you want to run against the selected computers and computer groups.
6. Select a script from **Script Name**. The scripts that appear in **Script Name** are stored in the `\<TPC_installation_directory>\scripts` directory on the Data server. The default installation directory where scripts are located is:
  - Windows: C:\Program Files\IBM\TPC\data\scripts
  - UNIX, Linux: /opt/IBM/TPC/data/scripts or /usr/IBM/TPC/data/scripts

**Note:** The scripts that appear in the Script Name list are stored on the computer where the Data server component is located. If you want to run a script that is stored on a Storage Resource agent or Data agent, you must type the name of that script in the Script Name field.

7. Click the **When to Run** tab; the When to Run page opens. Use this page to change when the scheduled action is set to run.
8. In the **How often to run** area, schedule how often you want to run the script associated with the action. You can choose from the following options:

#### **Run Now**

Run the script immediately.

#### **Run Once at**

Run the script once at a specified time and date. You can use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM.

**Note:** The Tivoli Storage Productivity Center framework that starts the Tivoli Storage Productivity Center jobs finds all jobs in an interval between one minute to the scheduled time and the scheduled start time. This process ensures that if many jobs are planned to run at a certain time, they will not all start after the scheduled start time.

#### **Run Repeatedly**

Run the script repeatedly according to a schedule you specify. You can:

- Use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM when the job should begin running.
- Indicate how often the job should run. You can use the drop-down lists to specify the number of minutes, hours, days, weeks, or months.
- Indicate which days on which run the job. A check mark is displayed next to the days that you select.

9. In the **How to Handle Time Zones** area, indicate the time zone to be used when scheduling and running the policy. For example, if you selected to run the job at 9:00 AM, you can use the fields in this section to run it at:
  - a. 9:00 AM of the time zone where the Data server resides
  - b. 9:00 AM of a specific time zone, such as 9:00 AM CST or 9:00 GMT. For example, if you select 9:00 AM CST, the job will run at 7:00 AM on an agent located in the PST time zone.

**Use the timezone that the server runs in**

Select this option to use the time zone of the location where the Data server resides.

**Use this timezone**

Select this option to indicate a specific time zone for when to run the job. When you select this option, a drop-down list is activated. Select the timezone from this drop-down list.

10. Click the **Alert** tab; the Alert page opens. Use the Alert tab to change the alerting criteria for a scheduled action.
11. In the **Triggering Condition** area, the only condition is **Script Failed**. This indicates that an alert will automatically be triggered if the scheduled action fails to run.
12. In the **Triggered Actions** area, select the actions that occur as a result of the triggering condition You can choose from the following actions:

**SNMP trap**

An SNMP trap is sent to any NMS, console, or terminal when the condition occurs.

**TEC / OMNIBus Event**

A IBM Tivoli Enterprise Console event is sent when the condition occurs. The Tivoli Enterprise Console administrator can write correlation and automation rules to analyze Tivoli Storage Productivity Center events according to the event definitions specified in the tivoliSRM.baroc file (provided with the product). It also performs responses such as sending further notification, creating or updating trouble tickets, running programs, and so on.

**Login notification**

The alert is sent to a Tivoli Storage Productivity Center user. The user receives the alert upon logging in to Tivoli Storage Productivity Center. In the **Login ID** field, type the user ID.

**Login ID**

The ID of the user who receives alert notification upon logging in to the system.

**Windows Event Log, UNIX Syslog**

The ID of the user who receives alert notification upon logging in to the system.

**Event Type (Windows Event Log only)**

The type of event that is recorded to the OS log.

**Facility (UNIX Syslog only)**

The location where the UNIX Syslog is sent. You can select User or Local.

**Level (UNIX Syslog only)**

The level of UNIX Syslog event. You can select Informational, Notice, Warning, Error, Critical, or Alert.

### Run script

A script is run when the condition occurs. Click **Define** to specify the script that is run when the triggering condition occurs. The parameters listed in the **Specify Script** window are passed to the script when the alert is triggered

**Email** An email is sent. Click **Add** or **Delete** to edit the list of email addresses to which an email is sent. Click **Edit email** to change the actual email message.

13. Click **File** > **Save** to save your changes.

## Archive and backup functions

Data Manager provides a method within the alerting function of a constraint by which you can automatically invoke a IBM Tivoli Storage Manager archive or backup to run against the files that violate that constraint.

An archive is a "snapshot in time". Each time an archive is done, a new "snapshot" is taken. When an archive is performed, everything that has been specified is captured. So, for example, if an archive was performed on a C: drive, everything on C: will be archived. If, the next day, another archive of C: was performed, everything on the C: drive would be archived again. Files and file systems that have been archived as part of the Archive/Backup job can be deleted after archiving, but you must select **Delete After Successful Archival** specifically.

Lets say that, as a result of running a report, you find a large number of files that haven't been accessed in over two years. Looking at the cumulative sizes of these files you determine they are taking up space that would be better utilized elsewhere. You can archive and delete these files to reclaim that space. If, at some time in the future those files are needed, they can be retrieved from the archive. The result of the archive job is more free space without data loss.

A backup can be incremental (**Selective Backup**) or full. Usually a full backup is done first and subsequent backups are incremental. For example, say that a backup is performed on C: drive. All the files on the C: drive are then backed up, which is the full backup operation. The next day we need to back up C: drive again. Usually, this will be an incremental backup since a full backup was done the day before. In the incremental backup, only the files that have changed on the drive since the last backup will be backed up.

The archived or backed up files are sent to the Tivoli Storage Manager server and are stored on that machine. Files are put into storage groups that are controlled through a Tivoli Storage Manager policy that the Tivoli Storage Manager server administrator usually creates.

### Constraints

Data Manager provides a method within the alerting function of a constraint by which you can automatically invoke a Tivoli Storage Manager archive or backup to run against files that violate constraints you have defined. You can do the following:

- Define a constraint that will invoke Tivoli Storage Manager to archive and (if that option is selected) delete those files
- Define a constraint to run an incremental or full backup

See the scenario *Archive and delete files* to see an example of how constraints are developed.

## Before you begin

Before you can use the Tivoli Storage Manager archive/backup functionality with Data Manager constraints, you must ensure the following:

- Your user ID has Administrator authority within IBM Tivoli Storage Productivity Center.
- Tivoli Storage Manager client software is installed on each of the hosts where a Storage Resource agent or Data agent is used to perform archive and backup functions.
- (for SAN attached storage only) Tivoli Storage Manager client software must be installed on the Storage Resource agent or Data agent host computer that is configured to act as the scanning agent for NAS storage.
- A Tivoli Storage Manager client must be configured to run without a password. This is typically done by either including the password in the client options (dsm.opt) file, or using the options `PASSWORDACCESS= GENERATE` in the client options file.
- The Tivoli Storage Manager client must be version 5.1 or higher.

## Create an archive/backup job

Create a IBM Tivoli Storage Manager archive/backup job for files in a report

You follow these general steps when you create an archive or backup.

1. Make sure you have followed the prerequisite steps
2. Decide whether to create a new constraint or use one of the default constraints
3. Generate the report using the constraint you decided to use
4. Create an archive or backup job from files in the report

To create an Archive/Backup job on files from a report, complete the following steps:

1. Generate and view a Largest Files, Most Obsolete Files, Orphan Files, Duplicate Files, Most At Risk, Constraint Violations report, or a report that you have created.
2. Click on the files you want to include in the archive or backup job. Use ctrl + click to select multiple, non-consecutive files; use shift + click to select multiple, consecutive files.
3. Right click on the reports and select **Create a new archive/backup job** from the pop-up menu. The **Create File Archive/Backup Action** window is displayed.
4. In the **Description** field, type a brief description of the job.
5. In the **Archive/Backup Options** tab, select the type of the job and its TSM command options, if any:

### Archive

Use this option to archive the files that violate a constraint. Archives are copies of data from online storage copies to offline storage.

### Delete After Successful Archival

Automatically delete the files that violated the constraint after they have been successfully archived. See the *IBM Tivoli Storage Manager Client User's Guide* for more information about Tivoli Storage Productivity Center archives.

**Note:** Tivoli Storage Productivity Center administrators (Productivity Center Administrator role) have the ability to delete files even if they do not have the required authority on the systems where the files are stored. This authority is provided by the Tivoli Storage Productivity Center agents which run as root on UNIX systems or with administrator privileges on Windows computers.

### **Selective Backup**

Select this option to perform a selective backup of the files that violate a constraint. A selective backup enables you to back up specified files. These files are not excluded in the include-exclude list and meet the requirement for serialization in the backup copy group of the management class assigned to each file. See the *IBM Tivoli Storage Manager Client User's Guide* for more information about selective backups.

### **Incremental Backup**

Select this option to perform an incremental backup of the files that violate a constraint. An incremental backup enables you to back up new or changed files or directories from a client domain or from specified directories or files. These directories or files are not excluded in the include-exclude list and meet the requirements for frequency, mode, and serialization as defined by a backup copy group of the management class assigned to each file. See the *IBM Tivoli Storage Manager Client User's Guide* for more information about incremental backups.

### **IBM Tivoli Storage Manager Command Options**

Enter additional Tivoli Storage Manager command line options in this field that will be passed on to the Tivoli Storage Manager `dsmc` command. You can enter up to 512 bytes of text. See the *IBM Tivoli Storage Manager Client User's Guide* for more information about valid Tivoli Storage Manager command-line options.

6. Click the **Files** tab; the **Files** page opens. Use this page to view or remove the files included in an archive/backup job.
7. Click the **When to Run** tab. Use the **How often to run** area to specify when the archive or backup job runs.
8. In the **How often to run** area, schedule how often you want the quota to be checked. You can choose from the following actions:

#### **Run Now**

Check the quota immediately.

#### **Run Once at**

Check the quota once at a specified time and date. You can use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM.

**Note:** The Tivoli Storage Productivity Center framework that starts the Tivoli Storage Productivity Center jobs finds all jobs in an interval between one minute to the scheduled time and the scheduled start time. This ensures that if many jobs are planned to run at a certain time, they will not all start after the scheduled start time.

9. In the **How to Handle Time Zones** area, indicate the time zone to be used when scheduling and running the policy. For example, if you selected to run the job at 9:00 AM, you can use the fields in this section to run it at:

- a. 9:00 AM of the time zone where the Data server resides
- b. 9:00 AM of a specific time zone, such as 9:00 AM CST or 9:00 GMT. For example, if you select 9:00 AM CST, the job will run at 7:00 AM on an agent located in the PST time zone.

**Use the timezone that the server runs in**

Select this option to use the time zone of the location where the Data server resides.

**Use this timezone**

Select this option to indicate a specific time zone for when to run the job. When you select this option, a drop-down list is activated. Select the timezone from this drop-down list.

- 10. Click the **Alert** tab; the Alert page opens. Use the Alert page to define the alerting criteria for an archive or backup job.

- a. In the **Triggering Condition** area, the only condition is **File Archive/Backup Failed**. This condition indicates that an alert is triggered automatically if the archive or backup fails to run.
- b. In the **Triggered Actions** area, select the actions that occur as a result of the triggering condition You can choose from the following actions:

**SNMP trap**

An SNMP trap is sent to any NMS, console, or terminal when the condition occurs.

**TEC / OMNibus Event**

A IBM Tivoli Enterprise Console event is sent when the condition occurs. The Tivoli Enterprise Console administrator can write correlation and automation rules to analyze Tivoli Storage Productivity Center events according to the event definitions specified in the tivoliSRM.baroc file (provided with the product). It also performs responses such as sending further notification, creating or updating trouble tickets, running programs, and so on.

**Login notification**

The alert is sent to a Tivoli Storage Productivity Center user. The user receives the alert upon logging in to Tivoli Storage Productivity Center. In the **Login ID** field, type the user ID.

**Login ID**

The ID of the user who receives alert notification upon logging on to the system.

**Windows Event Log, UNIX Syslog**

The ID of the user who receives alert notification upon logging on to the system.

**Event Type (Windows Event Log only)**

The type of event that is recorded to the OS log.

**Facility (UNIX Syslog only)**

The location where the UNIX Syslog is sent. You can select User or Local.

**Level (UNIX Syslog only)**

The level of UNIX Syslog event. You can select Informational, Notice, Warning, Error, Critical, or Alert.

**Run script**

A script is run when the condition occurs. Click **Define** to specify

the script that is run when the triggering condition occurs. The parameters listed in the **Specify Script** window are passed to the script when the alert is triggered

**Email** An email is sent. Click **Add** or **Delete** to edit the list of email addresses to which an email is sent. Click **Edit email** to change the actual email message.

11. Save the archive or backup:
  - a. Click **File > Save**. The **Save As** window opens.
  - b. In the **Specify File Archive/Backup Action name** field, type a name for the job and click **OK**. The new job is listed in **Data Manager > Policy Management > Archive/Backup** as **<creator>.<job name>**.

## View and edit an Archive/Backup job

Learn how to edit IBM Tivoli Storage Manager archive and backup jobs that were defined to run against the files selected from Data Manager reports or from reports you have generated yourself.

Each archive and backup that you have created appears as a node under **Archive/Backup**.

To view and edit a Tivoli Storage Manager archive or backup job, complete the following steps:

1. In the Navigation tree pane, expand **Data Manager > Policy Management > Archive/Backup**. Select the archive or backup job that you want to edit. Information about the job appears in the content pane. All the user-defined information can be edited.
2. Change the description for the archive/backup job.
3. In the **Options** tab, you can select the Archive/Backup options. You can change whether the job is an archive or a backup, and add or change any additional Tivoli Storage Manager commands that should be run with the job.
4. In the **Files** tab the files that were included in the job are listed.
5. In the **When to Run** tab, select how often to run and how to handle time zones. You can change the **How often to run** and **How to handle time zones** settings.
6. In the **Alert** tab, **File Archive/Backup Failed** is the only **Triggering-Condition**. In **Triggered-Actions**, change the action you wish to occur if the job fails. You do not need to select any of the actions. Notification will be written to the error log by default.
7. Select **File > Save**. Name the Archive/Backup job. After you save a the job, an entry for it will appear under the **Data Manager > Policy Management > Archive/Backup > <Creator>.<Name>**.

## Add additional files to an archive/backup job

Add files to an existing IBM Tivoli Storage Manager archive or backup job from a report.

To add files to an existing Archive/Backup job, complete the following steps:

1. Add files to an existing Tivoli Storage Manager archive or backup job from a report
2. Click on the files you want to add to an archive or backup job. Use **ctrl + click** to select multiple, non-consecutive files; use **shift + click** to select multiple, consecutive files.

3. Right click on the report and select **Add to an existing archive/backup job** from the pop-up menu. The Archive/Backup Job Selection window appears.
4. Select the archive or backup job to which you want to add the files from the list box.
5. Click **OK** to add the files. The Archive/Backup - Files window appears and shows the file(s) you added to the selected job.

---

## Working with storage resource groups

Use storage resource groups to organize logically related storage entities into named groups. For example, a storage resource group that represents a business critical email application might include all the hosts that participate in the email application cluster, the storage subsystems that provide storage to the application, and the switches and fabrics through which the application's data is configured to travel.

You can use storage resource groups as input to the SAN Planner for planning and provisioning considerations. For example, if a storage resource group represents a business critical email application, you can use that group as input into the SAN planner to help consistently determine when and where to add capacity to the application while minimizing the manual entry of storage entities.

### Storage resource group management

Use the storage resource group management list panel to view, create, and delete storage resource groups.

This panel contains the following information about each storage resource group:

**Storage resource group name**

Specifies a user-defined name of the storage resource group.

**State** Specifies the state of the storage resource group:

**Normal**

The storage resource group is operating normally.

**Warning**

At least one part of the storage resource group is not operating or has serious problems.

**Critical**

The storage resource group is either not operating or has serious problems.

**Missing**

The storage resource group was previously discovered by IBM Tivoli Storage Productivity Center, but was not detected in the most recent discovery.

**Unknown**

The storage resource group was discovered but is not recognized by IBM Tivoli Storage Productivity Center.

**Note:** The state of a storage resource group might display as **Unknown** after it is created. This occurs because the status of a new storage resource group might not yet be updated when the Storage Resource Group Management panel is redisplayed. To resolve this issue, exit the Storage Resource Group Management

panel, wait for the processing of the group to complete, and open the Storage Resource Group Management panel again to view the updated **State**.

**Type** The type of storage resource group. Two types are available:

**General**

A storage resource group made up of a combination of storage entities such as storage subsystems, switches, fabrics, and other entities. These storage entities can be a logical grouping based on a particular application or usage, such as accounting-related storage entities.

**Cloud Capacity Pool**

A storage resource group used specifically for cloud automation. This type of storage resource group is used by applications that provide cloud automation services.

**Description (optional)**

Displays the user-defined description for the storage resource group.

**Create** Creates a storage resource group that you selected.

**Delete**

Deletes a storage resource group that you selected.

**Refresh Table**

Refreshes the storage resource group management table with the most recent changes.

## Create or Edit a Storage Resource Group

Use the Create or Edit Storage Resource group panel to create or modify storage resource groups.

To create a storage resource group:

- In the navigation tree, expand **IBM Tivoli Storage Productivity Center**, click **Storage Resource Group Management**, then click **Create...** in the content pane.
- In the navigation tree, expand **IBM Tivoli Storage Productivity Center > Topology**, click a node that represents a storage entity, right-click an entity that appears in the content pane, and select **Add to new Storage Resource Group...** from the drop-down menu.

To edit a storage resource group:

- In the navigation tree, expand **IBM Tivoli Storage Productivity Center**, click **Storage Resource Group Management**, then click the magnifying glass icon next to the storage resource group you want to edit.
- In the navigation tree, expand **IBM Tivoli Storage Productivity Center > Topology**, click **Storage Resource Groups**, right-click the storage resource group you want to edit in the content pane, and select **Launch Detail Panel** from the drop down menu.

### Field Descriptions

**Creator**

Displays the user name of the creator.

**Name** Displays the name of the storage resource group or unnamed, if it is not yet named.

**Description**

Optional: Displays the user-defined description for the storage resource group.

**Selected Elements**

Lists the elements selected to be members of this storage resource group.

**Add** Adds one or more selected elements to the list.

The Storage resource group element selection panel is displayed.

**Remove**

Removes one or more selected elements from the Selected Elements list.

**Group Type**

Specifies the type of storage resource group to create.

**General**

A storage resource group comprised of a combination of storage entities such as storage subsystems, switches, fabrics, and other entities. These storage entities can be a logical grouping based on a particular application or usage, such as accounting-related storage entities.

**Cloud Capacity Pool**

A storage resource group used specifically for cloud automation. This type of storage resource group is used by applications that provide cloud automation services.

**Default Provisioning Profile**

Lists the available provisioning profiles which can be associated with storage resource groups. The list also includes None. If this storage resource group is used as input to the SAN Planner, the settings defined in this profile will be used to pre-populate the planner inputs.

**Create a New Profile**

Opens the Provisioning Profile creation wizard. When you complete the wizard, the **Provisioning Profile** list is updated.

**User-defined property 1 (UDP1)**

Specifies any user-defined properties that will be used by the topology viewer to provide custom groupings.

**User-defined property 2 (UDP2)**

Specifies any user-defined properties that will be used by the topology viewer to provide custom groupings.

**User-defined property 3 (UDP3)**

Specifies any user-defined properties that will be used by the topology viewer to provide custom groupings.

**Storage Resource Group Element Selection**

Use the Storage Resource Group Element Selection panel to select the storage entities that you want to include in a storage resource group. The storage entities that you can select are displayed in the topology viewer.

**Available elements section**

Displays the storage entities that you can include in a storage resource group. Use the topology viewer to select storage entities. See Overview of Topology Viewer for more information about the topology viewer.

### Topology viewer

Use the topology viewer to select the storage entities that you want to include in a storage resource group. To do this, perform the following steps.

1. Open a detailed view of a storage entity type on the topology viewer's **Overview** page.
2. Expand the storage entity type to view the storage entities that are part of that type.
3. Select the storage entities you want to include in the storage resource group.
4. Click >>.

### Selected elements section

>> Click >> to move the selected subsystems into the **Selected Elements** pane.

<< Click << to remove the selected subsystems from the **Selected Elements** pane.

### Selected Elements

Displays the storage entities that are included in a storage resource group. You can include the following entities in a storage resource group:

- computer (vm, physical or hypervisor)
- computer disk (including vm disks)
- fabric
- switch
- other entities
- storage subsystem
- storage pool
- subsystem disk
- subsystem volume
- tape drive
- tape library
- tape media changer
- other storage resource groups

**Restriction:** For storage resource groups that are defined as a Cloud Capacity Pool type, you can only include IBM SONAS and Storwize V7000 Unified systems.

**OK** Click **OK** when you are satisfied with all your selections. The Create Storage Resource Group panel displays with your selections.

### Cancel

Click **Cancel** if you do not want to add storage entities to a storage resource group. The Create Storage Resource Group panel displays. No data is saved.

### Working with storage resource group sessions

This topic describes viewing and deleting replication sessions that are created in the SAN Planner wizard for a storage resource group.

You can delete the replication session from IBM Tivoli Storage Productivity Center and optionally also from IBM Tivoli Storage Productivity Center for Replication.

1. In the navigation tree pane, expand **Replication Manager > Storage Resource Group Sessions**. A table of the currently defined storage resource group sessions is displayed in the content pane.
2. To select a storage resource group session to delete, click a row in the table. You can use Ctrl+click and Shift+click to select multiple sessions simultaneously.
3. Click **Delete Storage Resource Group Session**. Tivoli Storage Productivity Center does not automatically delete the replication session from Tivoli Storage Productivity Center for Replication. A dialog box opens enabling you to specify how you want to delete the session. You can select from the following options:
  - Click **Yes** to remove the selected replication session from the Tivoli Storage Productivity Center database and the Tivoli Storage Productivity Center for Replication database.
  - Click **No** to remove the selected replication session from the Tivoli Storage Productivity Center database only.
  - Click **Cancel** to close the dialog box without deleting the selected replication session from the Tivoli Storage Productivity Center database or Tivoli Storage Productivity Center for Replication database.

---

## Working with scripts

Use the triggered action facility to run scripts based upon conditions/alerts that are detected within your storage environment. Use the scheduled action facility to run scripts according to the schedule that you define, without having to associate the script with an alert.

Both the triggered action and scheduled action facilities are script-based, allowing you to use any third-party tools for actions, such as recovery and provisioning.

## Running scripts with alerts

Monitoring, alerting, and policy management jobs enable you to use the triggered action facility to run scripts based on storage events that you define.

The triggered action facility allows you to define thresholds and constraints that result in notification or action. A script can be run when a job fails, an alert condition is detected in a storage resource, a constraint is violated (Data Manager only), or a quota is exceeded (Data Manager only). The triggered action facility is script-based, allowing you to use any third-party tools for actions such as recovery or provisioning.

Perform the following steps to run a script in response to a condition in a job:

1. Create or edit a monitoring, alerting, or policy management job. For example, the following jobs enable you to define a condition that triggers a script:
  - Data Manager:
    - **Monitoring > <all\_monitoring\_jobs>**
    - **Alerting > <all\_alert\_jobs>**
    - **Policy Management > Constraints**
    - **Policy Management > Quotas**
    - **Policy Management > Scheduled Actions**

- Data Manager for Databases:
    - **Monitoring** > <all\_monitoring\_jobs>
    - **Alerting** > <all\_alert\_jobs>
    - **Policy Management** > **Quotas**
    - **Policy Management** > **Scheduled Actions**
  - Disk Manager:
    - **Monitoring** > **Subsystem Performance Monitors**
    - **Alerting** > **Storage Subsystem Alerts**
  - Fabric Manager:
    - **Monitoring** > **Switch Performance Monitors**
    - **Alerting** > <all\_alert\_jobs>
2. Check **Run Script** on the **Alert** page for the job.
  3. Click **Define**. The **Specify Script** dialog box displays.
  4. Enter the name of the script in the **Script Name** field. This script name is used to tell the server what script to send to the agent. If the script sent by the server is run by the agent, the name of the script will not be the name you specify in the **Script Name** field. Instead, the agent names the script as temporary file, runs it, then deletes it after the script has run. Because of this, you should not have code in your script that depends on this script name.
  5. Specify where you want the script to run in the **Where to Run** field. You can select a specific agent, or the triggering computer. For example, if a file system alert is triggered on a on a specific computer, you would typically want the script to run on the computer that triggered the alert. (For some types of alerts such as *Job Failed*, you will not have the option to run the script on the triggering computer. Here you can run the script on any agent you choose.)
  6. The **Script Parameters** section displays what parameters will be passed to the script when it is run. Each triggering condition passes different parameters. The parameters will be passed in the order specified on the dialog box.
  7. Click **OK**.

## Running scripts using scheduled actions

Use the scheduled action facility to run a script according to a schedule that you define. The scheduled action facility is available in Data Manager and Data Manager for Databases.

Use scheduled actions to run scripts against selected computers and computer groups. The scheduled actions facility is script-based, so you can use any third-party tools for actions, such as recovery, or provisioning. You can schedule scripts to run:

- Immediately
- Once at a specified time and date
- Repeatedly according to a schedule you specify

Scheduled actions are different from triggered actions. Use triggered actions to run scripts based upon conditions and alerts that are detected within your storage environment. Use scheduled actions to run scripts according to the schedule that you define, without having to associate the script with an alert.

To create a scheduled action, complete the following steps:

1. In the Navigation tree pane, expand **Data Manager > Policy Management > Scheduled Actions** or **Data Manager for Databases > Policy Management > Scheduled Actions**.
2. Right-click **Scripts**, and click **Create Script**. The Create Script panel opens.
3. In the **Description** field, type a brief description of the job.
4. Select computers and computer groups against which to run the action:
  - a. In the **Available** field, click the computers and computer groups against which you want to run the action. You can select individual computers as well as computer groups that you have previously defined using the group facility. Cluster resource groups in a PowerHA or MSCS clustered environment are listed as computers.
  - b. Click . The computers and computer groups are moved to the **Current Selections** field.
5. Click the **Script Options** tab; the Script Options page opens. Use this page to select the script that you want to run against the selected computers and computer groups.
6. Select a script from **Script Name**. The scripts that appear in **Script Name** are stored in the `\<TPC_installation_directory>\scripts` directory on the Data server. The default installation directory where scripts are located is:
  - Windows: `C:\Program Files\IBM\TPC\data\scripts`
  - UNIX, Linux: `/opt/IBM/TPC/data/scripts` or `/usr/IBM/TPC/data/scripts`

**Note:** The scripts that appear in the Script Name list are stored on the computer where the Data server component is located. If you want to run a script that is stored on a Storage Resource agent or Data agent, you must type the name of that script in the Script Name field.
7. Click the **When to Run** tab; the When to Run page opens. Use the When to Run page to specify when the scheduled action is run.
8. In the **How often to run** area, schedule how often you want to run the script associated with the action. You can choose from the following options:

#### **Run Now**

Run the script immediately.

#### **Run Once at**

Run the script once at a specified time and date. You can use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM.

**Note:** The Tivoli Storage Productivity Center framework that starts the Tivoli Storage Productivity Center jobs finds all jobs in an interval between one minute to the scheduled time and the scheduled start time. This process ensures that if many jobs are planned to run at a certain time, they will not all start after the scheduled start time.

#### **Run Repeatedly**

Run the script repeatedly according to a schedule you specify. You can:

- Use the drop-down lists to specify the month, day year, and the hour, minute, and AM/PM when the job should begin running.
- Indicate how often the job should run. You can use the drop-down lists to specify the number of minutes, hours, days, weeks, or months.

- Indicate which days on which run the job. A check mark is displayed next to the days that you select.
9. In the **How to Handle Time Zones** area, indicate the time zone to be used when scheduling and running the policy. For example, if you selected to run the job at 9:00 AM, you can use the fields in this section to run it at:
    - a. 9:00 AM of the time zone where the Data server resides
    - b. 9:00 AM of a specific time zone, such as 9:00 AM CST or 9:00 GMT. For example, if you select 9:00 AM CST, the job will run at 7:00 AM on an agent located in the PST time zone.

**Use the timezone that the server runs in**

Select this option to use the time zone of the location where the Data server resides.

**Use this timezone**

Select this option to indicate a specific time zone for when to run the job. When you select this option, a drop-down list is activated. Select the timezone from this drop-down list.

10. Click the **Alert** tab; the Alert page opens. Use the Alert page to define the alerting criteria for a scheduled action.
11. In the **Triggering Condition** area, the only condition is **Script Failed**. An alert is automatically triggered if the scheduled action fails to run.
12. In the **Triggered-Actions** pane, select the actions that occur as a result of the triggering condition. For an explanation of triggered actions, see “Triggered actions for alerts” on page 1504.
13. Save the scheduled action:
  - a. Click **File > Save**. The Save As window opens.
  - b. In the **Specify Script name** field, type a name for the job and click **OK**. The scheduled action is displayed in the navigation tree pane.

## How scripts are run

Scripts can be run from the Data server or Tivoli Storage Productivity Centers.

During installation, IBM Tivoli Storage Productivity Center creates a directory on every server and agent computer called: `<install_directory>\scripts`, where `<install_directory>` represents the directory where the agent or server is installed. The default installation directory is:

- (Windows Storage Resource agents) `C:\Program Files\IBM\TPC\agent\scripts`
- (UNIX, Linux Storage Resource agents) `/opt/IBM/TPC/agent/scripts` or `/usr/tivoli/ep/subagents/TPC/Data/scripts`
- (Windows Data server) `C:\Program Files\IBM\TPC\Data\scripts`
- (UNIX, Linux Data server) `/opt/IBM/TPC/Data/scripts` or `/usr/IBM/TPC/Data/scripts`

When a script is run:

1. The agent looks in the agent's local `\scripts` directory; if the agent can resolve that script name, it is executed from that location.
2. Otherwise (if the agent cannot resolve the script name) and the agent is configured to accept scripts from the server, the server looks in the local `\scripts` directory. If the server can resolve that script name, it loads that script and sends it to the agent where you designated the script to be run.

When you run a script against a NAS filer, the script is run from the agent that is assigned to the file system where the triggering condition occurred.

3. The agent receives the script, names it as a temporary file, and runs it.
4. After the agent finishes running the script, the temporary file is deleted. Because the script is handled in this way, any script which is written to redirect any output must specify a fully qualified unique directory path for that output.

You run a script:

- In response to an alert
- For batch reports

There are two reasons why a script might not run when sent by the server:

- The script exists in the `\scripts` directory fro the agent. In this case, the agent ignores the script sent by the server and run its local version.
- If you did not check the **Agent may run scripts sent by server** option in the installation parameters screen, the agent ignores the script sent by the server.

If you selected the **Agent may run scripts sent by server** option in the installation parameters screen, the agent runs scripts sent by the server.

The advantage of selecting this option is you need only store one copy of the script in the `\scripts` directory for the server and do not have to keep a copy of the script on every agent computer. When a script must be run on a particular agent, the server accesses the script from the local `\scripts` directory and sends it to the agent to be run.

**Note:**

- You can change this option by editing the `honorSentScripts` parameter in the `agent.config` file. The `agent.config` file exists in every installation directory for the agent. See *IBM Tivoli Storage Productivity Center and IBM Tivoli Storage Productivity Center for Replication Installation and Configuration Guide* for information about the `agent.config` file.
- After a Storage Resource agent is deployed, you can change the script configuration in the user interface. In the navigation tree, expand **Administrative Services > Data Sources > Data/Storage Resource Agents**. Select the target Storage Resource agent from the list, then open the **Select Action** menu and select the **Enable Scripts** or **Disable Scripts** option as appropriate.

When the script is deployed to the agent, it is named as a temporary file. After the agent finishes running the script, the temporary file is deleted.

If the **Agent may run scripts sent by server** option is cleared, you must make sure that the script is stored in every `\scripts` directory for the agent. If the **Agent may run scripts sent by server** option is checked, the server deploys the script to the agent computer that has the low free space condition. In this case, you must ensure that the script exists in the `\scripts` directory for the server, and not on any of the `\scripts` directory for the agents.

**Note:** A good practice is to store the scripts you want to run globally (across all your agents) on the server. Store the scripts that you want to run locally on the agent computers where you want them to run.

## How the server and agent resolve script names

An IBM Tivoli Storage Productivity Center server processes requests for agents running under UNIX, Linux, and Windows.

When associating and running scripts with triggered and scheduled actions, the Tivoli Storage Productivity Center server resolves the names of those scripts based on the following criteria:

- The OS under which an agent is running
- How the script name is specified on the Specify Script dialog box

### Agent and Operating System

The operating system under which an agent runs determines the scripts that can be run by that agent:

#### UNIX, Linux operating systems

An agent running under a UNIX or Linux operating system will not run or receive (from the server) scripts that have an extension. Agents running under UNIX or Linux only accept and run script files that do not contain an extension within their name. The first line in a script file determines what interpreter is needed to run the script.

#### Windows operating systems

An agent running under a Windows operating system will only run or receive (from the server) scripts that have an extension. The extension of a script file determines what interpreter is needed to run the script.

### Specifying a Script Name

Use the Specify Script dialog box when associating a script with a triggered or scheduled action. Enter the name of a script on the **Script Name** field to associate that script with the action you want to perform.

The name of the script you enter might or might not contain an extension (including an extension is optional). Depending on the agent that receives the script, the following occurs after a triggered or scheduled action that contains a script is run:

#### Agent running under UNIX or Linux operating systems

If the specified script name contains an extension, the agent ignores the extension and searches for a file of the same name (without an extension). For example, if you enter `backup.vbs` in the **Script Name** field, a UNIX or Linux agent will search for a file with the name `backup`. If the script exists, UNIX or Linux will read the first line of the script and use the appropriate interpreter to run the script. If the file does not exist, the triggered or scheduled action will not run the script.

#### Agent running under Windows operating systems

If the specified script name contains an extension, the agent will search for a file of the same name/extension. For example, if you enter `backup.vbs` in the **Script Name** field, an agent will search for a file with the name `backup.vbs`. If the script does exist, the agent will determine what interpreter is needed to run the script based on its extension. If the file does not exist, the triggered or scheduled action will not run the script. If the specified script name does not contain an extension, an agent will look for the file name in the following order (based on its extension): `.com`, `.exe`, `.bat`, `.cmd`, `.vbs`, `.vbe`, `.js`, `.jse`

The process for script name resolving enables you to run scripts with the same name across multiple operating systems. To run a script on both a UNIX or Linux and Windows operating systems, you must have two versions of that file on either the server or the agent. For example, if you want to run a provisioning script against a UNIX or Linux and Windows agent, you must have two versions of that file (provision.bat and provision) stored in the \scripts directory on either the server or agent.

---

## Using the topology viewer

This topic describes how to use the topology viewer to view detailed information about your storage environment and monitor entities and groups of entities.

You can view health status, performance, and other details about switches, computers, storage subsystem servers, fabrics, and other entities. To launch the topology viewer, expand **IBM Tivoli Storage Productivity Center Topology** in the Navigation Tree pane.

To display detailed information about an entity (for example, the host name of a computer, the used and unused capacity of a storage subsystem), right-click the entity and select **Launch Detail Panel**.

To select an entity in the graphical view, click the entity image. In the table view, click the name of the entity. To make multiple selections, press CTRL and click.

### Note:

- The availability of certain action items depends on the entity class and view level.
- When you right-click an object in the graphical view, a context menu is displayed. The action items in this menu are identical to the action items displayed when you right-click the corresponding object in the table view and click the arrow in the **Action** field.
- If the discovery process is not completed and there are entities in the environment that have not been rendered into the current view, the view will build dynamically as entities are discovered.
- Some columns and fields displayed within the Topology Viewer might not be populated with data for the storage resources that you are monitoring. Columns and fields appear empty if you have not configured Tivoli Storage Productivity Center to discover or collect the information intended for those columns and fields. Use discovery, probe, ping, or scan schedules to ensure that you collect information for all the columns and fields that appear in the Topology Viewer.

## The topology viewer

This topic describes how the topology viewer provides a graphical representation of the physical and logical resources that have been discovered in your storage environment by IBM Tivoli Storage Productivity Center.

The information displayed by the topology viewer is collected by discovery, probing, performance data collection, and alerting. The topology viewer consists of two views, a graphical view and a table view, organized vertically with the graphical view over of the table view. The table view shows the same information as the graphical view, but in a tabular format.

The topology viewer supports four levels of detail, from a high-level overview of the entire storage environment to detailed information about individual entities. This allows you to view as much or as little detail as you need.

### **Overview**

A global, highly aggregated view of the entire storage environment. This is the default view when you expand **IBM Tivoli Storage Productivity Center > Topology**.

### **Groups level (L0)**

This level focuses on groups of a particular type. The default groups are:

- **Computers:** All discovered computer groups in your storage environment
- **Fabrics:** All fabric groups in your storage environment. A *fabric* is a network of entities that are attached through one or more switches. The topology viewer also displays Virtual SANs (VSANs) and Logical SANs (LSANs).
- **Switches:** All switches in your environment.
- **Storage:** All storage subsystems and tape libraries in your environment.
- **Other:** All entities that are discovered in your environment but that do not fit in either the computer, fabric or storage classes.

The groups level is the default level upon launching the topology viewer by clicking either **Computers**, **Fabrics**, **Switches**, **Storage** or **Other** under the **Topology** node. The groups level shows one or more groups of entities that correspond to the topology class that you selected. Information in the graphical view at this level can include any individually pinned entities.

### **Group level (L1)**

This level focuses on one selected group and its related entities (for example, a group of computers). At L1, individual entities can be shown by expanding the group box. You can also display lines representing connections between entities or between entities and groups.

### **Detail level (L2)**

This level focuses on individual entities (for example, a single computer, switch, subsystem, or tape library) and the paths to associated logical and physical entities. This level shows details all the way to the port level.

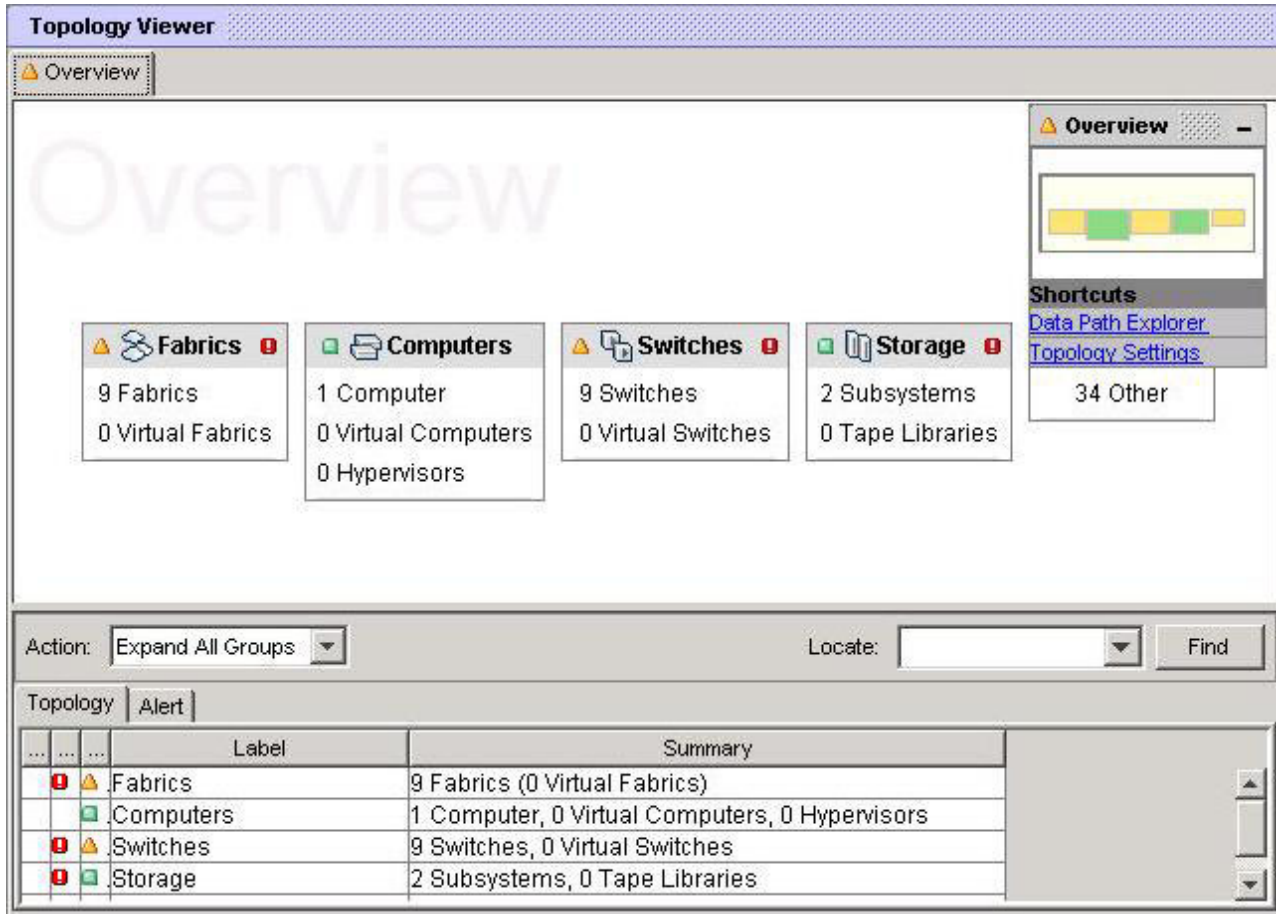

Figure 39. Topology overview

In addition, the topology viewer depicts the relationships among resources (for example, the disks comprising a particular storage subsystem). Detailed, tabular information (for example, attributes of a disk) is also provided. With all the information that the topology viewer provides, you can more quickly and easily monitor and troubleshoot your storage environment and perform critical storage-management tasks.

### Topology viewer interface controls

Progressive information disclosure reduces the visual complexity of a system. In the topology viewer, this means that you can identify and focus on entities in your storage environment that are of particular interest and hide other entities from view.

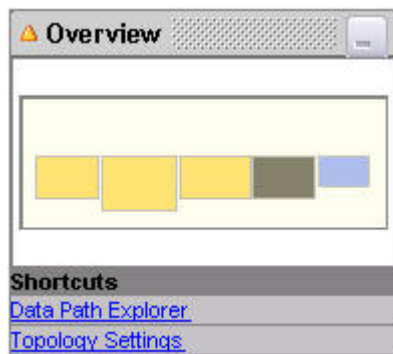

The tabs displayed in the tabular view represent classes of entities (a physical device or logical resource discovered by IBM Tivoli Storage Productivity Center). Individual entities (for example, a computer named *accounting1*, a tape library named *tapelib4*) are listed in their corresponding tabs. Entity attributes (for example, the operating system of a computer) are organized into table columns. The classes entities are assigned to are Computers, Fabrics, Storage Subsystems, and Other.

**Note:** The Other class contains entities discovered by Tivoli Storage Productivity Center but for which the type cannot be determined.

Changes to the graphical view or the tabular view are automatically applied to the other view, keeping both views synchronized. For example, if an entity is selected in the graphical view, it is also highlighted in the table view.

As more of your resources are discovered and displayed in the topology viewer, it is not possible to see all the discovered resources in a single topology window. To make it easier for you to find the resources you want to view, Tivoli Storage Productivity Center provides a tool called the *minimap*. The minimap allows you to shift the focus of the topology viewer to different areas within a particular view. The minimap is a small window within the topology view.

**Linux/AIX users:** you must use SHIFT+ALT+mouse drag to reposition the minimap.

*Figure 40. Minimap.* You can click the shortcuts to launch Data Path Explorer or to view or change topology settings.

The minimap provides a miniature representation of the current topology view. Clicking on the minimap displays a multidirectional cursor that allows you to move the focus of the current topology view in any direction. As you drag the cursor around the minimap, the topology view will move accordingly. This makes navigating around complex topologies much easier.

The minimap uses the following colors to indicate the aggregated health status of groups:

- Green (normal): All entities in the group are operating normally.
- Yellow (warning): At least one entity is operating normally, and one or more entities have a health status of warning, critical, unknown, or missing.
- Red (critical): The status of all entities is either critical or warning.
- Gray (unknown): None of the entities in the group has an known health status.
- Black (missing): All of the entities of the group are missing.

In the Configuration History page, the minimap uses the following colors to indicate the aggregated change status of groups:

- Blue (changed): One or more entities in the group changed (an addition or deletion of an entity is considered a change).
- Gray (unchanged): All entities in the group are unchanged.

Included in the minimap are shortcuts that you can click to launch the Data Path Explorer or to view or change the topology settings:

- To launch the Data Path Explorer, select one or more hosts, subsystems, disks, volumes, or Mdisks and click the Data Path Explorer shortcut.

**Note:** The shortcut to Data Path Explorer is not available in the Configuration History topology view.

- To view or change the topology settings, click the Topology Settings shortcut. The Settings window displays for you to specify the type of overlays to display, the type of filtering to perform, whether connections between topology objects should display, and whether the Zone tab should display in the table view.

### The graphical view:

This topic describes how the topology viewer groups entities that share certain characteristics. A collapsed group consisting of many entities or subgroups takes up much less space in the graphical view than the individual entities or subgroups would.

In the topology viewer, you can expand or collapse a group or subgroup by clicking the plus (+) character or minus (-) character, respectively, located in the group box.

**Note:** Pinned entities within a group remain visible, even when the group is collapsed.

By default, the topology viewer groups entities by class (computers, fabrics, switches, storage subsystems, and other entities). However, you can create additional groups (but not additional classes) using your own criteria. These custom groups can provide new perspectives on and important information about your storage environment. For example, you can create a special group belonging to the computer class that consists of computers that use the same operating system or storage subsystems of a particular model.

The following figure shows an expanded computer group representation in the graphical view:

Figure 41. Computer group

The title bar of the group box shows the following:

- An icon indicating the health status of the group (for example, normal).
- An icon indicating the types of entities contained in the group.
- The class of group (for example, computers).
- The grouping criterion (for example, Windows).
- The total number of entities in the group. If filtering is turned on, the number in the brackets is the ratio of displayed entities to total entities. For example, 5/10 indicates that 5 entities are shown out of 10 total entities.

The topology viewer provides the following default groups. These groups are accessible, if they exist in your topology, in the overview or by expanding the primary default groups (**Computers**, **Fabrics**, **Switches**, **Storage** and **Other**) that are displayed when you first launch the topology viewer.

Table 40. Group locations in the topology viewer

| Type of group  | Description                                                                                                                      | Path to group in topology viewer                                                                                                       |
|----------------|----------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| Computers      | All the computers that are discovered in your environment or a group of computers associated with a particular fabric or switch  | <b>Computers</b>                                                                                                                       |
| Fabrics        | All the fabrics and virtual fabrics that are discovered in your environment                                                      | <b>Fabrics</b>                                                                                                                         |
| Storage        | All the storage-related devices that are discovered in your environment                                                          | <b>Storage</b>                                                                                                                         |
| Other          | All the entities that are discovered in an environment but that do not fit in either the computer, fabric, or storage categories | <b>Other</b>                                                                                                                           |
| Fabric         | All entities (for example, switches) that belong to or are related to a fabric                                                   | <b>Fabrics &gt; Fabric</b>                                                                                                             |
| Virtual Fabric | All entities that belong to a virtual fabric                                                                                     | <b>Fabrics &gt; Fabric</b>                                                                                                             |
| Switches       | A set of switches                                                                                                                | <b>Fabrics &gt; Fabric</b>                                                                                                             |
| Subsystems     | A set of subsystems                                                                                                              | <b>Storage &gt; Subsystems</b>                                                                                                         |
| Tape libraries | A set of tape libraries                                                                                                          | <b>Storage &gt; Tape Libraries</b>                                                                                                     |
| Device         | Devices associated with a particular entity (for example, a computer)                                                            | <b>Computers &gt; Computers</b>                                                                                                        |
| Volumes        | A set of volumes that are associated with an entity                                                                              | Different types of volumes groups exist at the L2 level of each of the four main categories: <b>Computers, Fabrics, Storage, Other</b> |
| HBA            | A set of HBAs that are associated with an entity                                                                                 | <b>Computers &gt; Computers &gt; Computer</b>                                                                                          |
| Disks          | A set of disks that are associated with an entity                                                                                | <b>Storage &gt; Subsystems &gt; Subsystem</b>                                                                                          |
| Pools          | A set of pools that are associated with an entity                                                                                | <b>Storage &gt; Subsystems &gt; Subsystem</b>                                                                                          |
| FC Ports       | A set of FC ports that belong to an entity                                                                                       | <b>Fabrics &gt; Fabric &gt; Switch</b>                                                                                                 |
| Media          | All media attached to an entity                                                                                                  | <b>Storage &gt; Tape Libraries &gt; Tape Library</b>                                                                                   |
| Media Changers | All media changers attached to an entity                                                                                         | <b>Storage &gt; Tape Libraries &gt; Tape Library</b>                                                                                   |
| Tape Drives    | All tape drives attached to an entity                                                                                            | <b>Storage &gt; Tape Libraries &gt; Tape Library</b>                                                                                   |
| Tape Drive     | All ports on a tape drive attached to an entity                                                                                  | <b>Storage &gt; Tape Libraries &gt; Tape Library</b>                                                                                   |
| Switch         | All ports on a switch. Due to the large number of ports on some switches, ports are shown as FC port groups within the switch    | <b>Fabrics &gt; Fabric &gt; Switch</b>                                                                                                 |

As shown by the tabs of the graphical panel (**L0:Computers**, **L1:Computers**, and **L2:Computers**), other views have been opened but are hidden by the overview. The topology tab in the table view displays information about the entities in the groups. You can use the minimap to shift the focus in the view.

Right-click the object and select **Open Detail View** to view entities in a more detailed view. For example, at a high level an object representing a storage subsystem is depicted as an icon with a label. In a more detailed view, the same storage subsystem can be rendered as a box containing sub-entities representing disks, with the corresponding table view showing attributes of each individual disk. At yet another detail level, the ports of the storage subsystem might be shown as well as status information for each port.

*GUI Topology Viewer has new L0 and L1 Switches views:*

The IBM Tivoli Storage Productivity Center GUI has a Switches node under the Topology node. The Switches node opens the new L0 Switches view, from which you can also access the new L1 Switches view.

### **Overview**

The Overview panel now shows a box with the number of switches present in your environment.

### **L0 Switches**

The L0 Switches view shows all switches in your environment.

If you right-click on a Switches group, then click **Group By**, you will get a dialog box for group settings. You can choose to group by a single group or you can group by multiple categories:

- ByHealth
- ByUDP1
- ByUDP2
- ByUDP3
- ByFabric
- ByGroupSize

Click OK to close the dialog box and update the group settings.

### **L1 Switches**

The L1 Switches view shows information on a group of switches in your environment that you selected to display. This also includes connectivity information: what entities this group is connected to.

### **L2 Switch**

This view shows one switch, with all detailed port and connectivity information. You can access this view by double-clicking a single switch icon in either the L0 or L1 Switches view, or through the other Topology Viewer views.

### **The table view:**

This topic describes how tabs in the table view provide detailed information about the entities (for example, computers, subsystems, and fabrics) that are relevant in the current view.

The following is a list of all the tabs available in the topology viewer. Not all tabs are visible in all views.

**Topology**

Detailed information about all the entities in the topology grouped by class of the entity (computers, fabric, storage, and other).

**Computer**

Detailed information about any computer in the computer group or groups in the current topology view.

**Fabric** Detailed information about fabric groups and virtual fabric groups in the current topology view.

**Switch**

Detailed information about switch groups and switch entities in the current topology view.

**Subsystem**

Detailed information about volume groups and volume entities in the current topology view.

**Disk** Detailed information about disk groups and disk entities in the current topology view.

**Pool** Detailed information about pool groups and pool entities in the current topology view.

**Note:** One of the columns in the tabular view refers to whether a storage pool is primordial. A primordial pool represents unallocated storage capacity on a storage device. Storage capacity can be allocated from primordial pools to create storage pools. This means that primordial pools are disk/device sources for allocation of storage pools.

**Volume**

Detailed information about volume groups and volume entities in the current topology view.

**Tape Library**

Detailed information about tape-library groups and tape-library entities in the current topology view.

**Media Changer**

Detailed information about media-changer groups and media-changer entities in the current topology view.

**Tape Drive**

Detailed information about tape-drive groups and tape-drive entities in the current topology view.

**Other/Unknown**

Detailed information about objects in your environment other than computers, switches, subsystems, and tape libraries in the current topology view.

**FC Port**

Detailed information about port groups and port entities in the current topology view.

**Connection**

Detailed information about all relationships between objects in the current topology view.

**Alert** Detailed information about all alerts that are associated with entities in the current view of the topology.

**Zone** Detailed information about any of the following groups or entities in a zone. By default, the **Zone** tab is disabled.

- Fabric groups
- Zone-set groups
- Zone groups
- Computer entities
- Switch entities
- Subsystem entities
- Tape library entities

**Cluster**

Detailed information about clusters in the current topology view.

**Node** Detailed information about nodes in the current topology view.

**File Pool**

Detailed information about file pools in the current topology view.

**Filesystem**

Detailed information about file systems in the current topology view.

**Network Shared Disk**

Detailed information in Network Shared Disks in the current topology view.

**Export or Share**

Detailed information about exports or shares in the current topology view.

**File Set**

Detailed information about files sets in the current topology view.

**Identifying storage resources using icons:**

This topic describes how the topology viewer displays entities and groups of entities with an appropriate icon based on the entity class.

The storage resource icons can help you quickly and easily identify storage resources. For example, an entity of class "computer" is displayed in the graphical view with an icon that resembles a computer.

The following table shows the icons for individual resources and for resource groups.

| Topology Object | Icon                                                                                | Group Icon                                                                            |
|-----------------|-------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|
| Computer        |  |  |
| Computer HBA    |  |  |
| Fabric          |  |  |

| Topology Object                                                          | Icon                                                                                | Group Icon                                                                           |
|--------------------------------------------------------------------------|-------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| Switch                                                                   |    |    |
| Switch port                                                              |    |    |
| Storage subsystem                                                        |    |    |
| Storage subsystem port                                                   |    |    |
| Storage virtualizer (for example, SAN Volume Controller, HDS Tagmastore) |    |    |
| Tape library                                                             |    |    |
| Tape library media changer                                               |    |    |
| Database volume                                                          |    |    |
| File system volume                                                       |   |   |
| Storage volume                                                           |  |  |
| Other volume                                                             |  |  |
| Storage disk                                                             |  |  |
| Storage backend disk                                                     |  | n/a                                                                                  |
| Storage pool                                                             |  |  |
| Unknown                                                                  |  |  |

**Note:** *Unknown* entities are entities that are discovered by IBM Tivoli Storage Productivity Center but that do not have an agent installed or the agent is not working.

### Identifying icons for storage resources that contain full disk encryption disks

The icons in the following table identify whether a storage system contains encrypted or encryptable disks. The group icon for encrypted storage disks, pools, and volumes is the same as the group icons that are shown in the first table.

For more information on supported systems that provide full disk encryption, see “Supported storage systems providing full disk encryption and solid-state drives” on page 1477.

| Topology Object | Encrypted Icon                                                                    | Encryptable Icon                                                                    |
|-----------------|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| Storage disk    |  |  |
| Storage pool    |  |  |
| Storage volume  |  |  |

### Identifying icons for storage resources that contain solid state drives

A solid-state drive is a storage device that stores persistent data on solid-state flash memory. The icons in the following table identify whether a storage system contains solid-state drives. The group icons for storage disk, pool, and volume in the following table are the same as the group icons that are shown in the first table.

For more information on supported systems that provide solid-state drives, see “Supported storage systems providing full disk encryption and solid-state drives” on page 1477.

| Topology Object                | Icon                                                                                |
|--------------------------------|-------------------------------------------------------------------------------------|
| Solid-state drive storage disk |  |
| Solid-state drive storage pool |  |

### The topology viewer and virtual SANs:

Cisco switches support virtual SANs (VSANs), which is the logical partitioning of a fabric into multiple fabrics. The overall network is referred to as the physical infrastructure, and the logical fabrics are the VSANs.

SNMP queries to a Cisco switch collect information about the Cisco physical infrastructure and about any VSANs in that infrastructure. Storage Resource agents can also collect information about the VSANs but are unable to collect information about the physical infrastructure. The status of Cisco physical infrastructures that are shown in the topology view is determined based on the status that is propagated from the VSANs in the infrastructure and the status of the infrastructure itself. If the status of the physical infrastructure is missing but the status of all or some of the VSANs in the infrastructure is normal, infrastructure

information can no longer be collected. Typically, it indicated indicates that the out-of-band agent is no longer working properly or that SNMP queries to the Cisco switches are no longer configured because the switch was removed from the list of agents in the **Out of Band Fabric** node.

The consequences of this situation are illustrated in the following scenario: A fabric includes a Cisco switch with a VSAN on it. An out-of-band agent on the switch collects physical infrastructure and VSAN information. If the out-of-band agent is removed or Fabric Manager is no longer able to communicate with the agent, IBM Tivoli Storage Productivity Center still detects the VSAN through Storage Resource agents, but physical infrastructure information can no longer be collected. As a result, in the fabric topology view, the status of the physical infrastructure box is shown as missing, while the status of one or more VSANs in the infrastructure shows as normal. To correct this situation, ensure that the out-of-band agent is configured for the Cisco switch.

### **The topology viewer and VMware:**

This topic describes what the topology viewer displays for VMware support.

The Overview view of the topology viewer displays a count of hypervisors and virtual machines in the Computers summary.

The L0: Computers view displays the hypervisors and virtual machines in addition to other computers and includes the grouping By Virtualizer.

The L1: Computer view for a hypervisor displays volumes that were assigned to the hypervisor and the connectivity to fabrics.

The L1: Computer view for a virtual machine displays volumes that were assigned to the hypervisor and have been mapped to the VMware computer (virtual machine) as raw disks.

The L2: Computer view for a hypervisor includes a mapping of virtual machines and shows the virtual machine disk to physical disk relationship.

The L2: Computer view for a virtual machine displays the physical disk (what the virtual machine recognizes as a physical disk) to virtual machine disk relationship and hypervisor connectivity.

**Note:** IBM Tivoli Storage Productivity Center supports the mapping of storage between the storage system volume and ESX Server corresponding disk. This mapping is supported for the ESX Server 3.5 or VirtualCenter 2.5 or later. Previous versions of ESX Server or VirtualCenter are not supported for the mapping of storage to the storage system.

### **Viewing large environments in the Topology Viewer:**

In environments where you are monitoring a large number of storage entities, IBM Tivoli Storage Productivity Center might not be able to display all of those entities within the Topology Viewer. To avoid this issue, there are some tasks you can perform to improve overall scalability and performance of the user interface.

If the Topology Viewer is unable to display all the entities in your environment, the user interface generates javacore and heapdump files in its installation

directory. It is recommended that you check this directory to determine if this display problem is occurring in your environment. To do this, perform the following steps:

1. View the contents of the installation directory where Tivoli Storage Productivity Center's user interface is installed. The default installation directories are as follows:
  - Windows: C:\Program Files\IBM\TPC\gui\
  - UNIX/Linux: /<usr or opt>/IBM/TPC/gui/
2. Determine if javacore and heapdump files appear in the installation directory. You can identify these files by searching for files that begin with the word **javacore** or **heapdump** and have a **.txt** or **.phd** extension. For example: javacore.20080605.151906.8088.txt and heapdump.20080605.151903.8088.phd.

If these files appear in the installation directory, it might indicate that the display problem is occurring when you use the Topology Viewer.

There are two methods for working around this issue:

- Reducing the number of open topology views and disable unneeded overlays (such as the alert, performance, and zoning overlays). The number of topology views that are open and overlays that are enabled can affect how many storage entities are able to be displayed in the Topology Viewer.
- Increasing the memory allocation for IBM Tivoli Storage Productivity Center's user interface component. If reducing the number of open topology views and disabling unneeded overlays does not correct the problem, you can increase the amount of memory that is allocated to the user interface to help resolve the issue.

*Reducing the number of open topology views and disabling unneeded overlays:*

Perform these tasks to help improve the scalability of the Topology Viewer.

The number of topology views that are open can affect how many storage entities are able to be displayed within those views. The more views (tabs) that are open in the Topology Viewer, the more memory is used by the user interface. If the user interface requires more memory than is available to display all the entities within the open views of the Topology Viewer, some of the entities are not displayed. To workaroud this problem, close any views that you no longer need to view and refresh the content of the views that you leave open.

The number of overlays that are enabled in the Topology Viewer can also affect how many storage entities are able to be displayed. The topology viewer uses color and icons to indicate the status of objects in the topology and tabular views. Overlays are colors and icons that used to indicate health, performance, change, and alerts. To disable overlays that you do not need, complete the following steps:

1. Right-click on any blank space within a topology view.
2. Select **Global Settings...** from the pop-up menu.
3. Uncheck the overlays you do not need to view. For example, clear the **Performance** and **Alert** check boxes.
4. Click **OK** to accept the changes. The content of the open views within the Topology Viewer are automatically refreshed according to your changes.

*Increasing the memory allocation for the user interface:*

Perform this task to allocate more system memory to the IBM Tivoli Storage Productivity Center user interface.

Increasing the amount of allocated memory might enable the user interface to correctly display a large number of storage entities in the Topology Viewer. This task is generally recommended and encouraged in larger environments.

To do this, perform the following steps:

1. Close any current sessions of the Tivoli Storage Productivity Center user interface.
2. Locate the batch or script file that is used to start the user interface. This file is located in the Tivoli Storage Productivity Center installation directory on the computer where the user interface is installed. The default file names and installation directories are as follows:
  - Windows: C:\Program Files\IBM\TPC\gui\tpc.bat
  - UNIX/Linux: /<usr or opt>/IBM/TPC/gui/TPCD.sh
3. Open the tpc.bat or TPCD.sh file in a text editor and locate both occurrences of the parameter that defines how much memory is allocated to the GUI component:
  - Windows parameter: **-mx256M**. The default setting for Windows is 256 megabytes.
  - UNIX/Linux parameter: **-xmx512M**. The default setting for UNIX and Linux is 512 megabytes.
4. Increase the value for all occurrences of this parameter. For example:
  - Windows: change **-mx256M** to **-mx1024M**
  - UNIX/LINUX: change **-xmx512M** to **-xmx1024M**

**Note:** Make sure that the computer on which the user interface is installed has enough memory to support the setting that you define.

5. Save the batch or script file and restart the user interface.
6. Check the Topology Viewer to ensure that all the monitored storage entities are displayed as a result of increasing the amount of memory allocated to the user interface. If you still experience this display problem, repeat steps 1-5 and further increase the value for the parameter in the startup file.

Contact an IBM service representative if changing the memory allocation for the user interface does not help resolve the issue.

## Arranging entities in a group

This topic describes how to arrange entities in an expanded group.

You can arrange entities within the group box by health status or by entity label if an expanded group contains many entities. With either type of arrangement, you can specify ascending or descending order. To arrange entities, follow this procedure:

1. Right-click the graphical view and select **Arrange By**.
2. Select one of the following:
  - **Label (ascending)**
  - **Label (descending)**
  - **Health (ascending)**

- Health (descending)

## Checking the status of entities and groups

This topic describes how the topology viewer uses icons to indicate the health, performance, and operational status for entities.

To quickly check the health, performance, operational, change, and alert status of entities or groups of entities, look for the following icons associated with a particular entity or group in the topology. Position the cursor over these icons to see the health string in text format:

Table 41. Topology status indicators and their icons

| Indicator                                                              | Icon                                                                                  |
|------------------------------------------------------------------------|---------------------------------------------------------------------------------------|
| Health - Normal                                                        |    |
| Health - Warning                                                       |    |
| Health - Critical                                                      |    |
| Health - Unknown                                                       |    |
| Health - Missing                                                       |    |
| Operational - Running                                                  |    |
| Operational - Upgrading                                                |  |
| Operational - Missing                                                  |  |
| Performance - Normal                                                   |  |
| Performance - Unknown                                                  |  |
| Performance - Warning                                                  |  |
| Performance - Critical                                                 |  |
| Performance - Missing                                                  |  |
| Change - Objects did not exist at the two specified time periods       | Objects in light gray with no icon                                                    |
| Change - Objects changed between the two specified time periods        |  |
| Change - Objects did not change between the two specified time periods |  |
| Change - Objects were created between the two specified time periods   |  |
| Change - Objects were deleted between the two specified time periods   |  |

Table 41. Topology status indicators and their icons (continued)

| Indicator                                   | Icon                                                                                |
|---------------------------------------------|-------------------------------------------------------------------------------------|
| Alert - Critical, Warning, or Informational |  |

The operational status icons (running, upgrading, missing) are displayed by default and cannot be hidden. However, you can specify whether to display health, performance, or alert icons. To display these icons, follow this procedure:

1. Right-click a blank space in the background of the graphical panel and select **Global Settings**.
2. In the Settings window, select **Health, Performance, or Alert**. Click **OK**.

### Health status

This topic describes how the topology viewer displays the health status of entities.

The health of an entity falls into one of the following categories:

- Normal: The entity is operating normally.
- Warning: At least one part of the entity is not operating or has serious problems.
- Critical: The entity is either not operating or has serious problems.
- Unknown: The entity was discovered but is not recognized by IBM Tivoli Storage Productivity Center.
- Missing: The entity was previously discovered by Tivoli Storage Productivity Center, but was not detected in the most recent discovery.

The health of a group falls into one of the following four categories:

- Normal: All the entities in the group are operating normally.
- Warning: At least one entity in the group has normal status.
- Critical: All entities are either in critical or warning states.
- Unknown: None of the entities in the group have a known health status.

Health indicators for some entities, such as ports, are only normal and critical. In certain situations, the health of an entity might not be available. This happens, for example, when the entity is identified as missing. In the graphical view, missing entities are shown with a semitransparent light gray layer over an existing icon.

Level-indicator buttons on the graphical view (for example, **L0:Computers**) display icons for health.

Multiple states from single entities are aggregated into group states or states of entities, using the following rules:

- If all entities are in the same state, the aggregated state will represent this state.
- You will get an aggregated critical state (red) if:
  - One entity is in the missing state and at least one other entity shows a critical state.
  - One entity is in the critical state and at least one other entity shows a missing state.
- You will get an aggregated normal state if:
  - One entity is in the normal state and all others are in normal or undefined state.

- One entity is in the undefined state and all others are in normal or undefined state.
- All other combinations will aggregate to warning state (yellow).
- States displayed within the tabs of the topology view will be aggregated according to the focus of the specific entity class.
  - For Computers and Storage, only the states of these entities are used for aggregation.
  - For Fabric, only the switch status is used for aggregation.
  - For level 1 and 0, the states of all displayed entities are used for aggregation.

See “How status is determined for individual resources” for more information about how the status of individual entities are displayed in the topology viewer.

At the Overview level, the health status indicated by the icon on **Overview** for the graphical view indicates the aggregated status of all the groups inside the graphical view (**Computers, Fabrics, Switches, Storage and Other**). At the L0 level, the health status indicated by the icon on the **L0** tab of the graphical view indicates the aggregated status of all the groups inside that particular L0 graphical view (for example, the health status for the L0:Computers view would aggregate the health status of all discovered computers, including those that are missing, computers whose health status is critical, computers whose health status is warning). At the L1 level, the health status indicated by the icon on the **L1** tab of the graphical view indicates the status of the particular group that is the focus of the view. (The status of the group is based on the aggregated status of the entities within the group.) The health status for the group is also indicated in the table view. At the L2 level, the health status indicated by the icon on the **L2** tab of the graphical view is the same as the status of the particular entity that is the focus of the view. The health status for the entity is also indicated in the table view.

**Note:**

- At the L1:Fabric level the health status indicated by the icon on the **L1:Fabric** tab of the graphical view might not be the same as the overall health of the group, based upon the aggregated status of all the entities within the group.
- At the L2:Subsystem level, the status of the volume group is the aggregated status of all the volumes that comprise the group and not the status of the host that owns those volumes.
- The number of computers that are displayed in the Computers view of the topology viewer might be more than the number of Tivoli Storage Productivity Center agents that are deployed in the environment. These additional nodes are displayed with an "unknown" status. For example, if Tivoli Storage Productivity Center determines that a node in a fabric is an HBA, that node is displayed in the Computers view (rather than in the Other view). This situation occurs because during a probe, inband fabric agents can identify nodes in the topology viewer as HBAs in computers.

To update nodes that have an unknown status in the Computers view, deploy an Storage Resource agent on the computer that has the HBA whose WWN is shown in the topology viewer.

**How status is determined for individual resources:**

The topology viewer shows the status for individual resources and for groups of resources. The status of an individual resource is determined by its consolidated status and the propagated status of its internal resources.

The following statuses are possible for individual resources:

-  Normal: The resource is operating normally.
-  Warning: At least one part of the resource is not operating or has potential problems.
-  Missing: The resource was previously discovered by Tivoli Storage Productivity Center, but was not detected in the most recent discovery.
-  Critical: The resource is either not operating or has serious problems.
-  Unknown: The resource was discovered but is not recognized by Tivoli Storage Productivity Center.

Tivoli Storage Productivity Center determines the status of a resource by using its consolidated status and the propagated status of its internal components:

- A consolidated status is the status that is reported by the top-level resource for its own hardware. For example, if the cooling fans in a storage system are stopped and the internal temperature is too high, that status is reported to Tivoli Storage Productivity Center.
- A propagated status is the combined statuses of the monitored, internal resources for a top-level resource. For example, if a Warning status is detected on a volume in a storage system, that Warning status is used to determine the overall status of the storage system.

The statuses of the following internal resources are used to calculate the status of top-level resources.

*Table 42. Internal resources that are used to determine the status of top-level resources*

| Top-level resource                                                                                | Internal resources that are used to determine the status of a top-level resource                                                                                                                                                                                                                                                                                                                                                  |

Internal resources for a top-level resource might have different statuses. Tivoli Storage Productivity Center uses the most severe status of an internal resource when determining the overall status for a top-level resource. For example, in a storage system, a port might have a Critical status, a pool might have a Warning status, and a number of controllers might have an Unknown status. In this case, the overall status for the storage system is Critical because it is the most severe status that was detected on the internal resources.

Statuses for internal resources are propagated in the following way to determine the status of a top-level resource:

- If an internal resource has a Critical status, then the related top-level resource has a Critical status.
- If an internal resource has a Missing status, and no other internal resources have a Critical status, the related top-level resource has a Missing status.
- If an internal resource has a Warning status, and no other internal resources have a Critical or Missing status, the related top-level resource has a Warning status.
- If an internal resource has a Normal status, and no other internal resources have a Critical, Missing, or Warning status, the related top-level resources has a Normal status.

- If an internal resource has an Unknown status, and no other internal resources have a Critical, Missing, Warning, or Normal status, the related top-level resource has an Unknown status.

The following table shows some of the possible combinations of statuses and their resulting, propagated status.

Table 43. Propagation of the statuses for internal resources in the stand-alone GUI

| Critical<br> | Missing<br> | Warning<br> | Normal<br> | Unknown<br> | Resulting status for top-level resource                                                        |
|-----------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|
|                                                                                               |                                                                                              |                                                                                              |                                                                                             | X                                                                                              |  Unknown    |
|                                                                                               |                                                                                              |                                                                                              | X                                                                                           |                                                                                                |  Normal     |
|                                                                                               |                                                                                              |                                                                                              | X                                                                                           | X                                                                                              |  Normal     |
|                                                                                               |                                                                                              | X                                                                                            |                                                                                             |                                                                                                |  Warning    |

|                                                                                               |                                                                                              | X                                                                                            | X                                                                                           | X                                                                                              |  Warning    |
|                                                                                               | X                                                                                            |                                                                                              |                                                                                             |                                                                                                |  Missing    |
|                                                                                               | X                                                                                            |                                                                                              |                                                                                             | X                                                                                              |  Missing    |
|                                                                                               | X                                                                                            |                                                                                              | X                                                                                           | X                                                                                              |  Missing    |
|                                                                                               | X                                                                                            | X                                                                                            | X                                                                                           | X                                                                                              |  Missing  |
| X                                                                                             |                                                                                              |                                                                                              |                                                                                             |                                                                                                |  Critical |
| X                                                                                             |                                                                                              |                                                                                              |                                                                                             | X                                                                                              |  Critical |
| X                                                                                             |                                                                                              |                                                                                              | X                                                                                           | X                                                                                              |  Critical |
| X                                                                                             |                                                                                              | X                                                                                            | X                                                                                           | X                                                                                              |  Critical |
| X                                                                                             | X                                                                                            | X                                                                                            | X                                                                                           | X                                                                                              |  Critical |

## Operational status

This topic describes how the topology viewer has three categories of operational status for entities.

The operational status of most entities falls into one of the following three categories:

Table 44. Categories of operational status for storage entities

| Status    | Description                                                  |
|-----------|--------------------------------------------------------------|
| Running   | The entity is running.                                       |
| Upgrading | The entity is upgrading.                                     |
| Missing   | The entity was not discovered during the last refresh cycle. |

However, some entities display additional operational status. For example, switches can display a status of **OK**, **Error**, **Stopped**, and other types of status.

**Note:** When IBM Tivoli Storage Productivity Center no longer detects an entity that was previously displayed in the Topology viewer, the operational status of

that entity remains as the last known status before it went missing. This means that the operational status of an entity is not cleared or reset if that entity is not found in subsequent data collection jobs.

## Performance status

This topic describes performance status details collected for entities.

Performance information is collected for entities in the L2:Switch and L2:Subsystem views. You can see the performance indicators for individual switches and subsystems in these two views by turning on the performance feature in the Global Settings window. This feature is not enabled by default.

The performance status of an entity falls into one of the following five categories:

- Normal: The entity is performing at the expected level.
- Warning: At least one part of the entity is not operating at the expected performance level.
- Critical: The entity is not operating at the expected performance level.
- Unknown: The performance of the entity is not known.
- Missing: The entity was not found during the last refresh cycle and the performance status is not available.

The performance status does not get carried up to the L0 and L1 views. It is only available in the L2:Switch and L2:Subsystem views.

Performance status of an entity is not propagated upwards to its parent entity. For example, a SAN Volume Controller can cross several critical or warning stress thresholds (and show as yellow or red in the topology viewer) even though the underlying pools, disks or volumes do not have a degraded performance status.

After performance has been enabled, you will see a performance status indicator for any entity in these views that has performance data available. Position the cursor over a performance icon to see a list of performance metrics for that entity.

To enable the collection of performance information, perform the following steps:

1. Right-click a blank space in the background of the graphical panel and select **Global Settings**.
2. In the Settings window, select **Performance** and click **OK**.

## Change status

This topic describes how the Configuration History topology view displays the status of entities over time.

The Configuration History feature uses the icons and colors of the change overlay to indicate historical changes in a SAN configuration's entities. The same icons and colors are used in the graphical view, table view, and snapshot selection panel. The following table lists the five possible states of an entity and shows the associated icons and colors.

| State of an entity                                                                                        | Change overlay icon                                                                                    | Change overlay color indicator |
|-----------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|--------------------------------|
| Entity changed between the time that the snapshot was taken and the time that a later snapshot was taken. | <br>Yellow pencil | Blue background                |

| State of an entity                                                                                                       | Change overlay icon                                                                                      | Change overlay color indicator |
|--------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|--------------------------------|
| Entity did not change between the time that the snapshot was taken and the time that a later snapshot was taken.         | <br>Light gray circle | Dark gray background           |
| Entity was created or added between the time that the snapshot was taken and the time that a later snapshot was taken.   | <br>Green cross       | Green background               |
| Entity was deleted or removed between the time that the snapshot was taken and the time that a later snapshot was taken. | <br>Red minus sign    | Red background                 |
| Entity did not exist at the time that the snapshot was taken or at the time that a later snapshot was taken.             | Not applicable                                                                                           | Light gray background          |

Level-indicator buttons in the graphical view (for example, **L0:Computers**) display the change icons.

For groups and other collections, the change overlay provides only aggregated status. That is, the change status for a group of entities is either “changed” or “unchanged.” Details for the group as a whole are not provided. Aggregated status displays in the minimap. In the Configuration History page, the minimap uses the following colors to indicate the aggregated change status of groups:

- Blue (changed): One or more entities in the group changed (an addition or deletion of an entity is considered a change).
- Gray (unchanged): All entities in the group are unchanged.

An object that is moved from one group to another group appears only once in the new group in the graphical view. For example, if the health status of a computer has changed from Normal to Warning, the Configuration History page displays the computer as changed in the Warning health group (and no longer displays the computer in the Normal health group).

**Important:** If you manually deleted a missing entity from the Tivoli Storage Productivity Center, the configuration history function rediscovers and displays the entity in the configuration history viewer as both Missing and in a Normal state. For example, Entity A (with ID 12) is missing and you decide to manually delete it by using the Remove From Database option from the pop-up menu for Entity A in the topology viewer or configuration history viewer. Later, the Tivoli Storage Productivity Center rediscovers Entity A and assigns it a new ID (ID 22). The configuration history function treats the same Entity A (with ID 12 and ID 22) as two different entities and displays them in both Missing and Normal states in the configuration history viewer. This scenario can also occur if a missing entity is removed by the Tivoli Storage Productivity Center removed resource retention function and is rediscovered by the Tivoli Storage Productivity Center again at a later time.

To display a summary of change for the entire row, hover over the changed row. The summary displays the title of the column. It also displays the old and new value for each cell or tab that changed. For example, if a group contains one new entity but everything else in the group is unchanged, the group as a whole displays as “changed.” If you click the group, the one new entity displays as “created” and all other entities display as “unchanged.”

The Change column in the table view also indicates changed entities.

## Alert status

This topic describes how the topology viewer displays alert status for all entities in the current view.

The alert status of an entity falls into one of the following categories:

- Warning: At least one part of the entity is not operating or has serious problems.
- Critical: The entity is either not operating or has serious problems.
- Informational: Related data about the entity is supplied to aid you in decision making.

When enabled, in the topology viewer the alert overlay is located next to entity icons, near the pinning indicator. The icon for the alert overlay is a red exclamation

mark  for the presence of alerts. In the title bar of groups and tabs, the alert icon is similarly located near the entity label. The alert overlay is disabled in the Configuration History page.

To find alerts that are associated with an entity in the table view, click the alert overlay indicator to go to the corresponding alert on the Alert tab. Or, right-click the entity to display a pop-up menu and click **Show Alerts in Tabular View** to go to the Alert tab and any corresponding alerts that are associated with that entity. The corresponding alerts are highlighted in purple. When you select an alert in the Alert tab, the entities that are associated with that alert are highlighted in purple in the graphical view. Note that more than one entity may become highlighted. An alert icon for a collapsed group indicates that alerts exist within the collapsed group.

The alert overlay provides rollup, similar to pinning. If alerts are inside a collapsed group, the number of alerts within that group are aggregated and indicated in the collapsed group. All alerts are aggregated into one count, independent of type or entity involved. Hover over the alert indicator for a tab or group to determine the total number of alerts that are rolled up into that indicator and the time stamp of the newest alert.

In the table view, click the Alert tab to view all alerts associated with entities in the current view of the topology. The Alert tab contains alerts as a hierarchical list. For configuration analysis alerts, the highest level provides information about which policy was violated during a particular analyzer run. The next level indicates the number of times that the policy was violated. This list contains one node for each policy violation. The Alert tab only lists the policy violations that contain at least one of the affected entities that are displayed in the graphical view. The remaining policy violations are filtered. The only exception is the Overview panel where the Alert tab lists all of the policy violations. Click each violation to view a list of affected entities. The parent entities for these affected entities are displayed in a separate column. You can resort the alert list by clicking the headers in the table. For instance, by clicking on the header for the entity the alert table is reorganized into a hierarchical list sorted by entity, then by alert type. If no alert was generated for an entity, the Alert column is blank.

To find an entity associated with an alert in the graphical view, click the alert on the Alert tab. The corresponding entity and any associated entities are highlighted (but not selected) in the graphical view. The highlighting is purple.

For more information, see “Viewing alerts” on page 401.

## Creating custom groups

This topic describes how custom groups can be created based on criteria that is useful and relevant to you.

Custom groups are visible in both the graphical view and the table view. You can create custom groups using any of the following criteria. The grouping criterion is displayed in parentheses in the title bar of the group box.

For example, using the topology viewer, you can organize a collection of computers into groups based on the type of operating system (for example, Windows, Linux and so on). Using a UDP, you could also create subgroups for each operating system-based group of computers (for example, the Windows group could contain subgroups for Windows 2000 and Windows NT). Organization into groups can also be based on physical location of associated devices; for example, devices in Lab A could be organized in one group, devices in Lab B could be organized in another group, and so on. To create these types of groups, use UDPs (for example, a text string of "Lab A"). To set UDPs use the pop-up menu item, Launch Detail Panel.

If you specify grouping by UDP, the groups are sorted in alphanumeric order in the graphical view. If the grouping is by health status, groups are sorted in the following order: missing, critical, warning, normal and unknown. You can also specify the arrangement of entities within a group box based on health status and label.

To group entities, follow this procedure:

1. Right-click a group and select **Group By**.
2. Select a group-by option. Options differ depending upon the class of the group.

### **Single Group**

All entities are included in one group.

### **Health**

Groups are based on health status (for example, normal or warning).

**Model** The model of the storage subsystems server (for example, DS8000). This option is available for subsystem groups only.

### **OS Type**

Groups are based on operating systems. This option is available for computer groups only.

### **RAID level**

Groups are based on RAID level. This option is available only for pool groups at the **L2:Subsystems** level.

**Fabric** This option is available for switch groups only.

### **User-defined properties (UDPs)**

UDPs are characteristics that you define for an entity. For example, you could create a UDP for several entities using the text string "new installation." All the entities with that UDP would be grouped together. The topology viewer provides three UDPs so that you can group resources in three different ways, depending on your needs. UDPs are not available for fabric groups.

## Defining properties for grouping entities

This topic describes how User-defined properties (UDPs) are useful for describing specific properties of an entity or a set of entities.

You can also use UDPs to group entities with similar characteristics. The topology viewer lets you define three UDPs for an entity. UDPs are not available for fabric groups. To define one or more UDPs for an entity, follow this procedure:

1. Right-click an entity and select **Launch Detail Panel**.
2. Type a property in the **User Defined Property 1** field (for example, a specific operating system, location of computers, and so on).
3. Optional: Type additional properties in the **User Defined Property 2** and **User Defined Property 3** fields, and then click **Set**.
4. Type a description of the element manager and click **OK**.
5. Click **Launch**.

## Displaying data paths from one endpoint in the topology to another

This topic describes how to view connectivity for selected entities in the topology using Data Path Explorer.

### Data Path Explorer Overview

The Data Path Explorer allows you to follow connectivity between a host disk or computer and a storage subsystem. The Data Path Explorer also provides SAN Volume Controller support. Using Data Path Explorer you can follow the connectivity from a computer to SAN Volume Controller, and from an SAN Volume Controller to a storage subsystem.

Viewing a single data path allows you to monitor performance status and pinpoint weaknesses without navigating the many entities typically seen in Topology Viewer.

Data Path Explorer shows only those entities that are part of the selected data path, and only certain types of entities, such as host, switch, host bus adapter (HBA), port, storage subsystem, and storage volume.

Data Path Explorer functions like the rest of the Topology Viewer, with key variations.

**Note:** The shortcut to Data Path Explorer is not available in the Configuration History topology view.

### Before Using Data Path Explorer

Different amounts of information can be shown by the Data Path Explorer, depending on which agents are deployed throughout the fabric.

To use Data Path Explorer for debugging performance problems, complete the following steps to ensure that information in the view is current:

1. In the Topology Viewer, right-click and select **Global Settings**.
2. Select the **Performance** check box to enable the performance overlay.
3. Click **OK**.
4. Ensure that I/O is running on the host machine.

5. Create a threshold alert. For information about threshold alerts, see “Creating a performance threshold within an alert” on page 150.
6. Create and run performance monitors on the switches and storage subsystems that you want to view.
7. Run a discovery for the CIM agents and Storage Resource agents.
8. Run a probe to collect data about the storage subsystems, fabrics, and Storage Resource agents.
9. Run a performance monitor to collect performance data for the storage subsystems and switches that you want to view. For information about how to create and run performance monitors, see “Monitoring switch performance” on page 378 or “Monitoring storage-subsystem performance” on page 379.

See the section about planning for the Data Path Explorer view in the *IBM Tivoli Storage Productivity Center and IBM Tivoli Storage Productivity Center for Replication Installation and Configuration Guide* for more information on configuring data path explorer.

## Graphical View

When you open a data path view, three tiles display in the graphical view: Initiator Entities, Fabrics, and Target Entities. These contain all the entities in all the data paths related to the selected host or storage entity.

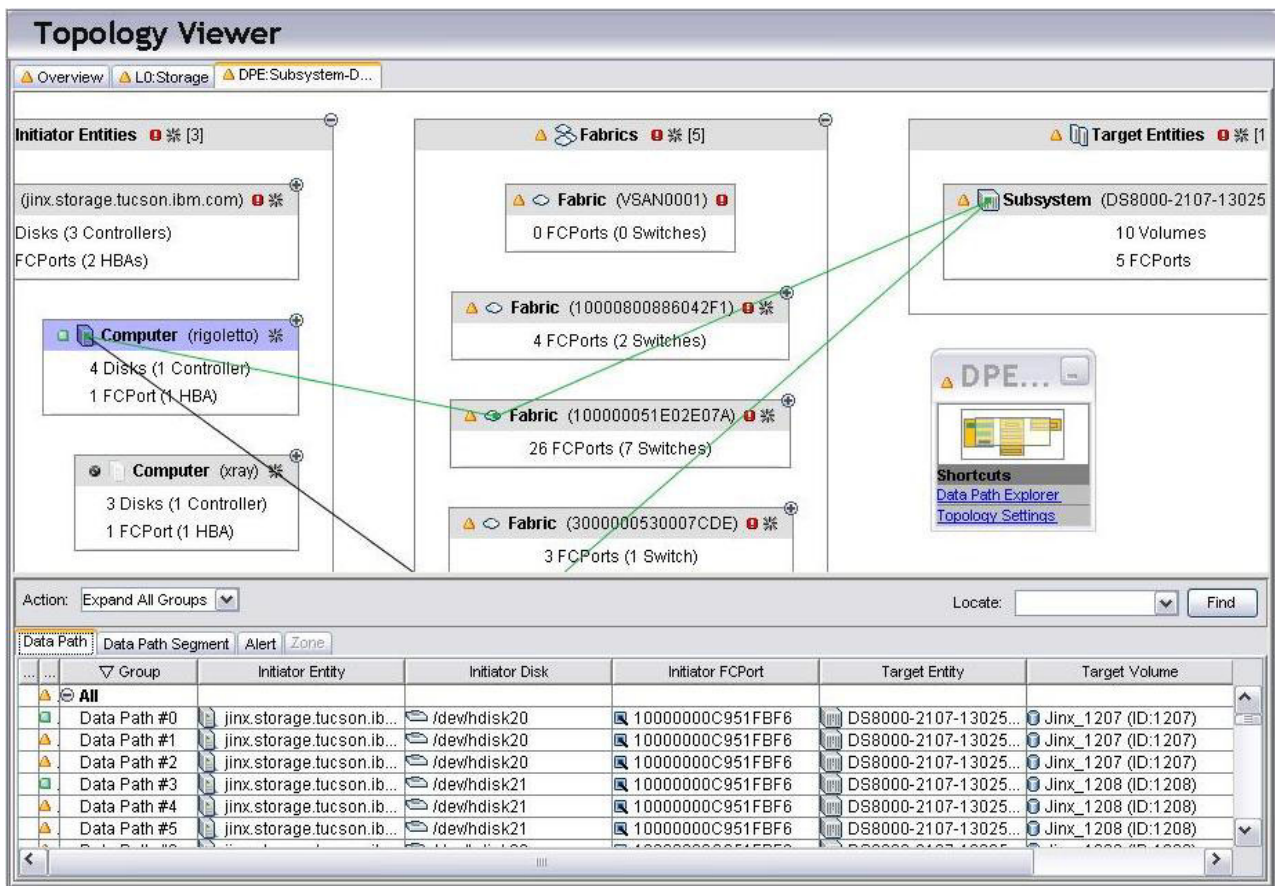

Figure 42. Data Path Explorer view

- Selecting an entity in any of the tile groups at any level displays connector lines showing the data paths the entity is involved in.
- Each tile behaves like an active topology viewer tab, allows grouping and regrouping, expanding and collapsing of groups and so forth. Each tile can be expanded to view the lower-level details such as the disks, ports and volumes involved in a data path.

### **Initiator Entities**

The Initiator Entities tile contains the computers and related volumes, disks, and HBA ports that have valid data paths to the storage system. Expanded computer tiles display each computer, its health status icons, and a count of the entities within the computer that are part of the valid data paths. Expanded computer tiles show the controllers and disks, HBA ports, and volumes on the computer that are part of valid data paths. The initiator entities tile can also contain SAN Volume Controllers. An SAN Volume Controller is a storage virtualization device and can act as an initiator entity. Expanded SAN Volume Controller tiles show the SAN Volume Controller managed disks and ports that are part of valid data paths.

### **Fabrics**

The Fabrics tile contains the fabrics entities, mainly switches and ports, through which valid data paths for the selected endpoint traverse. A count of the switches and switch ports with health status icons and labels are shown in the group title. Expanded Fabric tiles display a view of the switches to the port level. Only switches and ports with valid data paths traversing through them are displayed.

### **Target Entities**

The Target Entities tile contains the endpoint storage systems in data paths for the selected endpoint. Expanded Target tiles display each storage subsystem, its status icons, a count of entities, and the number of subsystem front-end ports and volumes involved. When these are expanded, the associated port and volume tiles display. These can also be expanded to show individual entities.

## **Table View**

The data path table displays under the graphical view. Each row in the table view shows a valid data path for the selected endpoint.

Display a single data path in the graphical view by selecting a row in the data path table.

The data path table has two tabs: Data Path and Data Path Segment.

### **Data Path tab**

This is the default view. This tab shows each data path associated with the entity for which the data path was opened.

- Select an entity in the graphical view to display individual data paths in the table.
- The health status shown for each data path is aggregated.
- The data path table can be sorted by any of the column headers.

See “Columns in Data Path tab” on page 530.

### **Data Path Segment tab**

This tab displays the segments in a data path. One segment is listed per row.

There are two ways to populate the Data Path Segment table:

- Select a data path in the Data Path tab. The Segment tab then lists the segments in the selected data path.
- Click an entity in the graphical view. The Segment tab lists the segments in all of the data paths the entity is involved in. These are identified by data path number (0, 1, 4, and so on).

See “Columns in Data Path Segment tab” on page 530.

### **Related reference:**

“Opening a Data Path View”

Data Path Explorer provides an end-to-end topology view of the storage environment from a host disk to a storage volume. It displays the different data paths (SAN access paths or I/O paths) for each host disk.

“Displaying an entity's data paths” on page 529

You can view the data paths associated with any entity by selecting the entity in the graphical view. Lines connect the related entities in the data path or paths.

“Example use cases for Data Path Explorer” on page 531

The following examples show some of the use scenarios for Data Path Explorer:

### **Opening a Data Path View**

Data Path Explorer provides an end-to-end topology view of the storage environment from a host disk to a storage volume. It displays the different data paths (SAN access paths or I/O paths) for each host disk.

You can open a data path view on any of the following endpoints:

**host** The host (computer) must have at least one disk that is assigned from a subsystem.

#### **subsystem**

The subsystem must have at least one volume assigned to a host.

#### **volume**

The volume must be assigned to a computer, and the fabric must be zoned so that the computer can see the volume.

**disk** The disk must be from a subsystem. Note that the disk can be host disk or SAN Volume Controller managed disk.

Open a data path explorer view in one of the following ways:

- Right click on an endpoint, and then select Open Data path view.
- Select an endpoint, and then select Open Data path view from the Action menu.
- Select an endpoint, and then select the Data Path Explorer shortcut in the minimap
- For multiple entities: Select one or more endpoints of the same type (for example, one or more storage volumes), and then select Open Data Path View. The data paths display for all of the endpoints selected. If you select an SAN Volume Controller entity, all other entities you select must be SAN Volume Controller entities.

### **Note:**

1. Opening the Data Path Explorer view for a subsystem (including an SAN Volume Controller) that has several associated data paths can consume extensive system resources. Select volumes or disks instead, and then open the Data Path Explorer view.
2. If the endpoint is an SAN Volume Controller, two data path views are opened because the SAN Volume Controller can act as both a initiator and target entity. The first view displays the data paths associated with the SAN Volume Controller acting as a storage subsystem or a target entity. The second view displays the data paths associated with the SAN Volume Controller acting as an initiator entity.

When a data path view is opened, three tiles display: the Initiator Entities, Fabric, and Target Entities tiles. These tiles contain all the associated entities in the data paths. Select an entity within one of the tiles to see the data paths associated with it. You may need to further expand the tiles.

If you select an entity or a group of entities that do not have a valid data path, a dialog box displays with the following message: "No available DataPath for the selected entities."

The Data Path Table lists each data path (one per row).

To return to a normal topology view, right-click an entity in the graphical or table view and select **Open Detail View** from the pop-up menu.

### Displaying an entity's data paths

You can view the data paths associated with any entity by selecting the entity in the graphical view. Lines connect the related entities in the data path or paths.

- In the table view-Data Path tab, the selected entity's data paths are highlighted.
- The table view-Data Path Segment tab displays the data paths belonging to the selected entity and the individual segments that make up the data path.

### Multiple paths

IBM Tivoli Storage Productivity Center shows the multiple paths from the disks to the storage subsystem volumes in the Data Path Explorer view. IBM Subsystem Device Driver (SDD) software allows the operating system to use multiple paths (that is, different initiator and target port pairs) through the SAN for storage access. On the L2 Computer View and the Data Path Explorer view, the disks with multiple paths managed by SDD are grouped in a controller representing the SDD driver.

For a Windows computer with multiple paths managed by SDD to subsystem volumes, a controller representing the SDD driver is displayed, and this controller contains the disks managed by the SDD.

For a non-Windows computer with multiple paths managed by SDD to subsystem volumes, Data Path Explorer displays a controller representing the SDD driver, and this controller contains the vpath disks. A separate disk (for example, hdisk on AIX) is created by the operating system on the non-Windows computer for each path to the storage volume. These disks are grouped by the controller that contains the initiator port present in the path.

The Linux SDD driver is no longer available. Starting with Red Hat Enterprise Linux Version 5 and SUSE Linux Enterprise Server Version 10, only the DM\_Multipath is available. The DM\_Multipath is supported by SAN Planner. The SDD driver is no longer supported on HP, starting with

HP-UX 11i v3 with Itanium®. HP-UX 11i v3 provides a native multipathing feature which is supported by SAN Planner.

**Related reference:**

“Columns in Data Path tab”

When an entity in the Data Path Explorer graphical view is selected, its data paths display in the Data Path tab.

“Columns in Data Path Segment tab”

The Data Path Explorer Segment tab shows each segment in a data path.

### **Columns in Data Path tab**

When an entity in the Data Path Explorer graphical view is selected, its data paths display in the Data Path tab.

The Data Path tab columns display the following information:

**Located**

This column is associated with the Locate function in the Topology Viewer. If search text is present in a row, the Locate column displays a magnifier icon.

**Health (status)**

The aggregated status of the data path.

**Group** The number of the data path.

**Initiator Entity**

The name of the computer or SAN Volume Controller in the data path.

**Initiator Disk**

The computer disk or SAN Volume Controller managed disk in the data path.

**Initiator FCPort**

The computer Fibre Channel port in the data path. Data in this column comes from the HBA port entity in the Computer tile. If an SAN Volume Controller is the initiator entity, this column contains the SAN Volume Controller fibre channel port in the data path.

**Target Entity**

The storage subsystem in the data path.

**Target Volume**

The storage volume in the data path. An asterisk indicates that this is a space-efficient volume or vdisk.

**Target FCPort**

The storage Fibre Channel port in the data path.

### **Columns in Data Path Segment tab**

The Data Path Explorer Segment tab shows each segment in a data path.

Each segment has two endpoints: the beginning device and the ending device connected by a communication link. Each endpoint resides in a parent entity, which can be a computer, fabric, or subsystem.

The Data Path Segment tab columns display the following information:

**Located**

This column is associated with the Locate function in the Topology Viewer. If search text is present in a row, the Locate column displays a magnifier icon.

**Segment Health**

The health status of the segment is an aggregation of From Endpoint Health, To Endpoint Health, From Entity Health, To Entity Health, and Connection Health.

**Label** The number of the data path and its segments. The data path number corresponds to the numbering on the Data Path tab. Segment numbering advances from computer tile through fabric tile to subsystem tile.

**From Entity Health**

The health status of the parent entity beginning the segment.

**From Entity Performance**

The performance status of the parent entity that begins the segment. This column is displayed only when the performance overlay is enabled.

**From Entity**

The name of the computer, fabric, or subsystem that is the parent of the beginning device (endpoint) in the segment.

**From Endpoint Health**

The health status of the endpoint device that begins the segment.

**From Endpoint Performance**

The performance status of the endpoint device that begins the segment. This column is displayed only when the performance overlay is enabled.

**From Endpoint**

The name of the endpoint device that begins the segment.

**To Entity Health**

The health status of the parent entity that ends a segment.

**To Entity Performance**

The performance status of the parent entity that ends the segment. This column is displayed only when the performance overlay is enabled.

**To Entity**

The name of the computer, fabric, or subsystem that is the parent of the ending device (endpoint) in the segment.

**To Endpoint Health**

The health status of the endpoint device that ends the segment.

**To Endpoint Performance**

The performance status of the endpoint device that ends the segment. This column is displayed only when the performance overlay is enabled.

**To Endpoint**

The name of the endpoint device that ends the segment.

**Connection Health**

The health status of the connection between the endpoint device that begins the segment (From Endpoint) and the endpoint device that ends the segment (To Endpoint). The Connection Health is displayed as N/A if the health status data for the connection is not available.

**Example use cases for Data Path Explorer**

The following examples show some of the use scenarios for Data Path Explorer:

- An application on a host is running slowly, which causes you to question the health of the I/O path for that application. Are there component level performance problems that might cause the slow application response?
- Disk utilization on the storage subsystem is high, triggering performance alerts. You decide to see which hosts or applications, residing on separate host disks, are causing the problem.
- You suspect that the I/O paths for two applications (on separate host disks) are in conflict with each other. They could be sharing a common component (such as a switch). After viewing the I/O paths for these two applications, you make the required zoning or connectivity change to alleviate the problem.
- I/O path information can be used do load balancing and storage planning. For example, a host adapter port on a host has I/O from three host disks passing through it, but a second port has I/O from ten host disks (and has more I/O). This information can be used to provision a new host disk using the first host adapter port.

**Note:** Application to host disk mapping is not shown in the Topology Viewer. This mapping must be done outside IBM Tivoli Storage Productivity Center. However, Tivoli Storage Productivity Center can provide mapping from database applications to host disks if configured to do so.

### Planning for Data Path Explorer view

Use the Data Path Explorer view to monitor the health and performance statistics of storage components.

The Data Path Explorer is a type of view in the topology viewer. It combines topology views into a visualization that you can use to follow the connectivity from one end point in the topology view to another. Storage administrators can use this view to debug connectivity and performance problems in the storage environment. Data Path Explorer displays the different data paths (SAN access paths or I/O paths) for each host disk so that you can check the health and performance statistics of the resources along the I/O path.

To use Data Path Explorer for debugging performance problems, complete the following steps to ensure that information in the view is current:

1. In the Topology Viewer, right-click and select **Global Settings**.
2. Select the **Performance** check box to enable the performance overlay.
3. Click **OK**.
4. Ensure that I/O is running on the host machine.
5. Create a threshold alert. For information about threshold alerts, see “Creating a performance threshold within an alert” on page 150.
6. Create and run performance monitors on the switches and storage subsystems that you want to view.
7. Run a discovery for the CIM agents and Storage Resource agents.
8. Run a probe to collect data about the storage subsystems, fabrics, and Storage Resource agents.
9. Run a performance monitor to collect performance data for the storage subsystems and switches that you want to view. For information about how to create and run performance monitors, see “Monitoring switch performance” on page 378 or “Monitoring storage-subsystem performance” on page 379.

Different agents have different roles when they discover information and affect what can be shown in the Topology Viewer. The Data Path Explorer view is also

subject to those limitations. Different amounts of information can be shown by the Data Path Explorer view depending on the agents that are deployed throughout the fabric.

To display data paths from a host to a subsystem in this view, it is necessary to install and configure the following agents:

- CIM agent to monitor the storage subsystem
- Storage Resource agent to monitor the host
- Storage Resource agent to monitor the fabric
- CIM agent to collect performance information about the fabric

To show the host disk assignment for a storage subsystem, the Tivoli Storage Productivity Center Data server requires access to the CIM agents (SMI-S agent) that are managing it. For storage subsystems, the data path is defined by the host masking or mapping information that is maintained by the CIM agent.

Analysis on the data path of a SAN Volume Controller requires that one or more CIM agents are managing it and the back-end system.

To show accurate information, you must have the most current information from CIM agents and Storage Resource agents. To ensure that you have the most current information, run probes on all the resources in the data path before you view the Data Path Explorer.

To show physical fabric connectivity, you must have a Storage Resource agent, out-of-band Fabric agent, or CIM agent for monitoring the fabric.

To show performance overlay in the Data Path Explorer, you must first create and run performance monitors on the switches and storage subsystems that you want to view.

To show zone overlay, you must have a Storage Resource agent that is connected to the fabric along the data paths or a CIM agent for the fabric. To view the zone overlay, complete the following steps:

1. In the Topology Viewer, right-click and select **Global Settings**.
2. Select the **Show zone tab**.
3. Click **OK**.

If you want to start the Data Path Explorer view for a host, you must deploy a Storage Resource agent to it.

Complete the following steps to set up the Data Path Explorer for viewing:

1. Install and configure the CIM agents for the storage subsystems and fabric. Contact your vendor for information about installing and configuring the CIM agent for a storage subsystem or fabric.
2. Install and configure a Storage Resource agent or out-of-band Fabric agent to monitor the fabric.
3. Install the Storage Resource agent on the hosts.

## Displaying membership in zones and zone sets

This topic describes how the topology viewer allows you to examine zones and zone sets.

Zone information is shown in the **Zone** tab in the table view. The **Zone** tab is disabled by default. Selecting a zone or zone set in the **Zone** tab highlights zone and zone set members in the graphical view. Ports and entities that are members of the selected zone or zone set are indicated in the graphical view by highlighting. You can select highlighted entities to show details (for example, connections).

The entities listed in the **Zone** tab are only those entities that are in the current view. However, zone or zone-set selections apply to all currently open views in the topology viewer. Therefore, switching to another view might indicate other entities in the selected zone.

**Note:** You cannot use the **Zone** tab to change membership status of entities.

To activate the **Zone** tab, follow this procedure:

1. Right-click in the graphical view and select **Global Settings**.
2. In the Settings window, select **Show zone tab** and click **OK**.

## Displaying detailed information about entities

This topic describes how to view detailed information about entities using the topology viewer.

There are two ways to display information about entities:

1. Right-click the entity and select **Launch Detail Panel** to display detailed information about an entity (for example, the operating system of a computer, the used and unused capacity of a storage subsystem)
2. Right-click the entity or entities and select **Reports**. From the dialog displayed, you can choose which report to create. The reports you can choose depend on which entities you selected. Asset reports are available only if you selected a single entity. Select a report and click **Create Report**

## Displaying storage resource connections

This topic describes how physical and logical connections among entities in the environment can be displayed using the topology viewer.

Connections are shown in both the graphical and table views. In the graphical view, connections are represented by lines between entities or groups. In the table view, a **Connections** tab lists both ends of a connection.

Figure 43. Connections

In the graphical view, the color of a connecting line between entities indicates the status of a connection. The color of the line between groups, individual entities, or between an individual entity and a group can be green (normal), yellow (warning), red (critical), black (missing), or grey (status unavailable).

**Note:** When you have a host with two HBAs or FC ports that are both in the same switch and you switch the ports between them, the connection will be shown with two yellow (warning) lines. This is because you have not reset the history retention setting. Until the settings are reset, the connecting lines will remain yellow.

Connections between two individual entities are represented by a thin line. Connections between groups or between a group and an individual entity are represented by a thick line. A connection to a collapsed group can represent either a single connection or several connections.

To show connections, follow this procedure:

1. Right-click a blank space in background of the graphical view and select **Global Settings**.
2. In the Settings window, select **Show Connections** and click **OK**.

## Filtering entities based on health status

This topic describes how to quickly narrow the health status of normal or non-normal entities in your environment.

In views with many entities and connections, the display can become very cluttered and can make it difficult to determine where problems are occurring. You can filter entities to display only those entities whose health status is non-normal (critical, warning, missing, or unknown).

When you apply filtering, you can also choose to display entities with a health status of normal but that are connected to entities whose health status is either critical or warning. To filter entities by health status:

1. Right-click in the background area of the graphical view and select **Global Settings**.

2. In the Settings window, select **Hide Normal Entities** and, optionally, **Unless connected to non-normal**, and click **OK**.

## Labeling entities

This topic describes how you can specify or change label entities.

In both the graphical and table views, entities are identified by labels (for example, the name of a computer). You can specify or change these labels. To specify or change the existing label for an entity, follow this procedure:

1. Right-click the entity and select **Launch Detail Panel**.
2. Type a label for the entity in the **Label** field.
3. Click the save icon in the menu bar to save the label, and then close the window.

## Starting element managers

If element managers on a system, tape library, switch, or other entity are defined in IBM Tivoli Storage Productivity Center, you can start the element managers to access vendor-provided management tools.

To start an element manager for an entity, right-click the entity. A menu that contains launch options is displayed. The options that are displayed depend on the element managers that you configured on the Element Manager page of the Configuration Utility. The following options are displayed on this menu:

- **Launch in context defined application.** This menu item is displayed for each application that is defined by a launch descriptor file. Tivoli Storage Productivity Center provides launch descriptor files for the following applications:
  - System Storage DS8000 Storage Manager
  - The management console for the storage systems that are listed under **Management GUI**.
  - Tivoli Storage Productivity Center for Replication

If the corresponding launch descriptor files are found for the applications, the following menu items are displayed:

### **DS8000 Storage Manager**

Click this menu item to start DS8000 Storage Manager.

### **Management GUI**

Click this menu item to start the management console for the following storage systems:

- SAN Volume Controller
- Storwize V3500
- Storwize V3700
- Storwize V7000
- Storwize V7000 Unified
- IBM SONAS

### **Replication Storage Systems Overview**

Click this menu item to start Tivoli Storage Productivity Center for Replication. The window that is opened in the Tivoli Storage Productivity Center for Replication GUI depends on the context for the entity that you selected. For example, if you right-click a storage device on the **Element Manager** tab of the Configuration Utility and click

**Replication Storage Systems Overview**, the Tivoli Storage Productivity Center for Replication Storage Systems window opens.

If the launch descriptor file cannot be found, the **Launch file items error** menu item is displayed. Click this item to view a description of the problem. The **Launch file items error** menu item is also displayed in situations such as the IBM Tivoli Integrated Portal server is not installed or is not accessible, the Tivoli Storage Productivity Center Data server is not accessible, or another system error occurred.

- **External Tools.** This menu item shows any external tools that are defined in the Configuration Utility. Examples of external tools include Web-based user interfaces and local executable files. For example, you might add the address of a website that you frequently access or an application that you often use such as a text editor or a spreadsheet.
- **Element Manager.** This menu item shows any element managers discovered for the device by a Storage Management Initiative Specification (SMI-S) query. To avoid menu item duplication, this item is not displayed when the associated element manager is defined by a launch descriptor file. In this situation, the element manager is displayed as a separate menu item.
- **User Defined Tools.** This menu item shows any user-defined element managers that are defined in the Configuration Utility. These element managers differ from the element managers in the Element Manager menu because they are user-defined and are not discovered by an SMI-S query.

If the selected entity has no element manager, these options are not available in the menu.

## Launching SAN Planner

This topic describes how to launch the SAN Planner wizard for an entity from the topology viewer. SAN Planner assists end-to-end planning for SAN components.

Right-click a computer, fabric, or storage subsystem and select **SAN Planner > New Plan**. A new SAN Planner wizard introduction page is displayed. When you have made your selections on the Select Planning Task and Select Provision Plan Details pages, the element you selected is added to input resources on the Specify Plan Content page. To provision replication for an existing session associated with a storage resource group, right-click the storage resource group, select **SAN Planner**, and then select the session you want to work with.

## Starting Storage Optimizer

This topic describes how to start the Storage Optimizer from the topology viewer. The Storage Optimizer uses data in the Tivoli Storage Productivity Center database to analyze your storage subsystems to identify performance bottlenecks, and recommend changes to improve performance.

Right-click one or more storage subsystems and select **Launch Optimizer**. A new Storage Optimizer analysis definition is created, and the storage subsystems you selected are added to the **Select Storage** pane.

### Related concepts:

“Storage Optimizer overview” on page 434

The Storage Optimizer uses data in the IBM Tivoli Storage Productivity Center database to analyze your storage subsystems to identify performance bottlenecks, and recommend changes to improve performance. This topic lists the supported subsystems and describes the general steps for using Storage Optimizer.

## Locating storage resources in the topology

This topic describes how you can search for a particular entity using the entity name or a keyword (for example, a host name or operating system).

The open view (for example, L0:Other) will be searched for the string you enter. The results of a locate action are shown by highlighting.

Figure 44. Highlighted entity

To locate an entity, type a search string in the **Locate** field in the table view and click **Find**. The current view (for example, L0:Other) will be searched for the string you enter. The locate function does not search the entire topology, only the currently open view.

When the entity is found, it will be displayed in both the graphical and table views. If the located entity is inside a collapsed group in the topology, you will not be able to see that entity until you expand that group. However, the entity will be highlighted in the table view. If the entity is in a collapsed group in the table view, that group will automatically be expanded and the highlighted table entry will receive focus. You can then click on that table entry to see the located entity in the topology view.

If you specify a Locate criterion that applies to more than one entity in a view, all the applicable entities are displayed.

## Managing Storage Subsystems

This topic describes how to display the Storage Subsystems page, where you can perform storage-subsystem management tasks.

Right-click a storage subsystem and select **Manage Storage Subsystems**.

## Managing Zone Control

This topic describes how to display the Fabric page, where you can perform zone-control tasks.

Right-click a fabric and select **Manage Zone Control**.

## Pinning entities

This topic describes how pinning entities is an easy way to identify selected entities for future reference or quick access.

Pinned entities display a small flag next to the entity. This flag is propagated to all views that contain that entity. This is useful for marking entities for various reasons, such as a reminder to look at this entity later and for upward propagation. For example, the user may pin a computer in an L0 or L1 Computers view and then quickly wish to see which fabric it belongs to by opening an L0 Fabrics view and looking at which fabric group contains the pinned entity - indicated by the small flag. Pinned objects remain visible as you change views in the topology viewer and when you log off and log back in. Pin lists are stored on a per user basis. This means that different users can have separate pin lists. Pinned objects are indicated by a pin icon in the **Pinned** column of a table or by a flag icon next to the entity in the graphical view.

Figure 45. Pinned entity

To pin an entity, right-click the entity in the graphical view and select **Pin**. To unpin an entity, right-click the entity in the graphical view and select **Unpin**. The same function is available in the **Action** list in the table view.

Pinned entities are visible in groups at all levels and in all views regardless whether the group is expanded or collapsed. You can only pin individual entities; you cannot pin groups (for example, a group of computers).

## Printing information from the topology viewer

You can print information displayed in the topology viewer on a single page for reference.

Printing capability is available for the graphical view but is not available in the tabular view. To print the information displayed in the topology viewer, right-click the graphical view and select **Print** or **Print Preview**. The content is scaled to fit onto one page if necessary.

## Refreshing views

This topic describes how you can refresh the topology viewer to view the most up-to-date details about your environment.

To provide you with the most up-to-date information, the topology viewer automatically refreshes all open views, including graphics and tables, every five minutes from the IBM Tivoli Storage Productivity Center database. You can also refresh views manually or change the default refresh rate. Opening a new view automatically shows the most current information. To manually refresh views or change the refresh rate, right-click in the graphical view or click the arrow in the **Action** field in the table view and choose one of the following options:

- **Refresh View:** Updates the view that is currently displayed.
- **Refresh All Views:** Updates all views that are currently open. You can also use this option to remove the alert indicators from the devices in the topology view.
- **Refresh Settings:** Opens the **Refresh Rate Settings** window, in which you can select a new automatic refresh rate (specified in minutes).

## Removing entities from the database

Computers in the missing state were once in the topology viewer, but were not discovered by IBM Tivoli Storage Productivity Center during the latest refresh cycle. You might want to remove them from the view and the database in order to make it easier to work with other resources.

To remove a computer from the topology viewer (both graphical and tabular views) and the database, you first need to uninstall the agents on that system.

**Note:** This action is available only for entities that are in the missing state.

1. See *Uninstalling the agents* in the *IBM Tivoli Storage Productivity Center and IBM Tivoli Storage Productivity Center for Replication Installation and Configuration Guide* for instructions on uninstalling the agents.
2. In the topology viewer *graphical* view, right-click the computer entity and select **Remove From Database..**
3. In the topology viewer *tabular* view, right-click the computer entity and select **Remove From Database.**

## Removing deleted entities

When a discovered entity (fabric, subsystem, switch, or volume) is deleted using another application, such as an element manager or other management application, the next discovery or probe of the topology viewer displays a missing entity. The status of missing entities is aggregated and propagated up through the device hierarchy.

It can be difficult to determine if there are other lower-level entities that have "missing" status, but have not been intentionally removed by a management application. The Removed Resource Retention setting in the topology viewer can be set to a low value, such as 0 or 1 day to remove the missing entity from the display. This removes the missing entities from the display the next time the Removed Resource Retention process runs.

You can also remove deleted entities from the topology viewer using the following procedure:

1. Highlight the intentionally deleted entities in the topology view and select **Remove Resource** in the **Action** list in the tabular view.

**Note:** Not all entity classes can be removed from the topology using the **Action** list. For those entities, use the Removed Resource Retention setting.

2. A prompt asks you if you are sure you want to remove the resource from the database. Click **Yes**.
3. To refresh the view, click **Refresh View** in the **Action** list. The missing entities will no longer be displayed in the topology viewer.

## Selecting entities in graphical and table views

This topic describes how to select entities in the graphical and table views of the topology viewer.

To select an entity in the graphical view, click the entity image. In the table view, click the name of the entity. To make multiple selections, press CTRL and click.

## Showing Alerts

This topic describes how to display alert logs for entities in the topology viewer.

You can display alert logs for:

- computers
- fabrics
- storage subsystems
- tape libraries
- switches

All alerts for the entity-type you select will be displayed, even if no alerts exist for the entity.

Right-click an entity and select **Show <entity type> Alerts**.

For example:

Right-click a computer and select **Show Computer Alerts**.

## Showing the monitoring status of entities

View how Tivoli Storage Productivity Center is monitoring a storage entity that is displayed in the topology viewer.

Display all the data collection schedules, runs, and jobs that are related to a storage entity in the topology viewer.

To view monitoring status, right-click an entity and select **Show Monitoring Status**. For example, right-click a computer and select **Show Monitoring Status**.

When you select this action, the Job Management panel is displayed. Use this panel to view information about how a storage entity is monitored by Tivoli Storage Productivity Center. For storage resource groups, when you click this option the schedules for all the storage entities in that group are displayed.

### Related reference:

“Managing schedules, jobs, and runs” on page 300

Use the Job Management panel to view and manage all the schedules, runs, and jobs related to the storage devices that are monitored by IBM Tivoli Storage Productivity Center.

## Working with tape libraries in the topology viewer

Perform storage management functions on your tape library using the topology viewer.

The topology viewer displays information about the discovered tape libraries and tape library groups. The topology viewer has two views:

- Topology view
- Tabular view

Each view shows information about the discovered storage devices in your enterprise. Changes to one view are automatically displayed in the other view, so that both views are always synchronized.

To see tape library information in the topology viewer, click the **Storage** node in the **IBM Tivoli Storage Productivity Center > Topology** node in the console. The level zero (L0) view of the storage topology view is displayed. The view includes the tape libraries and tape library groups that have been discovered.

## Viewing tape libraries in the topology view

This topic describes how you can see information about your tape libraries and tape library groups in the topology view.

Clicking a tape library icon in the topology view highlights (selects) that tape library in both the topology view and the tabular view. Right-click a tape library to display a pop-up menu that lists actions that you can perform on the library, as well as other general actions that you can perform. The actions specific to tape libraries are:

### Open Detail View

Opens the next level of detail for the selected topology object. For tape libraries, the view hierarchy is

- L0:Storage- overall view of the discovered storage subsystems and tape libraries
- L1:Tape Libraries- tape library groups
- L2:Tape Library- view of an individual tape library and its related devices and connections

### Launch Detail Panel

Displays the detail panel for the tape library. The detail panel shows detailed information about the tape library, such as the name of the tape library vendor, the serial number, status, owner/administrator contact information, and properties that can be defined by the user. It also has **Launch** button that will launch the element manager for the tape library.

### Launch Element Manager

Launches the element manager application for the selected tape library. The element manager is an application or Web site provided by the tape library vendor for performing management tasks for the selected tape library. For example, the element manager for an IBM 3584 tape library is the IBM Tivoli Storage UltraScalable Tape Library Specialist.

**Pin** Pins the selected tape library. When a topology object is pinned, it remains visible even after its respective group or view level has been collapsed. A small blue flag icon by the object's icon indicates that the object is pinned. Once an object has been pinned, this action will change to **Unpin** in the pop-up menu for the object.

As you add more storage devices to your enterprise, your topology view can become very crowded and increasingly difficult to navigate. You can use the **minimap** in the topology view to quickly move around the view and locate the objects you need to work with.

## Viewing tape libraries in the tabular view

This topic describes how you can see information about your tape libraries and tape library groups in a tabular view.

The tabular view presents the same information as the topology view. Changes to the tabular view are immediately reflected in the topology view, so that both views are always synchronized.

The tabular view contains the following fields:

### Action

Lists the actions that can be performed on the selected object in the table, as well as the more general actions, such as Expand All Groups, that can be performed. These actions are the same ones that appear in the context menu for a selected object.

**Locate** Allows you to find objects in the tabular view. This is very useful when your tabular view has many entries.

The columns in the tabular view change as you select different objects in the topology. For example, the columns available for objects in the L1:Tape Libraries view are different than the columns in the L2:Tape Library view. These columns show information about the tape libraries, such as the operational status, vendor name, and number of drives in the library.

---

## Managing disk storage

This section describes managing storage subsystems, virtual disks, volumes, and creating and managing alerts.

### Working with workload profiles

This topic describes creating, modifying, and deleting workload profiles.

Only storage subsystems that have been discovered and had performance data successfully collected can be used with the Volume Planner function of the SAN Planner. You can use the following products with SAN Planner:

- TotalStorage Enterprise Storage Server
- DS6000
- DS8000
- SAN Volume Controller
- Storwize V7000
- Storwize V7000 Unified block level support
- The XIV system

For information about storage subsystem discovery, see “Discover storage subsystem, tape library, and fabric information with CIM agents” on page 334. For information about the Volume Planner, see “Configuring a provisioning plan by using SAN Planner” on page 421.

### Creating a workload profile

In SAN Planner, you can create or reuse volumes based on a workload profile. Create a workload profile from the performance information of the selected storage-system volumes.

1. In the navigation tree pane, expand **Disk Manager > Profile Management > Workload Profiles**. In the content pane, the currently defined workload profiles are displayed.
2. Click **Create**; the Workload Profile wizard starts.
3. On the Welcome to the Workload Profile Wizard page, click **Next**.
4. On the Creation Method page, select the basis for the new workload profile. Click one of the following choices:

**Create profile from volume performance data**

Base the new profile on the volume-performance data that you provide.

**Create from an existing profile**

Base the new profile on an existing workload profile. In the **Profile Name** field, select the workload profile.

Click **Next**. If you clicked **Create from existing profile**, go to step 6. Otherwise, the Name and Description page opens.

5. On the Name and Description page, provide information about the new workload profile:
  - a. In the **Name** field, type the name of the workload profile.
  - b. Optional: In the **Description** field, type a description of the workload profile.
  - c. Click **Next**.
6. On the Select Volumes page, specify the volumes whose performance data will be used as the basis for the workload profile.
  - a. In the **Available volumes** field, select the volumes, and then move them to the **Selected volumes** field.
  - b. Click **Next**.
7. On the Peak Activity periods page, specify the time period for the performance data:
  - a. To use all available performance data, click **Use all available performance data**, and go to step 8.
  - Note:** Analyzing all performance data might be a lengthy process.
  - b. To use performance data for a specified time period, specify the time period. In the **Start date** field, select the month, day, and year. In the **End date** field, select the month, day, and year. By default, the time period is set to the previous month. In the **Time reference** field, select one of the following options:
    - Client Time**
    - Server Time**
    - GMT**
    - Device Time**
  - c. To specify that performance data is collected only during specified hours, click **Use only a portion of each day**. In the **Start time** field, select the hour and minutes. In the **End time** field, select the hour and minutes.
  - d. Click **Next**.
8. On the Review Profile Results page, review the following performance data:

### Data quality

Lists a data-quality rating. This rating is based on the percentage of volumes that had valid data:

- Good (100% - 67%)
- Fair (66% - 33%)
- Poor (32% - 0%)

### I/O Demand

#### I/O rate per GB per sec

The data-transfer rate in gigabytes per seconds (GBps).

#### Avg. transfer size (KB)

Default size for data transfer in kilobytes (KB). You can edit this value.

### Read / Write

#### Sequential reads (%)

Percentage of read/write activity that was sequential reads.

#### Sequential writes (%)

Percentage of read/write activity that was sequential writes.

#### Random reads (%)

Percentage of read/write activity that was random reads.

#### Random writes (%)

Percentage of read/write activity that was random writes.

#### Total (% , must be 100)

Total of the preceding percentages. This value must equal 100%. If it does not, you cannot continue with the wizard.

### Cache

#### Random read cache hits (%)

Percentage of cache activity that was random hits to read cache.

#### Random write destage (%)

Percentage of cache activity that consisted of moving data from cache to nonvolatile storage.

9. Click **Finish**.

## Deleting a workload profile

This topic describes how to delete a workload profile.

Only user-defined workload profiles can be deleted.

1. In the navigation tree pane, expand **Disk Manager > Profile Management > Workload Profiles**. A list of the currently defined workload profiles is displayed in the content pane.
2. Select the workload profile you want to delete.
3. Click **Delete**.

## Modifying a workload profile

This topic describes how to modify a workload profile.

Only user-defined workload profiles can be modified.

1. In the left-hand pane, expand **Disk Manager > Profile Management > Workload Profiles**. A list of the currently defined workload profiles is displayed in the right-hand pane.
2. Select a workload profile and click **Details**. The Workload Profile Properties window displays.
3. Click the **General** tab to view the name and description of the workload profile. You can modify only the description of the workload profile.
4. Click the **Performance** tab to view I/O demand, read/write, and cache performance data for the workload profile. You can modify any of the performance data for the workload profile.

### Viewing a workload profile

This topic describes how to view a workload profile.

1. In the navigation tree pane, expand **Disk Manager > Profile Management > Workload Profiles**.
2. In the content pane, select a workload profile and click **Details**. The Workload Profile Properties window displays.
3. Click the **General** tab to view the name and description of the workload profile.
4. Click the **Performance** tab to view I/O demand, read/write, and cache performance data for the workload profile.
5. Click the **Activity** tab to view peak activity settings for the workload profile. To view all data collected during a period of time, select **Use all available performance data** and specify a time reference (options are Client Time, Server Time, GMT, and Device Time) and start and end dates. To view only the data collected during a portion of each day, select **Use only a portion of each day** and specify start and end times. Click **OK** to view the peak activity.

## Working with provisioning profiles

This topic describes creating, modifying, and deleting provisioning profiles.

Only storage subsystems that have been discovered and had performance data successfully collected can be used with the storage provisioning function of the SAN Planner. SAN Planner and storage provisioning are only available for the following systems:

- TotalStorage Enterprise Storage Server
- SAN Volume Controller
- DS6000
- DS8000
- Storwize V7000
- Storwize V7000 Unified block-level support

For information about storage subsystem discovery, see “Discover storage subsystem, tape library, and fabric information with CIM agents” on page 334. For information about SAN Planner, see “Configuring a provisioning plan by using SAN Planner” on page 421

### Creating a provisioning profile

Create a provisioning profile for features that require a model for volume, multipathing, and zoning requirements. Provisioning profiles are used, for example, by SAN Planner.

1. In the navigation tree pane, expand **Disk Manager > Profile Management > Provisioning Profiles**. In the content pane, the currently defined provisioning profiles display.
2. Click **Create**. The Provisioning Profile wizard starts.
3. On the Welcome to the Provisioning Profile Wizard page, provide information about the new provisioning profile.
  - a. In the **Profile Name** field, type the name of the provisioning profile.
  - b. Optional: In the **Profile Description** field, type a description of the provisioning profile.
4. In the Creation Method section, choose the method that you want to use to create the profile. Select one of the following options:

**Create profile from scratch.**

Click to create the profile without using an existing profile.

**Create from an existing profile.**

Click to create the profile by using an existing provisioning profile as a template. Select the profile from the **Profile name** list.

Click **Next**.

5. If you want to include volume planning in the provisioning profile, use the Volume Settings page to configure and create volumes or virtual disks.
  - a. Select **Specify how the storage will be allocated and the storage performance characteristics** to enable the options on the page.
  - b. Select one of the following options:
    - **Provision Volumes**. Use volumes for provisioning.
    - **Provision Virtual Disks**. Use virtual disks for provisioning.
  - c. From the **RAID level** list, select one of the options for volumes or virtual disks:
    - **<system selected>**. User input and the available performance and capacity of the underlying storage systems determines which RAID level is selected.
    - **RAID 1**
    - **RAID 5**
    - **RAID 6**
    - **RAID 10**
  - d. In the **Volume/Virtual Disk Name Prefix** field, enter the prefix that you want to use for all volumes or virtual disks names.
  - e. From the **Workload Profile** list, select a workload profile for the volume or virtual disk. You can use one of the following predefined profiles or you can create a profile from the Workload Profiles panel. A performance monitor must run on the storage controller to select any predefined workload profile other than **Space only**.
    - Select **OLTP Standard** for online transaction processing.
    - Select **OLTP High** for active online transaction processing.
    - Select **Data Warehouse** for applications with inquires into large data warehouses.
    - Select **Batch Sequential** for batch applications that involve large volumes of data.
    - Select **Document Archival** for document archival applications.

- Select **Space only** when you want to choose pools that are based on pool space information, rather than storage controller performance. Use for a storage system that is not monitored for a performance data collection.
- f. From the **Thin Provisioning Profile** list, select a thin provisioning profile if you want to create thin volumes or virtual disks for IBM System Storage SAN Volume Controller, IBM System Storage DS8000, or IBM XIV Storage System. You can use one of the following predefined profiles or you can create a profile from the Thin Provisioning Profiles panel.
- Select **Ignore thin provisioning** if you do not want to use a thin provisioning profile.
  - Select the **Standard** profile to set the over-allocation limit for a pool to 200%. The virtual capacity is set to double the amount of the real capacity.
  - Select the **Conservative** profile to the over-allocation limit for a pool to 150%. The virtual capacity is set to one and a half times the amount of the real capacity.
  - Select the **Aggressive** profile to set the over-allocation limit for a pool to 300%. The virtual capacity is set to as much as three times the amount of the real capacity.

The over-allocation value identifies the limit on the virtual capacity that is allocated for a pool. A smaller over-allocation percentage is considered conservative because the virtual capacity is closer to the real capacity. A greater over-allocation percentage is considered aggressive because the virtual capacity is farther from the real capacity. For example, the over-allocation limit that is set in the **Aggressive** profile is 300%. Pools that contain volumes or virtual disks that are created using the **Aggressive** profile are allocated as much as three times the real capacity. If you use the **Aggressive** profile and the pool size is 15 GB, the virtual capacity that is allocated for the pool can be as much as 45 GB.

- g. Select one of the **Solid State Disks** options to specify whether you want to use or exclude solid-state disks from provisioning:
- **Do not use Solid State Disks**
  - **Use Solid State Disks**
- These options are disabled if you clicked **Provision virtual disks**.
- h. From the **Encryption Group** list, select an encryption group if you want new volumes to be created on extent pools that belong to that encryption group. If there are no encryption groups available, **<none selected>** is displayed in this box. This box is disabled if you clicked **Provision virtual disks**.
- i. Select **Use unassigned volumes not involved in copy relationship** if you want to use existing unassigned volumes. Unassigned volumes that are in a copy relationship are not used. If this check box is selected, the following volumes are excluded:
- Unassigned volumes on non-IBM storage systems.
  - Unassigned volumes on IBM storage systems that have copy relationships that were not created in IBM Tivoli Storage Productivity Center or IBM Tivoli Storage Productivity Center for Replication.
- j. Enter the number of days of performance data that you want to use for planning in the **Planning will be based on the performance data collected in the last x days** field.

Click **Next**.

6. If you want to include path planning in the provisioning profile, use this page to set multipath options. The supported multipath driver on a host is the IBM Subsystem Device Driver (SDD). The Linux SDD driver is no longer available. Starting with Red Hat Enterprise Linux Version 5 and SUSE Linux Enterprise Server Version 10, only the DM\_Multipath is available. The DM\_Multipath is supported by SAN Planner. The SDD driver is no longer supported on HP, starting with HP-UX 11i v3 with Itanium®. HP-UX 11i v3 provides a native multipathing feature which is supported by SAN Planner.

- a. To set up the multipath options, click **Setup multipath options (if supported by the host drivers)**.
- b. From the **Multipath Option** list, select one of the following options to specify how the driver uses the paths between the host and the storage system:
  - Select **Load Balancing** to send input/output on all paths.
  - Select **Round Robin** to send input/output on one path until a time interval that is set in an SDD setting at the host expires, then switches to another path.
  - Select **Fail-Over** to send input/output on one path until a failure occurs, then switches to another path.

On HP-UX 11i v3 with Itanium®, the multipath options that are used by the SAN Planner are as follows:

- **Load Balancing** on HP-UX 11i v3, is implemented as Least Command Load. This option selects the path with the least number of pending input/output requests for the next I/O operation.
  - **Round Robin** on HP-UX 11i v3, distributes the input/output load equally across all active paths irrespective of the current load on each path.
  - **Fail-Over** on HP-UX 11i v3, is implemented as Preferred Path. For this policy, you specify a path to an optimized controller. This path is preferred for input/output transfers. The preferred path must be set manually.
- c. Select the **Specify number of paths** check box and enter the number of paths that you want to configure between the host and storage system. If you do not specify the number of paths in this field, the default is two paths.
  - d. Select **Use fully redundant paths (requires at least 2 fabrics)** to use the paths from host to storage systems through a minimum of two fabrics.

Click **Next**.

7. Use the Security Settings section to specify zoning between ports on the hosts and systems in a fabric.

- a. Select **Automatically change zoning to ensure hosts can see the new storage** to enable the options on the page.
- b. Select from the **Automatically create zone** list to specify how the zones are created. The predefined options are:

**<auto-zone>**

This option is the default. The plan generates the maximum number of zones without grouping the data paths that are based on hosts, host ports, or host bus adapters (HBAs).

**...for each host**

Creates a zone for each host.

#### ...for each HBA

Creates a zone for each host bus adapter.

#### ...for each host port

Creates a zone for each host port.

- c. Select the **Specify maximum number of zones** check box and enter the maximum number of zones.
  - d. Select the **Maximum zone members per zone** check box and enter the maximum number of zone members per zone.
  - e. Select **No two controllers with different types should be used in the same zone** if you do not want two controllers with different types to be used in the same zone.
  - f. Select **Use active zone set** if you want any zone set that is available to be selected.
  - g. Select the **Append zone name prefix** check box and enter a prefix to be used in the zone name.
8. Click **Finish**.

## Deleting a provisioning profile

This topic describes how to delete a provisioning profile.

Only user-defined provisioning profiles can be deleted.

1. In the navigation tree pane, expand **Disk Manager > Profile Management > Provisioning Profiles**. A list of the currently defined provisioning profiles is displayed in the content pane.
2. Select the provisioning profile you want to delete.
3. Click **Delete**.

## Modifying and viewing a provisioning profile

This topic describes how to modify and view a provisioning profile.

Only user-defined provisioning profiles can be modified.

1. In the left-hand pane, expand **Disk Manager > Profile Management > Provisioning Profiles**. A list of the currently defined provisioning profiles is displayed in the right-hand pane.
2. Select a provisioning profile and click **Details**. The Provisioning Profile Properties window displays.
3. Click the **General** tab to view the name and description of the provisioning profile. You can modify only the description of the provisioning profile.
4. Click the **Volume Settings** tab to view or modify the volumes or virtual disks in the provisioning profile. You can modify any of the volume settings for the provisioning profile.
5. Click the **Path Settings** tab to view or modify multipath planning in the provisioning profile. You can modify any of the multipath settings for the provisioning profile.
6. Click the **Security Settings** tab to view or modify zoning between ports on the hosts and systems in a fabric. You can modify any of the security settings for the provisioning profile.

## Thin provisioning profiles

Learn how to create, modify, and delete thin provisioning profiles.

Only storage subsystems that have been discovered and had performance data successfully collected can be used with the volume planning function of SAN Planner. SAN Planner and the volume planning option are only available for the following systems:

- TotalStorage Enterprise Storage Server
- SAN Volume Controller
- DS6000
- DS8000
- Storwize V7000
- Storwize V7000 Unified block-level support

For information about storage subsystem discovery, see “Discover storage subsystem, tape library, and fabric information with CIM agents” on page 334. For information about the volume planning option, see “Configuring a provisioning plan by using SAN Planner” on page 421

### Creating a thin provisioning profile

Learn how to create a thin provisioning profile. Thin provisioning profiles serve as templates for specifying the parameters for thin provisioned volumes to be created through SAN Planner.

1. In the navigation tree pane, expand **Disk Manager > Profile Management > Thin Provisioning Profiles**. In the content pane, the currently defined thin provisioning profiles display.
2. Click **Create**. The Thin Provisioning Profile window opens.
3. On the Thin Provisioning Profile page, provide information about the new thin provisioning profile.
  - a. In the **Profile Name** field, type the name of the provisioning profile.
  - b. Optional: In the **Profile Description** field, type a description of the provisioning profile.
  - c. In the **Overallocation Limit (%)** field, type the over-allocation limit percentage. Specify this value as an integer. The over-allocation value identifies the limit on the virtual capacity that is allocated for a pool. A smaller over-allocation percentage is considered conservative because the virtual capacity is closer to the real capacity. A greater over-allocation percentage is considered aggressive because the virtual capacity is farther from the real capacity. For example, the over-allocation limit that is set in the Aggressive profile is 300%. Pools that contain volumes or virtual disks that are created using this profile will be allocated to as much as three times the real capacity. If you use the Aggressive profile and the pool size is 15 GB, the virtual capacity allocated for the pool can be as much as 45 GB.
4. In the **DS8000 Settings** section, specify the parameters for creating a thin provisioning profile for IBM System Storage DS8000.

#### Specify DS8000

Select the **Specify DS8000** check box to create a thin provisioning profile for System Storage DS8000.

#### Space-Efficiency Type

Specify the type of thin provisioning to use for System Storage DS8000. The options are:

##### Extent Space Efficient (ESE)

An ESE logical volume has a set of virtual extents that are not

associated with a repository. The logical volume is dynamically allocated and deallocated from the extent pool.

#### **Track Space Efficient (TSE)**

A TSE logical volume has a set of virtual extents and is associated with a repository.

5. In the **SVC Settings** section, specify the parameters for creating a thin provisioning profile for IBM System Storage SAN Volume Controller.

#### **Specify SVC**

Select the **Specify SVC** check box to create a thin provisioning profile for SAN Volume Controller.

#### **Real Size (%)**

Enter the percentage of disk space to be allocated for the space-efficient copy of the selected VDisk. Setting the real space for a space-efficient copy protects the copy from going offline when its managed disk (MDisk) group runs out of space.

#### **Auto Expand**

Select a value to specify whether the thin provisioning profile volumes automatically expand their real capacities by allocating new extents from their MDisk group.

#### **Grain Size (KB)**

Select the grain size in KB for a space-efficient copy of the VDisk.

#### **Warning Level (%)**

Enter a threshold to send a warning message for the VDisk copy when the capacity that is used exceeds the specified percentage level.

6. In the **XIV Settings** section, specify the parameters for creating a thin provisioning profile for the XIV system.

#### **Specify XIV**

Select the **Specify XIV** check box to create a thin provisioning profile for the XIV system.

#### **Locking Behavior**

Select the **Locking Behavior** required if the thin provisioned pool runs out of space:

##### **Read Only**

If the thin provisioned pool has run out of capacity, all the volumes in the pool are locked and no write commands are allowed. This option is the default.

**No IO** If the thin provisioned pool has run out of capacity, no write or read commands are allowed.

7. Click **Apply** to save your changes. To exit without adding a thin provisioning profile, click **Cancel**.

## **Deleting a thin provisioning profile**

Learn how to delete a thin provisioning profile.

You can only delete user-defined thin provisioning profiles.

1. In the navigation tree pane, expand **Disk Manager > Profile Management > Thin Provisioning Profiles**. A list of the currently defined thin provisioning profiles is displayed in the content pane.
2. Select the thin provisioning profile you want to delete.
3. Click **Delete**.

## Modifying and viewing a thin provisioning profile

Learn how to modify and view a thin provisioning profile.

You can only modify user-defined thin provisioning profiles.

1. In the left-hand pane, expand **Disk Manager > Profile Management > Thin Provisioning Profiles**. A list of the currently defined thin provisioning profiles is displayed in the right-hand pane.
2. Click the magnifying glass icon next to a thin provisioning profile. The Thin Provisioning Profile Properties window displays.
3. View the details of the thin provisioning profile. You can modify any of the profile settings except for the **Profile Name**.
4. Click **Apply** to save your changes. To exit without modifying a thin provisioning profile, click **Cancel**.

## Managing storage subsystems

This topic contains information about storage-subsystem management tasks.

### Grouping storage subsystems

A storage-subsystem group is a user-defined set of storage subsystems. You might want to group storage subsystems in order to make it easier to run monitoring or reporting jobs.

**Note:** A storage subsystem can belong to only one storage-subsystem monitoring group, but can belong to multiple storage subsystem reporting groups.

### Creating a storage subsystem group:

This topic describes how to create a storage subsystem group.

1. In the navigation tree pane, expand **Disk Manager > Monitoring > Groups**.
2. Right-click **Storage Subsystem** and then click **Create Storage Subsystem Group**. In the content pane, the Create Storage Subsystem Group window opens.
3. In the **Description** field, type a short description of the group.
4. In the **Available** field, click the storage subsystems that you want to add to the group, and then click . The storage subsystems are added to the **Current Selections** field.
5. Click **File > Save**. A window opens requesting a name for the storage-subsystem group.
6. Type the name of the storage-subsystem group and click **OK**.

### Deleting a storage-subsystem group:

This topic describes how to delete a storage-subsystem group.

1. In the left-hand pane, expand **Disk Manager > Monitoring > Groups > Storage Subsystems**. All existing storage-subsystem groups are listed.
2. Right-click the storage-subsystem group that you want to delete.
3. Click **Delete**. A window opens, asking if you are sure that you want to delete this group.
4. Click **Yes**.

## Editing a storage-subsystem group:

This topic describes how to edit a storage-subsystem group.

1. In the left-hand pane, expand **Disk Manager > Monitoring > Groups > Storage Subsystem**. All existing storage-subsystem groups are listed.
2. Click the storage-subsystem group that you want to edit. The **Edit Storage Subsystem Group** window opens.
3. Make any necessary changes.
4. Click **File > Save**.

## Defining element managers

Element managers are programs that you can use to configure and manage your storage devices. An example of an element manager is DS8000 Storage Manager, which is the default element manager that is provided with IBM System Storage DS8000.

Element managers are managed in Tivoli Storage Productivity Center using the Configuration Utility. You can access the Configuration Utility from a storage system that is visible in the Storage Subsystems page of Tivoli Storage Productivity Center as shown in the following steps:

1. Expand **Disk Manager > Storage Subsystems** in the navigation tree. The Storage Subsystems page is displayed.
2. In the **Storage Subsystems** table, double-click a storage subsystem. The Details dialog page is displayed.
3. Click **Element Management**. The **Element Manager** tab in the Configuration Utility is displayed.

### Related concepts:

“Managing DS8000 storage systems using element managers” on page 587

Use the Configuration Utility in IBM Tivoli Storage Productivity Center to add and manage element managers for IBM System Storage DS8000. *Element managers* are applications that are used to configure and manage a storage device. You can add and manage connections to the element manager that is provided with DS8000, DS8000 Storage Manager, or you can specify other element managers for a device.

“Managing other storage systems using element managers” on page 594

Use the Configuration Utility in IBM Tivoli Storage Productivity Center to add and manage element managers for storage devices other than IBM System Storage DS8000. *Element managers* are applications that are used to configure and manage a storage device. You manage connections to the element managers that are provided with the storage device or you can specify other element managers for a device.

## Starting element managers

You can start element managers from a storage system that is visible on the Storage Subsystems page of Tivoli Storage Productivity Center. You can also start element managers from other points in Tivoli Storage Productivity Center as described in other areas of this documentation.

To start an element manager from the Storage Subsystem page, complete the following steps:

1. Expand **Disk Manager > Storage Subsystems** in the navigation tree. The Storage Subsystems page is displayed.
2. In the **Storage Subsystems** table, select a storage system.
3. Use one of the following methods to start the element manager:

- To start the default element manager for the storage system, select **Launch Element Manager**.
- To start another element manager for the storage system, right-click the system and click **Launch Element Manager**. Select the element manager that you want to start from the menu.

If the connection information for an element manager is valid, the element manager is started. If unsuccessful, an error message is displayed. The error messages that you receive describes one of the following problems:

- that the element manager at the specified IP address could not be started
- that the required connection information for the element manager has not been provided.
- that the element manager is not installed and configured correctly (for local element manager installations such as XIV Storage Manager)

If you are prompted to enter additional information such as an ID and password for the element manager, complete the following steps:

1. Click **OK** in the message dialog box. The Modify Element Manager dialog box is displayed.
2. Enter the required information for the element manager and click **Save**.

## Removing a storage subsystem

This topic describes how to remove a storage subsystem.

1. In the navigation tree pane, expand **Disk Manager** and click **Storage Subsystems**. In the content pane, the Storage Subsystems page is displayed.
2. In the **Storage Subsystem** table, click a storage subsystem, and then click **Remove**. The Remove Storage Subsystem window opens.
3. Click **Yes**.

**Note:** You can also remove a storage subsystem using the following method: “Removing a storage system” on page 297.

## Removing a storage subsystem

This topic describes how to remove a storage subsystem.

1. In the navigation tree pane, expand **Disk Manager** and click **Storage Subsystems**. In the content pane, the Storage Subsystems page is displayed.
2. In the **Storage Subsystem** table, click a storage subsystem, and then click **Remove**. The Remove Storage Subsystem window opens.
3. Click **Yes**.

**Note:** You can also remove a storage subsystem using the following method: “Removing a storage system” on page 297.

## Setting user-defined properties

This topic describes how to set properties for storage subsystems. You can define a name and up to three properties for each storage subsystem.

1. In the navigation tree, expand **Disk Manager** and click **Storage Subsystems**. In the content pane, the Storage Subsystems page is displayed.
2. In the **Storage Subsystem** table, double-click a storage subsystem. The Storage-Subsystem Details page opens.

| Storage Subsystems                           | DS8000-2107-1300361-IBM Details                   |

Figure 46. Storage-Subsystem Details page

3. Set the user-defined properties:
  - a. In the **Label** field, type a name for the storage subsystem.
  - b. In the **User-defined properties** fields, type information that you want to associate with the storage subsystem.
4. Click **File > Save**.

## Viewing storage subsystem information

You can view information about the storage subsystems that are in your environment. You can view general information about all storage subsystems or you can view detailed information about a specific storage subsystem. This information includes the available and used space for the subsystem.

### Viewing general information about a storage subsystem

You can view general information about a storage subsystem.

In the navigation tree, expand **Disk Manager** and click **Storage Subsystems**. On the Storage Subsystems Page, the **Storage Subsystems** table contains the following information about each storage subsystem:

#### Subsystem

A system ID that is in the following format:

*Type-Model-ID-Vendor*

*Type* The type of the storage system, for example, TotalStorage Enterprise Storage Server or SAN Volume Controller.

*Model* The model number, for example, 2105 or 2145.

*ID* The serial number or cluster name. Cluster names are used only for storage systems such as SAN Volume Controller and Storwize V7000.

*Vendor* The manufacturer of the storage system, for example, IBM.

**Label** A user-defined name for the storage system or the ID of the storage system.

**Type** The type of system:

- DS4000
- DS5000
- DS6000
- DS8000
- EMC
- ESS
- Hitachi
- Storwize V7000 (This value is displayed for Storwize V7000, Storwize V3500, and Storwize V3700.)
- Storwize V7000U
- SONAS
- SVC
- XIV
- Other

**Model** The model of the storage system.

**Status** The status of the system:

- Normal
- Critical
- Warning
- Unreachable

**Available Space (GB)**

The total storage capacity that is not formatted in volumes or virtual disks and that is assigned to hosts.

For the following storage systems, this value represents managed disk space that is not allocated to virtual disk space within the managed disk groups and managed disk space that is not defined to a managed disk group:

- SAN Volume Controller
- Storwize V3500
- Storwize V3700
- Storwize V7000
- Storwize V7000 Unified

**Tip:** For space-efficient volumes, this value is the amount of storage space requested for these volumes, not the actual allocated amount. This can result in discrepancies in the overall storage space reported for a storage

system using space-efficient volumes. This also applies to other space calculations, such as the calculations for the storage system's Consumable (Available) Volume Space and FlashCopy Target Volume Space.

**Consumed Space (GB)**

The total storage capacity that is formatted in volumes or virtual disks and assigned to hosts.

For the following storage systems, this value represents all space that is allocated from MDisk groups to VDIs (space that is consumed by volumes):

- SAN Volume Controller
- Storwize V3500
- Storwize V3700
- Storwize V7000
- Storwize V7000 Unified

**Configured Capacity Limit (GB)**

The total amount of real available and formatted storage space in the storage pools that are associated with the storage system.

**Remaining Configured Capacity (GB)**

The amount of real storage space available to allocate to volumes in the storage pools that are associated with the storage system.

**Tiers** Indicates the tiers that are used by the storage system. Each tier is delimited by a semi-colon (;). Possible values are: generic\_hdd and generic\_ssd.

Information about tiers is available only for the following storage systems:

- SAN Volume Controller 6.1 or later
- Storwize V3500
- Storwize V3700
- Storwize V7000
- Storwize V7000 Unified

The value N/A is displayed in tier-related columns for other storage systems.

**Tier Capacities (GB)**

The total storage capacity of each tier that is used by the storage system. The capacity of each tier is delimited by a semi-colon (;).

**Tier Free Capacities (GB)**

The free storage capacity (available space) of each tier that is used by the storage system. The free capacity of each tier is delimited by a semi-colon (;).

**Viewing detailed storage subsystem information**

You can view detailed information about a specific storage subsystem. This information includes the available and used space for the subsystem.

To view detailed information about a specific storage subsystem, click the storage

subsystem, and then click the magnifying glass icon (  ).

The tab that you can view is determined by the type of storage subsystem that you selected:

- The Storage-Subsystems Details tab shows detailed information for storage systems such as System Storage DS4000, System Storage DS8000, or XIV system.
- The SAN Volume Controller, Storwize V7000, or Storwize V7000 Unified Details tab shows detailed information for those storage subsystems.
- The Storwize V7000 File Module Details tab shows detailed information about a Storwize V7000 File Module storage system.
- The IBM SONAS Details tab shows detailed information about an IBM SONAS system.

**Tip:** The contents of the Storage-Subsystem Details tab is determined by the type of storage subsystem that you selected.

#### **Storage-Subsystems Details tab**

The Storage-Subsystem Details tab contains the following information:

#### **Storage Subsystem**

The storage system identifier.

**Label** The user-defined name of the storage system. You can edit this field.

**Status** The status of the storage system:

- Normal
- Critical
- Warning
- Unreachable

#### **Vendor**

The manufacturer of the storage system.

**Type** The type of storage system:

- DS4000
- DS5000
- DS6000
- DS8000
- EMC
- ESS
- Hitachi
- XIV
- Other

**Model** The model of the storage system.

#### **Available Space (GB)**

The total storage capacity that is not formatted in volumes or virtual disks and assigned to hosts.

**Tip:** For space-efficient volumes, this value is the amount of storage space requested for these volumes, not the actual allocated amount. This can result in discrepancies in the overall storage space reported for a storage system using space-efficient volumes. This also applies to other space calculations, such as the calculations for the storage system's Consumable (Available) Volume Space and FlashCopy Target Volume Space.

#### **Consumed Space (GB)**

The total storage capacity that is formatted in volumes or virtual disks and assigned to hosts.

**Serial Number**

The serial number.

**Revision**

The revision number.

**User-defined property 1 (UDP1)**

A user-defined property. You can edit this field.

**User-defined property 2 (UDP2)**

A user-defined property. You can edit this field.

**User-defined property 3 (UDP3)**

A user-defined property. You can edit this field.

**IP Address**

The IP address of the element manager.

**Element Manager**

Identifies the element manager. This value can be a URL, the fully qualified name of the executable file that starts the element manager, or the short name for the XIV system.

**Element Management**

Opens the Configuration Utility. Use the Configuration Utility to modify the element manager information.

**Replication Information**

If the storage system is not configured for replication, one of the following messages is displayed:

- The device is not supported.
- The replication information for the device is unavailable.
- The device is not configured for replication.

If the storage system is configured for replication, the following information that is specific to the device type and connection type is displayed:

**IP Address/Domain Name**

Identifies the IP address or host name of the storage system. If the IP address was not defined, this field is blank.

**Port** Identifies the port number of the storage system. If the port number was not defined, this field is blank. This field is not applicable for storage systems that use the HMC connection method.

**Username**

Identifies the user name to access the storage system. If the user name was not defined, this field is blank.

**Connection Type**

Identifies the connection method.

**SAN Volume Controller, Storwize V7000, or Storwize V7000 Unified Details tab**

This tab contains the following information:

**Storage Subsystem**

The storage system identifier.

**Label** The user-defined name of the storage system. You can edit this field.

**Status** The status of the storage system:

- Normal
- Critical
- Warning
- Unreachable

**Vendor**

The manufacturer of the storage system.

**Type** The type of storage system:

- Storwize V7000 (This value is also displayed for Storwize V3500 and Storwize V3700 storage systems.)
- Storwize V7000U
- SVC

**Model** The model of the storage system.

**Available Space (GB)**

The total storage capacity that is not formatted in volumes or virtual disks and assigned to hosts.

For these types of storage systems, this value represents managed disk space that is not allocated to virtual disk space within the managed disk groups and managed disk space that is not defined to a managed disk group.

**Tip:** For space-efficient volumes, this value is the amount of storage space requested for these volumes, not the actual allocated amount. This can result in discrepancies in the overall storage space reported for a storage system using space-efficient volumes. This also applies to other space calculations, such as the calculations for the storage system's Consumable (Available) Volume Space and FlashCopy Target Volume Space.

**Consumed Space (GB)**

The total storage capacity that is formatted in volumes or virtual disks and assigned to hosts.

For these types of storage systems, this value represents all space that is allocated from MDisk groups to VDisks (space that is consumed by volumes).

**Tiers** Indicates the tier levels that are used by the storage system. Each tier is displayed as a row in a table. Information about tiers is available only for these types of storage systems.

**Tier** Indicates a tier level that is used by the storage system. Possible values are: generic\_hdd and generic\_ssd.

**Tier Capacity (GB)**

Total storage capacity of a tier.

**Tier Free Capacity (GB)**

Free storage capacity (available space) of a tier.

**Serial Number**

The serial number.

**Revision**

The revision number.

**User-defined property 1 (UDP1)**

A user-defined property. You can edit this field.

**User-defined property 2 (UDP2)**

A user-defined property. You can edit this field.

**User-defined property 3 (UDP3)**

A user-defined property. You can edit this field.

**IP Address**

The IP address of the element manager.

**Element Manager**

Identifies the element manager. This value can be a URL or the fully qualified name of the executable file that starts the element manager.

**Element Management**

Opens the Configuration Utility. Use the Configuration Utility to modify the element manager information.

**Replication Information**

If the storage system is not configured for replication, one of the following messages is displayed:

- The device is not supported.
- The replication information for the device is unavailable.
- The device is not configured for replication.

If the storage system is configured for replication, the following information that is specific to the device type and connection type is displayed:

**IP Address/Domain Name**

Identifies the IP address or host name of the storage system. If the IP address was not defined, this field is blank.

**Port** Identifies the port number of the storage system. If the port number was not defined, this field is blank. This field is not applicable for storage systems that use the HMC connection method.

**Username**

Identifies the user name to access the storage system. If the user name was not defined, this field is blank.

**Connection Type**

Identifies the connection method.

**Storwize V7000 File Module Details tab**

The Storwize V7000 File Module Details tab contains the following information:

**Available FileSystem Space**

The amount of available file system space for the file module.

**Consumed FileSystem Space**

The amount of used file system space for the file module.

**Version**

The version of the file module.

**IBM SONAS Details tab**

The IBM SONAS Details tab contains the following information:

**Storage Subsystem**

The storage system identifier.

**Label** The user-defined name of the storage system. You can edit this field.

**Status** The status of the storage system:

- Normal
- Critical
- Warning
- Unreachable

**Vendor**

The manufacturer of the storage system.

**Type** The type of storage system: IBM SONAS.

**Model** The model of the storage system.

**Available FileSystem Space**

The total amount of unique file system storage space that is not used or available to the computers where a Data agent or Storage Resource agent is installed. Tivoli Storage Productivity Center does not include the following file systems in its calculation of the value for this field:

- File systems that become missing after a probe
- File systems that are mounted remotely and are not identified to a network-attached storage server
- File systems that are not mounted

**Consumed FileSystem Space**

The total amount of unique file system storage space that is used or consumed by the computers where a Data agent or Storage Resource agent is installed. Tivoli Storage Productivity Center does not include the following file systems in its calculation of the value for this field:

- File systems that become missing after a probe
- File systems on discovered hypervisors that are assigned to virtual machines where an agent is installed
- File systems on virtual machines where an agent is installed, but the hypervisors for the virtual machines have not been discovered and the total used space exceeds the capacity of the total file system capacity
- File systems that are mounted remotely and are not identified to a network-attached storage server
- File systems that are not mounted

**Version**

The version number.

**User-defined property 1 (UDP1)**

A user-defined property. You can edit this field.

**User-defined property 2 (UDP2)**

A user-defined property. You can edit this field.

**User-defined property 3 (UDP3)**

A user-defined property. You can edit this field.

**IP Address**

The IP address of the element manager.

**Element Manager**

Identifies the element manager. This value can be a URL, the fully qualified name of the executable file that starts the element manager, or the short name for the IBM SONAS.

### Element Management

Opens the Configuration Utility. Use the Configuration Utility to modify the element manager information.

### Replication Information

You cannot use IBM SONAS for replication.

## Managing virtual disks

This topic contains information about managing virtual disks.

### Adding a managed disk to a managed-disk group

This topic describes how to add a managed disk to a managed-disk group.

**Attention:** If you add a managed disk that contains existing data to a managed disk group, you will lose the data that it contains. The *image mode* is the only mode that will preserve this data.

1. In the navigation tree pane, expand **Disk Manager** and click **Storage Subsystems**. In the content pane, the Storage Subsystems page is displayed.
2. In the **Storage Subsystems** table, click a SAN Volume Controller.
3. Click **Create Virtual Disk**. The Create Virtual Disk wizard starts and the "Define the virtual disks" page opens.
4. In the **Managed-disk group** field, select the managed-disk group to which you want to add a managed disk.
5. Click **Add Managed Disk**. The "Add managed disk" window opens.
6. Select the managed disk, and then click **OK**.

### Assigning host ports

This topic describes how to assign host ports to a virtual disk. You also can make host-port assignments when you create a virtual disk.

**Note:** When you assign a host port to a virtual disk, all host ports defined on the SAN Volume Controller model are assigned to the virtual disk. If you want to assign only one host port to a virtual disk, you must define the host with only one host port on the SAN Volume Controller.

1. In the navigation tree pane, expand **Disk Manager** and click **Storage Subsystems**. In the content pane, the Storage Subsystems window is displayed.
2. In the **Storage Subsystems** table, click the SAN Volume Controller with which you want to work.
3. Click **Virtual Disks**. The Virtual Disks page is displayed.
4. Click either **Filter by MDisk group** or **Filter by host port**, and then select the specific filtering condition.
5. Click **Go**. A list of virtual disks associated with the selected SAN Volume Controller is displayed.
6. In the **Virtual Disks** table, select the virtual disk, and then click **Assign Host Ports**. The Assign Host Ports wizard starts. A virtual disk that is marked with an asterisk (\*) indicates that the virtual disk is a space-efficient volume. The \* is not part of the actual virtual disk name.
7. On the "Assign the virtual disk to host ports" page, assign or unassign host ports:
  - a. Optional: In the **Available ports** field, select the ports that you want to assign to the virtual disks, and then click  .

- b. Optional: In the **Assigned ports** field, select any ports that you want to unassign from the virtual disks, and then click .
  - c. Click **Next**.
8. (This page only is displayed if Fabric Manager is installed, and you have Fabric administrator authority.) On the "Zone actions" page, perform one of the following zone actions:
- Create a new zone**  
Click **Create new Zone**. In the Zone name field, type the name of the zone. The ports listed on the page are added to the new zone.
- Update an existing zone**  
Click **Update existing zone**, and then select a zone. The ports listed on the page are added to the selected zone.
- Leave the zone configuration as it is**  
Click **Do neither** to avoid performing any fabric-control tasks. The ports listed on the page cannot communicate with the subsystem on this fabric.
9. Click **Next**. The "Review settings" page opens.
  10. Review the settings that you made earlier in the wizard, and then click **Finish**.

## Creating virtual disks

This topic describes how to create virtual disks.

1. Expand the **Disk Manager** node in the navigation tree and click **Storage Subsystems**. In the right pane, the Storage Subsystems page is displayed.
2. In the **Storage Subsystem** table, click a IBM System Storage SAN Volume Controller, and then click **Create Virtual Disk**. The Create Virtual Disk wizard starts.
3. On the Define the virtual disks page, specify the attributes for the virtual disks:
  - a. In the **Type** field, select one of the following values:
    - Striped
    - Sequential
  - b. In the **Number of virtual disks** field, select the number of virtual disks that you want to create. Each available input/output (I/O) group can contain 1024 virtual disks.
  - c. In the **Virtual-disk size** field, select the size of the virtual disks to be created.
  - d. In the **Units** field, select one of the following units of measurement for the size of the virtual disks:
    - Bytes (byte)
    - GB (gigabyte)
    - KB (kilobyte)
    - MB (megabyte)
    - PB (petabyte)
    - TB (terabyte)
  - e. In the **Name** field, enter a string to identify the virtual disk.
    - For SAN Volume Controller 4.x and 5.x, the following naming conventions apply:
      - The maximum length of the name is 14 characters. The number of virtual disks also determines the maximum length of the name. For

example, if the number of virtual disks is 10 - 99, the maximum length of the name is 13 characters. If the number of virtual disks is 100 - 999, the maximum length of the name is 12 characters, and so on.

- Permissible characters include uppercase letters (A-Z), lowercase letters (a-z), numerals (0-9), hyphens (-), and underscores (\_).
- For SAN Volume Controller 6.1 and Storwize V7000, and Storwize V7000 Unified block-level support, the following rules apply:
  - Specify a single virtual-disk name that is no longer than 63 characters. The number of virtual disks also determines the maximum length of the name. For example, if the number of virtual disks is 2 - 9, the maximum length of the name is 62 characters. If the number of virtual disks is 10 - 99, the maximum length of the name is 61 characters. If the number of virtual disks is 100 - 999, the maximum length of the name is 60 characters.
  - Specify a name that includes only the following characters:
    - uppercase letters (A-Z)
    - lowercase letters (a-z)
    - numerals (0 - 9)
    - hyphen (-)
    - underscore (\_)
    - blank space
    - period (.)
- Names must begin with a letter or an underscore. The first character cannot be a number, hyphen (-), blank space, or period(.
- Names cannot begin with text or abbreviations commonly used to specify the object type, for example, the name cannot begin with VDisk, VDISK, vdisk, or virtual disk.
- Names cannot end with a space.
- Object names must be unique within an object type. For example, it is acceptable to have a vdisk named "XYZ" and an mdisk named "XYZ", but not acceptable to have two vdisks named "XYZ".

If you leave this field blank, a name is generated automatically. If you create multiple virtual disks, the name is used as a prefix.

- f. In the **I/O group** field, select the I/O group. By default, **Let the system choose** is selected. Other options are the actual I/O groups on the cluster.
- g. In the **Space-efficient properties** pane, use the following options to specify the space-efficient properties of the virtual disk. This pane is disabled if the SAN Volume Controller does not support the creation of space-efficient virtual disks:
  - 1) Space efficient check box (precedes the **Real size** field). Select this check box to specify that the virtual disk will be space efficient. Selecting this check box activates the other fields in this section.
  - 2) **Real size** Specify the actual allocated size of the virtual disk at creation time. This size is the initial allocated disk size that can be increased as needed by the SAN Volume Controller when the applications using the VDisk need more storage. The real size of the disk cannot exceed the managed free space that is currently available. Use the dropdown list to specify the size of the allocation unit.
  - 3) **Summary** This field displays a summary of the space-efficient properties for this virtual disk.

- 4) **Define** Click this button to open the Define Space Efficient Properties window.
- h. Select the **Show solid state based Managed Disk Groups only** check box if you want only managed disk groups that are on solid-state drives to be displayed in the **Managed-disk group** field. Solid-state drives are available in SAN Volume Controller 5.1 and later.
- i. In the **Managed-disk group** field, select the managed disk group. The managed disk groups are listed using the following convention:  
MDisk-group name (*N*)  
  
where *N* is the available capacity. After you select the managed disk group, the managed disks in the managed disk group are displayed.  
To add a managed disk to the managed disk group, click **Add Managed Disk**.
- j. This check box is available only for sequential virtual disks. If you are creating more than one sequential virtual disk, select the **Round robin sequential assignment to managed disks** check box to ensure that the virtual disks are assigned to the managed disks in a round-robin manner. If selected, the number of virtual disks must equal the number of managed disks selected in the managed disk table.  
Clear the **Round robin sequential assignment to managed disks** check box to ensure that all virtual disks are created on a single managed disk. If the check box is cleared, there must be *only* one managed disk selected in the managed-disk table.
- k. Select the **Format virtual disks** check box to ensure that the virtual disks are formatted (written with zeros) after they are created.
- l. Click **Next**.
4. On the Assign the virtual disk to host ports page, assign host ports:
  - a. Optional: In the **Available ports** field, select the ports that you want to assign to the virtual disks, and then click  .
  - b. Click **Next**.
5. On the Zone actions page, perform one of the following zone actions. The Zone actions page is displayed only if Fabric Manager is installed, and you have Fabric administrator authority.
 

**Create a new zone**  
Click **Create new Zone**. In the **Zone name** field, type the name of the zone. The ports that are listed are added to the new zone.

**Update an existing zone**  
Click **Update existing zone**, and then select a zone. The ports that are listed are added to the selected zone.

**Leave the zone configuration as it is**  
Click **Do neither** to avoid performing any fabric-control tasks. The ports that are listed are not able to communicate with the subsystem on this fabric.
6. Click **Next**.
7. On the Summary page, review the selections that you made earlier in the wizard.
8. Click **Finish** to create the virtual disks.

## Deleting a virtual disk

This topic describes how to delete a virtual disk.

1. In the navigation tree pane, expand **Disk Manager** and click **Storage Subsystems**. In the content pane, the Storage Subsystems window is displayed.
2. In the **Storage Subsystems** table, click a SAN Volume Controller, and then click **Virtual Disks**. The Virtual Disks page opens.
3. Click either **Filter by MDisk group** or **Filter by host ports**, and then select the specific filtering condition.
4. Click **Go**. A list of virtual disks associated with the selected SAN Volume Controller is displayed.

| Name     | I/O Group | Status   | MDisk Group Name | Capacity (MB) | Type       | FlashCopy Pair Name | Metro Mirror Name |
|----------|-----------|----------|------------------|---------------|------------|---------------------|-------------------|
| c20_load | io_grp0   | Degraded | mdiskgrp4        | 1,477         | Striped    |                     |                   |
| mdm22    | io_grp0   | Degraded | mdiskgrp4        | 0.95          | Striped    |                     |                   |
| my       | io_grp0   | Degraded | mdiskgrp4        | 0.95          | Striped    |                     |                   |
| mydisk   | io_grp0   | Degraded | mdiskgrp4        | 0.95          | Striped    | fcmap2              |                   |
| rhvdisk  | io_grp0   | Degraded | mdiskgrp4        | 9.54          | Striped    |                     |                   |
| test123  | io_grp0   | Degraded | mdiskgrp4        | 0.95          | Striped    |                     |                   |
| vdisk35  | io_grp0   | Degraded | mdiskgrp4        | 64            | Striped    |                     |                   |
| vdisk36  | io_grp0   | Degraded | mdiskgrp4        | 64            | Striped    |                     |                   |
| vdisk37  | io_grp0   | Degraded | mdiskgrp4        | 64            | Sequential |                     |                   |
| vdisk38  | io_grp0   | Degraded | mdiskgrp4        | 953.67        | Image      |                     |                   |
| vdisk48  | io_grp0   | Degraded | mdiskgrp4        | .1            | Striped    |                     |                   |

Figure 47. Virtual Disks page

5. In the **VDisk** table, click the virtual disk that you want to delete, and then click **Delete**.
6. When prompted to confirm that you want to delete the virtual disk, click **Yes**.

## Viewing virtual-disk information

This topic describes how to view information about the virtual disks in your environment.

1. Expand the **Disk Manager** node in the navigation tree and click **Storage Subsystems**. In the content pane, the Storage Subsystems page is displayed.
2. In the **Storage Subsystems** table, click a SAN Volume Controller, and then click **Virtual Disks**. The Virtual Disks page opens.
3. Click either **Filter by MDisk group** or **Filter by host ports**, and then select the specific filtering condition.
4. Click **Go**. A list of virtual disks associated with the selected SAN Volume Controllers is displayed. The **VDisk** table contains the following information about each virtual disk:

**Name** Name of the virtual disk or mirror copy.

**I/O Group**

Name of the I/O group that is associated with the virtual disk or mirror copy.

**Status** Status of the virtual disk or mirror copy:

- Offline
- Online
- Degraded

**Copy Type**

Indicates the type of the virtual disk. Valid values for this column include the following:

- **Standard:** Indicates standard VDisks (from pre-SAN Volume Controller 4.3 systems)
- **Primary:** Indicates VDisks from SAN Volume Controller 4.3 or newer systems.
- **Copy:** Indicates a mirror copy (not the primary copy) of a VDisk.

**Note:** You can assign virtual disks to hosts if those disks have a **Copy Type** of **Standard** or **Primary**.

**Copy ID**

Indicates the ID of a mirror copy for a virtual disk. Depending on the configuration history, a single mirror copy might have an ID of either 0 or 1.

**Note:** The value **N/A** appears in this column for virtual disks.

**MDisk Group Name**

Name of the managed-disk groups to which the virtual disk or mirror copy belongs.

**Capacity (MB)**

Capacity of the virtual disk or mirror copy in MB. This value is rounded to 0.1 MB.

**Type** Type of virtual disk or mirror copy:

- Image
- Sequential
- Striped

**FlashCopy Name**

Name of the FlashCopy mapping to which the virtual disk belongs.

**MM Name**

Name of the Metro Mirror relationship to which the virtual disk belongs.

5. To view detailed information about a specific virtual disk, click the virtual disk, and then click  . The Virtual-Disk Details page opens.

| VDisks my Details             |           |
|-------------------------------|-----------|
| <b>VDisk ID</b>               | my        |

| <b>UID</b>                    |           |

Figure 48. Virtual-Disk Details page

The Virtual-Disk Details page contains the following information:

**VDisk ID**

ID of the virtual disk.

**Name** Name of the virtual disk. A virtual disk that is marked with an asterisk (\*) indicates that the virtual disk is a space-efficient volume. The \* is not part of the actual virtual disk name.

**I/O group ID**

ID of the I/O group.

**I/O group name**

Name of the I/O group.

**Status** Status of a virtual disk:

- Offline
- Online
- Degraded

**MDisk group name**

Name of the managed-disk group.

**Capacity (MB)**

Capacity of a virtual disk in MB. This value is rounded to 0.1 MB.

**Easy Tier**

Indicates the enablement of tiering. Possible values are: auto, on, off.

Information about virtual disk tiers is available for the following storage systems. The fields related to tiers are not displayed for other storage systems.

- SAN Volume Controller
- Storwize V3500

- Storwize V3700
- Storwize V7000

**Easy Tier Status**

Indicates the status of tiering. Possible values are: active, inactive.

**Tiers** Indicates the tier levels used by the virtual disk. Each tier is displayed as a row in a table. Possible values are: generic\_hdd, generic\_ssd.

**Tier Capacity**

Total storage capacity of a tier.

**Type** Type of a virtual disk:

- Image
- Sequential
- Striped

**Formatted**

Indicates if a virtual disk is formatted.

**MDisk ID**

IDs of the MDisks that a virtual disk is using.

**MDisk name**

Names of the MDisks that a virtual disk is using.

**FlashCopy**

Indicates if the virtual disk is in a FlashCopy (FC) relationship and whether it is an FC source or FC target. Virtual disks that are not in an FC relationship are displayed with a None value whether or not the virtual disk is on a system that supports FC.

**Note:**

- This value is available for virtual disks of the following systems only: IBM TotalStorage Enterprise Storage Server, IBM System Storage DS6000, IBM System Storage DS8000, and SAN Volume Controller.
- TotalStorage Enterprise Storage Server systems must have at least the following microcode levels: ess800mincodelevel = 2.4.3.56, essf20mincodelevel = 2.3.3.89. IBM Tivoli Storage Productivity Center does not report FC information if the TotalStorage Enterprise Storage Server systems do not meet this requirement.

**FlashCopy ID**

ID of the FlashCopy mapping to which the virtual disk belongs.

**FlashCopy name**

Name of the FlashCopy mapping to which the virtual disk belongs.

**Metro mirror ID**

ID of the Metro Mirror relationship to which the virtual disk belongs.

**Metro mirror name**

Name of the Metro Mirror relationship to which the virtual disk belongs.

**I/O throttling rate**

Maximum rate at which an I/O transaction is accepted for a virtual disk.

**Preferred node for I/O**

IP address of the node to be used for I/O operations.

### Mapped to a host

Yes or No.

### Fast-write state

Yes or No. This value indicates whether the virtual disk has data in the cache.

UID Unique ID.

## Managing volumes

This topic contains information about managing volumes.

### Assigning host ports

This topic describes how to assign host ports to volumes. You also can make host-port assignments when you create volumes.

1. In the navigation tree pane, expand **Disk Manager** and click **Storage Subsystems**. In the content pane, the Storage Subsystems window is displayed.
2. In the **Storage Subsystems** table, click the storage subsystem with which you want to work.
3. Click **Volumes**. The Volumes page is displayed.

| Volume           | Subsystem                      | Subsystem Name      | LCU       | Type      | Size        | Unit |
|------------------|--------------------------------|---------------------|-----------|-----------|-------------|------|
| Camera_1809      | DS8000-2107-1301901-IBM        | 2107.1301901        | 24        | FB        | 5 GB        |      |
| Camera_180A      | DS8000-2107-1301901-IBM        | 2107.1301901        | 24        | FB        | 5 GB        |      |
| Camera_180B      | DS8000-2107-1301901-IBM        | 2107.1301901        | 24        | FB        | 5 GB        |      |
| Cuda_3606        | DS8000-2107-1301901-IBM        | 2107.1301901        | 54        | FB        | 5 GB        |      |
| Cuda_3607        | DS8000-2107-1301901-IBM        | 2107.1301901        | 54        | FB        | 5 GB        |      |
| Cuda_3608        | DS8000-2107-1301901-IBM        | 2107.1301901        | 54        | FB        | 5 GB        |      |
| <b>FSVT_1000</b> | <b>DS8000-2107-1301901-IBM</b> | <b>2107.1301901</b> | <b>16</b> | <b>FB</b> | <b>5 GB</b> |      |
| FSVT_1001        | DS8000-2107-1301901-IBM        | 2107.1301901        | 16        | FB        | 5 GB        |      |
| FSVT_1002        | DS8000-2107-1301901-IBM        | 2107.1301901        | 16        | FB        | 5 GB        |      |
| FSVT_1003        | DS8000-2107-1301901-IBM        | 2107.1301901        | 16        | FB        | 5 GB        |      |
| FSVT_1004        | DS8000-2107-1301901-IBM        | 2107.1301901        | 16        | FB        | 5 GB        |      |
| FSVT_1005        | DS8000-2107-1301901-IBM        | 2107.1301901        | 16        | FB        | 5 GB        |      |
| FSVT_1006        | DS8000-2107-1301901-IBM        | 2107.1301901        | 16        | FB        | 5 GB        |      |
| FSVT_1007        | DS8000-2107-1301901-IBM        | 2107.1301901        | 16        | FB        | 5 GB        |      |

Figure 49. Volumes page

4. Select a filtering condition, and then click **Go**. A list of volumes is displayed.
5. In the **Volumes** table, select the volume, and then click **Assign Host Ports**. The Assign Host Ports wizard starts.
6. On the "Assign the volume to host ports" page, assign or unassign host ports:
  - a. Optional: In the **Available ports** field, select the ports that you want to assign to the virtual disks, and then click .

- b. Optional: In the **Assigned ports** field, select any ports that you want to unassign from the virtual disks, and then click . To avoid lost or inconsistent data, make sure that the volume is unmounted before unassigning.  
**Note:** if a host (agent) with multiple host ports is defined to a storage subsystem, assigning a volume to the host ports will create a single host definition with all of those ports.  
If a host (agent) with multiple host ports is **not** defined to a storage subsystem on the same fabric, assigning a volume to the host ports will create a separate host definition for each port (multiple host definitions, each with a single port).
  - c. Click **Next**.
7. On the "Assign the volume to subsystem ports" page, assign the volumes to specific subsystem ports.
    - a. Optional: In the **Available ports** list, select subsystem ports and click >> to assign them to the volumes. The ports are identified using the following convention: <Worldwide port name> (<host name>).
    - b. Click **Next**.
  8. (This page only is displayed if Fabric Manager is installed, and you have Fabric administrator authority.) On the "Zone actions" page, perform one of the following zone actions:
    - Create a new zone**  
Click **Create new Zone**. In the Zone name field, type the name of the zone. The ports listed on the page are added to the new zone.
    - Update an existing zone**  
Click **Update existing zone**, and then select a zone. The ports listed on the page are added to the selected zone.
    - Leave the zone configuration as it is**  
Click **Do neither** to avoid performing any fabric-control tasks. The ports listed on the page will not be able to communicate with the subsystem on this fabric.
  9. Click **Next**. The "Review settings" page opens.
  10. Review the selections that you made earlier in the wizard, and then click **Finish**.

## Creating volumes and assigning volumes to a host

This task describes how to create volumes and assign the volumes to a host storage system. This task also describes how to perform zone configuration tasks if Fabric Manager is installed, and you have Fabric administrator authority

The performance of a volume creation job and the general performance of a CIM object manager (CIMOM) might decrease if you create many volumes on a system at the same time that a performance monitor is collecting data about that system. To avoid this issue, create volumes on a system when a performance monitoring job is not running or is not scheduled to run on the target system.

The following steps describe how to create volumes, assign the volumes to a storage system. Some fields described in these steps are dependent on the type of storage system that you have selected.

1. Expand **Disk Manager** and click **Storage Subsystems**.

2. In the **Storage Subsystem** table, select a storage system, and click **Create Volume**. The Create Volume wizard is started.
3. On the Define the volumes page, specify the attributes for the volumes:
  - a. In the **RAID level** field, select one of the following Redundant Array of Independent Disks (RAID) levels, based on the type of storage system:
    - IBM System Storage DS6000 and IBM System Storage DS8000: RAID 5, RAID 6 (DS8000 only), RAID 10, or Mixed. RAID 5 is the default setting.
    - IBM TotalStorage Enterprise Storage Server: RAID 5 or RAID 10. RAID 5 is the default setting.
    - IBM System Storage FASTT/DS4000 and IBM System Storage DS5000 Storage Manager: RAID 0, RAID 1, RAID 3, or RAID 5. RAID 0 is the default setting.
  - b. In the **Encryption group** field, select an encryption group if you want the new volumes to be created on extent pools that use full disk encryption. If an encryption group is selected, only pools that belong to the selected encryption group are displayed in the **Available extent pools** field. If there are no encryption groups available, **No selection** is displayed in the **Encryption group** field.
  - c. Select the **Solid state based pools only** check box if you want the new volumes to be created on extent pools that are on solid-state drives. If this check box is selected, only pools on solid-state drives are displayed in the **Available extent pools** field. If there are no solid-state drives available, the **Solid state based pools only** check box is disabled.
  - d. In the **Available extent pools** field, select an extent pool from the list of extent pools with the specified RAID level. These extent pools are identified using the following convention: *Device-specific extent pool name (free space GB)*. This field is displayed if the system is DS6000 or DS8000. Only extent pools with fixed-block (FB) tracks are listed.
  - e. In the **Available arrays** field, select an array from the list of arrays with the specified RAID level. These arrays are identified using the following convention: *Device-specific array name (free space GB)*. This field is displayed if the system is neither DS6000 nor DS8000.
  - f. In the **Number of volumes** field, select the number of volumes that you want to create. The default is 1. For an TotalStorage Enterprise Storage Server system, the maximum is 255.
  - g. In the **Volume size** field, select the size of the volumes to be created. The maximum and minimum size depends on the type of storage system.
  - h. In the **Units** field, select one of the following units of measurement for the size of the volumes:
    - KB
    - MB
    - GB
  - i. In the **Name** field, type a name for the volume. If you are creating multiple volumes, this string is used as a prefix. The string cannot be longer than 15 characters. This field is disabled for TotalStorage Enterprise Storage Server systems. TotalStorage Enterprise Storage Server volume names are determined by TotalStorage Enterprise Storage Server.
  - j. Click **Next**.
4. On the Assign the volume to host ports page, assign the volume to specific host ports:

- a. In the **Available ports** list, select host ports and click  to assign the ports to the volumes. The ports are identified using the following convention: *Worldwide port name (host name)*.
  - b. Click **Next**.
5. On the Restrict access to subsystem ports page, you can restrict the host access to specific system ports:
    - a. Optional: In the **Unassigned ports** list, select system ports and click  to remove the ports from the list of ports assigned to the volume. The ports are identified using the following convention: *Worldwide port name (host name)*. To avoid lost or inconsistent data, make sure that the volume is unmounted before you unassign ports.
    - b. Click **Next**.
  6. On the Zone actions page, perform one of the following zone actions. This page is displayed only if Fabric Manager is installed, and you have Fabric administrator authority.

Use a Zone Action if you want to apply updates to the active zone set. This action applies changes to the inactive zone set that has the same name as the active zone set and then the zone set is activated. Before using this option, ensure that the zones and zone members in the active zone set matches the zones and zone members in the inactive zone set with the same name.

#### Create a new zone

Click **Create new Zone**. In the Zone name field, type the name of the zone. The ports that are listed are added to the new zone.

#### Update an existing zone

Click **Update existing zone**, and then select a zone. The ports that are listed are added to the selected zone.

#### Leave the zone configuration as it is

Click **Do neither** to avoid performing any fabric-control tasks. The ports listed that are listed are not able to communicate with the subsystem on this fabric.

Click **Next**.

7. On the Summary page, review the selections that you made earlier in the wizard.
8. Click **Finish**.

## Deleting volumes

This topic describes how to delete volumes.

Note that volumes that are part of a replication session cannot be deleted.

1. In the navigation tree pane, expand **Disk Manager** and click **Storage Subsystems**. In the content pane, the Storage Subsystems page is displayed.
2. In the **Storage Subsystems** table, click a storage subsystem, and then click **Volumes**. The Volumes page is displayed.
3. On the Volumes page, select the specific filtering condition, and then click **Go**. A list of volumes on the selected storage subsystem is displayed.
4. In the **Volumes** table, select the volume that you want to delete, and then click **Delete**. You can select one volume at a time only. You cannot delete TotalStorage Enterprise Storage Server volumes from within IBM Tivoli Storage Productivity Center.

5. When prompted to confirm that you want to delete the volume, click **Yes**. The volume is deleted automatically when you click Yes. You can reuse the volume name immediately after the volume is deleted.

**Note:** For SAN Volume Controller (SVC), if you choose to delete a volume using the SVC console rather than the IBM Tivoli Storage Productivity Center user interface, that volume is retained for 14 days before being deleted. You cannot reuse the volume name during that time.

## Viewing volume information

This topic describes how to view information about the volumes in your environment.

**Note:** If a probe is run against a CIM object manager (CIMOM) that is not available, the volumes defined on the storage system are not displayed in the IBM Tivoli Storage Productivity Center graphical user interface (GUI). Check that probes run successfully and consider configuring an alert to ensure that you are notified when a scheduled probe fails.

1. Expand the **Disk Manager** node in the navigation tree and click **Storage Subsystems**. In the content pane, the Storage Subsystems page is displayed.
2. In the **Storage Subsystems** table, click a storage system, and then click **Volumes**. The Volumes page opens.
3. Select the specific filtering condition, and then click **Go**. A list of volumes associated with the selected storage system is displayed. The **Volume** table contains the following information about each volume:

### Volume

Volume ID.

### Subsystem

A system ID in the following format:

*Type-Model-ID-Vendor*

- *Type* is the type of the storage system, for example, TotalStorage Enterprise Storage Server or SAN Volume Controller.
- *Model* is the model number, for example, 2105 or 2145.
- *ID* is the serial number or cluster name. Cluster names only are used for SAN Volume Controllers.
- *Vendor* is the manufacturer of the storage system, for example, IBM.

### Subsystem Label

A user-defined name or the system ID.

**LCU** Logical control unit (LCU), which can have one of the following values:

- DS6000, DS8000, and TotalStorage Enterprise Storage Server -- logical system (LSS) ID
- SAN Volume Controller --1

**Type** Type of volume, either fixed-block (FB) or count-key data (CKD).

### Volume Space

Size of the volume.

**Unit** GB for fixed-block (FB) volumes and cyl for count-key data (CKD) volumes.

4. To view detailed information about a specific volume, click the volume, and

then click . The Volume Details page is opened. The Volume Details page contains the following information:

**Volume**

Volume ID.

**Volume size**

Volume size.

**Volume real space**

Physical allocated space of the volume. For normal volumes, this value is equal to the volume space. For space efficient/thin provisioned volumes, this value is equal to the real space allocated when data is written to the volume. If IBM Tivoli Storage Productivity Center detects that a volume is thin provisioned but cannot retrieve the Volume real space value, N/A is displayed.

**Array** Array on which the volume is created.

**RAID level**

Redundant Array of Independent Disks (RAID) level of the volume.

**FlashCopy**

Indicates if the volume is in a FlashCopy (FC) relationship and whether it is an FC source or FC target. Volumes that are not in an FC relationship are displayed with a **None** value whether or not the volume is on a system that supports FC.

**Note:**

- This value is available for volumes of the following systems only: IBM TotalStorage Enterprise Storage Server (TotalStorage Enterprise Storage Server), IBM System Storage DS6000, IBM System Storage DS8000, and IBM System Storage SAN Volume Controller.
- TotalStorage Enterprise Storage Server systems must have at least the following microcode levels: `ess800mincodelevel = 2.4.3.56`, `essf20mincodelevel = 2.3.3.89`. IBM Tivoli Storage Productivity Center does not report FC information if the TotalStorage Enterprise Storage Server systems do not meet this requirement.

**Subsystem**

A system ID in the following format:

*Type-Model-ID-Vendor*

where:

- *Type* is the type of the storage system, for example, TotalStorage Enterprise Storage Server or SAN Volume Controller.
- *Model* is the model number, for example, 2105 or 2145.
- *ID* is the serial number or cluster name. Cluster names only are used in for SAN Volume Controllers.
- *Vendor* is the manufacturer of the storage system, for example, IBM.

**Subsystem Label**

This value can be either a user-defined name or the system ID.

**Is Encryptable**

Indicates **Yes** when the volume is encryptable and **No** when the volume is not encryptable.

**Is Encrypted**

Indicates **Yes** when the volume is encrypted and **No** when the volume is not encrypted.

**Assigned host ports**

Host ports to which the volume is assigned.

**Subsystem ports**

System ports to which the volume is assigned.

---

## Managing fabrics

This section describes operations available for directly manipulating the zone configuration in a fabric.

Zone control functions are integrated in the SAN Planner function.

For further information, see “Planning and modifying storage configurations” on page 421.

**Note:**

- After you click **Change** to begin your zone configuration changes and before you click **Update and Activate** or **Update Only** to conclude your changes, it is possible that other users might have made zoning changes to the same fabric. This situation might have happened through a switch element manager or switch CLI, as some switch vendors and models lack zone control session locking across the fabric. This lack of zone control session locking might allow overwrite conditions of the changes to the active zoneset for the fabric and to the set of inactive zonesets.
- If the zoning on a fabric has an active configuration and you use a switch element manager to delete the inactive copy of the active zoneset, Tivoli Storage Productivity Center still displays the inactive copy of the active zoneset on the Fabric Manager > Fabrics > Zone Configuration panels. Tivoli Storage Productivity Center displays the inactive copy even though it does not exist in the fabric zone configuration so that you can edit the active zoneset.

The contents of this inactive copy of zoneset displayed is identical to contents of the active copy of the zoneset. If you use Tivoli Storage Productivity Center to make any subsequent zoning changes for the fabric, the inactive copy of the active zoneset is created in the fabric zone configuration.

## Working with zones

This topic describes how to create, change, duplicate, activate or deactivate, and delete zones.

**Creating zones**

When you add zones, you assign assets to the zone and specify the zone set or sets to which the zone belongs.

To create a zone:

1. In the navigation pane, expand the **Fabric Manager** node and click **Fabrics**.
2. Click a fabric in the list and click **Zone Configuration**.
3. In the **Zone Configuration** area, click **Change**.
4. In the **Zones** area, click **Add**.

5. In the Zone Configuration window enter the name of the zone and, optionally, a description. The zone name must be unique in the fabric. Click **Next**.
6. In the next Zone Configuration window, select the assets (switches, devices, aliases) that you want to include in the zone, move them from the **Available Assets** column to the **Selected Assets** column, and click **Next**.  
If the fabric is set on Interop Mode, you can select only the port WWN number and the device port number from the **Available Assets** column.
7. In the next Zone Configuration window, select one or more zone sets, move them from the **Available Zone Sets** column to the **Selected Zone Sets** column, and click **Finish**.

## Adding storage to a server and setting up a zone

To add storage to a server and set up a zone, do the following:

### 1. Add the CIMOM

- a. Expand **Administrative Services** → **Data Sources** → **CIMOM Agents** .
- b. Click **Add CIMOM** in the content pane.
- c. In the **Add CIMOM** window, enter the required values and click **Save**.

### 2. Run a CIMOM discovery

- a. Expand **Administrative Services** → **Discovery**.
- b. Right-click **CIMOM** and select **Run Now**.
- c. Right-click **CIMOM** and select **Refresh Job List** for the submitted job to appear in the list of discovery jobs. The date and time of the job is displayed in the navigation tree pane. To see the latest status of the job, right-click **CIMOM** and select **Update Job Status**.

### 3. Run a probe

When the discovery has completed successfully, perform the following steps:

- a. Expand **IBM Tivoli Storage Productivity Center** → **Monitoring** .
- b. Right-click **Probes** and select **Create Probe**.
- c. Make your selections and click **Save** to submit the job.
- d. Right-click **Probes** and select **Refresh Job List** to display the job in the list of probes. The date and time of the job will be displayed in the navigation tree pane. To see the latest status of the job, right-click **Probes** and select **Update Job Status**.

4. In the navigation tree pane, expand **Data Manager** and click **Storage Subsystems**. In the content pane, the Storage Subsystems window opens.
5. In the **Storage Subsystems** table, click the storage subsystem with which you want to work.
6. Click **Volumes**.
7. In the Volumes page select a filtering condition, and click **Go**.
8. In the **Volumes** table, select the volume, and then click **Assign Host Ports**. The Assign Host Ports wizard starts.
9. On the "Assign the volume to host ports" page, you can assign and unassign host ports:
  - a. In the **Available ports** field, select the ports that you want to assign to the virtual disks, and then click  .
  - b. In the **Assigned ports** field, select any ports that you want to unassign from the virtual disks, and then click  .

- c. Click **Next**.
10. On the "Assign the volume to subsystem ports" page, assign the volumes to specific subsystem ports.
  - a. Optional: In the **Available ports** list, select subsystem ports and click  to assign them to the volumes. The ports are identified using the following convention: <Worldwide port name> (<host name>).
  - b. Click **Next**.
11. "Zone actions" page is displayed only if Fabric Manager is installed, and you have Fabric administrator authority. Perform one of the following zone actions:

**Create a new zone**

Click **Create new Zone**. In the Zone name field, type the name of the zone. The ports listed on the page are added to the new zone.

**Update an existing zone**

Click **Update existing zone**, and then select a zone. The ports listed on the page are added to the selected zone.

**Leave the zone configuration as it is**

Click **Do neither** to avoid performing any fabric-control tasks. The ports listed on the page will not be able to communicate with the subsystem on this fabric.

Click **Next**.

12. In the "Review settings" page, review your selections and click **Finish**.

## Changing zone properties

You can change a zone name, a description, the assets assigned to a zone, and the zone set or sets to which a zone belongs.

To change zone properties, perform the following steps:

1. In the navigation pane, expand the **Fabric Manager** node and click **Fabrics**.
2. Click a fabric in the list and click **Zone Configuration**.
3. In the **Zone Configuration** area, click **Change**.
4. In the **Zones** area, click **Change**.
5. In the Zone Configuration window enter the name of the zone and, optionally, a description. The zone name must be unique in the fabric. Click **Next**.
6. In the next Zone Set Configuration window, you can change the assets to be included in the zone:
  - In the **Available Assets** column, select any zone assets to be added and click  to move them to the **Selected Assets** column.
  - In the **Selected Assets** column, select any zone assets to be removed from the zone and click  to move them to the **Available Assets** column.
  - Click **Next**.
7. In the next Zone Set Configuration window, you can change the zone sets to which the zone is assigned:
  - In the **Available Zone Sets** column, select any zone sets to which the zone is to be assigned and click  to move them to the **Selected Zone Sets** column.

- In the **Selected Zone Sets** column, select any zone sets to which the zone is not to be assigned and click  to move them to the **Available Zone Sets** column.

8. Click **Finish**.

## Duplicating zones

You can use the Zones dialog to duplicate a zone.

To duplicate zones, perform the following steps:

1. In the navigation pane, expand the **Fabric Manager** node and click **Fabrics**.
2. Click a fabric in the list and click **Zone Configuration**.
3. In the **Zone Configuration** area, click **Change**.
4. In the **Zones** area, click **Duplicate**.
5. In the Zone Configuration window enter the name of the zone and, optionally, a description. The zone name must be unique in the fabric. Click **Next**.
6. In the next Zone Configuration window, you can change the assets to be included in the zone:
  - In the **Available Assets** column, select any zones to be added and click  to move them to the **Selected Assets** column. To remove selected zone assets, select the assets from the **Selected Assets** column and click  to move them to the **Available Assets** column.
  - Click **Finish**.
7. In the next Zone Configuration window, you can change the zone sets to which the zone is assigned:
  - In the **Available Zone Sets** column, select any zone sets to which the zone is to be assigned and click  to move them to the **Selected Zone Sets** column.
  - In the **Selected Zone Sets** column, select any zone sets to which the zone is not to be assigned and click  to move them to the **Available Zone Sets** column.
8. Click **Finish**.

## Removing zones

You can use the Zones dialog to remove one or more zones from the list of available zones.

To delete zones, perform the following steps:

1. In the navigation pane, expand the **Fabric Manager** node and click **Fabrics**.
2. Click a fabric in the list and click **Zone Configuration**.
3. In the **Zone Configuration** area, click **Change**.
4. In the **Zones** area, select one or more zones and click **Remove**. Hold down the Control or Shift key to select multiple zones.
5. In the Zone Deletion window, click **Yes** to delete the selected zones or **No** to cancel the deletion.

## Working with zone sets

This topic describes how to create, change, duplicate, activate or deactivate, and delete zone sets.

A zone set is group of zones that function together on the fabric. Each zone set can accommodate up to 256 zones. All devices in a zone detect only devices assigned to that zone, but any device in that zone can be a member of other zones in the zone set.

## Creating zone sets

This topic provides information about creating new zone sets.

To create a zone set, follow this procedure:

1. In the navigation pane, expand the **Fabric Manager** node and click **Fabrics**.
2. Click a fabric in the list and click **Zone Configuration**.
3. In the **Zone Configuration** area, click **Change**.
4. In the **Zone Sets** area, click **Add**.
5. Type a name and description for the zone set, and click **Next**. The zone set name must be unique within the fabric.
6. In the Zone Set Configuration window, do one of the following:
  - Select one or more zones from the **Available Zones** column, move them to the **Selected Zones** column, and click **Finish**.
  - If there are no zones yet defined or if you are not adding any of the zones available at this time, click **Finish**. A Zone Set Configuration Error window opens stating: "This zone set does not contain any zones. This could result in an error when the zone configuration is applied later. Do you want to continue?" Click **Yes**.

## Changing zone set properties

You can change the zone set definition, which includes the name, description, and the zones that belong to the zone set. When you change and save a zone set definition, the properties are checked by the switches when that definition is stored in the fabric. This can help identify possible problems with that definition before the definition is activated, giving you a chance to correct any problems found before they affect the operation of the fabric.

**Note:** Changing and saving the *definition* for the active zone set does not change the active zone set itself. You must perform an additional step to apply the new definition to the active zone set.

**Note:** After you click **Change** to begin your zoning changes and before you click **Update and Activate** or **Update Only** to conclude your zoning changes, it is possible that other users might have made zoning changes to the same fabric. This may have happened through a switch element manager or switch CLI, as some switch vendors and models lack zone control session locking across the fabric. This could allow overwrite conditions of the changes to the active zoneset for the fabric and to the set of inactive zonesets.

To change the zone set properties, perform the following steps:

1. In the navigation pane, expand the **Fabric Manager** node and click **Fabrics**.
2. Click a fabric in the list and click **Zone Configuration**.
3. In the **Zone Configuration** area, click **Change**.
4. In the **Zone Sets** area, click the zone set to be changed and click **Change**.
5. In the Zone Set Configuration window, type a name and description for the zone set, and click **Next**. The zone set name must be unique within the fabric.
6. In the next Zone Set Configuration window, you can change the zones to be included in the zone set:

- In the **Available Zones** column, select any zones to be added and click  to move them to the **Selected Zones** column.
  - In the **Selected Zones** column, select any zones to be removed from the zone set and click  to move them to the **Available Zones** column.
7. Click **Finish**.

### Activating and deactivating a zone set

Only one zone set can be active at a time. If you deactivate the active zone set, no zone sets are active until you activate another zone set.

To activate or deactivate a zone set, follow these steps:

1. In the navigation pane, expand the **Fabric Manager** node and click **Fabrics**.
2. Click a fabric in the list and click **Zone Configuration**.
3. In the **Zone Configuration** area, click **Change**.
4. In the **Zone Sets** area, click **Activate** or **Deactivate**.
5. In the **Zone Configuration** area, click one of the following actions:
  - **Update and Activate** to commit the changes you have made to the zone set configuration and immediately activate the zone set.
  - **Update Only** to commit the changes you have made to the zone set configuration without making them active.

### Duplicating zone sets

This section provides information about duplicating zone sets.

To create a duplicate zone set, perform the following tasks.

1. In the navigation pane, expand the **Fabric Manager** node and click **Fabrics**.
2. Click a fabric in the list and click **Zone Configuration**.
3. In the **Zone Configuration** area, click **Change**.
4. In the **Zone Sets** area, click the zone set to be duplicated and click **Duplicate**.
5. In the Zone Set Configuration window, type a name and description for the zone set, and click **Next**. The zone set name must be unique within the fabric.
6. In the Zone Set Configuration window, you can change the zones to be included in the new zone set:
  - In the **Available Zones** column, select any zones to be added and click  to move them to the **Selected Zones** column.
  - In the **Selected Zones** column, select any zones to be removed from the zone set and click  to move them to the **Available Zones** column.
7. Click **Finish**.

## Working with zone aliases

This topic describes how to add, change, duplicate, and remove zone aliases. Using zone aliases is a convenient way to work with a named collection of zone members that you want to manage together.

### Creating zone aliases

Creating a zone alias is a convenient way to assign a name to a collection of zone members that you want to manage together.

To create a zone alias:

1. In the navigation pane, expand the **Fabric Manager** node and click **Fabrics**.
2. Click a fabric in the list and click **Zone Configuration**.
3. In the **Zone Configuration** area, click **Change**.
4. In the **Zones Aliases** area, click **Add**.
5. Enter a unique name for the zone alias that will have zone members. Use the following guidelines for naming a zone alias:
  - a. The maximum length for the zone alias name is 54 characters.
  - b. Allowed characters are: A-Z and a-z; \_ (underscores)
  - c. The name must not begin with a number.
  - d. Spaces are not allowed.
6. Enter an optional description of the zone alias. The description can be any combination of alphanumeric characters.
7. Click **Next**.
8. In the next Zone Alias Configuration window, select the assets (switches, devices, aliases) that you want to include in the zone alias, and move them from the **Available assets** column to the **Selected assets** column, and click **Next**.
9. In the final Zone Alias Configuration window, select one or more zones, move them from the **Available Zones** column to the **Selected Zones** column, and click **Finish**.

**Note:** Not all devices support zone aliases. Please refer to the device manufacturer documentation for further information on zone aliases.

### Changing zone alias properties

You can change a zone alias name, description, the assets assigned to it, and the zone members that are specified in the zone alias.

To change zone alias properties, perform the following steps:

1. In the navigation pane, expand the **Fabric Manager** node and click **Fabrics**.
2. Click a fabric in the list and click **Zone Configuration**.
3. In the **Zone Configuration** area, click **Change**.
4. In the **Zone Aliases** area, select the zone alias you want to change and click **Change**.
5. In the Zone Alias Configuration window change the name of the zone alias and, optionally, enter or change the description. The zone alias name must be unique in the fabric. Use the following naming guidelines:
  - a. The maximum length for the zone alias name is 54 characters.
  - b. Allowed characters are: A-Z and a-z; \_ (underscores)
  - c. The name must not begin with a number.
  - d. Spaces are not allowed.
6. Click **Next**.
7. In the next Zone Alias Configuration window, you can change the assets to be included in the zone alias:
  - In the **Available Assets** column, select one or more assets to be added and click the  to move them to the **Selected Assets** column.

- In the **Selected Assets** column, select one or more assets to be removed from the zone alias and click the  to move them to the **Available Assets** column.
  - Click **Next**.
8. In the final Zone Alias Configuration window, you can change the zone members as follows:
    - In the **Available Zones** column, select one or more zone members and click the  to move them to the **Selected Zones** column.
    - In the **Selected Zones** column, select one or more zone members and click the  to move them to the **Available Zones** column.
  9. Click **Finish**.

### Duplicating zone aliases

To create a new zone alias that's based on an existing one, you can duplicate a zone alias and then make changes to it.

To duplicate an existing zone alias and make changes to it, perform the following steps:

1. In the navigation pane, expand the **Fabric Manager** node and click **Fabrics**.
2. Click a fabric in the list and click **Zone Configuration**.
3. In the **Zone Configuration** area, click **Change**.
4. In the **Zone Aliases** area, select the zone alias you want to duplicate and click **Duplicate**.
5. In the Zone Alias Configuration window change the name of the zone alias and, optionally, enter or change the description. The zone alias name must be unique in the fabric. Use the following naming guidelines:
  - a. The maximum length for the zone alias name is 54 characters.
  - b. Allowed characters are: A-Z and a-z; \_ (underscores)
  - c. The name must not begin with a number.
  - d. Spaces are not allowed.
6. Click **Next**.
7. In the next Zone Alias Configuration window, you can change the assets to be included in the new zone alias:
  - In the **Available Assets** column, select any assets to be added and click the  to move them to the **Selected Assets** column.
  - In the **Selected Assets** column, select any assets to be removed from the zone alias and click the  to move them to the **Available Assets** column.
  - Click **Next**.
8. In the final Zone Alias Configuration window, you can change the zone alias as follows:
  - In the **Available Zones** column, select one or more zones and click the  to move them to the **Selected Zones** column.
  - In the **Selected Zones** column, select one or more zones and click the  to move them to the **Available Zones** column.
9. Click **Finish**.

## Removing zone aliases

The following procedure removes a selected zone alias from all zones in the currently selected fabric, and removes the zone alias from the fabric's zoning configuration definition. To remove a zone alias from an individual zone or a specific set of zones, use the Zone Configuration wizard.

To remove a zone alias, perform the following steps:

1. In the navigation pane, expand the **Fabric Manager** node and click **Fabrics**.
2. Click a fabric in the list and click **Zone Configuration**.
3. In the **Zone Configuration** area, click **Change**.
4. In the **Zone Aliases** area, select the zone alias you want to remove and click **Remove**. Hold down the Control or Shift key to select multiple zone aliases.
5. In the Zone Alias Deletion window, click **Yes** to delete the selected zone alias.

---

## Managing Tape Libraries

IBM Tivoli Storage Productivity Center provides the capability to manage your tape libraries. For this release, tape library management capabilities are limited to support for the IBM 3584 tape library (full support) and the IBM 3494 tape library (partial support).

You must have at least Tape Operator authority in order to access the functions in the Tape Manager node. To view your authority level, open the "Role-to-Group Mappings" window in the **Administrative Services > Configuration** node in the navigation tree.

1. Discover IBM tape libraries attached to your SAN fabrics.
2. View tape library information.
3. Monitor the performance of groups of tape libraries by probing for data and viewing alerts. .
4. Create and view asset and capacity reports using data collected from your tape libraries.

Asset reports can include such information as the library identifier and the status of the library. Capacity reports include such information as the number of drives in a library, the number of tape slots, and the number of occupied tape slots.

5. Use the topology viewer to view information about tape libraries, as described in "Working with tape libraries in the topology viewer" on page 541.

## Discovering tape libraries

Discovering tape libraries uses the same general process for discovering CIMOMs as discovering storage subsystems does.

- Tape Manager automatically discovers available devices by contacting the CIM agent that is running on those devices.
- You can add Tape CIMOMs by automatic SLP or manually.
- You can create discovery jobs to discover other Tape Library CIM agents, as described in "Discover storage subsystem, tape library, and fabric information with CIM agents" on page 334.
- You can set up your discoveries to run on a regular schedule, for example weekly.

However, you view your tape libraries from a different location in the navigation tree.

- To confirm the tape libraries that were discovered, complete the following steps:
  1. In the navigation tree, expand **Tape Manager**.
  2. Click **Tape Libraries**. The tape libraries that have been discovered will be listed in the right pane.

IBM Tivoli Storage Productivity Center can detect a tape library that is connected to a fabric through queries to the switches in the fabric and through CIMOM queries. However, only basic information is available at this point, and the information from the two discoveries is not correlated. As a consequence, the tape library is displayed in the topology L0:Storage view as two separate icons:

- After the in-band discovery, as a tape library of unknown status (a blue diamond ) identified only by its world-wide name (WWN)
- After the CIMOM discovery, a tape library is identified as, for example, a 3494 or a TS3500

In order to correlate the information collected through the in-band and CIMOM discoveries, you must run a tape library probe. Then the tape library will be displayed by only one icon with its type identified.

## Viewing tape library information

View collected tape library data to stay aware of discovered tape libraries and usage information.

- Click **Tape Manager**. Left-click **Tape Libraries**. In the content pane, the Tape Libraries page is displayed, which lists the discovered tape libraries.  
Select a library from the table and then click one of the buttons to see further details about that library. For example, select a library and click **Drives** to open a page that lists all the drives for that library.  
You can also right-click a library in the **Tape Libraries** table and select **View Details**.
- Use the **View Details** feature in the topology viewer, as described in “Working with tape libraries in the topology viewer” on page 541.

## Monitoring tape libraries

Monitor the performance of tape libraries to be aware of events that occur, and to respond to alerts.

1. Create one or more tape library groups, as described in “Creating tape library groups” on page 374.
2. Create a probe job to collect data about your tape libraries and library groups, as described in “Creating tape library probes” on page 342.
3. View alerts that are generated by your tape libraries, as described in “Viewing alert logs” on page 405.

---

## Managing DS8000 storage systems using element managers

Use the Configuration Utility in IBM Tivoli Storage Productivity Center to add and manage element managers for IBM System Storage DS8000. *Element managers* are applications that are used to configure and manage a storage device. You can add and manage connections to the element manager that is provided with DS8000, DS8000 Storage Manager, or you can specify other element managers for a device.

The **Element Manager** tab in the Configuration Utility is used to add and manage DS8000 element managers. The **Element Manager** tab contains multiple sections. The **DS8000 Element Manager** section shows the DS8000 element managers that have been added to Tivoli Storage Productivity Center.

To expand or collapse the **DS8000 Element Manager** section, click the + or - icon by the section heading.

## The DS8000 Element Manager section

The **DS8000 Element Manager** section contains a table listing the element managers that are visible to Tivoli Storage Productivity Center and a **Select Action** list. This list enables you to add an element manager to the section and to manage existing element managers. The menu items that are shown in the **Select Action** list depend on whether you have selected an element manager in the table. This table contains the following fields:

### Element Manager

Shows the IP address of the element manager or the display name if a display name was defined.

### Connection Status

Shows the status of the element manager. The values that appear in this field are:

- **Online** (The element manager is accessible.)
- **Offline** (The element manager is not accessible.)

### Device

The name for the device as defined in Tivoli Storage Productivity Center.

### UID/PWD

Shows whether a user ID and password have been defined for authentication to the element manager. The values that appear in this field are:

- **Yes** (A user ID and password have been defined.)
- **No** (A user ID and password have not been defined.)

### LIC Enabled

Shows whether a launch descriptor file has been registered for the element manager. A launch descriptor file is an XML file that describes the menus and the detailed uniform resource locators (URLs) for applications. A launch descriptor file is required to enable the launch in context feature for the device. Tivoli Storage Productivity Center provides a launch descriptor file for the element manager that is provided with DS8000.

The values that appear in this field are:

- **Yes** (Launch descriptor file has been registered.)
- **No** (Launch descriptor file has not been registered.)

### Managed

Shows whether the element manager is associated with a DS8000 that has subsystem interface connection for the device. The values that appear in this field are:

- **Yes** (The element manager is associated with a DS8000 that has subsystem interface connection for the device.)
- **No** (The element manager is not associated with a DS8000 that has subsystem interface connection for the device.)

## Configuring the DS8000 element manager

DS8000 Storage Manager is the element manager that is provided with IBM System Storage DS8000. This section describes how to add and manage DS8000 Storage Manager in IBM Tivoli Storage Productivity Center.

You can perform the following tasks for DS8000 element managers:

- Add DS8000 element managers that you want to manage.
- Start a DS8000 element manager (for example, DS8000 Storage Manager) to configure and administer the storage subsystems associated with the element manager. On Windows, the DS8000 Storage Manager is started in a browser window that is embedded in Tivoli Storage Productivity Center. On AIX, Linux, and UNIX, DS8000 Storage Manager is started in an external Web browser window.
- Modify or remove element managers.
- Test the connection between Tivoli Storage Productivity Center and element managers.

### DS8000 credentials

The configuration of DS8000 credentials depends on whether you are using the single sign-on feature in your environment. *Single sign-on* is an authentication process that enables you to start an application from another application using a single user ID and password. For more information about single sign-on, refer to “Single sign-on” on page 55.

To use single sign-on with DS8000, the DS8000 system must be release 4.2 or later and must be configured for Lightweight Directory Access Protocol (LDAP). Tivoli Storage Productivity Center passes the DS8000 user credentials as a Lightweight Third Party (LTPA) token.

If you are not using single sign-on, the DS8000 element manager user name and password are stored for each Tivoli Storage Productivity Center user. A set of user credentials must be stored for each Tivoli Storage Productivity Center user who wants to access an DS8000 element manager. The **Element Manager** tab lists all element managers known to Tivoli Storage Productivity Center, regardless of the presence of valid user credentials. Element manager credentials might be out of date or absent for that Tivoli Storage Productivity Center user.

If the element manager has been added to Tivoli Storage Productivity Center using different credentials from the ones you are using, or if you attempt to open the DS8000 element manager for the first time after the element manager was added to Tivoli Storage Productivity Center by DS CIM Agent discovery, the following message is shown:

The element manager GUI cannot be accessed because the user name and password are missing. Update the required fields in the next dialog. The GUI will be displayed after the fields have been correctly completed and the dialog closed.

If you created an element manager with one set of credentials and are currently logged on to Tivoli Storage Productivity Center as another user with different credentials, you can open the DS8000 element manager in one of two ways:

- **Add credentials.** Close the warning message. The **Modify Element Manager** window opens. Add the current credentials and click **Save**. You can then open the DS8000 element manager for that element manager.

**Important:** Use this method with caution because anyone who knows the Tivoli Storage Productivity Center credentials can manage the DS8000 device, including performing destructive operations.

- **Log on as the user who added the element manager.** Close the warning message and the **Modify Element Manager** window. Log off of Tivoli Storage Productivity Center. Log on with the user ID that was used to create the element manager. From the Configuration Utility **Element Manager** tab, start the DS8000 element manager.

## Adding DS8000 element managers using the Configuration Utility

Use the Configuration Utility when you want to add one element manager at a time.

To add an element manager in Tivoli Storage Productivity Center, follow these steps:

1. Click **Element Management** in the toolbar, or expand the IBM Tivoli Storage Productivity Center node in the navigation tree, click **Configuration Utility**, and open the **Element Manager** tab. Any existing element managers are automatically added to the **Element Manager** section when the tab opens.
2. In the **DS8000 Element Manager** section, select **Add Element Manager** from the **Select Action** list. The add Element Manager dialog box displays.
3. Define the information that is required to connect to the element manager using the following fields. Required fields are specified in bold in the dialog box. In the following field descriptions, required fields are marked by an asterisk.

- \*Host** Enter the Domain Name System (DNS) name or Internet Protocol (IP) address of the host computer where the element manager is located. You can enter an IPv4 or IPv6 name or address depending on what address types are configured on the element manager and on the system where Tivoli Storage Productivity Center is installed.
- Enter an IPv4 address in the following format: **###.###.###.###**. For example: 192.168.1.65.
  - Enter an IPv6 address. These addresses are typically written as eight groups of four hexadecimal digits, but might vary from site to site. For example: 2001:db8:0:0:1812:5b9e:3391:3156. You can use IPv6 addresses if the computer where Tivoli Storage Productivity Center is dual-stack enabled (IPv4 and IPv6).

**Restriction:** If the computer on which the element manager is located is IPv6-only, the Tivoli Storage Productivity Center servers must be installed on an IPv6-only or dual stack (IPv4 and IPv6 addresses are configured) computer.

- \*Port** Enter the port number on which the element manager listens for requests. The default port number that is shown depends on the value that is selected in the **Protocol** field. You can modify the port number if required for your environment.

### **Username**

Enter the user name that Tivoli Storage Productivity Center will use to log on to the element manager.

**Password**

Enter the password associated with the user name that is defined in the **Username** field.

If the DS8000 element manager you want to add is a new installation and the enterprise storage server network interface (ESSNI) user password has not been changed from the initial value of **admin**, you are prompted to change the password. Be prepared to enter a password and record the new password in a safe place.

**\*Protocol**

Select the protocol (**http** or **https**) for the element manager.

**Display Name**

Enter a display name for the element manager. The display name is shown in the **Element Manager** field in the DS8000 element manager table. If this field is blank, the IP address of the computer on which the element manager is located is shown in the **Element Manager** field of the table. The display name is used in Tivoli Storage Productivity Center and does not affect the element manager itself.

**Save** Click this button to add the DS8000 element manager. Tivoli Storage Productivity Center tests the connection to the element manager. If the connection is successful, the element manager is displayed in the DS8000 element manager table. If the connection is unsuccessful, an error message displays indicating that the element manager at the specified IP address could not be added.

**Cancel**

Click this button to close the dialog box without adding the DS8000 element manager.

**Starting DS8000 element managers**

Use the Configuration Utility to start IBM System Storage DS8000 element managers from IBM Tivoli Storage Productivity Center. You can also start DS8000 element managers from other points in Tivoli Storage Productivity Center.

To start DS8000 element managers using the Configuration Utility follow these steps:

1. Expand the **IBM Tivoli Storage Productivity Center** node in the navigation tree, click **Configuration Utility**, and open the **Element Manager** tab. **Note:** You can also access the Element Manager tab by selecting **Element Management** in the tool bar.
2. In the **DS8000 Element Manager** section, click the element manager that you want to start from the DS8000 element manager table.
3. Use one of the following methods to start the element manager:
  - To start the default element manager for DS8000, select **Launch Default Element Manager** from the **Select Action** list.
  - To start another element manager for DS8000, right-click the element manager that you want to start and click **Launch Element Manager**. Select the element manager that you want to start from the menu.

If the connection information for an element manager is valid, the element manager is started. If unsuccessful, an error message is displayed. The error messages that you receive describes one of the following problems:

- that the element manager at the specified IP address could not be started

- that the required connection information for the element manager has not been provided
- that the element manager is not installed and configured correctly (for local element manager installations such as XIV Storage Manager)

If you are prompted to enter additional information such as an ID and password for the element manager, complete the following steps:

1. Click **OK** in the message dialog box. The Modify Element Manager dialog box is displayed.
2. Enter the required information for the element manager and click **Save**.

## Modifying DS8000 element managers

Use the Configuration Utility to modify information for IBM System Storage DS8000 element managers in IBM Tivoli Storage Productivity Center.

To modify an element manager in Tivoli Storage Productivity Center, follow these steps:

1. Click **Element Management** in the toolbar, or expand the IBM Tivoli Storage Productivity Center node in the navigation tree, click **Configuration Utility**, and open the **Element Manager** tab.
2. In the **DS8000 Element Manager** section, select the element manager that you want to modify from the DS8000 element manager table.
3. Select **Modify Element Manager** from the **Select Action** list. The Modify Element Manager dialog box is displayed.
4. Modify any of the following fields:

### Username

Enter the user name that Tivoli Storage Productivity Center will use to log on to the element manager.

### Password

Enter the password associated with the user name that is defined in the **Username** field.

If the DS8000 element manager you want to add is a new installation and the enterprise storage server network interface (ESSNI) user password has not been changed from the initial value of **admin**, you are prompted to change the password. Be prepared to enter a password and record the new password in a safe place.

### Password Confirm

Enter the same password that you entered in the **Password** field.

### Display Name

Enter a display name for the element manager. The display name is shown in the **Element Manager** field in the DS8000 element manager table. If this field is blank, the IP address of the computer on which the element manager is located is shown in the **Element Manager** field of the table. The display name is used in Tivoli Storage Productivity Center and does not affect the element manager itself.

**Save** Click this button to modify the element manager information. Tivoli Storage Productivity Center tests the connection to the element manager. If the connection is successful, the element manager information is saved. If the connection is unsuccessful, an error message appears indicating that the element manager at the specified IP address could not be added.

### Cancel

Click this button to close the dialog box without modifying the element manager information

## Removing DS8000 element managers

Use the Configuration Utility to remove IBM System Storage DS8000 element managers from IBM Tivoli Storage Productivity Center. This action does not affect DS8000 Storage Manager on the Hardware Management Console (HMC).

To remove an element manager from Tivoli Storage Productivity Center, complete the following steps:

1. Click **Element Management** in the toolbar, or expand the IBM Tivoli Storage Productivity Center node in the navigation tree, click **Configuration Utility**, and open the **Element Manager** tab.
2. In the **DS8000 Element Manager** section, select the element manager that you want to remove from the DS8000 element manager table.
3. Select **Remove Element Manager** from the **Select Action** list. A confirmation dialog box is displayed.
4. Click **OK**. The element manager is deleted from the DS8000 element manager table. When you remove an element manager, it is removed only from the list of element managers that are visible to Tivoli Storage Productivity Center.

To exit the window without removing the element manager, click **Cancel**.

You can remove only one element manager from the DS8000 element manager table at a time.

## Testing the connection to DS8000 element managers

Use the Configuration Utility to test the connection to DS8000 element managers from IBM Tivoli Storage Productivity Center.

To test the connection to an element manager from Tivoli Storage Productivity Center, follow these steps:

1. Click **Element Management** in the toolbar, or expand the IBM Tivoli Storage Productivity Center node in the navigation tree, click **Configuration Utility**, and open the **Element Manager** tab.
2. In the **DS8000 Element Manager** section, select the element manager for which you want to test the connection from the DS8000 element manager table.
3. Select **Test Element Manager Connection** from the **Select Action** list. IBM Tivoli Storage Productivity Center tests the status of the element manager connection. A message dialog box that states whether the test passed or failed is displayed.

## Configuring other element managers for DS8000

DS8000 Storage Manager is the element manager that is provided with IBM System Storage DS8000. However, you can add other element managers for DS8000 as described in this section.

### Adding user-defined element managers for DS8000

A *user-defined element manager* for IBM System Storage DS8000 is an element manager other than DS8000 Storage Manager. Use the Configuration Utility to add user-defined element managers for IBM System Storage DS8000 in IBM Tivoli Storage Productivity Center.

User-defined element managers are not displayed in the **DS8000 Element Manager** table. These element managers are displayed in the various launch menus that are provided in IBM Tivoli Storage Productivity Center.

To add user-defined element managers in Tivoli Storage Productivity Center, follow these steps:

1. In the navigation tree, expand **IBM Tivoli Storage Productivity Center**. Left-click **Configuration Utility**. In the content pane, click the **Element Manager** tab.
2. In the **DS8000 Element Manager** section, select the row in the DS8000 element manager table that contains the device to which you want to add a user-defined element manager.
3. Select **Add User Defined Element Manager** from the **Select Action** list. The Add User Defined Element Manager dialog box is displayed.
4. Enter a Uniform Resource Locator (URL) or command to start the element manager, and click **Save**.

To exit without adding a element manager, click **Cancel**.

### Removing user-defined element managers for DS8000

Use the Configuration Utility to remove user-defined element managers for IBM System Storage DS8000 in IBM Tivoli Storage Productivity Center.

To remove a user-defined element manager from Tivoli Storage Productivity Center, follow these steps:

1. Click **Element Management** in the toolbar, or expand the IBM Tivoli Storage Productivity Center node in the navigation tree, click **Configuration Utility**, and open the **Element Manager** tab.
2. In the **DS8000 Element Manager** section, select the row in the DS8000 element manager table that contains the device from which you want to remove a user-defined element manager.
3. Select **Remove Element Manager** from the **Select Action** list. The Remove Element Manager dialog box opens.
4. Select the element manager that you want to remove from the list and click **OK**. The element manager is removed. When you remove an element manager, it is removed only from the list of element managers that are visible to Tivoli Storage Productivity Center.

To exit the window without removing the element manager, click **Cancel**.

---

## Managing other storage systems using element managers

Use the Configuration Utility in IBM Tivoli Storage Productivity Center to add and manage element managers for storage devices other than IBM System Storage DS8000. *Element managers* are applications that are used to configure and manage a storage device. You manage connections to the element managers that are provided with the storage device or you can specify other element managers for a device.

The **Element Manager** tab in the Configuration Utility is used to add and manage element managers. The **Element Manager** tab contains multiple sections. The **Other Device Element Manager** section shows element managers that have been added using a discovery job or existing element managers that were added to Tivoli Storage Productivity Center prior to release 4.1.

If you are gathering data from IBM XIV Storage System, the XIV system element manager is displayed in the **Other Device Element Manager** section. However, the tasks available for the other element managers in this section are not available for the XIV system element manager. Use the Storage Subsystem page to work with the XIV system element manager (see “Managing storage subsystems” on page 553).

To expand or collapse the **Other Device Element Manager** section, click the + or - icon by the section heading.

## Other Device Element Manager section

The **Other Device Element Manager** section contains a table listing the element managers or external tools that are visible to Tivoli Storage Productivity Center and a **Select Action** list. This list enables you to manage existing element managers. The menu items that are shown in the **Select Action** list depend on whether you have selected an element manager in the table. This table contains the following fields:

### Element Manager

Shows the IP address of the element manager or the display name if a display name was defined.

### Connection Status

Shows the status of the element manager. The values that appear in this field are:

- **Online** (The element manager is accessible.)
- **Offline** (The element manager is not accessible.)

### Device

The name for the device as defined in Tivoli Storage Productivity Center.

### UID/PWD

Shows whether a user ID and password have been defined for authentication to the element manager. The values that appear in this field are:

- **Yes** (A user ID and password have been defined.)
- **No** (A user ID and password have not been defined.)

### LIC Enabled

Shows whether a launch descriptor file has been registered for the element manager. A launch descriptor file is an XML file that describes the menus and the detailed uniform resource locators (URLs) for applications. A launch descriptor file is required to enable the launch in context feature for the device.

The values that appear in this field are:

- **Yes** (Launch descriptor file has been registered.)
- **No** (Launch descriptor file has not been registered.)

## Adding element managers using CIMOM discovery

Use the CIM object manager (CIMOM) discovery process in IBM Tivoli Storage Productivity Center to add element managers that are managing the same storage subsystems as CIMOMs in your environment. The element managers discovered through the CIMOM discovery process are automatically added to the **Element Manager** tab in the Configuration Utility.

Use this method when you want to add multiple element managers to Tivoli Storage Productivity Center simultaneously. For example, use these steps when:

- You want to run a discovery against multiple CIMOMs and each of those CIMOMs has a registered storage system.
- You have more than one registered storage system per CIMOM.

This method does not apply to storage systems that use native interfaces:

- System Storage DS8000
- SAN Volume Controller
- The XIV system
- Storwize V7000
- Storwize V7000 Unified
- IBM SONAS

This procedure does not physically add the CIMOM to your environment, but provides Tivoli Storage Productivity Center with the information it requires to communicate with that CIMOM.

To add an element manager using CIMOM discovery in Tivoli Storage Productivity Center, complete the following steps:

1. Expand **Administrative Services > Data Sources > CIMOM Agents** in the navigation tree.
2. In the right-side pane, click **Add CIMOM**. The Add CIMOM dialog box is displayed.
3. Define the information that is required to add the CIMOM using the following fields. Required fields are specified in bold in the dialog box. In the following field descriptions, required fields are marked by an asterisk.

**\*Host** Enter the IP address of the computer on which the CIMOM is installed. You can enter an IPv4 or IPv6 address depending on what is supported on the computer where the CIMOM is located:

- Enter an IPv4 address in the following format: **###.###.###.###**. For example: 192.168.1.65
- Enter an IPv6 address. These addresses are typically written as eight groups of four hexadecimal digits, but might vary from site to site. For example: 2001:DB8::/32:1812:5b9e:3391:3156. You can use IPv6 addresses if the computer where Tivoli Storage Productivity Center is installed is IPv6 or dual stack (IPv4 and IPv6) enabled.

**Note:** If the computer on which the CIMOM is located is IPv6-only, the Tivoli Storage Productivity Center servers must be installed on an IPv6-only or dual stack (IPv4 and IPv6 enabled) computer.

**Port** Enter the port through which Tivoli Storage Productivity Center contacts the CIMOM. You can modify the default port number if required for your environment.

**Username**

If required by the CIMOM, enter the user name that Tivoli Storage Productivity Center uses to log on to the CIMOM.

**Password**

Enter the password for the user name that is defined in the **Username** field.

**\*Interoperability Namespace**

Enter the interoperability namespace of the CIMOM. This namespace within the CIMOM allows for accessing the CIM Interop Schema (including the class instances of the Server Profile) and determines how Tivoli Storage Productivity Center interacts with the CIMOM when retrieving information.

**Protocol**

Select the protocol (**http** or **https**) for the CIMOM.

**Truststore Location**

Enter the location (path on this computer) of the truststore for the CIMOM. The truststore is the certificate file for certificate-based authentication in the https protocol.

**Truststore Passphrase**

Enter the passphrase of the truststore for the CIMOM.

**Display Name**

Enter the name for the CIMOM as you want it to be shown in Tivoli Storage Productivity Center.

**Description**

Enter a short description for the CIMOM as you want it to be shown in Tivoli Storage Productivity Center.

**Test CIMOM connectivity before adding**

Select this check box to ensure that communication to the CIMOM is working properly before the CIMOM is added. If this box is not checked, the CIMOM is added without verifying connectivity with the specified parameters.

**Important:** Failure to check the CIMOM connection can cause a failure later if the CIMOM cannot be scanned or probed.

**Save** Click this button add the CIMOM.

- If you selected **Test CIMOM connectivity before adding**, Tivoli Storage Productivity Center attempts to connect to the CIMOM using the information provided in this dialog box. If the logon information for a CIMOM is incorrect, an error occurs and an associated error message dialog box is displayed.
- If you did not select **Test CIMOM connectivity before adding**, the CIMOM is associated with the element manager but connectivity with Tivoli Storage Productivity Center is not verified.

**Cancel**

Click this button to close the dialog box without adding the CIMOM.

4. Expand **Administrative Services > Discovery** in the navigation tree.
5. Right-click **CIMOM** and select **Run Now**. The CIMOM discovery process adds the element managers that are managing the same storage system as the CIMOM. The element managers are displayed on the appropriate element manager section on the Element Manager tab of the Configuration Utility. Element managers that are added through CIMOM discovery might exist on a Hardware Management Console (HMC) other than the HMC where the CIMOM is located.

## Modifying other element managers

Use the Configuration Utility to modify information for element managers in IBM Tivoli Storage Productivity Center.

To modify an element manager other than an IBM System Storage DS8000 element manager in Tivoli Storage Productivity Center, follow these steps:

1. Click **Element Management** in the toolbar, or expand the IBM Tivoli Storage Productivity Center node in the navigation tree, click **Configuration Utility**, and open the **Element Manager** tab.
2. In the **Other Device Element Manager** section, select the element manager that you want to modify from the element manager table.
3. Select **Modify Element Manager** from the **Select Action** list. The Modify Element Manager dialog box is displayed.
4. Modify any of the following fields:

### Username

Enter the user name that Tivoli Storage Productivity Center will use to log on to the element manager.

### Password

Enter the password associated with the user name that is defined in the **Username** field.

### Password Confirm

Enter the same password that you entered in the **Password** field.

### Display Name

Enter a display name for the element manager. The display name is shown in the **Element Manager** field in the element manager table. If this field is blank, the IP address of the computer on which the element manager is located is shown in the **Element Manager** field of the table. The display name is used in Tivoli Storage Productivity Center and does not affect the element manager itself.

**Save** Click this button to modify the element manager information. Tivoli Storage Productivity Center tests the connection to the element manager. If the connection is successful, the element manager information is saved. If the connection is unsuccessful, an error message appears indicating that the element manager at the specified IP address could not be added.

### Cancel

Click this button to close the dialog box without modifying the element manager information

## Starting other element managers

Use the Configuration Utility to start element managers from IBM Tivoli Storage Productivity Center. You can also start element managers from other points in Tivoli Storage Productivity Center.

To start element managers other than IBM System Storage DS8000 element managers from the Configuration Utility follow these steps:

1. Click **Element Management** in the toolbar, or expand the IBM Tivoli Storage Productivity Center node in the navigation tree, click **Configuration Utility**, and open the **Element Manager** tab.

2. In the **Other Device Element Manager** section, click the element manager that you want to start from the element manager table.
3. Use one of the following methods to start the element manager:
  - To start the default element manager for a storage system, select **Launch Default Element Manager** from the **Select Action** list.
  - To start another element manager for a storage system, right-click the element manager that you want to start and click **Launch Element Manager**. Select the element manager that you want to start from the menu.

If the connection information for an element manager is valid, the element manager is started. If unsuccessful, an error message is displayed. The error message that you receive describes one of the following problems:

- that the element manager at the specified IP address could not be started
- that the required connection information for the element manager has not been provided
- that the element manager is not installed and configured correctly (for local element manager installations such as XIV Storage Manager)

If you are prompted to enter additional information such as an ID and password for the element manager, complete the following steps:

1. Click **OK** in the message dialog box. The Modify Element Manager dialog box is displayed.
2. Enter the required information for the element manager and click **Save**.

## Testing the connection to other element managers

Use the Configuration Utility to test the connection to element managers from IBM Tivoli Storage Productivity Center.

To test the connection to an element manager other than an IBM System Storage DS8000 element manager from Tivoli Storage Productivity Center, follow these steps:

1. Click **Element Management** in the toolbar, or expand the IBM Tivoli Storage Productivity Center node in the navigation tree, click **Configuration Utility**, and open the **Element Manager** tab.
2. In the **Other Device Element Manager** section, select the element manager for which you want to test the connection from the element manager table.
3. Select **Test Element Manager Connection** from the **Select Action** list. IBM Tivoli Storage Productivity Center tests the status of the element manager connection. A message dialog box that states whether the test passed or failed is displayed.

## Adding user-defined element managers for other storage systems

A *user-defined element manager* is an element manager other than the manager that is provided with the storage system. Use the Configuration Utility to add user-defined element managers in IBM Tivoli Storage Productivity Center.

User-defined element managers are not displayed in the **Other Device Element Manager** table. These element managers are displayed in the various launch menus that are provided in IBM Tivoli Storage Productivity Center.

To add user-defined element managers for a storage device other than DS8000 in Tivoli Storage Productivity Center, follow these steps:

1. Click **Element Management** in the toolbar, or expand the IBM Tivoli Storage Productivity Center node in the navigation tree, click **Configuration Utility**, and open the **Element Manager** tab.
2. In the **Other Device Element Manager** section, select the row in the element manager table that contains the storage system to which you want to add a user-defined element manager.
3. Select **Add User Defined Element Manager** from the **Select Action** list. The Add User Defined Element Manager dialog box is displayed.
4. Enter a Uniform Resource Locator (URL) or command to start the element manager, and click **Save**.

To exit without adding a element manager, click **Cancel**.

## Removing user-defined element managers for other storage systems

Use the Configuration Utility to remove user-defined element managers for storage systems in IBM Tivoli Storage Productivity Center.

To remove a user-defined element managers for a storage device other than DS8000 in Tivoli Storage Productivity Center, follow these steps:

1. Click **Element Management** in the toolbar, or expand the IBM Tivoli Storage Productivity Center node in the navigation tree, click **Configuration Utility**, and open the **Element Manager** tab.
2. In the **Other Device Element Manager** section, select the row in the element manager table that contains the storage system from which you want to remove a user-defined element manager.
3. Select **Remove Element Manager** from the **Select Action** list. The Remove Element Manager dialog box opens.
4. Select the element manager that you want to remove from the list and click **OK**. The element manager is removed. When you remove an element manager, it is removed only from the list of element managers that are visible to Tivoli Storage Productivity Center.

To exit the window without removing the element manager, click **Cancel**.

---

## Launch and launch in context

The launch and launch in context features are used to start IBM Tivoli Storage Productivity Center and to start other applications from Tivoli Storage Productivity Center. The terms inbound and outbound are used to differentiate starting Tivoli Storage Productivity Center (inbound) and starting another application from Tivoli Storage Productivity Center (outbound).

Inbound launch in context refers to starting Tivoli Storage Productivity Center at a specific point in the graphical user interface (GUI). You can use inbound launch in context in either of the following ways:

- Configure an application such as Tivoli Enterprise Portal to start Tivoli Storage Productivity Center at functionally related locations in the Tivoli Storage Productivity Center GUI.
- Start Tivoli Storage Productivity Center from Java Web Start, the command line, or the Windows Start menu using parameters to specify the starting location in the Tivoli Storage Productivity Center GUI.

Outbound launch in context refers to starting other applications, such as administrative applications for storage systems and switches, from functionally related points in the Tivoli Storage Productivity Center GUI.

Launch refers to starting an application at the starting point for that application. Launch primarily refers to starting applications from the Tivoli Storage Productivity Center GUI. Starting applications from Tivoli Storage Productivity Center is referred to as an outbound launch.

**Related concepts:**

“Inbound launch in context feature” on page 58

With the inbound launch in context feature you can start IBM Tivoli Storage Productivity Center at a specified point in the graphical user interface (GUI).

“**Outbound launch and launch in context features**” on page 65

With the outbound launch and launch in context features, you can start the administrative applications for devices such as storage systems and switches from various points in the graphical user interface (GUI).

## Inbound launch in context feature

With the inbound launch in context feature you can start IBM Tivoli Storage Productivity Center at a specified point in the graphical user interface (GUI).

**Prerequisite:** You must have View and Modify permissions to use the launch in context feature.

You can use the launch in context feature to perform the following tasks in Tivoli Storage Productivity Center:

- Create a volume or VDisk
- Open the storage area network SAN Planner
- Create a capacity report
- Create a wasted space report

You can run the launch in context feature in the following ways:

- **Use Java Web Start** from a Web browser. See “Launch with Java Web Start” on page 59.
- **Use the command line on Windows, AIX, Linux, or UNIX** to enter the command and arguments on the command line. See “Launch from the command line” on page 61.
- **Use the Windows Start menu.** See “Launch from Start menu” on page 62.
- **Use the Tivoli Enterprise Portal GUI** to define, edit, and launch commands. See “Launch from Tivoli Enterprise Portal” on page 63.

The launch in context feature has a number of parameters. See “Launch in context parameters” on page 1482, “Launch in context task parameters” on page 1484, and “Available windows” on page 1485.

### Launch with Java Web Start

Using Java Web Start, you can use the launch in context feature from a Uniform Resource Locator (URL).

The launch in context feature requires Java Web Start 6 on the computer that is running the Web browser. If the correct release of Java Web Start is not present, you receive an error message when you enter the URL. The message states that

you must download the Java Runtime Environment, which includes Java Web Start. Follow the link provided in the message to install the required software.

If you are using Internet Protocol Version 6 (IPv6) and are using Java Web Start to start IBM Tivoli Storage Productivity Center on a Windows system, use a system host name such as **tpc332.storage.newyork.xyz.com:9549** in the Web browser address field rather than an IPv6 address such as **[2001:DB8:0000:1234:0000:0000:5678:ABCD]:9549**.

To use the launch in context feature to perform a task or display a window on a remote server from your browser, complete the following steps:

1. Open your browser and type the launch in context command.

URLs cannot include spaces. In the command, a parameter and its value are separated by an equal sign (=). Parameter=value pairs are separated by an ampersand (&).

The format of a command to create a volume is:

```
https://device_server:device_port/ITSRM/jsp/jnlp/tpcgui.jsp?consoleClass=com.ibm.usmi.console.lic.tpc.LICConsole&-server=server:port&-function=disk.create_volume&-subsystem_id=ESS-2105-17844-IBM&-name=myvol&-number=2&-size=10&-unit=MB
```

The format of a command to view a window on a remote server is:

```
http://device_server:device_port/ITSRM/jsp/jnlp/tpcgui.jsp?consoleClass=com.ibm.usmi.console.lic.tpc.LICConsole&-server=server:port&-function=window_name
```

**Tip:** The Data server port value is 9549. The port value for the Device server is 9551 for https and 9550 for http. If the wrong the Device server port value is used, the return page cannot be interpreted by the browser. If the wrong Data server port value is used, the following error message is returned.

Unable to connect to the server

2. The first time a window or task is started, you receive a security warning informing you that the downloaded jar files have been digitally signed using a certificate from a trusted company. To prevent this message from being displayed in the future, select **Always trust content from this publisher** and click **Run**. If the Tivoli Storage Productivity Center graphical user interface (GUI) has not been downloaded on the local computer using Java Web Start, or the local computer does not have the latest version of the Tivoli Storage Productivity Center GUI, the GUI is downloaded.
3. If you included the user ID and password in the command, the sign-in dialog is bypassed, otherwise log on to the Tivoli Storage Productivity Center GUI. The Tivoli Storage Productivity Center GUI navigates to the tree node corresponding to the window name that you specified. You are connected using the user name and password that you entered. Depending on the value you specified for the -function parameter, the following actions might occur:
  - The specified window opens
  - For disk.create\_volume, depending on the parameters, the Create Volume wizard or Create VDisk wizard opens.
  - For disk.san\_planner, the SAN Planner panel opens with the given SAN plan ID.
  - For data.filesystem\_capacity\_by\_computer, the Capacity Report opens.
  - For TPC.reports\_data\_wasted\_space, the Wasted Space Report opens.

### Restrictions:

- When you open a plan in the SAN Planner using launch in context, you must enter the exact name of the plan. The value for the **-plan\_id** parameter is case-sensitive and must match the name of the plan when it was created. For example, if you created a plan named **UserPlan1**, you must specify **-plan\_id UserPlan1** in the launch in context command.
- There is a known limitation when you launch the Filesystem Capacity > By Computer report using launch in context, you must specify the ID for the computer upon which you want to report. For example:

```
http://tpcserver14:9550/ITSRM/jsp/jnlp/tpcgui.jsp?consoleClass=com.ibm.usmi.console.lic.tpc.LICConsole&-server=tpcserver14.storage.xyz.com:9549&-function=data.filesystem_capacity_by_computer&-computer_id=tpcserver14
```

The value you enter for the **computer\_id** parameter might not match the ID for that computer that is stored in the Tivoli Storage Productivity Center database repository. You receive a warning message if the ID for the computer that you enter in the URL does not match the ID that is stored in the data repository. To ensure that this report is displayed properly when you run from the launch in context facility, enter an ID for the computer that matches the ID that is displayed for it through the Topology Viewer or appropriate report in the product user interface.

Use the information in the following links to enter parameters. If any of the parameters are spelled incorrectly, an error message indicates the incorrect parameter.

“Launch in context parameters” on page 1482

You can use the launch in context parameters, definitions, and examples.

“Launch in context task parameters” on page 1484

Use the launch in context feature task parameters to perform tasks.

“Available windows” on page 1485

You can use windows with the inbound launch in context feature to start IBM Tivoli Storage Productivity Center. These windows are called with the **-function window name** argument.

## Launch from the command line

This topic describes how to start windows and tasks from the Windows AIX, Linux, or UNIX command line.

The bat file `tpc.bat` is used for Windows operating systems. The `.sh` file `TPCD.sh` is used for AIX, Linux, or UNIX systems. The parameters follow the file name. Parameters are separated by spaces. Parameters are optional and can appear in any order. See “Launch in context parameters” on page 1482, “Launch in context task parameters” on page 1484, and “Available windows” on page 1485 for the parameters.

Frequently used commands can be saved as unique command files and rerun as needed.

1. In the Command Prompt window, type the command for the action that you want to take, and press Enter.  
The action occurs on the remote Data server. The graphical user interface (GUI) window for that action opens on the local computer.
2. Enter parameters if you previously did not enter any parameters. If you do not provide a user name, password, or server name, the IBM Tivoli Storage Productivity Center GUI opens the connection dialog box. If you do not

provide these values, the GUI presents an error message box and requests the values. If you specify incorrect parameters, you receive an error message.

The following example launches a task from the Windows command line:

```
tpc.bat -user admin -passwd password1 -server
tivoli122.storage.usca.ibm.com:9549 -function
data.filesystem_capacity_by_computer -computer_id <computerID>
```

The following example uses the launch in context feature to view a window on the remote machine:

```
tpc.bat -user admin -passwd password1 -server
tivoli122.storage.usca.ibm.com:9549 -function disk.storage_subsystem
```

### Restrictions:

- When you open a plan in the SAN Planner using the command line or a Web browser for launch in context, you must enter the exact name of the plan. The value for **-plan\_id** in the command line is case-sensitive and must match the name of the plan when it was created. For example, if you created a plan named **UserPlan1**, you might enter the following command on the command line:

```
./TPCD.sh -user administrator -passwd passw0rd -server
tpcserver14.storage.xyz.com:9549 -function disk.san_Planner -plan_id
UserPlan1
```

- There is a known limitation when you start the Filesystem Capacity > By Computer report using launch in context. To start this report, you must specify the ID for the computer upon which you want to report. For example:

```
./TPCD.sh -user root -passwd "passw0rd" -server
tpcserver14.storage.xyz.com:9549 -function
data.filesystem_capacity_by_computer -computer_id tpcserver14
```

The value you enter for "computer\_id" might not match the ID for that computer that is stored in the Tivoli Storage Productivity Center database repository. You will receive a warning message if the ID for the computer you enter in the command line does not match the ID stored in the data repository. To ensure that this report is displayed properly when run from the launch in context command line or through Java Web Start, make sure to enter an ID for the computer that matches the ID that is displayed for it through the Topology Viewer or appropriate report in the product's user interface.

### Launch from Start menu

This topic describes how to start windows and actions from the Windows Start menu.

The bat file, `tpc.bat`, is used for Windows operating systems. The parameters follow the bat file name. Parameters are optional and can appear in any order. To use the launch in context feature from the Windows Start menu, complete the following steps:

1. Click **Start > Programs > IBM Tivoli Storage Productivity Center**, right-click **Productivity Center** and select **Properties**. The Productivity Center Properties window opens.
2. Enter the command-line arguments in the **Target** text field and click **Enter**.  
If the Data server is remote, the action occurs on the Data server and the graphical user interface (GUI) window the action opens is on the local computer.

3. Enter the parameters if you did not previously enter the necessary parameters. If you do not provide the user name, password, or server name, the Tivoli Storage Productivity Center GUI opens the connection dialog box. If you do not provide these values, the GUI presents an error message box and requests the values.

The following example starts a task from the Windows Start menu:

```
"C:\Program Files\IBM\TPC\gui\tpc.bat" -user admin -passwd password1
-server tivoli122.storage.usca.ibm.com:9549 -function
data.filesystem_capacity_by_computer -computer_id computerID
```

The following example uses the Windows Start menu to view a window on the remote server:

```
"C:\Program Files\IBM\TPC\gui\tpc.bat" -user admin -passwd password1
-server tivoli122.storage.usca.ibm.com:9549 -function
disk.storage_subsystem
```

**For more information see:**

“Launch in context parameters” on page 1482

You can use the launch in context parameters, definitions, and examples.

“Launch in context task parameters” on page 1484

Use the launch in context feature task parameters to perform tasks.

“Available windows” on page 1485

You can use windows with the inbound launch in context feature to start IBM Tivoli Storage Productivity Center. These windows are called with the `-function window name` argument.

## Launch from Tivoli Enterprise Portal

This topic shows you how to start an existing launch definition from the Tivoli Enterprise Portal graphical user interface (GUI).

You must configure Tivoli Enterprise Portal before you can use the launch in context feature. For information on prerequisites and details on how to configure the launch in context feature with Tivoli Enterprise Portal, see “Configuring Tivoli Enterprise Portal” on page 63. After Tivoli Enterprise Portal has been configured, you can start the application from the configuration window or use **Launch** from the Tivoli Enterprise Portal navigation tree.

If you use the Tivoli Enterprise Portal navigation tree, **Launch** will open the Tivoli Enterprise Portal graphical user interface with your predefined launch in context commands. To use one of these commands, complete the following steps:

1. In the Tivoli Enterprise Portal window, expand **Enterprise > Windows Systems *your\_server\_name* > Windows OS**. Right-click **Disk** and select **Launch**. Disk is one of several values you can select. Values include Disk, Network, Enterprise Services, Memory, Printer, Process, Processor, and System.
2. The Create or Edit Launch Definitions window opens showing a list of defined launch definitions in the **Existing Launch Definitions** area.
3. Select the launch definition you want to use from the list and click **Launch**. The window or task that is defined by that launch definition opens.

For information on editing the launch in context command with the Tivoli Enterprise Portal GUI, see:

### Related tasks:

“Editing launch definitions” on page 65

You can edit an existing launch definition with the Tivoli Enterprise Portal graphical user interface (GUI).

### Configuring Tivoli Enterprise Portal:

You can configure Tivoli Enterprise Portal so that you can use the launch in context feature.

To configure Tivoli Enterprise Portal complete the following steps:

1. The initial steps depend on whether you are going to open a window or perform a task.
  - a. If you are opening a window, in the Tivoli Enterprise Portal navigation window on the local computer, select where you want the launch definition to originate from. This opens the corresponding view on the target computer. Right-click one of the following locations.
    - The navigator item
    - A row in a table or situation event console view
    - A slice of a pie chart
    - A bar of a bar chartIf the launch definition originates from a table, chart, or situation event console view, open the workspace containing the view. If you think you might edit the argument later, create the launch definition from a table or chart view.
  - b. If you are going to perform a task, create a launch definition for one of the following tasks:
    - Create a volume or VDisk
    - Open the SAN Planner
    - Create a capacity report
    - Create a wasted space report
2. In the Tivoli Enterprise Portal window, expand **Enterprise > Windows Systems > your\_server\_name > Windows OS**. Right-click **Disk** and select **Launch**. Disk is one of several values you can select. Values include Disk, Network, Enterprise Services, Memory, Printer, Process, Processor, and System.
3. The Create or Edit Launch Definitions window opens. Click **Create New**.
4. In the **Name** text field, type a descriptive name for this launch definition. This name is used in the definition list.
5. In the **Target** text box click **Browse** to locate the tpc.bat file. The Select files for directories for Launch Definitions window opens. A typical location for Windows systems is C:\Program Files\IBM\TPC\gui\tpc.bat. Select the correct directory and click **OK**.

When you start a launch definition from the command line, if any part of the path contains spaces, enclose the entire entry in quotation marks.

6. In the **Arguments** text field, enter any parameters that will be added when the application is started. Arguments are entered as *-parameter value*. In the Create or Edit Launch Definitions window, click **Browse** next to **Arguments** to locate the parameters that you want to use. The Select Browser Options window opens. Click **Substitutable Items** and then click **OK**. Select parameters from the **Selected Context** and **Extended Context** lists.

The **help** argument lists the available **function** values. You must type the help parameter by itself into the **Arguments** text field or into the form `tpc.bat -help functions` on the command line for Windows or `TPCD.sh -help functions` for UNIX. The **-help functions** parameter provides a window that lists the nodes in the navigation tree that are available to start. If you type **-help** without the **functions** parameter, it results in an error message.

When all parameters have been selected, click **OK** to return to the Create or Edit Launch Definitions window.

7. If the parameters can be changed at launch time (for example, you want to change the system ID), check the **Edit arguments before execution** box.
8. Specify a value for the **Start in** location. Click **Browse** to locate the IBM Tivoli Storage Productivity Center installation and select the folder **gui** where `tpc.bat` is located.
9. Click **Evaluate** to see how the command resolves when the application starts. Correct any of the parameters that are incorrect and reevaluate the command.
10. When you are satisfied with the launch definition, click **Apply** to save your changes. This keeps the window open so that you can start the current launch definition or create a new one. Click **OK** to save the launch definition and close the window.
11. To start the current definition, select **Launch**. The Tivoli Storage Productivity Center graphical user interface (GUI) with the function parameter that you have provided is opened.

**Related reference:**

“Launch in context parameters” on page 1482

You can use the launch in context parameters, definitions, and examples.

“Launch in context task parameters” on page 1484

Use the launch in context feature task parameters to perform tasks.

“Available windows” on page 1485

You can use windows with the inbound launch in context feature to start IBM Tivoli Storage Productivity Center. These windows are called with the `-function window name` argument.

**Editing launch definitions:**

You can edit an existing launch definition with the Tivoli Enterprise Portal graphical user interface (GUI).

If the **Edit arguments before execution** box was checked when a launch definition was configured, you can edit the launch definition by changing the attribute values. To edit a launch definition, complete the following steps:

1. In the Tivoli Enterprise Portal window, expand **Enterprise > Windows Systems > your\_server\_name > Windows OS**. Right-click **Disk** and select **Launch**. Disk is one of several nodes you can select. Nodes include Disk, Network, Enterprise Services, Memory, Printer, Process, Processor, and System.
2. The Create or Edit Launch Definitions window opens showing a list of launch definitions in the **Existing Launch Definitions** area.
3. Select the launch definition that you want to edit. The values are displayed.
4. Make the necessary changes in the text fields.
5. Click **Evaluate** to see how the arguments will resolve when the application starts. Correct any incorrect arguments and re-evaluate the command.
6. Click **Apply** to save the changes and keep the window open. Click **OK** to save the launch definition and close the window.

If you do not want to overwrite the existing launch definition, save the new launch definition with a unique name.

## Outbound launch and launch in context features

With the outbound launch and launch in context features, you can start the administrative applications for devices such as storage systems and switches from various points in the graphical user interface (GUI).

There are two options for starting an application from Tivoli Storage Productivity Center. The option that is available depends on the device that you want to start.

The launch feature starts an application at the starting point for that application.

The launch in context feature starts an application at a functionally related location in that application. Launch in context is available for the following applications:

- Tivoli Storage Productivity Center for Replication
- SAN Volume Controller 6.1 or later
- Storwize V3500
- Storwize V3700
- Storwize V7000
- Storwize V7000 Unified
- IBM SONAS

## Launch menu

When you right-click one of the following entities in Tivoli Storage Productivity Center GUI, you see a launch menu for that entity. The content of the launch menu varies as described in “Launch menu items” on page 67.

- Alert Log Viewer. Each row of the alert log is enabled for a launch in context menu. The context is determined by the type of the alert. Alert types include:
  - Replication
  - Storage Subsystem
  - Computer
  - Fabric
  - Switch
  - Port
  - Tape Library
- Disk Manager Storage Subsystems table
- Fabric Manager Fabrics table
- Tape Manager Tape Libraries table
- Element Manager page (of the Configuration Utility)
- Topology Viewer objects. To see the icons that are associated with each Topology Viewer object, refer to the following list.

## Topology Viewer objects

| Topology Object | Icon                                                                                |
|-----------------|-------------------------------------------------------------------------------------|
| Fabric          |  |

| Topology Object        | Icon                                                                               |
|------------------------|------------------------------------------------------------------------------------|
| Switch                 |   |
| Switch port            |   |
| Tape library           |   |
| Storage subsystem      |   |
| Storage subsystem port |   |
| File system volume     |   |
| Storage disk           |   |
| Storage pool           |  |

## Launch menu items

The following are the possible menu items that can be displayed in the launch menu:

### Launch in context defined application

This menu item is displayed for each application that is defined by a launch descriptor file. Tivoli Storage Productivity Center provides launch descriptor files for the following applications:

- DS8000 Storage Manager
- The management console for the storage systems that are listed under **Management GUI**.
- Tivoli Storage Productivity Center for Replication

If the corresponding launch descriptor files are found for the applications, the following menu items are displayed:

### DS8000 Storage Manager

Click this menu item to start DS8000 Storage Manager.

### Management GUI

Click this menu item to start the management console for the following storage systems:

- SAN Volume Controller 6.1 or later
- Storwize V3500
- Storwize V3700
- Storwize V7000

- Storwize V7000 Unified
- IBM SONAS

### Replication Storage Systems Overview

Click this menu item to start Tivoli Storage Productivity Center for Replication. The window that is opened in the Tivoli Storage Productivity Center for Replication GUI depends on the context for the entity that you selected. For example, if you right-click a storage device on the **Element Manager** tab of the Configuration Utility and click **Replication Storage Systems Overview**, the Tivoli Storage Productivity Center for Replication Storage Systems window opens.

If the launch descriptor file cannot be found, the **Launch file items error** menu item is displayed. Click this item to view a description of the problem. The **Launch file items error** menu item is also displayed in situations such as the IBM Tivoli Integrated Portal server is not installed or is not accessible, the Tivoli Storage Productivity Center Data server is not accessible, or another system error occurred.

### External Tools

This menu item shows any external tools that are defined in the Configuration Utility. Examples of external tools include web-based user interfaces and local executable files. For example, you might add the address of a website that you frequently access or an application that you often use such as a text editor or a spreadsheet.

### Element Manager

This menu item shows any element managers that were discovered for the device by a Storage Management Initiative Specification (SMI-S) query. To avoid menu item duplication, this item is not displayed when the associated element manager is defined by a launch descriptor file. In this situation, the element manager is displayed as a separate menu item.

### User Defined Tools

This menu item shows any user-defined element managers that are defined in the Configuration Utility. These element managers differ from the element managers in the **Element Manager** menu because they are user-defined and are not discovered by an SMI-S query.

## Example launch menu

The following figure shows an example launch menu for a storage system in the **L0:Storage** topology view. In this example, the menu items **Replication Storage Systems Overview**, **DS8000 Storage Manager**, and **External Tools** are displayed. The **Element Manager** menu item is not displayed because no element managers other than **DS8000 Storage Manager** were discovered. The **User Defined Tools** menu item is not displayed because there are no user-defined element managers that are defined in the Configuration Utility.

## Using the single sign-on feature with launch or launch in context

*Single sign-on* is an authentication process in which you can access more than one system or application by entering a single user ID and password. Single sign-on enables you to start applications from Tivoli Storage Productivity Center without providing logon credentials for the application. Single sign-on is available only for Tivoli Storage Productivity Center for Replication, DS8000, SAN Volume Controller 6.1 and later, and Storwize V7000.

For Tivoli Storage Productivity Center for Replication Storage Manager, single sign-on is enabled by default. For DS8000 Storage Manager, SAN Volume Controller, and Storwize V7000, single sign-on must be enabled.

To enable single sign-on, see the following topics in the Tivoli Storage Productivity Center information center:

- Configuring Tivoli Storage Productivity Center for DS8000 LDAP authentication
- Configuring Tivoli Storage Productivity Center for SAN Volume Controller and Storwize V7000 single sign-on

### Related concepts:

“Single sign-on” on page 55

*Single sign-on* is an authentication process that enables you to enter one user ID and password to access multiple applications. For example, you can access IBM Tivoli Integrated Portal and then access IBM Tivoli Storage Productivity Center and IBM Tivoli Storage Productivity Center for Replication from Tivoli Integrated Portal using a single user ID and password. Single sign-on integrates with the launch and launch-in-context features to enable you to move smoothly from one application to another application.

---

## External tools

External tools include Web-based user interfaces and local executable files, scripts, and batch files that you want to access from IBM Tivoli Storage Productivity Center. For example, you might define the address of a Web site that you frequently access or an application that you often use (a text editor, a spreadsheet application, and so on) as an external tool. External tools such as executable files, scripts, and batch files must exist on the same system as the Tivoli Storage Productivity Center graphical user interface (GUI).

Both element managers and external tools are configured on the **Element Manager** tab of the Configuration Utility (**IBM Tivoli Storage Productivity Center > Configuration**). The following tasks can be performed for external tools in the **External Tools** section of the **Element Manager** tab. The tasks that you can perform depend on your Tivoli Storage Productivity Center authorization

- Add external tools (Administrator)
- Start external tools (all authorization levels)
- View external tools (all authorization levels)
- Edit external tools (Administrator)
- Remove external tools (Administrator)

## Adding external tools

Use the Configuration Utility to add external tools to IBM Tivoli Storage Productivity Center.

Possibilities for external tools include:

- Executable files, shell scripts, or batch files. These files must exist on the same system as the Tivoli Storage Productivity Center graphical user interface (GUI).
- Uniform Resource Locators (URLs) for search engines or web encyclopedias

To add an external tool in Tivoli Storage Productivity Center, follow these steps:

1. Expand the **IBM Tivoli Storage Productivity Center** node in the navigation tree, click **Configuration Utility**, and open the **Element Manager** page.
2. In the **External Tools** section, select **Add Tool** from the **Select Action** list. The Add External Tool dialog box is displayed.
3. Define the information that is required to connect to the element manager in the following fields. Required fields are specified in bold in the dialog box. In the following field descriptions, required fields are marked by an asterisk.
4. The **Add External Tool** window opens. Enter definitions in the following fields:

#### **\*URL/Command**

Enter the URL or shell command representing the external tool. You can enter an IPv4 or IPv6 address depending on what is supported on the machine where the external tool is located:

- Enter an IPv4 address in the following format: ###.###.###.###. For example: 127.0.0.1
- Enter an IPv6 address. The preferred IPv6 address representation is written as eight groups of four hexadecimal digits: xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx, where each x is a hexadecimal digit representing 4 bits. For example: 2001:DB8:0000:1234:0000:0000:5678:ABCD. You can also specify IPv6 addresses using shortened formats that omit leading zeros (2001:DB8:0:1234:0:0:5678:ABCD) or use double colons (2001:DB8:0000:1234::5678:ABCD) in place of a series of zeros. You must include brackets [] around IPv6 addresses to separate those addresses from their port numbers. For example: [2001:DB8::1234:0000:0000:5678:ABCD]:9550.

**Note:** If the computer on which the element manager is located is IPv6-only, the Tivoli Storage Productivity Center servers must be installed on an IPv6-only or dual stack (IPv4 and IPv6 addresses are configured) computer.

**Label** Enter the name of the tool. The label name is shown in the **Name** field in the external tools table. If this field is blank, the **Name** field is blank.

**Description**

Enter a short description for the external tool.

**Save** Click this button to save the external tool. Information about the external tool is stored in the tools.xml file. This file is stored in the following locations:

- Windows: \Documents and Settings\Administrator\Application Data\IBM\TPC\config\
- UNIX and Linux: .TPC/config/

**Cancel**

Click this button to close the dialog box without saving the external tool.

## Modifying external tools

Use the Configuration Utility to modify information for external tools in IBM Tivoli Storage Productivity Center.

To modify an external tool in Tivoli Storage Productivity Center, follow these steps:

1. Expand the **IBM Tivoli Storage Productivity Center** node in the navigation tree, click **Configuration Utility**, and open the **Element Manager** tab.
2. In the **External Tools** section, select the tool that you want to modify from the external tools table.
3. Select **Modify Tool** from the **Select Action** list. The Modify External Tool dialog box is displayed.
4. Modify any of the following fields:

**URL/Command**

Enter the URL or shell command representing the external tool. You can enter an IPv4 or IPv6 address depending on what is supported on the machine where the external tool is located:

- Enter an IPv4 address in the following format: ###.###.###.###. For example: 127.0.0.1

- Enter an IPv6 address. The preferred IPv6 address representation is written as eight groups of four hexadecimal digits: `xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx`, where each x is a hexadecimal digit representing 4 bits. For example: `2001:DB8:0000:1234:0000:0000:5678:ABCD`. You can also specify IPv6 addresses using shortened formats that omit leading zeros (`2001:DB8:0:1234:0:0:5678:ABCD`) or use double colons (`2001:DB8:0000:1234::5678:ABCD`) in place of a series of zeros. You must include brackets `[]` around IPv6 addresses to separate those addresses from their port numbers. For example: `[2001:DB8::1234:0000:0000:5678:ABCD]:9550`.

**Note:** If the computer on which the element manager is located is IPv6-only, the Tivoli Storage Productivity Center servers must be installed on an IPv6-only or dual stack (IPv4 and IPv6 addresses are configured) computer.

**Label** Enter the name of the tool. The label name is shown in the **Name** field in the external tools table. If this field is blank, the **Name** field is blank.

**Description**

Enter a short description for the external tool.

**Save** Click this button to save the external tool.

**Cancel**

Click this button to close the dialog box without saving the external tool.

## Starting external tools

Use the Configuration Utility to start external tools from IBM Tivoli Storage Productivity Center.

To start an external tool from Tivoli Storage Productivity Center, follow these steps:

1. Expand the **IBM Tivoli Storage Productivity Center** node in the navigation tree, click **Configuration Utility**, and open the **Element Manager** tab.
2. In the **External Tools** section, select the tool that you want to start from the external tools table.
3. Select **Launch Tool** from the **Select Action** list. The URL or command defined for the tool is run immediately.

## Removing external tools

Use the Configuration Utility to remove external tools from IBM Tivoli Storage Productivity Center.

To remove an external tool from Tivoli Storage Productivity Center, follow these steps:

1. Expand the **IBM Tivoli Storage Productivity Center** node in the navigation tree, click **Configuration Utility**, and open the **Element Manager** tab.
2. In the **External Tools** section, select the tool that you want to remove from the external tools table.
3. Select **Remove Tool** from the **Select Action** list. The Remove External Tool dialog box is displayed.
4. Click **OK**. The element manager is deleted from the external tools table.

To exit the window without removing the external tool, click **Cancel**.

**Note:** If the computer on which the element manager is located is IPv6-only, the Tivoli Storage Productivity Center servers must be installed on an IPv6-only or dual stack (IPv4 and IPv6 addresses are configured) computer.

---

## Working with invoices

With IBM Tivoli Storage Productivity Center you can develop invoice definitions and create invoices associated with data or resource usage.

Using Tivoli Storage Productivity Center you can:

- Charge users for the amount of *storage they are consuming* across a network and within relational database management system (RDBS) instances
- Charge users for the amount of *space they own* within the database and tablespace of RDBMS instances.

With Tivoli Storage Productivity Center you can collect usage information on a departmental, group, or user level. You can allocate costs by storage usage by user, disk capacity by computer, tablespace, or file system or physical device. You can create cost centers by creating user, computer, or tablespace groups, allowing organizations to chargeback individuals or business units for their storage usage. By understanding the costs associated with existing and future storage usage, you can improve the use of that storage and reduce the costs associated with its maintenances and upgrades.

Tivoli Storage Productivity Center uses the storage usage information gathered by probes and scans to generate invoices that chargeback for storage usage. Chargeback is the process of breaking down costs associated with data or resource usage and then distributing those costs back to the organizational consumers.

To collect the information needed for chargeback, you need to run probes and scans:

### Probes

Define probes when you want to charge by Disk Capacity. Probes collect statistics on the storage assets in your enterprise, such as computers, disk controllers, hard disks, file systems, storage subsystems, instances, logs, RDBMS objects, and so on. The results of probes are stored in the database repository and are used to supply the data necessary for Tivoli Storage Productivity Center's reporting function.

**Scans** Define scans when you want to charge by OS User groups. Scans collect statistics on the usage and trending of your actual storage consumption. The results of scans are stored in the database repository and are used to supply the data necessary for Tivoli Storage Productivity Center's Capacity, Usage, Usage Violations, and Backup Reporting facilities.

In addition to providing basic storage usage invoicing, Tivoli Storage Productivity Center integrates with the chargeback systems already implemented in your environment. It provides you with a higher level, application-specific CIMS output format. CIMS is IBM Tivoli Usage and Accounting Manager (ITUAM) which provides IT financial knowledge by measuring, analyzing, reporting, and billing based on usage and costs of shared computing resources. With Tivoli Storage Productivity Center, you can export chargeback data directly into ITUAM, giving you the ability to integrate your storage usage data with other enterprise chargeback information and processes.

## Planning for chargeback

Before generating data that will be used for chargeback, it is a good idea to plan ahead and gather basic information about your system and organization.

### Understand your environment

Understanding the users, data, and resources within your organization will help you determine the most reasonable and enforceable chargeback policies. In the planning stages of developing a chargeback policy, it will help you to understand such things as:

- The types of data stored within your environment
- Patterns of data usage
- Different types of users and user groups
- The IT resources that exist within your organization

### Determine the chargeback policy you want to implement

It is important to learn and understand the advantages and disadvantages of the charge back policy you want to implement. For example, with IBM Tivoli Storage Productivity Center, you can:

- Divide the cost of storage usage by all users
- Divide the cost of storage usage by individual users or groups of users
- Charge by resource
- Charge by individual usage of resources

### Define monitoring groups

Organize the IT resources within your environment into functional groups. Defining groups enables you to classify your data and resources into billable entities, which in turn provides the information on who is using what storage. This enables you to bill specific groups according to their usage of storage space. See "Creating a group" on page 374.

#### Computer groups

Computer groups collect operating system and RDBMS storage statistics on computers that are related to each other or belong to a common group such as a department, a location, a territory, and so forth. Examples of computer groups are Sales, Accounting, Development, IT.

A computer can belong to one computer group only.

#### User groups

User groups are users that are related to each other or belong to a common group such as a department, a location, a territory, and so forth. Examples of user groups are Administrators, Developers, Marketing staff, HR staff.

A user can belong to one user group only.

#### OS User groups

OS user groups are users that are grouped together within the operating system.

#### Database-tablespace groups

Database-tablespace groups monitor entire databases or tablespaces across multiple instances or databases. Examples of tablespace groups are System Tablespaces, System Databases, databases-tablespaces related to a specific application or applications, and so forth.

A database-tablespace can belong to one database-tablespace group only.

### **Determine what information you want to gather**

Determining what information you want to gather about the storage resources within your enterprise is critical to helping you implement a chargeback strategy. Probes and scans are the monitoring jobs you can define to collect information about operating system and RDBMS storage resources. The information gathered by these jobs is reflected in the data included within a Tivoli Storage Productivity Center invoice.

As you become more familiar with how a specific charge back model works for your organization, you can continue to review and implement to more advanced charge back models.

## **Setting up invoices**

This topic takes you through the task of setting up an invoice.

To set up an invoice, complete the following steps:

1. In the Navigation Tree pane, expand **Data Manager for Chargeback > Parameter Definition**. Data Manager for Chargeback - Configuration window opens.
2. In the **Output Format** area, specify the format for the output. You can click either of the following options:

#### **Invoice**

Creates a formatted text file suitable for opening in or importing into word processing applications.

**CIMS** Creates a text file with comma-separated fields suitable for importing into a ITUAM application.

3. In the **Type of Charges** area, specify the information that you want the invoice to contain. You can select one or more of the following check boxes:

#### **OS Storage Usage By User**

The resulting invoice includes the following information:

- Total space consumed by user groups and the cost of that usage
- Total space consumed by each user in the environment and the cost charged to each user

#### **OS Disk Capacity By Computer**

The resulting invoice includes the following information:

- Total space consumed by computer groups and the cost of that usage
- Total space consumed on each computer in the environment and the cost of that usage

#### **Storage Usage By Database User**

The resulting invoice includes the following information:

- Total space consumed by DB user groups and the cost of that usage
- Total space consumed by each DB user in the environment and the cost charged to each user

#### **Total Size By Database-Tablespace**

The resulting invoice includes the following information:

- Total space consumed by database-tablespace groups and the cost of that usage

- Total space consumed on each database or tablespace in the environment and the cost of that usage
4. (Invoice output format only) For each type of charge that you selected in step 3 on page 617, select the unit of measurement (kilobyte, megabyte, or gigabyte) and type a numerical value. For example, if you want to charge \$1.25 per megabyte of storage usage, select **Megabyte** and type 1.25 in the **Cost per** field. (CIMS output format only) If you select CIMS as the output type, the **Cost Per** field will be deselected. This is because you will set the rates and costing within the ITUAM application.
  5. If you selected **OS Storage Usage by User** or **Storage Usage by Database User**, select the profile that is used in the scan job. By default, this is either TPCUser.Summary By Owner for **OS Storage by User** or TPCUser.Db User Space for **Storage Usage by Database User**.
  6. Click  to save the invoice definition.

Invoice definitions are not saved in actual files, but the last invoice definition saved is the one that will be used to create the invoice.

## Generating an invoice

Generate an invoice and save it as a file.

To generate an invoice, complete the following steps:

1. In the Navigation Tree pane, expand the **Data Manager for Chargeback** node.
2. Click **Online Execution**. The Online Execution page opens.
3. Click the **Browse** button. The Open window opens, listing previously generated invoice files in the default directory. The default directory, or the directory where you have chosen to save the invoice files, is not part of the IBM Tivoli Storage Productivity Center application but on the computer where Tivoli Storage Productivity Center is installed.
  - a. Click on an existing file or type a new file name, including extension, in the **File name** text field. A text file (.txt) is the default file type for both output types.
 

**Note:** Unless you save the invoice as a separate file name, the default file (StorageChargeback.txt) will be overwritten each time you run an invoice. It is recommended that you save your invoices as a separate file name each time you run them.
  - b. Click the **Open** button. You will be returned to the Online Execution page. Alternatively, in the Online Execution page, without clicking the **Browse** button, type the full path name of the invoice file to be generated in the **Output File** text field.
4. Click the **Generate Output File** button to generate the invoice.

The invoice is saved to the file name and path you specified.

## Viewing and printing invoices

This topic discusses viewing or printing a generated invoice in both Invoice and CIMS output formats.

If you have generated the invoice in the Invoice output format, you can view and print that invoice with any text editor or word processing program. If you chose CIMS as the output format, use your ITUAM application to work with the invoice data.

To view and print an invoice generated in the Invoice output format, complete the following steps:

1. Start the text editor or word processing program.
2. Follow the steps in the word processing program to open the invoice. Open the invoice from the location you specified in the **Output File** field in the Online Execution page.
3. View the file and make any changes. If you make any changes to the file, be sure and save it under a different name.
4. Print the file from the word processing program.

To view and print an invoice generated in the CIMS output format, integrate IBM Tivoli Storage Productivity Center accounting data into the Tivoli Usage and Accounting Manager, by following the instructions in the Tivoli Usage and Accounting Manager Information Center. Alternatively, you can view the original invoice data in a text editor or word processing program. Remember that the data will be in the form of comma-separated fields.

## Sample Invoices

This section gives examples of sample invoices.

## Chapter 6. Managing resources in the web-based GUI

You can use the web-based GUI to monitor the condition, capacity, and relationships of the monitored resources within your storage environment.

Tivoli Storage Productivity Center also provides a stand-alone GUI for managing the storage infrastructure in an enterprise environment. Each GUI provides different functions for working with monitored resources. To view a comparison of the functions that are available in each GUI, see “Available functions and report information in the interfaces” on page 21.

Use the web-based GUI to complete the following storage-management tasks:

- View and acknowledge the status of resources that are monitored by Tivoli Storage Productivity Center. Resources include storage systems, servers, hypervisors, fabrics, and switches. Use this information to quickly determine the state of your storage environment.
- View summary and detailed information about resources, including properties, storage usage, storage capacity, and several key performance metrics. Use this information to monitor the storage on your hardware. For example, when migrating large amounts of data, you can identify the target resources that have enough storage capacity to accommodate the data and require the least amount of reconfiguration.
- View the relationships and storage mapping among resources. For example, you can view the resources such as servers and hypervisors to which volumes from a storage system are assigned.
- View the connectivity between host connections, servers, hypervisors, virtual machines, storage systems, and the fabrics through which they share storage. You can use this view to monitor status and pinpoint problem areas in selected data paths. This view includes graphical and tabular representations of the top-level resources in a data path.
- Identify potential problems and troubleshoot existing problems in a storage environment. For example, you can locate the internal resources of a storage system that might be causing a bottleneck in storage utilization.
- In the reporting, web-based interface, use a drag-and-drop approach to design custom reports that contain detailed information about the properties and performance of monitored resources. All the performance metrics from the stand-alone GUI are available in the reporting interface. For example, you can drag key metrics into a report to create and generate a performance chart for a specific volume of a storage system. The reporting interface also includes a set of predefined reports that provides quick access to preformatted data about resources.

**Related concepts:**

“Starting Tivoli Storage Productivity Center” on page 177

IBM Tivoli Storage Productivity Center provides two graphical user interface (GUI) applications for managing and monitoring the resources in a storage environment: a stand-alone GUI and a web-based GUI. You can start these GUIs on the Tivoli Storage Productivity Center server or on a remote system.

**Related reference:**

Chapter 5, “Managing resources in the stand-alone GUI,” on page 309

You can use the stand-alone GUI to manage and monitor the resources and storage infrastructure in an enterprise environment. This interface provides all the tools to manage data, disk, fabric, tape, and replication.

“Available functions and report information in the interfaces” on page 21

IBM Tivoli Storage Productivity Center 5.1 provides two graphical user interfaces (GUI) for managing the resources in a storage environment: a stand-alone GUI and a web-based GUI. Each interface provides different functions for working with monitored resources.

---

## Configuring resources for monitoring

You can use the stand-alone GUI to configure the resources that you want to monitor in web-based GUI. You must configure before you can collect data, generate reports, and manage storage that is related to those resources.

The Configure Devices wizard in the stand-alone GUI guides you through the steps for adding resources as a data source, running a discovery, specifying alerts, and setting up data collection schedules. After data is collected, you can use the web-based GUI to monitor the following resources:

- Storage systems
- Servers
- Fabrics
- Switches
- Hypervisors

To configure storage resources for monitoring, complete the following steps:

1. Start the stand-alone GUI for Tivoli Storage Productivity Center.
2. Access the Configure Devices wizard. There are two methods for accessing the wizard:
  - To start the wizard and then select the type of resource that you want to configure, click the **Configure Devices** icon on the toolbar or select the **Configure Devices** node in the navigation tree.
  - To start the wizard for a specific type of resource that you want to configure, access the panel for that resource and click **Add *resource\_type***, where *resource\_type* represents the type of resource. For example, click the **Add Storage Subsystem** button on the **Disk Manager > Storage Subsystem** panel.
3. Follow the steps in the wizard to add storage resources, set up alerts, and define data collection schedules.
4. After data is collected, use the web-based GUI to quickly monitor, manage, and troubleshoot resources and generated alerts.

### Related concepts:

“Starting Tivoli Storage Productivity Center” on page 177

IBM Tivoli Storage Productivity Center provides two graphical user interface (GUI) applications for managing and monitoring the resources in a storage environment: a stand-alone GUI and a web-based GUI. You can start these GUIs on the Tivoli Storage Productivity Center server or on a remote system.

## Resources that you can monitor in the web-based GUI

You can use the web-based GUI to monitor storage systems, servers, hypervisors, fabrics, and switches. Information about these top-level resources includes information about their internal resources and related resources. Internal resources are components that exist in a top-level resource. Related resources are external to a top-level resource, but are related to it through assigned storage, a network connection, or virtual hosting.

### Fabrics

A *fabric* is a network of hubs, switches, adapter endpoints, and connecting cables that support a communication protocol between devices. The following table shows the internal resources and related resources that you can monitor for fabrics.

Table 45. Fabric resources that you can monitor in the web-based GUI

| Top-level resource icon                                                            | Internal resources                                                                                                                                                                                                                                                                                                                                                                                                                                    | Related resources                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Servers

A *server* is a computer or host that is connected to a network and provides an access point to that network. If a server is part of a cluster, information about that cluster is also available. The following table shows the internal resources and related resources that you can monitor for servers.

Table 47. Server resources that you can monitor in the web-based GUI

| Top-level resource icon                                                           | Internal resources                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Related resources                                                                                                                                                                                                                                                                                                                                                |

## Storage systems

A *storage system* is a device, such as a Redundant Array of Independent Disks (RAID) controller, that creates and manages other storage devices. A storage virtualizer is a storage system that virtualizes storage space from internal storage or from another storage system.

Storage systems can be configured for block storage, file storage, or a combination of block and file storage. The method that a storage system uses for managing data determines the internal resources that are monitored.

The following table shows the internal resources and related resources that you can monitor for storage systems.

Table 48. Storage system resources that you can monitor in the web-based GUI

| Top-level resource icon                                                           | Internal resources                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Related resources                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Switches

A *switch* is a network infrastructure component to which multiple nodes attach. In Tivoli Storage Productivity Center, you can monitor Fibre Channel (FC) switches. The following table shows the internal resources and related resources that you can monitor for switches.

Table 49. Switch resources that you can monitor in the web-based GUI

| Top-level resource icon                                                           | Internal resources                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Related resources                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Display differences in the interfaces

Tivoli Storage Productivity Center stores information about monitored resources in a database repository. You can view this information in the stand-alone GUI or in the web-based GUI. Depending on the interface that you use, there might be some differences in how the information is presented.

### The web-based GUI does not show a fabric for a physical, Cisco SAN

The stand-alone GUI shows a "fabric" for a physical, Cisco SAN, whereas the web-based GUI does not show a "fabric" for a physical, Cisco SAN.

- In the stand-alone GUI, Tivoli Storage Productivity Center automatically generates a worldwide name (WWN) to represent a physical, CISCO SAN as a fabric. This WWN typically starts with the numbers "3000". The WWN for the fabric is shown on the **Topology > Fabrics** panel and in reports for fabrics.
- In the web-based GUI, a fabric is not shown for physical, Cisco SANs on the Fabrics page. Only the virtual fabrics, physical switches, and logical switches for Cisco Fibre Channel switches are shown in the web-based GUI.

### The number of unidentified endpoints on fabrics is different from the stand-alone GUI

The web-based GUI and stand-alone GUI might display a different number of unidentified endpoints on a fabric:

- In the web-based GUI, unidentified endpoints are labeled as **Unknown Resources** and each endpoint *port* is considered one **Unknown Resource**.
- In the stand-alone GUI, unidentified endpoints are labeled as **Other** and each endpoint *node* is considered one **Other**.

For example, an endpoint with two ports is shown as one **Other** resource in the stand-alone GUI, but in the web-based GUI it is shown as two **Unknown Resources**.

### Pool space for NetApp filers

For NetApp filers that are configured with block data, the values for pool space that are shown in the web-based GUI are different from the values shown in a storage management tool for NetApp filers, such as FilerView. The values that are different include total pool capacity and available pool space.

This discrepancy occurs because the pool space information that is collected by SMI-S agents for Tivoli Storage Productivity Center includes Write Anywhere File Layout (WAFL) and Snapshot reserve space, whereas tools like FilerView do not include this additional space.

---

## Viewing information about resources

You can view detailed information about the resources that are monitored by Tivoli Storage Productivity Center. Resources include storage systems, volumes, pools, servers, hypervisors, fabrics, and switches. You can also view information about internal and related resources.

**Remember:** Data collection jobs retrieve information about monitored resources. To ensure that the latest information about resources is available in the web-based GUI, run data collection jobs regularly. To learn about how to collect data, see “Collecting data” on page 339.

## How information is organized

Information about monitored resources is organized into different pages in the web-based GUI. You can use these pages to view summary information about all resources, detailed information about top-level resources, and detailed information about internal and related resources.

### The dashboard

The dashboard is displayed when you start a new session of Tivoli Storage Productivity Center or when you click **Home > Dashboard** in the navigation pane. Use the dashboard to view the following summary information about a storage environment:

- A topology or resource diagram of the top-level resources that are monitored by Tivoli Storage Productivity Center. This diagram shows the number of top-level resources that are monitored and their overall status. You can also click the icons in the resource diagram to view more detailed information about a top-level resource on a resource list page.
- Capacity information that was aggregated for storage systems, servers, and hypervisors. Use this information to view the overall storage capacity for each type of resource. This information is presented as horizontal bar charts.
- The status of Tivoli Storage Productivity Center jobs that were run during a specific time. You can also click links to access a complete list of jobs.
- The number of unacknowledged alerts that were detected on resources during a specific time. You can also click a link to access a complete list of alerts that were detected on all monitored resources.

To learn about how to view summary information on the dashboard, see “Viewing summary information about all resources” on page 633.

### Jobs page

Use the Jobs page to view the following information about Tivoli Storage Productivity Center jobs:

- The overall status of all jobs. Use this information to identify the number of jobs that are encountering problems when running.
- Information about specific jobs, including status, related resource, type, and schedule.

- Information about performance monitors, including status, last successful collection attempt, start time, end time, and remaining duration.
- Information in the log files for jobs.

To access the Jobs page, click **Home** > **Jobs** in the navigation pane.

## Alerts page

Use the Alerts page to view and manage the alert conditions that were detected on monitored resources. You can complete the following tasks on this page:

- View the overall number of alerts that were detected on monitored resources. This information is presented in a bar chart for the following types of alerts:
  - Database
  - Fabric
  - Hypervisor
  - Other
  - Performance
  - Replication
  - Server
  - Storage system
  - Tape library
  - Tivoli Storage Productivity Center
- View information about specific alerts, including severity, last occurrence, and the resources where they were detected.
- Acknowledge alerts that were reviewed but are not yet resolved.
- Unacknowledge alerts.
- Remove alerts from the page.

To access the Alerts page, click **Home** > **Alerts** in the navigation pane.

## Resource list pages

Use a resource list page as central location for viewing information about the top-level resources of a specific type. For example, use the Storage Systems page to view a list of the storage systems that are monitored by Tivoli Storage Productivity Center. Each resource list page corresponds to a specific type of resource, which includes storage systems, volumes, pools, servers, hypervisors, switches, and fabrics. You can view the following information on resource list pages:

- The overall status of the resources
- Key information about the resources
- Alerts that were generated for the resources
- Jobs that were run for the resources

To learn about how to access the list pages for resources, see “Viewing information about top-level resources” on page 635.

**Note:** Volumes and pools are internal resources of storage systems, but have their own resource list pages so that you can view them all in a central location.

## Resource detail pages

Use resource details pages to view information about resources that are internal or related to a top-level resource. For example, use the Storage System details page to view detailed information about a specific storage system. You can view the following information on resource detail list pages:

- The overall capacity and storage usage for a resource
- Key information about a resource
- Alerts that were generated for a resource
- Jobs that were run for a resource
- Information about components that exist in top-level resources
- Information about the resources that are related to another resource

To learn about how to access detail pages for resources, see “Viewing information about internal and related resources” on page 636.

## Reporting

Use the IBM Tivoli Common Reporting tool in the web-based GUI to view detailed reports about resources. The following reports are available:

### Predefined reports

These reports are included with Tivoli Storage Productivity Center. The following types of predefined reports are available:

- Resources
- Performance
- Historical space
- Storage tiering

### Custom reports

Unlike predefined reports, you can select the information that you want to include in custom reports. Custom reports can contain detailed information about the relationships between monitored resources, the properties of monitored resources, and detailed information about the performance of monitored resources.

To learn about how to use the IBM Tivoli Common Reporting tool, see Chapter 9, “Reporting in the web-based GUI,” on page 1163.

## Viewing summary information about all resources

Use the dashboard to monitor the overall status of monitored resources and identify potential problem areas in a storage environment. You can learn about the status and capacity of top-level resources, the jobs that are running monitoring actions, and the unacknowledged alert conditions that were detected.

1. In the navigation pane, click **Home** > **Dashboard**. The information on the dashboard is organized into the following sections:
  - The resource diagram
  - Capacity
  - Recent Jobs
  - Unacknowledged Alerts
2. Use the following sections on the dashboard to monitor resources, jobs, and alerts:

## The resource diagram

You can use the resource diagram to complete the following tasks:

- View the number of resources that are monitored for a resource type. A number in parentheses is shown next to each resource icon. This number represents the number of resources for a type that is monitored. For example, if 20 storage systems are monitored, the value **Storage Systems (20)** is shown.
- View a list of the resources that are monitored for a resource type. Each type of resource in the diagram is represented by an icon. To learn more about the individual resources for a resource type, click the related icon in the diagram. For example, if you click the icon for storage systems, a resource list page shows the storage systems that are being monitored.
- View the overall status for each resource type. A status icon is shown with each resource icon. The status icon represents the most critical status that was detected on a top-level resource. For example, if Tivoli Storage Productivity Center monitors 20 storage systems, and an error condition was detected for one of those storage systems, an error status icon is shown with the storage systems icon in the diagram. If no errors, warnings, or unreachable statuses were detected for the monitored storage systems, then a normal status icon is shown. To learn more about the status of resources, see “Monitoring the status of resources” on page 637.
- View the number of statuses that were detected and acknowledged for each resource type. To view the total number of statuses for a type of resource, move the mouse pointer over the status icon for that resource type. Hover help shows the total number of occurrences for each status, and the number of statuses that were acknowledged by a Tivoli Storage Productivity Center user.

## Capacity

You can use the **Capacity** section of the dashboard to view horizontal bar charts that show aggregated storage information for each type of top-level resource. You can use these charts to quickly determine overall storage capacity and available space.

To cycle through the storage information for different types of resources, click the forward and backward arrows  . Hover the mouse pointer over areas in the charts that are not labeled for additional information.

## Recent Jobs

You can use the **Recent Jobs** section of the dashboard to view a status summary of the Tivoli Storage Productivity Center jobs that completed during the selected time. This summary includes the number of jobs that have the following statuses: Running, Error, Warning, and Normal. Use the following actions to manage the display of job statuses:

- To select the time period for showing job statuses, click the forward and backward arrows  . You can view the status of all jobs that were run in the last hour, last day, or last week.
- To view detailed information about all jobs, click **View all jobs** to access the Jobs page.
- To view detailed information about performance jobs only, click **View performance jobs** to access the **Performance Monitors** tab on the Jobs page.

## Unacknowledged Alerts

You can use the **Unacknowledged Alerts** section of the dashboard to view the status summary of alerts that were detected on monitored resources during a specified time period. Alerts are generated when Tivoli Storage Productivity Center detects certain conditions or events on monitored resources. An unacknowledged alert is an alert that was not reviewed or resolved by a Tivoli Storage Productivity Center user.

Use the following actions to manage the display of statuses for unacknowledged alerts:

- To select the time period in which you want to view alert statuses, click the forward and backward arrows   to cycle through the choices. You can view the status of all unacknowledged alerts that were detected in the last hour, last day, or last week.
  - To view detailed information about alerts, click **View all alerts** to access the Alerts home page.
3. Optional: To view descriptions of the information that is available on the dashboard, click the help icon  in the upper-right corner of the page.

## Viewing information about top-level resources

Use a resource list page as a central location for viewing information about all the monitored resources of a specific type. Resources that have a list page include storage systems, volumes, pools, servers, hypervisors, switches, and fabrics.

1. In the navigation pane, hover the mouse pointer over the resource icon for the type of resource that you want to view. You can use the icons to access the following types of resources:
  - **Storage Resources:** storage systems, volumes, pools
  - **Server Resources:** servers, hypervisors
  - **Network Resources:** switches, fabrics
2. Select the type of resource that you want to view. For example, if you want to view information about servers, select **Server Resources > Servers**. A list of monitored servers is displayed on Servers page.
3. Locate the resource that you want to view in the list. Each column in the list shows information about the resource.
4. Optional: To view key attributes of a specific top-level resource without leaving the page, right-click the resource and select **View Properties**. A properties notebook is displayed. Information in a properties notebook can include storage statistics, hardware attributes, volume assignments, disk assignment, and performance metrics.
5. Optional: To view more detailed information about a specific top-level resource, including its internal and related resources, right-click the resource and select **View Details**. A resource details page is displayed. This page includes information about storage statistics, alerts, jobs, internal resources, and related resources.

A resource list page shows information about the monitored resources for the selected type. You can view the following information on this page:

- The overall status of the resources for a specific type
- Key information about the resources
- Alerts that were generated for the resources
- Jobs that were run for the resources

**Tip:** To view descriptions of the information that is available on a resource list page, click the **Help** icon  in the upper-right corner of the page.

**Related reference:**

“Resources that you can monitor in the web-based GUI” on page 627

You can use the web-based GUI to monitor storage systems, servers, hypervisors, fabrics, and switches. Information about these top-level resources includes information about their internal resources and related resources. Internal resources are components that exist in a top-level resource. Related resources are external to a top-level resource, but are related to it through assigned storage, a network connection, or virtual hosting.

## Viewing information about internal and related resources

Use resource details pages to view information about a specific top-level resource and its internal and related resources.

1. In the navigation pane, hover the mouse pointer over the resource icon for the type of resource that you want to view. The icons provide access to the following types of resources:
  - **Storage Resources:** storage systems, volumes, pools
  - **Server Resources:** servers, hypervisors
  - **Network Resources:** switches, fabrics
2. Select the type of the resource that you want to view. A resource list page shows the monitored resources for the selected type. For example, if you want to view a storage system, select **Storage Resources > Storage Systems**. A list of monitored storage systems is displayed on the Storage Systems page.
3. In the list of resources, right-click the resource that you want to view and select **View Details**. A resource details page is displayed. This page includes information about storage statistics, alerts, jobs, internal resources, and related resources.
4. To view information about the internal resources of the top-level resource, click the name of the internal resource in the **Internal Resources** section. A list of the internal resources is displayed. Each column in the list shows information about the resources. For example, on the details page for a server, click **Controllers** to view a list of the controllers that are associated with the server.
5. Optional: To view key attributes of a specific internal resource without leaving the page, right-click the resource and select **View Properties**.
6. To view information about resources that are related to the top-level resource, click the name of the related resource in the **Related Resources** section. A list of the related resources is displayed. For example, on the server details page, click **Storage Systems** to view a list of the storage systems that have at least one disk (volume) assigned to the server.
7. Optional: To view key attributes of a specific related resource without leaving the page, right-click the resource and select **View Properties**.
8. Optional: To view the resource details page for a related resource, right-click the resource and select **View Details**.

A resource details page shows information about a top-level resource. The information is available in the following links and sections on the page:

- **Overview:** The overall capacity and storage usage for a resource.
- **Properties:** Key information about a resource.
- **Alerts:** Alerts that were generated for a resource.
- **Jobs:** Jobs that were run for a resource.

- **Internal Resources:** Information about the components that exist in a higher-level resource.
- **Related Resources:** Information about the resources that are related to another resource. A related resource is external to a higher-level resource, but is related to it through assigned storage, a network connection, or virtual hosting.

**Tip:** To view descriptions of the information that is available on a resource details page, click the **Help** icon  in the upper-right corner of the page.

“Resources that you can monitor in the web-based GUI” on page 627

You can use the web-based GUI to monitor storage systems, servers, hypervisors, fabrics, and switches. Information about these top-level resources includes information about their internal resources and related resources. Internal resources are components that exist in a top-level resource. Related resources are external to a top-level resource, but are related to it through assigned storage, a network connection, or virtual hosting.

---

## Monitoring the status of resources

You can use the web-based GUI to monitor the status of resources and identify potential problem areas in a storage environment. Monitored resources include top-level resources and their internal and related resources.

Use status information to quickly determine the condition of your storage and if any actions must be taken. Tivoli Storage Productivity Center provides a number of different statuses to help you determine the condition of resources. Each status is represented by an icon in the web-based GUI.

*Table 50. Possible statuses of monitored resources*

| Icon                                                                                | Status               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------------------------|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | Error                | A serious problem was detected on a resource or on its internal resources. Resolve these problems as soon as possible.                                                                                                                                                                                                                                                                                                                                                                                           |
|  | Error - Acknowledged | An Error status was detected and acknowledged. An Error - Acknowledged status indicates that a status was reviewed and is either resolved or can be ignored.<br><br>An acknowledged status is not used when determining the status of related, higher-level resources. For example, if the status of a volume is Error, the status of the related storage system is also Error. If the Error status of the volume is acknowledged, its status is not used to determine the overall status of the storage system. |
|  | Unreachable          | A resource is not responding to requests from the Tivoli Storage Productivity Center server. This status might be caused by a problem in the network or by a Storage Resource agent that is no longer running and did not communicate that it was shutting down.                                                                                                                                                                                                                                                 |

Table 50. Possible statuses of monitored resources (continued)

| Icon                                                                                | Status                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------------------------------------------------------|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|    | Unreachable - Acknowledged | An Unreachable status was detected and acknowledged. An Unreachable - Acknowledged status indicates that a status was reviewed and is either resolved or can be ignored.<br><br>An acknowledged status is not used when determining the status of related, higher-level resources. For example, if the status of a controller is Unreachable, the status of the related server is also unreachable. If the Unreachable status of the controller is acknowledged, its status is not used to determine the overall status of the server. |
|    | Warning                    | A Warning status represents potential problems on a resource or on its internal resources. This status is not critical.                                                                                                                                                                                                                                                                                                                                                                                                                |
|    | Warning - Acknowledged     | A Warning status was detected and acknowledged. A Warning - Acknowledged status indicates that a status was reviewed and is either resolved or can be ignored.<br><br>An Warning - Acknowledged status is not used when determining the status of related, higher-level resources. For example, if the status of a controller is Warning, the status of the related server is also Warning. If the Warning status of the controller is acknowledged, its status is not used to determine the overall status of the server.             |
|    | Normal                     | No warnings or errors were detected on a monitored resource.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|  | Unknown                    | A resource is known to Tivoli Storage Productivity Center but is not monitored. To change an Unknown status, use a data collection job to collect status information about the resource.                                                                                                                                                                                                                                                                                                                                               |

For top-level resources, use the resource details page to view the status of their internal resources.

## How status is determined

Top-level resources that are monitored in the web-based GUI include storage systems, servers, hypervisors, fabrics, and switches. The status of a top-level resource is determined by its consolidated status and the propagated status of its internal resources.

A consolidated status is the status that is reported by the top-level resource for its own hardware. For example, if the cooling fans in a storage system are stopped and the internal temperature is too high, that status is reported to Tivoli Storage Productivity Center.

A propagated status is the combined statuses of the monitored, internal resources for a top-level resource. For example, if a Warning status is detected on a volume in a storage system, that Warning status is used to determine the overall status of the storage system.

Tivoli Storage Productivity Center uses the values for consolidated status and propagated status to calculate the overall status of a top-level resource. The statuses of the following internal resources are used to calculate the status of top-level resources.

Table 51. Internal resources that are used to determine the status of top-level resources

| Top-level resource                                                                                        | Internal resources that are used to determine the status of a top-level resource                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Tivoli Storage Productivity Center uses the following statuses of internal resources to help calculate the status top-level resources:

- Unknown
- Normal
- Error
- Warning
- Unreachable

**Tip:** Statuses that are acknowledged are not used to calculate the overall status of a top-level resource.

Internal resources for a top-level resource might have different statuses. Tivoli Storage Productivity Center uses the most severe status of an internal resource when determining the overall status for a top-level resource. For example, in a storage system, a port might have an Error status, a pool might have a Warning status, and a number of controllers might have an Unknown status. In this case, the overall status for the storage system is Error because it is the most severe status that was detected on the internal resources.

Statuses for internal resources are propagated in the following way to determine the status of a top-level resource:

- If an internal resource has an Error status, then the related top-level resource has an Error status.
- If an internal resource has an Unreachable status, and no other internal resources have an Error status, the related top-level resource has an Unreachable status.
- If an internal resource has a Warning status, and no other internal resources have an Error or Unreachable status, the related top-level resource has a Warning status.
- If an internal resource has a Normal status, and no other internal resources have an Error, Unreachable, or Warning status, the related top-level resources has a Normal status.
- If an internal resource has an Unknown status, and no other internal resources have an Error, Unreachable, Warning, or Normal status, the related top-level resource has an Unknown status.

The following table shows some of the possible combinations of statuses and their resulting, propagated status.

*Table 52. Propagation of the statuses for internal resources in the web-based GUI*

| Error<br> | Unreachable<br> | Warning<br> | Normal<br> | Unknown<br> | Resulting status for top-level resource                                                       |

|                                                                                            | X                                                                                                | X                                                                                            | X                                                                                            | X                                                                                              |  Unreachable |
| X                                                                                          |                                                                                                  |                                                                                              |                                                                                              |                                                                                                |  Error       |
| X                                                                                          |                                                                                                  |                                                                                              |                                                                                              | X                                                                                              |  Error       |
| X                                                                                          |                                                                                                  |                                                                                              | X                                                                                            | X                                                                                              |  Error       |
| X                                                                                          |                                                                                                  | X                                                                                            | X                                                                                            | X                                                                                              |  Error       |
| X                                                                                          | X                                                                                                | X                                                                                            | X                                                                                            | X                                                                                              |  Error       |

## Viewing the overall status of resources

Use the dashboard to monitor the overall status of monitored resources and identify potential problem areas in a storage environment. The dashboard shows the overall status of storage systems, servers, hypervisors, fabrics, and switches, and the total number of different statuses that were detected on the individual resources for each type.

1. In the navigation pane, click **Home > Dashboard**. Information about the overall status of top-level resources is shown on the resource diagram.
2. View the status icon that is shown with each resource icon to determine the overall status of a resource type. The status icon represents the most critical status that was detected on the resources for a specific type.

For example, if Tivoli Storage Productivity Center monitors 20 storage systems, and an error condition was detected for one of those storage systems, the following status icon is shown with the storage systems icon:

 **Storage Systems (20)**

If no Error, Warning, or Unreachable statuses were detected on the monitored storage systems, the following status icon is shown with the storage systems icon:

 **Storage Systems (20)**

3. Move the mouse pointer over the status icon for a resource type to view the number of statuses that were detected and acknowledged for that resource type. Hover help shows the total number of occurrences for each status, and the number of statuses that were acknowledged by a Tivoli Storage Productivity Center user.

For example, move the mouse pointer over the status symbol for fabrics to view the number of monitored fabrics that have an Error, Unreachable, Warning, Normal, or Unknown status. If five fabrics have an Unreachable status, three fabrics have a Normal status, and no fabrics have an Error or Warning status, the following information is shown when you hover over the status icon for fabrics:

**Related reference:**

“How status is determined” on page 638

Top-level resources that are monitored in the web-based GUI include storage systems, servers, hypervisors, fabrics, and switches. The status of a top-level resource is determined by its consolidated status and the propagated status of its internal resources.

## Viewing the status of top-level resources

Use a resource list page as a central location for viewing the propagated statuses of top-level resources. Resources that have a list page with status information include storage systems, volumes, pools, servers, hypervisors, switches, and fabrics.

1. In the navigation pane, select the type of top-level resource that you want to view. For example, if you want to view the status of monitored switches, select **Network Resources > Switches**.
2. To view the total number of different statuses that were detected for the type of resource, check the status icons at the top of the resource list page. The number next to the icon represents how many of each status was detected.

For example, if 20 switches are monitored, and 10 have a Normal status while the other 10 have a Warning status, the following status information is displayed at the top of the page:

3. To view the status for specific resources, check the Status column in the list of resources. The value in the Status column represents the propagated status for a top-level resource.
4. Optional: Click the **Search** icon  to filter the list so that only resources with a specified status are shown. You can use filtering to identify the resources with the most serious Error conditions in your environment.
5. Optional: Select **Status**.
6. Optional: In the **Choose Value** list, select the status on which you want to filter. The list of resources is automatically refreshed and only resources with the filtered status are shown. For example, select **Warning**  to view only the resources on which a Warning status was detected.

## Viewing the status of internal resources

Use a resource details page to view the propagated status of a top-level resource and the status of its internal resources.

1. In the navigation pane, select a type of top-level resource. For example, if you want to view the status of monitored storage systems and their internal resources, select **Storage Resources > Storage Systems**.
2. Locate the resource in the list and check the Status column. The value in the Status column represents the propagated status for the top-level resource.
3. To view the status of internal resources, right-click the top-level resource and select **View Details**. A resource details page shows the internal resources for the selected resource.
4. Check for any status icons that are associated with an internal resource. If Tivoli Storage Productivity Center detects a status other than normal, an icon is displayed for the most critical status.

For example, if a server has three controllers with an Error status and two controllers with a Warning status, the Error status icon is shown for controllers in the **Internal Resources** section:

 **Controllers (5)** .

5. To view the status of specific internal resources, click the name of the internal resource in the **Internal Resources** section. A list of the monitored internal resources is displayed. For example, on the details page for a server, click **Controllers (5)** to view a list of the five controllers that are associated with the server.
6. Check the Status column to view the status for each internal resource.

**Tip:** When viewing information about some internal resources, the Status column might show values that are more specific than Error, Unreachable, Warning, Unreachable, Unknown, and Normal. Use this additional status to determine the cause of the problem for an internal resource.

For example, in the **Internal Resources** section on the details page for a storage system, an Error status is shown for managed disks:

 **Managed Disks (5)** .

This status means that one or more managed disks have an Error condition. When you view the list of managed disks, the Status column might show an Offline status for a specific managed disk. When an Offline status is detected, the web-based GUI shows it as an Error status on the details page for the storage system.

## Acknowledging the status of resources

The web-based GUI shows Error, Unreachable, and Warning statuses for top-level resources and internal resources. Sometimes these statuses might represent problems that commonly occur but can be ignored. In such cases, you can acknowledge the resources so that they are not used when propagating statuses for top-level resources or when calculating the total number of Error, Warning, and Unreachable conditions that were detected.

## Acknowledging the status of top-level resources

The web-based GUI shows a summary of the statuses for top-level resources on the dashboard and resource list pages. You can acknowledge the status of a top-level resource so that its status is not shown as Error, Unreachable, or Warning on those pages.

1. In the navigation pane, select the type of resource that has a status you want to acknowledge. For example, if you want to acknowledge the status of a switch, select **Network Resources > Switches**.
2. In the list of resources, locate the resource with the Error, Unreachable, or Warning status that you want to acknowledge.
3. Right-click the resource and select **Acknowledge status**. A window shows that the status for the specified resource was acknowledged.
4. Optional: To acknowledge multiple resources at the same time, press Ctrl and click each resource. To select a series of resources, select the first resource, and then press Shift and click the last resource. When the resources are selected, right-click a row in the list and select **Acknowledge status**.
5. Click **Close**.

When you acknowledge the status of a top-level resource, the following actions are taken on pages in the web-based GUI:

- The dashboard:
  - The status of the acknowledged resource is not used to determine the status icon that is displayed for that resource on the resource diagram. For example, if you acknowledge the Unreachable status for a switch, that Unreachable status is not used to determine the status icon that is displayed for the switch icon on the dashboard.
  - The acknowledged status is shown as **Acknowledged** when you point to the status icon for a resource. For example, if 10 switches have an Unreachable status and you acknowledge the status for one of them, the following information is shown when you hover the mouse over the switch icon:

 **9 Unreachable (1 Acknowledged)**

**Restriction:** The dashboard shows status icons and hover information for servers, hypervisors, switches, fabrics, and storage systems. The statuses of pools and volumes are used to calculate the status of these top-level resources, so their individual statuses are not shown on the dashboard.

- The resource details page:
  - The status icons at the top of the page are updated. For example, if 10 switches have an Unreachable status, and you acknowledge one of them, the total number Unreachable statuses decreases by one and the number of Unreachable - Acknowledged statuses increases by one. The following information is updated at the top of the Switches page:

 **9 Unreachable**  **1 Unreachable - Acknowledged**

- The value in the **Status** column for the resource is updated to show an acknowledged status. For example, if you acknowledge the Unreachable status for a switch, the following value is shown in the **Status** column:

 **Unreachable**

“Resources that you can monitor in the web-based GUI” on page 627

You can use the web-based GUI to monitor storage systems, servers, hypervisors, fabrics, and switches. Information about these top-level resources includes information about their internal resources and related resources. Internal resources are components that exist in a top-level resource. Related resources are external to a top-level resource, but are related to it through assigned storage, a network connection, or virtual hosting.

**Acknowledging the status of internal resources**

The web-based GUI uses the status of internal resources to determine the status of top-level resources. Sometimes these statuses might represent problems that commonly occur or are known, but can be ignored. In such cases, you can acknowledge the status of an internal resource so that it is not used when determining the status of a top-level resource.

For example, if the status of a volume is Error, the status of the related storage system is also Error. If the Error status of the volume is acknowledged, its status is not used to determine the overall status of the storage system. In this case, if the other internal resources of the storage system are Normal, then the status of the storage system is also Normal.

1. In the navigation pane, select the type of resource in which the internal resource is located. For example, if you want to acknowledge the status of internal resources for a switch, select **Network Resources > Switches**.
2. Right-click a resource and select **View Details**. For example, if you want to acknowledge the status of a port on a switch, right-click that switch and select **View Details**.
3. In the **Internal Resources** section of the resource details page, click the name of the internal resource. For example, if you want to acknowledge the status of a port on a switch, click **Ports**.
4. Right-click the resource and select **Acknowledge status**. A window shows that the status for the specified resource was acknowledged. For example, if you want to acknowledge the status of a port, right-click the port and select **Acknowledge status**.
5. Optional: To acknowledge multiple resources at the same time, press Ctrl and click each resource. To select a series of resources, select the first resource, and then press Shift and click the last resource. When the resources are selected, right-click a row in the list and select **Acknowledge status**.
6. Click **Close**. The status of the related, top-level resource might take several minutes to update.

When you acknowledge the status of an internal resource, the following actions occur:

- The status of the internal resource is no longer used to determine the status of the related, top-level resource.

For example, if you acknowledge the Error status for a controller on a server, the status of that controller is not used when determining the overall status of the server.

- The status icons at the top of the page for the internal resource are updated.

For example, if you acknowledge the Error status for a controller on a server, the total number of Error statuses decreases by one and the number of Error - Acknowledged statuses increases by one on the Controllers page. If originally

there were five controllers with Error statuses, the following updated status information is shown at the top of the page:

 4 Error  1 Error - Acknowledged

“Resources that you can monitor in the web-based GUI” on page 627

You can use the web-based GUI to monitor storage systems, servers, hypervisors, fabrics, and switches. Information about these top-level resources includes information about their internal resources and related resources. Internal resources are components that exist in a top-level resource. Related resources are external to a top-level resource, but are related to it through assigned storage, a network connection, or virtual hosting.

---

## Viewing data paths

A data path shows the connectivity between host connections, servers, hypervisors, virtual machines, storage systems, and the fabrics through which they share storage. You can use the data path view to monitor status and pinpoint problem areas in selected data paths. This view includes graphical and tabular representations of the top-level resources in a data path.

If a resource does not map storage to other resources, or the resource is not assigned storage from other resources, the data path view is not available.

To view the data path for a resource, complete these steps:

1. In the navigation pane, select the type of resource that you want to view. You can view the data path for servers, hypervisors, and storage systems. For example, if you want to view the data path for a server, select **Server Resources > Servers**.
2. Right-click the resource and select **View Data Path**.

Depending on how resources are configured, a data path can show between three to six types of top-level resources. For example, a data path with three types of top-level resources might show the following relationships:

server <> fabric <> storage system

A data path with six types of top-level resources might show the following relationships:

virtual machine <> hypervisor <> fabric <>  
storage virtualizer <> fabric <> storage system

Before you can view a data path, you must complete the following tasks:

- Add the resource that has the data path you want view. Learn more about how to add a resource for monitoring by Tivoli Storage Productivity Center. If you want to view detailed information about the resources that are part of the data path, you must also add them for monitoring.

**Tip:** Resources that are not monitored by Tivoli Storage Productivity Center are also shown in a data path view. However, detailed information about their status and internal resources is not available.

- Schedule a probe to collect data about your monitored resources to ensure that the most recent information is shown for a data path. You can define probes in the stand-alone GUI.

You can use the data path view to complete the following actions:

- View the path of data that is shared between resources. The data path view shows only the resources that have storage mapped between them. For example, if you view the data path for a storage system, only the host connections that are assigned volume space from that storage system are shown. Host connections that are connected to the storage system, but do not have storage assigned storage to them, are not shown.
- View the fabrics through which resources in a data path are communicating.
- View the propagated status of the top-level resources that are in a data path.
- View the status of the internal resources for top-level resources that are in a data path.
- Customize the appearance of the data path view to suit the needs of your environment.
- Export the data paths view as an image or CSV file.

Information about a data path is organized into two views: a graphical view and a table view. The graphical view shows icons for connected resources and uses lines to represent the path of data through them. The table view includes a row for each resource in a data path. The row is divided into columns that contain information about the resource.

## Resources that you can view in a data path

The **Topology View** tab in the data path view includes a visual representation of the data path for a top-level resource. In a data path, icons represent the connected resources and lines represent the path of data through them. For example, resources that are storage systems are shown with an icon that resembles a storage system.

The following table shows the icons for each type of resource that can be shown in a data path.

Table 53. Resource icons in a data path

| Resource        | Icon                                                                                |
|-----------------|-------------------------------------------------------------------------------------|
| Server          |  |
| Hypervisor      |  |
| Virtual machine |  |

Table 53. Resource icons in a data path (continued)

| Resource                    | Icon                                                                                |
|-----------------------------|-------------------------------------------------------------------------------------|
| Fabric                      |    |
| Virtual fabric              |    |
| DS8000                      |    |
| DS6000                      |    |
| SAN Volume Controller       |   |
| Storwize V7000 <sup>†</sup> |  |
| XIV system                  |  |
| ESS                         |  |

| Resource                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Icon                                                                               |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| Other storage systems                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |   |
| Host connections                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |  |
| <p><b>Note:</b></p> <ul style="list-style-type: none"> <li> <p><sup>†</sup> If a Storwize V7000 is not monitored by Tivoli Storage Productivity Center, but is connected to a monitored resource, it is shown in the data path with the icon for a SAN Volume Controller.</p> <p>For example, when a virtual machine is monitored, a probe collects information about its disks. If the disks are attached to a SAN-attached storage system that is not monitored, Tivoli Storage Productivity Center uses the probe information to determine the type of storage system. If the storage system is a Storwize V7000, the icon for SAN Volume Controller is shown instead of the icon for a Storwize V7000.</p> </li> <li> <p>Only the resources that are sharing storage in a data path are shown.</p> </li> <li> <p>Servers and hypervisors that are not monitored by Tivoli Storage Productivity Center, but are assigned storage from a monitored storage system, are shown as host connections. For example, if a storage system has a volume that is mapped to an unknown server, the server is represented by a host connection in the view.</p> </li> <li> <p>For storage systems with multiple host connections, the host connections are included in the same resource box if they communicate with the storage system through the same fabric. For example, if a storage system has volumes that are mapped to 20 host connections that use the same fabric, a single resource box represents the 20 host connections.</p> </li> <li> <p>Storage systems can have volumes that are provisioned to more than one server in a clustered environment. Because all the clustered servers can be part of the data path, each server is shown in the view.</p> </li> </ul> |                                                                                    |

## The status of resources

Each resource in a data path is represented by a resource box. A resource box contains an icon that represents the overall status of a resource. This status is determined by the propagated status of the internal resources for the resource. For example, in a storage system, a port might have an Error status and a pool might have a Warning status. In this case, the Error icon is shown on the resource box for the storage system because the Error condition is the most severe status that was detected on its internal resources.

Some resources in a data path might be shown with an unknown status. Resources can have an unknown status if they not monitored by Tivoli Storage Productivity Center, but are connected to other, monitored resources. Tivoli Storage Productivity Center uses the information that it collects about monitored resources to determine basic information about the connected resources that are not monitored.

For example, if a host connection is assigned volumes, but Tivoli Storage Productivity Center is not monitoring the fabric through with the host connection communicates with the storage system, the fabric is shown with an unknown status.

## Navigating in a data path

A data path might contain more resources that can be fit in the view at the same time. In these cases, you can scroll the view to show different parts of a data path.

1. In the **Topology View** tab, click the **Pointer** button .
2. Click an empty area in the view and drag the mouse pointer to scroll to different areas of a data path.

## Viewing information about top-level resources

You can view detailed information about the top-level resources in a data path. Top-level resources that can be shown in a data path include storage systems, servers, hypervisors, and fabrics.

1. To view key attributes of a specific top-level resource without leaving the **Topology View** tab, right-click the resource and select **View Properties**. A properties notebook is displayed. Information in a properties notebook can include storage statistics, hardware attributes, volume assignments, disk assignment, and performance metrics.
2. To view more detailed information about a specific top-level resource, including its internal and related resources, right-click the resource and select **View Details**. A resource details page is displayed and includes information about storage statistics, alerts, jobs, internal resources, and related resources.

## Viewing information about internal resources

You can view information about the internal resources that are associated with the top-level resources in a data path. Internal resources are components that exist in a top-level resource.

1. In the **Topology View** tab, hover the mouse pointer over a top-level resource in the data path.
2. View the following information about internal resources:
  - The number of internal resources that are associated with a top-level resource. For example, if a server has 20 disks, the value **Disks (20)** is shown.
  - The overall status of the internal resources. For information about how the overall status of internal resources is determined, see “How status is determined” on page 638.

## Zooming in

You can use the zoom buttons in the toolbar or the mouse to magnify areas in a data path.

1. To zoom in on a specific area in a data path, click the **Zoom to selected** button  and click and drag the mouse pointer over the area.
2. Optional: To use the mouse to zoom in on a specific area in a data path, move the mouse pointer over the area where you want to zoom in and scroll the middle mouse button forward.
3. Optional: To zoom in on the area that is in the center of the view, click the **Zoom in** button .
4. Optional: To adjust the zoom level of the view so that all the resources in a data path are shown at the same time, click the **Fit to view** button .

## Zooming out

You can use the zoom out button in the toolbar or the mouse to zoom out in the view.

1. To zoom out from the area that is in the center of the view, click the zoom out button .
2. Optional: To use the mouse to zoom out from a specific area in a data path, move the mouse pointer over the area where you want to zoom out and scroll the middle mouse button backward.
3. Optional: To adjust the zoom level of the view so that all the resources in a data path are shown at the same time, click the **Fit to view** button .

## Changing the layout

You can change the layout of the resources in a data path. The layout determines how resources are arranged in the view.

1. Click the **Layout** button in the toolbar. The icon that is displayed for the **Layout** button represents the current layout of the data path.
2. Select one of the following layouts:

### Hierarchical

Organize resources in a vertical format. Resources that use storage are shown at the top of the view. Resources that provide storage are shown at the bottom of the view.

### Tree

Organize resources in a vertical and horizontal layout.

### Customize

Customize the layout of a data path. When you customize a layout, use the hierarchical or tree layouts as the base and specify values for the associated options.

3. Optional: If you selected **Customize**, click **OK** to apply your settings.

## Saving the display settings

You can save the display settings that are defined for a data path view. The next time that you view the data path for the resource, the same display settings are applied.

1. In the **Topology View** tab, click the **Save** button .
2. Optional: To use the keyboard to save the display settings, press Ctrl+S.

3. Click **Save Customizations**.

## Printing a view

You can print the current view of a data path in the **Topology View** tab. The printing capability is not available in the **Table View** tab.

1. Click the **Print** button .
2. Specify the following options when printing:
  - In the **Page margin** field, enter the amount of space between the edges of the page and the view. The default setting is 1 inch.
  - In the **Maximum pages in width or height** field, specify the number of pages across which the content of a view is printed. This number determines the maximum number of pages that are printed. For example, if you enter **1**, the content of a view is printed on one page. If you enter **2**, the view is printed across four pages: two pages horizontally and two pages vertically.
3. Click **OK**.
4. Select the printer settings and click **OK** to print the view.

## Exporting a data path to a file

You can save the contents of a data path to an image file or CSV file for offline viewing.

1. In the **Topology View** tab, right-click on an empty area in the data path.
2. Complete one of the following actions to select an output format for the file:
  - Select **Export as Image** to save the data path as a JPEG or PNG file.
  - Select **Export** to save the data path to a CSV file. A CSV file is a file that contains comma-delimited values and can be viewed with a text editor or imported into a spreadsheet application. The information for a data path is organized into the following column in the CSV files: Name, Type, From, RelType, To.
3. Specify the location and name of the file.
4. Save the file.

---

## Viewing jobs

Jobs are used to collect data about storage resources and complete other tasks that are related to monitoring a storage environment. Use the Jobs page in the web-based GUI to view all the jobs that are used by Tivoli Storage Productivity Center to monitor resources. Use resource list and resource details pages to view the jobs for specific resources and types.

Specifically, you can use the web-based GUI to complete the following tasks:

- View the status of all jobs in a central location
- View the status of performance monitor jobs on a dedicated tab
- Identify all the jobs that are related a specific type of resource
- Identify all the jobs that are related a specific resource
- Identify all the jobs that are encountering problems when running

The following terms are used in the web-based GUI:

- **Job:** A unit of work that monitors, manages, or collects data about a storage resource. In the stand-alone GUI, the term *schedule* is also used. These monitoring tasks include the following job actions:

- Collecting data about resources with scans, probes, quotas, discovery, or performance monitors. For example, define a probe job to collect asset and status data about storage systems; define a scan job to collect file-level information about servers.
- Running scripts.
- Checking for quota violations.
- Backing up and archiving files.
- Analyzing storage configurations to determine whether existing SAN configurations violate defined best practices or policies.
- Creating and implementing end-to-end storage plans.
- Creating volumes.
- Upgrading or deploying agents.
- **Run:** A run is a single invocation of a job.

**Tip:** If multiple resources are included in the same data collection job, a separate row for each resource is shown in the list of jobs. For example, if five storage systems are monitored by the same probe, a row for each storage system is shown in the list.

There is an exception for fabric jobs. Probes that collect data about multiple fabrics are not shown in the list. Only probes that collect data about one fabric are shown. For example, if five fabrics are monitored by the same probe, there is no entry for the probe or fabrics in the list. If one fabric is monitored by a probe, a row for the fabric is shown.

## Configuring the display of jobs

You can use the stand-alone GUI to configure how jobs are displayed in the web-based GUI.

### Setting the retention of jobs and logs

The jobs and logs that are shown in the web-based GUI are determined by configuration settings in the stand-alone GUI. The default setting is to show the last five runs of a job. Use the stand-alone GUI to change how many runs of a job are displayed in the web-based GUI.

1. Start the stand-alone GUI.
2. In the navigation pane, go to **Administrative Services > Configuration**.
3. Click **Log File and Cached Batch Report Retention**.
4. In the **Maximum number of runs to keep of each schedule** field, enter the maximum number of runs for a job (schedule) that you want to display in the web-based GUI.
5. Save the changes.

After you update the value for **Maximum number of runs to keep of each schedule** in the stand-alone GUI, the list of jobs on the Jobs page in the web-based GUI is automatically updated within a few minutes.

### Setting the retention of removed resources

Removed resources are resources that are no longer monitored by Tivoli Storage Productivity Center. When a resource is no longer monitored, use the stand-alone GUI to determine how long its related jobs are show in the web-based GUI.

For example, if a storage system is removed from Tivoli Storage Productivity Center, and the retention setting is set to two weeks, the jobs for that storage system are shown for an additional two weeks before they are removed from the Jobs page. The default setting for retaining job information about removed storage systems is two weeks.

1. Start the stand-alone GUI.
2. In the navigation pane, go to **Administrative Services > Configuration**.
3. Click **Removed Resource Retention**.
4. Select a resource and enter the number of days to retain information after it is no longer monitored by Tivoli Storage Productivity Center.
5. Save the changes.

After you change the retention settings in the stand-alone GUI, the list of jobs on the Jobs page in the web-based GUI is automatically updated within a few minutes.

## Viewing all jobs

Use the Jobs page as a central location to view and manage all the jobs that Tivoli Storage Productivity Center is using to monitor resources. You can view all data collection jobs for resources, including performance monitors.

1. In the navigation pane, go to **Home > Jobs**.
2. Use the **Jobs** tab to view a list of all Tivoli Storage Productivity Center jobs. The information about jobs is organized into columns. These columns include information about the status of jobs, the names of resources that are associated with jobs, the schedule for jobs, and links to job logs.
3. Optional: Click the **Performance Monitors** tab to only view information about performance monitor jobs. Performance monitor jobs collect performance statistics about storage systems and switches.

The information about performance monitors is organized into columns. These columns include information about the status of jobs, the name of the storage systems or switches that are monitored, the most recent success percentage and collection attempt, the number of failed collections, and links to job logs.

4. Optional: View the icons at the top of the page to view a summary of the statuses for jobs. This summary includes the number of jobs that have a Failed, Warning, Successful, or Running status.

**Tip:** To view descriptions of the icons and columns on the Jobs page, click the **Help** icon  in the upper-right corner of the page.

## Viewing jobs for a type of resource

Use resource list pages to view only the jobs for a specific type of top-level resource. Each resource list page has a **Jobs** tab that lists only the jobs for monitored storage systems, servers, hypervisors, switches, or fabrics. For example, you can use the list page for storage systems to view only the jobs that are associated with storage systems.

1. In the navigation pane, select a type of top-level resource. For example, if you want to view the jobs that are related to storage systems, select **Storage Resources > Storage Systems**.
2. Click the **Jobs** tab to view a list of all the jobs for the monitored resources of that type. For storage systems and switches, performance jobs are also listed in the **Jobs** tab.

The information about jobs is organized into columns. These columns include information about the status of jobs, the names of resources that are associated with jobs, the schedule for jobs, and links to job logs.

**Tip:** The icon on the **Jobs** tab represents the most critical status of the jobs that are associated with monitored resources. For example, if one of the jobs for storage systems failed, the following icon is shown on the tab:

3. Optional: View the icons at the top of the **Jobs** tab for a summary of job statuses. This summary includes the number of jobs that have a Failed, Warning, Successful, or Running status.

**Tip:** To view descriptions of the icons and columns on the **Jobs** tab, click the **Help** icon  in the upper-right corner of the page.

## Viewing jobs for a specific resource

Use resource detail pages to view only the jobs for a specific resource. Each resource details page has a **Jobs** link that lists only the jobs for a monitored storage system, server, hypervisor, switch, or fabric.

1. In the navigation pane, select a type of top-level resource. For example, if you want to view the jobs that are related to storage systems, select **Storage Resources > Storage Systems**.
2. Right-click a resource in the list and select **View Details**. In the **General** section, the number next to **Jobs** represents the number of jobs that are associated with the resource. For example, **Jobs (3)** indicates that there are three jobs that you can view.

The icon next to the **Jobs** link represents the most critical status of the jobs that are associated with the resource. For example, if a job failed, the following icon is shown:

3. Click the **Jobs** link in the **General** section to view the jobs for the resource. The information about jobs is organized into columns. These columns include information about the status of jobs, the names of resources that are associated with jobs, the schedule for jobs, and links to job logs.
4. Optional: View the icons at the top of the page to view a summary of the statuses for jobs. This summary includes the number of jobs that have a Failed, Warning, Successful, or Running status.

**Tip:** To view descriptions of the icons and columns that are shown for jobs, click the **Help** icon  in the upper-right corner of the page.

## Viewing job logs

Job logs include detailed information about the status, actions, and progress of a job. Status information includes informational, warning, and error messages that are related to each action in a job that is taken during processing. You can use this information to troubleshoot any errors that might occur when a job is run.

1. In the navigation pane, go to the **Jobs** page, a list of jobs for a specific type of resource, or a list of jobs for a specific resource. For example, to view a list of jobs for storage systems, go to **Storage Resources > Storage Systems** and click the **Jobs** tab.

2. Locate the job that has a log file you want to view.
3. In the **Logs** column, click **View Logs**. A separate window opens to show information about the most recent run of the job.
4. Optional: In the Logs window, to view the log for previous runs of a job, select a run from the **Select a log** list.
5. Optional: To view only the actions in a job run that have a Warning or Error status, select an option from the **Show all** list. You can choose to view only actions that have the following statuses:
  -  Only error entries
  -  Only warning entries
  -  Error and warning entries
6. Optional: To view an explanation of the message that is associated with an action, click the link in the **ID** column.

The information on the Logs page is automatically updated every 30 seconds. New entries are added to end of the log. You can view the following information on a Logs page:

- The overall status of a job. The icon that is shown in the **Select a log** list represents the most critical status that was generated by an action in the job.
- The status for each action in a job. An icon and type of status is shown in the **Status** column for each action.
- The date and time when an action was completed. The date, time, and time zone when the action was taken is shown in the **Date and Time** column.
- The ID of the message that is associated with an action. You can click the value in **ID** column to view more information about a message.
- A description of an action. This value is shown in the **Description** column.

**Tip:** You can use the navigation and search functions of the web browser to locate information on the page.

---

## Managing alerts

Alerts are generated when Tivoli Storage Productivity Center detects certain conditions or events on monitored resources. Many conditions can trigger alerts. You can set up Tivoli Storage Productivity Center so that it generates alert notifications for conditions that you specify.

Before you use the web-based GUI to view and manage alerts, you must complete these tasks:

- Add resources for monitoring by Tivoli Storage Productivity Center. Use the **Configure Devices** wizard in the stand-alone GUI to add resources for monitoring.
- Specify the conditions on resources that trigger alert notifications. Use the stand-alone GUI to create alerts.
- Collect data about storage resources. Alerts are triggered by conditions that are detected during data collection. Use the stand-alone GUI to create data collection schedules.

The conditions that trigger alert notifications depend on the type of resource that you are monitoring. Some triggering conditions, like thresholds, require you to enter values for triggering alerts. In general, the following types of conditions can trigger alerts:

- A data collection schedule did not complete
- A change occurred in the storage infrastructure
- A performance threshold was violated

**Tip:** Tivoli Storage Productivity Center does not use the alert conditions that are detected on a resource to determine the overall status of the resource.

**Related concepts:**

“Monitoring the status of resources” on page 637

You can use the web-based GUI to monitor the status of resources and identify potential problem areas in a storage environment. Monitored resources include top-level resources and their internal and related resources.

**Related tasks:**

“Configuring resources for monitoring” on page 626

You can use the stand-alone GUI to configure the resources that you want to monitor in web-based GUI. You must configure before you can collect data, generate reports, and manage storage that is related to those resources.

“Working with alerts” on page 386

Create an alert, configure how the alert is publicized, or edit, delete, disable, rename, or view an alert.

“Collecting data” on page 339

Create data collection jobs to gather information about the storage resources in your environment. There are different data collection jobs within IBM Tivoli Storage Productivity Center depending on the type of information is collected and from which types of resources the information is retrieved: discovery, probes, Tivoli Storage Productivity Center Server probes, scans, and pings.

## Alert severities

Tivoli Storage Productivity Center determines the severity of alert conditions that it detects on monitored resources. Use the severity level to help determine the priority in which you resolve alerts.

Each severity is represented by an icon in the web-based GUI.

*Table 54. Possible severities of alerts*

| Icon                                                                                | Status                  | Description                                                                                                                                                           |
|-------------------------------------------------------------------------------------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | Critical                | An alert with a Critical severity represents a serious problem on a resource or on its internal resources. Resolve these problems as soon as possible.                |
|  | Critical - Acknowledged | An alert with a Critical severity was acknowledged. A Critical - Acknowledged severity indicates that an alert was reviewed and is either resolved or can be ignored. |
|  | Warning                 | An alert with a Warning severity represents potential problems on a resource or on its internal resources. The condition that generated the alert is not critical.    |
|  | Warning - Acknowledged  | An alert with a Warning severity was acknowledged. A Warning - Acknowledged severity indicates that an alert was reviewed and is either resolved or can be ignored.   |

Table 54. Possible severities of alerts (continued)

| Icon                                                                              | Status                       | Description                                                                                                                                                 |
|-----------------------------------------------------------------------------------|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | Informational                | An alert with an Informational severity does not represent a problem, but is intended to provide information about actions related to a resource.           |
|  | Informational - Acknowledged | An alert with an Informational severity was acknowledged. An Informational - Acknowledged severity indicates that an alert was reviewed and can be ignored. |

**Related reference:**

“Triggering conditions for alerts” on page 1489

You can define alerts so that IBM Tivoli Storage Productivity Center notifies you when a specified event occurs. Such events are the *triggering conditions* for the alert. The specific triggering conditions that you can use to define an alert depend on the sort of storage resource that you are monitoring.

## Viewing all alerts

Use the Alerts page as a central location to view and manage all the alerts that were detected by Tivoli Storage Productivity Center.

The Alerts page is organized into two sections:

**Alerts summary chart**

The summary chart at the top of the page is a visual representation of the alerts that were detected on monitored resources. The chart consists of stacked bars with the number and severity of current alerts on the y-axis and the resource type on the x-axis. The y-axis labeling scales dynamically according to the highest number of alerts in any of the categories.

**Alerts list**

The alerts list shows information about all the alerts that were detected on monitored resources. Information in the list is organized into columns. These columns include information about the condition that was detected, the severity of the alert, when the alert was detected, and the names of the resources where the alert condition was detected.

The version of Tivoli Storage Productivity Center that detected an alert determines where information about the alert is displayed. Alerts that were generated in version 5.1 or later are displayed on the Alerts page and in the **Alerts** tab on the pages for the related resources. Alerts that were generated in versions of the product before 5.1, also called migrated alerts, are only displayed on the Alerts page.

**Tip:** Depending on how data is configured for a NetApp filer, alerts are shown on different pages in the interface:

- Alerts for the block data in a NetApp filer are shown in the **Alerts** tab on the Storage Systems page and in the list of alerts on the Alerts page.
  - Alerts for the file data in a NetApp filer are only shown in the list of alerts on the Alerts page.
1. In the navigation pane, go to **Home > Alerts**. Information about alerts is shown in the list of alerts.
  2. Optional: To view the number of alerts for a specific type of resource, hover the mouse pointer over the related icon in the summary chart. For example, if you

want to view the number of Critical, Warning, and Informational alerts that were triggered by hypervisors, hover the mouse pointer over the **Hypervisors** icon .

3. Optional: To filter the list of alerts for a specific type of resource, click the icon for that resource in the summary chart. For example, if you only want to view a list of alerts for hypervisors, click the **Hypervisors** icon .

**Tip:** To view descriptions of the icons and columns on the Jobs page, click the **Help** icon  in the upper-right corner of the page.

## Viewing alerts for a type of resource

Use resource list pages to view only the alerts for a specific type of top-level resource. Each resource list page has an **Alerts** tab that lists only the alerts for monitored storage systems, servers, hypervisors, switches, or fabrics. For example, you can use the list page for storage systems to view only the alerts that were detected on monitored storage systems.

1. In the navigation pane, select a type of top-level resource. For example, if you want to view the alerts that are related to storage systems, select **Storage Resources > Storage Systems**.
2. Click the **Alerts** tab to view a list of all the alerts for the monitored resources of that type. The information about alerts is organized into columns. These columns include information about the condition that was detected, the severity of the alert, when the alert was detected, and the names of the resources where the alert condition was detected.

**Tip:** The icon on the **Alerts** tab represents the most severe alert condition that was detected on the monitored resources. For example, if one of the jobs for storage systems failed, the following icon is shown on the tab:

**Alerts.**

3. Optional: View the icons at the top of the **Alerts** tab for a summary of alert severities. This summary includes the number of alerts that have a Critical, Warning, Informational, or Acknowledged status.

**Tip:** To view descriptions of the icons and columns on the **Alerts** tab, click the **Help** icon  in the upper-right corner of the page.

## Viewing alerts for a specific resource

Use resource detail pages to view only the alerts for a specific top-level resource. Each resource details page has an **Alerts** link that lists only the alerts for a monitored storage system, server, hypervisor, switch, or fabric. For example, you can use the details page for a storage system to view only the alerts that were detected for that storage system.

1. In the navigation pane, select a type of top-level resource. For example, if you want to view the alerts that are related to storage systems, select **Storage Resources > Storage Systems**.
2. Right-click a resource in the list and select **View Details**. In the **General** section, the number next to **Alerts** represents the number of alert conditions that were detected on the resource. For example, **Alerts (25)** indicates that 25 alerts were detected on the resource.

The icon next to the Alerts link represents the most severe alert condition that was detected on the resource. For example, if alerts with an Error severity were detected the following icon is shown:

**Alerts (25)** 

3. Click the **Alerts** link in the **General** section to view the alerts that were detected on the resource. The information about alerts is organized into columns. These columns include information about the condition that was detected, the severity of the alert, when the alert was detected, and the names of the resources where the alert condition was detected.
4. Optional: View the icons at the top of the page for a summary of alert severities that were detected. This summary includes the number of alerts that have a Critical, Warning, Informational, or Acknowledged status.

**Tip:** To view descriptions of the icons and columns that are shown for alerts, click the **Help** icon  in the upper-right corner of the page.

## Removing alerts

Remove alerts when you no longer require to view them in the web-based GUI. By default, alerts are automatically removed based on retention settings that are defined in the stand-alone GUI. However, you can use the remove actions to manually remove alerts from the web-based GUI.

1. Go to a list of alerts that includes the alerts that you want to remove. For example, if you want to remove alerts for different types of top-level resources, go to **Home > Alerts**.
2. Right-click the alert that you want to remove and select **Remove alerts**.
3. Click **Remove** to remove the alert. When you remove an alert, it is no longer shown on the Alerts page or in the **Alerts** tabs on the related resource list and resource detail pages.  
For example, if you remove an alert for a fabric, that alert is removed from the Alerts page, Fabrics page, and Fabric details page.
4. Optional: To remove all the alerts that are shown in a list, select **Remove all alerts** from the **Actions** menu.
5. Optional: To remove all the acknowledged alerts that are shown in a list, select **Remove acknowledged alerts** from the **Actions** menu.

## Acknowledging alerts

Some alerts in Tivoli Storage Productivity Center are triggered by conditions that commonly occur and can be ignored. In such cases, you acknowledge these alerts to indicate that they were reviewed and do not require immediate resolution. By acknowledging alerts, you can more quickly identify the other alerts in lists that must still be reviewed and resolved.

1. Go to a list of alerts that includes the alerts that you want to acknowledge. For example, if you want to acknowledge the alerts for a specific server, complete the following steps.
  - a. In the navigation pane, go to **Server Resources > Servers**.
  - b. Right-click the server that has alerts you want to acknowledge and select **View Details**.
  - c. Click the **Alerts** link.
2. Right-click the alert that you want to acknowledge and select **Acknowledge alerts**. The severity of the alert is changed to Acknowledged on the Alerts page, resource list page, and resource details page.

For example, if you acknowledge a server alert that has a Warning severity, it is shown on the Alerts page, Servers page, and Server details page with the following severity:

#### **Warning - Acknowledged**

3. Optional: To acknowledge multiple alerts at the same time, press Ctrl and click each alert. To select a series of alerts, select the first alert, and then press Shift and click the last alert. When the alerts are selected, right-click a row in the list and select **Acknowledge alerts**.
4. Optional: To acknowledge all the alerts that are shown in a list, select **Acknowledge all alerts** from the **Actions** menu.
5. Optional: To acknowledge all the alerts with an Informational severity in a list, select **Acknowledged informational alerts** from the **Actions** menu. You might want to acknowledge all Informational alerts when you want to view only alerts that represent potential or serious problems that require action to resolve.

---

## **Opening the management GUI for a resource**

Resources such as storage systems and switches can have their own management GUIs or element managers. In Tivoli Storage Productivity Center, you can open the start page in these GUIs from resource list pages, such as the Storage Systems page and Switches page.

The action for opening a management GUI is available for storage systems and switches under the following conditions:

- The resource is monitored by Tivoli Storage Productivity Center.
  - The resource has a management GUI that is web-based or can be accessed with Java Web Start.
1. In the navigation pane of Tivoli Storage Productivity Center, select a type of top-level resource. For example, if you want open the GUI for a storage system, select **Storage Resources > Storage Systems**. If you want open the GUI for a switch, select **Network Resources > Switches**.
  2. Right-click the resource and select the action to open the GUI. For storage systems, select **Open Storage System GUI**. For a switch, select **Open Switch GUI**. The start page for the management GUI is opened in a separate web browser window.

---

## **Exporting information about resources, jobs, and alerts**

You can save information about resources, jobs, or alerts to a PDF, CSV, or HTML file. Information that you can export from the web-based GUI includes all the values that are being shown in the columns for a list of resources, jobs, or alerts.

The information that you export to a file is organized according to the sorting, filtering, and column order that is defined for a list. Before you export information, complete the following tasks to configure a list:

- Change the order of columns in the list as you want them to appear in the generated file.
- Hide columns in the list that you do not want to include in the generated file. Information in hidden columns is not exported.
- Sort the rows in the list as you want them to appear in the generated file. Each list in the web-based GUI has a column or set of columns that determines the order of its rows.

- Filter the list to show only the resources, jobs, or alerts that you want to export. Use filtering to limit the rows that are shown in a list based on value in a specific column or set of default columns.

You can export information that is shown on the following pages:

### Resource list and resource details pages

You can export information about the top-level resources, internal resources, or related resources that are shown on resource list pages and resource details pages. For top-level resources, you can also export information about related jobs or alerts.

For example, you can export information about monitored switches on the Switches page. When you select the export action, the generated file includes the column values for each monitored switch in the list. In the **Jobs** or **Alerts** tabs on the Switches page, you can export information about all the jobs or alerts that are related to switches.

### The Alerts page

On the **Home > Alerts** page, you can export information about all the alerts that were detected for monitored resources. Information that you can export includes all the values that are being shown in the columns for the list of alerts.

### The Jobs page

On the **Home > Jobs** page, you can export information about all the jobs that are associated with monitored resources. Information that you can export includes all the values that are being shown in the columns for the list of jobs.

1. In the web-based GUI, go to a list of resources, jobs, or alerts for which you want to export information.
2. Click **Actions** and select **Export > file\_format**, where *file\_format* represents the format that you want to use for a file. The following formats are available:

#### CSV (comma-separated values)

A CSV file is a file that contains comma-delimited values and can be viewed with a text editor or imported into a spreadsheet application. The information in a CSV file has the following format:

```
"Column_name","Column_name","Column_name","Column_name","Column_name","Column_name"
"data","data","data","data","data","data"
```

where `Column_name` represents the name of a column in a table and `data` represents the data that is associated with a column.

- PDF** You can view a PDF file with Acrobat reader. The information that you export to a PDF file is formatted into a table.

**Tip:** When you export a table of data that contains many columns, the rows in that table might span multiple pages in the resulting PDF. For example, if a table contains 20 columns, then the row for a specific resource might be shown on more than one page (10 columns on the first page and 10 columns on the second page).

To reduce the amount of pages that a table spans, before you select the export action, hide the columns that you do not want to include in the PDF. Continue hiding columns until the table no longer spans multiple pages.

## HTML

You can view an HTML file with a web browser. The information that you export to an HTML file is formatted into a table.

3. Optional: Depending on how your web browser is configured, you can specify the name and location of the generated file.
4. Click the save option to export the information to a file.

### Related concepts:

“Viewing information about resources” on page 631

You can view detailed information about the resources that are monitored by Tivoli Storage Productivity Center. Resources include storage systems, volumes, pools, servers, hypervisors, fabrics, and switches. You can also view information about internal and related resources.

“Customizing lists of resources, jobs, and alerts”

The web-based GUI uses lists to show information about resources, jobs, and alerts. The information in each list is organized into columns and rows. You can customize these lists by filtering information, sorting rows, and showing, hiding, and reordering columns.

---

## Customizing lists of resources, jobs, and alerts

The web-based GUI uses lists to show information about resources, jobs, and alerts. The information in each list is organized into columns and rows. You can customize these lists by filtering information, sorting rows, and showing, hiding, and reordering columns.

### Filtering lists

You can filter the items that are shown in a list. Use filtering when you want to limit the rows that are shown in a list based on values in a specific column or set of columns. For example, when viewing alerts, you can filter the list so that only alerts with a value of Warning in the Severity column are shown.

1. In the web-based GUI, go to a list of resources, jobs, or alerts that you want to filter.
2. Click the **Filter** icon  to determine how to filter the list. The following options are available:

#### Filter by Default Columns

Select this option to apply the filter to the set of the default columns in a list. Each list contains a set of default columns on which you can filter.

For example, in the lists of alerts on the **Home > Alerts** page, select this option to apply filter text to the following columns at the same time: Condition, Severity, Alert Category, Resource, Internal Resource, Total Occurrences, Alert Name.

#### Filter by a Specific Column

Select this option to apply filter text to a specific column in a list. For example, on the **Home > Alerts** page, select the **Condition** column if you want to apply filter text to values in that column only.

**Restriction:** Some columns in lists cannot be used for filtering and are not shown under the **Filter by a Specific Column** option.

3. In **Filter** text box , type the text for filtering a list. You can type letters, whole words, partial words, and numbers. When filtering on certain columns, you can select from a list of values rather than typing in filter text.

For example, when filtering on the **Status** column, you can select one of the following values as the filter text: Error, Unreachable, Warning, Normal, Unknown.

4. Press Enter to apply the filter to the list. Only rows with values that match or partially match the filter text are shown.

For example, on the **Home > Alerts** page, if you select to filter on the Severity column and type critical as the filter text, only alerts that have a severity of critical and critical - acknowledged are shown in the list.

**Tip:** The name of a column to which a filter applies is shown next to the **Filter** icon .

5. Optional: To remove the filtering for a list, click **Reset**.

## Sorting lists

Each list of resources in the web-based GUI has a column or set of columns that determines the order of its rows. You can sort the columns in a list to organize the rows according to your requirements.

For example, the list of ports on a fabric is ordered by switch name, blade slot, and port number, in that order. You can change the sort order of these columns to organize a list of resources according to your requirements.

**Tip:** A visual indicator  is shown next to the primary column that determines the sort order of a list.

1. In the web-based GUI, go to a list of resources, jobs, or alerts that you want to sort.
2. Complete the following tasks to sort the rows in the list:
  - To change whether the rows in a list are sorted by ascending or descending order, click the name of the primary column in the heading row. Click the name of the column again to reverse the sort order.
  - To change the column that determines the sort order of resources, click the name of that column. For example, click the Name column to sort the list of resources alphabetically, or click the **Status** column to sort the list according to the status of resources.

**Tip:** When you click a column other than the primary sort column, that column becomes the new primary sort column. However, the previous primary column maintains its sort order (ascending or descending).

For example, if a list of resources is ordered by the Name column in ascending order and you click the Status column, the rows are sorted according to the statuses of resources. At the same time, the resources for each type of status are still sorted in ascending order by the Name column. There is a maximum of three columns that can be sorted upon at the same time.

3. Optional: To reset the order of the rows for a column to the default setting, right-click the heading row in the list and select **Reset Table Preferences**.

## Showing, hiding, and reordering columns in lists

Each list in the web-based GUI has a set of columns that contain information about resources, jobs, or alerts. You can change the order of columns, show columns that are hidden, and hide columns that are shown in these lists.

1. In the web-based GUI, go to a list of resources, jobs, or alerts that you want to customize.
2. Complete the following tasks to customize the columns in the list:
  - To show or hide the columns in a list, right-click any of the column headings and select or clear the check box next to a column name.
  - To change the order of columns, click a column heading and drag it to a new position in the list.

**Tip:** The changes that you make to column settings are saved from session to session.

3. Optional: To reset the order and display of columns to the default setting, right-click any of the column headings and select **Reset Table Preferences**.

---

## Chapter 7. Managing replication

Manage replication components, including setting up the management servers, adding storage connections and paths, creating sessions and copy sets, setting up data replication, performing planned maintenance, and recovering from a disaster.

---

### Administering

Administer IBM Tivoli Storage Productivity Center for Replication to authorize users, start and use the graphical user interface (GUI), start and stop services, and many other administrative tasks.

### Starting and stopping Tivoli Storage Productivity Center for Replication

Use these procedures to start and stop Tivoli Storage Productivity Center for Replication, including the embedded WebSphere Application Server and DB2.

#### Starting Tivoli Storage Productivity Center for Replication

To start IBM Tivoli Storage Productivity Center for Replication, the embedded IBM WebSphere Application Server instance must be started. WebSphere Application Server is started by default after Tivoli Storage Productivity Center for Replication is installed.

This topic contains references to *WAS\_HOME*, which refers to the path for the Tivoli Storage Productivity Center for Replication *ewas* directory. The path depends on the operating system and the location of the Tivoli Storage Productivity Center for Replication installation. The default path for Windows operating systems is `C:\Program Files\IBM\TPC\ewas`. The default path for AIX and UNIX operating systems is `opt/IBM/TPC/ewas`.

#### Starting Tivoli Storage Productivity Center for Replication on Windows:

You can start Tivoli Storage Productivity Center for Replication from the desktop or from the command line.

From the desktop, start the WebSphere Application Server service by using the Windows **Services** interface.

From the command line, issue the following command:

```
WAS_HOME/profiles/ReplicationServerProfile/bin/
startServer.bat ReplicationServer
```

#### Starting Tivoli Storage Productivity Center for Replication on AIX or Linux:

To start Tivoli Storage Productivity Center for Replication, issue the following command from the command line:

```
WAS_HOME/profiles/ReplicationServerProfile/bin/
startServer.sh -username user_name -password password ReplicationServer
```

Where *user\_name* and *password* are your WebSphere Application Server user name and password.

#### Starting Tivoli Storage Productivity Center for Replication on z/OS:

If you use IBM WebSphere Application Server OEM Edition for z/OS with IBM Tivoli Storage Productivity Center for Replication for System z, see the *IBM WebSphere Application Server OEM Edition for z/OS Configuration Guide* to start Tivoli Storage Productivity Center for Replication for System z.

If you use WebSphere Application Server for z/OS, complete the following steps to start Tivoli Storage Productivity Center for Replication for System z:

1. Ensure that the WebSphere Application Server hierarchical file system (HFS), IBM DB2 HFS, and Tivoli Storage Productivity Center for Replication for System z HFS are all mounted on the UNIX System Services. The root installation directory for Tivoli Storage Productivity Center for Replication for System z is *path\_prefix*/usr/lpp/Tivoli/RM. The root production directory is *path\_prefix*/opt/lpp/Tivoli/RM.
2. Obtain the symbolic link for the was.env file. The symbolic link is in the format *cell\_short\_name.node\_short\_name.server\_short\_name*. For example, SYS7.SYS7.BBOS001. To get the symbolic link, complete the following steps:
  - a. Issue the **TSO ISH** command to start the Interactive System Productivity Facility (ISPF) shell.
  - b. Enter the path for the was.env file. For example, *path\_prefix*/zWebSphere/*version*/config1.
  - c. Find the symbolic link to the was.env file. This is the value that is required for the **ENV** parameter in the following step.
3. Issue the command from the IBM z/OS System Display and Search Facility (SDSF) panel to start the WebSphere Application Server, as shown in the following example. The address spaces that are shown might be different in your environment.

```
/START BB06ACR,JOBNAME=BBOS001,ENV=was.env_symbolic_link
```

The initiator is BB06ACR, and the job name is BBOS001. When you start the BB06ACR address space, the BBODMNB address space also starts.

## Stopping Tivoli Storage Productivity Center for Replication

To stop IBM Tivoli Storage Productivity Center for Replication, you must stop the embedded IBM WebSphere Application Server instance.

This topic contains references to *WAS\_HOME*, which refers to the path for the Tivoli Storage Productivity Center for Replication ewas directory. The path depends on the operating system and the location of the Tivoli Storage Productivity Center for Replication installation. The default path for Windows operating systems is C:\Program Files\IBM\TPC\ewas. The default path for AIX and UNIX operating systems is opt/IBM/TPC/ewas.

### Stopping Tivoli Storage Productivity Center for Replication on Windows:

You can stop Tivoli Storage Productivity Center for Replication from the desktop or from the command line.

From the desktop, stop the WebSphere Application Server service from the Windows **Services** interface.

From the command line, issue the following command:

```
WAS_HOME/profiles/ReplicationServerProfile/bin/
stopServer.bat ReplicationServer
```

### Stopping Tivoli Storage Productivity Center for Replication on AIX or Linux:

To stop Tivoli Storage Productivity Center for Replication, issue the following command from the command line:

```
WAS_HOME/profiles/ReplicationServerProfile/bin/
stopServer.sh -username user_name -password password ReplicationServer
```

Where *user\_name* and *password* are your WebSphere Application Server user name and password.

### **Stopping Tivoli Storage Productivity Center for Replication on z/OS:**

If you use IBM WebSphere Application Server OEM Edition for z/OS with IBM Tivoli Storage Productivity Center for Replication for System z, see the *IBM WebSphere Application Server OEM Edition for z/OS Configuration Guide* to stop Tivoli Storage Productivity Center for Replication for System z.

If you use WebSphere Application Server for z/OS, complete the following steps to stop Tivoli Storage Productivity Center for Replication for System z:

1. Issue commands from the IBM z/OS System Display and Search Facility (SDSF) panel to stop the WebSphere Application Server for z/OS daemon, as shown in the following example commands. The address spaces that are shown might be different in your environment.

```
/STOP BBOS001
```

```
/STOP BBODMNB
```

Where **/STOP BBOS001** stops the server address space and **/STOP BBODMNB** stops the WebSphere Application Server for z/OS daemon address space.

2. Issue the **/D A,L** command to display the processes that are running and verify that the stop command completed. If the BBOS001 or BBODMNB address spaces are displayed, issue the **/CANCEL** command for each address space.

## **Verifying that components are running**

This information describes how to verify that the IBM Tivoli Storage Productivity Center for Replication components are running.

### **Verifying that WebSphere Application Server is running**

The method that you use to verify that IBM WebSphere Application Server is running in your environment depends on the operating system. By default, the WebSphere Application Server is started automatically after IBM Tivoli Storage Productivity Center for Replication is installed.

#### **Verifying that WebSphere Application Server is running on Windows:**

To verify that IBM WebSphere Application Server is running, open the Windows **Services** interface and check the status of the WebSphere Application Server service.

#### **Verifying that WebSphere Application Server is running on AIX or Linux:**

To verify that WebSphere Application Server is running, issue the **ps** command.

#### **Verifying that WebSphere Application Server is running on z/OS:**

To verify that WebSphere Application Server is running, use the IBM z/OS System Display and Search Facility (SDSF) panel to issue the **/D A,L** command.

If the server and daemon address spaces for IBM WebSphere Application Server for z/OS are started, for example BBOS001 and BBODMNB, then WebSphere Application Server for z/OS is running.

If the server and daemon address spaces for IBM WebSphere Application Server OEM Edition for z/OS are started, for example WASOM1S, WASOM1, and WASOM1D, then WebSphere Application Server OEM Edition for z/OS is running.

## Verifying that the IBM Tivoli Storage Productivity Center for Replication server is running

This information describes how to verify whether the IBM Tivoli Storage Productivity Center for Replication server is running.

Perform one or more of these tasks to determine whether the IBM Tivoli Storage Productivity Center for Replication server is running:

- Start the IBM Tivoli Storage Productivity Center for Replication GUI or start up the IBM Tivoli Storage Productivity Center for Replication command line interface shell. If either of these methods is successful, then the IBM Tivoli Storage Productivity Center for Replication server is running.
- Determine whether IBM WebSphere Application Server is running. If IBM WebSphere Application Server is not running, then the IBM Tivoli Storage Productivity Center for Replication server is also not running.
- If IBM WebSphere Application Server is running, perform these steps to determine if IBM Tivoli Storage Productivity Center for Replication is configured correctly in IBM WebSphere Application Server:
  1. From a command prompt, change to the `WAS_HOME/profiles/ReplicationServerProfile/bin` directory.
  2. Enter the `wsadmin` command.
  3. Enter the `$AdminApp list` command.  
If you see CSM and CSMGUI in the resulting list, then IBM Tivoli Storage Productivity Center for Replication is configured correctly.
- View the `csmTrace.log` file in the `WAS_HOME/profiles/ReplicationServerProfile/logs/CSM` directory. If the `csmTrace.log` is being updated regularly and increasing in size, then IBM Tivoli Storage Productivity Center for Replication is running.

## Identifying the version of IBM Tivoli Storage Productivity Center for Replication

The version of code on the IBM Tivoli Storage Productivity Center for Replication server determines the available features and enhancements added to the product.

By clicking **About**, located in the Main menu, you can view the version and release of the IBM Tivoli Storage Productivity Center for Replication. The `-ver` command that is described in the *IBM Tivoli Storage Productivity Center Command-Line Interface Reference* also displays the current version of the product.

## Backing up and restoring IBM Tivoli Storage Productivity Center for Replication configuration data

You can back up the entire IBM Tivoli Storage Productivity Center for Replication database. You can also back up copy sets in a specific session. You can then use the backup files to restore a previous configuration or recover from a disaster.

### Back up and recovery

You can backup and recover copy set data for a specific session and the complete Tivoli Storage Productivity Center for Replication database.

## Copy sets

You can export data about all copy sets in a specific session to maintain a backup copy that you can use to recover if you lose the session or to upgrade to a different management server.

When exporting copy sets, Tivoli Storage Productivity Center for Replication creates a backup of the session and saves the data in a comma separated value (CSV) file, which you can view or edit in a spreadsheet program such as Microsoft Excel. The exported CSV file includes the session name, session type, date that the data was exported, and the copy sets for each role pair. There is one line per copy set, and the volumes in the copy set are separated by a comma (for example: ESS:2105.FCA57:VOL:17C7,ESS:2105.12043:VOL:17C7).

The following example illustrates the content of the CSV file for a FlashCopy session. Note that the first valid row must contain the appropriate role names for the session. The order of the copy sets does not matter, and you can include extra roles. A copy set is created from each row that follows the role names. All rows must have data in each column to be a valid row. Note that the number sign (#) indicates that the line is a comment. Lines that are comments are ignored.

```
#Session1,
#FlashCopy,
#Oct 2, 2009 10:03:18 AM

H1,T1
DS8000:2107.FRLL1:VOL:1004,DS8000:2107.FRLL1:VOL:1104
DS8000:2107.FRLL1:VOL:1011,DS8000:2107.FRLL1:VOL:1101
DS8000:2107.FRLL1:VOL:1005,DS8000:2107.FRLL1:VOL:1105
```

**Important:** You must manually save this file on the local system when you export copy sets from the Tivoli Storage Productivity Center for Replication Web interface.

## IBM Tivoli Storage Productivity Center for Replication database

Tivoli Storage Productivity Center for Replication database contains all product data, including data about storage systems, sessions, copy sets, paths, user administration and management servers. You can back up this data and use the backup file to recover from a disaster or restore a previous configuration.

**Important:** You must have Administrator privileges to back up and recover the database.

The current data is stored in a new file each time you create a backup. The backup file is named *yyyyMMdd\_HHmmsSSS.zip*, where *yyyy* is the year, *MM* is the month, *dd* is the day, *HH* is the hour, *mm* is the minute, *ss* is the seconds, *SSS* is the milliseconds when the backup command was run. It is your responsibility to delete backup versions that are no longer needed.

By default, the backup file is stored in the *WAS\_HOME/profiles/ReplicationServerProfile/database/backup* directory. You can change the default location by editing the **db.backup.location** property in the *rmserver.properties* file, which is located in the *WAS\_HOME/profiles/ReplicationServerProfile/properties* directory.

The backup file contains the Tivoli Storage Productivity Center for Replication database data at the time the backup was performed. Any changes that were made

after the backup are not reflected when the backup files are used to restore an Tivoli Storage Productivity Center for Replication database. It is recommended that you create a new backup file:

- After changing the Tivoli Storage Productivity Center for Replication database data, such as adding or deleting a storage system, changing properties, and changing user privileges
- After an Tivoli Storage Productivity Center for Replication session changes direction. For example, if a Metro Mirror session was copying data from H1 to H2 when the backup was taken, and later, the session was started in the H2 to H1 direction. The session must be in the Prepared state before you create the backup.
- After a site switch has been declared and the Enable Copy To Site command has been issued. After you create a backup, consider deleting the previous backup to prevent Tivoli Storage Productivity Center for Replication from starting the copy in the wrong direction.

When you create a backup, ensure that all Tivoli Storage Productivity Center for Replication sessions are either in the Defined, Prepared or Target Available state.

Restoring the Tivoli Storage Productivity Center for Replication database from a backup copy puts Tivoli Storage Productivity Center for Replication back to the point in time when the backup was made. Relationships that exist on the storage systems that were created by Tivoli Storage Productivity Center for Replication after the backup was made will no longer be managed by Tivoli Storage Productivity Center for Replication until you add the copy set to the session and Tivoli Storage Productivity Center for Replication assimilates the relationship into the session. Copy sets that were deleted after the backup will be restored and a subsequent Start command to the session will create new relationships; therefore, you must remove the deprecated copy sets before issuing the Start command.

After restoring a Global Mirror session, you must stop the Global Mirror master and subordinates before restarting the Global Mirror session. Refer to your DS6000 and DS8000 storage system documentation for more information.

## Backing up the IBM Tivoli Storage Productivity Center for Replication database

This topic describes how to create a backup of the IBM Tivoli Storage Productivity Center for Replication database, including data about storage systems, sessions, copy sets, user administration and management server configuration.

To back up the IBM Tivoli Storage Productivity Center for Replication database, run the **mkbackup** command from the command line, for example:

```
csmdi> mkbackup
```

### Prerequisites:

- You must have Administrator privileges to run this command.
- This procedure applies to only the zero-administration embedded repository. This procedure *is not* applicable when DB2 is being used as the persistent datastore for the Tivoli Storage Productivity Center for Replication database. For information about restoring your DB2 environment, refer to your DB2 documentation.

By default, the backup file is stored in the `WAS_HOME/profiles/ReplicationServerProfile/database/backup` directory. You can change the default

location by editing the **db.backup.location** property in the `rmserver.properties` file, which is located in the `WAS_HOME/profiles/ReplicationServerProfile/properties` directory.

## Restoring the IBM Tivoli Storage Productivity Center for Replication database

You can restore IBM Tivoli Storage Productivity Center for Replication database that was previously backed up to the local system.

### Important:

- Restoring the database does not require Administrator privileges. However, you must be able to access the files on the IBM Tivoli Storage Productivity Center for Replication server that are listed in the procedure.
- This procedure applies to only the zero-administration embedded repository. This procedure *is not* applicable when DB2 is being used as the persistent datastore for the Tivoli Storage Productivity Center for Replication database. For information about restoring your DB2 environment, refer to your DB2 documentation.

Perform these steps to restore the IBM Tivoli Storage Productivity Center for Replication database from a backed up version:

1. Stop IBM Tivoli Storage Productivity Center for Replication on the active management server by running the **stopServer** command from a command line.
2. Delete the `WAS_HOME/profiles/ReplicationServerProfile/database/csmdb` directory and all contents in it.
3. Uncompress the backup file into the `WAS_HOME/profiles/ReplicationServerProfile/database` directory.
4. If IBM Tivoli Storage Productivity Center for Replication is running on z/OS, change the permissions of the `csmdb` directory by running the following commands:
  - `chgrp -R $WAS_GROUP csmdb`
  - `chmod -R u+rwx csmdb`
  - `chmod -R g+rwx csmdb`
  - `chmod -R o+r csmdb`
5. Restart IBM Tivoli Storage Productivity Center for Replication on the active management server by running the **startServer** command from a command line.
6. Resolve any changes that might have occurred since the backup was created.
7. Start the IBM Tivoli Storage Productivity Center for Replication sessions using the appropriate start commands. The start commands reestablish the relationship between the volume pairs and synchronize data on those volumes.
8. If you have a standby management server, reestablish that standby relationship to update the database on the standby server.

## Exporting copy set data

You can export data about all copy sets in a specific session, to maintain a backup copy that can be used to recover if you lose your session or upgrade to a different server.

Perform these steps to export the copy sets in a specific session:

1. In the navigation tree, select **Sessions**. The Sessions panel is displayed
2. Select the session for which you want to export copy sets.

3. Select **Export Copy Sets** from the **Actions** list, and click **Go**. The Export Copy Set wizard displays the status of the export and a link to the exported file.
4. Click that link and save the file to the local system.

**Important:** You must save the file to your local system. After you close the panel, the data will be lost.

5. Click **Finish**.

### Importing copy set data

You can import copy set data that was previously exported to a comma separated value (CSV) file.

Perform the following steps to import copy sets into an existing session:

1. In the navigation tree, select **Sessions**. The Session panel is displayed.
2. Select the session for which you want to import copy sets.
3. Select **Add Copy Sets** from the **Actions** list, and click **Go**. The Add Copy Sets wizard is displayed.
4. Select **Use a CSV file to import copy sets**.
5. Type the location and name of the CSV file to import, or use **Browse** to select the file. Then, click **Next**.
6. Verify that the matching results were successful, and then click **Next**.
7. Select the copy sets you want to add, and then click **Next**.
8. Confirm the number of copy sets that you want to create, and click **Next**. A progress bar displays.
9. Click **Next**.
10. Verify the matches, and click **Finish**.

---

## Managing management servers

This section provides information about how to set up active and standby management servers, restore a lost connection between the management servers, or perform a takeover on the standby management server.

### Management servers

The *management server* is a system that has IBM Tivoli Storage Productivity Center for Replication installed. The management server provides a central point of control for managing data replication.

You can create a high-availability environment by setting up a *standby management server*. A standby management server is a second instance of Tivoli Storage Productivity Center for Replication that runs on a different physical system, but is continuously synchronized with the primary (or active) Tivoli Storage Productivity Center for Replication server. The active management server issues commands and processes events, while the standby management server records the changes to the active server. As a result, the standby management server contains identical data to the active management server and can take over and run the environment without any loss of data. If the active management server fails, you can issue the Takeover command to make the standby management server take over.

## Connecting the active management server to the standby management server

Ensure that the active management server is connected to the standby management server. This connection creates the *management server relationship* that begins the synchronization process. Each management server can be in only one management server relationship.

A management server relationship might become disconnected for a number of reasons, including a connectivity problem or a problem with the alternate server. Issue the Reconnect command to restore synchronization.

## Completing a takeover on the standby management server

If you must perform a takeover and use the standby server, ensure that you shut down the active management server first. You must ensure that you do not have two active management servers. If there are two active management servers and a condition occurs on the storage systems, both management servers respond to the same conditions, which might lead to unexpected behavior.

If you complete an action on the active management server when the servers are disconnected, the servers will be out of synchrony.

## Viewing the status of the management servers

You can view the status of the active and standby management servers from the Management Servers panel in the Tivoli Storage Productivity Center for Replication graphical user interface (GUI). If you are logged on to the active management server, the icons on this panel show the status of the standby management server. If you are logged on to the standby management server, the icons on this panel show the status of the active management server.

When the status is Synchronized, the standby management server contains the same data that the active management server contains. Any update to the active management server database is replicated to the standby server database.

## Managing volumes on storage systems

When you add direct connections, Hardware Management Console (HMC) connections, or z/OS connections on the active management server, Tivoli Storage Productivity Center for Replication automatically enables the management of attached extended count key data (ECKD™) volumes, non-attached count key data (CKD) volumes, and all fixed-block volumes on the storage system. To disable management of volumes on the storage system, use the volume protection function.

## Setting exceptions for ephemeral port numbers

For management servers that use an Internet Protocol version 4 (IPv4) connection, the port that is shown on the Management Servers page of the Tivoli Storage Productivity Center for Replication GUI is the *listener* port. This port was set when Tivoli Storage Productivity Center for Replication was installed.

However, when the management server initiates a connection to standby server, the management server uses an *ephemeral* port.

An ephemeral port is a temporary port number that is assigned for the duration the connection. When the connection terminates, the ephemeral port is available for reuse. When the management server reconnects to the standby server, a new ephemeral port number is assigned.

If you are using a firewall, you must create exceptions that enable the management server to connect to the standby server by using outbound ephemeral ports.

### **Information specific to management servers in z/OS environments**

If the standby management server is not in the active server z/OS sysplex, the standby server is not able to communicate with the storage systems by using a z/OS connection. Therefore, another connection must be made by using a TCP/IP connection.

If DB2 is configured for data sharing mode across the z/OS sysplex, one of the Tivoli Storage Productivity Center for Replication servers must be configured to use the zero-administration embedded repository. If the embedded repository is not used, the two servers will overwrite the same data in the Tivoli Storage Productivity Center for Replication database.

## **SNMP alerts**

This topic describes the SNMP alerts that are sent by IBM Tivoli Storage Productivity Center for Replication and the associated object IDs (OIDs).

SNMP alerts are sent during the following general events:

- Session state change
- Configuration change
- Suspending-event notification
- Communication failure
- Management Server state change

### **Session state change SNMP trap descriptions**

This topic lists the SNMP traps that are sent during a session state change. A different trap is sent for each state change. These alerts are sent by only the active management server.

A session state change SNMP trap is sent each time the session changes to one of the following states:

- Defined
- Preparing
- Prepared
- Suspended
- Recovering
- Flashing
- Target Available
- Suspending
- (Metro Global Mirror only) SuspendedH2H3
- (Metro Global Mirror only) SuspendedH1H3

An SNMP trap is also sent when a recovery point objective (RPO) threshold is exceeded for a role pair that is in the session.

Table 55. Session state change traps

| Object ID (OID)          | Description                                                                                                     |
|--------------------------|-----------------------------------------------------------------------------------------------------------------|
| 1.3.6.1.4.1.2.6.208.0.1  | The state of session X has transitioned to Defined.                                                             |
| 1.3.6.1.4.1.2.6.208.0.2  | The state of session X has transitioned to Preparing.                                                           |
| 1.3.6.1.4.1.2.6.208.0.3  | The state of session X has transitioned to Prepared.                                                            |
| 1.3.6.1.4.1.2.6.208.0.4  | The state of session X has transitioned to Suspended.                                                           |
| 1.3.6.1.4.1.2.6.208.0.5  | The state of session X has transitioned to Recovering.                                                          |
| 1.3.6.1.4.1.2.6.208.0.6  | The state of session X has transitioned to Target Available.                                                    |
| 1.3.6.1.4.1.2.6.208.0.19 | The state of session X has transitioned to Suspending.                                                          |
| 1.3.6.1.4.1.2.6.208.0.20 | The state of session X has transitioned to SuspendedH2H3.                                                       |
| 1.3.6.1.4.1.2.6.208.0.21 | The state of session X has transitioned to SuspendedH1H3.                                                       |
| 1.3.6.1.4.1.2.6.208.0.22 | The state of session X has transitioned to Flashing.                                                            |
| 1.3.6.1.4.1.2.6.208.0.23 | The state of session X has transitioned to Terminating.                                                         |
| 1.3.6.1.4.1.2.6.208.0.26 | The recovery point objective for the role pair of X in session Y has passed the warning threshold of Z seconds. |
| 1.3.6.1.4.1.2.6.208.0.27 | The recovery point objective for the role pair of X in session Y has passed the severe threshold of Z seconds.  |

**Related reference:**

“Session states” on page 778

You can view the health and status of a session in the Tivoli Storage Productivity Center for Replication GUI.

**Configuration change SNMP trap descriptions**

This topic lists the SNMP traps that are sent when the configuration changes. These alerts are sent by only the active management server.

Configuration change SNMP traps are sent after the following configurations changes are made:

- One or more copy sets have been added or deleted from a session  
 An alert is sent for each set of copy sets added to or removed from a session. Note that an alert for copy set changes is sent only once within 15 minutes of a configuration change, so you might not see alerts from successive changes that occur within that 15-minute period. For example, if you make a copy set configuration change that causes an alert to be sent at 10:41:01, and if you were to make additional copy set changes at 10:42:04 and 10:50:09, no alerts would be sent for these two changes because they occurred within the 15-minute minimum interval from the first alert.
- PPRC path definitions have been changed  
 An alert is sent for each path configuration change made.

Table 56. Configuration change traps

| Object ID (OID)         | Description                                                                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.3.6.1.4.1.2.6.208.0.7 | One or more copy sets have been added or deleted from this session.<br><b>Note:</b> An event is sent for each session at least every 15 minutes. |
| 1.3.6.1.4.1.2.6.208.0.8 | Peer-to-Peer Remote Copy (PPRC) path definitions have been changed. An event is sent for each path configuration change.                         |

## Suspending-event notification SNMP trap descriptions

These SNMP traps that are sent during a suspending-event notification. The traps are sent by the active and standby management server.

Suspending-event notification SNMP traps indicate that a session has transitioned to a Severe status due to an unexpected error.

Table 57. Suspending-event notification traps

| Object ID (OID)         | Description                                                  |
|-------------------------|--------------------------------------------------------------|
| 1.3.6.1.4.1.2.6.208.0.9 | The session is in a Severe state due to an unexpected error. |

## Communication-failure SNMP trap descriptions

This topic lists the SNMP traps that are sent during a communication-failure. These alerts are sent by both the active and standby management servers.

Communication-failure SNMP traps are sent after the following events occur:

- A server times out attempting to communicate with a storage system.
- A server encounters errors attempting to communicate with a storage system.
- An active server terminates communication with a standby server as a result of communication errors.
- A standby encounters communication errors with an active server.

After an SNMP trap for a given failure is sent, it is not resent unless communication has been reestablished and failed again.

Table 58. Communication-failure traps

| Object ID (OID)          | Description                                                                                             |
|--------------------------|---------------------------------------------------------------------------------------------------------|
| 1.3.6.1.4.1.2.6.208.0.10 | Server X has timed out attempting to communicate with storage system Y.                                 |
| 1.3.6.1.4.1.2.6.208.0.11 | Server X has encountered errors attempting to communicate with storage system Y.                        |
| 1.3.6.1.4.1.2.6.208.0.12 | Active server X has terminated communication with standby server Y as a result of communication errors. |
| 1.3.6.1.4.1.2.6.208.0.13 | Standby server X has encountered communication errors with active server Y.                             |

## Management Servers state-change SNMP trap descriptions

This topic lists the SNMP traps that are sent when the state of the management server changes. These alerts are sent by both the active and standby management servers.

A management server state change SNMP trap is sent each time the management server changes to one of the following states:

- Unknown
- Synchronization Pending
- Synchronized
- Disconnected Consistent
- Disconnected

Table 59. Management Servers state-change traps

| Object ID (OID)          | Description                                                                                                                                                                       |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.3.6.1.4.1.2.6.208.0.14 | The IBM Tivoli Storage Productivity Center for Replication Server Management Server connection X->Y has changed state to Unknown (previously Offline).                            |
| 1.3.6.1.4.1.2.6.208.0.15 | The IBM Tivoli Storage Productivity Center for ReplicationServer Management Server connection X->Y has changed state to Synchronized.                                             |
| 1.3.6.1.4.1.2.6.208.0.16 | The IBM Tivoli Storage Productivity Center for Replication Server Management Server connection X->Y has changed state to Disconnected Consistent (previously Consistent Offline). |
| 1.3.6.1.4.1.2.6.208.0.17 | The IBM Tivoli Storage Productivity Center for Replication Server Management Server connection X->Y has changed state to Synchronization Pending.                                 |
| 1.3.6.1.4.1.2.6.208.0.18 | The IBM Tivoli Storage Productivity Center for Replication Server Management Server connection X->Y has changed state to Disconnected.                                            |

## Setting up a standby management server

You can set up a standby management server in two ways: setting up the management server you are logged in to as the standby management server, or designating another server as the standby management server.

**Note:** When you define a standby management server, the IBM Tivoli Storage Productivity Center for Replication code must be at the same level on both the standby and active management servers.

### Setting the local management server as the standby server

This topic describes how to set the management server on which you are currently logged in as the standby management server.

**Attention:** When you set the local management server, the server you are logged in at will be wiped of all session information, and replaced with the session information belonging to the server you specified.

**Important:** The standby management server port number must be the same on both the management server and the standby management server in a high-availability relationship. If you change the standby management server port number on either the management server or the standby management server, you must also change the port number on the other server.

Perform these steps to set the local management server as the standby server:

1. In the navigation tree, select **Management Servers**.
2. From the **Action** menu, select **Set This Server as Standby**, and click **Go**. This opens the Set This Server As Standby panel.
3. Enter the domain name or IP address of the desired active management server.
4. Click **OK** to connect to the active server. You have now designated the server you are logged in at as the standby server.

### Setting a remote management server as the standby server

This topic describes how to set up a management server on which you are not logged in as the standby server.

**Attention:** When you set a remote management server as the standby server, the remote management server is wiped of all session information and replaced with the session information belonging to the management server you specified.

**Important:** The standby management server port number must be the same on both the management server and the standby management server in a high-availability relationship. If you change the standby management server port number on either the management server or the standby management server, you must also change the port number on the other server.

Perform these steps to set a remote management server as the standby server:

1. In the navigation tree, select **Management Servers**.
2. Select **Define Standby** from the drop-down menu, and click **Go**. The Define Standby panel appears.
3. Type the domain name or IP address of the server that you are defining as the new standby management server. Log in to the standby management server by entering the username and password.
4. Click **OK** to connect to the standby management server.

## Applying maintenance to an active management server

If an active management server develops a problem during an active session, you can reinstall Tivoli Storage Productivity Center for Replication on the server without affecting the session.

Follow these steps to reinstall Tivoli Storage Productivity Center for Replication on the active management server.

1. If the heartbeat is enabled, disable it:
  - a. In the navigation tree, select **Advanced Tools**.
  - b. Click **Disable Heartbeat**.
2. On the standby server, Server 2, issue a take-over. This makes Server 2 the active server. It is possible that the original active server, Server 1, is still listed on the Server 2 Management Servers page. If so, select **Remove Standby**.
3. Disable the heartbeat on Server 2, in case there are any problems.
4. Uninstall Tivoli Storage Productivity Center for Replication on Server 1.
5. Reinstall Tivoli Storage Productivity Center for Replication on Server 1.

**Note:** If no changes have been made to the configuration while Server 1 was being reinstalled, steps 6 and 7 are not necessary.

6. When Tivoli Storage Productivity Center for Replication is running on Server 1, log into Server 2 and set Server 1 as the standby server for Server 2.  
This step copies the configuration from Server 2 to Server 1. This process takes a few minutes.
7. When the management servers status is synchronized, issue a take-over on Server 1.  
This makes Server 1 an active server, able to control sessions.

**Note:** It is possible that Server 2 is still listed on the Server 1 Management Servers page. If this is the case, select **Remove Standby**.

8. Disable the heartbeat on Server 1 to make sure this active server does not have any problems.

**Note:** If you do not need to reinstall Tivoli Storage Productivity Center for Replication on Server 2, skip steps 9 and 10.

9. Uninstall Tivoli Storage Productivity Center for Replication from Server 2.
10. Reinstall Tivoli Storage Productivity Center for Replication on Server 2.
11. On Server 2, go to the Management Servers page and select the **Set This Server As Standby** option, entering the information for Server 1. When this step is complete, Server 1 is the active server, and Server 2 is the standby server.
12. When you are confident that the active server is running without any problems, enable the heartbeat again, if desired.

## Reconnecting the active and standby management servers

If the active and standby management servers become disconnected, reestablish that connection.

Perform these steps to cause the standby management server to become the active management server:

1. In the navigation tree, select **Management Servers**. The Management Servers panel is displayed.
2. Select **Reconnect** from the **Actions** list, and click **Go**.

## Performing a takeover on the standby management server

If the active management server fails, you can force the standby management server to take over monitoring and managing replication responsibilities.

**Important:** If the current active management server is still active, you must not attempt to control the replication environment simultaneously from both management servers. Instead, either reconfigure the current active management server to be a standby management server, or shut it down.

Perform these steps to cause the standby management server to become the active management server:

1. If the active management server is functioning, take it offline so you do not have two active management servers managing the same sessions.
2. Log in to the IBM Tivoli Storage Productivity Center for Replication Web interface running on the standby management server.
3. In the navigation tree, select **Management Servers**. The Management Servers panel is displayed.
4. Select **Takeover** from the **Actions** list, and click **Go**.
5. To reestablish high-availability, perform one of these steps:
  - Choose another server to be the standby management server. See instructions for setting up a standby management server.
  - Bring the failed management server back online, and then make that server the standby management server. See “Setting up a standby management server” on page 679.
  - Bring the failed management server back online, and then make that server the active management server to return to the original configuration. Repeat the steps in this section and then add the original standby server as the standby server.

**Important:** Do *not* use the **Reconnect** command if you perform a takeover. You would use the **Reconnect** command when the active server loses its connection with the standby server; it reconnects the two servers. Do *not* use the **Reconnect** command after a takeover to reconnect to the original active server.

## Configuring SNMP

The SNMP community name has a default value of `public`.

To change the community name, modify or add the **`csn.server.snmp_community_string`** property in the `rmserver.properties` file, which is located in the `WAS_HOME/profiles/ReplicationServerProfile/properties` directory.

## Adding SNMP managers

Use the **`mksnmp`** command to add an SNMP manager to the list of servers to which IBM Tivoli Storage Productivity Center for Replication sends SNMP alerts.

IBM Tivoli Storage Productivity Center for Replication uses management information base (MIB) files to provide a textual description of each SNMP alert sent by IBM Tivoli Storage Productivity Center for Replication. You must configure the SNMP manager to use both the `SYSAPPL-MIB.mib` and `ibm-TPC-Replication.mib` files. These MIB files are located in the `WAS_HOME/profiles/ReplicationServerProfile/etc` directory. Follow the directions provided by your SNMP manager application to configure it to use the MIB files.

**Tip:** You can also find the MIB files on the installation DVD in the `TPCRM/CSM-Client/etc` directory.

**Note:** IBM Tivoli Storage Productivity Center for Replication sends all SNMP alerts to each registered SNMP manager. SNMP alerts are not specific to any particular session, and all alerts for any session are sent. You cannot choose to send a subset of SNMP alerts.

## Changing the standby management server port number

The standby management server port is used for communication between the active and standby management server. This port is initially defined during the installation. You can manually change this port after installation.

**Important:** The standby management server port number must be the same on both the management server and the standby management server in a high-availability relationship. If you change the standby management server port number on either the management server or the standby management server, you must also change the port number on the other server.

1. Open the `rmserver.properties` file in the `WAS_HOME/profiles/ReplicationServerProfile/properties` directory.
2. Modify the port number for the following property:  
`communications.haPort=port_number`
3. Restart IBM Tivoli Storage Productivity Center for Replication. You must restart IBM Tivoli Storage Productivity Center for Replication to activate property changes. Properties are not synchronized between the IBM Tivoli Storage Productivity Center for Replication management servers and must be done on each IBM Tivoli Storage Productivity Center for Replication management server.

## Changing the client port number

The client port is used to log in to the graphical user interface and command line interface from a remote system. This port is initially defined during the installation. You can manually change this port after installation.

**Important:** The client port number must be the same on both the management server and the standby management server in a high-availability relationship. If you change the client port number on either the management server or the standby management server, you must also change the port number on the other server.

1. Open the `rmserver.properties` file in the `WAS_HOME/profiles/ReplicationServerProfile/properties` directory.
2. Modify the port number for the following property:  
`communications.port=port_number`
3. Open the `repcli.properties` file in the `install_root/cli` directory.
4. Modify the port number for the following property:  
`port=port_number`
5. Restart IBM Tivoli Storage Productivity Center for Replication. You must restart IBM Tivoli Storage Productivity Center for Replication to activate property changes. Properties are not synchronized between the IBM Tivoli Storage Productivity Center for Replication management servers and must be maintained on each IBM Tivoli Storage Productivity Center for Replication management server.

---

## Managing storage systems

To replicate data among storage systems using IBM Tivoli Storage Productivity Center for Replication, you must add connections to the storage systems. After a storage system is added, you can associate a location, modify connection properties, set volume protection, and refresh the storage configuration for that storage system.

### Storage systems

A *storage system* is a hardware device that contains data storage. Tivoli Storage Productivity Center for Replication can control data replication within and between various storage systems.

To replicate data among storage systems using Tivoli Storage Productivity Center for Replication, you must manually add a connection to each storage system in the Tivoli Storage Productivity Center for Replication configuration. You can then omit storage systems for which Tivoli Storage Productivity Center for Replication is not to manage replication and omit storage systems that are being managed by another Tivoli Storage Productivity Center for Replication management server.

For redundancy, you can connect a single storage system using a combination of direct, Hardware Management Console (HMC), and z/OS connections.

You can use the following storage systems:

- IBM TotalStorage Enterprise Storage Server (ESS) Model 800
- IBM System Storage DS6000
- IBM System Storage DS8000
- IBM System Storage SAN Volume Controller
- IBM Storwize V3500

- IBM Storwize V3700
- IBM Storwize V7000
- IBM Storwize V7000 Unified
- IBM XIV Storage System

SAN Volume Controller can virtualize various storage systems. Although Tivoli Storage Productivity Center for Replication does not support all storage systems, you can manage other storage systems through a single SAN Volume Controller cluster interface. Tivoli Storage Productivity Center for Replication connects directly to the SAN Volume Controller clusters.

You can define a location for each storage system and for each site in a session. When adding copy sets to the session, only the storage systems whose location matches the location of the site are allowed for selection. This ensures that a session relationship is not established in the wrong direction.

**Notes:**

- Tivoli Storage Productivity Center for Replication does not automatically discover the physical locations of storage systems. You can manually assign a location to a storage system from the GUI and CLI.
- Throughout this document, *ESS/DS* refers to the following models:
  - IBM TotalStorage Enterprise Storage Server Model 800
  - IBM System Storage DS8000
  - IBM System Storage DS6000

## Storage connections

You must create a connection from the IBM Tivoli Storage Productivity Center for Replication management server to each storage system. You can connect either directly or through a Hardware Management Console (HMC) or IBM z/OS connection.

A single storage system can be connected using multiple connections for redundancy. For example, you can connect a IBM System Storage DS8000 storage system using an HMC connection and a z/OS connection. Tivoli Storage Productivity Center for Replication monitors how a storage system has been added to the configuration.

When you add a storage connection to the Tivoli Storage Productivity Center for Replication configuration, the storage system and the connection are added to the active management server configuration. For direct and HMC connections, the storage system and connection are also added to the standby management server configuration. For z/OS connections, only the storage system is added to the standby management server configuration. The connection is not added because the standby management server might not be running on z/OS and might not have access to the volumes on the storage system through a z/OS connection.

The storage systems are not required to be connected to the standby management server. However, if a storage system does not have a connection on the standby management server, you cannot manage copy services on the storage system from the standby server.

**Important:** If the Metro Mirror heartbeat is enabled, do not connect to a IBM TotalStorage Enterprise Storage Server Model 800, System Storage DS8000, or

System Storage DS6000 storage system using both an HMC connection and a direct connection. If you have both types of connections and the direct connection is lost, the session changes to the suspended state even though the HMC connection is still valid. If both connections are lost and the session is in the suspended state, restart the session when connectivity is regained to synchronize the session with the hardware.

When Tivoli Storage Productivity Center for Replication is running on z/OS and a storage system is added to the Tivoli Storage Productivity Center for Replication configuration through a TCP/IP (direct or HMC) connection, all ECKD volumes that are attached to the management server are managed through the TCP/IP connection. To use the Fibre Channel connection, you must explicitly add the storage system to the Tivoli Storage Productivity Center for Replication configuration through a z/OS connection.

If a storage system was previously added to the Tivoli Storage Productivity Center for Replication configuration through a z/OS connection and later the storage system is added through a TCP/IP connection, all non-attached ECKD volumes and fixed block volumes are added to the Tivoli Storage Productivity Center for Replication configuration.

When you remove a storage system, Tivoli Storage Productivity Center for Replication automatically removes all connections that the storage system is using with exception of the z/OS connection. You can also individually remove each connection through which the storage system is connected.

If Tivoli Storage Productivity Center for Replication has multiple connections to a specific storage system, the order in which you remove the connections produces different results:

- If you remove all direct and HMC connections first, the fixed block and non-attached ECKD volumes are removed from the Tivoli Storage Productivity Center for Replication configuration. The remaining ECKD volumes that are attached through the z/OS connection remain in the Tivoli Storage Productivity Center for Replication configuration until the z/OS connection is removed. Removing the TCP/IP connection also disables the Metro Mirror heartbeat.
- If you remove the z/OS connection first and if there is an HMC or direct connection to volumes, those volumes are not removed from the Tivoli Storage Productivity Center for Replication configuration.
- HyperSwap can run provided that volumes are attached and available to z/OS storage, even if you are using a TCP/IP connection to storage.

### **Direct connection**

By using a TCP/IP connection, the Tivoli Storage Productivity Center for Replication management server can connect directly to certain storage systems. The TCP/IP connection is required to discover a system's configuration (such as LSSs, volumes, volume size, and format), issue queries, and receive asynchronous events.

The Tivoli Storage Productivity Center for Replication management server can connect directly with the following systems:

- TotalStorage Enterprise Storage Server
- DS6000
- DS8000
- SAN Volume Controller
- Storwize V3500

- Storwize V3700
- Storwize V7000
- Storwize V7000 Unified
- The XIV system

DS8000 storage systems on an IPv4 network can be connected directly to the management server. A direct connection requires an Ethernet card in the cluster. DS8000 systems on an IPv6 network cannot use a direct connection. They can be connected only through an HMC or z/OS connection.

When you add a direct connection to a DS or ESS cluster, specify the following information for cluster 0 and 1:

- IP addresses or domain names
- Ports
- User names
- Passwords

System Storage SAN Volume Controller or Storwize V7000 can virtualize various storage systems. Although Tivoli Storage Productivity Center for Replication does not support all storage systems, you can manage these storage systems through a single System Storage SAN Volume Controller or Storwize V7000 cluster interface. Tivoli Storage Productivity Center for Replication connects directly to the System Storage SAN Volume Controller or Storwize V7000 clusters. When you add a direct connection to a System Storage SAN Volume Controller or Storwize V7000 cluster to the Tivoli Storage Productivity Center for Replication configuration, specify the cluster IP address of the System Storage SAN Volume Controller or Storwize V7000 cluster, which in turn points to multiple System Storage SAN Volume Controller or Storwize V7000 storage systems. Ensure that the user name and password are correct for the cluster. If incorrect values are used, significant communication problems can occur, such as never advancing to the Prepared state.

**Important:** The storage system user name must have privileges to maintain SSH keys. For information about troubleshooting Secure Shell connections to the storage system, see the Ethernet Connection Restrictions on SAN Volume Controller website at [www-01.ibm.com/support/docview.wss?uid=ssg1S1002896](http://www-01.ibm.com/support/docview.wss?uid=ssg1S1002896).

### Hardware Management Console connection

The IBM Tivoli Storage Productivity Center for Replication management server can connect to DS8000 storage systems through a Hardware Management Console (HMC). An HMC can have multiple DS8000 storage systems connected to it. When you add an HMC to the IBM Tivoli Storage Productivity Center for Replication configuration, all DS8000 storage systems that are behind the HMC are also added. You cannot add or remove individual storage systems that are behind an HMC.

You can also add a dual-HMC configuration, in which you have two HMCs for redundancy. You must configure both HMCs identically, including the user ID and password.

If planned maintenance is necessary on the HMC, it is recommended that you disable the Metro Mirror heartbeat on the management server while the maintenance is performed.

If the HMC needs to go down frequently or reboots frequently, it is recommended that you disable the Metro Mirror heartbeat. If the Metro Mirror heartbeat is required, the direct connection is recommended instead of an HMC connection.

**Important:** If a DS8000 storage system uses an HMC connection, the Metro Mirror heartbeat could trigger a freeze on the storage system and impact applications for the duration of the long busy timeout timer if the HMC is shut down for any reason, including upgrading microcode. The long busy timeout timer is the time after which the storage system will allow I/O to begin again after a freeze occurs if no run command has been issued by Tivoli Storage Productivity Center for Replication. The default value is two minutes for ECKD volumes or one minute for fixed block volumes.

**Notes:**

- The user ID that you use to connect to the HMC must have admin, op\_storage, or op\_copy\_services privileges on the DS8000 storage system. In addition, the user ID must have Copy Services access to any volumes that are in resource groups on the DS8000 storage system.
- For minimum microcode requirements to connect to a DS8000 through a management console, see the Supported Storage Products List website at [www-01.ibm.com/support/docview.wss?uid=swg21386446](http://www-01.ibm.com/support/docview.wss?uid=swg21386446).

### **z/OS connections**

An IBM Tivoli Storage Productivity Center for Replication management server that runs on z/OS can connect to IBM TotalStorage Enterprise Storage Server (ESS) Model 800, DS8000, and DS6000 storage systems through a z/OS connection. The z/OS connection is used to issue replication commands and queries for attached ECKD volumes over an existing Fibre Channel network and to receive asynchronous events. When a storage system is added to IBM Tivoli Storage Productivity Center for Replication through the z/OS connection, all ECKD volumes that are attached to the IBM Tivoli Storage Productivity Center for Replication management system are added to the IBM Tivoli Storage Productivity Center for Replication configuration. ECKD volumes that are not attached to the IBM Tivoli Storage Productivity Center for Replication z/OS management server are not added to the IBM Tivoli Storage Productivity Center for Replication configuration through the z/OS connection.

**Notes:**

- Ensure that all volumes in the logical storage subsystem (LSS) that you want to manage through a z/OS connection are attached to z/OS. Either the entire LSS must be attached to z/OS or none of the volumes in the LSS should be attached to z/OS for IBM Tivoli Storage Productivity Center for Replication to properly manage queries to the hardware.
- The z/OS connection is limited to storage systems that are connected to an IBM Tivoli Storage Productivity Center for Replication management server running z/OS.
- The Metro Mirror heartbeat is not supported through the z/OS connection. To use the Metro Mirror heartbeat, the storage systems must be added using a direct connection or Hardware Management Console (HMC) connection. If the Metro Mirror heartbeat is enabled, a storage system is added through a direct connection and z/OS connection, and the direct connection becomes disconnected, then a suspend results as there is no heartbeat through the z/OS connection.

If at least one volume in a Logical Storage Subsystem (LSS) is attached through a z/OS connection, then all volumes in that LSS must be similarly attached. For example, if there are two ECKD volumes in an LSS, and one volume is attached to the IBM Tivoli Storage Productivity Center for Replication system using a z/OS connection and the other is attached through a direct connection, IBM Tivoli

Storage Productivity Center for Replication would have knowledge of direct-connected volume. IBM Tivoli Storage Productivity Center for Replication issues commands to both volumes over the Fibre Channel network; however, commands issued to the direct-connection volume will fail, and IBM Tivoli Storage Productivity Center for Replication will show that the copy set that contains that volume has an error.

Use the following guidelines to add storage systems through a z/OS connection:

- Use the z/OS connection to manage ECKD volumes that are attached to an IBM Tivoli Storage Productivity Center for Replication management server running z/OS.
- To manage z/OS attached volumes through a z/OS connection (for example, for HyperSwap), you must explicitly add the z/OS connection for that storage system in addition to a TCP/IP connection (either the direct connection or the HMC connection).
- Create a z/OS connection before all TCP/IP connections if you want to continue to have IBM Tivoli Storage Productivity Center for Replication manage only the attached ECKD volumes.

**Tip:** It is recommended that you create both TCP/IP and z/OS connections for ECKD volumes to allow for greater storage accessibility.

## Protected volumes

You can mark volumes as protected if you do not want those volumes used for replication.

When a volume is marked as protected, you cannot include that volume in a copy set. This protection applies only to IBM Tivoli Storage Productivity Center for Replication.

You might want to protect a volume in the following instances:

- The volume contains data that you never want to be copied to another volume. For example, the volume is secure, but if the data is copied to an unsecured volume, the data could be read. For this reason, the volume should not be the source for a relationship.
- The volume contains data that you do not want to be overwritten. For this reason, the volume should not be the target of a relationship.

Only administrators can change the volume protection settings.

## Site awareness

You can associate a location with each storage system and each site in a session. This *site awareness* ensures that only the volumes whose location matches the location of the site are allowed for selection when you add copy sets to the session. This prevents a session relationship from being established in the wrong direction.

**Note:** To filter the locations for site awareness, you must first assign a site location to each storage system.

IBM Tivoli Storage Productivity Center for Replication does not perform automatic discovery of locations. Locations are user-defined and specified manually.

You can change the location associated with a storage system that has been added to the IBM Tivoli Storage Productivity Center for Replication configuration. You

can choose an existing location or add a new one. Locations are deleted when there is no longer a storage system with an association to that location.

When adding a copy set to a session, a list of candidate storage systems is presented, organized by location. Storage systems that do not have a location are displayed and available for use when you create a copy set.

You can also change the location for any site in a session. Changing the location of a session does not affect the location of the storage systems that are in the session.

Changing the location of a storage system might have consequences. When a session has a volume role with a location that is linked to the location of the storage system, changing the location of the storage system could change the session's volume role location. For example, if there is one storage system with the location of A\_Location and a session with the location of A\_Location for its H1 role, changing the location of the storage system to a different location, such as B\_Location, also changes the session's H1 location to Site 1. However, if there is a second storage system that has the location of A\_Location, the session's role location is not changed.

**Important:** Location matching is enabled only when adding copy sets. If you change the location of a storage system or volume role, IBM Tivoli Storage Productivity Center for Replication does not audit existing copy sets to confirm or deny location mismatches.

## Adding a storage connection

You can add one or more connections to a storage system. To replicate data among storage systems by using Tivoli Storage Productivity Center for Replication, you must add connections to the storage systems.

**Prerequisites:** You must have Administrator privileges to add a storage connection.

A single storage system can be connected by a combination of direct, management-console, and z/OS connections. Perform these steps to add a storage system connection:

1. In the navigation tree, select **Storage Systems**. The Storage Systems panel is displayed in the Storage Systems view.
2. Click **Add Storage Connection**. The Add Storage System wizard Type page is displayed.
3. Select the connection type that you want to use to add the storage systems and click **Next**. The Connection page is displayed.
4. Perform one of these steps depending on the type of storage connection that you selected:
  - **DS8000 / ESS 800 / DS6000 (Direct Connection):** Enter the IP address or domain name, port number, user name, and password for both cluster 0 and cluster 1 in the appropriate fields.

In a System Storage DS8000 environment, if resource groups are defined on the System Storage DS8000 that you are connecting to, the user name you define here must have the appropriate access level on the System Storage DS8000 to manage copy services for the volumes that are used by Tivoli Storage Productivity Center for Replication.

- **DS8000 (HMC Connection):** Enter the primary HMC IP address or domain, user name, password, and optionally the secondary HMC IP address or domain name in the appropriate fields.
- **SAN Volume Controller / Storwize V3500 / Storwize V3700 / Storwize V7000 / Storwize V7000 Unified (Direct Connection):** Click this button to add a single IBM System Storage SAN Volume Controller, IBM Storwize V3500, IBM Storwize V3700, IBM Storwize V7000, or IBM Storwize V7000 Unified cluster.

The following are considerations for connection:

- a. Authentication with the storage system cluster is performed by public key exchange. When adding a storage system cluster to the Tivoli Storage Productivity Center for Replication configuration, specify the user ID and password of an administrator on the cluster that has sufficient privileges to maintain the Secure Shell (SSH) keys.
- b. When a valid user name and password are specified, Tivoli Storage Productivity Center for Replication audits the public keys installed on the storage system cluster to ensure that the Tivoli Storage Productivity Center for Replication key has the correct access levels. If the key is not installed on the cluster, Tivoli Storage Productivity Center for Replication attempts to install the key. If you install the key yourself, install the public key found in the `WAS_HOME/profiles/ReplicationServerProfile/etc` directory on the storage system cluster by using the SSH Key Maintenance panel on the storage system graphical user interface. The public key ID is installed under `tpcr`.
- c. You must use a storage system cluster superuser user name and password to correctly receive indications from the storage system cluster.
- d. For Storwize V3500, Storwize V3700, Storwize V7000, Storwize V7000 Unified, or SAN Volume Controller version 5.0 or later, you must create a user ID through the storage system administration console on the cluster to which you want to attach Tivoli Storage Productivity Center for Replication. This user ID must have local authentication type and have the Administrator role authority.

- **XIV (Direct Connection):** Enter the IP address or domain name of the XIV system node. Enter a user name and password of a user with appropriate access rights to the XIV system.
- **z/OS (FICON Connection):** Select one or more storage systems from the list of candidate systems that match the selected storage type, or click **All** to select all storage systems. This option is displayed only for IBM Tivoli Storage Productivity Center for Replication for System z.

5. Click **Next**.

6. Click **Finish**.

**Related information:**

## Removing a storage connection

You can remove a single connection to a storage system from the IBM Tivoli Storage Productivity Center for Replication configuration.

**Prerequisites:** You must have Administrator privileges to remove a storage connection.

When removing a connection, the storage system might have other connections and therefore still be connected to IBM Tivoli Storage Productivity Center for Replication.

When removing a connection, all storage systems that rely on only that connection are removed. If a storage system is removed, the volumes for that storage system are removed from management server control. All copy sets with a volume on the removed storage systems are also removed from their respective sessions, making the target volume unrecoverable.

If Tivoli Storage Productivity Center for Replication has multiple connections to a specific storage system, the order in which you remove the connections produces different results:

- If you remove all direct and HMC connections first, the fixed block and non-attached ECKD volumes are removed from the Tivoli Storage Productivity Center for Replication configuration. The remaining ECKD volumes that are attached through the z/OS connection remain in the Tivoli Storage Productivity Center for Replication configuration until the z/OS connection is removed. Removing the TCP/IP connection also disables the Metro Mirror heartbeat.
- If you remove the z/OS connection first and if there is an HMC or direct connection to volumes, those volumes are not removed from the Tivoli Storage Productivity Center for Replication configuration.
- HyperSwap can run provided that volumes are attached and available to z/OS storage, even if you are using a TCP/IP connection to storage.

Perform one of these procedures to remove a storage connection:

1. In the navigation tree, select **Storage Systems**. The Storage Systems panel is displayed in the Storage Systems view.
2. Click the **Connections** tab.
3. Select the storage connection that you want to remove.

**Important:** If you choose to delete an HMC connection, all storage systems that share the HMC connection will also be removed.

4. Select **Remove Connection** from the **Actions** list, and click **Go**.
5. Click **Yes** to remove the storage system.

## Removing a storage system

You can remove a storage system from the IBM Tivoli Storage Productivity Center for Replication configuration.

**Prerequisites:** You must have Administrator privileges to remove a storage system.

Removing a storage system removes all volumes on that storage system from management server control. All copy sets with a volume on the removed storage system are removed from their respective sessions, making the target volume unrecoverable. All connections to the removed storage system are removed, and any storage systems sharing these connections are also removed.

Perform these steps to remove a storage system:

1. In the navigation tree, select **Storage Systems**. The Storage Systems panel is displayed in the Storage Systems view.
2. Select the storage system that you want to remove.

**Important:** All connections to this storage system will be removed, all volumes on the storage system will be removed from management server control, and all copy sets that have a volume on this storage system will be removed from their respective sessions, leaving the target volume unrecoverable. Any storage systems sharing these connections will be removed as well.

3. Select **Remove Storage System** from the **Actions** list, and click **Go**.
4. Click **Yes** to remove the storage system.

## Modifying the location of storage systems

You can associate a location with a storage system after a connection has been made to that storage system.

**Prerequisites:** You must have Administrator privileges to modify the location of a storage system.

Changing the location of a storage system might have consequences. When a session has a volume role with a location that is linked to the location of the storage system, changing the location of the storage system could change the session's volume role location. For example, if there is one storage system with the location of A\_Location and a session with the location of A\_Location for its H1 role, changing the location of the storage system to a different location, such as B\_Location, also changes the session's H1 location to Site 1. However, if there is a second storage system that has the location of A\_Location, the session's role location is not changed.

Perform these steps to modify the location of a storage system:

1. In the navigation tree, select **Storage Systems**. The Storage Systems panel is displayed in the Storage Systems view.
2. Change the location of the storage system by selecting a previously defined location from the drop-down list or type a new name in the table cell.

To disable site awareness, set the location to None.

**Note:** Locations are deleted from the drop-down list when there is no longer a storage system with an association to that location.

## Modifying storage connection properties

You can modify the connection properties for a storage system, including IP addresses, user name and password.

**Prerequisites:**

- You must have Administrator privileges to modify storage connection properties.
- The storage system must be in the Disconnected state to change most storage connection parameters. You can add a secondary HMC to an existing HMC connection without the HMC being disconnected.

A storage system can lose connection to the management server, for example, if a port is blocked by a firewall or the user name or password is changed on the storage system. If the storage system loses connection, you might need to modify parameters (for example, user name or password) manually on the storage system, and then update the parameters in IBM Tivoli Storage Productivity Center for Replication.

Perform these steps to modify storage connection properties:

1. In the navigation tree, select **Storage Systems**. The Storage Systems panel is displayed in the Storage Systems view.
2. Click the **Connections** tab.
3. Perform one of these steps to view details for a specific storage connection:
  - Click the storage connection ID.
  - Select the storage connection, click **View/modify Connection Details** from the actions list, and then click **Go**.
4. Modify the appropriate settings match the settings for the storage system.
5. Click **Apply** to continue making changes, and click **OK** when finished.

## Refreshing the storage system configuration

You can refresh the storage system configuration to query the storage system for changes, such as which volumes are contained in an LSS. You might do this when you reconfigure a storage system and you want IBM Tivoli Storage Productivity Center for Replication to be aware of the changes.

**Prerequisites:** You must have Administrator privileges to modify storage connection settings.

Perform these steps to refresh the storage configuration:

1. In the navigation tree, select **Storage Systems**. The Storage Systems panel is displayed in the Storage Systems view.
2. Select the storage system for which you want to refresh the configuration.
3. Select **Refresh Configuration** from the **Actions** list, and click **Go**.

## Setting volume protection

To ensure that data on a volume is not overwritten, you set its status to protected. Protected volumes are excluded from replication.

You must have Administrator privileges to change the protection setting of a volume.

1. In the navigation tree, select **Storage Systems**. The Storage Systems page is opened.
2. Click **Volume Protection**. The Volume Protection wizard is opened.
3. Select a storage system.
4. Optional: Depending on the type of storage system:
  - a. Select **All IO Groups** or a specific I/O group.
  - b. Select **All Logical Storage Subsystems** or a specific logical storage subsystem.
  - c. Select **All Pools** or a specific pool.
5. Optional: In the **Volume** field, select a single volume.
6. Optional: In the **Volume Mask** field, enter a sequence of characters and wildcards that match user-defined or system-defined volume IDs. To protect a specific volume, enter the volume ID such as ESS:2105.FCA57:VOL:1000. To use a pattern to retrieve one or more volume IDs, you can enter a partial volume ID and use the wildcard character (\*) to represent zero or more characters. For example, to retrieve all volume IDs that contain the characters FCA57, you enter \*FCA57\*.
7. Click **Next**.
8. Verify the search results, and click **Next**.

9. Click **Select All** to protect all the volumes. Alternatively, select a check box next to the volumes that you want to protect.
10. Click **Next**.
11. Click **Finish**.

## Restoring data from a journal volume

This topic provides information on restoring data from a journal (J) volume. It describes how to restore data from journal volume used as part of a ESS/DS6000/DS8000 Global Mirror session, or as part of a Metro Global Mirror session, if data was corrupted on a host volume after you issued a **Recover** command. Following these steps will enable you to return to a consistent copy of the data on the host volume.

Perform the following steps to move the data from the journal volume back to the host volume:

**Note:** Follow these instructions only if you have already issued a **Recover** command to the site containing the journal volume. After the **Recover** command is issued, the journal volume will hold a copy of the consistent data at the time the command was issued.

1. Outside of IBM Tivoli Storage Productivity Center for Replication, using the DS8000 GUI /CLI, issue withdraw initiate background copy (issue a **rmflash -cp** command) on pairs containing the journal volume (for example, H2J2). This copies the remaining uncopied tracks from the host to the journal. Then, ensure all the Out of Sync (OOS) tracks reach zero.
2. Create a separate FlashCopy session either with IBM Tivoli Storage Productivity Center for Replication, or with the DS8000 GUI /CLI (issue a **mkflash** command with background copy), with the following conditions:
  - The journal volume (Jx) is the source volume.
  - The host volume (Hx or Ix if using a session with Practice capabilities) is the target volume.
  - x is the site the **Recover** command was issued to.

---

## Managing host systems

*Host system* refers to an IBM AIX 5.3 or 6.1 server that is connected to IBM System Storage DS8000 devices. A connection from Tivoli Storage Productivity Center for Replication to the host system is used to enable the automatic swap of input/output (I/O) from the primary storage unit to the secondary storage unit in the case of a primary error.

A connection to the host system is required to use the Tivoli Storage Productivity Center for Replication Open HyperSwap feature. For the software and hardware required to support Open HyperSwap, see “Setting up the environment for Open HyperSwap” on page 101.

Connecting to a host system requires the IP address or host name of the system and the port number for communication. All connections are secured via a Secure Socket Layer (SSL) connection.

**Restriction:** Open HyperSwap is not supported for AIX host servers that are in a clustered environment such as PowerHA (previously known as HACMP).

**Related tasks:**

“Managing a session with HyperSwap and Open HyperSwap replication” on page 100

HyperSwap and Open HyperSwap provide high availability of data if a primary disk storage system failure occurs. When a failure occurs in writing I/O to the primary storage system, the failure is detected by IOS, and IOS automatically swaps the I/O to the secondary site with no user interaction and minimal application effect.

## Adding a host system connection

You can add a connection to one or more host systems to the IBM Tivoli Storage Productivity Center for Replication configuration.

**Prerequisites:** You must have Administrator privileges to add a host system connection.

For the software and hardware required to support Open HyperSwap, see “Setting up the environment for Open HyperSwap” on page 101.

Perform these steps to add a host system connection:

1. In the navigation tree, select **Host Systems**. The Host Systems panel is displayed.
2. Click **Add Host Connection**. The Add Host Connection dialog box is displayed.
3. Enter the host name or IP address and the port for the host system and click **Add Host**. The host system is displayed on the Host Systems panel. The default port is 9930. Unless the port has been modified in Subsystem Device Driver Path Control Module (SDDPCM), use the default port.

The host system is displayed in the Host System table. If the connection is successful, the status **Connected** is displayed for the connection. If the connection was not successful, the status **Disconnected** is displayed.

## Modifying a host system connection

You can modify host system connections in the IBM Tivoli Storage Productivity Center for Replication configuration.

**Prerequisites:** You must have Administrator privileges to modify a host system connection and the connection must be in a disconnected state.

Perform these steps to modify a host system connection:

1. In the navigation tree, select **Host Systems**. The Host Systems panel is displayed.
2. Select the host system connection that you want to modify.
3. Select **Modify Host Connection** from the **Select Action** list, and click **Go**.
4. Modify the information that is presented for the host system and click **Update Host**. The updated host system information is displayed on the Host Systems panel.

The updated host system information is displayed in the Host System table. If the connection is successful, the status **Connected** is displayed for the connection. If the connection was not successful, the status **Disconnected** is displayed.

## Removing a host system connection

You can remove host system connections from the IBM Tivoli Storage Productivity Center for Replication configuration.

**Prerequisites:** You must have Administrator privileges to remove a host system.

Removing a host system connection disables the ability to use Open HyperSwap. Any session using the host system to provide Open HyperSwap capabilities can no longer communicate with the host and Open HyperSwap is disabled for the entire session.

Perform these steps to remove a host system connection:

1. In the navigation tree, select **Host Systems**. The Host Systems panel is displayed.
2. Select the host system connection that you want to remove.
3. Select **Remove Host Connection** from the **Select Action** list, and click **Go**.
4. Click **OK** to remove the host system connection.

## Removing a session from a host system connection

You can remove a session that is associated with a host system from the IBM Tivoli Storage Productivity Center for Replication configuration. Once removed, the host no longer recognizes the session that is managing the volumes attached to that host. This function is to be used primarily for cleanup purposes.

When a session has Open HyperSwap enabled, the session communicates with the host system and the host system stores an association to that session on the IBM Tivoli Storage Productivity Center for Replication server. If the Tivoli Storage Productivity Center for Replication server that made the association becomes inaccessible, it might be necessary to clean up and remove the session association from a different Tivoli Storage Productivity Center for Replication server.

If a host system has an associated session, the session name is displayed in the **Sessions** column of the Host Systems table. If the session is a session that is currently defined on the Tivoli Storage Productivity Center for Replication server, the session name is displayed as a link. The link opens the Session Details panel.

If the session name is not a session on the server, an icon is displayed. This session must be removed because the host system can support only a single session association. The session association must be removed before a Tivoli Storage Productivity Center for Replication server can re-establish capabilities with the host system.

**Prerequisites:** You must have Administrator privileges to remove a host system.

Perform these steps to remove session association from a host system connection:

1. In the navigation tree, select **Host Systems**. The Host Systems panel is displayed.
2. Select the host system connection that contains the session that you want to remove.
3. Select **Remove Session Association** from the **Select Action** list, and click **Go**.
4. Click **OK** to remove the host system connection.

The session name is removed from the **Session** column on the Host Systems table.

---

## Managing logical paths

Logical paths define the relationship between a source logical subsystem (LSS) and a target LSS that is created over a physical path. To configure logical paths for TotalStorage Enterprise Storage Server, System Storage DS8000, and DS6000, use the ESS/DS Paths panel in Tivoli Storage Productivity Center.

To configure partnerships for the following storage systems, use the graphical user interface (GUI) or command-line interface (CLI) for the storage system:

- SAN Volume Controller
- Storwize V3500
- Storwize V3700
- Storwize V7000
- Storwize V7000 Unified
- The XIV system

## Viewing logical paths

You can view all logical paths that are defined on an IBM TotalStorage Enterprise Storage Server, IBM System Storage DS8000, or IBM System Storage DS6000 storage system.

Perform one of these procedures to view logical paths:

- From the ESS/DS Paths panel of IBM Tivoli Storage Productivity Center for Replication:
  1. In the navigation tree, select **ESS/DS Paths**. The ESS/DS Paths panel is displayed.
  2. Click the storage system ID to display logical paths for that storage system.
- From the Storage Systems panel:
  1. In the navigation tree, select **Storage Systems**. The Storage Systems panel is displayed in the Storage Systems view.
  2. Select an ESS, DS6000, or DS8000 storage system for which you want to view logical paths.
  3. Select **View Paths** from the **Select Action** list, and click **Go**. The ESS/DS Paths panel is displayed with a list of defined logical paths.

## Adding logical paths

This topic describes how to add IBM TotalStorage Enterprise Storage Server, IBM System Storage DS8000, and IBM System Storage DS6000 logical paths.

Ensure that you have defined the appropriate storage systems on the Storage Systems panel.

Perform these steps to add logical paths:

1. In the IBM Tivoli Storage Productivity Center for Replication navigation tree, select **ESS/DS Paths**.
2. Click **Manage Paths**. The Path Management wizard is displayed.
3. From the drop-down boxes in the Path Management wizard, select the source storage system, source logical storage system, target storage system, and target logical storage system. Then, click **Next**.

4. From the drop-down boxes in the Path Management wizard, select the source port and target port and click **Add**. You can add multiple paths between the logical storage subsystems, or just one at a time. When you have made your selections, click **Next**.
5. Confirm your selections and click **Next**.
6. Verify the remaining wizard panels and click **Next**.
7. Click **Finish**.

## Adding logical paths using a CSV file

You can create a comma separated (CSV) file to define logical paths. The CSV file specifies storage systems pairings and associated port pairings that are used for replication. IBM Tivoli Storage Productivity Center for Replication uses the port pairings defined in the CSV file to establish logical paths

Perform these steps to add IBM TotalStorage Enterprise Storage Server, IBM System Storage DS8000, and IBM System Storage DS6000 logical paths using a CSV file:

1. Create a CSV file named portpairings.csv in the *WAS\_HOME/profiles/ReplicationServerProfile/properties* directory. You can create the CSV file in a spreadsheet such as Microsoft Excel or in a text editor. An example CSV file is as follows:

```
#
Example CSV file
#
2107.04131:2107.01532,0x0331:0x0024,0x0330:0x0100,0x0331:0x000C
2107.05131:2107.01532,0x0330:0x0029,0x0331:0x0001
```

Each line represents a storage system to storage system pairing. The first value represents the storage systems, which are delimited by a colon. The remaining values are the port pairs, which are delimited by a colon. All values are separated by a comma. Commented lines must start with #,

2. To enable the changes in the file, perform a task that requires new paths to be established. For example, suspend a session to remove the logical paths and then issue the **Start H1->H2** command to enable the paths to use the port pairings in the CSV file.

### Considerations when creating and using the CSV file:

- The CSV file does not affect Global Mirror control paths.
- Port mapping is bi-directional. A logical path is established from system A to system B and from system B to system A depending on the direction of the pairs on the hardware.
- If the CSV file contains multiple lines that specify the same storage system to storage system pairing, Tivoli Storage Productivity Center for Replication uses the last line. This rule applies regardless of the order of the storage system pairing. For example, if you have storage systems 2107.04131:2107.01532 defined on the first line of the CSV file and then have 2107.01532:2107.04131 defined on the second line, Tivoli Storage Productivity Center for Replication uses second line.
- If a line in the CSV contains information that is not formatted correctly, the line is ignored. This rule includes lines that specify storage systems but do not include ports or include ports that are not formatted correctly.

- If the CSV file contains valid and invalid port pairs, the valid port pairs might or might not be established. Invalid port pairs can cause the following errors to be displayed in the Tivoli Storage Productivity Center for Replication console and in the ESS/DS Paths panel:

- Return Code F52: This error is displayed if a port is invalid.
- Return Code 0400: This error is displayed if a port is invalid and out of the range for the device.

Other storage system error codes might be displayed also, depending on the path topology, types of paths, and the incorrect port pairings specified in the CSV file.

- If the CSV file contains no valid port pairs, no logical paths are established and subsequent commands to the storage systems that require logical paths might fail. If there are existing logical paths for a storage system, those paths are used until they are removed.

## Removing logical paths

This topic describes how to remove IBM TotalStorage Enterprise Storage Server, IBM System Storage DS8000, and IBM System Storage DS6000 logical paths.

1. In the IBM Tivoli Storage Productivity Center for Replication navigation tree, select **ESS/DS Paths**.
2. Click the link for the storage system that contains the paths that you want to remove.
3. Select the paths that you want to remove.
4. From the drop-down box, select **Remove**.
5. Click **Go**.

---

## Setting up data replication

This topic describes the how to set up data replication in your environment, including creating sessions and adding copy sets to those sessions.

A *session* is a container of multiple copy sets managed by a replication manager. A *copy set* is a set of volumes that contain copies of the same data. All the volumes in a copy set are the same format (count key data [CKD] or fixed block) and size. In a replication session, the number of volumes in a copy set and the role that each volume in the copy set plays are determined by the session type.

## Sessions

A *session* is used to perform a specific type of data replication against a specific set of volumes. The source volume and target volumes that contain copies of the same data are collectively referred to as a copy set. A session can contain one or more copy sets.

The type of data replication that is associated with the session determines the actions that you can perform against all copy sets in the session, the number of volumes that a copy set can contain, and the role that each volume plays.

**Attention:** Use only the Tivoli Storage Productivity Center for Replication graphical user interface (GUI) or command-line interface CLI to manage session relationships, such as volume pairs and copy sets. Do not modify session relationships through other interfaces such as the System Storage DS CLI. If you modify relationships through other interfaces, a loss of consistency can occur

across the relationships that are managed by the session. The exceptions to this requirement are failover operations that are managed by external applications for certain session and storage system types as described in “Failover and failback operations” on page 705.

## Copy sets

During data replication, data is copied from a source volume to one or more target volumes, depending on the session type. The source volume and target volumes that contain copies of the same data are collectively referred to as a *copy set*.

Each volume in a copy set must be of the same size and volume type (for example, 3380 volumes must be used with other 3380 volumes and SAN Volume Controller volumes must be used with other SAN Volume Controller volumes). The number of volumes in the copy set and the role that each volume plays is determined by the session type (or copy type) that is associated with the session to which the copy set belongs.

Use the Add Copy Sets wizard to add copy sets to an existing session. You can select a storage system; a logical subsystem (LSS), I/O group, or pool; or single volume for each role and then create one or more copy sets for the session.

You can use one of the following volume pairing options to automatically create multiple copy sets in the same session.

### **Storage system matching (System Storage DS8000, System Storage DS6000, or TotalStorage Enterprise Storage Server Model 800 Metro Mirror sessions only)**

Creates copy sets by matching volumes (based on the volume IDs) across all logical subsystems (LSSs) for the selected storage systems. For example, volume 01 on the source LSS is matched with volume 01 on the target LSS.

You cannot select the storage system and select **All Logical Subsystems** in the list of LSSs. You can also do auto-matching at the LSS level for Metro Mirror sessions.

### **LSS, I/O group, or pool matching**

Creates copy sets by matching all volumes based on the selected LSS, I/O group, or pool for each role in copy set.

Select the storage system and LSS, I/O group, or pool, and then select **All Volumes** in the **Volume** list.

If you do not want to use the auto-generated volume pairing for a copy set, clear that copy set so that it is not added during the wizard. Then, add the remaining copy sets and reopen the Add Copy Set wizard and manually enter the volume pairings that you want.

Invalid copy sets are not added to the session. Copy sets can be invalid if their volumes are not the same type or size.

You can remove copy sets that you do not want to add to the session, even if they are valid. This process enables you to filter and eliminate unwanted copy sets before they are added to the session.

You can export the copy sets to take a snapshot of your session at a particular point in time for backup purposes.

**Note:** You can copy an entire storage system only for Metro Mirror sessions.

## Considerations for adding copy sets

When you create a copy set for a session, a warning is displayed if one or more of the selected volumes exist in another session. If the volume you selected is in another session, confirm whether you want to add the volume to this session. Ensure that you intend to have the volume in multiple sessions because having the volume in multiple sessions can create conflicts. A scenario in which you would want the same volumes in multiple sessions is one in which you create a session for normal replication and then create another session for a disaster recovery practice. You must use the same target volumes in both sessions.

You can use extent space-efficient volumes as copy set volumes for the following System Storage DS8000 session types. Extent space-efficient volumes must be fixed block (FB). You cannot use count key data (CKD) volumes.

### FlashCopy (System Storage DS8000 6.2 or later)

You can use a combination of extent space-efficient and other volume types as source and target volumes in the copy set.

### Metro Mirror (System Storage DS8000 6.3 or later)

If you use an extent space-efficient volume as a source or target volume in the copy set, you must use extent space-efficient volumes for all source and target volumes in the copy set.

### Global Mirror or Metro Global Mirror (System Storage DS8000 6.3 or later)

You can use extent space-efficient volumes as source, target, and journal volumes. If you use an extent space-efficient volume as a source or target volume in the copy set, you must use extent space-efficient volumes for all source and target volumes in the copy set. In this situation, the journal volumes can be extent space-efficient volumes, track space-efficient volumes, or a combination of both volume types. If extent space-efficient volumes are not used as source or target volumes, journal volumes can be extent space-efficient, track space-efficient, and other types of volumes.

## Considerations for removing copy sets

You remove a copy set or range of copy sets by selecting the following items:

- Source volume
- LSS, I/O group, or pool
- Storage system

When the list of copy sets that meet your criteria is displayed, you can select the copy sets that you want to remove.

The consequence of removing copy sets varies depending on the state of the session:

### Defined

There is no relationship on the hardware. The copy set is removed from Tivoli Storage Productivity Center for Replication data store.

### Preparing or Prepared

The copy set is currently copying data, so Tivoli Storage Productivity Center for Replication terminates the hardware relationship for the copy set. The rest of the copy sets continue to run uninterrupted.

### Suspended or Target Available

Any existing relationships on the hardware are removed for the copy set.

Before removing all copy sets from that session, terminate the session. Removing the copy sets when the session is active can considerably increase the amount of time it takes for the copy set removal to complete. Copy sets are removed one at a time, and when the session is active, commands are issued to the hardware. However, if you terminate the session first, then commands are not issued to the hardware and the removal process completes faster.

**Tip:** When you a remove copy set from Tivoli Storage Productivity Center for Replication, you might want to keep hardware relationships on the storage systems. These relationships are useful when you want to migrate from one session type to another or when resolving problems. For more information about keeping the hardware relationships when removing copy sets, see *Removing Copy Sets*.

The behavior that occurs when a copy set is removed varies depending on the storage system:

**ESS 800, DS6000, and DS8000:**

- The complete copy set is removed from Tivoli Storage Productivity Center for Replication.
- Any peer-to-peer remote copy (PPRC) pair that is part of a Global Mirror consistency group is removed from the consistency group on the storage system.
- If the PPRC pair is part of a Global Mirror consistency group and is the last remaining source volume in a subordinate session, the subordinate session is removed from the storage system.
- If the PPRC pair is the last remaining participant in a Global Mirror session, the Global Mirror session is removed from the storage system.
- Any PPRC relationship remains on the storage system.
- A Metro Mirror (synchronous PPRC) pair that is in a HyperSwap configuration is removed from that configuration but the pair remains on the hardware.
- FlashCopy relationship remains on the storage system if the hardware has not completed any background copy.

**SAN Volume Controller, Storwize V3500, Storwize V3700, Storwize V7000, Storwize V7000 Unified, or the XIV system**

- The complete copy set is removed from Tivoli Storage Productivity Center for Replication.
- FlashCopy, Metro Mirror, and Global Mirror relationships are pulled out of their consistency group. If they are the last remaining relationship in a consistency group, that consistency group is removed from the hardware.

When you specify the force removal option, all knowledge of the specified copy set is removed from Tivoli Storage Productivity Center for Replication, even if the relationship itself still exists. In this situation, you are not able to remove the relationship using Tivoli Storage Productivity Center for Replication, because no information about the relationship exists. If you force a removal of a copy set and the removal fails, you must manually remove the relationship from the hardware. If you do not, you cannot to create new relationships.

One benefit of forcing a removal of the copy sets is that Tivoli Storage Productivity Center for Replication does not manage the consistency of copy sets that it has no

knowledge of. This means that additional commands to the session do not affect the removed copy sets, even though they are still in a relationship on the hardware.

If you do not specify the force removal option and an error occurs that prevents the hardware relationships from being removed, the copy set is not removed from Tivoli Storage Productivity Center for Replication. The copy set remains as part of the session, and you can still perform actions on it.

### **Volume roles**

Volume roles are given to every volume in the copy set. The role defines how the volume is used in the copy set and, for multi-site sessions, the site location of the volume. For example, the H1 role is made up of host-attached volumes that are located at the primary site.

The site determines the location of the volumes. The number of sites in a copy set is determined by the type of data replication (also known as the session type) that is associated with the session. Tivoli Storage Productivity Center for Replication supports up to three sites:

- Site 1** The location of the primary storage that contain the source data. Upon initial configuration, this site contains the host volumes with updates that are copied to the target volumes.
- Site 2** The location of the secondary storage that receives the copy updates from the primary storage.
- Site 3** (Metro Global Mirror only) The location of the tertiary storage that receives data updates from the secondary storage.

The volume roles that are needed in a copy set are determined by the type of replication that is associated with the session. Tivoli Storage Productivity Center for Replication supports these volume roles:

#### **Host volume**

A volume that is connected to a server that reads and writes I/O. A host volume can be the source of updated tracks when the server connected to the host volume is actively issuing read and write input/output (I/O). A host volume can also be the target of the replication. When the host volume is the target, writes are inhibited.

Host volumes are abbreviated as H $x$ , where  $x$  identifies the site.

#### **Journal volume**

A volume that stores data that has changed since the last consistent copy was created. This volume functions like a journal and holds the required data to reconstruct consistent data at the Global Mirror remote site. When a session must be recovered at the remote site, the journal volume is used to restore data to the last consistency point. A FlashCopy replication session can be created between the host or intermediate volume and the corresponding journal volume after a recover request is initiated to create another consistent version of the data.

Journal volumes are abbreviated as J $x$ , where  $x$  identifies the site.

#### **Intermediate volume**

A volume that receives data from the primary host volume during a replication with practice session. During a practice, data on the intermediate volumes is flash copied to the practice host volumes.

Depending on the replication method being used, data on intermediate volumes might not be consistent.

Intermediate volumes are abbreviated as Ix, where x identifies the site.

### **Target volume**

(FlashCopy only) A volume that receives data from a source, either a host or intermediate volume. Depending on the replication type, that data might or might not be consistent. A target volume can also function as a source volume. For example, a common use of the target volume is as a source volume to allow practicing for a disaster (such as data mining at the recovery site while still maintaining disaster recovery capability at the production site).

### **Role pairs**

A *role pair* is the association of two volume roles in a session that take part in a copy relationship. For example, in a Metro Mirror session, the role pair can be the association between host volumes at the primary site and host volumes at the secondary site (H1-H2).

The flow of data in the role pair is shown using an arrow. For example, H1>H2 denotes that H1 is the source and H2 is the target.

*Participating role pairs* are role pairs that are currently participating in the session's copy.

*Non-participating role pairs* are role pairs that are not actively participating in the session's copy.

Snapshot sessions do not use role pairs.

### **Practice volumes**

You can use a *practice volume* to practice what you would do in the event of a disaster, without interrupting current data replication. Practice volumes are available in Metro Mirror, Global Mirror, and Metro Global Mirror sessions.

To use the practice volumes, the session must be in the prepared state. Issuing the Flash command against the session while in the Prepared state creates a usable practice copy of the data on the target site.

**Note:** You can test disaster-recovery actions without using practice volumes; however, without practice volumes, you cannot continue to copy data changes between volumes while testing disaster-recovery actions.

### **Consistency groups**

For Global Mirror and Metro Global Mirror sessions, IBM Tivoli Storage Productivity Center for Replication manages the consistency of dependant writes by creating a consistent point-in-time copy across multiple volumes or storage systems. A *consistency group* is a set of target volumes in a session that have been updated to preserve write order and are therefore recoverable.

*Data exposure* is the period when data is written to the storage at the primary site until data is replicated to storage at the secondary site. Data exposure is influenced by factors such as:

- Requested consistency-group interval time
- Type of storage systems
- Physical distance between the storage systems

- Available bandwidth of the data link
- Input/output (I/O) load on the storage systems

To manage data exposure, you can change the consistency group interval time. The *consistency group time interval* specifies how often a Global Mirror and Metro Global Mirror session attempts to form a consistency group. When you reduce this value, it might be possible to reduce the data exposure of the session. A smaller interval value causes the session to attempt to create consistency groups more frequently, which might also increase the processing load and message-traffic load on the storage systems.

### Failover and failback operations

If a session has *failover* and *failback* capabilities, you can perform a site switch in which you move the operation of Tivoli Storage Productivity Center for Replication from one site to another, and change the direction of the copy without completing a full copy.

Failover is the process of temporarily switching production to a backup facility following a scheduled maintenance period or a disaster at a production site. A failover operation can be followed by a failback operation, which is the process of returning production to its original location and resuming the copy between the two sites.

The failover and failback operations use remote mirror and copy functions for these tasks:

- To reduce the time that is required to synchronize volumes after switching sites during planned or unplanned outages.
- To eliminate the need to perform a full volume copy from the recovery site to the production site, which can reduce the time that is required to resume operations at the production site.

### Failover operations that are managed by other applications

Applications such as the IBM Series i Toolkit, VMware Site Recovery Manager, and Veritas Cluster Server can also manage failover operations for the session types that are listed in the following table.

| Session type                   | Storage systems                                                                                                                                                                                                                                  |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Metro Mirror Single Direction  | <ul style="list-style-type: none"> <li>• System Storage DS8000</li> <li>• System Storage DS6000</li> <li>• System Storage SAN Volume Controller</li> <li>• Storwize V7000</li> <li>• Storwize V7000 Unified</li> </ul>                           |
| Metro Mirror Failover/Failback | <ul style="list-style-type: none"> <li>• System Storage DS8000</li> <li>• System Storage DS6000</li> <li>• System Storage SAN Volume Controller</li> <li>• Storwize V7000</li> <li>• Storwize V7000 Unified</li> <li>• The XIV system</li> </ul> |

| Session type                                          | Storage systems                                                                                                                                                                                                                                  |
|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Metro Mirror Failover/Failback with Practice          | <ul style="list-style-type: none"> <li>• System Storage DS8000</li> <li>• System Storage DS6000</li> <li>• System Storage SAN Volume Controller</li> <li>• Storwize V7000</li> <li>• Storwize V7000 Unified</li> </ul>                           |
| Global Mirror Single Direction                        | <ul style="list-style-type: none"> <li>• System Storage DS8000</li> <li>• System Storage DS6000</li> <li>• System Storage SAN Volume Controller</li> <li>• Storwize V7000</li> <li>• Storwize V7000 Unified</li> </ul>                           |
| Global Mirror Either Direction with Two-Site Practice | <ul style="list-style-type: none"> <li>• System Storage DS8000</li> <li>• System Storage DS6000</li> </ul>                                                                                                                                       |
| Global Mirror Failover/Failback                       | <ul style="list-style-type: none"> <li>• System Storage DS8000</li> <li>• System Storage DS6000</li> <li>• System Storage SAN Volume Controller</li> <li>• Storwize V7000</li> <li>• Storwize V7000 Unified</li> <li>• The XIV system</li> </ul> |
| Global Mirror Failover/Failback with Practice         | <ul style="list-style-type: none"> <li>• System Storage DS8000</li> <li>• System Storage DS6000</li> <li>• System Storage SAN Volume Controller</li> <li>• Storwize V7000</li> <li>• Storwize V7000 Unified</li> </ul>                           |

If an application completes a failover operation for a session, the Severe status is displayed for the session on the Session Details page in Tivoli Storage Productivity Center for Replication and an error message is generated for the role pairs for which the failover occurred. To view the error message:

1. On the Session Details page, click the link for each role pair for which the failover occurred.
2. On the Role Pair Details page, click the **Show** link for each role pair. This link is in the **Details** column.

To change the session status to Normal, use the application to confirm that the role pairs that are in the session are consistent and then restart the session.

## Session Types

Tivoli Storage Productivity Center for Replication provides several methods to replicate data. The type of data replication that is associated with a session is known as the *session type*.

The session types that are available depend on the storage system type and the edition of Tivoli Storage Productivity Center or Tivoli Storage Productivity Center for Replication that you are using as shown in this topic.

## Basic HyperSwap

Basic HyperSwap is a copy services solution for IBM z/OS version 1.9 and later. Basic HyperSwap provides high availability of data if a storage system failure occurs.

The Basic HyperSwap session type enables Tivoli Storage Productivity Center for Replication to manage Basic HyperSwap by using Metro Mirror or Metro Global Mirror replication.

For more information about the Basic HyperSwap session type, see “Basic HyperSwap (ESS, DS6000, and DS8000)” on page 83.

Basic HyperSwap sessions are available for the following Tivoli Storage Productivity Center for Replication editions and storage systems.

*Table 60. Basic HyperSwap*

| Supported editions                                                                                                                                                                                        | Supported storage systems                                                                                                                                          |

## FlashCopy

FlashCopy replication creates a point-in-time copy of the data on a source volume to a target volume. Data that existed on the target volume is replaced by the copied data.

For more information about the FlashCopy session type, see “FlashCopy” on page 84.

FlashCopy sessions are available for the following Tivoli Storage Productivity Center and Tivoli Storage Productivity Center for Replication editions and storage systems.

*Table 61. FlashCopy*

| Supported editions                                                                                                                                                                                                                                                     | Supported storage systems                                                                                                                                                                                                                                                                                      |

## Snapshot

Snapshot replication creates a point-in-time copy of a volume or set of volumes without having to define a specific target volume. The target volumes of a Snapshot session are automatically created when the snapshot is created.

For more information about the Snapshot session type, see “Snapshot” on page 85.

Snapshot sessions are available for the following Tivoli Storage Productivity Center and Tivoli Storage Productivity Center for Replication editions and storage systems.

*Table 62. Snapshot*

| Supported editions                                                                                                                                                                                                                                                     | Supported storage systems |

## Metro Mirror Single Direction

Metro Mirror is synchronous replication that operates between two sites that are up to 300 KM apart. The source volumes are on one storage system and the target volumes are on another storage system.

Metro Mirror replication maintains identical data in both the source and target volumes. When a write operation is issued to a source volume, the changes are propagated to the target volume before the write operation finishes processing.

With the Metro Mirror Single Direction session type, Metro Mirror replication is available only from the primary site.

For more information about the Metro Mirror Single Direction session type, see “Metro Mirror” on page 86.

Metro Mirror Single Direction sessions are available for the following Tivoli Storage Productivity Center for Replication editions and storage systems.

*Table 63. Metro Mirror Single Direction*

## Metro Mirror Failover/Failback

Metro Mirror Failover/Failback replication enables you to switch the direction of the data flow so that you can use your secondary site as your production site. You can then copy changes that are made at the secondary site back to the primary site.

For more information about the Metro Mirror Failover/Failback session type, see “Metro Mirror” on page 86.

Metro Mirror Failover/Failback sessions are available for the following Tivoli Storage Productivity Center for Replication editions and storage systems.
