AIX Version 7.2

Base Operating System (BOS) Runtime Services

Note

Before using this information and the product it supports, read the information in “Notices” on page 2387.

This edition applies to AIX Version 7.2 and to all subsequent releases and modifications until otherwise indicated in new editions.

Contents

About this document

This document provides users and system administrators with complete information about AIX Base Operating System Runtime Services.

Highlighting

The following highlighting conventions are used in this document:

Bold	Identifies commands, subroutines, keywords, files, structures, directories, and other items whose names are predefined by the system. Also identifies graphical objects such as buttons, labels, and icons that the user selects.
Italics	Identifies parameters whose actual names or values are to be supplied by the user.
`Monospace`	Identifies examples of specific data values, examples of text similar to what you might see displayed, examples of portions of program code similar to what you might write as a programmer, messages from the system, or information you should actually type.

Case-sensitivity in AIX

Everything in the AIX® operating system is case-sensitive, which means that it distinguishes between uppercase and lowercase letters. For example, you can use the **ls** command to list files. If you type LS, the system responds that the command `is not found`. Likewise, **FILEA**, **FiLea**, and **filea** are three distinct file names, even if they reside in the same directory. To avoid causing undesirable actions to be performed, always ensure that you use the correct case.

ISO 9000

ISO 9000 registered quality systems were used in the development and manufacturing of this product.

Base Operating System (BOS) Runtime Services

This topic collection contains information, for experienced C programmers, about system calls, subroutines, functions, macros, and statements associated with base operating system runtime services.

The AIX operating system is designed to support The Open Group's Single UNIX Specification Version 3 (UNIX 03) for portability of operating systems based on the UNIX operating system. Many new interfaces, and some current ones, have been added or enhanced to meet this specification. To determine the correct way to develop a UNIX 03 portable application, see The Open Group's UNIX 03 specification on The UNIX System website (http://www.unix.org).

What's new in AIX 7.2

Read about new or significantly changed information for the AIX 7.2 operating system.

How to see what's new or changed

To help you see where technical changes have been made, the AIX 7.2 information uses:

- The >| image to mark where new or changed information begins.
- The |< image to mark where new or changed information ends.

November 2020

The following information is a summary of the updates made to this topic collection:

- Added information about the `locobj` argument in the duplocale topic.
- Added information about the `EOVERFLOW` error code in the printf topic.
- Update the information about the `RLIMIT_AS` resource parameter in the getrlimit_64 and kgettrlimit64 topics.
- Added information about the pthread_mutexattr_getrobust_setrobust and pthread_mutex_consistent. Updated information about the behavior description for the robust mutex and added new error code values in the pthread_mutex_lock and pthread_mutex_timedlock topics. Also, added new error code values in the pthread_mutex_getprioceiling and pthread_cond_wait topics.
- Added information about the `pollest.h` header file in the pollset topic. The file defines structures and flags that are used by `pollset` subroutines.
- Updated information about the items %c, %y and %Y in the strptime topic.

November 2019

The following information is a summary of the updates made to this topic collection:

- Updated information about the `ffsl()`, `ffsll()` APIs and `libc` in the bcopy, bcmp, bzero, ffs, ffsl, or ffsll Subroutine topic.
- Added information about a new subroutine in pthread_rwlock_attr_setfavorwriters_np or pthread_rwlock_attr_getfavorwriters_np Subroutine topic.
- Added information about the **`strftime_l`** subroutine in the strftime or strftime_l Subroutine topic.

a

The following Base Operating System (BOS) runtime services begin with the letter *a*.

a64l or l64a Subroutine

Purpose

Converts between long integers and base-64 ASCII strings.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdlib.h>
```

long a64l (*String*)
char ***String**;

char *l64a (*LongInteger*)
long *LongInteger*;

Description

The **a64l** and **l64a** subroutines maintain numbers stored in base-64 ASCII characters. This is a notation in which long integers are represented by up to 6 characters, each character representing a digit in a base-64 notation.

The following characters are used to represent digits:

Character	Description
.	Represents 0.
/	Represents 1.
0 -9	Represents the numbers 2-11.
A-Z	Represents the numbers 12-37.
a-z	Represents the numbers 38-63.

Parameters

Item	Description
String	Specifies the address of a null-terminated character string.
LongInteger	Specifies a long value to convert.

Return Values

The **a64l** subroutine takes a pointer to a null-terminated character string containing a value in base-64 representation and returns the corresponding **long** value. If the string pointed to by the *String* parameter contains more than 6 characters, the **a64l** subroutine uses only the first 6.

Conversely, the **l64a** subroutine takes a **long** parameter and returns a pointer to the corresponding base-64 representation. If the *LongInteger* parameter is a value of 0, the **l64a** subroutine returns a pointer to a null string.

The value returned by the **l64a** subroutine is a pointer into a static buffer, the contents of which are overwritten by each call.

If the **String* parameter is a null string, the **a64l** subroutine returns a value of 0L.

If *LongInteger* is 0L, the **l64a** subroutine returns a pointer to a null string.

abort Subroutine

Purpose

Sends a **SIGIOT** signal to end the current process.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdlib.h>
```

```
int abort (void)
```

Description

The **abort** subroutine sends a **SIGIOT** signal to the current process to terminate the process and produce a memory dump. If the signal is caught and the signal handler does not return, the **abort** subroutine does not produce a memory dump.

If the **SIGIOT** signal is neither caught nor ignored, and if the current directory is writable, the system produces a memory dump in the **core** file in the current directory and prints an error message.

The abnormal-termination processing includes the effect of the **fclose** subroutine on all open streams and message-catalog descriptors, and the default actions defined as the **SIGIOT** signal. The **SIGIOT** signal is sent in the same manner as that sent by the **raise** subroutine with the argument **SIGIOT**.

The status made available to the **wait** or **waitpid** subroutine by the **abort** subroutine is the same as a process terminated by the **SIGIOT** signal. The **abort** subroutine overrides blocking or ignoring the **SIGIOT** signal.

Note: The **SIGABRT** signal is the same as the **SIGIOT** signal.

Return Values

The **abort** subroutine does not return a value.

abs, div, labs, ldiv, imul_dbl, umul_dbl, llabs, or lldiv Subroutine

Purpose

Computes absolute value, division, and double precision multiplication of integers.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdlib.h>
```

```
int abs ( i  )
int i;
```

```
#include <stdlib.h>
```

```
long labs ( i )
long i;
```

```
#include <stdlib.h>
```

```
div_t div ( Numerator,  Denominator)
int Numerator: Denominator;
```

```
#include <stdlib.h>
```

```
void imul_dbl ( i,  j,  Result)
long i, j;
long *Result;
```

```
#include <stdlib.h>
```

```
ldiv_t ldiv (Numerator, Denominator)
long Numerator: Denominator;
```

```
#include <stdlib.h>
```

```
void umul_dbl (i, j, Result)
unsigned long i, j;
unsigned long *Result;
```

```
#include <stdlib.h>
```

```
long long int llabs(i)
long long int i;
```

```
#include <stdlib.h>
```

```
lldiv_t lldiv (Numerator, Denominator)
long long int Numerator, Denominator;
```

Description

The **abs** subroutine returns the absolute value of its integer operand.

Note: A twos-complement integer can hold a negative number whose absolute value is too large for the integer to hold. When given this largest negative value, the **abs** subroutine returns the same value.

The **div** subroutine computes the quotient and remainder of the division of the number represented by the *Numerator* parameter by that specified by the *Denominator* parameter. If the division is inexact, the sign of the resulting quotient is that of the algebraic quotient, and the magnitude of the resulting quotient is the largest integer less than the magnitude of the algebraic quotient. If the result cannot be represented (for example, if the denominator is 0), the behavior is undefined.

The **labs** and **ldiv** subroutines are included for compatibility with the ANSI C library, and accept long integers as parameters, rather than as integers.

The **imul_dbl** subroutine computes the product of two signed longs, *i* and *j,* and stores the double long product into an array of two signed longs pointed to by the *Result* parameter.

The **umul_dbl** subroutine computes the product of two unsigned longs, *i* and *j,* and stores the double unsigned long product into an array of two unsigned longs pointed to by the *Result* parameter.

The **llabs** and **lldiv** subroutines compute the absolute value and division of long long integers. These subroutines operate under the same restrictions as the **abs** and **div** subroutines.

Note: When given the largest negative value, the **llabs** subroutine (like the **abs** subroutine) returns the same value.

Parameters

Item	Description
i	Specifies, for the **abs** subroutine, some integer; for **labs** and **imul_dbl,** some long integer; for the **umul_dbl** subroutine, some unsigned long integer; for the **llabs** subroutine, some long long integer.
Numerator	Specifies, for the **div** subroutine, some integer; for the **ldiv** subroutine, some long integer; for **lldiv**, some long long integer.
j	Specifies, for the **imul_dbl** subroutine, some long integer; for the **umul_dbl** subroutine, some unsigned long integer.
Denominator	Specifies, for the **div** subroutine, some integer; for the **ldiv** subroutine, some long integer; for **lldiv**, some long long integer.
Result	Specifies, for the **imul_dbl** subroutine, some long integer; for the **umul_dbl** subroutine, some unsigned long integer.

Return Values

The **abs**, **labs**, and **llabs** subroutines return the absolute value. The **imul_dbl** and **umul_dbl** subroutines have no return values. The **div** subroutine returns a structure of type **div_t**. The **ldiv** subroutine returns a structure of type **ldiv_t**, comprising the quotient and the remainder. The structure is displayed as:

```
struct ldiv_t {
  int quot; /* quotient */
  int rem;  /* remainder */
};
```

The **lldiv** subroutine returns a structure of type **lldiv_t**, comprising the quotient and the remainder.

access, accessx, faccessx, accessxat, or faccessat Subroutine

Purpose

Determines the accessibility of a file.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <unistd.h>
```

int access (*PathName*,*Mode*)
char **PathName*;

```
int Mode;

int accessx (PathName,  Mode,  Who)
char *PathName;
int Mode, Who;

int faccessx (FileDescriptor, Mode, Who)
int FileDescriptor;
int Mode, Who;

int accessxat (DirFileDescriptor, PathName, Mode, Who)
int DirFileDescriptor;
char *PathName;
int Mode, Who;

int faccessat (DirFileDescriptor, PathName, Mode, Flag)
int DirFileDescriptor;
char *PathName;
int Mode, Flag;
```

Description

The **access**, **accessx**, **accessxat**, **faccessat** and **faccessx** subroutines determine the accessibility of a file system object. The **accessx**, **accessxat**, and **faccessx** subroutines allow the specification of a class of users or processes for whom access is to be checked.

The caller must have search permission for all components of the *PathName* parameter.

The **accessxat** subroutine is equivalent to the **accessx** subroutine, and the **faccessat** subroutine is equivalent to the **access** subroutine if the *PathName* parameter specifies an absolute path or if the *DirFileDescriptor* parameter is set to **AT_FDCWD**. The file accessibility is determined by the relative path to the directory that is associated with the *DirFileDescriptor* parameter instead of the current working directory. If the directory is accessed without the **O_SEARCH** open flag, the subroutine checks to determine whether directory searches are permitted by using the current permissions of the directory. If the directory is accessed with the **O_SEARCH** open flag, the subroutine does not perform the check.

Parameters

Item	Description
PathName	Specifies the path name of the file. If the *PathName* parameter refers to a symbolic link, the **access** subroutine returns information about the file pointed to by the symbolic link. If the *DirFileDescriptor* is specified and *PathName* is relative, then the *DirFileDescriptor* specifies the effective current working directory for the *PathName*.
FileDescriptor	Specifies the file descriptor of an open file.

Item	Description
Mode	Specifies the access modes to be checked. This parameter is a bit mask containing 0 or more of the following values, which are defined in the **<sys/access.h>** file: **R_OK** Check read permission. **W_OK** Check write permission. **X_OK** Check execute or search permission. **F_OK** Check the existence of a file. If none of these values are specified, the existence of a file is checked.
Who	Specifies the class of users for whom access is to be checked. This parameter must be one of the following values, which are defined in the **<sys/access.h>** file: **ACC_SELF** Determines if access is permitted for the current process. The effective user and group IDs, the concurrent group set and the privilege of the current process are used for the calculation. **ACC_INVOKER** Determines if access is permitted for the invoker of the current process. The real user and group IDs, the concurrent group set, and the privilege of the invoker are used for the calculation. **Note:** The expression **access (***PathName***,** *Mode***)** is equivalent to **accessx (***PathName***,** *Mode***, ACC_INVOKER)**. **ACC_OTHERS** Determines if the specified access is permitted for any user other than the object owner. The *Mode* parameter must contain only one of the valid modes. Privilege is not considered in the calculation. **ACC_ALL** Determines if the specified access is permitted for all users. The *Mode* parameter must contain only one of the valid modes. Privilege is not considered in the calculation . **Note:** The **accessx** subroutine shows the same behavior by both the user and root with **ACC_ALL**.
DirFileDescriptor	Specifies the file descriptor of an open directory, which is used as the effective current working directory for the *PathName* argument. If the *DirFileDescriptor* parameter equals **AT_FDCWD**, the *DirFileDescriptor* parameter is ignored and the *PathName* argument specifies the complete file.
Flag	Specifies a bit field argument. If the *Flag* parameter equals **AT_EACCESS**, the effective user and group IDs are checked (**ACC_SELF**). If the *Flag* parameter is zero, the real IDs are checked (**ACC_INVOKER**).

Return Values

If the requested access is permitted, the **access**, **accessx**, **faccessx**, **accessxat**, and **faccessat** subroutines return a value of 0. If the requested access is not permitted or the function call fails, a value of -1 is returned and the **errno** global variable is set to indicate the error.

The **access** subroutine indicates success for **X_OK** even if none of the execute file permission bits are set.

Error Codes

The **access faccessat**, **accessx**, and **accessx** subroutines fail if one or more of the following are true:

Item	Description
EACCES	Search permission is denied on a component of the *PathName* prefix.
EFAULT	The *PathName* parameter points to a location outside the allocated address space of the process.
ELOOP	Too many symbolic links were encountered in translating the *PathName* parameter.
ENAMETOOLONG	A component of the *PathName* parameter exceeded 255 characters or the entire *PathName* parameter exceeded 1022 characters.
ENOENT	A component of the *PathName* does not exist or the process has the **disallow truncation** attribute set.
ENOENT	The named file does not exist.
ENOENT	The *PathName* parameter was null.
ENOENT	A symbolic link was named, but the file to which it refers does not exist.
ENOTDIR	A component of the *PathName* is not a directory.
ESTALE	The process root or current directory is located in a virtual file system that has been unmounted.

The **faccessx** subroutine fails if the following is true:

Item	Description
EBADF	The value of the *FileDescriptor* parameter is not valid.

The **access**, **accessx**, and **faccessx** subroutines fail if one or more of the following is true:

Item	Description
EACCES	The file protection does not allow the requested access.
ENOMEM	Unable to allocate memory.
EIO	An I/O error occurred during the operation.
EROFS	Write access is requested for a file on a read-only file system.

The **accessxat** and **faccessat** subroutines fail if one or more of the following settings are true:

Item	Description
EBADF	The *PathName* parameter does not specify an absolute path and the *DirFileDescriptor* argument is neither AT_FDCWD nor a valid file descriptor.
EINVAL	The value of the **Flag** parameter is not valid.
ENOTDIR	The *PathName* parameter is not an absolute path and **DirFileDescriptor** is a file descriptor but is not associated with a directory.

If Network File System (NFS) is installed on your system, the **accessx**, **accessxat**, and **faccessx** subroutines can also fail if the following settings are true:

Item	Description
ETIMEDOUT	The connection timed out.

Item	Description
ETXTBSY	Write access is requested for a shared text file that is being executed.
EINVAL	The value of the *Mode* argument is invalid.

accel_compress Subroutine

Purpose

Compresses data by using hardware accelerated memory compression.

Syntax

```
#include <sys/types.h>

#include <sys/vminfo.h>

int accel_compress (void *uc_buf, size_t uc_len,
void *c.buf, size_t *c_lenp, int flags);
```

Description

Given a pointer to a buffer with data to compress, the **accel_compress** subroutine compresses the data into the buffer pointed to by the **c_buf** parameter.

The compression subroutine should be called with the **c_lenp** parameter initialized to the total size of the **c_buf** parameter. Upon successful return, the **c_lenp** parameter is updated with the size of the compressed data in the **c_buf** parameter. The following restrictions apply to this subroutine.

- There is no overlapping of the **uc_buf** parameter and the **c_buf** parameter. An overlap results in an error.
- The **uc_buf** and **c_buf** parameters must be aligned at least on a 128 byte boundary. For the best results, both **uc_buf** and **c_buf** parameters must be aligned on a 4096 byte boundary.
- The **c_len** and ***uc_lenp** parameters are limited to a maximum of 1044480 bytes per subroutine call when buffers are aligned on a 4096 byte boundary. For buffers that are not aligned on a 4096 byte boundary, but are aligned on a 128 byte boundary, the **c_len** and ***uc_lenp** parameters are limited to 1040384 bytes per subroutine call plus any alignment offset from a 4096 byte boundary.
- The **uc_len** and **c_lenp** parameters must be a multiple of 8 bytes.
- The mapping of file segments with the **shmat()** function and the **mmap()** function are not allowed. However, the mapping of non-file segments with the **shmat()** function and the **mmap()** function are allowed (for example, `MMAP_ANONYMOUS`).
- The caller is responsible for supplying a large enough **c_buf**.

The subroutine uses the 842 algorithm to compress the data. The compressed buffer includes a cyclic redundancy check (CRC) which is automatically checked by the **accel_decompress()** subroutine. The Active Memory Expansion (AME) and Active Memory Sharing (AMS) features must not be enabled to use this call. The subroutine supports both 32 and 64 bit applications. The subroutine can be called from either a single or multi-threaded process.

Hardware accelerators are a finite resource on any system and you must be careful to not overwhelm the accelerators. If you have a large pool of threads all competing for a few of the available accelerators, you can end up with worse performance than with pure software compression.

Parameters

Item	Description
uc_buf	Pointer to input buffer with data to compress.
uc_len	Length of data in the **uc_buf** parameter to compress.
c_buf	Pointer to out buffer written with compressed data.
c_lenp	Pointer to in/out parameter. On entry, the **c_lenp** parameter is the total available size in the **c_buf** parameter and on exit, the **c_lenp** parameter is the number of bytes written to the **c_buf** parameter.
flags	Reserved for future use. This parameter must be set to zero.

Execution environment

The **accel_compress** subroutine can be called from the process environment only.

Return Values

Item	Description
0	Success
-1	Error. On failure, the errno global variable is set as follows:

EFAULT
Error accessing memory pointed to by the **c_lenp** parameter or access error on the source or target buffer.

EINVAL
Error due to one of the following conditions:

- The **uc_buf** and **c_buf** parameters have wrong alignment.
- The **uc_buf** and **c_buf** parameter overlap.
- The **uc_len** or **c_lenp** parameter is not a multiple of 8.
- The **uc_buf**, **c_buf,** or **c_lenp** parameter is NULL.
- Failed to create a list of the **uc_buf** or **c_buf** parameter pages to pass on to the accelerator hardware.
- The **uc_buf** or **c_buf** parameters are in a file.
- The **flags** parameter is a nonzero value.

ENOSYS
The hardware accelerator is not available, or AME is enabled, or AMS is enabled.

ENOMEM
Failed to allocate memory inside the subroutine.

EFBIG
The **uc_len** or the **c_lenp** parameter exceed 1,044,480 bytes.

EIO
The firmware call failed or the accelerator hardware returned a failure of unknown type. This might include errors caused by incorrect input arguments to the **accel_compress()** subroutine.

ENOSPC
The **c_buf** parameter is too small to hold the entire compressed output.

ERANGE
The compressed data is larger than the uncompressed data.

accel_decompress Subroutine

Purpose

Decompresses data by using hardware accelerated memory decompression or a slower software decompression if a hardware accelerator is not available.

Syntax

```
#include <sys/types.h>

#include <sys/vminfo.h>

int accel_decompress (void *c_buf, size_t c_len,
void *uc buf, size_t *uc_lenp, int flags);
```

Description

Given a pointer to a buffer with data to decompress (the **c_buf** parameter), the **accel_decompress** subroutine returns the decompressed data in the buffer pointed to by the **uc_buf** parameter.

The compression subroutine should be called with the **uc_lenp** parameter initialized to the total size of the **uc_buf** parameter. Upon successful return, the **uc_lenp** parameter is updated with the size of the compressed data in the **uc_buf** parameter. The following restrictions apply to this subroutine.

- There is no overlapping of the **uc_buf** parameter and the **c_buf** parameter. An overlap results in an error.
- The **uc_buf** and **c_buf** parameters must be aligned at least on a 128 byte boundary. For the best result, both **uc_buf** and **c_buf** parameters must be aligned on a 4096 byte boundary.
- The **c_len** and ***uc_lenp** parameters are limited to a maximum of 1044480 bytes per subroutine call when buffers are aligned on a 4096 byte boundary. For buffers that are not aligned on a 4096 byte boundary, but are aligned on a 128 byte boundary, the **c_len** and ***uc_lenp** parameters are limited to 1040384 bytes per subroutine call plus any alignment offset from a 4096 byte boundary.
- The **uc_lenp** and **c_len** parameters must be a multiple of 8 bytes.
- The mapping of file segments with the **shmat()** function and the **mmap()** function are not allowed. However, the mapping of non-file segments with the **shmat()** function and the **mmap()** function are allowed (for example, `MMAP_ANONYMOUS`).
- The caller is responsible for supplying a large enough **uc_buf**.

The subroutine uses the 842 algorithm to decompress the data. The compressed buffer includes a cyclic redundancy check (CRC) that is added by the **accel_compress()** subroutine, which is verified against the uncompressed data. If an hardware accelerator is not available in the system that is used for decompression, the call uses the software decompression method. The subroutine supports both 32 bit and 64 bit applications.

Hardware accelerators are a finite resource on any system and you must be careful to not overwhelm the accelerators. If you have a large pool of threads all competing for a few of the available accelerators, you can end up with worse performance than with pure software decompression.

Parameters

Item	Description
c_buf	Pointer to input buffer with data to decompress.
c_len	Length of compressed data in the **c_buf** parameter.
uc_buf	Pointer to out buffer written with decompressed data.

Item	Description
uc_lenp	Pointer to in/out parameter. On entry, the **uc_lenp** parameter is the total available size in the **uc_buf** parameter and on exit, the **uc_lenp** parameter is the number of bytes written to the **uc_buf** parameter.
flags	Reserved for future use. This parameter must be set to zero.

Execution environment

The **accel_decompress** subroutine can be called from the process environment only.

Return Values

Item	Description
0	Success
1	Error. On failure, the errno global variable is set as follows: **EFAULT** Error accessing memory pointed to by the **c_lenp** parameter or access error on the source or target buffer. **EINVAL** Error due to one of the following conditions: • The **uc_buf** and **c_buf** parameters have wrong alignment. • The **uc_buf** and **c_buf** parameter overlap. • The **uc_lenp** or **c_len** parameter is not a multiple of 8. • The **uc_buf**, **c_buf,** or **c_lenp** parameter is NULL. • Failed to create a list of the **uc_buf** or **c_buf** parameter pages to pass on to the accelerator hardware. • The **uc_buf** or **c_buf** parameters are in a file. • The **flags** parameter is a nonzero value. **ENOMEM** Failed to allocate memory inside the subroutine. **EFBIG** The **uc_lenp** or the **c_len** parameter exceed 1,044,480 bytes. **EIO** The firmware call failed or the accelerator hardware returned a failure of unknown type. This might include errors caused by incorrect input arguments to the **accel_decompress()** subroutine. **ECORRUPT** The compressed data is invalid or doesn't match embedded CRC. **ENOSPC** The output buffer is too small to hold all decompressed data.

accredrange Subroutine

Purpose

Checks whether the sensitivity label (SL) is in accreditation.

Library

Trusted AIX Library (**libmls.a**)

Syntax

```
#include <mls/mls.h>

int accredrange (sl)
const sl_t *sl;
```

Description

The **accredrange** subroutine checks whether the sensitivity label (SL) is in the accreditation range that the initialized label database defines. The *sl* parameter specifies the sensitivity label to be checked. The label encodings file defines the accreditation range.

Requirement: Must initialize the database before running this subroutine.

Parameter

Item	Description
sl	Specifies the sensitivity label to be checked.

Files Access

Mode	File
r	**/etc/security/enc/LabelEncodings**

Return Values

If the sensitivity label is in the accreditation range, the **accredrange** subroutine returns a value of zero. If the sensitivity label is not in the accreditation range, it returns a value of -1.

Error Codes

If the **accredrange** subroutine fails, it sets one of the following error codes:

Item	Description
EINVAL	The *sl* parameter specifies a sensitivity label that is not valid.
ENOTREADY	The database is not initialized.

acct Subroutine

Purpose

Enables and disables process accounting.

Library

Standard C Library (**libc.a**)

Syntax

```
int acct ( Path)
char *Path;
```

Description

The **acct** subroutine enables the accounting routine when the *Path* parameter specifies the path name of the file to which an accounting record is written for each process that terminates. When the *Path* parameter is a 0 or null value, the **acct** subroutine disables the accounting routine.

If the *Path* parameter refers to a symbolic link, the **acct** subroutine causes records to be written to the file pointed to by the symbolic link.

If Network File System (NFS) is installed on your system, the accounting file can reside on another node.

Note: To ensure accurate accounting, each node must have its own accounting file. Although no two nodes should share accounting files, a node's accounting files can be located on any node in the network.

The calling process must have root user authority to use the **acct** subroutine.

Parameters

Item	Description
Path	Specifies a pointer to the path name of the file or a null pointer.

Return Values

Upon successful completion, the **acct** subroutine returns a value of 0. Otherwise, a value of -1 is returned and the global variable **errno** is set to indicate the error.

Error Codes

The **acct** subroutine is unsuccessful if one or more of the following are true:

Item	Description
EACCES	Write permission is denied for the named accounting file.
EACCES	The file named by the *Path* parameter is not an ordinary file.
EBUSY	An attempt is made to enable accounting when it is already enabled.
ENOENT	The file named by the *Path* parameter does not exist.
EPERM	The calling process does not have root user authority.
EROFS	The named file resides on a read-only file system.

If NFS is installed on the system, the **acct** subroutine is unsuccessful if the following is true:

Item	Description
ETIMEDOUT	The connection timed out.

acct_wpar Subroutine

Purpose

Enables and disables process accounting.

Syntax

```
int acct_wpar(PathName, flag)
char * PathName;
int flag;
```

Description

The **acct_wpar** subroutine enables the accounting routine when the *PathName* parameter specifies the path name of the file to which an accounting record is written for each process that terminates. When the *PathName* parameter is a 0 or null value, the **acct_wpar** subroutines disables the accounting routine.

The *flag* parameter can be used to indicate whether to include workload partition accounting records into the global workload partition's accounting file.

If Network File System (NFS) is installed on your system, the accounting file can reside on another node.

Note: To ensure accurate accounting, each node must have its own accounting file. Although no two nodes should share accounting files, a node's accounting file can be located on any node in the network.

The calling process must have root user authority to use the **acct_wpar** subroutine.

Parameters

Item	Description
PathName	Specifies a pointer to the path name of the file or a null pointer. If the *PathName* parameter refers to a symbolic link, the **acct_wpar** subroutine causes records to be written to the file pointed to by the symbolic link.
flag	Specifies whether to include workload partition accounting records into the global accounting records file. Valid flags are the following: **ACCT_INC_GLOBAL** Include the global workload partition's accounting records. **ACCT_INC_ALL_WPARS** Include all workload partition's accounting records.

Return Values

Item	Description
0	The command completed successfully.
-1	The command did not complete successfully. The global variable **errno** is set to indicate the error.

Error Codes

Item	Description
EINVAL	Invalid *flag* argument.
EACCES	Write permission is denied for the named accounting file.
EACCES	The file named by the *PathName* parameter is not an ordinary file.
EBUSY	An attempt is made to enable accounting when it is already enabled.
ENOENT	The file named by the *PathName* parameter does not exist.
EPERM	The calling process does not have root user authority.
EROFS	The named file resides on a read-only file system.

If NFS is installed on the system, the **acct_wpar** subroutine is unsuccessful if the following is true:

Item	Description
ETIMEDOUT	The connection timed out.

acl_chg or acl_fchg Subroutine

Purpose

Changes the AIXC ACL type access control information on a file.

Library

Security Library (**libc.a**)

Syntax

```
#include <sys/access.h>
```

```
int acl_chg (Path, How, Mode, Who)
char * Path;
int  How;
int  Mode;
int  Who;
```

```
int acl_fchg (FileDescriptor, How, Mode, Who)
int  FileDescriptor;
int How;
int Mode;
int Who;
```

Description

The **acl_chg** and **acl_fchg** subroutines modify the AIXC ACL-type-based access control information of a specified file. This call can fail for file system objects with any non-AIXC ACL.

Parameters

Item	Description
FileDescriptor	Specifies the file descriptor of an open file.
How	Specifies how the permissions are to be altered for the affected entries of the Access Control List (ACL). This parameter takes one of the following values: **ACC_PERMIT** Allows the types of access included in the *Mode* parameter. **ACC_DENY** Denies the types of access included in the *Mode* parameter. **ACC_SPECIFY** Grants the access modes included in the *Mode* parameter and restricts the access modes not included in the *Mode* parameter.

Item	Description
Mode	Specifies the access modes to be changed. The *Mode* parameter is a bit mask containing zero or more of the following values: **R_ACC** Allows read permission. **W_ACC** Allows write permission. **X_ACC** Allows execute or search permission.
Path	Specifies a pointer to the path name of a file.
Who	Specifies which entries in the ACL are affected. This parameter takes one of the following values: **ACC_OBJ_OWNER** Changes the owner entry in the base ACL. **ACC_OBJ_GROUP** Changes the group entry in the base ACL. **ACC_OTHERS** Changes all entries in the ACL except the base entry for the owner. **ACC_ALL** Changes all entries in the ACL.

Return Values

On successful completion, the **acl_chg** and **acl_fchg** subroutines return a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **acl_chg** subroutine fails and the access control information for a file remains unchanged if one or more of the following is true:

Item	Description
EACCES	Search permission is denied on a component of the *Path* prefix.
EFAULT	The *Path* parameter points to a location outside of the allocated address space of the process.
ELOOP	Too many symbolic links were encountered in translating the *Path* parameter.
ENAMETOOLONG	A component of the *Path* parameter exceeded 255 characters, or the entire *Path* parameter exceeded 1023 characters.
ENOENT	A component of the *Path* does not exist or has the **disallow truncation** attribute (see the **ulimit** subroutine).
ENOENT	The *Path* parameter was null.
ENOENT	A symbolic link was named, but the file to which it refers does not exist.
ENOTDIR	A component of the *Path* prefix is not a directory.
ESTALE	The process' root or current directory is located in a virtual file system that has been unmounted.

The **acl_fchg** subroutine fails and the file permissions remain unchanged if the following is true:

Item	Description
EBADF	The *FileDescriptor* value is not valid.

The **acl_chg** or **acl_fchg** subroutine fails and the access control information for a file remains unchanged if one or more of the following is true:

Item	Description
EINVAL	The *How* parameter is not one of **ACC_PERMIT**, **ACC_DENY**, or **ACC_SPECIFY**.
EINVAL	The *Who* parameter is not **ACC_OWNER**, **ACC_GROUP**, **ACC_OTHERS**, or **ACC_ALL**.
EROFS	The named file resides on a read-only file system.

The **acl_chg** or **acl_fchg** subroutine fails and the access control information for a file remains unchanged if one or more of the following is true:

Item	Description
EIO	An I/O error occurred during the operation.
EPERM	The effective user ID does not match the ID of the owner of the file and the invoker does not have root user authority.

If Network File System (NFS) is installed on your system, the **acl_chg** and **acl_fchg** subroutines can also fail if the following is true:

Item	Description
ETIMEDOUT	The connection timed out.

acl_get or acl_fget Subroutine

Purpose

Gets the access control information of a file if the ACL associated is of the AIXC type.

Library

Security Library (**libc.a**)

Syntax

```
#include <sys/access.h>
```

```
char *acl_get (Path)
char * Path;

char *acl_fget (FileDescriptor)
int  FileDescriptor;
```

Description

The **acl_get** and **acl_fget** subroutines retrieve the access control information for a file system object. This information is returned in a buffer pointed to by the return value. The structure of the data in this buffer is unspecified. The value returned by these subroutines should be used only as an argument to the **acl_put** or **acl_fput** subroutines to copy or restore the access control information. Note that **acl_get** and **acl_fget**

subroutines could fail if the ACL associated with the file system object is of a different type than AIXC. It is recommended that applications make use of **aclx_get** and **aclx_fget** subroutines to retrieve the ACL.

The buffer returned by the **acl_get** and **acl_fget** subroutines is in allocated memory. After usage, the caller should deallocate the buffer using the **free** subroutine.

Parameters

Item	Description
Path	Specifies the path name of the file.
FileDescriptor	Specifies the file descriptor of an open file.

Return Values

On successful completion, the **acl_get** and **acl_fget** subroutines return a pointer to the buffer containing the access control information. Otherwise, a null pointer is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **acl_get** subroutine fails if one or more of the following are true:

Item	Description
EACCES	Search permission is denied on a component of the *Path* prefix.
EFAULT	The *Path* parameter points to a location outside of the allocated address space of the process.
ELOOP	Too many symbolic links were encountered in translating the *Path* parameter.
ENAMETOOLONG	A component of the *Path* parameter exceeded 255 characters, or the entire *Path* parameter exceeded 1023 characters.
ENOTDIR	A component of the *Path* prefix is not a directory.
ENOENT	A component of the *Path* does not exist or the process has the **disallow truncation** attribute (see the **ulimit** subroutine).
ENOENT	The *Path* parameter was null.
ENOENT	A symbolic link was named, but the file to which it refers does not exist.
ESTALE	The process' root or current directory is located in a virtual file system that has been unmounted.

The **acl_fget** subroutine fails if the following is true:

Item	Description
EBADF	The *FileDescriptor* parameter is not a valid file descriptor.

The **acl_get** or **acl_fget** subroutine fails if the following is true:

Item	Description
EIO	An I/O error occurred during the operation.

If Network File System (NFS) is installed on your system, the **acl_get** and **acl_fget** subroutines can also fail if the following is true:

Item	Description
ETIMEDOUT	The connection timed out.

Security

Item	Description
Access Control	The invoker must have search permission for all components of the *Path* prefix.
Audit Events	None.

acl_put or acl_fput Subroutine

Purpose

Sets AIXC ACL type access control information of a file.

Library

Security Library (**libc.a**)

Syntax

```
#include <sys/access.h>
```

```
int acl_put (Path, Access, Free)
char * Path;
char * Access;
int  Free;
```

```
int acl_fput (FileDescriptor, Access, Free)
int  FileDescriptor;
char * Access;
int  Free;
```

Description

The **acl_put** and **acl_fput** subroutines set the access control information of a file system object. This information is contained in a buffer returned by a call to the **acl_get** or **acl_fget** subroutine. The structure of the data in this buffer is unspecified. However, the entire Access Control List (ACL) for a file cannot exceed one memory page (4096 bytes) in size. Note that **acl_put**/**acl_fput** operation could fail if the existing ACL associated with the file system object is of a different kind or if the underlying physical file system does not support AIXC ACL type. It is recommended that applications make use of **aclx_put** and **aclx_fput** subroutines to set the ACL instead of **acl_put**/**acl_fput** routines.

Parameters

Item	Description
Path	Specifies the path name of a file.
FileDescriptor	Specifies the file descriptor of an open file.
Access	Specifies a pointer to the buffer containing the access control information.

Item	Description
Free	Specifies whether the buffer space is to be deallocated. The following values are valid: **0** Space is not deallocated. **1** Space is deallocated.

Return Values

On successful completion, the **acl_put** and **acl_fput** subroutines return a value of 0. Otherwise, -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **acl_put** subroutine fails and the access control information for a file remains unchanged if one or more of the following are true:

Item	Description
EACCES	Search permission is denied on a component of the *Path* prefix.
EFAULT	The *Path* parameter points to a location outside of the allocated address space of the process.
ELOOP	Too many symbolic links were encountered in translating the *Path* parameter.
ENAMETOOLONG	A component of the *Path* parameter exceeded 255 characters, or the entire *Path* parameter exceeded 1023 characters.
ENOENT	A component of the *Path* does not exist or has the **disallow truncation** attribute (see the **ulimit** subroutine).
ENOENT	The *Path* parameter was null.
ENOENT	A symbolic link was named, but the file to which it refers does not exist.
ENOTDIR	A component of the *Path* prefix is not a directory.
ESTALE	The process' root or current directory is located in a virtual file system that has been unmounted.

The **acl_fput** subroutine fails and the file permissions remain unchanged if the following is true:

Item	Description
EBADF	The *FileDescriptor* parameter is not a valid file descriptor.

The **acl_put** or **acl_fput** subroutine fails and the access control information for a file remains unchanged if one or more of the following are true:

Item	Description
EINVAL	The *Access* parameter does not point to a valid access control buffer.
EINVAL	The *Free* parameter is not 0 or 1.
EIO	An I/O error occurred during the operation.
EROFS	The named file resides on a read-only file system.

If Network File System (NFS) is installed on your system, the **acl_put** and **acl_fput** subroutines can also fail if the following is true:

Item	Description
ETIMEDOUT	The connection timed out.

Security

Access Control: The invoker must have search permission for all components of the *Path* prefix.

Auditing Events:

Item	Description
Event	**Information**
chacl	*Path*
fchacl	*FileDescriptor*

acl_set or acl_fset Subroutine

Purpose

Sets the AIXC ACL type access control information of a file.

Library

Security Library (**libc.a**)

Syntax

```
#include <sys/access.h>

int acl_set (Path, OwnerMode, GroupMode, DefaultMode)
char * Path;
int  OwnerMode;
int  GroupMode;
int  DefaultMode;

int acl_fset (FileDescriptor, OwnerMode, GroupMode, DefaultMode)
int * FileDescriptor;
int OwnerMode;
int GroupMode;
int DefaultMode;
```

Description

The **acl_set** and **acl_fset** subroutines set the base entries of the Access Control List (ACL) of the file. All other entries are discarded. Other access control attributes are left unchanged. Note that if the file system object is associated with any other ACL type access control information, it will be replaced with just the Base mode bits information. It is strongly recommended that applications stop using these interfaces and instead make use of **aclx_put** and **aclx_fput** subroutines to set the ACL.

Parameters

Item	Description
DefaultMode	Specifies the access permissions for the default class.

Item	Description
FileDescriptor	Specifies the file descriptor of an open file.
GroupMode	Specifies the access permissions for the group of the file.
OwnerMode	Specifies the access permissions for the owner of the file.
Path	Specifies a pointer to the path name of a file.

The mode parameters specify the access permissions in a bit mask containing zero or more of the following values:

Item	Description
R_ACC	Authorize read permission.
W_ACC	Authorize write permission.
X_ACC	Authorize execute or search permission.

Return Values

Upon successful completion, the **acl_set** and **acl_fset** subroutines return the value 0. Otherwise, the value -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **acl_set** subroutine fails and the access control information for a file remains unchanged if one or more of the following are true:

Item	Description
EACCES	Search permission is denied on a component of the *Path* prefix.
EFAULT	The *Path* parameter points to a location outside of the allocated address space of the process.
ELOOP	Too many symbolic links were encountered in translating the *Path* parameter.
ENAMETOOLONG	A component of the *Path* parameter exceeded 255 characters, or the entire *Path* parameter exceeded 1023 characters.
ENOENT	A component of the *Path* does not exist or has the **disallow truncation** attribute (see the **ulimit** subroutine).
ENOENT	The *Path* parameter was null.
ENOENT	A symbolic link was named, but the file to which it refers does not exist.
ENOTDIR	A component of the *Path* prefix is not a directory.
ESTALE	The process' root or current directory is located in a virtual file system that has been unmounted.

The **acl_fset** subroutine fails and the file permissions remain unchanged if the following is true:

Item	Description
EBADF	The file descriptor *FileDescriptor* is not valid.

The **acl_set** or **acl_fset** subroutine fails and the access control information for a file remains unchanged if one or more of the following are true:

Item	Description
EIO	An I/O error occurred during the operation.
EPERM	The effective user ID does not match the ID of the owner of the file and the invoker does not have root user authority.
EROFS	The named file resides on a read-only file system.

If Network File System (NFS) is installed on your system, the **acl_set** and **acl_fset** subroutines can also fail if the following is true:

Item	Description
ETIMEDOUT	The connection timed out.

Security

Access Control: The invoker must have search permission for all components of the *Path* prefix.

Auditing Events:

Event	Information
chacl	*Path*
fchacl	*FileDescriptor*

aclx_convert Subroutine

Purpose

Converts the access control information from one ACL type to another.

Library

Security Library (**libc.a**)

Syntax

```
#include <sys/acl.h>
```

```
int aclx_convert (from_acl, from_sz, from_type, to_acl, to_sz, to_type, fs_obj_path)
void * from_acl;
size_t   from_sz;
acl_type_t   from_type;
void * to_acl;
size_t  * to_sz;
acl_type_t   to_type;
char  * fs_obj_path;
```

Description

The **aclx_convert** subroutine converts the access control information from the binary input given in *from_acl* of the ACL type *from_type* into a binary ACL of the type *to_type* and stores it in *to_acl*. Values *from_type* and *to_type* can be any ACL types supported in the system.

The ACL conversion takes place with the help of an ACL type-specific algorithm. Because the conversion is approximate, it can result in a potential loss of access control. Therefore, the user of this call must make sure that the converted ACL satisfies the required access controls. The user can manually review

the access control information after the conversion for the file system object to ensure that the conversion was successful and satisfied the requirements of the intended access control.

Parameters

Item	Description
from_acl	Points to the ACL that has to be converted.
from_sz	Indicates the size of the ACL information pointed to by *from_acl*.
from_type	Indicates the ACL type information of the ACL. The *acl_type* is 64 bits in size and is unique on the system. If the given *acl_type* is not supported in the system, this function fails and **errno** is set to **EINVAL**. The supported ACL types are **ACLX** and **NFS4**.
to_acl	Points to a buffer in which the target binary ACL has to be stored. The amount of memory available in this buffer is indicated by the *to_sz* parameter.
to_sz	Indicates the amount of memory, in bytes, available in *to_acl*. If *to_sz* contains less than the required amount of memory for storing the converted ACL, **to_sz* is set to the required amount of memory and **ENOSPC** is returned by **errno**.
to_type	Indicates the ACL type to which conversion needs to be done. The ACL type is 64 bits in size and is unique on the system. If the given *acl_type* is not supported in the system, this function fails and **errno** is set to **EINVAL** The supported ACL types are **ACLX** and **NFS4**.
fs_obj_path	File System Object Path for which the ACL conversion is being requested. Gets information about the object, such as whether it is file or directory.

Return Values

On successful completion, the **aclx_convert** subroutine returns a value of 0. Otherwise, -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **aclx_convert** subroutine fails if one or more of the following is true:

Item	Description
EINVAL	Invalid input parameter. The same error can be returned if an invalid *acl_type* is specified as input to this routine, either in *from_type* or in *to_type*. This **errno** could also be returned if the binary ACL given in *from_acl* is not the type specified by *from_type*.
ENOSPC	Insufficient storage space is available in *to_acl*.

Security

Access Control: The invoker must have search permission for all components of the *Path* prefix.

Auditing Events: If the auditing subsystem has been properly configured and is enabled, the **aclx_convert** subroutine generates the following audit record (event) every time the command is executed:

Item	Description
Event	**Information**
FILE_Acl	Lists access controls.

aclx_get or aclx_fget Subroutine

Purpose

Gets the access control information for a file system object.

Library

Security Library (**libc.a**)

Syntax

```
#include <sys/acl.h>
```

```
int aclx_get (Path, ctl_flags, acl_type, acl, acl_sz,  mode_info)
char * Path;
uint64_t   ctl_flags;
acl_type_t  * acl_type;
void * acl;
size_t  * acl_sz;
mode_t  * mode_info;
```

```
int aclx_fget (FileDescriptor, ctl_flags, acl_type, acl, acl_sz,  mode_info)
int  FileDescriptor;
uint64_t   ctl_flags;
acl_type_t  * acl_type;
void * acl;
size_t  * acl_sz;
mode_t  * mode_info;
```

Description

The **aclx_get** and **aclx_fget** subroutines retrieve the access control information for a file system object in the native ACL format. Native ACL format is the format as defined for the particular ACL type in the system. These subroutines are advanced versions of the **acl_get** and **acl_fget** subroutines and should be used instead of the older versions. The **aclx_get** and **aclx_fget** subroutines provide for more control for the user to interact with the underlying file system directly.

In the earlier versions (**acl_get** or **acl_fget**), OS libraries found out the ACL size from the file system and allocated the required memory buffer space to hold the ACL information. The caller does all this now with the **aclx_get** and **aclx_fget** subroutines. Callers are responsible for finding out the size and allocating memory for the ACL information, and later freeing the same memory after it is used. These subroutines allow for an *acl_type* input and output argument. The data specified in this argument can be set to a particular ACL type and a request for the ACL on the file system object of the same type. Some physical file systems might do emulation to return the ACL type requested, if the ACL type that exists on the file system object is different. If the *acl_type* pointer points to a data area with a value of **ACL_ANY** or 0, then the underlying physical file system has to return the type of the ACL associated with the file system object.

The *ctl_flags* parameter is a bit mask that allows for control over the **aclx_get** requests.

The value returned by these subroutines can be use as an argument to the **aclx_get** or **aclx_fget** subroutines to copy or restore the access control information.

Parameters

Item	Description
Path	Specifies the path name of the file system object.
FileDescriptor	Specifies the file descriptor of an open file.

Item	Description
ctl_flags	This 64-bit sized bit mask provides control over the ACL retrieval. The following flag value is defined: **GET_ACLINFO_ONLY** Gets only the ACL type and length information from the underlying file system. When this bit is set, the *acl* argument can be set to NULL. In all other cases, these must be valid buffer pointers (or else an error is returned). If this bit is not specified, then all the other information about the ACL, such as ACL data and mode information, is returned.
acl_type	Points to a buffer that will hold ACL type information. The ACL type is 64 bits in size and is unique on the system. The caller can provide an ACL type in this area and a request for the ACL on the file system object of the same type. If the ACL type requested does not match the one on the file system object, the physical file system might return an error or emulate and provide the ACL information in the ACL type format requested. If the caller does not know the ACL type and wants to retrieve the ACL associated with the file system object, then the caller should set the buffer value pointed to by *acl_type* to **ACL_ANY** or 0. The supported ACL types are **ACLX** and **NFS4**.
acl	Points to a buffer where the ACL retrieved is stored. The size of this buffer is indicated by the *acl_sz* parameter.
acl_sz	Indicates the size of the buffer area passed through the *acl* parameter.
mode_info	Pointer to a buffer where the mode word associated with the file system object is returned. Note that this mode word's meaning and formations depend entirely on the ACL type concerned.

Return Values

On successful completion, the **aclx_get** and **aclx_get** subroutines return a value of 0. Otherwise, -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **aclx_get** subroutine fails if one or more of the following is true:

Item	Description
EACCES	Search permission is denied on a component of the *Path* prefix.
EFAULT	The *Path* parameter points to a location outside of the allocated address space of the process.
ELOOP	Too many symbolic links were encountered in translating the *Path* parameter.
ENAMETOOLONG	A component of the *Path* parameter exceeded 255 characters, or the entire *Path* parameter exceeded 1023 characters.
ENOENT	A component of the *Path* does not exist or has the **disallow truncation** attribute (see the **ulimit** subroutine).
ENOENT	The *Path* parameter was null.
ENOENT	A symbolic link was named, but the file to which it refers does not exist.
ENOTDIR	A component of the *Path* prefix is not a directory.
ESTALE	The process' root or current directory is located in a virtual file system that has been unmounted.

The **aclx_fget** subroutine fails if the following is true:

Item	Description
EBADF	The *FileDescriptor* parameter is not a valid file descriptor.

The **aclx_get** or **aclx_fget** subroutine fails if one or more of the following is true:

Item	Description
EINVAL	Invalid input parameter. The same error can be returned if an invalid *acl_type* is specified as input to this routine.
EIO	An I/O error occurred during the operation.
ENOSPC	Input buffer size *acl_sz* is not sufficient to store the ACL data in *acl*.

If Network File System (NFS) is installed on your system, the **aclx_get** and **aclx_fget** subroutines can also fail if the following condition is true:

Item	Description
ETIMEDOUT	The connection timed out.

Security

Access Control: The invoker must have search permission for all components of the *Path* prefix.

Auditing Events: None

aclx_gettypeinfo Subroutine

Purpose

Retrieves the ACL characteristics given to an ACL type.

Library

Security Library (**libc.a**)

Syntax

```
#include <sys/acl.h>

int aclx_gettypeinfo (Path, acl_type, buffer, buffer_sz)
char * Path;
acl_type_t   acl_type;
caddr_t  buffer;
size_t  * buffer_sz;
```

Description

The **aclx_gettypeinfo** subroutine helps obtain characteristics and capabilities of an ACL type on the file system. The buffer space provided by the caller is where the ACL type-related information is returned. If the length of this buffer is not enough to fit the characteristics for the ACL type requested, then **aclx_gettypeinfo** returns an error and sets the *buffer_len* field to the amount of buffer space needed.

Parameters

Item	Description
Path	Specifies the path name of the file.
acl_type	ACL type for which the characteristics are sought. The supported ACL types are **ACLX** and **NFS4**.
buffer	Specifies the pointer to a buffer space, where the characteristics of *acl_type* for the file system is returned. The structure of data returned is ACL type-specific. Refer to the ACL type-specific documentation for more details.
buffer_sz	Points to an area that specifies the length of the buffer *buffer* in which the characteristics of *acl_type* are returned by the file system. This is an input/output parameter. If the length of the buffer provided is not sufficient to store all the ACL type characteristic information, then the file system returns an error and indicates the length of the buffer required in this variable. The length is specified in number of bytes.

Return Values

On successful completion, the **aclx_gettypeinfo** subroutine returns a value of 0. Otherwise, -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **aclx_gettypeinfo** subroutine fails and the access control information for a file remains unchanged if one or more of the following is true:

Item	Description
EACCES	Search permission is denied on a component of the *Path* prefix.
EFAULT	The *Path* parameter points to a location outside of the allocated address space of the process.
ELOOP	Too many symbolic links were encountered in translating the *Path* parameter.
ENAMETOOLONG	A component of the *Path* parameter exceeded 255 characters, or the entire *Path* parameter exceeded 1023 characters.
ENOENT	A component of the *Path* does not exist or has the **disallow truncation** attribute (see the **ulimit** subroutine).
ENOENT	The *Path* parameter was null.
ENOENT	A symbolic link was named, but the file to which it refers does not exist.
ENOSPC	Buffer space provided is not enough to store all the *acl_type* characteristics of the file system.
ENOTDIR	A component of the *Path* prefix is not a directory.
ESTALE	The process' root or current directory is located in a virtual file system that has been unmounted.

If Network File System (NFS) is installed on your system, the **acl_gettypeinfo** subroutine can also fail if the following condition is true:

Item	Description
ETIMEDOUT	The connection timed out.

Security

Auditing Events: None

aclx_gettypes Subroutine

Purpose

Retrieves the list of ACL types supported for the file system associated with the path provided.

Library

Security Library (**libc.a**)

Syntax

```
#include <sys/acl.h>

int aclx_gettypes (Path, acl_type_list, acl_type_list_len)
char  * Path;
acl_types_list_t  * acl_type_list;
size_t  * acl_type_list_len;
```

Description

The **aclx_gettypes** subroutine helps obtain the list of ACL types supported on the particular file system. A file system can implement policies to support one to many ACL types simultaneously. The first ACL type in the list is the default ACL type for the file system. This default ACL type is used in ACL conversions if the target ACL type is not supported on the file system. Each file system object in the file system is associated with only one piece of ACL data of a particular ACL type.

Parameters

Item	Description
Path	Specifies the path name of the file system object within the file system for which the list of supported ACLs are being requested.
acl_type_list	Specifies the pointer to a buffer space, where the list of ACL types is returned. The size of this buffer is indicated using the *acl_type_list_len* argument in bytes. The supported ACL types are **ACLX** and **NFS4**.
acl_type_list_len	Pointer to a buffer that specifies the length of the buffer *acl_type_list* in which the list of ACLs is returned by the file system. This is an input/output parameter. If the length of the buffer is not sufficient to store all the ACL types, the file system returns an error and indicates the length of the buffer required in this same area. The length is specified in bytes. If the subroutine call is successful, this field contains the number of bytes of information stored in the *acl_type_list* buffer. This information can be used by the caller to get the number of ACL type entries returned.

Return Values

On successful completion, the **aclx_gettypes** subroutine returns a value of 0. Otherwise, -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **aclx_gettypes** subroutine fails and the access control information for a file remains unchanged if one or more of the following is true:

Item	Description
EACCES	Search permission is denied on a component of the *Path* prefix.
EFAULT	The *Path* parameter points to a location outside of the allocated address space of the process.
ELOOP	Too many symbolic links were encountered in translating the *Path* parameter.
ENAMETOOLONG	A component of the *Path* parameter exceeded 255 characters, or the entire *Path* parameter exceeded 1023 characters.
ENOENT	A component of the *Path* does not exist or has the **disallow truncation** attribute (see the **ulimit** subroutine).
ENOENT	The *Path* parameter was null.
ENOENT	A symbolic link was named, but the file to which it refers does not exist.
ENOSPC	The *acl_type_list* buffer provided is not enough to store all the ACL types supported by this file system.
ENOTDIR	A component of the *Path* prefix is not a directory.
ESTALE	The process' root or current directory is located in a virtual file system that has been unmounted.

If Network File System (NFS) is installed on your system, the **acl_gettypes** subroutine can also fail if the following condition is true:

Item	Description
ETIMEDOUT	The connection timed out.

Security

Access Control: Caller must have search permission for all components of the *Path* prefix.

Auditing Events: None

aclx_print or aclx_printStr Subroutine

Purpose

Converts the binary access control information into nonbinary, readable format.

Library

Security Library (**libc.a**)

Syntax

```
#include <sys/acl.h>

int aclx_print (acl_file, acl, acl_sz, acl_type, fs_obj_path, flags)
FILE * acl_file;
void  * acl;
```

```
size_t    acl_sz;
acl_type_t   acl_type;
char  * fs_obj_path;
int32_t    flags;

int aclx_printStr (str, str_sz, acl, acl_sz, acl_type, fs_obj_path, flags)
char * str;
size_t * str_sz;
void  * acl;
size_t    acl_sz;
acl_type_t   acl_type;
char  * fs_obj_path;
int32_t    flags;
```

Description

The **aclx_print** and **aclx_printStr** subroutines print the access control information in a nonbinary, readable text format. These subroutines take the ACL information in binary format as input, convert it into text format, and print that text format output to either a file or a string. The **aclx_print** subroutine prints the ACL text to the file specified by *acl_file*. The **aclx_printStr** subroutine prints the ACL text to *str*. The amount of space available in *str* is specified in *str_sz*. If this memory is insufficient, the subroutine sets *str_sz* to the needed amount of memory and returns an **ENOSPC** error.

Parameters

Item	Description
acl_file	Points to the file into which the textual output is printed.
str	Points to the string into which the textual output should be printed.
str_sz	Indicates the amount of memory in bytes available in *str*. If the text representation of *acl* requires more space than *str_sz*, this subroutine updates the *str_sz* with the amount of memory required and fails by setting **errno** to **ENOSPC**.
acl	Points to a buffer which contains the binary ACL data that has to be printed. The size of this buffer is indicated by the *acl_sz* parameter.
acl_sz	Indicates the size of the buffer area passed through the *acl* parameter.
acl_type	Indicates the ACL type information of the *acl*. The ACL type is 64 bits in size and is unique on the system. If the given ACL type is not supported in the system, this function fails and **errno** is set to **EINVAL**. The supported ACL types are **ACLX** and **NFS4**.
fs_obj_path	File System Object Path for which the ACL data format and print are being requested. Gets information about the object (such as whether the object is a file or directory, who the owner is, and the associated group ID).
flags	Allows for control over the print operation. A value of **ACL_VERBOSE** indicates whether additional information has to be printed in text format in comments. This bit is set when the **aclget** command is issued with the **-v** (verbose) option.

Return Values

On successful completion, the **aclx_print** and **aclx_printStr** subroutines return a value of 0. Otherwise, -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **aclx_print** subroutine fails if one or more of the following is true:

Note: The errors in the following list occur only because **aclx_print** calls the **fprintf** subroutine internally. For more information about these errors, refer to the **fprintf** subroutine.

Item	Description
EAGAIN	The **O_NONBLOCK** flag is set for the file descriptor underlying the file specified by the *acl_file* parameter, and the process would be delayed in the write operation.
EBADF	The file descriptor underlying the file specified by the *acl_file* parameter is not a valid file descriptor open for writing.
EFBIG	An attempt was made to write to a file that exceeds the file size limit of this process or the maximum file size. For more information, refer to the **ulimit** subroutine.
EINTR	The write operation terminated because of a signal was received, and either no data was transferred or a partial transfer was not reported.
EIO	The process is a member of a background process group attempting to perform a write to its controlling terminal, the **TOSTOP** flag is set, the process is neither ignoring nor blocking the **SIGTTOU** signal, and the process group of the process has no parent process.
ENOSPC	No free space remains on the device that contains the file.
ENOSPC	Insufficient storage space is available.
ENXIO	A request was made of a nonexistent device, or the request was outside the capabilities of the device.
EPIPE	An attempt was made to write to a pipe or first-in-first-out (FIFO) that is not open for reading by any process. A **SIGPIPE** signal is sent to the process.

The **aclx_printStr** subroutine fails if the following is true:

Item	Description
ENOSPC	Input buffer size *strSz* is not sufficient to store the text representation of *acl* in *str*.
ENOSPC	Insufficient storage space is available. This error is returned by **sprintf**, which is called by the **aclx_printStr** subroutine internally.

The **aclx_print** or **aclx_printStr** subroutine fails if the following is true:

Item	Description
EINVAL	Invalid input parameter. The same error can be returned if an invalid *acl_type* is specified as input to this routine. This **errno** can also be returned if the *acl* is not of the type specified by *acl_type*.

aclx_put or aclx_fput Subroutine

Purpose

Stores the access control information for a file system object.

Library

Security Library (**libc.a**)

Syntax

```
#include <sys/acl.h>
```

```
int aclx_put (Path, ctl_flags, acl_type, acl, acl_sz,  mode_info)
char * Path;
uint64_t   ctl_flags;
acl_type_t   acl_type;
void * acl;
size_t   acl_sz;
mode_t   mode_info;
```

```
int aclx_fput (FileDescriptor, ctl_flags, acl_type, acl, acl_sz,  mode_info)
int  FileDescriptor;
uint64_t   ctl_flags;
acl_type_t   acl_type;
void * acl;
size_t   acl_sz;
mode_t   mode_info;
```

Description

The **aclx_put** and **aclx_fput** subroutines store the access control information for a file system object in the native ACL format. Native ACL format is the format as defined for the particular ACL type in the system. These subroutines are advanced versions of the **acl_put** and **acl_fput** subroutines and should be used instead of the older versions. The **aclx_put** and **aclx_fput** subroutines provide for more control for the user to interact with the underlying file system directly.

A caller specifies the ACL type in the *acl_type* argument and passes the ACL information in the *acl* argument. The *acl_sz* parameter indicates the size of the ACL data. The *ctl_flags* parameter is a bitmask that allows for variation of **aclx_put** requests.

The value provided to these subroutines can be obtained by invoking **aclx_get** or **aclx_fget** subroutines to copy or restore the access control information.

The **aclx_put** and **aclx_fput** subroutines can also be used to manage the special bits (such as SGID and SUID) in the mode word associated with the file system object. For example, you can set the **mode_info** value to any special bit mask (as in the mode word defined for the file system), and a request can be made to set the same bits using the *ctl_flags* argument. Note that special privileges (such as root) might be required to set these bits.

Parameters

Item	Description
Path	Specifies the path name of the file system object.
FileDescriptor	Specifies the file descriptor of an open file system object. This 64-bit sized bit mask provides control over the ACL retrieval. These bits are divided as follows: **Lower 16 bits** System-wide (nonphysical file-system-specific) ACL control flags **32 bits** Reserved. **Last 16 bits** Any physical file-system-defined options (that are specific to physical file system ACL implementation).

Item	Description
ctl_flags	Bit mask with the following system-wide flag values defined: **SET_MODE_S_BITS** Indicates that the **mode_info** value is set by the caller and the ACL put operation needs to consider this value while completing the ACL put operation. **SET_ACL** Indicates that the *acl* argument points to valid ACL data that needs to be considered while the ACL put operation is being performed. **Note:** Both of the preceding values can be specified by the caller by ORing the two masks.
acl_type	Indicates the type of ACL to be associated with the file object. If the *acl_type* specified is not among the ACL types supported for the file system, then an error is returned. The supported ACL types are **ACLX** and **NFS4**.
acl	Points to a buffer where the ACL information exists. This ACL information is associated with the file system object specified. The size of this buffer is indicated by the *acl_sz* parameter.
acl_sz	Indicates the size of the ACL information sent through the *acl* parameter.
mode_info	This value indicates any mode word information that needs to be set for the file system object in question as part of this ACL put operation. When mode bits are being altered by specifying the **SET_MODE_S_BITS** flag (in *ctl_flags*) ACL put operation fails if the caller does not have the required privileges.

Return Values

On successful completion, the **aclx_put** and **aclx_fput** subroutines return a value of 0. Otherwise, -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **aclx_put** subroutine fails and the access control information for a file remains unchanged if one or more of the following are true:

Item	Description
EACCES	Search permission is denied on a component of the *Path* prefix.
EFAULT	The *Path* parameter points to a location outside of the allocated address space of the process.
ELOOP	Too many symbolic links were encountered in translating the *Path* parameter.
ENAMETOOLONG	A component of the *Path* parameter exceeded 255 characters, or the entire *Path* parameter exceeded 1023 characters.
ENOENT	A component of the *Path* does not exist or has the **disallow truncation** attribute (see the **ulimit** subroutine).
ENOENT	The *Path* parameter was null.
ENOENT	A symbolic link was named, but the file to which it refers does not exist.
ENOTDIR	A component of the *Path* prefix is not a directory.

Item	Description
ESTALE	The process' root or current directory is located in a virtual file system that has been unmounted.

The **aclx_fput** subroutine fails and the file permissions remain unchanged if the following is true:

Item	Description
EBADF	The *FileDescriptor* parameter is not a valid file descriptor.

The **aclx_put** or **aclx_fput** subroutine fails if one or more of the following is true:

Item	Description
EINVAL	Invalid input parameter. The same error can be returned if an invalid *acl_type* is specified as input to this routine.
EIO	An I/O error occurred during the operation.
EROFS	The named file resides on a read-only file system.

If Network File System (NFS) is installed on your system, the **acl_put** and **acl_fput** subroutines can also fail if the following condition is true:

Item	Description
ETIMEDOUT	The connection timed out.

Security

Access Control: The invoker must have search permission for all components of the *Path* prefix.

Auditing Events:

Item	Description
Event	**Information**
chacl	*Path*-based event
fchacl	*FileDescriptor*-based event

aclx_scan or aclx_scanStr Subroutine

Purpose

Reads the access control information that is in nonbinary, readable text format, and converts it into ACL type-specific native format binary ACL data.

Library

Security Library (**libc.a**)

Syntax

```
#include <sys/acl.h>

int aclx_scan (acl_file, acl, acl_sz, acl_type, err_file)
FILE * acl_file;
void  * acl;
size_t   * acl_sz;
```

```
acl_type_t   acl_type;
FILE  * err_file;

int aclx_scanStr (str, acl, acl_sz, acl_type)
char * str;
void  * acl;
size_t   * acl_sz;
acl_type_t   acl_type;
```

Description

The **aclx_scan** and **aclx_scanStr** subroutines read the access control information from the input given in nonbinary, readable text format and return a binary ACL data in the ACL type-specific native format. The **aclx_scan** subroutine provides the ACL data text in the file specified by *acl_file*. In the case of **aclx_scanStr**, the ACL data text is provided in the string pointed to by *str*. When the *err_file* parameter is not Null, it points to a file to which any error messages are written out by the **aclx_scan** subroutine in case of syntax errors in the input ACL data. The errors can occur if the syntax of the input text data does not adhere to the required ACL type-specific data specifications.

Parameters

Item	Description
acl_file	Points to the file from which the ACL text output is read.
str	Points to the string from which the ACL text output is printed.
acl	Points to a buffer in which the binary ACL data has to be stored. The amount of memory available in this buffer is indicated by the *acl_sz* parameter.
acl_sz	Indicates the amount of memory, in bytes, available in the *acl* parameter.
acl_type	Indicates the ACL type information of the *acl*. The ACL type is 64 bits in size and is unique on the system. If the given ACL type is not supported in the system, this function fails and **errno** is set to **EINVAL**. The supported ACL types are **ACLX** and **NFS4**.
err_file	File pointer to an error file. When this pointer is supplied, the subroutines write out any errors in the syntax/composition of the ACL input data.

Return Values

On successful completion, the **aclx_scan** and **aclx_scanStr** subroutines return a value of 0. Otherwise, -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **aclx_scan** subroutine fails if one or more of the following is true:

Note: The errors in the following list occur only because **aclx_scan** calls the **fscanf** subroutine internally. For more information about these errors, refer to the **fscanf** subroutine.

Item	Description
EAGAIN	The **O_NONBLOCK** flag is set for the file descriptor underlying the file specified by the *acl_file* parameter, and the process would be delayed in the write operation.
EBADF	The file descriptor underlying the file specified by the *acl_file* parameter is not a valid file descriptor open for writing.

Item	Description
EINTR	The write operation terminated because of a signal was received, and either no data was transferred or a partial transfer was not reported.
EIO	The process is a member of a background process group attempting to perform a write to its controlling terminal, the **TOSTOP** flag is set, the process is neither ignoring nor blocking the **SIGTTOU** signal, and the process group of the process has no parent process.
ENOSPC	Insufficient storage space is available.

The **aclx_scanStr** subroutine fails if the following is true:

Item	Description
ENOSPC	Insufficient storage space is available. This error is returned by **sscanf**, which is called by the **aclx_scanStr** subroutine internally.

The **aclx_scan** or **aclx_scanStr** subroutine fails if the following is true:

Item	Description
EINVAL	Invalid input parameter. The same error can be returned if an invalid *acl_type* is specified as input to this routine. This **errno** can also be returned if the text ACL given in the input/file string is not of the type specified by *acl_type*.

acos, acosf, acosl, acosd32, acosd64, or acosd128 Subroutines

Purpose

Computes the inverse cosine of a given value.

Syntax

```
#include <math.h>

float acosf (x)
float x;

long double acosl (x)
long double x;

double acos (x)
double x;
_Decimal32 acosd32 (x)
_Decimal32 x;

_Decimal64 acosd64 (x)
_Decimal64 x;

_Decimal128 acosd128 (x)
_Decimal128 x;
```

Description

The **acosf**, **acosl**, **acos**, **acosd32**, **acosd64**, and **acosd128** subroutines compute the principal value of the arc cosine of the *x* parameter. The value of *x* should be in the range [-1,1].

An application wishing to check for error situations should set the **errno** global variable to zero and call **fetestexcept(FE_ALL_EXCEPT)** before calling these functions. On return, if **errno** is nonzero or **fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW)** is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, these subroutines return the arc cosine of *x*, in the range [0, pi] radians.

For finite values of *x* not in the range [-1,1], a domain error occurs, and a NaN is returned.

If *x* is NaN, a NaN is returned.

If *x* is +1, 0 is returned.

If *x* is ±Inf, a domain error occurs, and a NaN is returned.

acosh, acoshf, acoshl, acoshd32, acoshd64, and acoshd128 Subroutines

Purpose

Computes the inverse hyperbolic cosine.

Syntax

```
#include <math.h>

float acoshf (x)
float x;

long double acoshl (X)
long double x;

double acosh (x)
double x;
_Decimal32 acoshd32 (x)
_Decimal32 x;

_Decimal64 acoshd64 (x)
_Decimal64 x;

_Decimal128 acoshd128 (x)
_Decimal128 x;
```

Description

The **acoshf**, **acoshl**, **acoshd32**, **acoshd64**, and **acoshd128** subroutines compute the inverse hyperbolic cosine of the *x* parameter.

The **acosh** subroutine returns the hyperbolic arc cosine specified by the *x* parameter, in the range 1 to the **+HUGE_VAL** value.

An application wishing to check for error situations should set **errno** to zero and call **fetestexcept(FE_ALL_EXCEPT)** before calling these subroutines. Upon return, if the **errno** global variable is nonzero or **fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW)** is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **acoshf**, **acoshl**, **acoshd32**, **acoshd64**, and **acoshd128** subroutines return the inverse hyperbolic cosine of the given argument.

For finite values of *x* < 1, a domain error occurs, and a NaN is returned.

If *x* is NaN, a NaN is returned.

If *x* is +1, 0 is returned.

If *x* is +Inf, +Inf is returned.

If *x* is -Inf, a domain error occurs, and a NaN is returned.

Error Codes

The **acosh** subroutine returns **NaNQ** (not-a-number) and sets **errno** to **EDOM** if the *x* parameter is less than the value of 1.

addch, mvaddch, mvwaddch, or waddch Subroutine

Purpose

Adds a single-byte character and rendition to a window and advances the cursor.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
int addch(const chtype ch);
```

```
int mvaddch(int y,
int x,
const chtype ch);
```

```
int mvwaddch(WINDOW *in,
const chtype ch);
```

```
int waddch(WINDOW *win,
const chtype ch);
```

Description

The **addch**, **waddch**, **mvaddch**, and **mvwaddch** subroutines add a character to a window at the logical cursor location. After adding the character, curses advances the position of the cursor one character. At the right margin, an automatic new line is performed.

The **addch** subroutine adds the character to the stdscr at the current logical cursor location. To add a character to a user-defined window, use the **waddch** and **mvwaddch** subroutines. The **mvaddch** and **mvwaddch** subroutines move the logical cursor before adding a character.

If you add a character to the bottom of a scrolling region, curses automatically scrolls the region up one line from the bottom of the scrolling region if **scrollok** is enabled. If the character to add is a tab, new-line, or backspace character, curses moves the cursor appropriately in the window to reflect the addition. Tabs are set at every eighth column. If the character is a new-line, curses first uses the **wclrtoeol** subroutine to erase the current line from the logical cursor position to the end of the line before moving the cursor.

You can also use the **addch** subroutines to add control characters to a window. Control characters are drawn in the ^X notation.

Adding Video Attributes and Text

Because the *Char* parameter is an integer, not a character, you can combine video attributes with a character by ORing them into the parameter. The video attributes are also set. With this capability you can copy text and video attributes from one location to another using the **inch** (inch) and **addch** subroutines.

Parameters

Item	Description
ch	
y	
x	
**win*	

Return Values

Upon successful completion, these subroutines return OK. Otherwise, they return ERR.

Examples

1. To add the character *H* represented by variable *x* to stdscr at the current cursor location, enter:

```
chtype x;
x='H';
addch(x);
```

2. To add the x character to stdscr at the coordinates y = 10, x = 5, enter:

```
mvaddch(10, 5, 'x');
```

3. To add the x character to the user-defined window `my_window` at the coordinates y = 10, x = 5, enter:

```
WINDOW *my_window;
mvwaddch(my_window, 10, 5, 'x');
```

4. To add the x character to the user-defined window `my_window` at the current cursor location, enter:

```
WINDOW *my_window;
waddch(my_window, 'x');
```

5. To add the character *x* in standout mode, enter:

```
waddch(my_window, 'x' | A_STANDOUT);
```

This allows 'x' to be highlighted, but leaves the rest of the window alone.

addnstr, addstr, mvaddnstr, mvaddstr, mvwaddnstr, mvwaddstr, waddnstr, or waddstr Subroutine

Purpose

Adds a string of multi-byte characters without rendition to a window and advances the cursor.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
int addnstr(const char *str,
int n);
```

```
int addstr(const char *str);
```

```
int mvaddnstr(int y,
int x,
const char *str,
int n);
```

```
int mvaddstr(int y,
int x,
const char *str);
```

```
int mvwaddnstr(WINDOW *win,
int y,
int x,
const char *str,
int n);
```

```
int mvwaddstr(WINDOW *win,
int y,
int x,
const char *str);
```

```
int waddnstr(WINDOW *win,
const char *str,
int n);
```

```
int waddstr(WINDOW *win,
const char *str);
```

Description

These subroutines write the characters of the string *str* on the current or specified window starting at the current or specified position using the background rendition.

These subroutines advance the cursor position, perform special character processing, and perform wrapping.

The **addstr**, **mvaddstr**, **mvwaddstr** and **waddstr** subroutines are similar to calling **mbstowcs** on *str*, and then calling **addwstr**, **mvaddwstr**, **mvwaddwstr**, and **waddwstr**, respectively.

The **addnstr**, **mvaddnstr**, **mvwaddnstr** and **waddnstr** subroutines use at most, *n* bytes from *str*. These subroutines add the entire string when *n* is -1.

Parameters

Item	Description
Column	Specifies the horizontal position to move the cursor to before adding the string.
Line	Specifies the vertical position to move the cursor to before adding the string.
String	Specifies the string to add.
Window	Specifies the window to add the string to.

Return Values

Upon successful completion, these subroutines return OK. Otherwise, they return ERR.

Examples

1. To add the string represented by `xyz` to the stdscr at the current cursor location, enter:

```
char *xyz;
xyz="Hello!";
addstr(xyz);
```

2. To add the `"Hit a Key"` string to the stdscr at the coordinates y=10, x=5, enter:

```
mvaddstr(10, 5, "Hit a Key");
```

3. To add the `xyz` string to the user-defined window `my_window` at the coordinates y=10, x=5, enter:

```
mvwaddstr(my_window, 10, 5, "xyz");
```

4. To add the `xyz` string to the user-defined string at the current cursor location, enter:

```
waddstr(my_window, "xyz");
```

addproj Subroutine

Purpose

Adds an API-based project definition to the kernel project registry.

Library

The **libaacct.a** library.

Syntax

```
<sys/aacct.h>

addproj(struct project *)
```

Description

The **addproj** subroutine defines the application-based project definition to the kernel repository. An application can assign a project defined in this way using the `proj_execve` system call.

Projects that are added this way are marked as being specified by applications so that they do not overlap with system administrator-specified projects defined using the `projctl` command. The `PROJFLAG_API` flag is turned on in the structure project to indicate that the project definition was added by an application.

Projects added by a system administrator using the `projctl` command are flagged as being derived from the local or LDAP-based project repositories by the `PROJFLAGS_LDAP` or `PROJFLAGS_PDF` flag. If one of these flags is specified, the `addproj` subroutine fails with `EPERM`.

The `getproj` routine can be used to determine the origin of a loaded project.

The **addproj** validates the input project number to ensure that it is within the expected range of 0x00000001 - 0x00ffffff. It also validates that the project name is a POSIX compliant alphanumeric character string. If any invalid input is found errno will be set to **EINVAL** and the **addproj** subroutine returns -1.

Parameters

Item	Description
project	Points to a project structure that holds the definition of the project to be added.

Security

Only for privileged users. Privilege can be extended to nonroot users by granting the CAP_AACCT capability to a user.

Return Values

Item	Description
0	Success
-1	Failure

Error Codes

Item	Description
EINVAL	Invalid Project Name / Number or the passed pointer is NULL
EEXIST	Project Definition exists
EPERM	Permission Denied, not a privileged user

addprojdb Subroutine

Purpose

Adds a project definition to the specified project database.

Library

The **libaacct.a** library.

Syntax

```
<sys/aacct.h>

addprojdb(void *handle, struct project *project, char *comment)
```

Description

The **addprojdb** subroutine appends the project definition stored in the struct *project* variable into the project database named by the *handle* parameter. The project database must be initialized before calling this subroutine. The **projdballoc** subroutine is provided for this purpose. This routine verifies whether the supplied project definition already exists. If it does exist, the **addprojdb** subroutine sets errno to **EEXIST** and returns -1.

The **addprojdb** subroutine validates the input project number to ensure that it is within the expected range 0x00000001 - 0x00ffffff and validates that the project name is a POSIX-compliant alphanumeric character string. If any invalid input is found, the **addprojdb** subroutine sets errno to **EINVAL** and returns -1.

If the user does not have privilege to add an entry to project database, the **addprojdb** subroutine sets errno to **EACCES** and returns -1.

There is an internal state (that is, the current project) associated with the project database. When the project database is initialized, the current project is the first project in the database. The **addprojdb** subroutine appends the specified project to the end of the database. It advances the current project assignment to the next project in the database, which is the end of the project data base. At this point, a call to the **getnextprojdb** subroutine would fail, because there are no additional project definitions. To read the project definition that was just added, use the **getprojdb** subroutine. To read other projects, first call **getfirstprojdb** subroutine to reset the internal current project assignment so that subsequent reads can be performed.

The format of the records added to the project database are given as follows:

```
ProjectName:ProjectNumber:AggregationStatus:Comment::
```

Example:

```
Biology:4756:no:Project Created by projctl command::
```

Parameters

Item	Description
handle	Pointer to project database handle
project	Pointer to a project structure that holds the definition of the project to be added
comment	Pointer to a character string that holds the comments about the project

Security

Only for privileged users. Privilege can be extended to nonroot users by granting the CAP_AACCT capability to a user.

Return Values

Item	Description
0	Success
-1	Failure

Error Codes

Item	Description
EINVAL	Invalid project name or number, or the passed pointer is NULL.
EEXIST	Project definition already exists.
EPERM	Permission denied. The user is not a privileged user.

addssys Subroutine

Purpose

Adds the **SRCsubsys** record to the subsystem object class.

Library

System Resource Controller Library (**libsrc.a**)

Syntax

```
#include <sys/srcobj.h>
#include <spc.h>
```

int addssys (*SRCSubsystem*)
**struct SRCsubsys ***SRCSubsystem*;

Description

The **addssys** subroutine adds a record to the subsystem object class. You must call the **defssys** subroutine to initialize the *SRCSubsystem* buffer before your application program uses the **SRCsubsys** structure. The **SRCsubsys** structure is defined in the **/usr/include/sys/srcobj.h** file.

The executable running with this subroutine must be running with the group system.

Parameters

Item	Description
SRCSubsystem	A pointer to the **SRCsubsys** structure.

Return Values

Upon successful completion, the **addssys** subroutine returns a value of 0. Otherwise, it returns a value of -1 and the **odmerrno** variable is set to indicate the error, or an SRC error code is returned.

Error Codes

The **addssys** subroutine fails if one or more of the following are true:

Item	Description
SRC_BADFSIG	Invalid stop force signal.
SRC_BADNSIG	Invalid stop normal signal.
SRC_CMDARG2BIG	Command arguments too long.
SRC_GRPNAM2BIG	Group name too long.
SRC_NOCONTACT	Contact not signal, sockets, or message queue.
SRC_NONAME	No subsystem name specified.
SRC_NOPATH	No subsystem path specified.
SRC_PATH2BIG	Subsystem path too long.
SRC_STDERR2BIG	stderr path too long.
SRC_STDIN2BIG	stdin path too long.
SRC_STDOUT2BIG	stdout path too long.
SRC_SUBEXIST	New subsystem name already on file.
SRC_SUBSYS2BIG	Subsystem name too long.
SRC_SYNEXIST	New subsystem synonym name already on file.
SRC_SYN2BIG	Synonym name too long.

Security

Privilege Control: This command has the Trusted Path attribute. It has the following kernel privilege:

Item	Description
SET_PROC_AUDIT	
Files Accessed:	

Mode	File
644	**/etc/objrepos/SRCsubsys**

Auditing Events:

If the auditing subsystem has been properly configured and is enabled, the **addssys** subroutine generates the following audit record (event) each time the subroutine is executed:

Event	Information
SRC_addssys	Lists the SRCsubsys records added.

Files

Item	Description
/etc/objrepos/SRCsubsys	SRC Subsystem Configuration object class.
/dev/SRC	Specifies the **AF_UNIX** socket file.
/dev/.SRC-unix	Specifies the location for temporary socket files.
/usr/include/spc.h	Defines external interfaces provided by the SRC subroutines.
/usr/include/sys/srcobj.h	Defines object structures used by the SRC.

adjtime Subroutine

Purpose

Corrects the time to allow synchronization of the system clock.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/time.h>
int adjtime ( Delta,  Olddelta)
struct timeval *Delta;
struct timeval *Olddelta;
```

Description

The **adjtime** subroutine makes small adjustments to the system time, as returned by the **gettimeofday** subroutine, advancing or retarding it by the time specified by the *Delta* parameter of the **timeval** structure. If the *Delta* parameter is negative, the clock is slowed down by periodically subtracting a small amount from it until the correction is complete. If the *Delta* parameter is positive, a small amount is periodically added to the clock until the correction is complete. The skew used to perform the correction is generally ten percent. If the clock is sampled frequently enough, an application program can see time apparently jump backwards. For information on a way to avoid this, see **getimeofday** subroutine. A time correction from an earlier call to the **adjtime** subroutine may not be finished when the **adjtime** subroutine

is called again. If the *Olddelta* parameter is nonzero, then the structure pointed to will contain, upon return, the number of microseconds still to be corrected from the earlier call.

This call may be used by time servers that synchronize the clocks of computers in a local area network. Such time servers would slow down the clocks of some machines and speed up the clocks of others to bring them to the average network time.

The **adjtime** subroutine is restricted to the users with root user authority.

Parameters

Item	Description
Delta	Specifies the amount of time to be altered.
Olddelta	Contains the number of microseconds still to be corrected from an earlier call.

Return Values

A return value of 0 indicates that the **adjtime** subroutine succeeded. A return value of -1 indicates than an error occurred, and **errno** is set to indicate the error.

Error Codes

The **adjtime** subroutine fails if the following are true:

Item	Description
EFAULT	An argument address referenced invalid memory.
EPERM	The process's effective user ID does not have root user authority.

agg_proc_stat, agg_lpar_stat, agg_arm_stat, or free_agg_list Subroutine

Purpose

Aggregate advanced accounting data.

Library

The `libaacct.a` library.

Syntax

```
#define <sys/aacct.h>
int agg_arm_stat(tran_list, arm_list);
struct aacct_tran_rec *tran_list
struct agg_arm_stat **arm_list
int agg_proc_stat(sortcrit1, sortcrit2, sortcrit3, sortcrit4, tran_list, proc_list);
int sortcrit1, sortcrit2, sortcrit3, sortcrit4
struct aacct_tran_rec *tran_list
struct agg_proc_stat **proc_list
int agg_lpar_stat(l_type, *tran_list, l_list);
int l_type
struct aacct_tran_rec *tran_list
union agg_lpar_rec *l_list
void free_agg_list(list);
void *list
```

Description

The agg_proc_stat, agg_lpar_stat, and agg_arm_stat subroutines return a linked list of aggregated transaction records for process, LPAR, and ARM, respectively.

The agg_proc_stat subroutine performs the process record aggregation based on the criterion values passed as input parameters. The aggregated process transaction records are sorted based on the sorting criteria values *sortcrit1*, *sortcrit2*, *sortcrit3*, and *sortcrit4*. These four can be one of the following values defined in the sys/aacct.h file:

- CRIT_UID
- CRIT_GID
- CRIT_PROJ
- CRIT_CMD
- CRIT_NONE

The order of their usage determines the sorting order applied to the retrieved aggregated list of process transaction records. For example, the sort criteria values of PROJ_GID, PROJ_PROJ, PROJ_UID, PROJ_NONE first sorts the aggregated list on group IDs, which are further sorted based on project IDs, followed by another level of sorting based on user IDs.

Some of the process transaction records (of type TRID_agg_proc) cannot be aggregated based on group IDs and command names. For such records, agg_proc_stat returns an asterisk (*) character as the command name and a value of -2 as the group ID. This indicates to the caller that these records cannot be aggregated.

If the aggregation is not necessary on a specific criteria, agg_proc_stat returns a value of -1 in the respective field. For example, if the aggregation is not necessary on the group ID (CRIT_GID), the retrieved list of aggregation records has a value of -1 filled in the group ID fields.

The agg_lpar_stat retrieves an aggregated list of LPAR transaction records. Because there are several types of LPAR transaction records, the caller must specify the type of LPAR transaction record that is to be aggregated. The transaction record type can be one of the following values, defined in the sys/aacct.h file:

- AGG_CPUMEM
- AGG_FILESYS
- AGG_NETIF
- AGG_DISK
- AGG_VTARGET
- AGG_VCLIENT

The agg_lpar_stat subroutine uses a union argument of type struct agg_lpar_rec. For this argument, the caller must provide the address of the linked list to which the aggregated records should be returned.

The agg_arm_list retrieves an aggregated list of ARM transaction records from the list of transaction records provided as input. The aggregated transaction records are returned to the caller through the structure pointer of type struct agg_arm_stat.

The free_agg_list subroutine frees the memory allocated to the aggregated records returned by the agg_proc_stat, agg_lpar_stat, or agg_arm_stat subroutine.

Parameters

Item	Description
arm_list	Pointer to the linked list of struct agg_arm_stat nodes to be returned.

Item	Description
l_list	Pointer to `union agg_lpar_rec` address to which the aggregated LPAR records are returned.
l_type	Integer value that represents the type of LPAR resource to be aggregated.
list	Pointer to the aggregated list to be freed.
proc_list	Pointer to the linked list of `struct agg_proc_stat` nodes to be returned.
sortcrit1, *sortcrit2*, *sortcrit3*, *sortcrit4*	Integer values that represent the sorting criteria to be passed to `agg_proc_stat`.
tran_list	Pointer to the input list of transaction records

Security

No restrictions. Any user can call this function.

Return Values

Item	Description
0	The call to the subroutine was successful.
-1	The call to the subroutine failed.

Error Codes

Item	Description
EINVAL	The passed pointer is NULL.
ENOMEM	Insufficient memory.
EPERM	Permission denied. Unable to read the data file.

aio_cancel or aio_cancel64 Subroutine

The **aio_cancel** or **aio_cancel64** subroutine includes information for the POSIX AIO **aio_cancel** subroutine (as defined in the IEEE std 1003.1-2001), and the Legacy AIO **aio_cancel** subroutine.

POSIX AIO aio_cancel Subroutine

Purpose

Cancels one or more outstanding asynchronous I/O requests.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <aio.h>

int aio_cancel (fildes, aiocbp)
int fildes;
struct aiocb *aiocbp;
```

Description

The **aio_cancel** subroutine cancels one or more asynchronous I/O requests currently outstanding against the *fildes* parameter. The *aiocbp* parameter points to the asynchronous I/O control block for a particular request to be canceled. If *aiocbp* is NULL, all outstanding cancelable asynchronous I/O requests against *fildes* are canceled.

Normal asynchronous notification occurs for asynchronous I/O operations that are successfully canceled. If there are requests that cannot be canceled, the normal asynchronous completion process takes place for those requests when they are completed.

For requested operations that are successfully canceled, the associated error status is set to **ECANCELED**, and a -1 is returned. For requested operations that are not successfully canceled, the *aiocbp* parameter is not modified by the **aio_cancel** subroutine.

If *aiocbp* is not NULL, and if *fildes* does not have the same value as the file descriptor with which the asynchronous operation was initiated, unspecified results occur.

The implementation of the subroutine defines which operations are cancelable.

Parameters

Item	Description
fildes	Identifies the object to which the outstanding asynchronous I/O requests were originally queued.
aiocbp	Points to the **aiocb** structure associated with the I/O operation.

aiocb Structure

The **aiocb** structure is defined in the **/usr/include/aio.h** file and contains the following members:

```
int               aio_fildes
off_t             aio_offset
char             *aio_buf
size_t            aio_nbytes
int               aio_reqprio
struct sigevent   aio_sigevent
int               aio_lio_opcode
```

Execution Environment

The **aio_cancel** and **aio_cancel64** subroutines can be called from the process environment only.

Return Values

The **aio_cancel** subroutine returns AIO_CANCELED to the calling process if the requested operation(s) were canceled. AIO_NOTCANCELED is returned if at least one of the requested operations cannot be canceled because it is in progress. In this case, the state of the other operations, referenced in the call to **aio_cancel** is not indicated by the return value of **aio_cancel**. The application may determine the state of affairs for these operations by using the **aio_error** subroutine. AIO_ALLDONE is returned if all of the operations are completed. Otherwise, the subroutine returns -1 and sets the **errno** global variable to indicate the error.

Error Codes

Item	Description
EBADF	The *fildes* parameter is not a valid file descriptor.

Legacy AIO aio_cancel Subroutine

Purpose: Cancels one or more outstanding asynchronous I/O requests.

Library (Legacy AIO aio_cancel Subroutine)

Standard C Library (**libc.a**)

Syntax (Legacy AIO aio_cancel Subroutine)

```
#include <aio.h>
```

aio_cancel (*FileDescriptor*, *aiocbp*)
int *FileDescriptor*;
struct aiocb ***aiocbp**;

aio_cancel64 (*FileDescriptor*, *aiocbp*)
int *FileDescriptor*;
struct aiocb64 ***aiocbp**;

Description (Legacy AIO aio_cancel Subroutine)

The **aio_cancel** subroutine attempts to cancel one or more outstanding asynchronous I/O requests issued on the file associated with the *FileDescriptor* parameter. If the pointer to the **aio control block (aiocb)** structure (the *aiocbp* parameter) is not null, then an attempt is made to cancel the I/O request associated with this **aiocb**. The *aiocbp* parameter used by the thread calling **aix_cancel** must have had its request initiated by this same thread. Otherwise, a -1 is returned and **errno** is set to EINVAL. However, if the *aiocbp* parameter is null, then an attempt is made to cancel all outstanding asynchronous I/O requests associated with the *FileDescriptor* parameter without regard to the initiating thread.

The **aio_cancel64** subroutine is similar to the **aio_cancel** subroutine except that it attempts to cancel outstanding large file enabled asynchronous I/O requests. Large file enabled asynchronous I/O requests make use of the **aiocb64** structure instead of the aiocb structure. The **aiocb64** structure allows asynchronous I/O requests to specify offsets in excess of OFF_MAX (2 gigbytes minus 1).

In the large file enabled programming environment, **aio_cancel** is redefined to be **aio_cancel64**.

When an I/O request is canceled, the **aio_error** subroutine called with the handle to the corresponding **aiocb** structure returns **ECANCELED**.

Note: The _AIO_AIX_SOURCE macro used in **aio.h** must be defined when using **aio.h** to compile an aio application with the Legacy AIO function definitions. The default compilation using the **aio.h** file is for an application with the POSIX AIO definitions. In the source file enter:

```
#define _AIO_AIX_SOURCE
#include <sys/aio.h>
```

or, on the command line when compiling enter:

```
->xlc ... -D_AIO_AIX_SOURCE ... legacy_aio_program.c
```

Parameters (Legacy AIO aio_cancel Subroutine)

Item	Description
FileDescriptor	Identifies the object to which the outstanding asynchronous I/O requests were originally queued.
aiocbp	Points to the **aiocb** structure associated with the I/O operation.

aiocb Structure

The **aiocb** structure is defined in the **/usr/include/aio.h** file and contains the following members:

```
struct aiocb
{
       int                aio_whence;
       off_t              aio_offset;
       char               *aio_buf;
       ssize_t            aio_return;
       int                aio_errno;
       size_t             aio_nbytes;
       union {
              int         reqprio;
              struct {
                     int   version:8;
                     int   priority:8;
                     int   cache_hint:16;
              } ext;
       } aio_u1;
       int                aio_flag;
       int                aio_iocpfd;
       aio_handle_t       aio_handle;
}

#define aio_reqprio        aio_u1.reqprio
#define aio_version        aio_u1.ext.version
#define aio_priority       aio_u1.ext.priority
#define aio_cache_hint     aio_u1.ext.cache_hint
```

Execution Environment (Legacy AIO aio_cancel Subroutine)

The **aio_cancel** and **aio_cancel64** subroutines can be called from the process environment only.

Return Values (Legacy AIO aio_cancel Subroutine)

Item	Description
AIO_CANCELED	Indicates that all of the asynchronous I/O requests were canceled successfully. The **aio_error** subroutine call with the handle to the **aiocb** structure of the request will return **ECANCELED**.
AIO_NOTCANCELED	Indicates that the **aio_cancel** subroutine did not cancel one or more outstanding I/O requests. This may happen if an I/O request is already in progress. The corresponding error status of the I/O request is not modified.
AIO_ALLDONE	Indicates that none of the I/O requests is in the queue or in progress.
-1	Indicates that the subroutine was not successful. Sets the **errno** global variable to identify the error.

A return code can be set to the following **errno** value:

Item	Description
EBADF	Indicates that the *FileDescriptor* parameter is not valid.

aio_error or aio_error64 Subroutine

The **aio_error** or **aio_error64** subroutine includes information for the POSIX AIO **aio_error** subroutine (as defined in the IEEE std 1003.1-2001), and the Legacy AIO **aio_error** subroutine.

POSIX AIO aio_error Subroutine

Purpose

Retrieves error status for an asynchronous I/O operation.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <aio.h>

int aio_error (aiocbp)
const struct aiocb *aiocbp;
```

Description

The **aio_error** subroutine returns the error status associated with the **aiocb** structure. This structure is referenced by the *aiocbp* parameter. The error status for an asynchronous I/O operation is the synchronous I/O **errno** value that would be set by the corresponding **read**, **write**, or **fsync** subroutine. If the subroutine has not yet completed, the error status is equal to **EINPROGRESS**.

Parameters

Item	Description
aiocbp	Points to the **aiocb** structure associated with the I/O operation.

aiocb Structure

The **aiocb** structure is defined in the **/usr/include/aio.h** file and contains the following members:

```
int               aio_fildes
off_t             aio_offset
char             *aio_buf
size_t            aio_nbytes
int               aio_reqprio
struct sigevent   aio_sigevent
int               aio_lio_opcode
```

Execution Environment

The **aio_error** and **aio_error64** subroutines can be called from the process environment only.

Return Values

If the asynchronous I/O operation has completed successfully, the **aio_error** subroutine returns a 0. If unsuccessful, the error status (as described for the **read**, **write**, and **fsync** subroutines) is returned. If the asynchronous I/O operation has not yet completed, **EINPROGRESS** is returned.

Error Codes

Item	Description
EINVAL	The *aiocbp* parameter does not refer to an asynchronous operation whose return status has not yet been retrieved.

Legacy AIO aio_error Subroutine

Purpose: Retrieves the error status of an asynchronous I/O request.

Library (Legacy AIO aio_error Subroutine)

Standard C Library (**libc.a**)

Syntax (Legacy AIO aio_error Subroutine)

```
#include <aio.h>
```

int
aio_error(*handle***)**
aio_handle_t *handle***;**

int aio_error64(*handle***)**
aio_handle_t *handle***;**

Description (Legacy AIO aio_error Subroutine)

The **aio_error** subroutine retrieves the error status of the asynchronous request associated with the *handle* parameter. The error status is the **errno** value that would be set by the corresponding I/O operation. The error status is **EINPROG** if the I/O operation is still in progress.

The **aio_error64** subroutine is similar to the **aio_error** subroutine except that it retrieves the error status associated with an **aiocb64** control block.

Note: The _AIO_AIX_SOURCE macro used in **aio.h** must be defined when using **aio.h** to compile an aio application with the Legacy AIO function definitions. The default compile using the **aio.h** file is for an application with the POSIX AIO definitions. In the source file enter:

```
#define _AIO_AIX_SOURCE
#include <sys/aio.h>
```

or, on the command line when compiling enter:

```
->xlc ... -D_AIO_AIX_SOURCE ... legacy_aio_program.c
```

Parameters (Legacy AIO aio_error Subroutine)

Item	Description
handle	The handle field of an **aio control block** (**aiocb** or **aiocb64**) structure set by a previous call of the **aio_read**, **aio_read64**, **aio_write**, **aio_write64**, **lio_listio**, **aio_listio64** subroutine. If a random memory location is passed in, random results are returned.

aiocb Structure

The **aiocb** structure is defined in the **/usr/include/aio.h** file and contains the following members:

```
struct aiocb
{
       int                aio_whence;
       off_t              aio_offset;
       char               *aio_buf;
       ssize_t            aio_return;
       int                aio_errno;
       size_t             aio_nbytes;
       union {
              int         reqprio;
              struct {
                     int   version:8;
                     int   priority:8;
                     int   cache_hint:16;
              } ext;
       } aio_u1;
       int                aio_flag;
       int                aio_iocpfd;
       aio_handle_t       aio_handle;
}

#define aio_reqprio       aio_u1.reqprio
#define aio_version       aio_u1.ext.version
```

```
#define aio_priority       aio_u1.ext.priority
#define aio_cache_hint     aio_u1.ext.cache_hint
```

Execution Environment (Legacy AIO aio_error Subroutine)

The **aio_error** and **aio_error64** subroutines can be called from the process environment only.

Return Values (Legacy AIO aio_error Subroutine)

Item	Description
0	Indicates that the operation completed successfully.
ECANCELED	Indicates that the I/O request was canceled due to an **aio_cancel** subroutine call.
EINPROG	Indicates that the I/O request has not completed. An **errno** value described in the **aio_read** , **aio_write**, and **lio_listio** subroutines: Indicates that the operation was not queued successfully. For example, if the **aio_read** subroutine is called with an unusable file descriptor, it (**aio_read**) returns a value of -1 and sets the **errno** global variable to **EBADF**. A subsequent call of the **aio_error** subroutine with the handle of the unsuccessful **aio control block** (**aiocb**) structure returns **EBADF**. An **errno** value of the corresponding I/O operation: Indicates that the operation was initiated successfully, but the actual I/O operation was unsuccessful. For example, calling the **aio_write** subroutine on a file located in a full file system returns a value of 0, which indicates the request was queued successfully. However, when the I/O operation is complete (that is, when the **aio_error** subroutine no longer returns **EINPROG**), the **aio_error** subroutine returns **ENOSPC**. This indicates that the I/O was unsuccessful.

aio_fsync Subroutine

Purpose

Synchronizes asynchronous files.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <aio.h>

int aio_fsync (op, aiocbp)
int op;
struct aiocb *aiocbp;
```

Description

The **aio_fsync** subroutine asynchronously forces all I/O operations to the synchronized I/O completion state. The function call returns when the synchronization request has been initiated or queued to the file or device (even when the data cannot be synchronized immediately).

If the *op* parameter is set to O_DSYNC, all currently queued I/O operations are completed as if by a call to the **fdatasync** subroutine. If the *op* parameter is set to O_SYNC, all currently queued I/O operations are completed as if by a call to the **fsync** subroutine. If the **aio_fsync** subroutine fails, or if the operation queued by **aio_fsync** fails, outstanding I/O operations are not guaranteed to be completed.

If **aio_fsync** succeeds, it is only the I/O that was queued at the time of the call to **aio_fsync** that is guaranteed to be forced to the relevant completion state. The completion of subsequent I/O on the file descriptor is not guaranteed to be completed in a synchronized fashion.

The *aiocbp* parameter refers to an asynchronous I/O control block. The *aiocbp* value can be used as an argument to the **aio_error** and **aio_return** subroutines in order to determine the error status and return status, respectively, of the asynchronous operation while it is proceeding. When the request is queued, the error status for the operation is **EINPROGRESS**. When all data has been successfully transferred, the error status is reset to reflect the success or failure of the operation. If the operation does not complete successfully, the error status for the operation is set to indicate the error. The *aio_sigevent* member determines the asynchronous notification to occur when all operations have achieved synchronized I/O completion. All other members of the structure referenced by the *aiocbp* parameter are ignored. If the control block referenced by *aiocbp* becomes an illegal address prior to asynchronous I/O completion, the behavior is undefined.

If the **aio_fsync** subroutine fails or *aiocbp* indicates an error condition, data is not guaranteed to have been successfully transferred.

Parameters

Item	Description
op	Determines the way all currently queued I/O operations are completed.
aiocbp	Points to the **aiocb** structure associated with the I/O operation.

aiocb Structure

The **aiocb** structure is defined in the **/usr/include/aio.h** file and contains the following members:

```
int               aio_fildes
off_t             aio_offset
char             *aio_buf
size_t            aio_nbytes
int               aio_reqprio
struct sigevent   aio_sigevent
int               aio_lio_opcode
```

Execution Environment

The **aio_error** and **aio_error64** subroutines can be called from the process environment only.

Return Values

The **aio_fsync** subroutine returns a 0 to the calling process if the I/O operation is successfully queued. Otherwise, it returns a -1, and sets the **errno** global variable to indicate the error.

Error Codes

Item	Description
EAGAIN	The requested asynchronous operation was not queued due to temporary resource limitations.
EBADF	The *aio_fildes* member of the **aiocb** structure referenced by the *aiocbp* parameter is not a valid file descriptor open for writing.

In the event that any of the queued I/O operations fail, the **aio_fsync** subroutine returns the error condition defined for the **read** and **write** subroutines. The error is returned in the error status for the asynchronous **fsync** subroutine, which can be retrieved using the **aio_error** subroutine.

aio_nwait Subroutine

Purpose

Suspends the calling process until a certain number of asynchronous I/O requests are completed.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <aio.h>

int aio_nwait (cnt, nwait, list)
int cnt;
int nwait;
struct aiocb **list;
```

Description

Although the **aio_nwait** subroutine is included with POSIX AIO, it is not part of the standard definitions for POSIX AIO.

The **aio_nwait** subroutine suspends the calling process until a certain number (*nwait*) of asynchronous I/O requests are completed. These requests are initiated at an earlier time by the **lio_listio** subroutine, which uses the LIO_NOWAIT_AIOWAIT *cmd* parameter. The **aio_nwait** subroutine fills in the **aiocb** pointers to the completed requests in *list* and returns the number of valid entries in *list*. The *cnt* parameter is the maximum number of **aiocb** pointers that *list* can hold (*cnt* >= *nwait*). The subroutine also returns when less than *nwait* number of requests are done if there are no more pending aio requests.

Note: If the **lio_listio64** subroutine is used, the **aiocb** structure changes to **aiocb64**.

Note: The aio control block's **errno** field continues to have the value EINPROG until after the **aio_nwait** subroutine is completed. The **aio_nwait** subroutine updates this field when the **lio_listio** subroutine has run with the LIO_NOWAIT_AIOWAIT *cmd* parameter. No utility, such as **aio_error**, can be used to look at this value until after the **aio_nwait** subroutine is completed.

The **aio_suspend** subroutine returns after any one of the specified requests gets done. The **aio_nwait** subroutine returns after a certain number (*nwait* or more) of requests are completed.

There are certain limitations associated with the **aio_nwait** subroutine, and a comparison between it and the **aio_suspend** subroutine is necessary. The following table is a comparison of the two subroutines:

aio_suspend:	**aio_nwait:**
Requires users to build a list of control blocks, each associated with an I/O operation they want to wait for.	Requires the user to provide an array to put **aiocb** address information into. No specific aio control blocks need to be known.
Returns when any one of the specified control blocks indicates that the I/O associated with that control block completed.	Returns when *nwait* amount of requests are done or no other requests are to be processed.
The aio control blocks may be updated before the subroutine is called. Other polling methods (such as the **aio_error** subroutine) can also be used to view the aio control blocks.	Updates the aio control blocks itself when it is called. Other polling methods can't be used until after the **aio_nwait** subroutine is called enough times to cover all of the aio requests specified with the **lio_listio** subroutine.

aio_suspend:

aio_nwait:

Is only used in accordance with the **LIO_NOWAIT_AIOWAIT** command, which is one of the commands associated with the **lio_listio** subroutine. If the **lio_listio** subroutine is not first used with the **LIO_NOWAIT_AIOWAIT** command, **aio_nwait** can not be called. The **aio_nwait** subroutine only affects those requests called by one or more **lio_listio** calls for a specified process.

Parameters

Item	Description
cnt	Specifies the number of entries in the list array. This number must be greater than 0 and less than 64 000.
nwait	Specifies the minimal number of requests to wait on. This number must be greater than 0 and less than or equal to the value specified by the *cnt* parameter.
list	An array of pointers to aio control structures defined in the **aio.h** file.

Return Values

The return value is the total number of requests the **aio_nwait** subroutine has waited on to complete. It can not be more than *cnt*. Although *nwait* is the desired amount of requests to find, the actual amount returned could be less than, equal to, or greater than *nwait*. The return value indicates how much of the list array to access.

The return value may be greater than the *nwait* value if the **lio_listio** subroutine initiated more than *nwait* requests and the *cnt* variable is larger than *nwait*. The *nwait* parameter represents a minimal value desired for the return value, and *cnt* is the maximum value possible for the return.

The return value may be less than the *nwait* value if some of the requests initiated by the **lio_listio** subroutine occur at a time of high activity, and there is a lack of resources available for the number of requests. **EAGAIN** (error try again later) may be returned in some request's aio control blocks, but these requests will not be seen by the **aio_nwait** subroutine. In this situation **aiocb** addresses not found on the list have to be accessed by using the **aio_error** subroutine after the **aio_nwait** subroutine is called. You may need to increase the aio parameters *max servers* or *max requests* if this occurs. Increasing the parameters will ensure that the system is well tuned, and an **EAGAIN** error is less likely to occur.

In the event of an error, the **aio_nwait** subroutine returns a value of -1 and sets the **errno** global variable to identify the error. Return codes can be set to the following **errno** values:

Item	Description
EBUSY	An **aio_nwait** call is in process.
EINVAL	The application has retrieved all of the **aiocb** pointers, but the user buffer does not have enough space for them.
EINVAL	There are no outstanding async I/O calls.
EINVAL	Specifies *cnt* or *nwait* values that are not valid.

aio_nwait_timeout Subroutine

Purpose

Extends the capabilities of the **aio_nwait** subroutine by specifying timeout values.

Library

Standard C library (**libc.a**).

Syntax

```
int aio_nwait_timeout (cnt, nwait, list, timeout)
int cnt;
int nwait;
struct aiocbp **list;
int timeout;
```

Description

The **aio_nwait_timeout** subroutine waits for a certain number of asynchronous I/O operations to complete as specified by the *nwait* parameter, or until the call has blocked for a certain duration specified by the *timeout* parameter.

Parameters

Item	Description
cnt	Indicates the maximum number of pointers to the **aiocbp** structure that can be copied into the **list** array.
list	An array of pointers to aio control structures defined in the **aio.h** file.
nwait	Specifies the number of asynchronous I/O operations that must complete before the **aio_nwait_timout** subroutine returns.
timeout	Specified in units of milliseconds. A *timeout* value of `-1` indicates that the subroutine behaves like the **aio_nwait** subroutine, blocking until all of the requested I/O operations complete or until there are no more asynchronous I/O requests pending from the process. A *timeout* value of `0` indicates that the subroutine returns immediately with the current completed number of asynchronous I/O requests. All other positive *timeout* values indicate that the subroutine must block until either the *timeout* value is reached or the requested number of asynchronous I/O operations complete.

Return Values

The return value is the total number of requests the **aio_nwait** subroutine has waited on to complete. It can not be more than *cnt*. Although *nwait* is the desired amount of requests to find, the actual amount returned could be less than, equal to, or greater than *nwait*. The return value indicates how much of the list array to access.

The return value may be greater than the *nwait* value if the **lio_listio** subroutine initiated more than *nwait* requests and the *cnt* variable is larger than *nwait*. The *nwait* parameter represents a minimal value desired for the return value, and *cnt* is the maximum value possible for the return.

The return value may be less than the *nwait* value if some of the requests initiated by the **lio_listio** subroutine occur at a time of high activity, and there is a lack of resources available for the number of requests. The **EAGAIN** return code (error try again later) might be returned in some request's aio control blocks, but these requests will not be seen by the **aio_nwait** subroutine. In this situation, the**aiocb** structure addresses that are not found on the list must be accessed using the **aio_error** subroutine after the **aio_nwait** subroutine is called. You might need to increase the aio parameters max servers or max requests if this occurs. Increasing the parameters will ensure that the system is well tuned, and an **EAGAIN** error is less likely to occur. The return value might be less than the *nwait* value due to the setting of the new timeout parameter in the following cases:

- *timeout* > 0 and a timeout has occurred before nwait requests are done
- *timeout* = 0 and the current requests completed at the time of the **aio_nwait_timeout** call are less then *nwait* parameter

In the event of an error, the **aio_nwait** subroutine returns a value of -1 and sets the **errno** global variable to identify the error. Return codes can be set to the following **errno** values:

Item	Description
EBUSY	An **aio_nwait** call is in process.
EINVAL	The application has retrieved all of the **aiocb** pointers, but the user buffer does not have enough space for them.
EINVAL	There are no outstanding async I/O calls.

aio_read or aio_read64 Subroutine

The **aio_read** or **aio_read64** subroutine includes information for the POSIX AIO **aio_read** subroutine (as defined in the IEEE std 1003.1-2001), and the Legacy AIO **aio_read** subroutine.

POSIX AIO aio_read Subroutine

Purpose

Asynchronously reads a file.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <aio.h>

int aio_read (aiocbp)
struct aiocb *aiocbp;
```

Description

The **aio_read** subroutine reads *aio_nbytes* from the file associated with *aio_fildes* into the buffer pointed to by *aio_buf*. The subroutine returns when the read request has been initiated or queued to the file or device (even when the data cannot be delivered immediately).

The *aiocbp* value may be used as an argument to the **aio_error** and **aio_return** subroutines in order to determine the error status and return status, respectively, of the asynchronous operation while it is proceeding. If an error condition is encountered during queuing, the function call returns without having initiated or queued the request. The requested operation takes place at the absolute position in the file as given by *aio_offset* , as if the **lseek** subroutine were called immediately prior to the operation with an offset equal to *aio_offset* and a whence equal to SEEK_SET. After a successful call to enqueue an asynchronous I/O operation, the value of the file offset for the file is unspecified.

The *aio_lio_opcode* field is ignored by the **aio_read** subroutine.

If prioritized I/O is supported for this file, the asynchronous operation is submitted at a priority equal to the scheduling priority of the process minus *aiocbp->aio_reqprio*.

The *aiocbp* parameter points to an **aiocb** structure. If the buffer pointed to by *aio_buf* or the control block pointed to by *aiocbp* becomes an illegal address prior to asynchronous I/O completion, the behavior is undefined.

Simultaneous asynchronous operations using the same *aiocbp* produce undefined results.

If synchronized I/O is enabled on the file associated with *aio_fildes*, the behavior of this subroutine is according to the definitions of synchronized I/O data integrity completion and synchronized I/O file integrity completion.

For any system action that changes the process memory space while an asynchronous I/O is outstanding, the result of that action is undefined.

For regular files, no data transfer occurs past the offset maximum established in the open file description.

If you use the **aio_read** or **aio_read64** subroutine with a file descriptor obtained from a call to the **shm_open** subroutine, it will fail with **EINVAL**.

Parameters

Item	Description
aiocbp	Points to the **aiocb** structure associated with the I/O operation.

aiocb Structure

The **aiocb** structure is defined in the **/usr/include/aio.h** file and contains the following members:

```
int               aio_fildes
off_t             aio_offset
char             *aio_buf
size_t            aio_nbytes
int               aio_reqprio
struct sigevent   aio_sigevent
int               aio_lio_opcode
```

Execution Environment

The **aio_read** and **aio_read64** subroutines can be called from the process environment only.

Return Values

The **aio_read** subroutine returns 0 to the calling process if the I/O operation is successfully queued. Otherwise, it returns a -1 and sets the **errno** global variable to indicate the error.

Error Codes

Item	Description
EAGAIN	The requested asynchronous I/O operation was not queued due to system resource limitations.

Each of the following conditions may be detected synchronously at the time of the call to the **aio_read** subroutine, or asynchronously. If any of the conditions below are detected synchronously, the **aio_read** subroutine returns -1 and sets the **errno** global variable to the corresponding value. If any of the conditions below are detected asynchronously, the return status of the asynchronous operation is set to -1, and the error status of the asynchronous operation is set to the corresponding value.

Item	Description
EBADF	The *aio_fildes* parameter is not a valid file descriptor open for reading.
EINVAL	The file offset value implied by *aio_offset* is invalid, *aio_reqprio* is an invalid value, or *aio_nbytes* is an invalid value. The **aio_read** or **aio_read64** subroutine was used with a file descriptor obtained from a call to the **shm_open** subroutine.

If the **aio_read** subroutine successfully queues the I/O operation but the operation is subsequently canceled or encounters an error, the return status of the asynchronous operation is one of the values

normally returned by the **read** subroutine. In addition, the error status of the asynchronous operation is set to one of the error statuses normally set by the **read** subroutine, or one of the following values:

Item	Description
EBADF	The *aio_fildes* argument is not a valid file descriptor open for reading.
ECANCELED	The requested I/O was canceled before the I/O completed due to an explicit **aio_cancel** request.
EINVAL	The file offset value implied by *aio_offset* is invalid.

The following condition may be detected synchronously or asynchronously:

Item	Description
EOVERFLOW	The file is a regular file, *aio_nbytes* is greater than 0, and the starting offset in *aio_offset* is before the end-of-file and is at or beyond the offset maximum in the open file description associated with *aio_fildes*.

Legacy AIO aio_read Subroutine

Purpose: Reads asynchronously from a file.

Library (Legacy AIO aio_read Subroutine)

Standard C Library (**libc.a**)

Syntax (Legacy AIO aio_read Subroutine)

```
#include <aio.h>

int aio_read( FileDescriptor,  aiocbp)
int FileDescriptor;
struct aiocb *aiocbp;

int aio_read64( FileDescriptor,  aiocbp)
int FileDescriptor;
struct aiocb64 *aiocbp;
```

Description (Legacy AIO aio_read Subroutine)

The **aio_read** subroutine reads asynchronously from a file. Specifically, the **aio_read** subroutine reads from the file associated with the *FileDescriptor* parameter into a buffer.

The **aio_read64** subroutine is similar to the **aio_read** subroutine execpt that it takes an **aiocb64** reference parameter. This allows the **aio_read64** subroutine to specify offsets in excess of **OFF_MAX** (2 gigbytes minus 1).

In the large file enabled programming environment, **aio_read** is redefined to be **aio_read64** .

If you use the **aio_read** or **aio_read64** subroutine with a file descriptor obtained from a call to the **shm_open** subroutine, it will fail with **EINVAL**.

The details of the read are provided by information in the **aiocb** structure, which is pointed to by the *aiocbp* parameter. This information includes the following fields:

Item	Description
`aio_buf`	Indicates the buffer to use.
`aio_nbytes`	Indicates the number of bytes to read.

When the read request has been queued, the **aio_read** subroutine updates the file pointer specified by the `aio_whence` and `aio_offset` fields in the **aiocb** structure as if the requested I/O were already completed. It then returns to the calling program. The `aio_whence` and `aio_offset` fields have the same meaning as the *whence* and *offset* parameters in the **lseek** subroutine. The subroutine ignores them for file objects that are not capable of seeking.

If an error occurs during the call, the read request is not queued. To determine the status of a request, use the **aio_error** subroutine.

To have the calling process receive the **SIGIO** signal when the I/O operation completes, set the AIO_SIGNAL bit in the `aio_flag` field in the **aiocb** structure.

Note: The **event** structure in the **aiocb** structure is currently not in use but is included for future compatibility.

Note: The _AIO_AIX_SOURCE macro used in **aio.h** must be defined when using **aio.h** to compile an aio application with the Legacy AIO function definitions. The default compile using the **aio.h** file is for an application with the POSIX AIO definitions. In the source file enter:

```
#define _AIO_AIX_SOURCE
#include <sys/aio.h>
```

or, on the command line when compiling enter:

```
->xlc ... -D_AIO_AIX_SOURCE ... legacy_aio_program.c
```

Since prioritized I/O is not supported at this time, the *aio_reqprio* field of the structure is not presently used.

Parameters (Legacy AIO aio_read Subroutine)

Item	Description
FileDescriptor	Identifies the object to be read as returned from a call to open.
aiocbp	Points to the asynchronous I/O control block structure associated with the I/O operation.

aiocb Structure

The **aiocb** and the **aiocb64** structures are defined in the **aio.h** file and contain the following members:

```
struct aiocb
{
       int                 aio_whence;
       off_t               aio_offset;
       char                *aio_buf;
       ssize_t             aio_return;
       int                 aio_errno;
       size_t              aio_nbytes;
       union {
              int          reqprio;
              struct {
                     int   version:8;
                     int   priority:8;
                     int   cache_hint:16;
              } ext;
       } aio_u1;
       int                 aio_flag;
       int                 aio_iocpfd;
       aio_handle_t        aio_handle;
}

#define aio_reqprio        aio_u1.reqprio
#define aio_version        aio_u1.ext.version
#define aio_priority       aio_u1.ext.priority
#define aio_cache_hint     aio_u1.ext.cache_hint
```

Execution Environment (Legacy AIO aio_read Subroutine)

The **aio_read** and **aio_read64** subroutines can be called from the process environment only.

Return Values (Legacy AIO aio_read Subroutine)

When the read request queues successfully, the **aio_read** subroutine returns a value of 0. Otherwise, it returns a value of -1 and sets the global variable **errno** to identify the error.

Return codes can be set to the following **errno** values:

Item	Description
EAGAIN	Indicates that the system resources required to queue the request are not available. Specifically, the transmit queue may be full, or the maximum number of opens may be reached.
EBADF	Indicates that the *FileDescriptor* parameter is not valid.
EFAULT	Indicates that the address specified by the *aiocbp* parameter is not valid.
EINVAL	Indicates that the `aio_whence` field does not have a valid value, or that the resulting pointer is not valid. The **aio_read** or **aio_read64** subroutine was used with a file descriptor obtained from a call to the **shm_open** subroutine.

When using I/O Completion Ports with AIO Requests, return codes can also be set to the following errno values:

Item	Description
EBADF	Indicates that the `aio_iocpfd` field in the aiocb structure is not a valid I/O Completion Port file descriptor.
EINVAL	Indicates that an I/O Completion Port service failed when attempting to start the AIO Request.
EPERM	Indicates that I/O Completion Port services are not available.

Note: Other error codes defined in the **sys/errno.h** file can be returned by the **aio_error** subroutine if an error during the I/O operation is encountered.

aio_return or aio_return64 Subroutine

The **aio_return** or **aio_return64** subroutine includes information for the POSIX AIO **aio_return** subroutine (as defined in the IEEE std 1003.1-2001), and the Legacy AIO **aio_return** subroutine.

POSIX AIO aio_return Subroutine

Purpose

Retrieves the return status of an asynchronous I/O operation.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <aio.h>

size_t aio_return (aiocbp);
struct aiocb *aiocbp;
```

Description

The **aio_return** subroutine returns the return status associated with the **aiocb** structure. The return status for an asynchronous I/O operation is the value that would be returned by the corresponding **read**, **write**, or **fsync** subroutine call. If the error status for the operation is equal to **EINPROGRESS**, the return status for the operation is undefined. The **aio_return** subroutine can be called once to retrieve the return status of a given asynchronous operation. After that, if the same **aiocb** structure is used in a call to **aio_return** or **aio_error**, an error may be returned. When the **aiocb** structure referred to by *aiocbp* is used to submit another asynchronous operation, the **aio_return** subroutine can be successfully used to retrieve the return status of that operation.

Parameters

Item	Description
aiocbp	Points to the **aiocb** structure associated with the I/O operation.

aiocb Structure

The **aiocb** structure is defined in the **/usr/include/aio.h** file and contains the following members:

```
int               aio_fildes
off_t             aio_offset
char             *aio_buf
size_t            aio_nbytes
int               aio_reqprio
struct sigevent   aio_sigevent
int               aio_lio_opcode
```

Execution Environment

The **aio_return** and **aio_return64** subroutines can be called from the process environment only.

Return Values

If the asynchronous I/O operation has completed, the return status (as described for the **read**, **write**, and **fsync** subroutines) is returned. If the asynchronous I/O operation has not yet completed, the results of the **aio_return** subroutine are undefined.

Error Codes

Item	Description
EINVAL	The *aiocbp* parameter does not refer to an asynchronous operation whose return status has not yet been retrieved.

Legacy AIO aio_return Subroutine

Purpose: Retrieves the return status of an asynchronous I/O request.

Library (Legacy AIO aio_return Subroutine)

Standard C Library (**libc.a**)

Syntax (Legacy AIO aio_return Subroutine)

```
#include <aio.h>
```

int aio_return(*handle***)**
aio_handle_t *handle***;**

```
int aio_return64( handle)
aio_handle_t handle;
```

Description (Legacy AIO aio_return Subroutine)

The **aio_return** subroutine retrieves the return status of the asynchronous I/O request associated with the **aio_handle_t** handle if the I/O request has completed. The status returned is the same as the status that would be returned by the corresponding **read** or **write** function calls. If the I/O operation has not completed, the returned status is undefined.

The **aio_return64** subroutine is similar to the **aio_return** subroutine except that it retrieves the error status associated with an **aiocb64** control block.

Note: The _AIO_AIX_SOURCE macro used in **aio.h** must be defined when using **aio.h** to compile an aio application with the Legacy AIO function definitions. The default compile using the **aio.h** file is for an application with the POSIX AIO definitions. In the source file enter:

```
#define _AIO_AIX_SOURCE
#include <sys/aio.h>
```

or, on the command line when compiling enter:

```
->xlc ... -D_AIO_AIX_SOURCE ... legacy_aio_program.c
```

Parameters (Legacy AIO aio_return Subroutine)

Item	Description
handle	The handle field of an **aio control block** (**aiocb** or **aiocb64**) structure is set by a previous call of the **aio_read**, **aio_read64**, **aio_write**, **aio_write64**, **lio_listio**, **aio_listio64** subroutine. If a random memory location is passed in, random results are returned.

aiocb Structure

The **aiocb** structure is defined in the **/usr/include/aio.h** file and contains the following members:

```
struct aiocb
{
       int                 aio_whence;
       off_t               aio_offset;
       char                *aio_buf;
       ssize_t             aio_return;
       int                 aio_errno;
       size_t              aio_nbytes;
       union {
              int          reqprio;
              struct {
                     int   version:8;
                     int   priority:8;
                     int   cache_hint:16;
              } ext;
       } aio_u1;
       int                 aio_flag;
       int                 aio_iocpfd;
       aio_handle_t        aio_handle;
}

#define aio_reqprio        aio_u1.reqprio
#define aio_version        aio_u1.ext.version
#define aio_priority       aio_u1.ext.priority
#define aio_cache_hint     aio_u1.ext.cache_hint
```

Execution Environment (Legacy AIO aio_return Subroutine)

The **aio_return** and **aio_return64** subroutines can be called from the process environment only.

Return Values (Legacy AIO aio_return Subroutine)

The **aio_return** subroutine returns the status of an asynchronous I/O request corresponding to those returned by **read** or **write** functions. If the error status returned by the **aio_error** subroutine call is **EINPROG**, the value returned by the **aio_return** subroutine is undefined.

Examples (Legacy AIO aio_return Subroutine)

An **aio_read** request to read 1000 bytes from a disk device eventually, when the **aio_error** subroutine returns a 0, causes the **aio_return** subroutine to return 1000. An **aio_read** request to read 1000 bytes from a 500 byte file eventually causes the **aio_return** subroutine to return 500. An **aio_write** request to write to a read-only file system results in the **aio_error** subroutine eventually returning **EROFS** and the **aio_return** subroutine returning a value of -1.

aio_suspend or aio_suspend64 Subroutine

The **aio_suspend** subroutine includes information for the POSIX AIO **aio_suspend** subroutine (as defined in the IEEE std 1003.1-2001), and the Legacy AIO **aio_suspend** subroutine.

POSIX AIO aio_suspend Subroutine

Purpose

Waits for an asynchronous I/O request.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <aio.h>

int aio_suspend (list, nent,
 timeout)
const struct aiocb * const list[];
int nent;
const struct timespec *timeout;
```

Description

The **aio_suspend** subroutine suspends the calling thread until at least one of the asynchronous I/O operations referenced by the *list* parameter has completed, until a signal interrupts the function, or, if timeout is not NULL, until the time interval specified by *timeout* has passed. If any of the **aiocb** structures in the list correspond to completed asynchronous I/O operations (the error status for the operation is not equal to **EINPROGRESS**) at the time of the call, the subroutine returns without suspending the calling thread. The *list* parameter is an array of pointers to asynchronous I/O control blocks. The *nent* parameter indicates the number of elements in the array. Each **aiocb** structure pointed to has been used in initiating an asynchronous I/O request through the **aio_read**, **aio_write**, or **lio_listio** subroutine. This array may contain NULL pointers, which are ignored. If this array contains pointers that refer to **aiocb** structures that have not been used in submitting asynchronous I/O, the effect is undefined.

If the time interval indicated in the **timespec** structure pointed to by *timeout* passes before any of the I/O operations referenced by *list* are completed, the **aio_suspend** subroutine returns with an error. If the Monotonic Clock option is supported, the clock that is used to measure this time interval is the CLOCK_MONOTONIC clock.

Parameters

Item	Description
list	Array of asynchronous I/O operations.
nent	Indicates the number of elements in the *list* array.
timeout	Specifies the time the subroutine has to complete the operation.

Execution Envrionment

The **aio_suspend** and **aio_suspend64** subroutines can be called from the process environment only.

Return Values

If the **aio_suspend** subroutine returns after one or more asynchronous I/O operations have completed, it returns a 0. Otherwise, it returns a -1 and sets the **errno** global variable to indicate the error.

The application can determine which asynchronous I/O completed by scanning the associated error and returning status using the **aio_error** and **aio_return** subroutines, respectively.

Error Codes

Item	Description
EAGAIN	No asynchronous I/O indicated in the list referenced by *list* completed in the time interval indicated by *timeout*.
EINTR	A signal interrupted the **aio_suspend** subroutine. Since each asynchronous I/O operation may possibly provoke a signal when it completes, this error return may be caused by the completion of one (or more) of the very I/O operations being awaited.

Legacy AIO aio_suspend Subroutine

Purpose: Suspends the calling process until one or more asynchronous I/O requests is completed.

Library (Legacy AIO aio_suspend Subroutine)

Standard C Library (**libc.a**)

Syntax (Legacy AIO aio_suspend Subroutine)

```
#include <aio.h>
```

```
aio_suspend( count,  aiocbpa)
int count;
struct aiocb *aiocbpa[ ];
```

```
aio_suspend64( count,  aiocbpa)
int count;
struct aiocb64 *aiocbpa[ ];
```

Description (Legacy AIO aio_suspend Subroutine)

The **aio_suspend** subroutine suspends the calling process until one or more of the *count* parameter asynchronous I/O requests are completed or a signal interrupts the subroutine. Specifically, the **aio_suspend** subroutine handles requests associated with the **aio control block (aiocb)** structures pointed to by the *aiocbpa* parameter.

The **aio_suspend64** subroutine is similar to the **aio_suspend** subroutine except that it takes an array of pointers to **aiocb64** structures. This allows the **aio_suspend64** subroutine to suspend on asynchronous I/O requests submitted by either the **aio_read64**, **aio_write64**, or the **lio_listio64** subroutines.

In the large file enabled programming environment, **aio_suspend** is redefined to be **aio_suspend64**.

The array of **aiocb** pointers may include null pointers, which will be ignored. If one of the I/O requests is already completed at the time of the **aio_suspend** call, the call immediately returns.

Note: The _AIO_AIX_SOURCE macro used in **aio.h** must be defined when using **aio.h** to compile an aio application with the Legacy AIO function definitions. The default compile using the **aio.h** file is for an application with the POSIX AIO definitions. In the source file enter:

```
#define _AIO_AIX_SOURCE
#include <sys/aio.h>
```

or, on the command line when compiling enter:

```
->xlc ... -D_AIO_AIX_SOURCE ... legacy_aio_program.c
```

Parameters (Legacy AIO aio_suspend Subroutine)

Item	Description
count	Specifies the number of entries in the *aiocbpa* array.
aiocbpa	Points to the **aiocb** or **aiocb64** structures associated with the asynchronous I/O operations.

aiocb Structure

The **aiocb** structure is defined in the **/usr/include/aio.h** file and contains the following members:

```
struct aiocb
{
       int                 aio_whence;
       off_t               aio_offset;
       char                *aio_buf;
       ssize_t             aio_return;
       int                 aio_errno;
       size_t              aio_nbytes;
       union {
              int          reqprio;
              struct {
                     int   version:8;
                     int   priority:8;
                     int   cache_hint:16;
              } ext;
       } aio_u1;
       int                 aio_flag;
       int                 aio_iocpfd;
       aio_handle_t        aio_handle;
}

#define aio_reqprio        aio_u1.reqprio
#define aio_version        aio_u1.ext.version
#define aio_priority       aio_u1.ext.priority
#define aio_cache_hint     aio_u1.ext.cache_hint
```

Execution Envrionment (Legacy AIO aio_suspend Subroutine)

The **aio_suspend** and **aio_suspend64** subroutines can be called from the process environment only.

Return Values (Legacy AIO aio_suspend Subroutine)

If one or more of the I/O requests completes, the **aio_suspend** subroutine returns the index into the aiocbpa array of one of the completed requests. The index of the first element in the *aiocbpa* array is 0. If more than one request has completed, the return value can be the index of any of the completed requests.

In the event of an error, the **aio_suspend** subroutine returns a value of -1 and sets the **errno** global variable to identify the error. Return codes can be set to the following **errno** values:

Item	Description
EINTR	Indicates that a signal or event interrupted the **aio_suspend** subroutine call.
EINVAL	Indicates that the `aio_whence` field does not have a valid value or that the resulting pointer is not valid.

aio_write or aio_write64 Subroutine

The **aio_write** subroutine includes information for the POSIX AIO **aio_write** subroutine (as defined in the IEEE std 1003.1-2001), and the Legacy AIO **aio_write** subroutine.

POSIX AIO aio_write Subroutine

Purpose

Asynchronously writes to a file.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <aio.h>

int aio_write (aiocbp)
struct aiocb *aiocbp;
```

Description

The **aio_write** subroutine writes *aio_nbytes* to the file associated with *aio_fildes* from the buffer pointed to by *aio_buf*. The subroutine returns when the write request has been initiated or queued to the file or device.

The *aiocbp* parameter may be used as an argument to the **aio_error** and **aio_return** subroutines in order to determine the error status and return status, respectively, of the asynchronous operation while it is proceeding.

The *aiocbp* parameter points to an **aiocb** structure. If the buffer pointed to by *aio_buf* or the control block pointed to by *aiocbp* becomes an illegal address prior to asynchronous I/O completion, the behavior is undefined.

If **O_APPEND** flag is not set for the *aio_fildes* file descriptor, the requested operation takes place at the absolute position in the file as given by *aio_offset*. This is done as if the **lseek** subroutine were called immediately prior to the operation with an offset equal to *aio_offset* and a whence equal to *SEEK_SET*. If **O_APPEND** flag is set for the file descriptor, write operations append data in bytes to the file in the same order as the calls were made, except under circumstances described in the Asynchronous I/O section in the *System Interfaces and XBD Headers* website. After a successful call to enqueue an asynchronous I/O operation, the value of the file offset for the file is unspecified.

The *aio_lio_opcode* field is ignored by the **aio_write** subroutine.

If prioritized I/O is supported for this file, the asynchronous operation is submitted at a priority equal to the scheduling priority of the process minus *aiocbp->aio_reqprio*.

Simultaneous asynchronous operations using the same *aiocbp* produce undefined results.

If synchronized I/O is enabled on the file associated with *aio_fildes*, the behavior of this subroutine is according to the definitions of synchronized I/O data integrity completion, and synchronized I/O file integrity completion.

For any system action that changes the process memory space while an asynchronous I/O is outstanding, the result of that action is undefined.

For regular files, no data transfer occurs past the offset maximum established in the open file description associated with *aio_fildes*.

If you use the **aio_write** or **aio_write64**subroutine with a file descriptor obtained from a call to the **shm_open** subroutine, it will fail with **EINVAL**.

Parameters

Item	Description
aiocbp	Points to the **aiocb** structure associated with the I/O operation.

aiocb Structure

The **aiocb** structure is defined in the **/usr/include/aio.h** file and contains the following members:

```
int               aio_fildes
off_t             aio_offset
char             *aio_buf
size_t            aio_nbytes
int               aio_reqprio
struct sigevent   aio_sigevent
int               aio_lio_opcode
```

Execution Environment

The **aio_write** and **aio_write64** subroutines can be called from the process environment only.

Return Values

The **aio_write** subroutine returns a 0 to the calling process if the I/O operation is successfully queued. Otherwise, a -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

Item	Description
EAGAIN	The requested asynchronous I/O operation was not queued due to system resource limitations.

Each of the following conditions may be detected synchronously at the time of the call to **aio_write**, or asynchronously. If any of the conditions below are detected synchronously, the **aio_write** subroutine returns a -1 and sets the **errno** global variable to the corresponding value. If any of the conditions below are detected asynchronously, the return status of the asynchronous operation is set to -1, and the error status of the asynchronous operation is set to the corresponding value.

Item	Description
EBADF	The *aio_fildes* parameter is not a valid file descriptor open for writing.
EINVAL	The file offset value implied by *aio_offset* is invalid, *aio_reqprio* is an invalid value, or *aio_nbytes* is an invalid value. The **aio_write** or **aio_write64** subroutine was used with a file descriptor obtained from a call to the **shm_open** subroutine.

If the **aio_write** subroutine successfully queues the I/O operation, the return status of the asynchronous operation is one of the values normally returned by the **write** subroutine call. If the operation is

successfully queued but is subsequently canceled or encounters an error, the error status for the asynchronous operation contains one of the values normally set by the **write** subroutine call, or one of the following:

Item	Description
EBADF	The *aio_fildes* parameter is not a valid file descriptor open for writing.
EINVAL	The file offset value implied by *aio_offset* would be invalid.
ECANCELED	The requested I/O was canceled before the I/O completed due to an **aio_cancel** request.

The following condition may be detected synchronously or asynchronously:

Item	Description
EFBIG	The file is a regular file, *aio_nbytes* is greater than 0, and the starting offset in *aio_offset* is at or beyond the offset maximum in the open file description associated with *aio_fildes*.

Legacy AIO aio_write Subroutine

Purpose: Writes to a file asynchronously.

Library (Legacy AIO aio_write Subroutine)

Standard C Library (**libc.a**)

Syntax (Legacy AIO aio_write Subroutine)

```
#include <aio.h>

int aio_write( FileDescriptor,  aiocbp)
int FileDescriptor;
struct aiocb *aiocbp;

int aio_write64( FileDescriptor,  aiocbp)
int FileDescriptor;
struct aiocb64 *aiocbp;
```

Description (Legacy AIO aio_write Subroutine)

The **aio_write** subroutine writes asynchronously to a file. Specifically, the **aio_write** subroutine writes to the file associated with the *FileDescriptor* parameter from a buffer. To handle this, the subroutine uses information from the **aio control block (aiocb)** structure, which is pointed to by the *aiocbp* parameter. This information includes the following fields:

Item	Description
`aio_buf`	Indicates the buffer to use.
`aio_nbytes`	Indicates the number of bytes to write.

The **aio_write64** subroutine is similar to the **aio_write** subroutine except that it takes an **aiocb64** reference parameter. This allows the **aio_write64** subroutine to specify offsets in excess of OFF_MAX (2 gigbytes minus 1).

In the large file enabled programming environment, **aio_read** is redefined to be **aio_read64**.

If you use the **aio_write** or **aio_write64** subroutine with a file descriptor obtained from a call to the **shm_open** subroutine, it will fail with **EINVAL**.

When the write request has been queued, the **aio_write** subroutine updates the file pointer specified by the `aio_whence` and `aio_offset` fields in the **aiocb** structure as if the requested I/O completed. It then

returns to the calling program. The `aio_whence` and `aio_offset` fields have the same meaning as the *whence* and *offset* parameters in the **lseek** subroutine. The subroutine ignores them for file objects that are not capable of seeking.

If an error occurs during the call, the write request is not initiated or queued. To determine the status of a request, use the **aio_error** subroutine.

To have the calling process receive the **SIGIO** signal when the I/O operation completes, set the AIO_SIGNAL bit in the `aio_flag` field in the **aiocb** structure.

Note: The **event** structure in the **aiocb** structure is currently not in use but is included for future compatibility.

Note: The _AIO_AIX_SOURCE macro used in **aio.h** must be defined when using **aio.h** to compile an aio application with the Legacy AIO function definitions. The default compile using the **aio.h** file is for an application with the POSIX AIO definitions. In the source file enter:

```
#define _AIO_AIX_SOURCE
#include <sys/aio.h>
```

or, on the command line when compiling enter:

```
->xlc ... -D_AIO_AIX_SOURCE ... legacy_aio_program.c
```

Since prioritized I/O is not supported at this time, the *aio_reqprio* field of the structure is not presently used.

Parameters (Legacy AIO aio_write Subroutine)

Item	Description
FileDescriptor	Identifies the object to be written as returned from a call to open.
aiocbp	Points to the asynchronous I/O control block structure associated with the I/O operation.

aiocb Structure

The **aiocb** structure is defined in the **/usr/include/aio.h** file and contains the following members:

```
struct aiocb
{
       int                 aio_whence;
       off_t               aio_offset;
       char                *aio_buf;
       ssize_t             aio_return;
       int                 aio_errno;
       size_t              aio_nbytes;
       union {
              int          reqprio;
              struct {
                     int   version:8;
                     int   priority:8;
                     int   cache_hint:16;
              } ext;
       } aio_u1;
       int                 aio_flag;
       int                 aio_iocpfd;
       aio_handle_t        aio_handle;
}

#define aio_reqprio        aio_u1.reqprio
#define aio_version        aio_u1.ext.version
#define aio_priority       aio_u1.ext.priority
#define aio_cache_hint     aio_u1.ext.cache_hint
```

Execution Environment (Legacy AIO aio_write Subroutine)

The **aio_write** and **aio_write64** subroutines can be called from the process environment only.

Return Values (Legacy AIO aio_write Subroutine)

When the write request queues successfully, the **aio_write** subroutine returns a value of 0. Otherwise, it returns a value of -1 and sets the **errno** global variable to identify the error.

Return codes can be set to the following **errno** values:

Item	Description
EAGAIN	Indicates that the system resources required to queue the request are not available. Specifically, the transmit queue may be full, or the maximum number of opens may have been reached.
EBADF	Indicates that the *FileDescriptor* parameter is not valid.
EFAULT	Indicates that the address specified by the *aiocbp* parameter is not valid.
EINVAL	Indicates that the `aio_whence` field does not have a valid value or that the resulting pointer is not valid. The **aio_write** or **aio_write64** subroutine was used with a file descriptor obtained from a call to the **shm_open** subroutine.

When using I/O Completion Ports with AIO Requests, return codes can also be set to the following errno values:

Item	Description
EBADF	Indicates that the `aio_iocpfd` field in the aiocb structure is not a valid I/O Completion Port file descriptor.
EINVAL	Indicates that an I/O Completion Port service failed when attempting to start the AIO Request.
EPERM	Indicates that I/O Completion Port services are not available.

Note: Other error codes defined in the **/usr/include/sys/errno.h** file may be returned by the **aio_error** subroutine if an error during the I/O operation is encountered.

alloc, dealloc, print, read_data, read_regs, symbol_addrs, write_data, and write_regs Subroutine

Purpose

Provide access to facilities needed by the pthread debug library and supplied by the debugger or application.

Library

pthread debug library (**libpthdebug.a**)

Syntax

```
#include <sys/pthdebug.h>

int alloc (user, len, bufp)
pthdb_user_t user;
size_t len;
void **bufp;
```

```
int dealloc (user, buf)
pthdb_user_t user;
void *buf;
```

```
int print (user, str)
pthdb_user_t user;
char *str;
```

```
int read_data (user, buf, addr, size)
pthdb_user_t user;
void *buf;
pthdb_addr_t addr;
int size;
```

```
int read_regs (user, tid, flags, context)
pthdb_user_t user;
tid_t tid;
unsigned long long flags;
struct context64 *context;
```

```
int symbol_addrs (user, symbols[],count)
pthdb_user_t user;
pthdb_symbol_t symbols[];
int count;
```

```
int write_data (user, buf, addr, size)
pthdb_user_t user;
void *buf;
pthdb_addr_t addr;
int size;
```

```
int write_regs (user, tid, flags, context)
pthdb_user_t user;
tid_t tid;
unsigned long long flags;
struct context64 *context;
```

Description

int alloc()
Allocates *len* bytes of memory and returns the address. If successful, 0 is returned; otherwise, a nonzero number is returned. This call back function is always required.

int dealloc()
Takes a buffer and frees it. If successful, 0 is returned; otherwise, a nonzero number is returned. This call back function is always required.

int print()
Prints the character string to the debugger's stdout. If successful, 0 is returned; otherwise, a nonzero number is returned. This call back is for debugging the library only. If you aren't debugging the pthread debug library, pass a NULL value for this call back.

int read_data()
Reads the requested number of bytes of data at the requested location from an active process or core file and returns the data through a buffer. If successful, 0 is returned; otherwise, a nonzero number is returned. This call back function is always required.

int read_regs()
Reads the context information of a debuggee kernel thread from an active process or from a core file. The information should be formatted in **context64** form for both a 32-bit and a 64-bit process. If successful, 0 is returned; otherwise, a nonzero number is returned. This function is only required when using the **pthdb_pthread_context** and **pthdb_pthread_setcontext** subroutines.

int symbol_addrs()
Resolves the address of symbols in the debuggee. The pthread debug library calls this subroutine to get the address of known debug symbols. If the symbol has a name of NULL or "", set the address to 0LL instead of doing a lookup or returning an error. If successful, 0 is returned; otherwise, a nonzero number is returned. In introspective mode, when the **PTHDB_FLAG_SUSPEND** flag is set, the application can use the pthread debug library by passing NULL, or it can use one of its own.

int write_data()
Writes the requested number of bytes of data to the requested location. The **libpthdebug.a** library may use this to write data to the active process. If successful, 0 is returned; otherwise, a nonzero number is returned. This call back function is required when the **PTHDB_FLAG_HOLD** flag is set and when using the **pthdb_pthread_setcontext** subroutine.

int write_regs()
Writes requested context information to specified debuggee's kernel thread id. If successful, 0 is returned; otherwise, a nonzero number is returned. This subroutine is only required when using the **pthdb_pthread_setcontext** subroutine.

Note: If the **write_data** and **write_regs** subroutines are NULL, the pthread debug library will not try to write data or regs. If the **pthdb_pthread_set_context** subroutine is called when the **write_data** and **write_regs** subroutines are NULL, **PTHDB_NOTSUP** is returned.

Parameters

Item	Description
user	User handle.
symbols	Array of symbols.
count	Number of symbols.
buf	Buffer.
addr	Address to be read from or wrote to.
size	Size of the buffer.
flags	Session flags, must accept **PTHDB_FLAG_GPRS**, **PTHDB_FLAG_SPRS**, **PTHDB_FLAG_FPRS**, and **PTHDB_FLAG_REGS**.
tid	Thread id.
flags	Flags that control which registers are read or wrote.
context	Context structure.
len	Length of buffer to be allocated or reallocated.
bufp	Pointer to buffer.
str	String to be printed.

Return Values

If successful, these subroutines return 0; otherwise they return a nonzero value.

alloclmb Subroutine

Purpose

Allocates a contiguous block of contiguous real memory for exclusive use by the caller. The block of memory reserved will be the size of a system LMB.

Syntax

```
#include <sys/dr.h>

int alloclmb(long long *laddr, int flags)
```

Description

The **alloclmb()** subroutine reserves an LMB sized block of contiguous real memory for exclusive use by the caller. It returns the partition logical address of that memory in **laddr*.

alloclmb() is only valid in an LPAR environment, and it fails (with **ENOTSUP**) if called in another environment.

Only a privileged user should call **alloclmb()**.

Parameters

Item	Description
laddr	On successful return, contains the logical address of the allocated LMB.
flags	Must be 0.

Execution Environment

This **alloclmb()** interface should only be called from the process environment.

Return Values

Item	Description
0	The LMB is successfully allocated.

Error Codes

Item	Description
ENOTSUP	LMB allocation not supported on this system.
EINVAL	Invalid flags value.
EINVAL	Not in the process environment.
ENOMEM	A free LMB could not be made available.

asinh, asinhf, asinhl, asinhd32, asinhd64, and asinhd128 Subroutines

Purpose

Computes the inverse hyperbolic sine.

Syntax

```
#include <math.h>

float asinhf (x)
float x;

long double asinhl (x)
long double x;

double asinh ( x)
double x;
_Decimal32 asinhd32 (x)
_Decimal32 x;

_Decimal64 asinhd64 (x)
_Decimal64 x;
```

```
_Decimal128 asinhd128 (x)
_Decimal128 x;
```

Description

The **asinhf**, **asinhl**, **asinh**, **asinhd32**, **asinhd64**, and **asinhd128** subroutines compute the inverse hyperbolic sine of the*x* parameter.

An application wishing to check for error situations should set **errno** to zero and call **fetestexcept(FE_ALL_EXCEPT)** before calling these subroutines. Upon return, if the **errno** global variable is nonzero or **fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW)** is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **asinhf**, **asinhl**, **asinh**, **asinhd32**, **asinhd64**, and **asinhd128** subroutines return the inverse hyperbolic sine of the given argument.

If *x* is NaN, a NaN is returned.

If *x* is 0, or ±Inf, *x* is returned.

If *x* is subnormal, a range error may occur and *x* will be returned.

asinf, asinl, asin, asind32, asind64, and asind128 Subroutines

Purpose

Computes the arc sine.

Syntax

```
#include <math.h>

float asinf (x)
float x;

long double asinl (x)
long double x;

double asin (x)
double x;
_Decimal32 asind32 (x)
_Decimal32 x;

_Decimal64 asind64 (x)
_Decimal64 x;

_Decimal128 asind128 (x)
_Decimal128 x;
```

Description

The **asinf**, **asinl**, **asin**, **asind32**, **asind64**, and **asind128** subroutines compute the principal value of the arc sine of the *x* parameter. The value of *x* should be in the range [-1,1].

An application wishing to check for error situations should set the **errno** global variable to zero and call **feclearexcept(FE_ALL_EXCEPT)** before calling these subroutines. On return, if **errno** is nonzero or **fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW)** is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **asinf**, **asinl**, **asin**, **asind32**, **asind64**, and **asind128** subroutines return the arc sine of *x*, in the range [-pi /2, pi/2] radians.

For finite values of *x* not in the range [-1,1], a domain error occurs, and a NaN is returned.

If *x* is NaN, a NaN is returned.

If *x* is 0, *x* is returned.

If *x* is ±Inf, a domain error occurs, and a NaN is returned.

If *x* is subnormal, a range error may occur and *x* is returned.

assert Macro

Purpose

Verifies a program assertion.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <assert.h>

void assert ( Expression)
int  Expression;
```

Description

The **assert** macro puts error messages into a program. If the specified expression is false, the **assert** macro writes the following message to standard error and stops the program:

```
Assertion failed: Expression, file FileName, line LineNumber
```

In the error message, the *FileName* value is the name of the source file and the *LineNumber* value is the source line number of the **assert** statement.

Parameters

Item	Description
Expression	Specifies an expression that can be evaluated as true or false. This expression is evaluated in the same manner as the C language IF statement.

at_quick_exit Subroutine

Purpose

Registers the function that is specified by the *func* parameter during a call to the **quick_exit** subroutine.

Library

Standard C library (**libc.a**)

Syntax

```
#include <stdlib.h>
int at_quick_exit (void * func (void));
```

Description

The **at_quick_exit** subroutine registers the function that is specified by the *func* parameter that is called without any arguments. If the **quick_exit** subroutine is called, it calls the registered functions before the exit.

If a call to the **at_quick_exit** subroutine does not occur before a call to the **quick_exit** subroutine, the function call is successful.

Parameters

Item	Description
func	Specifies the function that gets registered and that is called during the **quick_exit** subroutine call.

Environmental limits

The implementation supports a minimum registration of up to 32 functions.

Return Values

Upon successful completion, the subroutine returns a value of zero, if the registration succeeds.

If unsuccessful, a value of nonzero is returned.

Files

The **stdlib.h** file defines standard macros, data types, and subroutines.

atan2f, atan2l, atan2, atan2d32, atan2d64, and atan2d128 Subroutines

Purpose

Computes the arc tangent.

Syntax

```
#include <math.h>

float atan2f (y, x)
```

```
float y, float x;

long double atan2l (y, x)
long double y, long double x;

double atan2 (y, x)
double y, x;
_Decimal32 atan2d32 (y, x)
_Decimal32 y, x;

_Decimal64 atan2d64 (y, x)
_Decimal64 y, x;

_Decimal128 atan2d128 (y, x)
_Decimal128 y, x;
```

Description

The **atan2f**, **atan2l**, **atan2**, **atan2d32**, **atan2d64** and **atan2d128** subroutines compute the principal value of the arc tangent of *y/x*, using the signs of both parameters to determine the quadrant of the return value.

An application wishing to check for error situations should set the **errno** global variable to zero and call **feclearexcept(FE_ALL_EXCEPT)** before calling these functions. On return, if **errno** is nonzero or **fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW)** is nonzero, an error has occurred.

Parameters

Item	Description
y	Specifies the value to compute.
x	Specifies the value to compute.

Return Values

Upon successful completion, the **atan2f**, **atan2l**, **atan2**, **atan2d32**, **atan2d64**, and **atan2d128** subroutines return the arc tangent of *y/x* in the range [-pi, pi] radians.

If *y* is 0 and *x* is < 0, ±pi is returned.

If *y* is 0 and *x* is > 0, 0 is returned.

If *y* is < 0 and *x* is 0, -pi/2 is returned.

If *y* is > 0 and *x* is 0, pi/2 is returned.

If *x* is 0, a pole error does not occur.

If either *x* or *y* is NaN, a NaN is returned.

If the result underflows, a range error may occur and *y/x* is returned.

If *y* is 0 and *x* is -0, ±x is returned.

If *y* is 0 and *x* is +0, 0 is returned.

For finite values of ±*y* >0, if *x* is -Inf, ±x is returned.

For finite values of ±*y* >0, if *x* is +Inf, 0 is returned.

For finite values of *x*, if *y* is ±Inf, ±x/2 is returned.

If *y* is ±Inf and *x* is -Inf, ±3pi/4 is returned.

If *y* is ±Inf and *x* is +Inf, ±pi/4 is returned.

If both arguments are 0, a domain error does not occur.

atan, atanf, atanl, atand32, atand64, and atand128 Subroutines

Purpose

Computes the arc tangent.

Syntax

```
#include <math.h>

float atanf (x)
float x;

long double atanl (x)
long double x;

double atan (x)
double x;
_Decimal32 atand32 (x)
_Decimal32 x;

_Decimal64 atand64 (x)
_Decimal64 x;

_Decimal128 atand128 (x)
_Decimal128 x;
```

Description

The **atanf**, **atanl**, **atan**, **atand32**, **atand64**, and **atand128** subroutines compute the principal value of the arc tangent of the *x* parameter.

An application wishing to check for error situations should set the **errno** global variable to zero and call **feclearexcept(FE_ALL_EXCEPT)** before calling these functions. On return, if **errno** is nonzero or **fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW)** is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **atanf**, **atanl**, **atan**, **atand32**, **atand64**, and **atand128** subroutines return the arc tangent of *x* in the range [-pi /2, pi/2] radians.

If *x* is NaN, a NaN is returned.

If *x* is 0, *x* is returned.

If *x* is ±Inf, ±x/2 is returned.

If *x* is subnormal, a range error may occur and *x* is returned.

atanh, atanhf, atanhl, atanhd32, atanhd64, and atanhd128 Subroutines

Purpose

Computes the inverse hyperbolic tangent.

Syntax

```
#include <math.h>

float atanhf (x)
float x;

long double atanhl (x)
long double x;

double atanh (x)
double x;
_Decimal32 atanhd32 (x)
_Decimal32 x;

_Decimal64 atanhd64 (x)
_Decimal64 x;

_Decimal128 atanhd128 (x)
_Decimal128 x;
```

Description

The **atanhf**, **atanhl**, **atanh**, **atanhd32**, **atanhd64**, and **atanhd128** subroutines compute the inverse hyperbolic tangent of the *x* parameter.

An application wishing to check for error situations should set the **errno** global variable to zero and call **feclearexcept(FE_ALL_EXCEPT)** before calling these functions. On return, if **errno** is nonzero or **fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW)** is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **atanhf**, **atanhl**, **atanh**, **atanhd32**, **atanhd64**, and **atanhd128** subroutines return the inverse hyperbolic tangent of the given argument.

If *x* is ±1, a pole error occurs, and **atanhf**, **atanhl** , **atanh**, **atanhd32**, **atanhd64**, and **atanhd128** return the value of the macro HUGE_VALF, HUGE_VALL, HUGE_VAL, HUGE_VAL_D32, HUGE_VAL_D64, and HUGE_VAL_D128 respectively, with the same sign as the correct value of the function.

For finite |*x*|>1, a domain error occurs, and a NaN is returned.

If *x* is NaN, a NaN is returned.

If *x* is 0, *x* is returned.

If *x* is ±Inf, a domain error shall occur, and a NaN is returned.

If *x* is subnormal, a range error may occur and *x* is returned.

Error Codes

The **atanhf**, **atanhl**, **atanh**, **atanhd32**, **atanhd64**, and **atanhd128** subroutines return **NaNQ** and set **errno** to **EDOM** if the absolute value of x is greater than the value of one.

atof atoff Subroutine

Purpose

Converts an ASCII string to a floating-point or double floating-point number.

Libraries

Standard C Library (**libc.a**)

Syntax

```
#include <stdlib.h>
```

```
double atof (NumberPointer)
const char *NumberPointer;
```

```
float atoff (NumberPointer)
char *NumberPointer;
```

Description

The **atof** subroutine converts a character string, pointed to by the *NumberPointer* parameter, to a double-precision floating-point number. The **atoff** subroutine converts a character string, pointed to by the *NumberPointer* parameter, to a single-precision floating-point number. The first unrecognized character ends the conversion.

Except for behavior on error, the **atof** subroutine is equivalent to the **strtod** subroutine call, with the *EndPointer* parameter set to (**char****) NULL.

Except for behavior on error, the **atoff** subroutine is equivalent to the **strtof** subroutine call, with the *EndPointer* parameter set to (**char****) NULL.

These subroutines recognize a character string when the characters are in one of two formats: numbers or numeric symbols.

- For a string to be recognized as a number, it should contain the following pieces in the following order:
  1. An optional string of white-space characters
  2. An optional sign
  3. A nonempty string of digits optionally containing a radix character
  4. An optional exponent in E-format or e-format followed by an optionally signed integer.
- For a string to be recognized as a numeric symbol, it should contain the following pieces in the following order:
  1. An optional string of white-space characters
  2. An optional sign
  3. One of the strings: **INF**, **infinity**, **NaNQ**, **NaNS**, or **NaN** (case insensitive)

The **atoff** subroutine is not part of the ANSI C Library. These subroutines are at least as accurate as required by the *IEEE Standard for Binary Floating-Point Arithmetic*. The **atof** subroutine accepts at least 17 significant decimal digits. The **atoff** and subroutine accepts at least 9 leading 0's. Leading 0's are not counted as significant digits.

Note: Starting with the IBM® AIX 6 with Technology Level 7 and the IBM AIX 7 with Technology Level 1, the precision of the floating-point conversion routines, printf and scanf family of functions has been increased from 17 digits to 37 digits for double and long double values.

Parameters

Item	Description
NumberPointer	Specifies a character string to convert.
EndPointer	Specifies a pointer to the character that ended the scan or a null value.

Return Values

Upon successful completion, the **atof**, and **atoff** subroutines return the converted value. If no conversion could be performed, a value of 0 is returned and the **errno** global variable is set to indicate the error.

Error Codes

If the conversion cannot be performed, a value of 0 is returned, and the **errno** global variable is set to indicate the error.

If the conversion causes an overflow (that is, the value is outside the range of representable values), **+/- HUGE_VAL** is returned with the sign indicating the direction of the overflow, and the **errno** global variable is set to **ERANGE**.

If the conversion would cause an underflow, a properly signed value of 0 is returned and the **errno** global variable is set to **ERANGE**.

The **atoff** subroutine has only one rounding error. (If the **atof** subroutine is used to create a double-precision floating-point number and then that double-precision number is converted to a floating-point number, two rounding errors could occur.)

atol or atoll Subroutine

Purpose

Converts a string to a long integer.

Syntax

```
#include <stdlib.h>

long long atoll (nptr)
const char *nptr;

long atol (nptr)
const char *nptr;
```

Description

The **atoll** and **atol** subroutines (*str*) are equivalent to `strtoll(nptr, (char **)NULL, 10)` and `strtol(nptr, (char **)NULL, 10)`, respectively. If the value cannot be represented, the behavior is undefined.

Parameters

Item	Description
nptr	Points to the string to be converted into a long integer.

Return Values

The **atoll** and **atol** subroutines return the converted value if the value can be represented.

attrset or wattrset Subroutine

Purpose

Sets the current attributes of a window to the specified attributes.

Libraries

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

attrset( Attributes)
char *Attributes;
wattrset( Window, Attributes)
WINDOW *Window;
char *Attributes;
```

Description

The **attrset** and **wattrset** subroutines set the current attributes of a window to the specified attributes. The **attrset** subroutine sets the current attribute of stdscr. The **wattrset** subroutine sets the current attribute of the specified window.

Parameters

Item	Description
Attributes	Specifies which attributes to set.
Window	Specifies the window in which to set the attributes.

Examples

1. To set the current attribute in the **stdscr** global variable to blink, enter:

   ```
   attrset(A_BLINK);
   ```

2. To set the current attribute in the user-defined window `my_window` to blinking, enter:

   ```
   wattrset(my_window, A_BLINK);
   ```

3. To turn off all attributes in the **stdscr** global variable, enter:

   ```
   attrset(0);
   ```

4. To turn off all attributes in the user-defined window `my_window`, enter:

   ```
   wattrset(my_window, 0);
   ```

attroff, attron, attrset, wattroff, wattron, or wattrset Subroutine

Purpose

Restricted window attribute control functions.

Library

Curses Library (**libcurses.a**)

Syntax

#include <curses.h>

int attroff (int **attrs****);**

int attron (int **attrs****);**

int attrset (int **attrs****);**

int wattroff (WINDOW **win*, **int** **attsr****);**

int wattron (WINDOW **win*, **int** **attrs****);**

int wattrset (WINDOW **win*, **int** **attsr****);**

Description

These subroutines manipulate the window attributes of the current or specified window.

The **attroff** and **wattroff** subroutines turn off *attrs* in the current or specified specified window without affecting any others.

The **attron** and **wattron** subroutines turn on *attrs* in the current or specified specified window without affecting any others.

The **attrset** and **wattrset** subroutines set the background attributes of the current or specified specified window to *attrs.*

It unspecified whether these subroutines can be used to manipulate attributes than A_BLINK, A_BOLD, A_DIM, A_REVERSE, A_STANDOUT and A_UNDERLINE.

Parameters

Item	Description
**attrs*	Specifies which attributes to turn off.
**win*	Specifies the window in which to turn off the specified attributes.

Return Values

These subroutines always return either OK or 1.

Examples

For the **attroff** or **wattroff** subroutines:

1. To turn the off underlining attribute in stdscr, enter:

```
attroff(A_UNDERLINE);
```

2. To turn off the underlining attribute in the user-defined window `my_window`, enter:

```
wattroff(my_window, A_UNDERLINE);
```

For the **attron** or **wattron** subroutines:

1. To turn on the underlining attribute in stdscr, enter:

```
attron(A_UNDERLINE);
```

2. To turn on the underlining attribute in the user-defined window `my_window`, enter:

```
wattron(my_window, A_UNDERLINE);
```

For the **attrset** or **wattrset** subroutines:

1. To set the current attribute in the **stdscr** global variable to blink, enter:

```
attrset(A_BLINK);
```

2. To set the current attribute in the user-defined window `my_window` to blinking, enter:

```
wattrset(my_window, A_BLINK);
```

3. To turn off all attributes in the **stdscr** global variable, enter:

```
attrset(0);
```

4. To turn off all attributes in the user-defined window `my_window`, enter:

```
wattrset(my_window, 0);
```

attron or wattron Subroutine

Purpose

Turns on specified attributes.

Library

Curses Library (**libcurses.a**)

Syntax

#include <curses.h>

```
attron( Attributes)
char *Attributes;
```

```
wattron( Window, Attributes)
WINDOW *Window;
char *Attributes;
```

Description

The **attron** and **wattron** subroutines turn on specified attributes without affecting any others. The **attron** subroutine turns the specified attributes on in stdscr. The **wattron** subroutine turns the specified attributes on in the specified window.

Parameters

Item	Description
Attributes	Specifies which attributes to turn on.
Window	Specifies the window in which to turn on the specified attributes.

Examples

1. To turn on the underlining attribute in stdscr, enter:

```
attron(A_UNDERLINE);
```

2. To turn on the underlining attribute in the user-defined window `my_window`, enter:

```
wattron(my_window, A_UNDERLINE);
```

audit Subroutine

Purpose

Enables and disables system auditing.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/audit.h>
```

```
int audit ( Command,  Argument)
int Command;
int Argument;
```

Description

The **audit** subroutine enables or disables system auditing.

When auditing is enabled, audit records are created for security-relevant events. These records can be collected through the **auditbin** subroutine, or through the **/dev/audit** special file interface.

Parameters

Item	Description
Command	Defined in the **sys/audit.h** file, can be one of the following values: **AUDIT_QUERY** Returns a mask indicating the state of the auditing subsystem. The mask is a logical ORing of the **AUDIT_ON**, **AUDIT_OFF**, **AUDIT_PANIC**, and **AUDIT_FULLPATH** flags. **AUDIT_ON** Enables auditing. If auditing is already enabled, only the failure-mode behavior changes. The *Argument* parameter specifies recovery behavior in the event of failure and may be either 0 or the value **AUDIT_PANIC** or **AUDIT_FULLPATH**. **Note:** If **AUDIT_PANIC** is specified, bin-mode auditing must be enabled before the **audit** subroutine call. **AUDIT_OFF** Disables the auditing system if auditing is enabled. If the auditing system is disabled, the **audit** subroutine does nothing. The *Argument* parameter is ignored. **AUDIT_RESET** Disables the auditing system and resets the auditing system. If auditing is already disabled, only the system configuration is reset. Resetting the audit configuration involves clearing the audit events and audited objects table, and terminating bin auditing and stream auditing. **AUDIT_EVENT_THRESHOLD** Audit event records will be buffered until a total of *Argument* records have been saved, at which time the audit event records will be flushed to disk. An *Argument* value of zero disables this functionality. **AUDIT_BYTE_THRESHOLD** Audit event data will be buffered until a total of *Argument* bytes of data have been saved, at which time the audit event data will be flushed to disk. An *Argument* value of zero disables this functionality.
Argument	Specifies the behavior when a bin write fails (for **AUDIT_ON**) or specifies the size of the audit event buffer (for **AUDIT_EVENT_THRESHOLD** and **AUDIT_BYTE_THRESHOLD**). For **AUDIT_RESET** and **AUDIT_QUERY**, the value of the **Argument** is the WPAR ID. For all other commands, the value of **Argument** is ignored. The valid values are: **AUDIT_PANIC** The operating system halts abruptly if an audit record cannot be written to a bin. **Note:** If **AUDIT_PANIC** is specified, bin-mode auditing must be enabled before the **audit** subroutine call. **AUDIT_FULLPATH** The operating system starts capturing full path name for the FILE_Open, FILE_Read, FILE_Write auditing events. **BufferSize** The number of bytes or audit event records which will be buffered. This parameter is valid only with the command **AUDIT_BYTE_THRESHOLD** and **AUDIT_EVENT_THRESHOLD**. A value of zero will disable either byte (for **AUDIT_BYTE_THRESHOLD**) or event (for **AUDIT_EVENT_THRESHOLD**) buffering.

Return Values

For a *Command* value of **AUDIT_QUERY**, the **audit** subroutine returns, upon successful completion, a mask indicating the state of the auditing subsystem. The mask is a logical ORing of the **AUDIT_ON**, **AUDIT_OFF**, **AUDIT_PANIC**, **AUDIT_NO_PANIC**, and **AUDIT_FULLPATH** flags. For any other *Command* value, the **audit** subroutine returns 0 on successful completion.

If the **audit** subroutine fails, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **audit** subroutine fails if either of the following is true:

Item	Description
EINVAL	The *Command* parameter is not one of **AUDIT_ON**, **AUDIT_OFF**, **AUDIT_RESET**, or **AUDIT_QUERY**.
EINVAL	The *Command* parameter is **AUDIT_ON** and the *Argument* parameter specifies values other than **AUDIT_PANIC** or **AUDIT_FULLPATH**.
EPERM	The calling process does not have root user authority.

Files

Item	Description
dev/audit	Specifies the audit pseudo-device from which the audit records are read.

auditbin Subroutine

Purpose

Defines files to contain audit records.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/audit.h>

int auditbin (Command, Current, Next, Threshold)
int  Command;
int  Current;
int  Next;
int  Threshold;
```

Description

The **auditbin** subroutine establishes an audit bin file into which the kernel writes audit records. Optionally, this subroutine can be used to establish an overflow bin into which records are written when the current bin reaches the size specified by the *Threshold* parameter.

Parameters

Item	Description
Command	If nonzero, this parameter is a logical ORing of the following values, which are defined in the **sys/audit.h** file: **AUDIT_EXCL** Requests exclusive rights to the audit bin files. If the file specified by the *Current* parameter is not the kernel's current bin file, the **auditbin** subroutine fails immediately with the **errno** variable set to **EBUSY**. **AUDIT_WAIT** The **auditbin** subroutine should not return until: **bin full** The kernel writes the number of bytes specified by the *Threshold* parameter to the file descriptor specified by the *Current* parameter. Upon successful completion, the **auditbin** subroutine returns a 0. The kernel writes subsequent audit records to the file descriptor specified by the *Next* parameter. **bin failure** An attempt to write an audit record to the file specified by the *Current* parameter fails. If this occurs, the **auditbin** subroutine fails with the **errno** variable set to the return code from the **auditwrite** subroutine. **bin contention** Another process has already issued a successful call to the **auditbin** subroutine. If this occurs, the **auditbin** subroutine fails with the **errno** variable set to **EBUSY**. **system shutdown** The auditing system was shut down. If this occurs, the **auditbin** subroutine fails with the **errno** variable set to **EINTR**.
Current	A file descriptor for a file to which the kernel should immediately write audit records.
Next	Specifies the file descriptor that will be used as the current audit bin if the value of the *Threshold* parameter is exceeded or if a write to the current bin fails. If this value is -1, no switch occurs.
Threshold	Specifies the maximum size of the current bin. If 0, the auditing subsystem will not switch bins. If it is nonzero, the kernel begins writing records to the file specified by the *Next* parameter, if writing a record to the file specified by the *Cur* parameter would cause the size of this file to exceed the number of bytes specified by the *Threshold* parameter. If no next bin is defined and **AUDIT_PANIC** was specified when the auditing subsystem was enabled, the system is shut down. If the size of the *Threshold* parameter is too small to contain a bin header and a bin tail, the **auditbin** subroutine fails and the **errno** variable is set to **EINVAL**.

Return Values

If the **auditbin** subroutine is successful, a value of 0 returns.

If the **auditbin** subroutine fails, a value of -1 returns and the **errno** global variable is set to indicate the error. If this occurs, the result of the call does not indicate whether any records were written to the bin.

Error Codes

The **auditbin** subroutine fails if any of the following is true:

Item	Description
EBADF	The *Current* parameter is not a file descriptor for a regular file open for writing, or the *Next* parameter is neither -1 nor a file descriptor for a regular file open for writing.
EBUSY	The *Command* parameter specifies **AUDIT_EXCL** and the kernel is not writing audit records to the file specified by the *Current* parameter.
EBUSY	The *Command* parameter specifies **AUDIT_WAIT** and another process has already registered a bin.
EINTR	The auditing subsystem is shut down.
EINVAL	The *Command* parameter specifies a nonzero value other than **AUDIT_EXCL** or **AUDIT_WAIT**.
EINVAL	The *Threshold* parameter value is less than the size of a bin header and trailer.
EPERM	The caller does not have root user authority.

auditevents Subroutine

Purpose

Gets or sets the status of system event auditing.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/audit.h>
```

```
int auditevents ( Command,  Classes,  NClasses)
int Command;
struct audit_class *Classes;
int NClasses;
```

Description

The **auditevents** subroutine queries or sets the audit class definitions that control event auditing. Each audit class is a set of one or more audit events.

System auditing need not be enabled before calling the **auditevents** subroutine. The **audit** subroutine can be directed with the **AUDIT_RESET** command to clear all event lists.

Parameters

Item	Description
Command	Specifies whether the event lists are to be queried or set. The values, defined in the **sys/audit.h** file, for the *Command* parameter are: **AUDIT_SET** Sets the lists of audited events after first clearing all previous definitions. **AUDIT_GET** Queries the lists of audited events. **AUDIT_LOCK** Queries the lists of audited events. This value also blocks any other process attempting to set or lock the list of audit events. The lock is released when the process holding the lock dies or calls the **auditevents** subroutine with the *Command* parameter set to **AUDIT_SET**.
Classes	Specifies the array of **a_event** structures for the **AUDIT_SET** operation, or after an **AUDIT_GET** or **AUDIT_LOCK** operation. The **audit_class** structure is defined in the **sys/audit.h** file and contains the following members: **ae_name** A pointer to the name of the audit class. **ae_list** A pointer to a list of null-terminated audit event names for this audit class. The list is ended by a null name (a leading null byte or two consecutive null bytes). **Note:** Event and class names are limited to 15 significant characters. **ae_len** The length of the event list in the **ae_list** member. This length includes the terminating null bytes. On an **AUDIT_SET** operation, the caller must set this member to indicate the actual length of the list (in bytes) pointed to by `ae_list`. On an **AUDIT_GET** or **AUDIT_LOCK** operation, the **auditevents** subroutine sets this member to indicate the actual size of the list.
NClasses	Serves a dual purpose. For **AUDIT_SET**, the *NClasses* parameter specifies the number of elements in the events array. For **AUDIT_GET** and **AUDIT_LOCK**, the *NClasses* parameter specifies the size of the buffer pointed to by the *Classes* parameter.

Attention: Only 32 audit classes are supported. One class is implicitly defined by the system to include all audit events (ALL). The administrator of your system should not attempt to define more than 31 audit classes.

Security

The calling process must have root user authority in order to use the **auditevents** subroutine.

Return Codes

If the **auditevents** subroutine completes successfully, the number of audit classes is returned if the *Command* parameter is **AUDIT_GET** or **AUDIT_LOCK**. A value of 0 is returned if the *Command* parameter is **AUDIT_SET**. If this call fails, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **auditevents** subroutine fails if one or more of the following are true:

Item	Description
EPERM	The calling process does not have root user authority.
EINVAL	The value of *Command* is not **AUDIT_SET**, **AUDIT_GET**, or **AUDIT_LOCK**.
EINVAL	The *Command* parameter is **AUDIT_SET**, and the value of the *NClasses* parameter is greater than or equal to 32.
EINVAL	A class name or event name is longer than 15 significant characters.
ENOSPC	The value of *Command* is **AUDIT_GET** or **AUDIT_LOCK** and the size of the buffer specified by the *NClasses* parameter is not large enough to hold the list of event structures and names. If this occurs, the first word of the buffer is set to the required buffer size.
EFAULT	The *Classes* parameter points outside of the process' address space.
EFAULT	The `ae_list` member of one or more **audit_class** structures passed for an **AUDIT_SET** operation points outside of the process' address space.
EFAULT	The *Command* value is **AUDIT_GET** or **AUDIT_LOCK** and the size of the *Classes* buffer is not large enough to hold an integer.
EBUSY	Another process has already called the **auditevents** subroutine with **AUDIT_LOCK**.
ENOMEM	Memory allocation failed.

auditlog Subroutine

Purpose

Appends an audit record to the audit trail file.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/audit.h>

int auditlog ( Event,  Result,  Buffer,  BufferSize)
char *Event;
int Result;
char *Buffer;
int BufferSize;
```

Description

The **auditlog** subroutine generates an audit record. The kernel audit-logging component appends a record for the specified *Event* if system auditing is enabled, process auditing is not suspended, and the *Event* parameter is in one or more of the audit classes for the current process.

The audit logger generates the audit record by adding the *Event* and *Result* parameters to the audit header and including the resulting information in the *Buffer* parameter as the audit tail.

Parameters

Item	Description
Event	The name of the audit event to be generated. This parameter should be the name of an audit event. Audit event names are truncated to 15 characters plus null.
Result	Describes the result of this event. Valid values are defined in the **sys/audit.h** file and include the following: **AUDIT_OK** The event was successful. **AUDIT_FAIL** The event failed. **AUDIT_FAIL_ACCESS** The event failed because of any access control denial. **AUDIT_FAIL_DAC** The event failed because of a discretionary access control denial. **AUDIT_FAIL_PRIV** The event failed because of a privilege control denial. **AUDIT_FAIL_AUTH** The event failed because of an authentication denial. Other nonzero values of the *Result* parameter are converted into the **AUDIT_FAIL** value.
Buffer	Points to a buffer containing the tail of the audit record. The format of the information in this buffer depends on the event name.
BufferSize	Specifies the size of the *Buffer* parameter, including the terminating null.

Return Values

Upon successful completion, the **auditlog** subroutine returns a value of 0. If **auditlog** fails, a value of -1 is returned and the **errno** global variable is set to indicate the error.

The **auditlog** subroutine does not return any indication of failure to write the record where this is due to inappropriate tailoring of auditing subsystem configuration files or user-written code. Accidental omissions and typographical errors in the configuration are potential causes of such a failure.

Error Codes

The **auditlog** subroutine fails if any of the following are true:

Item	Description
EFAULT	The *Event* or *Buffer* parameter points outside of the process' address space.
EINVAL	The auditing system is either interrupted or not initialized.
EINVAL	The length of the audit record is greater than 32 kilobytes.
EPERM	The process does not have root user authority.
ENOMEM	Memory allocation failed.

auditobj Subroutine

Purpose

Gets or sets the auditing mode of a system data object.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/audit.h>

int auditobj ( Command,  Obj_Events,  ObjSize)
int Command;
struct o_event *Obj_Events;
int ObjSize;
```

Description

The **auditobj** subroutine queries or sets the audit events to be generated by accessing selected objects. For each object in the file system name space, it is possible to specify the event generated for each access mode. Using the **auditobj** subroutine, an administrator can define new audit events in the system that correspond to accesses to specified objects. These events are treated the same as system-defined events.

System auditing need not be enabled to set or query the object audit events. The **audit** subroutine can be directed with the **AUDIT_RESET** command to clear the definitions of object audit events.

Parameters

Item	Description
Command	Specifies whether the object audit event lists are to be read or written. The valid values, defined in the **sys**/**audit.h** file, for the *Command* parameter are: **AUDIT_SET** Sets the list of object audit events, after first clearing all previous definitions. **AUDIT_GET** Queries the list of object audit events. **AUDIT_LOCK** Queries the list of object audit events and also blocks any other process attempting to set or lock the list of audit events. The lock is released when the process holding the lock dies or calls the **auditobj** subroutine with the *Command* parameter set to **AUDIT_SET**.

Item	Description
Obj_Events	Specifies the array of **o_event** structures for the **AUDIT_SET** operation or for after the **AUDIT_GET** or **AUDIT_LOCK** operation. The **o_event** structure is defined in the **sys/audit.h** file and contains the following members: **o_type** Specifies the type of the object, in terms of naming space. Currently, only one object-naming space is supported: **AUDIT_FILE** Denotes the file system naming space. **o_name** Specifies the name of the object. **o_event** Specifies any array of event names to be generated when the object is accessed. Note that event names are currently limited to 16 bytes, including the trailing null. The index of an event name in this array corresponds to an access mode. Valid indexes are defined in the **audit.h** file and include the following: • **AUDIT_READ** • **AUDIT_WRITE** • **AUDIT_EXEC** **Note:** The C++ compiler will generate a warning indicating that **o_event** is defined both as a structure and a field within that structure. Although the **o_event** field can be used within C++, the warning can by bypassed by defining **O_EVENT_RENAME**. This will replace the **o_event** field with **o_event_array**. **o_event** is the default field.
ObjSize	For an **AUDIT_SET** operation, the *ObjSize* parameter specifies the number of object audit event definitions in the array pointed to by the *Obj_Events* parameter. For an **AUDIT_GET** or **AUDIT_LOCK** operation, the *ObjSize* parameter specifies the size of the buffer pointed to by the *Obj_Events* parameter.

Return Values

If the **auditobj** subroutine completes successfully, the number of object audit event definitions is returned if the *Command* parameter is **AUDIT_GET** or **AUDIT_LOCK**. A value of 0 is returned if the *Command* parameter is **AUDIT_SET**. If this call fails, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **auditobj** subroutine fails if any of the following are true:

Item	Description
EFAULT	The *Obj_Events* parameter points outside the address space of the process.
EFAULT	The *Command* parameter is **AUDIT_SET**, and one or more of the o_name members points outside the address space of the process.
EFAULT	The *Command* parameter is **AUDIT_GET** or **AUDIT_LOCK**, and the buffer size of the *Obj_Events* parameter is not large enough to hold the integer.
EINVAL	The value of the *Command* parameter is not **AUDIT_SET**, **AUDIT_GET** or **AUDIT_LOCK**.

Item	Description
EINVAL	The *Command* parameter is **AUDIT_SET**, and the value of one or more of the o_type members is not **AUDIT_FILE**.
EINVAL	An event name was longer than 15 significant characters.
ENOENT	The *Command* parameter is **AUDIT_SET**, and the parent directory of one of the file-system objects does not exist.
ENOSPC	The value of the *Command* parameter is **AUDIT_GET** or **AUDIT_LOCK**, and the size of the buffer as specified by the *ObjSize* parameter is not large enough to hold the list of event structures and names. If this occurs, the first word of the buffer is set to the required buffer size.
ENOMEM	Memory allocation failed.
EBUSY	Another process has called the **auditobj** subroutine with **AUDIT_LOCK**.
EPERM	The caller does not have root user authority.

auditpack Subroutine

Purpose

Compresses and uncompresses audit bins.

Library

Security Library (**libc.a**)

Syntax

```
#include <sys/audit.h>
#include <stdio.h>
```

char *auditpack (*Expand*, *Buffer*)
int *Expand*;
char **Buffer*;

Description

The **auditpack** subroutine can be used to compress or uncompress bins of audit records.

Parameters

Item	Description
Expand	Specifies the operation. Valid values, as defined in the **sys/audit.h** header file, are one of the following: **AUDIT_PACK** Performs standard compression on the audit bin. **AUDIT_UNPACK** Unpacks the compressed audit bin.
Buffer	Specifies the buffer containing the bin to be compressed or uncompressed. This buffer must contain a standard bin as described in the **audit.h** file.

Return Values

If the **auditpack** subroutine is successful, a pointer to a buffer containing the processed audit bin is returned. If unsuccessful, a null pointer is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **auditpack** subroutine fails if one or more of the following values is true:

Item	Description
EINVAL	The *Expand* parameter is not one of the valid values (**AUDIT_PACK** or **AUDIT_UNPACK**).
EINVAL	The *Expand* parameter is **AUDIT_UNPACK** and the packed data in *Buffer* does not unpack to its original size.
EINVAL	The *Expand* parameter is **AUDIT_PACK** and the bin in the *Buffer* parameter is already compressed, or the *Expand* parameter is **AUDIT_UNPACK** and the bin in the *Buffer* parameter is already unpacked.
ENOSPC	The **auditpack** subroutine is unable to allocate space for a new buffer.

auditproc Subroutine

Purpose

Gets or sets the audit state of a process.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/audit.h>

int auditproc (ProcessID, Command, Argument, Length)
int  ProcessID;
int  Command;
char *  Argument;
int  Length;
```

Description

The **auditproc** subroutine queries or sets the auditing state of a process. There are two parts to the auditing state of a process:

- The list of classes to be audited for this process. Classes are defined by the **auditevents** subroutine. Each class includes a set of audit events. When a process causes an audit event, that event may be logged in the audit trail if it is included in one or more of the audit classes of the process.
- The audit status of the process. Auditing for a process may be suspended or resumed. Functions that generate an audit record can first check to see whether auditing is suspended. If process auditing is suspended, no audit events are logged for a process. For more information, see the **auditlog** subroutine.

Parameters

Item	Description
ProcessID	The process ID of the process to be affected. If *ProcessID* is 0, the **auditproc** subroutine affects the current process.
Command	The action to be taken. Defined in the **audit.h** file, valid values include: **AUDIT_KLIST_EVENTS** Sets the list of audit classes to be audited for the process and also sets the user's default audit classes definition within the kernel. The *Argument* parameter is a pointer to a list of null-terminated audit class names. The *Length* parameter is the length of this list, including null bytes. **AUDIT_QEVENTS** Returns the list of audit classes defined for the current process if *ProcessID* is 0. Otherwise, it returns the list of audit classes defined for the specified process ID. The *Argument* parameter is a pointer to a character buffer. The *Length* parameter specifies the size of this buffer. On return, this buffer contains a list of null-terminated audit class names. A null name terminates the list. **AUDIT_EVENTS** Sets the list of audit classes to be audited for the process. The *Argument* parameter is a pointer to a list of null-terminated audit class names. The *Length* parameter is the length of this list, including null bytes. **AUDIT_QSTATUS** Returns the audit status of the current process. You can only check the status of the current process. If the *ProcessID* parameter is nonzero, a -1 is returned and the **errno** global variable is set to **EINVAL**. The *Length* and *Argument* parameters are ignored. A return value of **AUDIT_SUSPEND** indicates that auditing is suspended. A return value of **AUDIT_RESUME** indicates normal auditing for this process. **AUDIT_STATUS** Sets the audit status of the current process. The *Length* parameter is ignored, and the *ProcessID* parameter must be zero. If *Argument* is **AUDIT_SUSPEND**, the audit status is set to suspend event auditing for this process. If the *Argument* parameter is **AUDIT_RESUME**, the audit status is set to resume event auditing for this process.
Argument	A character pointer for the audit class buffer for an **AUDIT_EVENT** or **AUDIT_QEVENTS** value of the *Command* parameter or an integer defining the audit status to be set for an **AUDIT_STATUS** operation.
Length	Size of the audit class character buffer.

Return Values

The **auditproc** subroutine returns the following values upon successful completion:

- The previous audit status (**AUDIT_SUSPEND** or **AUDIT_RESUME**), if the call queried or set the audit status (the *Command* parameter specified **AUDIT_QSTATUS** or **AUDIT_STATUS**)
- A value of 0 if the call queried or set audit events (the *Command* parameter specified **AUDIT_QEVENTS** or **AUDIT_EVENTS**)

Error Codes

If the **auditproc** subroutine fails if one or more of the following are true:

Item	Description
EINVAL	An invalid value was specified for the *Command* parameter.
EINVAL	The *Command* parameter is set to the **AUDIT_QSTATUS** or **AUDIT_STATUS** value and the **pid** value is nonzero.
EINVAl	The *Command* parameter is set to the **AUDIT_STATUS** value and the *Argument* parameter is not set to **AUDIT_SUSPEND** or **AUDIT_RESUME**.
ENOSPC	The *Command* parameter is **AUDIT_QEVENTS**, and the buffer size is insufficient. In this case, the first word of the *Argument* parameter is set to the required size.
EFAULT	The *Command* parameter is **AUDIT_QEVENTS** or **AUDIT_EVENTS** and the *Argument* parameter points to a location outside of the process' allocated address space.
ENOMEM	Memory allocation failed.
EPERM	The caller does not have root user authority.

auditread, auditread_r Subroutines

Purpose

Reads an audit record.

Library

Security Library (**libc.a**)

Syntax

```
#include <sys/audit.h>
#include <stdio.h>
char *auditread ( FilePointer, AuditRecord)
FILE *FilePointer;
struct aud_rec *AuditRecord;

char *auditread_r ( FilePointer, AuditRecord,  RecordSize,  StreamInfo)
FILE *FilePointer;
struct aud_rec *AuditRecord;
size_t RecordSize;
void **StreamInfo;
```

Description

The **auditread** subroutine reads the next audit record from the specified file descriptor. Bins on this input stream are unpacked and uncompressed if necessary.

The **auditread** subroutine can not be used on more than one *FilePointer* as the results can be unpredictable. Use the **auditread_r** subroutine instead.

The **auditread_r** subroutine reads the next audit from the specified file descriptor. This subroutine is thread safe and can be used to handle multiple open audit files simultaneously by multiple threads of execution.

The **auditread_r** subroutine is able to read multiple versions of audit records. The version information contained in an audit record is used to determine the correct size and format of the record. When an input record header is larger than *AuditRecord*, an error is returned. In order to provide for binary compatibility

with previous versions, if *RecordSize* is the same size as the original (**struct aud_rec**), the input record is converted to the original format and returned to the caller.

Parameters

Item	Description
FilePointer	Specifies the file descriptor from which to read.
AuditRecord	Specifies the buffer to contain the header. The first short in this buffer must contain a valid number for the header.
RecordSize	The size of the buffer referenced by *AuditRecord*.
StreamInfo	A pointer to an opaque datatype used to hold information related to the current value of *FilePointer*. For each new value of *FilePointer*, a new *StreamInfo* pointer must be used. *StreamInfo* must be initialized to NULL by the user and is initialized by **auditread_r** when first used. When *FilePointer* has been closed, the value of *StreamInfo* can be passed to the **free** subroutine to be deallocated.

Return Values

If the **auditread** subroutine completes successfully, a pointer to a buffer containing the tail of the audit record is returned. The length of this buffer is returned in the `ah_length` field of the header file. If this subroutine is unsuccessful, a null pointer is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **auditread** subroutine fails if one or more of the following is true:

Item	Description
EBADF	The *FilePointer* value is not valid.
ENOSPC	The **auditread** subroutine is unable to allocate space for the tail buffer.

Other error codes are returned by the **read** subroutine.

auditwrite Subroutine

Purpose

Writes an audit record.

Library

Security Library (**libc.a**)

Syntax

```
#include <sys/audit.h>
#include <stdio.h>
```

```
int auditwrite (Event, Result, Buffer1, Length1, Buffer2, Length2, ...)
char * Event;
int  Result;
char * Buffer1, *Buffer2 ...;
int  Length1, Length2 ...;
```

Description

The **auditwrite** subroutine builds the tail of an audit record and then writes it with the **auditlog** subroutine. The tail is built by gathering the specified buffers. The last buffer pointer must be a null.

If the **auditwrite** subroutine is to be called from a program invoked from the **initab** file, the **setpcred** subroutine should be called first to establish the process' credentials.

Parameters

Item	Description
Event	Specifies the name of the event to be logged.
Result	Specifies the audit status of the event. Valid values are defined in the **sys/audit.h** file and are listed in the **auditlog** subroutine.
Buffer1, Buffer2	Specifies the character buffers containing audit tail information. Note that numerical values must be passed by reference. The correct size can be computed with the **sizeof** C function.
Length1, Length2	Specifies the lengths of the corresponding buffers.

Return Values

If the **auditwrite** subroutine completes successfully, a value of 0 is returned. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **auditwrite** subroutine fails if the following is true:

Item	Description
ENOSPC	The **auditwrite** subroutine is unable to allocate space for the tail buffer.

Other error codes are returned by the **auditlog** subroutine.

authenticate Subroutine

Purpose

Verifies a user's name and password.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>

int authenticate (UserName, Response, Reenter, Message)
char *UserName;
char *Response;
int *Reenter;
char **Message;
```

Description

The **authenticate** subroutine maintains requirements users must satisfy to be authenticated to the system. It is a recallable interface that prompts for the user's name and password. The user must supply a character string at the prompt issued by the *Message* parameter. The *Response* parameter returns the user's response to the **authenticate** subroutine. The calling program makes no assumptions about the number of prompt messages the user must satisfy for authentication.

The *Reenter* parameter indicates when a user has satisfied all prompt messages. The parameter remains nonzero until a user has passed all prompts. After the returned value of *Reenter* is 0, the return code signals whether authentication has succeeded or failed. When progressing through prompts for a user, the value of *Reenter* must be maintained by the caller between invocations of **authenticate**.

The **authenticate** subroutine ascertains the authentication domains the user can attempt. The subroutine reads the **SYSTEM** line from the user's stanza in the **/etc/security/user** file. Each token that appears in the **SYSTEM** line corresponds to a method that can be dynamically loaded and processed. Likewise, the system can provide multiple or alternate authentication paths.

The **authenticate** routine maintains internal state information concerning the next prompt message presented to the user. If the calling program supplies a different user name before all prompts are complete for the user, the internal state information is reset and prompt messages begin again. The calling program maintains the value of the *Reenter* parameter while processing prompts for a given user.

If the user has no defined password, or the **SYSTEM** grammar explicitly specifies no authentication required, the user is not required to respond to any prompt messages. Otherwise, the user is always initially prompted to supply a password.

The **authenticate** subroutine can be called initially with the cleartext password in the *Response* parameter. If the user supplies a password during the initial invocation but does not have a password, authentication fails. If the user wants the **authenticate** subroutine to supply a prompt message, the *Response* parameter is a null pointer on initial invocation.

The **authenticate** subroutine sets the **AUTHSTATE** environment variable used by name resolution subroutines, such as the **getpwnam** subroutine. This environment variable indicates the registry to which to user authenticated. Values for the **AUTHSTATE** environment variable include **DCE**, **compat**, and token names that appear in a **SYSTEM** grammar. A null value can exist if the **cron** daemon or other utilities that do not require authentication is called.

Parameters

Item	Description
UserName	Points to the user's name that is to be authenticated.
Response	Specifies a character string containing the user's response to an authentication prompt.
Reenter	Points to a Boolean value that signals whether the **authenticate** subroutine has completed processing. If the *Reenter* parameter is a nonzero value, the **authenticate** subroutine expects the user to satisfy the prompt message provided by the *Message* parameter. If the *Reenter* parameter is 0, the **authenticate** subroutine has completed processing.
Message	Points to a pointer that the **authenticate** subroutine allocates memory for and fills in. This string is suitable for printing and issues prompt messages (if the *Reenter* parameter is a nonzero value). It also issues informational messages such as why the user failed authentication (if the *Reenter* parameter is 0). The calling application is responsible for freeing this memory.

Return Values

Upon successful completion, the **authenticate** subroutine returns a value of 0. If this subroutine fails, it returns a value of 1.

Error Codes

The **authenticate** subroutine is unsuccessful if one of the following values is true:

Item	Description
ENOENT	Indicates that the user is unknown to the system.
ESAD	Indicates that authentication is denied.
EINVAL	Indicates that the parameters are not valid.
ENOMEM	Indicates that memory allocation (malloc) failed.

Note: The DCE mechanism requires credentials on successful authentication that apply only to the authenticate process and its children.

authenticatex Subroutine

Purpose

Verifies a user's name and password.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
```

```
int authenticatex (UserName, Response, Reenter, Message, State)
char *UserName;
char *Response;
int *Reenter;
char **Message;
void **State;
```

Description

The **authenticatex** subroutine maintains requirements that users must satisfy to be authenticated to the system. It is a recallable interface that prompts for the user's name and password. The user must supply a character string at the prompt issued by the *Message* parameter. The *Response* parameter returns the user's response to the **authenticatex** subroutine. The calling program makes no assumptions about the number of prompt messages the user must satisfy for authentication. The **authenticatex** subroutine maintains information about the results of each part of the authentication process in the *State* parameter. This parameter can be shared with the **chpassx**, **loginrestrictionsx** and **passwdexpiredx** subroutines. The proper sequence of library routines for authenticating a user in order to create a new session is:

1. Call the **loginrestrictionsx** subroutine to determine which administrative domains allow the user to log in.
2. Call the **authenticatex** subroutine to perform authentication using those administrative domains that grant login access.
3. Call the **passwdexpiredx** subroutine to determine if any of the passwords used during the authentication process have expired and must be changed in order for the user to be granted access.
4. If the **passwdexpiredx** subroutine indicated that one or more passwords have expired and must be changed by the user, call the **chpassx** subroutine to update all of the passwords that were used for the authentication process.

The *Reenter* parameter remains a nonzero value until the user satisfies all prompt messages or answers incorrectly. When the *Reenter* parameter is 0, the return code signals whether authentication passed or failed. The value of the *Reenter* parameter must be 0 on the initial call. A nonzero value for the *Reenter* parameter must be passed to the **authenticatex** subroutine on subsequent calls. A new authentication can be begun by calling the **authenticatex** subroutine with a 0 value for the *Reenter* parameter or by using a different value for *UserName*.

The *State* parameter contains information about the authentication process. The *State* parameter from an earlier call to **loginrestrictionsx** can be used to control how authentication is performed. Administrative domains that do not permit the user to log in cause those administrative domains to be ignored during authentication even if the user has the correct authentication information.

The **authenticatex** subroutine ascertains the authentication domains the user can attempt. The subroutine uses the **SYSTEM** attribute for the user. Each token that is displayed in the **SYSTEM** line corresponds to a method that can be dynamically loaded and processed. Likewise, the system can provide multiple or alternate authentication paths.

The **authenticatex** subroutine maintains internal state information concerning the next prompt message presented to the user. If the calling program supplies a different user name before all prompts are complete for the user, the internal state information is reset and prompt messages begin again. The **authenticatex** subroutine requires that the *State* parameter be initialized to reference a null value when changing user names or that the *State* parameter from an earlier call to **loginrestrictionsx** for the new user be provided.

If the user has no defined password, or the **SYSTEM** grammar explicitly specifies no authentication required, the user is not required to respond to any prompt messages. Otherwise, the user is always initially prompted to supply a password.

The **authenticatex** subroutine can be called initially with the `cleartext` password in the *Response* parameter. If the user supplies a password during the initial invocation but does not have a password, authentication fails. If the user wants the **authenticatex** subroutine to supply a prompt message, the *Response* parameter is a null pointer on initial invocation.

The **authenticatex** subroutine sets the **AUTHSTATE** environment variable used by name resolution subroutines, such as the **getpwnam** subroutine. This environment variable indicates the first registry to which the user authenticated. Values for the **AUTHSTATE** environment variable include **DCE**, **compat**, and token names that appear in a **SYSTEM** grammar. A null value can exist if the **cron** daemon or another utility that does not require authentication is called.

Parameters

Item	Description
Message	Points to a pointer that the **authenticatex** subroutine allocates memory for and fills in. This string is suitable for printing and issues prompt messages (if the *Reenter* parameter is a nonzero value). It also issues informational messages, such as why the user failed authentication (if the *Reenter* parameter is 0). The calling application is responsible for freeing this memory.
Reenter	Points to an integer value that signals whether the **authenticatex** subroutine has completed processing. If the integer referenced by the *Reenter* parameter is a nonzero value, the **authenticatex** subroutine expects the user to satisfy the prompt message provided by the *Message* parameter. If the integer referenced by the *Reenter* parameter is 0, the **authenticatex** subroutine has completed processing. The initial value of the integer referenced by *Reenter* must be 0 when the **authenticatex** function is initially invoked and must not be modified by the calling application until the **authenticationx** subroutine has completed processing.
Response	Specifies a character string containing the user's response to an authentication prompt.

Item	Description
State	Points to a pointer that the **authenticatex** subroutine allocates memory for and fills in. The *State* parameter can also be the result of an earlier call to the **loginrestrictionsx** subroutine. This parameter contains information about the results of the authentication process for each term in the user's **SYSTEM** attribute. The calling application is responsible for freeing this memory when it is no longer needed for a subsequent call to the **passwdexpiredx** or **chpassx** subroutines.
UserName	Points to the user's name that is to be authenticated.

Return Values

Upon successful completion, the **authenticatex** subroutine returns a value of 0. If this subroutine fails, it returns a value of 1.

Error Codes

The **authenticatex** subroutine is unsuccessful if one of the following values is true:

Item	Description
EINVAL	The parameters are not valid.
ENOENT	The user is unknown to the system.
ENOMEM	Memory allocation (malloc) failed.
ESAD	Authentication is denied.

Note: Additional information about the behavior of a loadable authentication module can be found in the documentation for that module.

b

The following Base Operating System (BOS) runtime services begin with the letter *b*.

basename Subroutine

Purpose

Return the last element of a path name.

Library

Standard C Library **(libc.a)**

Syntax

#include <libgen.h>

char *basename (char **path*)

Description

Given a pointer to a character string that contains a path name, the **basename** subroutine deletes trailing "/" characters from *path*, and then returns a pointer to the last component of *path*. The "/" character is defined as trailing if it is not the first character in the string.

If *path* is a null pointer or points to an empty string, a pointer to a static constant "." is returned.

Return Values

The **basename** function returns a pointer to the last component of *path*.

The **basename** function returns a pointer to a static constant "." if *path* is a null pointer or points to an empty string.

The **basename** function may modify the string pointed to by *path* and may return a pointer to static storage that may then be overwritten by a subsequent call to the **basename** subroutine.

Examples

Input string	Output string
"/usr/lib"	"lib"
"/usr/"	"usr"
"/"	"/"

baudrate Subroutine

Purpose

Gets the terminal baud rate.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
int baudrate(void)
```

Description

The **baudrate** subroutine extracts the output speed of the terminal in bits per second.

Return Values

The **baudrate** subroutine returns the output speed of the terminal.

Examples

To query the baud rate and place the value in the user-defined integer variable `BaudRate`, enter:

```
BaudRate = baudrate();
```

bcopy, bcmp, bzero, ffs, ffsl, or ffsll Subroutine

Purpose

Performs bit and byte string operations.

Library

Standard C Library (**libc.a**)

Syntax

#include <strings.h>

void bcopy (*Source***,** *Destination***,** *Length***) const void ****Source***, char ****Destination***; size_t** *Length***;**

int bcmp (*String1***,** *String2***,** *Length***) const void ****String1***, ****String2***; size_t** *Length***;**

void bzero (*String***,***Length***) char ****String***; int** *Length***;**

int ffs (*Index***) int** *Index***;**

int ffsl(*Index*) **longint***Index*;

int ffsll(*Index*)**longlongint***Index*;

Description

Note: The **bcopy** subroutine takes parameters backwards from the **strcpy** subroutine.

The **bcopy**, **bcmp**, and **bzero** subroutines operate on variable length strings of bytes. They do not check for null bytes as do the **string** routines.

The **bcopy** subroutine copies the value of the *Length* parameter in bytes from the string in the *Source* parameter to the string in the *Destination* parameter.

The **bcmp** subroutine compares the byte string in the *String1* parameter against the byte string of the *String2* parameter, returning a zero value if the two strings are identical and a nonzero value otherwise. Both strings are assumed to be *Length* bytes long.

The **bzero** subroutine zeroes out the string in the *String* parameter for the value of the *Length* parameter in bytes.

The **ffs** subroutine finds the first bit set in the *Index* parameter passed to it and returns the index of that bit. Bits are numbered starting at 1. A return value of 0 indicates that the value passed is 0. The least significant bit is position 1 and the most significant position is 32 or 64.

The **ffsl()** and **ffsll()** subroutines perform the same function as the **ffs** subroutine for arguments of different sizes.

beep Subroutine

Purpose

Sounds the audible alarm on the terminal.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

int beep(void);
```

Description

The **beep** subroutine alerts the user. It sounds the audible alarm on the terminal, or if that is not possible, it flashes the screen (visible bell). If neither signal is possible, nothing happens.

Return Values

The **beep** subroutine always returns OK.

Examples

To sound an audible alarm, enter:

```
beep();
```

bessel: j0, j1, jn, y0, y1, or yn Subroutine

Purpose

Computes Bessel functions.

Libraries

```
IEEE Math Library (libm.a)
or System V Math Library (libmsaa.a)
```

Syntax

```
#include <math.h>
```

```
double j0 (x)
double  x;
```

```
double j1 (x)
double x;
```

```
double jn (n, x)
int  n;
double x;
```

```
double y0 (x)
double x;
```

```
double y1 (x)
double x;
```

```
double yn (n, x)
int n;
double x;
```

Description

Bessel functions are used to compute wave variables, primarily in the field of communications.

The **j0** subroutine and **j1** subroutine return Bessel functions of *x* of the first kind, of orders 0 and 1, respectively. The **jn** subroutine returns the Bessel function of *x* of the first kind of order *n*.

The **y0** subroutine and **y1** subroutine return the Bessel functions of *x* of the second kind, of orders 0 and 1, respectively. The **yn** subroutine returns the Bessel function of *x* of the second kind of order *n*. The value of *x* must be positive.

Note: Compile any routine that uses subroutines from the **libm.a** library with the **-lm** flag. To compile the **j0.c** file, for example:

```
cc j0.c -lm
```

Parameters

Item	Description
x	Specifies some double-precision floating-point value.
n	Specifies some integer value.

Return Values

When using **libm.a** (**-lm**), if *x* is negative, **y0**, **y1**, and **yn** return the value NaNQ. If *x* is 0, **y0**, **y1**, and **yn** return the value **-HUGE_VAL**.

When using **libmsaa.a** (**-lmsaa**), values too large in magnitude cause the functions **j0**, **j1**, **y0**, and **y1** to return 0 and to set the **errno** global variable to ERANGE. In addition, a message indicating TLOSS error is printed on the standard error output.

Nonpositive values cause **y0**, **y1**, and **yn** to return the value **-HUGE** and to set the **errno** global variable to **EDOM**. In addition, a message indicating argument DOMAIN error is printed on the standard error output.

These error-handling procedures may be changed with the **matherr** subroutine when using **libmsaa.a** (**-lmsaa**).

bindprocessor Subroutine

Purpose

Binds kernel threads to a processor.

Library

Standard C library (**libc.a**)

Syntax

```
#include <sys/processor.h>

int bindprocessor ( What,  Who,  Where)
int What;
int Who;
cpu_t Where;
```

Description

The **bindprocessor** subroutine binds a single kernel thread, or all kernel threads in a process, to a processor, forcing the bound threads to be scheduled to run on that processor. It is important to understand that a process itself is not bound, but rather its kernel threads are bound. Once kernel threads are bound, they are always scheduled to run on the chosen processor, unless they are later unbound. When a new thread is created, it has the same bind properties as its creator. This applies to the initial thread in the new process created by the **fork** subroutine: the new thread inherits the bind properties of the thread which called **fork**. When the **exec** subroutine is called, thread properties are left unchanged.

The **bindprocessor** subroutine will fail if the target process has a *Resource Attachment*.

Programs that use processor bindings should become Dynamic Logical Partitioning (DLPAR) aware.

Parameters

Item	Description
What	Specifies whether a process or a thread is being bound to a processor. The *What* parameter can take one of the following values: **BINDPROCESS** A process is being bound to a processor. **BINDTHREAD** A thread is being bound to a processor.
Who	Indicates a process or thread identifier, as appropriate for the *What* parameter, specifying the process or thread which is to be bound to a processor.
Where	If the *Where* parameter is a bind CPU identifier, it specifies the processor to which the process or thread is to be bound. A value of **PROCESSOR_CLASS_ANY** unbinds the specified process or thread, which will then be able to run on any processor. The **sysconf** subroutine can be used to retrieve information about the number of online processors in the system.

Return Values

On successful completion, the **bindprocessor** subroutine returns 0. Otherwise, a value of -1 is returned, and the **errno** global variable is set to indicate the error.

Error Codes

The **bindprocessor** subroutine is unsuccessful if one of the following is true:

Item	Description
EINVAL	The *What* parameter is invalid, or the *Where* parameter indicates an invalid processor number or a processor class which is not currently available.
ESRCH	The specified process or thread does not exist.
EPERM	The caller does not have root user authority, and the *Who* parameter specifies either a process, or a thread belonging to a process, having a real or effective user ID different from that of the calling process. The target process has a *Resource Attachment*.

box Subroutine

Purpose

Draws borders from single-byte characters and renditions.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

int box(WINDOW  *win,
chtype  verch,
chtype  horch);
```

Description

The **box** subroutine draws a border around the edges of the specified window. This subroutine does not advance the cursor position. This subroutine does not perform special character processing or perform wrapping.

The **box** subroutine (**win*, *verch*, *horch*) has an effect equivalent to:

```
wborder(win, verch, verch, horch, horch, 0, 0, 0, 0);
```

Parameters

Item	Description
horch	Specifies the character to draw the horizontal lines of the box. The character must be a 1-column character.
verch	Specifies the character to draw the vertical lines of the box. The character must be a 1-column character.
**win*	Specifies the window to draw the box in or around.

Return Values

Upon successful completion, the **box** function returns OK. Otherwise, it returns ERR.

Examples

1. To draw a box around the user-defined window, `my_window`, using | (pipe) as the vertical character and - (minus sign) as the horizontal character, enter:

```
WINDOW *my_window;
box(my_window, '|', '-');
```

2. To draw a box around my_window using the default characters ACS_VLINE and ACS_HLINE, enter:

```
WINDOW *my_window;
box(my_window, 0, 0);
```

brk or sbrk Subroutine

Purpose

Changes data segment space allocation.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <unistd .h>
```

int brk (*EndDataSegment*)
char **EndDataSegment*;

void *sbrk (*Increment*)
intptr_t *Increment*;

Description

The **brk** and **sbrk** subroutines dynamically change the amount of space allocated for the data segment of the calling process. (For information about segments, see the **exec** subroutine. For information about the maximum amount of space that can be allocated, see the **ulimit** and **getrlimit** subroutines.)

The change is made by resetting the break value of the process, which determines the maximum space that can be allocated. The break value is the address of the first location beyond the current end of the data region. The amount of available space increases as the break value increases. The available space is initialized to a value of 0 at the time it is used. The break value can be automatically rounded up to a size appropriate for the memory management architecture.

The **brk** subroutine sets the break value to the value of the *EndDataSegment* parameter and changes the amount of available space accordingly.

The **sbrk** subroutine adds to the break value the number of bytes contained in the *Increment* parameter and changes the amount of available space accordingly. The *Increment* parameter can be a negative number, in which case the amount of available space is decreased.

Parameters

Item	Description
EndDataSegment	Specifies the effective address of the maximum available data.
Increment	Specifies any integer.

Return Values

Upon successful completion, the **brk** subroutine returns a value of 0, and the **sbrk** subroutine returns the old break value. If either subroutine is unsuccessful, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **brk** subroutine and the **sbrk** subroutine are unsuccessful and the allocated space remains unchanged if one or more of the following are true:

Item	Description
ENOMEM	The requested change allocates more space than is allowed by a system-imposed maximum. (For information on the system-imposed maximum on memory space, see the **ulimit** system call.)
ENOMEM	The requested change sets the break value to a value greater than or equal to the start address of any attached shared-memory segment. (For information on shared memory operations, see the **shmat** subroutine.)

bsearch Subroutine

Purpose

Performs a binary search.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdlib.h>
```

void *bsearch (*Key*, *Base*, *NumberOfElements*, *Size*, *ComparisonPointer*)

```
const void *Key;
const void *Base;
size_t NumberOfElements;
size_t Size;
int (*ComparisonPointer) (const void *, const void *);
```

Description

The **bsearch** subroutine is a binary search routine.

The **bsearch** subroutine searches an array of *NumberOfElements* objects, the initial member of which is pointed to by the *Base* parameter, for a member that matches the object pointed to by the *Key* parameter. The size of each member in the array is specified by the *Size* parameter.

The array must already be sorted in increasing order according to the provided comparison function *ComparisonPointer* parameter.

Parameters

Item	Description
Key	Points to the object to be sought in the array.

Item	Description
Base	Points to the element at the base of the table.
NumberOfElements	Specifies the number of elements in the array.
ComparisonPointer	Points to the comparison function, which is called with two arguments that point to the *Key* parameter object and to an array member, in that order.
Size	Specifies the size of each member in the array.

Return Values

If the *Key* parameter value is found in the table, the **bsearch** subroutine returns a pointer to the element found.

If the *Key* parameter value is not found in the table, the **bsearch** subroutine returns the null value. If two members compare as equal, the matching member is unspecified.

For the *ComparisonPointer* parameter, the comparison function compares its parameters and returns a value as follows:

- If the first parameter is less than the second parameter, the *ComparisonPointer* parameter returns a value less than 0.
- If the first parameter is equal to the second parameter, the *ComparisonPointer* parameter returns a value of 0.
- If the first parameter is greater than the second parameter, the *ComparisonPointer* parameter returns a value greater than 0.

The comparison function need not compare every byte, so arbitrary data can be contained in the elements in addition to the values being compared.

The *Key* and *Base* parameters should be of type pointer-to-element and cast to type pointer-to-character. Although declared as type pointer-to-character, the value returned should be cast into type pointer-to-element.

btowc Subroutine

Purpose

Single-byte to wide-character conversion.

Library

Standard Library (**libc.a**)

Syntax

```
#include <stdio.h>
#include <wchar.h>
```

```
wint_t btowc (intc);
```

Description

The *btowc* function determines whether c constitutes a valid (one-byte) character in the initial shift state.

The behavior of this function is affected by the LC_CTYPE category of the current locale.

Return Values

The btowc function returns WEOF if c has the value EOF or if (unsigned char) c does not constitute a valid (one-byte) character in the initial shift state. Otherwise, it returns the wide-character representation of that character.

buildproclist Subroutine

Purpose

Retrieves a list of process transaction records based on the criteria specified.

Library

The `libaacct.a` library.

Syntax

```
#define <sys/aacct.h>
int buildproclist(crit, crit_list, n_crit, p_list, sublist)
int crit;
union proc_crit *crit_list;
int n_crit;
struct aacct_tran_rec *p_list;
struct aacct_tran_rec **sublist;
```

Description

The `buildproclist` subroutine retrieves a subset of process transaction records from the master process transaction records that are given as input based on the selection criteria provided. This selection criteria can be one of the following values defined in `sys/aacct.h`:

- `CRIT_UID`
- `CRIT_GID`
- `CRIT_PROJ`
- `CRIT_CMD`

For example, if the criteria is specified as `CRIT_UID`, the list of process transaction records for specific user IDs will be retrieved. The list of user IDs are passed through the *crit_list* argument of type `union proc_crit`. Based on the specified criteria, the caller has to pass an array of user IDs, group IDs, project IDs or command names in this union.

Usually, the master list of transaction records is obtained by a prior call to the `getproclist` subroutine.

Parameters

Item	Description
crit	Integer value representing the selection criteria for the process records.
crit_list	Pointer to `union proc_crit` where the data for the selection criteria is passed.
n_crit	Number of elements to be considered for the selection, such as the number of user IDs.
p_list	Master list of process transaction records.
sublist	Pointer to the linked list of `aacct_tran_rec` structures, which hold the retrieved process transaction records.

Security

No restrictions. Any user can call this function.

Return Values

Item	Description
0	The call to the subroutine was successful.
-1	The call to the subroutine failed.

Error Codes

Item	Description
EINVAL	The passed pointer is NULL.
ENOMEM	Insufficient memory.
EPERM	Permission denied. Unable to read the data file.

buildtranlist or freetranlist Subroutine

Purpose

Read the advanced accounting records from the advanced accounting data file.

Library

The libaacct.a library.

Syntax

```
#define <sys/aacct.h>
buildtranlist(filename, trid[], ntrids, begin_time, end_time, tran_list)
char *filename;
unsigned int trid[];
unsigned int ntrids;
long long begin_time;
long long end_time;
struct aacct_tran_rec **tran_list;
freetranlist(tran_list)
struct aacct_tran_rec *tran_list;
```

Description

The buildtranlist subroutine retrieves the transaction records of the specified transaction type from the accounting data file. The required transaction IDs are passed as arguments, and these IDs are defined in sys/aacct.h. The list of transaction records are returned to the calling program through the *tran_list* pointer argument.

This API can be called multiple times with different accounting data file names to generate a consolidated list of transaction records from multiple data files. It appends the new file data to the end of the linked list pointed to by the *tran_list* argument. In addition, it internally sorts the transaction records based on the time of transaction so users can get a time-sorted list of transaction records from this routine. This subroutine can also be used to retrieve the intended transaction records for a particular interval of time by specifying the begin and end times of this interval as arguments.

The freetranlist subroutine frees the memory allocated to these transaction records. It can be used to deallocate memory that has been allocated to the transaction record lists created by routines such as buildtranlist, getproclist, getlparlist, and getarmlist.

Parameters

Item	Description
begin_time	Specifies the start timestamp for collecting records in a particular intervals. The input is in seconds since EPOCH. Specifying `-1` retrieves all the records.
end_time	Specifies the end timestamp for collecting records in a particular intervals. The input is in seconds since EPOCH. Specifying `-1` retrieves all the records.
filename	Name of the advanced accounting data file.
ntrids	Count of transaction IDs passed in the array *trid*.
tran_list	Pointer to the linked list of `aacct_tran_rec` structures that are to be returned to the caller or freed.
trid	An array of transaction record type identifiers.

Security

No restrictions. Any user can call this function.

Return Values

Item	Description
0	The call to the subroutine was successful.
-1	The call to the subroutine failed.

Error Codes

Item	Description
`EINVAL`	The passed pointer is NULL.
`ENOENT`	Specified data file does not exist.
`ENOMEM`	Insufficient memory.
`EPERM`	Permission denied. Unable to read the data file.

c

The following Base Operating System (BOS) runtime services begin with the letter *c*.

_check_lock Subroutine

Purpose

Conditionally updates a single word variable atomically.

Library

Standard C library (**libc.a**)

Syntax

```
#include <sys/atomic_op.h>
```

```
boolean_t _check_lock ( word_addr,  old_val,  new_val)
atomic_p word_addr;
int old_val;
int new_val;
```

Parameters

Item	Description
word_addr	Specifies the address of the single word variable.
old_val	Specifies the old value to be checked against the value of the single word variable.
new_val	Specifies the new value to be conditionally assigned to the single word variable.

Description

The **_check_lock** subroutine performs an atomic (uninterruptible) sequence of operations. The **compare_and_swap** subroutine is similar, but does not issue synchronization instructions and therefore is inappropriate for updating lock words.

Note: The word variable must be aligned on a full word boundary.

Return Values

Item	Description
FALSE	Indicates that the single word variable was equal to the old value and has been set to the new value.
TRUE	Indicates that the single word variable was not equal to the old value and has been left unchanged.

_clear_lock Subroutine

Purpose

Stores a value in a single word variable atomically.

Library

Standard C library (**libc.a**)

Syntax

```
#include <sys/atomic_op.h>

void _clear_lock ( word_addr,  value)
atomic_p word_addr;
int value
```

Parameters

Item	Description
word_addr	Specifies the address of the single word variable.
value	Specifies the value to store in the single word variable.

Description

The **_clear_lock** subroutine performs an atomic (uninterruptible) sequence of operations.

This subroutine has no return values.

Note: The word variable must be aligned on a full word boundary.

cabs, cabsf, or cabsl Subroutine

Purpose

Returns a complex absolute value.

Syntax

```
#include <complex.h>

double cabs (z)
double complex z;

float cabsf (z)
float complex z;

long double cabsl (z)
long double complex z;
```

Description

The **cabs**, **cabsf**, or **cabsl** subroutines compute the complex absolute value (also called norm, modulus, or magnitude) of the *z* parameter.

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

Returns the complex absolute value.

cacos, cacosf, or cacosl Subroutine

Purpose

Computes the complex arc cosine.

Syntax

```
#include <complex.h>

double complex cacos (z)
double complex z;

float complex cacosf (z)
float complex z;

long double complex cacosl (z)
long double complex z;
```

Description

The **cacos**, **cacosf**, or **cacosl** subroutine computes the complex arc cosine of *z*, with branch cuts outside the interval [–1, +1] along the real axis.

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

The **cacos**, **cacosf**, or **cacosl** subroutine returns the complex arc cosine value, in the range of a strip mathematically unbounded along the imaginary axis and in the interval [0, pi] along the real axis.

cacosh, cacoshf, or cacoshl Subroutines

Purpose

Computes the complex arc hyperbolic cosine.

Syntax

```
#include <complex.h>

double complex cacosh (z)
double complex z;

float complex cacoshf (z)
float complex z;

long double complex cacoshl (z)
long double complex z;
```

Description

The **cacosh**, **cacoshf**, or **cacoshl** subroutine computes the complex arc hyperbolic cosine of the *z* parameter, with a branch cut at values less than 1 along the real axis.

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

The **cacosh**, **cacoshf**, or **cacoshl** subroutine returns the complex arc hyperbolic cosine value, in the range of a half-strip of non-negative values along the real axis and in the interval [-*i* pi , +*i* pi] along the imaginary axis.

call_once Subroutine

Purpose

Runs the function that is specified by the *func* parameter only once, even if the function is called from several threads.

Library

Standard C library (**libc.a**)

Syntax

```
#include <threads.h>
void call_once (once_flag * flag void * func (void));
```

Description

The **call_once** subroutine uses the *once_flag* value specified by the **flag** parameter to ensure that the function specified by the **func** parameter is called exactly once when the **call_once** subroutine is called for the first time, with the value of the **flag** parameter.

An effective call to the **call_once** subroutine synchronizes all the subsequent calls to the **call_once** subroutine by using the same value of the **flag** parameter.

Parameters

Item	Description
flag	Specifies the value of the parameter to call the **call_once** subroutine and to synchronize all further calls with this flag.
func	Specifies the function that is called only once.

Return Values

No return value.

Files

The **threads.h** file defines standard macros, data types, and subroutines.

can_change_color, color_content, has_colors,init_color, init_pair, start_color or pair_content Subroutine

Purpose

Color manipulation functions and external variables for color support.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

bool can_change_color(void);

int color_content(short color,
short *red,
short *green,
short *blue);

int COLOR_PAIR(int n);

bool has_colors(void);

int init_color
(short color,
short red,
short green,
short blue);

int init_pair
(short pair,
short f,
short b);

int pair_content
(short pair,
short *f,
short *b);

int PAIR_NUMBER
(int value);
int start_color
(void);

extern int COLOR_PAIRS;
extern int COLORS;
```

Description

These functions manipulate color on terminals that support color.

Querying Capabilities

The **has_colors** subroutine indicates whether the terminal is a color terminal. The **can_change_color** subroutine indicates whether the terminal is a color terminal on which colors can be redefined.

Initialisation

The **start_color** subroutine must be called in order to enable use of colors and before any color manipulation function is called. This subroutine initializes eight basic colors (black, blue, green, cyan, red, magenta, yellow, and white) that can be specified by the color macros (such as **COLOR_BLACK**) defined in <**curses.h**>. The initial appearance of these eight colors is not specified.

The function also initialises two global external variables:

- **COLORS** defines the number of colors that the terminal supports. If **COLORS** is 0, the terminal does not support redefinition of colors (and **can_change_color** subroutine will return **FALSE**).
- **COLOR_PAIRS** defines the maximum number of color-pairs that the terminal supports.

Color Identification

The **init_color** subroutine redefines color number color, on terminals that support the redefinition of colors, to have the red, green, and blue intensity components specified by red, green, and blue, respectively. Calling **init_color** subroutine also changes all occurrences of the specified color on the screen to the new definition.

The **color_content** subroutine identifies the intensity components of color number color. It stores the red, green, and blue intensity components of this color in the addresses pointed to by red, green, and blue, respectively.

For both functions, the color argument must be in the range from **0** to and including **COLORS -1**. Valid intensity values range from **0** (no intensity component) up to and including **1000** (maximum intensity in that component).

User-Defined Color Pairs

Calling **init_pair** defines or redefines color-pair number pair to have foreground color f and background color b. Calling **init_pair** changes any characters that were displayed in the color pair's old definition to the new definition and refreshes the screen.

After defining the color pair, the macro **COLOR_PAIR**(n) returns the value of color pair n. This value is the color attribute as it would be extracted from a **chtype**. Conversely, the macro **PAIR_NUMBER**(value) returns the color pair number associated with the color attribute value.

The **pair_content** subroutine retrieves the component colors of a color-pair number pair. It stores the foreground and background color numbers in the variables pointed to by *f* and *b*, respectively.

With **init_pair** and **pair_content** subroutines, the value of pair must be in a range from **0** to and including **COLOR_PAIRS -1**. (There may be an implementation-specific upper limit on the valid value of pair, but any such limit is at least 63.) Valid values for *f* and *b* are the range from **0** to and including **COLORS -1**.

The **can_change_color** subroutine returns TRUE if the terminal supports colors and can change their definitions; otherwise, it returns FALSE.

Parameters

Item	Description
color	
**red*	
**green*	
**blue*	
pair	
f	
b	
value	

Return Values

The **has_colors** subroutine returns TRUE if the terminal can manipulate colors; otherwise, it returns FALSE.

Upon successful completion, the other functions return OK. Otherwise, they return ERR.

Examples

For the **can_change_color** subroutine:

To test whether or not a terminal can change its colors, enter the following and check the return for TRUE or FALSE:

```
can_change_color();
```

For the **color_content** subroutine:

To obtain the RGB component information for color 10 (assuming the terminal supports at least 11 colors), use:

```
short *r, *g, *b;
color_content(10,r,g,b);
```

For the **has_color** subroutine:

To determine whether or not a terminal supports color, use:

```
has_colors();
```

For the **pair_content** subroutine:

To obtain the foreground and background colors for color-pair 5, use:

```
short *f, *b;
pair_content(5,f,b);
```

For this subroutine to succeed, you must have already initialized the color pair. The foreground and background colors will be stored at the locations pointed to by *f* and *b*.

For the **start_color** subroutine:

To enable the color support for a terminal that supports color, use:

```
start_color();
```

For the **init_pair** subroutine:

To initialize the color definition for color-pair 2 to a black foreground (color 0) with a cyan background (color 3), use:

```
init_pair(2,COLOR_BLACK, COLOR_CYAN);
```

For the **init_color** subroutine:

To initialize the color definition for color 11 to violet on a terminal that supports at least 12 colors, use:

```
init_color(11,500,0,500);
```

carg, cargf, or cargl Subroutine

Purpose

Returns the complex argument value.

Syntax

```
#include <complex.h>

double carg (z)
double complex z;
```

```
float cargf (z)
float complex z;

long double cargl (z)
long double complex z;
```

Description

The **carg**, **cargf**, or **cargl** subroutine computes the argument (also called phase angle) of the *z* parameter, with a branch cut along the negative real axis.

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

The **carg**, **cargf**, or **cargl** subroutine returns the value of the argument in the interval [-pi , +pi].

casin, casinf, or casinl Subroutine

Purpose

Computes the complex arc sine.

Syntax

```
#include <complex.h>

double complex casin (z)
double complex z;

float complex casinf (z)
float complex z;

long double complex casinl (z)
long double complex z;
```

Description

The **casin**, **casinf**, or **casinl** subroutine computes the complex arc sine of the *z* parameter, with branch cuts outside the interval [–1, +1] along the real axis.

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

The **casin**, **casinf**, or **casinl** subroutine returns the complex arc sine value, in the range of a strip mathematically unbounded along the imaginary axis and in the interval [-pi/2, +pi/2] along the real axis.

casinh, casinfh, or casinlh Subroutine

Purpose

Computes the complex arc hyperbolic sine.

Syntax

```
#include <complex.h>

double complex casinh (z)
double complex z;

float complex casinhf (z)
float complex z;

long double complex casinhl (z)
long double complex z;
```

Description

The **casinh**, **casinfh**, and **casinlh** subroutines compute the complex arc hyperbolic sine of the *z* parameter, with branch cuts outside the interval [*-i, +i*] along the imaginary axis.

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

The **casinh**, **casinfh**, and **casinlh** subroutines return the complex arc hyperbolic sine value, in the range of a strip mathematically unbounded along the real axis and in the interval [*-i* pi/2, *+i* pi/2] along the imaginary axis.

catan, catanf, or catanl Subroutine

Purpose

Computes the complex arc tangent.

Syntax

```
#include <complex.h>

double complex catan (z)
double complex z;

float complex catanf (z)
float complex z;

long double complex catanl (z)
long double complex z;
```

Description

The **catan**, **catanf**, and **catanl** subroutines compute the complex arc tangent of *z*, with branch cuts outside the interval [*-i*, *+i*] along the imaginary axis.

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

The **catan**, **catanf**, and **catanl** subroutines return the complex arc tangent value, in the range of a strip mathematically unbounded along the imaginary axis and in the interval [-pi/2, +pi/2] along the real axis.

catanh, catanhf, or catanhl Subroutine

Purpose

Computes the complex arc hyperbolic tangent.

Syntax

```
#include <complex.h>

double complex catanh (z)
double complex z;

float complex catanhf (z)
float complex z;

long double complex catanhl (z)
long double complex z;
```

Description

The **catanh**, **catanhf**, and **catanhl** subroutines compute the complex arc hyperbolic tangent of *z*, with branch cuts outside the interval [-1, +1] along the real axis.

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

The **catanh**, **catanhf**, and **catanhl** subroutines return the complex arc hyperbolic tangent value, in the range of a strip mathematically unbounded along the real axis and in the interval [-*i* pi/2, +*i* pi/2] along the imaginary axis.

catclose Subroutine

Purpose

Closes a specified message catalog.

Library

Standard C Library (**libc.a**)

Syntax

#include <nl_types.h>

```
int catclose ( CatalogDescriptor)
nl_catd CatalogDescriptor;
```

Description

The **catclose** subroutine closes a specified message catalog. If your program accesses several message catalogs and you reach the maximum number of opened catalogs (specified by the **NL_MAXOPEN** constant), you must close some catalogs before opening additional ones. If you use a file descriptor to implement the **nl_catd** data type, the **catclose** subroutine closes that file descriptor.

The **catclose** subroutine closes a message catalog only when the number of calls it receives matches the total number of calls to the **catopen** subroutine in an application. All message buffer pointers obtained by prior calls to the **catgets** subroutine are not valid when the message catalog is closed.

Parameters

Item	Description
CatalogDescriptor	Points to the message catalog returned from a call to the **catopen** subroutine.

Return Values

The **catclose** subroutine returns a value of 0 if it closes the catalog successfully, or if the number of calls it receives is fewer than the number of calls to the **catopen** subroutine.

The **catclose** subroutine returns a value of -1 if it does not succeed in closing the catalog. The **catclose** subroutine is unsuccessful if the number of calls it receives is greater than the number of calls to the **catopen** subroutine, or if the value of the *CatalogDescriptor* parameter is not valid.

catgets Subroutine

Purpose

Retrieves a message from a catalog.

Library

Standard C Library (**libc.a**)

Syntax

#include <nl_types>

```
char *catgets (CatalogDescriptor, SetNumber, MessageNumber, String)
nl_catd  CatalogDescriptor;
int  SetNumber,  MessageNumber;
const char * String;
```

Description

The **catgets** subroutine retrieves a message from a catalog after a successful call to the **catopen** subroutine. If the **catgets** subroutine finds the specified message, it loads it into an internal character string buffer, ends the message string with a null character, and returns a pointer to the buffer.

The **catgets** subroutine uses the returned pointer to reference the buffer and display the message. However, the buffer can not be referenced after the catalog is closed.

Parameters

Item	Description
CatalogDescriptor	Specifies a catalog description that is returned by the **catopen** subroutine.
SetNumber	Specifies the set ID.
MessageNumber	Specifies the message ID. The *SetNumber* and *MessageNumber* parameters specify a particular message to retrieve in the catalog.
String	Specifies the default character-string buffer.

Return Values

If the **catgets** subroutine is unsuccessful for any reason, it returns the user-supplied default message string specified by the *String* parameter.

catopen Subroutine

Purpose

Opens a specified message catalog.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <nl_types.h>

nl_catd catopen ( CatalogName,  Parameter)
const char *CatalogName;
int Parameter;
```

Description

The **catopen** subroutine opens a specified message catalog and returns a catalog descriptor used to retrieve messages from the catalog. The contents of the catalog descriptor are complete when the **catgets** subroutine accesses the message catalog. The **nl_catd** data type is used for catalog descriptors and is defined in the **nl_types.h** file.

If the catalog file name referred to by the *CatalogName* parameter contains a leading / (slash), it is assumed to be an absolute path name. If the catalog file name is not an absolute path name, the user environment determines which directory paths to search. The **NLSPATH** environment variable defines the directory search path. When this variable is used, the **setlocale** subroutine must be called before the **catopen** subroutine.

A message catalog descriptor remains valid in a process until that process or a successful call to one of the **exec** functions closes it.

You can use two special variables, **%N** and **%L**, in the **NLSPATH** environment variable. The **%N** variable is replaced by the catalog name referred to by the call that opens the message catalog. The **%L** variable is replaced by the value of the **LC_MESSAGES** category.

The value of the **LC_MESSAGES** category can be set by specifying values for the **LANG**, **LC_ALL**, or **LC_MESSAGES** environment variable. The value of the **LC_MESSAGES** category indicates which locale-specific directory to search for message catalogs. For example, if the **catopen** subroutine specifies a catalog with the name `mycmd`, and the environment variables are set as follows:

```
NLSPATH=../%N:./%N:/system/nls/%L/%N:/system/nls/%N LANG=fr_FR
```

then the application searches for the catalog in the following order:

```
../mycmd
./mycmd
/system/nls/fr_FR/mycmd
/system/nls/mycmd
```

If you omit the **%N** variable in a directory specification within the **NLSPATH** environment variable, the application assumes that it defines a catalog name and opens it as such and will not traverse the rest of the search path.

If the **NLSPATH** environment variable is not defined, the **catopen** subroutine uses the default path. See the **/etc/environment** file for the **NLSPATH** default path. If the **LC_MESSAGES** category is set to the default value C, and the **LC__FASTMSG** environment variable is set to `true`, then subsequent calls to the **catgets** subroutine generate pointers to the program-supplied default text.

The **catopen** subroutine treats the first file it finds as a message file. If you specify a non-message file in a **NLSPATH**, for example, **/usr/bin/ls**, **catopen** treats **/usr/bin/ls** as a message catalog. Thus no messages are found and default messages are returned. If you specify **/tmp** in a **NLSPATH**, /**tmp** is opened and searched for messages and default messages are displayed.

Parameters

Item	Description
CatalogName	Specifies the catalog file to open.
Parameter	Determines the environment variable to use in locating the message catalog. If the value of the *Parameter* parameter is 0, use the **LANG** environment variable without regard to the **LC_MESSAGES** category to locate the catalog. If the value of the *Parameter* parameter is the **NL_CAT_LOCALE** macro, use the **LC_MESSAGES** category to locate the catalog.

Return Values

The **catopen** subroutine returns a catalog descriptor. If the **LC_MESSAGES** category is set to the default value C, and the **LC__FASTMSG** environment variable is set to `true`, the **catopen** subroutine returns a value of -1.

If the **LC_MESSAGES** category is not set to the default value C but the **catopen** subroutine returns a value of -1, an error has occurred during creation of the structure of the **nl_catd** data type or the catalog name referred to by the *CatalogName* parameter does not exist.

cbreak, nocbreak, noraw, or raw Subroutine

Purpose

Puts the terminal into or out of CBREAK mode.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
int cbreak(void);
```

```
int nocbreak(void);
```

```
int noraw(void);
```

```
int raw(void);
```

Description

The **cbreak** subroutine sets the input mode for the current terminal to cbreak mode and overrides a call to the **raw** subroutine.

The **nocbreak** subroutine sets the input mode for the current terminal to Cooked Mode without changing the state of the **ISIG** and **IXON** flags.

The **noraw** subroutine sets the input mode for the current terminal to Cooked Mode and sets the **ISIG** and **IXON** flags.

The **raw** subroutine sets the input mode for the current terminal to Raw Mode.

Return Values

Upon successful completion, these subroutines return OK. Otherwise, they return ERR.

Examples

For the **cbreak** and **nocbreak** subroutines:

1. To put the terminal into CBREAK mode, enter:

   ```
   cbreak();
   ```

2. To take the terminal out of CBREAK mode, enter:

   ```
   nocbreak();
   ```

3. To place the terminal into raw mode, use:

   ```
   raw();
   ```

4. To place the terminal out of raw mode, use:

   ```
   noraw();
   ```

For the **noraw** and **raw** subroutines:

1. To place the terminal into raw mode, use:

   ```
   raw();
   ```

2. To place the terminal out of raw mode, use:

   ```
   noraw();
   ```

cbrtf, cbrtl, cbrt, cbrtd32, cbrtd64, and cbrtd128 Subroutines

Purpose

Computes the cube root.

Syntax

```
#include <math.h>

float cbrtf (x)
float x;

long double cbrtl (x)
long double x;

double cbrt (x)
double x;
_Decimal32 cbrtd32 (x)
_Decimal32 x;

_Decimal64 cbrtd64 (x)
_Decimal64 x;
_Decimal128 cbrtd128 (x)
_Decimal128 x;
```

Description

The **cbrtf**, **cbrtl**, **cbrt**, **cbrtd32**, **cbrtd64**, and **cbrtd128** subroutines compute the real cube root of the *x* argument.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **cbrtf**, **cbrtl**, **cbrt**, **cbrtd32**, **cbrtd64**, and **cbrtd128** subroutines return the cube root of *x*.

If *x* is NaN, an NaN is returned.

If *x* is ±0 or ±Inf, *x* is returned.

ccos, ccosf, or ccosl Subroutine

Purpose

Computes the complex cosine.

Syntax

```
#include <complex.h>

double complex ccos (z)
double complex z;

float complex ccosf (z)
float complex z;
```

```
long double complex ccosl (z)
long double complex z;
```

Description

The **ccos**, **ccosf**, and **ccosl** subroutines compute the complex cosine of *z*.

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

The **ccos**, **ccosf**, and **ccosl** subroutines return the complex cosine value.

ccosh, ccoshf, or ccoshl Subroutine

Purpose

Computes the complex hyperbolic cosine.

Syntax

```
#include <complex.h>

double complex ccosh (z)
double complex z;

float complex ccoshf (z)
float complex z;

long double complex ccoshl (z)
long double complex z;
```

Description

The **ccosh**, **ccoshf**, and **ccoshl** subroutines compute the complex hyperbolic cosine of *z*.

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

The **ccosh**, **ccoshf**, and **ccoshl** subroutines return the complex hyperbolic cosine value.

ccsidtocs or cstoccsid Subroutine

Purpose

Provides conversion between coded character set IDs (CCSID) and code set names.

Library

The iconv Library (**libiconv.a**)

Syntax

```
#include <iconv.h>

CCSID cstoccsid (* Codeset)
const char *Codeset;

char *ccsidtocs ( CCSID)
CCSID CCSID;
```

Description

The **cstoccsid** subroutine returns the CCSID of the code set specified by the *Codeset* parameter. The **ccsidtocs** subroutine returns the code set name of the CCSID specified by *CCSID* parameter. CCSIDs are registered IBM coded character set IDs.

Parameters

Item	Description
Codeset	Specifies the code set name to be converted to its corresponding CCSID.
CCSID	Specifies the CCSID to be converted to its corresponding code set name.

Return Values

If the code set is recognized by the system, the **cstoccsid** subroutine returns the corresponding CCSID. Otherwise, null is returned.

If the CCSID is recognized by the system, the **ccsidtocs** subroutine returns the corresponding code set name. Otherwise, a null pointer is returned.

ceil, ceilf, ceill, ceild32, ceild64, and ceild128 Subroutines

Purpose

Compute the ceiling value.

Syntax

```
#include <math.h>

float ceilf (x)
float x;

long double ceill (x)
long double x;

double ceil (x)
double x;

_Decimal32 ceild32(x)
_Decimal32 x;

_Decimal64 ceild64(x)
_Decimal64 x;

_Decimal128 ceild128(x)
_Decimal128 x;
```

Description

The **ceilf**, **ceill**, **ceil**, **ceild32**, **ceild64**, and **ceild128** subroutines compute the smallest integral value that is not less than *x*.

An application wishing to check for error situations should set the **errno** global variable to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these functions. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the smallest integral value to be computed.

Return Values

Upon successful completion, the **ceilf**, **ceill** , **ceil**, **ceild32**, **ceild64**, and **ceild128** subroutines return the smallest integral value that is not less than *x*, expressed as a type **float**, **long double**, **double**, **_Decimal32**, **_Decimal64**, or **_Decimal128** respectively.

If *x* is NaN, a NaN is returned.

If *x* is ±0 or ±Inf, *x* is returned.

If the correct value would cause overflow, a range error occurs and the **ceilf**, **ceill**, **ceil**, **ceild32**, **ceild64**, and **ceild128** subroutines return the value of the macro **HUGE_VALF**, **HUGE_VALL**, **HUGE_VAL**, **HUGE_VAL_D32**, **HUGE_VAL_D64**, and **HUGE_VAL_D128** respectively.

cexp, cexpf, or cexpl Subroutine

Purpose

Performs complex exponential computations.

Syntax

```
#include <complex.h>

double complex cexp (z)
double complex z;

float complex cexpf (z)
float complex z;

long double complex cexpl (z)
long double complex z;
```

Description

The **cexp**, **cexpf**, and **cexpl** subroutines compute the complex exponent of *z*, defined as e^z .

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

The **cexp**, **cexpf**, and **cexpl** subroutines return the complex exponential value of *z*.

cfgetospeed, cfsetospeed, cfgetispeed, or cfsetispeed Subroutine

Purpose

Gets and sets input and output baud rates.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <termios.h>
```

```
speed_t cfgetospeed ( TermiosPointer)
const struct termios *TermiosPointer;
```

```
int cfsetospeed (TermiosPointer,  Speed)
struct termios *TermiosPointer;
speed_t Speed;
```

```
speed_t cfgetispeed (TermiosPointer)
const struct termios *TermiosPointer;
```

```
int cfsetispeed (TermiosPointer, Speed)
struct termios *TermiosPointer;
speed_t Speed;
```

Description

The baud rate subroutines are provided for getting and setting the values of the input and output baud rates in the **termios** structure. The effects on the terminal device described below do not become effective and not all errors are detected until the **tcsetattr** function is successfully called.

The input and output baud rates are stored in the **termios** structure. The supported values for the baud rates are shown in the table that follows this discussion.

The **termios.h** file defines the type **speed_t** as an unsigned integral type.

The **cfgetospeed** subroutine returns the output baud rate stored in the **termios** structure pointed to by the *TermiosPointer* parameter.

The **cfsetospeed** subroutine sets the output baud rate stored in the **termios** structure pointed to by the *TermiosPointer* parameter to the value specified by the *Speed* parameter.

The **cfgetispeed** subroutine returns the input baud rate stored in the **termios** structure pointed to by the *TermiosPointer* parameter.

The **cfsetispeed** subroutine sets the input baud rate stored in the **termios** structure pointed to by the *TermiosPointer* parameter to the value specified by the *Speed* parameter.

Certain values for speeds have special meanings when set in the **termios** structure and passed to the **tcsetattr** function. These values are discussed in the **tcsetattr** subroutine**.**

The following table lists possible baud rates:

Baud Rate Values	
Name	**Description**
B0	Hang up
B5	50 baud
B75	75 baud
B110	110 baud
B134	134 baud
B150	150 baud
B200	200 baud
B300	300 baud
B600	600 baud
B1200	1200 baud
B1800	1800 baud
B2400	2400 baud
B4800	4800 baud
B9600	9600 baud
B19200	19200 baud
B38400	38400 baud

The **termios.h** file defines the name symbols of the table.

Parameters

Item	Description
TermiosPointer	Points to a **termios** structure.
Speed	Specifies the baud rate.

Return Values

The **cfgetospeed** and **cfgetispeed** subroutines return exactly the value found in the **termios** data structure, without interpretation.

Both the **cfsetospeed** and **cfsetispeed** subroutines return a value of 0 if successful and -1 if unsuccessful.

Examples

To set the output baud rate to 0 (which forces modem control lines to stop being asserted), enter:

```
cfsetospeed (&my_termios, B0);
tcsetattr (stdout, TCSADRAIN, &my_termios);
```

chacl or fchacl Subroutine

Purpose

Changes the AIXC ACL type access control information of a file.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/acl.h>
#include <sys/mode.h>
```

```
int chacl ( Path,  ACL,  ACLSize)
char *Path;
struct acl *ACL;
int ACLSize;
```

```
int fchacl ( FileDescriptor, ACL, ACLSize)
int FileDescriptor;
struct acl *ACL;
int ACLSize;
```

Description

The **chacl** and **fchacl** subroutines set the access control attributes of a file according to the AIXC ACL Access Control List (ACL) structure pointed to by the *ACL* parameter. Note that these routines could fail if the current ACL associated with the file system object is of a different type or if the underlying physical file system does not support AIXC ACL type. It is strongly recommended that applications stop using these interfaces and instead make use of **aclx_get** /**aclx_fget** and **aclx_put**/**aclx_fput** subroutines to change the ACL.

Parameters

Item	Description
Path	Specifies the path name of the file.

Item	Description
ACL	Specifies the AIXC ACL to be established on the file. The format of an AIXC ACL is defined in the **sys/acl.h** file and contains the following members: **acl_len** Specifies the size of the ACL (Access Control List) in bytes, including the base entries. **Note:** The entire ACL for a file cannot exceed one memory page (4096 bytes). **acl_mode** Specifies the file mode. The following bits in the **acl_mode** member are defined in the **sys/mode.h** file and are significant for this subroutine: **S_ISUID** Enables the **setuid** attribute on an executable file. **S_ISGID** Enables the **setgid** attribute on an executable file. Enables the group-inheritance attribute on a directory. **S_ISVTX** Enables linking restrictions on a directory. **S_IXACL** Enables extended ACL entry processing. If this attribute is not set, only the base entries (owner, group, and default) are used for access authorization checks. Other bits in the mode, including the following, are ignored: **u_access** Specifies access permissions for the file owner. **g_access** Specifies access permissions for the file group. **o_access** Specifies access permissions for the default class of *others*. **acl_ext[]** Specifies an array of the extended entries for this access control list. The members for the base ACL (owner, group, and others) can contain the following bits, which are defined in the **sys/access.h** file: **R_ACC** Allows read permission. **W_ACC** Allows write permission. **X_ACC** Allows execute or search permission.
FileDescriptor	Specifies the file descriptor of an open file.
ACLSize	Specifies the size of the buffer containing the ACL.

Note: The **chacl** subroutine requires the *Path*, *ACL*, and *ACLSize* parameters. The **fchacl** subroutine requires the *FileDescriptor*, *ACL*, and *ACLSize* parameters.

ACL Data Structure for chacl

Each access control list structure consists of one **struct acl** structure containing one or more **struct acl_entry** structures with one or more **struct** *ace_id* structures.

If the **struct ace_id** structure has *id_type* set to **ACEID_USER** or **ACEID_GROUP**, there is only one *id_data* element. To add multiple IDs to an ACL you must specify multiple **struct ace_id** structures when *id_type* is set to **ACEID_USER** or **ACEID_GROUP**. In this case, no error is returned for the multiple elements, and the access checking examines only the first element. Specifically, the errno value **EINVAL** is not returned for *acl_len* being incorrect in the ACL structure although more than one uid or gid is specified.

Return Values

Upon successful completion, the **chacl** and **fchacl** subroutines return a value of 0. If the **chacl** or **fchacl** subroutine fails, a value of -1 is returned, and the **errno** global variable is set to indicate the error.

Error Codes

The **chacl** subroutine fails and the access control information for a file remains unchanged if one or more of the following are true:

Item	Description
ENOTDIR	A component of the *Path* prefix is not a directory.
ENOENT	A component of the *Path* does not exist or has the disallow truncation attribute (see the **ulimit** subroutine).
ENOENT	The *Path* parameter was null.
EACCES	Search permission is denied on a component of the *Path* prefix.
EFAULT	The *Path* parameter points to a location outside of the allocated address space of the process.
ESTALE	The process' root or current directory is located in a virtual file system that has been unmounted.
ELOOP	Too many symbolic links were encountered in translating the *Path* parameter.
ENOENT	A symbolic link was named, but the file to which it refers does not exist.
ENAMETOOLONG	A component of the *Path* parameter exceeded 255 characters, or the entire *Path* parameter exceeded 1023 characters.

The **chacl** or **fchacl** subroutine fails and the access control information for a file remains unchanged if one or more of the following are true:

Item	Description
EROFS	The file specified by the *Path* parameter resides on a read-only file system.
EFAULT	The *ACL* parameter points to a location outside of the allocated address space of the process.
EINVAL	The *ACL* parameter does not point to a valid ACL.
EINVAL	The `acl_len` member in the ACL is not valid.
EIO	An I/O error occurred during the operation.
ENOSPC	The size of the *ACL* parameter exceeds the system limit of one memory page (4KB).
EPERM	The effective user ID does not match the ID of the owner of the file, and the invoker does not have root user authority.

The **fchacl** subroutine fails and the file permissions remain unchanged if the following is true:

Item	Description
EBADF	The file descriptor *FileDescriptor* is not valid.

If Network File System (NFS) is installed on your system, the **chacl** and **fchacl** subroutines can also fail if the following is true:

Item	Description
ETIMEDOUT	The connection timed out.

Security

Access Control: The invoker must have search permission for all components of the *Path* prefix.

Auditing Events:

Event	Information
chacl	*Path*
fchacl	*FileDescriptor*

chdir Subroutine

Purpose

Changes the current directory.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <unistd.h>

int chdir ( Path)
const char *Path;
```

Description

The **chdir** subroutine changes the current directory to the directory indicated by the *Path* parameter.

Parameters

Item	Description
Path	A pointer to the path name of the directory. If the *Path* parameter refers to a symbolic link, the **chdir** subroutine sets the current directory to the directory pointed to by the symbolic link. If Network File System (NFS) is installed on the system, this path can cross into another node.

The current directory, also called the current working directory, is the starting point of searches for path names that do not begin with a / (slash). The calling process must have search access to the directory specified by the *Path* parameter.

Return Values

Upon successful completion, the **chdir** subroutine returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to identify the error.

Error Codes

The **chdir** subroutine fails and the current directory remains unchanged if one or more of the following are true:

Item	Description
EACCES	Search access is denied for the named directory.
ENOENT	The named directory does not exist.
ENOTDIR	The path name is not a directory.

The **chdir** subroutine can also be unsuccessful for other reasons. See *Base Operating System error codes for services* that require path-name resolution for a list of additional error codes.

If NFS is installed on the system, the **chdir** subroutine can also fail if the following is true:

Item	Description
ETIMEDOUT	The connection timed out.

checkauths Subroutine

Purpose

Compares the passed-in list of authorizations to the authorizations associated with the current process.

Library

Security Library (**libc.a**)

Syntax

```
# include <usersec.h>

int checkauths(CommaListOfAuths, Flag)
    char *CommaListOfAuths;
    int Flag;
```

Description

The **checkauths** subroutine compares a comma-separated list of authorizations specified in the *CommaListOfAuths* parameter with the authorizations associated with the calling process. The *Flag* parameter specifies the type of checks the subroutine performs. If the *Flag* parameter specifies the **CHECK_ANY** value, and the calling process contains any of the authorizations specified in the *CommaListOfAuths* parameter, the subroutine returns the value of zero. If the *Flag* parameter specifies the **CHECK_ALL** value, and the calling process contains all of the authorizations that are specified in the *CommaListOfAuths* parameter, the subroutine returns the value of zero.

You can use the **checkauths** subroutine for both Enhanced and Legacy RBAC modes. The set of authorizations that are available to a process depends on the mode that the system is operating in. In Enhanced RBAC Mode, the set of authorizations comes from the current active role set of the process, while in Legacy RBAC Mode, the set of authorizations comes from all of the roles associated with the process owner.

Parameters

Item	Description
CommaListOfAuths	Specifies one or more authorizations. The authorizations are separated by commas.
Flag	Specifies an integer value that controls the type of checking for the subroutine to perform. The *Flag* parameter contains the following possible values: **CHECK_ANY** Returns **0** if the process has any of the authorizations that the *CommaListOfAuths* parameter specifies. **CHECK_ALL** Returns **0** if the process has all of the authorizations that the *CommaListOfAuths* parameter specifies.

Return Values

If the process matches the required set of authorizations, the **checkauths** subroutine returns the value of zero. Otherwise, a value of -1 is returned and the **errno** value is set to indicate the error.

Error Codes

If the **checkauths** subroutine returns -1, one of the following **errno** values can be set:

Item	Description
EINVAL	The *CommaListOfAuths* parameter is NULL or the NULL string.
EINVAL	The *Flag* parameter contains an unrecognized flag.
ENOMEM	Memory cannot be allocated.

chmod, fchmod, or fchmodat Subroutine

Purpose

Changes file system object base file mode bits.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/stat.h>
```

```
int chmod (Path,  Mode)
const char *Path;
mode_t Mode;
```

```
int fchmod (FileDescriptor, Mode)
int FileDescriptor;
mode_t Mode;
```

```
int fchmodat (DirFileDescriptor, Path, Mode, Flag)
int DirFileDescriptor;
const char *Path;
mode_t Mode;
int  Flag;
```

Description

The **chmod** subroutine sets the access permissions of the file specified by the *Path* parameter. If Network File System (NFS) is installed on your system, this path can cross into another node.

Use the **fchmod** subroutine to set the access permissions of an open file pointed to by the *FileDescriptor* parameter.

If *FileDescriptor* references a shared memory object, the **fchmod** subroutine affects the **S_IRUSR**, **S_IWUSR**, **S_IRGRP**, **S_IWGRP**, **S_IROTH**, and **S_IWOTH** file permission bits.

The access control information is set according to the *Mode* parameter. Note that these routines will replace any existing ACL associated with the file system object.

The **fchmodat** subroutine is equivalent to the **chmod** subroutine if the *Path* parameter specifies an absolute path or if the *DirFileDescriptor* parameter is set to **AT_FDCWD**. The file to be changed is determined by the relative path to the directory that is associated with the *DirFileDescriptor* parameter instead of the current working directory. If the directory is opened without the **O_SEARCH** open flag, the subroutine checks to determine whether directory searches are permitted by using the current permissions of the directory. If the directory is opened with the **O_SEARCH** open flag, the subroutine does not perform the check.

Parameters

Item	Description
FileDescriptor	Specifies the file descriptor of an open file or shared memory object.

Item	Description
Mode	Specifies the bit pattern that determines the access permissions. The *Mode* parameter is constructed by logically ORing one or more of the following values, which are defined in the **sys/mode.h** file: **S_ISUID** Enables the **setuid** attribute for an executable file. A process executing this program acquires the access rights of the owner of the file. **S_ISGID** Enables the **setgid** attribute for an executable file. A process executing this program acquires the access rights of the group of the file. Also, enables the group-inheritance attribute for a directory. Files created in this directory have a group equal to the group of the directory. The following attributes apply only to files that are directly executable. They have no meaning when applied to executable text files such as shell scripts and **awk** scripts. **S_ISVTX** Enables the **link/unlink** attribute for a directory. Files cannot be linked to in this directory. Files can only be unlinked if the requesting process has write permission for the directory and is either the owner of the file or the directory. **S_ISVTX** Enables the **save text** attribute for an executable file. The program is not unmapped after usage. This attribute can only be enabled by the root user. When specified by anyone else, this attribute is ignored. **S_ENFMT** Enables enforcement-mode record locking for a regular file. File locks requested with the **lockf** subroutine are enforced. **S_IRUSR** Permits the file's owner to read it. **S_IWUSR** Permits the file's owner to write to it. **S_IXUSR** Permits the file's owner to execute it (or to search the directory). **S_IRGRP** Permits the file's group to read it. **S_IWGRP** Permits the file's group to write to it. **S_IXGRP** Permits the file's group to execute it (or to search the directory). **S_IROTH** Permits others to read the file. **S_IWOTH** Permits others to write to the file. **S_IXOTH** Permits others to execute the file (or to search the directory). Other mode values exist that can be set with the **mknod** subroutine but not with the **chmod** subroutine.
Path	Specifies the path name of the file. For **fchmodat**, if the *DirFileDescriptor* is specified and Path is relative, then the *DirFileDescriptor* specifies the effective current working directory for the *Path*.

Item	Description
DirFileDescriptor	Specifies the file descriptor of an open directory, which is used as the effective current working directory for the *Path* parameter. If *DirFileDescriptor* equals **AT_FDCWD**, the *DirFileDescriptor* parameter is ignored and the *Path* argument specifies the complete file.
Flag	Specifies a bit field argument. If the *Flag* parameter contains the **AT_SYMLINK_NOFOLLOW** bit and the *Path* parameter specifies a symbolic link, the mode of the symbolic link is changed.

Return Values

Upon successful completion, the **chmod**, **fchmod**, and **fchmodat** subroutines return a value of 0. If the **chmod**, **fchmod**, or **fchmodat** subroutine is unsuccessful, a value of -1 is returned, and the **errno** global variable is set to identify the error.

Error Codes

The **chmod** or **fchmodat** subroutine is unsuccessful and the file permissions remain unchanged if one of the following is true:

Item	Description
ENOTDIR	A component of the *Path* prefix is not a directory.
EACCES	Search permission is denied on a component of the *Path* prefix.
EFAULT	The *Path* parameter points to a location outside of the allocated address space of the process.
ELOOP	Too many symbolic links were encountered in translating the *Path* parameter.
ENOENT	The named file does not exist.
ENAMETOOLONG	A component of the *Path* parameter exceeded 255 characters, or the entire *Path* parameter exceeded 1023 characters.

The **fchmod** subroutine is unsuccessful and the file permissions remain unchanged if the following is true:

Item	Description
EBADF	The value of the *FileDescriptor* parameter is not valid.

The **chmod**, **fchmod** or **fchmodat** subroutine is unsuccessful and the access control information for a file remains unchanged if one of the following is true:

Item	Description
EPERM	The effective user ID does not match the owner of the file, and the process does not have appropriate privileges.
EROFS	The named file resides on a read-only file system.
EIO	An I/O error occurred during the operation.

If NFS is installed on your system, the **chmod** and **fchmod** subroutines can also be unsuccessful if the following is true:

Item	Description
ESTALE	The root or current directory of the process is located in a virtual file system that has been unmounted.
ETIMEDOUT	The connection timed out.

The **fchmodat** subroutine is unsuccessful and the file permissions remain unchanged if one of the following is true:

Item	Description
EBADF	The *Path* parameter does not specify an absolute path and the *DirFileDescriptor* argument is neither **AT_FDCWD** nor a valid file descriptor.
EINVAL	The value of the *Flag* argument is not valid.
ENOTDIR	The *Path* parameter is not an absolute path and *DirFileDescriptor* is a file descriptor but is not associated with a directory.

Security

Access Control: The invoker must have search permission for all components of the *Path* prefix.

If you receive the **EBUSY** error, toggle the **enforced locking** attribute in the *Mode* parameter and retry your operation. The **enforced locking** attribute should never be used on a file that is part of the Trusted Computing Base.

chown, fchown, lchown, chownx, fchownx, chownxat, or fchownat Subroutine

Purpose

Changes file ownership.

Library

Standard C Library (**libc.a**)

Syntax

#include <sys/types.h> #include <unistd.h>

int chown (*Path*, *Owner*, *Group* **) const char ***Path**; uid_t** *Owner***; gid_t** *Group***;**

int fchown (*FileDescriptor*, *Owner*, Group **)**

int *FileDescriptor***; uid_t** *Owner***; gid_t** *Group***;**

int lchown (*Path*, *Owner*, *Group* **)**

const char **fname* **uid_t** *uid* **gid_t***gid*

#include <sys/types.h>

#include <sys/chownx.h>

int chownx (*Path*, *Owner*, *Group*, *Flags* **)**

char ***Path; uid_t** *Owner***; gid_t** *Group***; int** *Flags***;**

int fchownx (*FileDescriptor*, *Owner*, *Group*, *Flags* **)**

int *FileDescriptor*; **uid_t** *Owner*; **gid_t** *Group*; **int** *Flags*;

int chownxat (*DirFileDescriptor*, *Path*, *Owner*, Group, *Flags*)

int *DirFileDescriptor*;

char * *Path*;

uid_t *Owner*;

gid_t *Group*;

int *Flags*;

int fchownat (*DirFileDescriptor*, *Path*, *Owner*, Group, *Flag*)

int *DirFileDescriptor*;

char*Path*;

uid_t *Owner*;

gid_t *Group*;

int *Flag;*

Description

The **chown**, **chownx**, **fchown**, **fchownx**, **chownxat**, **fchownat**, and **lchown** subroutines set the file owner and group IDs of the specified file system object. Root user authority is required to change the owner of a file.

A function **lchown** function sets the owner ID and group ID of the named file similarity to **chown** function except in the case where the named file is a symbolic link. In this case **lchown** function changes the ownership of the symbolic link file itself, while **chown** function changes the ownership of the file or directory to which the symbolic link refers.

The **chownxat** subroutine is equivalent to the **chownx** subroutine and the **fchownat** subroutine is equivalent to the **chown** or the **lchown** subroutine if the *Path* parameter specifies an absolute path or if the *DirFileDescriptor* parameter is set to **AT_FDCWD**. The file to be changed is determined by the relative path to the directory that is associated with the *DirFileDescriptor* parameter instead of the current working directory. If the directory is opened without the **O_SEARCH** open flag, the subroutine checks to determine whether directory searches are permitted by using the current permissions of the directory. If the directory is opened with the **O_SEARCH** open flag, the subroutine does not perform the check.

Parameters

Item	Description
FileDescriptor	Specifies the file descriptor of an open file.
Flags	Specifies whether the file owner ID or group ID should be changed. This parameter is constructed by logically ORing the following values: **T_OWNER_AS_IS** Ignores the value specified by the Owner parameter and leaves the owner ID of the file unaltered. **T_GROUP_AS_IS** Ignores the value specified by the Group parameter and leaves the group ID of the file unaltered.
Flag	Specifies a bit field. If the AT_SYMLINK_NOFOLLOW bit is set and the Path specifies a symbolic link, then the owner and group of the symbolic link is changed.

Item	Description
Group	Specifies the new group of the file. For the **chown**, **fchown**, **fchownat**, and **lchown** commands, if this value is -1, the group is not changed. (A value of -1 indicates only that the group is not changed; it does not indicate a group that is not valid. An owner or group ID cannot be invalid.) For the **chownx**, **chownxat**, and **fchownx** commands, the subroutines change the Group to -1 if -1 is supplied for Group and **T_GROUP_AS_IS** is not set.
Owner	Specifies the new owner of the file. For the **chown**, **fchown**, **fchownat**, and **lchown** commands, if this value is -1, the group is not changed. (A value of -1 indicates only that the group is not changed; it does not indicate a group that is not valid. An owner or group ID cannot be invalid.) For the **chownx**, **chownxat**, and **fchownx** commands, the subroutines change the Owner to -1 if -1 is supplied for Owner and **T_OWNER_AS_IS** is not set.
Path	Specifies the path name of the file. For **chownxat** and **fchownat**, if the *DirFileDescriptor* is specified and Path is relative, then the *DirFileDescriptor* specifies the effective current working directory for the Path.
DirFileDescriptor	Specifies the file descriptor of an open directory, which is used as the effective current working directory for the *Path* parameter. If the *DirFileDescriptor* parameter equals **AT_FDCWD**, the *DirFileDescriptor* parameter is ignored and the *Path* argument specifies the complete file.

Return Values

Upon successful completion, the **chown**, **chownx**, **fchown**, **fchownx**, **chownxat**, **fchownat**, and **lchown** subroutines return a value of 0. If the **chown**, **chownx**, **fchown**, **fchownx**, **chownxat**, **fchownat**, or **lchown** subroutine is unsuccessful, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **chown**, **fchownat**, **chownx**, **chownxat**, or **lchown** subroutine is unsuccessful and the owner and group of a file remain unchanged if one of the following is true:

Item	Description
EACCES	Search permission is denied on a component of the *Path* parameter.
EDQUOT	The new group for the file system object cannot be set because the group's quota of disk blocks or i-nodes has been exhausted on the file system.
EFAULT	The *Path* parameter points to a location outside of the allocated address space of the process.
EINVAL	The owner or group ID supplied is not valid.
ELOOP	Too many symbolic links were encountered in translating the *Path* parameter.
ENAMETOOLONG	A component of the *Path* parameter exceeded 255 characters, or the entire *Path* parameter exceeded 1023 characters.
ENOENT	A symbolic link was named, but the file to which it refers does not exist; or a component of the *Path* parameter does not exist; or the process has the **disallow truncation** attribute set; or the *Path* parameter is null.
ENOTDIR	A component of the path prefix is not a directory.
EPERM	The effective user ID does not match the owner of the file, and the calling process does not have the appropriate privileges.

Item	Description
EROFS	The named file resides on a read-only file system.
ESTALE	The root or current directory of the process is located in a virtual file system that has been unmounted.

The **fchown** or **fchownx** subroutine is unsuccessful and the file owner and group remain unchanged if one of the following is true:

Item	Description
EBADF	The named file resides on a read-only file system.
EDQUOT	The new group for the file system object cannot be set because the group's quota of disk blocks or i-nodes has been exhausted on the file system.
EIO	An I/O error occurred during the operation.

The **chownxat** or the **fchownat** subroutine is unsuccessful and the file owner and group remain unchanged if one of the following is true:

Item	Description
EBADF	The *Path* parameter does not specify an absolute path and the *DirFileDescriptor* argument is neither **AT_FDCWD** nor a valid file descriptor.
EINVAL	The value of the *Flag* parameter is not valid.
ENOTDIR	The *Path* parameter is not an absolute path and *DirFileDescriptor* is a file descriptor but is not associated with a directory.

Security

Access Control: The invoker must have search permission for all components of the *Path* parameter.

chpass Subroutine

Purpose

Changes user passwords.

Library

Standard C Library (**libc.a**)

Thread Safe Security Library (**libs_r.a**)

Syntax

```
int chpass (UserName, Response, Reenter, Message)
char *UserName;
char *Response;
int *Reenter;
char **Message;
```

Description

The **chpass** subroutine maintains the requirements that the user must meet to change a password. This subroutine is the basic building block for changing passwords and handles password changes for local, NIS, and DCE user passwords.

The *Message* parameter provides a series of messages asking for old and new passwords, or providing informational messages, such as the reason for a password change failing. The first *Message* prompt is a prompt for the old password. This parameter does not prompt for the old password if the user has a real user ID of 0 (zero) and is changing a local user, or if the user has no current password. The **chpass** subroutine does not prompt a user with root authority for an old password. It informs the program that no message was sent and that it should invoke **chpass** again. If the user satisfies the first *Message* parameter's prompt, the system prompts the user to enter the new password. Each message is contained in the *Message* parameter and is displayed to the user. The *Response* parameter returns the user's response to the **chpass** subroutine.

The *Reenter* parameter indicates when a user has satisfied all prompt messages. The parameter remains nonzero until a user has passed all prompts. After the returned value of *Reenter* is 0, the return code signals whether the password change has succeeded or failed. When progressing through prompts for a user, the value of *Reenter* must be maintained by the caller between invocations of **chpass**.

The **chpass** subroutine maintains internal state information concerning the next prompt message to present to the user. If the calling program supplies a different user name before all prompt messages are complete for the user, the internal state information is reset and prompt messages begin again. State information is also kept in the *Reenter* variable. The calling program must maintain the value of *Reenter* between calls to **chpass**.

The **chpass** subroutine determines the administration domain to use during password changes. It determines if the user is defined locally, defined in Network Information Service (NIS), or defined in Distributed Computing Environment (DCE). Password changes occur only in these domains. System administrators may override this convention with the registry value in the **/etc/security/user** file. If the registry value is defined, the password change can only occur in the specified domain. System administrators can use this registry value if the user is administered on a remote machine that periodically goes down. If the user is allowed to log in through some other authentication method while the server is down, password changes remain to follow only the primary server.

The **chpass** subroutine allows the user to change passwords in two ways. For normal (non-administrative) password changes, the user must supply the old password, either on the first call to the **chpass** subroutine or in response to the first message from **chpass**. If the user is root, real user ID of 0, local administrative password changes are handled by supplying a null pointer for the *Response* parameter during the initial call

Users that are not administered locally are always queried for their old password.

The **chpass** subroutine is always in one of the following states:

1. Initial state: The caller invokes the **chpass** subroutine with NULL *response* parameter and receives the initial password prompt in the *message* parameter.
2. Verify initial password: The caller invokes the **chpass** subroutine with the results of prompting the user with earlier *message* parameter as the *response* parameter. The caller is given a prompt to enter the new password in the *message* parameter.
3. Enter new password: The caller invokes the **chpass** subroutine with the results of prompting user with the new password prompt in the *response* parameter. The caller will be given a prompt to repeat the new password in the *message* parameter.
4. Verify new password: The caller invokes the **chpass** subroutine with the results of prompting the user to repeat the new password in the *response* parameter. The **chpass** subroutine then performs the actual password change.

Any step in the above process can result in the **chpass** subroutine terminating the dialog. This is signalled when the *reenter* variable is set to 0. The return code indicates the nature of the failure.

Note: Set the setuid and owner to root for your own programs that use the **chpass** subroutine.

Parameters

Item	Description
UserName	Specifies the user's name whose password is to be changed.
Response	Specifies a character string containing the user's response to the last prompt.
Reenter	Points to a Boolean value used to signal whether the **chpass** subroutine has completed processing. If the *Reenter* parameter is a nonzero value, the **chpass** subroutine expects the user to satisfy the prompt message provided by the *Message* parameter. If the *Reenter* parameter is 0, the **chpass** subroutine has completed processing.
Message	Points to a pointer that the **chpass** subroutine allocates memory for and fills in. This replacement string is then suitable for printing and issues challenge messages (if the *Reenter* parameter is a nonzero value). The string can also issue informational messages such as why the user failed to change the password (if the *Reenter* parameter is 0). The calling application is responsible for freeing this memory.

Return Values

Upon successful completion, the **chpass** subroutine returns a value of 0. If the **chpass** subroutine is unsuccessful, it returns the following values:

Item	Description
-1	Indicates the call failed in the thread safe library **libs_r.a**. **ERRNO** will indicate the failure code.
1	Indicates that the password change was unsuccessful and the user should attempt again. This return value occurs if a password restriction is not met, such as if the password is not long enough.
2	Indicates that the password change was unsuccessful and the user should not attempt again. This return value occurs if the user enters an incorrect old password or if the network is down (the password change cannot occur).

Error Codes

The **chpass** subroutine is unsuccessful if one of the following values is true:

Item	Description
ENOENT	Indicates that the user cannot be found.
ESAD	Indicates that the user did not meet the criteria to change the password.
EPERM	Indicates that the user did not have permission to change the password.
EINVAL	Indicates that the parameters are not valid.
ENOMEM	Indicates that memory allocation (malloc) failed.

chpassx Subroutine

Purpose

Changes multiple method passwords.

Library

Standard C Library (**libc.a**)

Syntax

```
int chpassx (UserName, Response, Reenter, Message, State)
char *UserName;
char *Response;
int *Reenter;
char **Message;
void **State;
```

Description

The **chpassx** subroutine maintains the requirements that the user must meet to change a password. This subroutine is the basic building block for changing passwords, and it handles password changes for local, NIS, and loadable authentication module user passwords. It uses information provided by the **authenticatex** and **passwdexpiredx** subroutines to indicate which passwords were used when a user authenticated and whether or not those passwords are expired.

The *Message* parameter provides a series of messages asking for old and new passwords, or providing informational messages, such as the reason for a password change failing. The first *Message* prompt is a prompt for the old password. This parameter does not prompt for the old password if the user has a real user ID of 0 and is changing a local user, or if the user has no current password. The **chpassx** subroutine does not prompt a user with root authority for an old password when only a local password is being changed. It informs the program that no message was sent and that it should invoke **chpass** again. If the user satisfies the first *Message* parameter's prompt, the system prompts the user to enter the new password. Each message is contained in the *Message* parameter and is displayed to the user. The *Response* parameter returns the user's response to the **chpass** subroutine.

The *Reenter* parameter remains a nonzero value until the user satisfies all of the prompt messages or until the user incorrectly responds to a prompt message. When the *Reenter* parameter is 0, the return code signals whether the password change completed or failed. The calling application must initialize the *Reenter* parameter to 0 before the first call to the **chpassx** subroutine and the application cannot modify the *Reenter* parameter until the sequence of **chpassx** subroutine calls has completed.

The **authenticatex** subroutine ascertains the authentication domains the user can attempt. The subroutine uses the **SYSTEM** attribute for the user. Each token that is displayed in the **SYSTEM** line corresponds to a method that can be dynamically loaded and processed. Likewise, the system can provide multiple or alternate authentication paths.

The *State* parameter contains information from an earlier call to the **authenticatex** or **passwdexpirex** subroutines. That information indicates which administration domains were used when the user was authenticated and which passwords have expired and can be changed by the user. The *State* parameter must be initialized to null when the **chpassx** subroutine is not being called after an earlier call to the **authenticatex** or **passwdexpiredx** subroutines, or if the calling program does not wish to use the information from an earlier call.

The **chpassx** subroutine maintains internal state information concerning the next prompt message to present to the user. If the calling program supplies a different user name before all prompt messages are complete for the user, the internal state information is reset and prompt messages begin again.

The **chpassx** subroutine determines the administration domain to use during password changes. It determines if the user is defined locally, defined in Network Information Service (NIS), defined in Distributed Computing Environment (DCE), or defined in another administrative domain supported by a loadable authentication module. Password changes use the user's **SYSTEM** attribute and information in the *State* parameter. When the *State* parameter includes information from an earlier call to the **authenticatex** subroutine, only the administrative domains that were used for authentication are changed. When the *State* parameter includes information from an earlier call to the **passwdexpiredx** subroutine, only the administrative domains that have expired passwords are changed. The *State* parameter can contain information from calls to both **authenticatex** and **passwdexpiredx**, in which case

passwords that were used for authentication are changed, even if they are not expired, so that passwords remain synchronized between administrative domains.

The **chpassx** subroutine allows the user to change passwords in two ways. For normal (nonadministrative) password changes, the user must supply the old password, either on the first call to the **chpassx** subroutine or in response to the first message from **chpassx**. If the user is root (with a real user ID of 0), local administrative password changes are handled by supplying a null pointer for the *Response* parameter during the initial call.

Users that are not administered locally are always queried for their old password.

The **chpassx** subroutine is always in one of three states: entering the old password, entering the new password, or entering the new password again. If any of these states do not need to be complied with, the **chpassx** subroutine returns a null challenge.

Parameters

Item	Description
Message	Points to a pointer that the **chpassx** subroutine allocates memory for and fills in. This replacement string is then suitable for printing and issues challenge messages (if the *Reenter* parameter is a nonzero value). The string can also issue informational messages, such as why the user failed to change the password (if the *Reenter* parameter is 0). The calling application is responsible for freeing this memory.
Reenter	Points to an integer value used to signal whether the **chpassx** subroutine has completed processing. If the *Reenter* parameter is a nonzero value, the **chpassx** subroutine expects the user to satisfy the prompt message provided by the *Message* parameter. If the Reenter parameter is 0, the **chpassx** subroutine has completed processing.
Response	Specifies a character string containing the user's response to the last prompt.
State	Points to a pointer that the **chpassx** subroutine allocates memory for and fills in. The *State* parameter can also be the result of an earlier call to the **authenticatex** or **passwdexpiredx** subroutines. This parameter contains information about each password that has been changed for the user. The calling application is responsible for freeing this memory after the **chpassx** subroutine has completed.
UserName	Specifies the user's name whose password is to be changed.

Return Values

Upon successful completion, the **chpassx** subroutine returns a value of 0. If this subroutine fails, it returns the following values:

Item	Description
-1	The call failed in the **libs_r.a** thread safe library. **errno** indicates the failure code.
1	The password change was unsuccessful and the user should try again. This return value occurs if a password restriction is not met (for example, the password is not long enough).
2	The password change was unsuccessful and the user should not try again. This return value occurs if the user enters an incorrect old password or if the network is down (the password change cannot occur).

Error Codes

The **chpassx** subroutine is unsuccessful if one of the following values is true:

Item	Description
EINVAL	The parameters are not valid.
ENOENT	The user cannot be found.
ENOMEM	Memory allocation (malloc) failed.
EPERM	The user did not have permission to change the password.
ESAD	The user did not meet the criteria to change the password.

chprojattr Subroutine

Purpose

Updates and modifies the project attributes in kernel project registry for the given project.

Library

The **libaacct.a** library.

Syntax

```
<sys/aacct.h>
chprojattr(struct project *, int cmd)
```

Description

The **chprojattr** subroutine alters the attributes of a project defined in the kernel project registry. A pointer to struct project containing the project definition and the operation command is sent as input arguments. The following operations are permitted:

- PROJ_ENABLE_AGGR - Enables aggregation for the specified project
- PROJ_DISABLE_AGGR - Disables aggregation for the specified project

If PROJ_ENABLE_AGGR is passed, then the aggregation status bit is set to 1. If PROJ_DISABLE_AGGR is passed, then the aggregation status bit set to 0.

Note: To initialize the project structure, the user must call the **getprojdef** subroutine before calling the **chprojattr** subroutine.

Parameters

Item	Description
project	Pointer containing the project definition.
cmd	An integer command indicating whether to perform a set or clear operation.

Security

Only for privileged users. Privilege can be extended to nonroot users by granting the CAP_AACCT capability to a user.

Return Values

Item	Description
0	Success

Item	Description
-1	Failure

Error Codes

Item	Description
EINVAL	Invalid arguments passed. The passed command flag is invalid or the passed pointer is NULL.
ENONENT	Project not found.

chprojattrdb Subroutine

Purpose

Updates the project attributes in the project database.

Library

The **libaacct.a** library.

Syntax

```
<sys/aacct.h>

chprojattrdb(void *handle, struct project *project, int cmd)
```

Description

The **chprojattrdb** subroutine alters the attributes of the named project in the specified project database, which is controlled through the *handle* parameter. The following commands are permitted:

- **PROJ_ENABLE_AGGR** — Enables aggregation for the specified project
- **PROJ_DISABLE_AGGR** — Disables aggregation for the specified project

The project database must be initialized before calling this subroutine. The **projdballoc** subroutine is provided for this purpose. The **chprojattrdb** subroutine must be called after the **getprojdb** subroutine, which sets the record pointer to point to the project that needs to be modified.

Note: The **chprojattrdb** subroutine must be called after the **getprojdb** subroutine, which makes the named project the current project.

Parameters

Item	Description
handle	Pointer to the handle allocated for the project database.
project	Pointer containing the project definition.
cmd	An integer command indicating whether to perform a set or clear operation.

Security

Only for privileged users. Privilege can be extended to nonroot users by granting the CAP_AACCT capability to a user.

Return Values

Item	Description
0	Success
-1	Failure

Error Codes

Item	Description
EINVAL	Invalid arguments passed. The passed command flag is invalid or the passed pointer is NULL.
ENONENT	Project not found.

chroot Subroutine

Purpose

Changes the effective root directory.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <unistd.h>

int chroot (const char * Path)
char *Path;
```

Description

The **chroot** subroutine causes the directory named by the *Path* parameter to become the effective root directory. If the *Path* parameter refers to a symbolic link, the **chroot** subroutine sets the effective root directory to the directory pointed to by the symbolic link. If Network File System (NFS) is installed on your system, this path can cross into another node.

The effective root directory is the starting point when searching for a file's path name that begins with / (slash). The current directory is not affected by the **chroot** subroutine.

The calling process must have root user authority in order to change the effective root directory. The calling process must also have search access to the new effective root directory.

The .. (double period) entry in the effective root directory is interpreted to mean the effective root directory itself. Thus, this directory cannot be used to access files outside the subtree rooted at the effective root directory.

Parameters

Item	Description
Path	Pointer to the new effective root directory.

Return Values

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **chroot** subroutine fails and the effective root directory remains unchanged if one or more of the following are true:

Item	Description
ENOENT	The named directory does not exist.
EACCES	The named directory denies search access.
EPERM	The process does not have root user authority.

The **chroot** subroutine can be unsuccessful for other reasons. See *Appendix A. Base Operating System Error Codes for Services* that Require Path-Name Resolution for a list of additional errors.

If NFS is installed on the system, the **chroot** subroutine can also fail if the following is true:

Item	Description
ETIMEDOUT	The connection timed out.

chssys Subroutine

Purpose

Modifies the subsystem objects associated with the *SubsystemName* parameter.

Library

System Resource Controller Library (**libsrc.a**)

Syntax

```
#include <sys/srcobj.h>
#include <spc.h>
```

```
int chssys( SubsystemName,  SRCSubsystem)
char *SubsystemName;
struct SRCsubsys *SRCSubsystem;
```

Description

The **chssys** subroutine modifies the subsystem objects associated with the specified subsystem with the values in the **SRCsubsys** structure. This action modifies the objects associated with subsystem in the following object classes:

- Subsystem Environment
- Subserver Type
- Notify

The Subserver Type and Notify object classes are updated only if the subsystem name has been changed.

The **SRCsubsys** structure is defined in the **/usr/include/sys/srcobj.h** file.

The program running with this subroutine must be running with the group system.

Parameters

Item	Description
SRCSubsystem	Points to the **SRCsubsys** structure.
SubsystemName	Specifies the name of the subsystem.

Return Values

Upon successful completion, the **chssys** subroutine returns a value of 0. Otherwise, it returns a value of -1 and the **odmerrno** variable is set to indicate the error, or a System Resource Controller (SRC) error code is returned.

Error Codes

The **chssys** subroutine is unsuccessful if one or more of the following are true:

Item	Description
SRC_NONAME	No subsystem name is specified.
SRC_NOPATH	No subsystem path is specified.
SRC_BADNSIG	Invalid stop normal signal.
SRC_BADFSIG	Invalid stop force signal.
SRC_NOCONTACT	Contact not signal, sockets, or message queues.
SRC_SSME	Subsystem name does not exist.
SRC_SUBEXIST	New subsystem name is already on file.
SRC_SYNEXIST	New subsystem synonym name is already on file.
SRC_NOREC	The specified **SRCsubsys** record does not exist.
SRC_SUBSYS2BIG	Subsystem name is too long.
SRC_SYN2BIG	Synonym name is too long.
SRC_CMDARG2BIG	Command arguments are too long.
SRC_PATH2BIG	Subsystem path is too long.
SRC_STDIN2BIG	stdin path is too long.
SRC_STDOUT2BIG	stdout path is too long.
SRC_STDERR2BIG	stderr path is too long.
SRC_GRPNAM2BIG	Group name is too long.

Security

Privilege Control: This command has the Trusted Path attribute. It has the following kernel privilege:

```
SET_PROC_AUDIT kernel privilege
```

Item	Description
Files Accessed:	

Mode	File
644	**/etc/objrepos/SRCsubsys**

Mode	File
644	**/etc/objrepos/SRCsubsvr**
644	**/etc/objrepos/SRCnotify**

Auditing Events:

Event	Information
SRC_Chssys	

Files

Item	Description
/etc/objrepos/SRCsubsys	SRC Subsystem Configuration object class.
/etc/objrepos/SRCsubsvr	SRC Subserver Configuration object class.
/etc/objrepos/SRCnotify	SRC Notify Method object class.
/dev/SRC	Specifies the **AF_UNIX** socket file.
/dev/.SRC-unix	Specifies the location for temporary socket files.

cimag, cimagf, or cimagl Subroutine

Purpose

Performs complex imaginary computations.

Syntax

```
#include <complex.h>

double cimag (z)
double complex z;

float cimagf (z)
float complex z;

long double cimagl (z)
long double complex z;
```

Description

The **cimag**, **cimagf**, and **cimagl** subroutines compute the imaginary part of *z*.

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

The **cimag**, **cimagf**, and **cimagl** subroutines return the imaginary part value (as a real).

ckuseracct Subroutine

Purpose

Checks the validity of a user account.

Library

Security Library (**libc.a**)

Syntax

```
#include <login.h>

int ckuseracct ( Name,  Mode,  TTY)
char *Name;
int Mode;
char *TTY;
```

Description

Note: This subroutine is obsolete and is provided only for backwards compatibility. Use the **loginrestrictions** subroutine, which performs a superset of the functions of the **ckuseracct** subroutine, instead.

The **ckuseracct** subroutine checks the validity of the user account specified by the *Name* parameter. The *Mode* parameter gives the mode of the account usage, and the *TTY* parameter defines the terminal being used for the access. The **ckuseracct** subroutine checks for the following conditions:

- Account existence
- Account expiration

The *Mode* parameter specifies other mode-specific checks.

Parameters

Item	Description
Name	Specifies the login name of the user whose account is to be validated.
Mode	Specifies the manner of usage. Valid values as defined in the **login.h** file are listed below. The *Mode* parameter must be one of these or 0: **S_LOGIN** Verifies that local logins are permitted for this account. **S_SU** Verifies that the **su** command is permitted and that the current process has a group ID that can invoke the **su** command to switch to the account. **S_DAEMON** Verifies the account can be used to invoke daemon or batch programs using the **src** or **cron** subsystems. **S_RLOGIN** Verifies the account can be used for remote logins using the **rlogind** or **telnetd** programs.
TTY	Specifies the terminal of the originating activity. If this parameter is a null pointer or a null string, no TTY origin checking is done.

Security

Item	Description

Files Accessed:

Mode	File
r	**/etc/passwd**
r	**/etc/security/user**

Return Values

If the account is valid for the specified usage, the **ckuseracct** subroutine returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to the appropriate error code.

Error Codes

The **ckuseracct** subroutine fails if one or more of the following are true:

Item	Description
ENOENT	The user specified in the *Name* parameter does not have an account.
ESTALE	The user's account is expired.
EACCES	The specified terminal does not have access to the specified account.
EACCES	The *Mode* parameter is **S_SU**, and the current process is not permitted to use the **su** command to access the specified user.
EACCES	Access to the account is not permitted in the specified *Mode*.
EINVAL	The *Mode* parameter is not one of **S_LOGIN**, **S_SU**, **S_DAEMON**, **S_RLOGIN**.

ckuserID Subroutine

Purpose

Authenticates the user.

Note: This subroutine is obsolete and is provided for backwards compatibility. Use the **authenticate** subroutine, instead.

Library

Security Library (**libc.a**)

Syntax

```
#include <login.h>
int ckuserID ( User,  Mode)
int Mode;
char *User;
```

Description

The **ckuserID** subroutine authenticates the account specified by the *User* parameter. The mode of the authentication is given by the *Mode* parameter. The **login** and **su** commands continue to use the **ckuserID** subroutine to process the **/etc/security/user auth1** and **auth2** authentication methods.

The **ckuserID** subroutine depends on the **authenticate** subroutine to process the **SYSTEM** attribute in the **/etc/security/user** file. If authentication is successful, the **passwdexpired** subroutine is called.

Errors caused by grammar or load modules during a call to the **authenticate** subroutine are displayed to the user if the user was authenticated. These errors are audited with the **USER_Login** audit event if the user failed authentication.

Parameters

Item	Description
User	Specifies the name of the user to be authenticated.
Mode	Specifies the mode of authentication. This parameter is a bit mask and may contain one or more of the following values, which are defined in the **login.h** file: **S_PRIMARY** The primary authentication methods defined for the *User* parameter are checked. All primary authentication checks must be passed. **S_SECONDARY** The secondary authentication methods defined for the *User* parameter are checked. Secondary authentication checks are not required to be successful. Primary and secondary authentication methods for each user are set in the /**etc**/**security**/**user** file by defining the **auth1** and **auth2** attributes. If no primary methods are defined for a user, the **SYSTEM** attribute is assumed. If no secondary methods are defined, there is no default.

Security

Item	Description

Files Accessed:

Mode	File
r	/**etc**/**passwd**
r	/**etc**/**security**/**passwd**
r	/**etc**/**security**/**user**
r	/**etc**/**security**/**login.cfg**

Return Values

If the account is valid for the specified usage, the **ckuserID** subroutine returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **ckuserID** subroutine fails if one or more of the following are true:

Item	Description
ESAD	Security authentication failed for the user.
EINVAL	The *Mode* parameter is neither **S_PRIMARY** nor **S_SECONDARY** or the *Mode* parameter is both **S_PRIMARY** and **S_SECONDARY**.

class, _class, finite, isnan, or unordered Subroutines

Purpose

Determines classifications of floating-point numbers.

Libraries

IEEE Math Library (**libm.a**) or System V Math Library (**libmsaa.a**)

Syntax

```
#include <math.h>
#include <float.h>
```

```
int
class( x)
double x;
```

```
#include <math.h>
#include <float.h>
```

```
int
_class( x)
double x;
```

```
#include <math.h>
```

```
int finite(x)
double x;
```

```
#include <math.h>
```

```
int isnan(x)
double x;
```

```
#include <math.h>
```

```
int unordered(x, y)
double x, y;
```

Description

The **class** subroutine, **_class** subroutine, **finite** subroutine, **isnan** subroutine, and **unordered** subroutine determine the classification of their floating-point value. The **unordered** subroutine determines if a floating-point comparison involving *x* and *y* would generate the IEEE floating-point unordered condition (such as whether *x* or *y* is a NaN).

The **class** subroutine returns an integer that represents the classification of the floating-point *x* parameter. Since **class** is a reversed key word in C++. The **class** subroutine can not be invoked in a C++ program. The **_class** subroutine is an interface for C++ program using the **class** subroutine. The interface and the return value for class and **_class** subroutines are identical. The values returned by the **class** subroutine are defined in the **float.h** header file. The return values are the following:

Item	Description
FP_PLUS_NORM	Positive normalized, nonzero *x*
FP_MINUS_NORM	Negative normalized, nonzero *x*

Item	Description
FP_PLUS_DENORM	Positive denormalized, nonzero *x*
FP_MINUS_DENORM	Negative denormalized, nonzero *x*
FP_PLUS_ZERO	*x* = +0.0
FP_MINUS_ZERO	*x* = -0.0
FP_PLUS_INF	*x* = +INF
FP_MINUS_INF	*x* = -INF
FP_NANS	*x* = Signaling Not a Number (NaNS)
FP_NANQ	*x* = Quiet Not a Number (NaNQ)

Since class is a reserved keyword in C++, the **class** subroutine cannot be invoked in a C++ program. The **_class** subroutine is an interface for the C++ program using the **class** subroutine. The interface and the return values for **class** and **_class** subroutines are identical.

The **finite** subroutine returns a nonzero value if the *x* parameter is a finite number; that is, if *x* is not +-, INF, NaNQ, or NaNS.

The **isnan** subroutine returns a nonzero value if the *x* parameter is an NaNS or a NaNQ. Otherwise, it returns 0.

The **unordered** subroutine returns a nonzero value if a floating-point comparison between *x* and *y* would be unordered. Otherwise, it returns 0.

Note: Compile any routine that uses subroutines from the **libm.a** library with the **-lm** flag. To compile the **class.c** file, for example, enter:

```
cc class.c -lm
```

Parameters

Item	Description
x	Specifies some double-precision floating-point value.
y	Specifies some double-precision floating-point value.

Error Codes

The **finite**, **isnan**, and **unordered** subroutines neither return errors nor set bits in the floating-point exception status, even if a parameter is an NaNS.

clear, erase, wclear or werase Subroutine

Purpose

Clears a window.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
int clear(void);
```

```
int erase(void);
```

int wclear(WINDOW *win);

```
int werase(WINDOW *win);
```

Description

The **clear**, **erase**, **wclear**, and **werase** subroutines clear every position in the current or specified window.

The **clear** and **wclear** subroutines also achieve the same effect as calling the **clearok** subroutine, so that the window is cleared completely on the next call to the **wrefresh** subroutine for the window and is redrawn in its entirety.

Parameters

Item	Description
*win	Specifies the window to clear.

Return Values

Upon successful completion, these subroutines return OK. Otherwise, they return ERR.

Examples

For the **clear** and **wclear** subroutines:

1. To clear stdscr and set a clear flag for the next call to the **refresh** subroutine, enter:

   ```
   clear();
   ```

2. To clear the user-defined window `my_window` and set a clear flag for the next call to the **wrefresh** subroutine, enter:

   ```
   WINDOW *my_window;
   wclear(my_window);
   waddstr (my_window, "This will be cleared.");
   wrefresh (my_window);
   ```

3. To erase the standard screen structure, enter:

   ```
   erase();
   ```

4. To erase the user-defined window `my_window`, enter:

   ```
   WINDOW *my_window;
   werase (my_window);
   ```

   Note: After the **wrefresh**, the window will be cleared completely. You will not see the string "This will be cleared."

For the **erase** and **werase** subroutines:

1. To erase the standard screen structure, enter:

```
erase();
```

2. To erase the user-defined window `my_window`, enter:

```
WINDOW *my_window;
werase(my_window);
```

clearok, idlok, leaveok, scrollok, setscrreg or wsetscrreg Subroutine

Purpose

Terminal output control subroutines.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

int clearok(WINDOW *win,
bool bf);

int idlok(WINDOW *win,
bool bf);

int leaveok(WINDOW *win,
bool bf);

int scrollok(WINDOW *win,
bool bf);

int setscrreg(int top,
int bot);

int wsetscrreg(WINDOW *win,
int top,
int bot);
```

Description

These subroutines set options that deal with output within Curses.

The **clearok** subroutine assigns the value of *bf* to an internal flag in the specified window that governs clearing of the screen during a refresh. If, during a refresh operation on the specified window, the flag in **curscr** is TRUE or the flag in the specified window is TRUE, then the implementation clears the screen, redraws it in its entirety, and sets the flag to FALSE in **curscr** and in the specified window. The initial state is unspecified.

The **idlok** subroutine specifies whether the implementation may use the hardware insert-line, delete-line, and scroll features of terminals so equIpped. If *bf* is TRUE, use of these features is enabled. If *bf* is FALSE, use of these features is disabled and lines are instead redrawn as required. The initial state is FALSE.

The **leaveok** subroutine controls the cursor position after a refresh operation. If *bf* is TRUE, refresh operations on the specified window may leave the terminal's cursor at an arbitrary position. If *bf* is FALSE, then at the end of any refresh operation, the terminal's cursor is positioned at the cursor position contained in the specified window. The initial state is FALSE.

The **scrollok** subroutine controls the use of scrolling. If *bf* is TRUE, then scrolling is enabled for the specified window, with the consequences discussed in Truncation, Wrapping and Scrolling on page 28. If *bf* is FALSE, scrolling is disabled for the specified window. The initial state is FALSE.

The **setscrreg** and **wsetscrreg** subroutines define a software scrolling region in the current or specified window. The *top* and *bot* arguments are the line numbers of the first and last line defining the scrolling region. (Line 0 is the top line of the window.) If this option and the **scrollok** subroutine are enabled, an attempt to move off the last line of the margin causes all lines in the scrolling region to scroll one line in the direction of the first line. Only characters in the window are scrolled. If a software scrolling region is set and the **scrollok** subroutine is not enabled, an attempt to move off the last line of the margin does not reposition any lines in the scrolling region.

Parameters

The parameters for the **clearok** subroutine are:

Item	Description
Flag	Sets the window clear flag. If TRUE, curses clears the window on the next call to the **wrefresh** or **refresh** subroutines. If FALSE, curses does not clear the window.
Window	Specifies the window to clear.

The parameters for the **idlok** subroutine are:

Item	Description
Flag	Specifies whether to enable curses to use the hardware insert/delete line feature (TRUE) or not (FALSE).
Window	Specifies the window it will affect.

The parameters for the **leaveok** subroutine are:

Item	Description
Flag	Specifies whether to leave the physical cursor alone after a refresh (TRUE) or to move the physical cursor to the logical cursor after a refresh (FALSE).
Window	Specifies the window for which to set the *Flag* parameter.

The parameters for the **scrollok** subroutine are:

Item	Description
Flag	Enables scrolling when set to TRUE. Otherwise, set the *Flag* parameter to FALSE to disable scrolling.
Window	Identifies the window in which to enable or disable scrolling.

The parameters for the **setscrreg** and **wsetscrreg** subroutines are:

Item	Description
Bmargin	Specifies the last line number in the scrolling region.
Tmargin	Specifies the first line number in the scrolling region (0 is the top line of the window.).
Window	Specifies the window in which to place the scrolling region. You specify this parameter only with the **wsetscrreg** subroutine.

Return Values

Upon successful completion, the **setscrreg** and **wsetscrreg** subroutines return OK. Otherwise, they return ERR.

The other subroutines always return OK.

Examples

Examples for the **clearok** subroutine are:

1. To set the user-defined screen `my_screen` to clear on the next call to the **wrefresh** subroutine, enter:

```
WINDOW *my_screen;
clearok(my_screen, TRUE);
```

2. To set the standard screen structure to clear on the next call to the **refresh** subroutine, enter:

```
clearok(stdscr, TRUE);
```

Examples for the **idlok** subroutine are:

1. To enable curses to use the hardware insert/delete line feature in stdscr, enter:

```
idlok(stdscr, TRUE);
```

2. To force curses not to use the hardware insert/delete line feature in the user-defined window `my_window` , enter:

```
idlok(my_window, FALSE);
```

Examples for the **leaveok** subroutine are:

1. To move the physical cursor to the same location as the logical cursor after refreshing the user-defined window `my_window`, enter:

```
WINDOW *my_window;
leaveok(my_window, FALSE);
```

2. To leave the physical cursor alone after refreshing the user-defined window `my_window`, enter:

```
WINDOW *my_window;
leaveok(my_window, TRUE);
```

Examples for the **scrollok** subroutine are:

1. To turn scrolling on in the user-defined window `my_window`, enter:

```
WINDOW *my_window;
scrollok(my_window, TRUE);
```

2. To turn scrolling off in the user-defined window `my_window`, enter:

```
WINDOW *my_window;
scrollok(my_window, FALSE);
```

Examples for the **setscrreg** or **wsetscrreg** subroutine are:

1. To set a scrolling region starting at the 10th line and ending at the 30th line in the stdscr, enter:

```
setscrreg(9, 29);
```

   Note: Zero is always the first line.

2. To set a scrolling region starting at the 10th line and ending at the 30th line in the user-defined window `my_window`, enter:

```
WINDOW *my_window;
wsetscrreg(my_window, 9, 29);
```

clrtobot or wclrtobot Subroutine

Purpose

Erases the current line from the logical cursor position to the end of the window.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
int clrtobot(void);
```

int wclrtobot(WINDOW **win*);

Description

The **clrtobot** and **wclrtobot** subroutines erase all lines following the cursor in the current or specified window, and erase the current line from the cursor to the end of the line, inclusive. These subroutines do not update the cursor.

Parameters

Item	Description
**win*	Specifies the window in which to erase lines.

Return Values

Upon successful completion, these subroutines return OK. Otherwise, they return ERR.

Examples

1. To erase the lines below and to the right of the logical cursor in the stdscr, enter:

   ```
   clrtobot();
   ```

2. To erase the lines below and to the right of the logical cursor in the user-defined window `my_window`, enter:

   ```
   WINDOW *my_window;
   wclrtobot(my_window);
   ```

clrtoeol or wclrtoeol Subroutine

Purpose

Erases the current line from the logical cursor position to the end of the line.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
int clrtoeol(void);
```

int wclrtoeol(WINDOW * *win*);

Description

The **clrtoeol** and **wclrtoeol** subroutines erase the current line from the cursor to the end of the line, inclusive, in the current or specified window. These subroutines do not update the cursor.

Parameters

Item	Description
**win*	Specifies the window in which to clear the line.

Return Values

Upon successful completion, these subroutines return OK. Otherwise, they return ERR.

Examples

1. To clear the line to the right of the logical cursor in the stdscr, enter:

   ```
   clrtoeol();
   ```

2. To clear the line to the right of the logical cursor in the user-defined window `my_window`, enter:

   ```
   WINDOW *my_window;
   wclrtoeol(my_window);
   ```

clock Subroutine

Purpose

Reports central processing unit (CPU) time used.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <time.h>
```

```
clock_t clock (void);
```

Description

The **clock** subroutine reports the amount of CPU time used. The reported time is the sum of the CPU time of the calling process and its terminated child processes for which it has executed **wait**, **system**, or **pclose** subroutines. To measure the amount of time used by a program, the **clock** subroutine should be called at the beginning of the program, and that return value should be subtracted from the return value

of subsequent calls to the **clock** subroutine. To find the time in seconds, divide the value returned by the **clock** subroutine by the value of the macro **CLOCKS_PER_SEC**, which is defined in the **time.h** file.

Return Values

The **clock** subroutine returns the amount of CPU time used.

clock_getcpuclockid Subroutine

Purpose

Accesses a process CPU-time clock.

Syntax

```
#include <time.h>
int clock_getcpuclockid(pid_t pid, clockid_t *clock_id);
```

Description

The **clock_getcpuclockid** subroutine returns the clock ID of the CPU-time clock of the process specified by *pid*. If the process described by *pid* exists and the calling process has permission, the clock ID of this clock returns in *clock_id*.

If *pid* is zero, the **clock_getcpuclockid** subroutine returns the clock ID specified in *clock_id* of the CPU-time clock of the process making the call.

To obtain the CPU-time clock ID of other processes, the calling process should be root or have the same effective or real user ID as the process that owns the targetted CPU-time clock.

Parameters

Item	Description
clock_id	Specifies the clock ID of the CPU-time clock.
pid	Specifies the process ID of the CPU-time clock.

Return Values

Upon successful completion, the **clock_getcpuclockid** subroutine returns 0; otherwise, an error code is returned indicating the error.

Error Codes

Item	Description
ENOTSUP	The function is not supported with checkpoint-restart processes.
EPERM	The requesting process does not have permission to access the CPU-time clock for the process.
ESRCH	No process can be found corresponding to the process specified by *pid*.

clock_getres, clock_gettime, and clock_settime Subroutine

Purpose

Clock and timer functions.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <time.h>

int clock_getres (clock_id, res)
clockid_t clock_id;
struct timespec *res;

int clock_gettime (clock_id, tp)
clockid_t clock_id;
struct timespec *tp;

int clock_settime (clock_id, tp)
clockid_t clock_id;
const struct timespec *tp;
```

Description

The **clock_getres** subroutine returns the resolution of any clock. Clock resolutions are implementation-defined and cannot be set by a process. If the *res* parameter is not NULL, the resolution of the specified clock is stored in the location pointed to by the *res* parameter. If the *res* parameter is NULL, the clock resolution is not returned. If the *time* parameter of the **clock_settime** subroutine is not a multiple of the *res* parameter, the value is truncated to a multiple of the *res* parameter.

The **clock_gettime** subroutine returns the current value, *tp*, for the specified clock, *clock_id*.

The **clock_settime** subroutine sets the specified clock, *clock_id*, to the value specified by the *tp* parameter. Time values that are between two consecutive non-negative integer multiples of the resolution of the specified clock will be truncated down to the smaller multiple of the resolution.

A clock may be system-wide (visible to all processes) or per-process (measuring time that is meaningful only within a process). All implementations support a *clock_id* of **CLOCK_REALTIME** as defined in the **time.h** file. This clock represents the Realtime clock for the system. For this clock the values returned by the **clock_gettime** subroutine and specified by the **clock_settime** subroutine represent the amount of time (in seconds and nanoseconds) since the epoch.

If the value of the **CLOCK_REALTIME** clock is set through the **clock_settime** subroutine, the new value of the clock is used to determine the time of expiration for absolute time services based upon the **CLOCK_REALTIME** clock. This applies to the time at which armed absolute timers expire. If the absolute time requested at the invocation of such a time service is before the new value of the clock, the time service expires immediately as if the clock had reached the requested time normally.

Setting the value of the **CLOCK_REALTIME** clock through the **clock_settime** subroutine has no effect on threads that are blocked waiting for a relative time service based upon this clock, including the **nanosleep** subroutine; nor on the expiration of relative timers based upon this clock. Consequently, these time services expire when the requested relative interval elapses, independently of the new or old value of the clock.

A *clock_id* of **CLOCK_MONOTONIC** is defined in the **time.h** file. This clock represents the monotonic clock for the system. For this clock, the value returned by the **clock_gettime** subroutine represents the amount of time (in seconds and nanoseconds) since an unspecified point in the past. This point does not change after system start time (for example, this clock cannot have backward jumps). The value of the

CLOCK_MONOTONIC clock cannot be set through the **clock_settime** subroutine. This subroutine fails if it is invoked with a *clock_id* parameter of **CLOCK_MONOTONIC**.

The calling process should have **SYS_OPER** authority to set the value of the **CLOCK_REALTIME** clock.

Process CPU-time clocks are supported by the system. For these clocks, the values returned by **clock_gettime** and specified by **clock_settime** represent the amount of execution time of the process associated with the clock. **Clockid_t** values for CPU-time clocks are obtained by calling **clock_getcpuclockid**. A special **clockid_t** value, **CLOCK_PROCESS_CPUTIME_ID**, is defined in the **time.h** file. This value represents the CPU-time clock of the calling process when one of the **clock_*** or **timer_*** functions is called.

To get or set the value of a CPU-time clock, the calling process must have root permissions or have the same effective or real user ID as the process that owns the targeted CPU-time clock. The same rule applies to a process that tries to get the resolution of a CPU-time clock.

Thread CPU-time clocks are supported by the system. For these clocks, the values returned by **clock_gettime** and specified by **clock_settime** represent the amount of execution time of the thread associated with the clock. **Clockid_t** values for thread CPU-time clocks are obtained by calling the **pthread_getcpuclockid** subroutine. A special **clockid_t** value, **CLOCK_THREAD_CPUTIME_ID**, is defined in the **time.h** file. This value represents the thread CPU-time clock of the calling thread when one of the **clock_*()** or **timer_*** functions is called.

To get or set the value of a thread CPU-time clock, the calling thread must be a thread in the same process as the one that owns the targeted thread CPU-time clock. The same rule applies to a thread that tries to get the resolution of a thread CPU-time clock.

Parameters

Item	Description
clock_id	Specifies the clock.
res	Stores the resolution of the specified clock.
tp	Stores the current value of the specified clock.

Return Values

If successful, 0 is returned. If unsuccessful, -1 is returned, and **errno** will be set to indicate the error.

Error Codes

The **clock_getres**, **clock_gettime**, and **clock_settime** subroutines fail if:

Item	Description
EINVAL	The *clock_id* parameter does not specify a known clock.
ENOTSUP	The function is not supported with checkpoint-restart processes.

The **clock_settime** subroutine fails if:

Item	Description
EINVAL	The *tp* parameter to the **clock_settime** subroutine is outside the range for the given clock ID.
EINVAL	The *tp* parameter specified a nanosecond value less than zero or greater than or equal to 1000 million.
EINVAL	The value of the *clock_id* argument is **CLOCK_MONOTONIC**.

The **clock_settime** subroutine might fail if:

Item	Description
EPERM	The requesting process does not have the appropriate privilege to set the specified clock.

clock_nanosleep Subroutine

Purpose

Specifies clock for high resolution sleep.

Syntax

```
#include <time.h>
 int clock_nanosleep(clockid_t clock_id, int flags,
       const struct timespec *rqtp, struct timespec *rmtp);
```

Description

If the **TIMER_ABSTIME** flag is not set in the *flags* argument, the **clock_nanosleep** subroutine causes the current thread to be suspended from execution until either the time interval specified by the *rqtp* argument has elapsed, or a signal is delivered to the calling thread and its action is to invoke a signal-catching function, or the process is terminated. The *clock_id* argument specifies the clock used to measure the time interval.

If the **TIMER_ABSTIME** flag is set in the *flags* argument, the **clock_nanosleep** subroutine causes the current thread to be suspended from execution until either the time value of the clock specified by *clock_id* reaches the absolute time specified by the *rqtp* argument, or a signal is delivered to the calling thread and its action is to invoke a signal-catching function, or the process is terminated. If, at the time of the call, the time value specified by *rqtp* is less than or equal to the time value of the specified clock, then the **clock_nanosleep** subroutine returns immediately and the calling process shall not be suspended.

The suspension time caused by this function might be longer than requested either because the argument value is rounded up to an integer multiple of the sleep resolution, or because of the scheduling of other activity by the system. Except for the case of being interrupted by a signal, the suspension time for the relative **clock_nanosleep** subroutine (that is, with the TIMER_ABSTIME flag not set) shall not be less than the time interval specified by the *rqtp* argument, as measured by the corresponding clock. The suspension for the absolute **clock_nanosleep** subroutine (that is, with the TIMER_ABSTIME flag set) is in effect at least until the value of the corresponding clock reaches the absolute time specified by the *rqtp* argument, except for the case of being interrupted by a signal.

The **clock_nanosleep** subroutine has no effect on the action or blocking of any signal.

The subroutine fails if the *clock_id* argument refers to a process or a thread CPU-time clock.

Parameters

Item	Description
clock_id	Specifies the clock used to measure the time.
flags	Identifies the type of timeout. If **TIMER_ABSTIME** is set, the time value pointed to by *rqtp* is an absolute time value; otherwise, it is a time interval.
rmtp	Points to the **timespec** structure used to return the remaining amount of time in an interval (the requested time minus the time actually slept) if the sleep is interrupted.
rqtp	Points to the **timespec** structure that contains requested sleep time.

Return Values

The **clock_nanosleep** subroutine returns 0 when the requested time has elapsed.

The **clock_nanosleep** subroutine returns the corresponding error value when it has been interrupted by a signal. For the relative **clock_nanosleep**subroutine, when the *rmtp* argument is not NULL, the referenced **timespec** structure is updated to contain the amount of time remaining in the interval (the requested time minus the time actually slept). If the *rmtp* argument is NULL, the remaining time is not returned. The absolute **clock_nanosleep** subroutine has no effect on the structure referenced by the *rmtp* argument.

Error Codes

Item	Description
EINTR	The **clock_nanosleep** subroutine was interrupted by a signal.
EINVAL	The *rqtp* parameter specified a nanosecond value less than 0 or greater than or equal to 1000 million; or the **TIMER_ABSTIME** flag was specified in the **flags** parameter and the *rqtp* parameter is outside the range for the clock specified by *clock_id*; or the *clock_id* parameter does not specify a known clock, or specifies the CPU-time clock of the calling thread.
ENOTSUP	The *clock_id* argument specifies a clock for which the *clock_nanosleep* subroutine is not supported, such as a CPU-time clock.
ENOTSUP	The subroutine is not supported with checkpoint-restarted processes.

Files

timer.h

clog, clogf, or clogl Subroutine

Purpose

Computes the complex natural logarithm.

Syntax

```
#include <complex.h>

double complex clog (z)
double complex z;

float complex clogf (z)
float complex z;

long double complex clogl (z)
long double complex z;
```

Description

The **clog**, **clogf**, and **clogl** subroutines compute the complex natural (base *e*) logarithm of *z*, with a branch cut along the negative real axis.

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

The **clog**, **clogf**, and **clogl** subroutines return the complex natural logarithm value, in the range of a strip mathematically unbounded along the real axis and in the interval [-*i* pi, +*i* pi] along the imaginary axis.

close Subroutine

Purpose

Closes a file descriptor.

Syntax

```
#include <unistd.h>

int close (
 FileDescriptor)
int FileDescriptor;
```

Description

The **close** subroutine closes the file or shared memory object associated with the *FileDescriptor* parameter. If Network File System (NFS) is installed on your system, this file can reside on another node.

All file regions associated with the file specified by the *FileDescriptor* parameter that this process has previously locked with the **lockf** or **fcntl** subroutine are unlocked. This occurs even if the process still has the file open by another file descriptor.

If the *FileDescriptor* parameter resulted from an **open** subroutine that specified **O_DEFER**, and this was the last file descriptor, all changes made to the file since the last **fsync** subroutine are discarded.

If the *FileDescriptor* parameter is associated with a mapped file, it is unmapped. The **shmat** subroutine provides more information about mapped files.

The **close** subroutine attempts to cancel outstanding **asynchronous I/O requests** on this file descriptor. If the asynchronous I/O requests cannot be canceled, the application is blocked until the requests have completed.

If the *FileDescriptor* parameter is associated with a shared memory object and the shared memory object remains referenced at the last close (that is, a process has it mapped), the entire contents of the memory object persists until the memory object becomes unreferenced. If this is the last close of a shared memory object and the close results in the memory object becoming unreferenced, and the memory object has been unlinked, the memory object is removed. The **shm_open** subroutine provides more information about shared memory objects.

The **close** subroutine is blocked until all subroutines which use the file descriptor return to **usr** space. For example, when a thread is calling **close** and another thread is calling **select** with the same file descriptor, the **close** subroutine does not return until the **select** call returns.

When all file descriptors associated with a pipe or FIFO special file have been closed, any data remaining in the pipe or FIFO is discarded. If the link count of the file is 0 when all file descriptors associated with the file have been closed, the space occupied by the file is freed, and the file is no longer accessible.

Note: If the *FileDescriptor* parameter refers to a device and the **close** subroutine actually results in a device **close**, and the device **close** routine returns an error, the error is returned to the application. However, the *FileDescriptor* parameter is considered closed and it may not be used in any subsequent calls.

All open file descriptors are closed when a process exits. In addition, file descriptors may be closed during the **exec** subroutine if the **close-on-exec** flag has been set for that file descriptor.

Parameters

Item	Description
FileDescriptor	Specifies a valid open file descriptor.

Return Values

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and the **errno** global variable is set to identify the error.

The underlying file system implementation might report any one of the values from the `/usr/include/errno.h` file to the **close** subroutine. The **close** subroutine returns a value of -1 and the **errno** global variable is set to the return value from the file system, but the file is still closed. The state of the *FileDescriptor* parameter is closed except for the conditions specified in the **Error Codes** section.

Error Codes

The **close** subroutine is unsuccessful if the following is true:

Item	Description
EBADF	The *FileDescriptor* parameter does not specify a valid open file descriptor.

The **close** subroutine may also be unsuccessful if the file being closed is NFS-mounted and the server is down under the following conditions:

- The file is on a hard mount.
- The file is locked in any manner.

The **close** subroutine may also be unsuccessful if NFS is installed and the following is true:

Item	Description
ETIMEDOUT	The connection timed out.

The success of the **close** subroutine is undetermined if the following is true:

Item	Description
EINTR	The state of the *FileDescriptor* is undetermined. Retry the **close** routine to ensure that the *FileDescriptor* is closed.

cnd_broadcast, cnd_destroy, cnd_init, cnd_signal, cnd_timedwait and cnd_wait Subroutine

Purpose

The **cnd_broadcast** subroutine unblocks all the threads that are blocked by using the *cond* condition variable.

The **cnd_destroy** subroutine releases all the resources that are used by the *cond* condition variable.

The **cnd_init** subroutine creates a *cond* condition variable.

The **cnd_signal** subroutine unblocks one of the threads that is blocked by using the condition that is specified by the *cond* parameter.

The **cnd_timedwait** subroutine unblocks the condition that is specified by the *cond* condition variable after a specified time indicated by the **ts** parameter.

The **cnd_wait** subroutine blocks the condition that is specified by the *cond* condition variable until it gets a signal from the **cnd_signal** or **cnd_broadcast** subroutines.

Library

Standard C library (**libc.a**)

Syntax

```
#include <threads.h>
int cnd_broadcast (cnd_t * cond);

void cnd_destroy (cnd_t * cond);

int cnd_init (cnd_t * cond);

int cnd_signal (cnd_t * cond);

int cnd_timedwait (cnd_t * restrict cond, mtx_t * restrict mtx, const struct timespec *
restrict ts);

int cnd_wait (cnd_t * cond, mtx_t * mtx);
```

Description

The **cnd_broadcast** subroutine unblocks all the threads that are blocked by using the condition variable specified by the **cond** parameter during the function call.

If no threads are blocked by using the condition variable specified by the **cond** parameter during the function call, the function is inactive.

The **cnd_destroy** subroutine releases all the resources that are used by the condition variable specified by the **cond** parameter.

The **cnd_destroy** subroutine requires that threads are not blocked while waiting for the condition variable specified by the **cond** parameter.

The **cnd_init** subroutine creates a condition variable. If the subroutine is successful, it sets the variable specified by the **cond** parameter to a value that uniquely identifies the newly created condition variable.

A thread that calls the **cnd_wait** subroutine on a newly created condition variable is blocked.

The **cnd_signal** subroutine unblocks one of the threads that are blocked by using the condition variable specified by the **cond** parameter during the function call. If threads are not blocked by using the condition variable during the function call, the function is inactive and returns success.

The **cnd_timedwait** and **cnd_wait** subroutine automatically unlocks and locks the mutex specified by the **mtx** parameter and tries to block until the condition variable pointed to by the **cond** is signaled by a call to the **cnd_signal** or **cnd_broadcast** subroutine, or until the **TIME_UTC** based calendar time is specified by the value of the **ts** parameter.

When the calling thread is unblocked, it locks the variable specified by the **mtx** parameter before it returns a value. The **cnd_timedwait** subroutine requires that the mutex specified by the **mtx** parameter is locked by the calling thread.

Parameters

Item	Description
cond	Specifies the condition variable to be created or released, depending on the type of the subroutine in which the parameter is referenced.
mtx	Specifies the mutex to be unlocked.
ts	Specifies the maximum time for the condition variable to be blocked.

Return Values

The **cnd_broadcast**, **cnd_signal**, and **cnd_wait** subroutine returns the value of **thrd_success** on success, and returns the value of **thrd_error** if the request cannot be processed.

The **cnd_destroy** subroutine returns no value.

The **cnd_init** subroutine returns the value of **thrd_success** on success.

The **cnd_init** subroutine returns the value of **thrd_nomem** if memory cannot be allocated for the newly created condition, and returns the value of **thrd_error** if the request cannot be processed.

The **cnd_timedwait** subroutine returns the value of **thrd_success** on success, or returns the value of **thrd_timedout** if the time specified in the call is reached without acquiring the requested resource, and returns the value of **thrd_error** if the request cannot be processed.

Files

The **threads.h** file defines standard macros, data types, and subroutines.

compare_and_swap and compare_and_swaplp Subroutines

Purpose

Conditionally updates or returns a variable atomically.

Library

Standard C library (**libc.a**)

Syntax

```
#include <sys/atomic_op.h>
boolean_t compare_and_swap ( addr, old_val_addr, new_val)
atomic_p addr;
int *old_val_addr;
int new_val;

boolean_t compare_and_swaplp ( addr, old_val_addr, new_val)
atomic_l addr;
long *old_val_addr;
long new_val;
```

Description

The **compare_and_swap** and **compare_and_swaplp** subroutines perform an atomic operation that compares the contents of a variable with a stored old value. If the values are equal, a new value is stored in the variable and **TRUE** is returned. If the values are not equal, the old value is set to the current value of the variable and **FALSE** is returned.

For 32-bit applications, the **compare_and_swap** and **compare_and_swaplp** subroutines are identical and operate on a word aligned single word (32-bit variable aligned on a 4-byte boundary).

For 64-bit applications, the **compare_and_swap** subroutine operates on a word aligned single word (32-bit variable aligned on a 4-byte boundary) and the **compare_and_swaplp** subroutine operates on a double word aligned double word (64-bit variable aligned on an 8-byte boundary).

The **compare_and_swap** and **compare_and_swaplp** subroutines are useful when a word value must be updated only if it has not been changed since it was last read.

Note: If the **compare_and_swap** or the **compare_and_swaplp** subroutine is used as a locking primitive, insert an **isync** at the start of any critical sections.

Parameters

Item	Description
addr	Specifies the address of the variable.
old_val_addr	Specifies the address of the old value to be checked against (and conditionally updated with) the value of the variable.
new_val	Specifies the new value to be conditionally assigned to the variable.

Return Values

Item	Description
TRUE	Indicates that the variable was equal to the old value, and has been set to the new value.
FALSE	Indicates that the variable was not equal to the old value, and that its current value has been returned to the location where the old value was previously stored.

compile, step, or advance Subroutine

Purpose

Compiles and matches regular-expression patterns.

Note: Commands use the **regcomp**, **regexec**, **regfree**, and **regerror** subroutines for the functions described in this article.

Library

Standard C Library (**libc.a**)

Syntax

```
#define INIT declarations
#define GETC( ) getc_code
#define PEEKC( ) peekc_code
#define UNGETC(c) ungetc_code
#define RETURN(pointer) return_code
#define ERROR(val) error_code
```

```
#include <regexp.h>
#include <NLregexp.h>
```

```
char *compile (InString, ExpBuffer, EndBuffer, EndOfFile)
char * ExpBuffer;
char  * InString, * EndBuffer;
int  EndOfFile;

int step (String, ExpBuffer)
const char * String, *ExpBuffer;
```

```
int advance (String, ExpBuffer)
const char *String, *ExpBuffer;
```

Description

The **/usr/include/regexp.h** file contains subroutines that perform regular-expression pattern matching. Programs that perform regular-expression pattern matching use this source file. Thus, only the **regexp.h** file needs to be changed to maintain regular expression compatibility between programs.

The interface to this file is complex. Programs that include this file define the following six macros before the **#include <regexp.h>** statement. These macros are used by the **compile** subroutine:

Item	Description
INIT	This macro is used for dependent declarations and initializations. It is placed right after the declaration and opening { (left brace) of the **compile** subroutine. The definition of the **INIT** buffer must end with a ; (semicolon). **INIT** is frequently used to set a register variable to point to the beginning of the regular expression so that this register variable can be used in the declarations for the **GETC**, **PEEKC**, and **UNGETC** macros. Otherwise, you can use **INIT** to declare external variables that **GETC**, **PEEKC**, and **UNGETC** require.
GETC( )	This macro returns the value of the next character in the regular expression pattern. Successive calls to the **GETC** macro should return successive characters of the pattern.
PEEKC( )	This macro returns the next character in the regular expression. Successive calls to the **PEEKC** macro should return the same character, which should also be the next character returned by the **GETC** macro.
UNGETC(*c***)**	This macro causes the parameter *c* to be returned by the next call to the **GETC** and **PEEKC** macros. No more than one character of pushback is ever needed, and this character is guaranteed to be the last character read by the **GETC** macro. The return value of the **UNGETC** macro is always ignored.
RETURN(*pointer***)**	This macro is used for normal exit of the **compile** subroutine. The *pointer* parameter points to the first character immediately following the compiled regular expression. This is useful for programs that have memory allocation to manage.

Item	Description
ERROR(*val***)**	This macro is used for abnormal exit from the **compile** subroutine. It should never contain a **return** statement. The *val* parameter is an error number. The error values and their meanings are: **Error** **Meaning** **11** Interval end point too large **16** Bad number **25** \ *digit* out of range **36** Illegal or missing delimiter **41** No remembered search String **42** \ (?\) imbalance **43** Too many \.(**44** More than two numbers given in \{ \} **45** } expected after \. **46** First number exceeds second in \{ \} **49** [ ] imbalance **50** Regular expression overflow **70** Invalid endpoint in range

The **compile** subroutine compiles the regular expression for later use. The *InString* parameter is never used explicitly by the **compile** subroutine, but you can use it in your macros. For example, you can use the **compile** subroutine to pass the string containing the pattern as the *InString* parameter to **compile** and use the **INIT** macro to set a pointer to the beginning of this string. The example in the "Examples" on page 189 section uses this technique. If your macros do not use *InString*, then call **compile** with a value of **((char *) 0)** for this parameter.

The *ExpBuffer* parameter points to a character array where the compiled regular expression is to be placed. The *EndBuffer* parameter points to the location that immediately follows the character array where the compiled regular expression is to be placed. If the compiled expression cannot fit in (*EndBuffer-ExpBuffer*) bytes, the call **ERROR(***50***)** is made.

The *EndOfFile* parameter is the character that marks the end of the regular expression. For example, in the **ed** command, this character is usually / (slash).

The **regexp.h** file defines other subroutines that perform actual regular-expression pattern matching. One of these is the **step** subroutine.

The *String* parameter of the **step** subroutine is a pointer to a null-terminated string of characters to be checked for a match.

The *Expbuffer* parameter points to the compiled regular expression, obtained by a call to the **compile** subroutine.

The **step** subroutine returns the value 1 if the given string matches the pattern, and 0 if it does not match. If it matches, then **step** also sets two global character pointers: **loc1**, which points to the first character that matches the pattern, and **loc2**, which points to the character immediately following the last character that matches the pattern. Thus, if the regular expression matches the entire string, **loc1** points to the first character of the *String* parameter and **loc2** points to the null character at the end of the *String* parameter.

The **step** subroutine uses the global variable **circf**, which is set by the **compile** subroutine if the regular expression begins with a ^ (circumflex). If this variable is set, **step** only tries to match the regular expression to the beginning of the string. If you compile more than one regular expression before executing the first one, save the value of **circf** for each compiled expression and set **circf** to that saved value before each call to **step**.

Using the same parameters that were passed to it, the **step** subroutine calls a subroutine named **advance**. The **step** function increments through the *String* parameter and calls the **advance** subroutine until it returns a 1, indicating a match, or until the end of *String* is reached. To constrain the *String* parameter to the beginning of the string in all cases, call the **advance** subroutine directly instead of calling the **step** subroutine.

When the **advance** subroutine encounters an * (asterisk) or a \{ \} sequence in the regular expression, it advances its pointer to the string to be matched as far as possible and recursively calls itself, trying to match the rest of the string to the rest of the regular expression. As long as there is no match, the **advance** subroutine backs up along the string until it finds a match or reaches the point in the string that initially matched the * or \{ \}. You can stop this backing-up before the initial point in the string is reached. If the **locs** global character is equal to the point in the string sometime during the backing-up process, the **advance** subroutine breaks out of the loop that backs up and returns 0. This is used for global substitutions on the whole line so that expressions such as `s/y*//g` do not loop forever.

Note: In 64-bit mode, these interfaces are not supported: they fail with a return code of 0. In order to use the 64-bit version of this functionality, applications should migrate to the **fnmatch**, **glob**, **regcomp**, and **regexec** functions which provide full internationalized regular expression functionality compatible with ISO 9945-1:1996 (IEEE POSIX 1003.1) and with the UNIX98 specification.

Parameters

Item	Description
InString	Specifies the string containing the pattern to be compiled. The *InString* parameter is not used explicitly by the **compile** subroutine, but it may be used in macros.
ExpBuffer	Points to a character array where the compiled regular expression is to be placed.
EndBuffer	Points to the location that immediately follows the character array where the compiled regular expression is to be placed.
EndOfFile	Specifies the character that marks the end of the regular expression.
String	Points to a null-terminated string of characters to be checked for a match.

Examples

The following is an example of the regular expression macros and calls:

```
#define INIT         register char *sp=instring;
#define GETC()         (*sp++)
#define PEEKC()         (*sp)
#define UNGETC(c)      (--sp)
#define RETURN(c)      return;
#define ERROR(c)      regerr()

#include <regexp.h>
 . . .
compile (patstr,expbuf, &expbuf[ESIZE], '\0');
```

```
 . . .
if (step (linebuf, expbuf))
   succeed( );
 . . .
```

confstr Subroutine

Purpose

Gets configurable variables.

Library

Standard C library (**libc.a**)

Syntax

#include <unistd.h>

size_t confstr (int *name*, *char* ***** *buf*, size_t *len* **);**

Description

The **confstr** subroutine determines the current setting of certain system parameters, limits, or options that are defined by a string value. It is mainly used by applications to find the system default value for the **PATH** environment variable. Its use and purpose are similar to those of the **sysconf** subroutine, but it returns string values rather than numeric values.

If the *Len* parameter is not 0 and the *Name* parameter has a system-defined value, the **confstr** subroutine copies that value into a *Len*-byte buffer pointed to by the *Buf* parameter. If the string returns a value longer than the value specified by the *Len* parameter, including the terminating null byte, then the **confstr** subroutine truncates the string to *Len*-1 bytes and adds a terminating null byte to the result. The application can detect that the string was truncated by comparing the value returned by the **confstr** subroutine with the value specified by the *Len* parameter.

Parameters

Item	Description
Name	Specifies the system variable setting to be returned. Valid values for the *Name* parameter are defined in the **unistd.h** file.
Buf	Points to the buffer into which the **confstr** subroutine copies the value of the *Name* parameter.
Len	Specifies the size of the buffer storing the value of the *Name* parameter.

Return Values

If the value specified by the *Name* parameter is system-defined, the **confstr** subroutine returns the size of the buffer needed to hold the entire value. If this return value is greater than the value specified by the *Len* parameter, the string returned as the *Buf* parameter is truncated.

If the value of the *Len* parameter is set to 0 and the *Buf* parameter is a null value, the **confstr** subroutine returns the size of the buffer needed to hold the entire system-defined value, but does not copy the string value. If the value of the *Len* parameter is set to 0 but the *Buf* parameter is not a null value, the result is unspecified.

Error Codes

The **confstr** subroutine will fail if:

Item	Description
EINVAL	The value of the name argument is invalid.

Example

To find out what size buffer is needed to store the string value of the *Name* parameter, enter:

```
confstr(_CS_PATH, NULL, (size_t) 0)
```

The **confstr** subroutine returns the size of the buffer.

Files

Item	Description
/usr/include/limits.h	Contains system-defined limits.
/usr/include/unistd.h	Contains system-defined environment variables.

conj, conjf, or conjl Subroutine

Purpose

Computes the complex conjugate.

Syntax

```
#include <complex.h>

double complex conj (z)
double complex z;

float complex conjf (z)
float complex z;

long double complex conjl (z)
long double complex z;
```

Description

The **conj**, **conjf**, or **conjl** subroutines compute the complex conjugate of *z*, by reversing the sign of its imaginary part.

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

The **conj**, **conjf**, or **conjl** subroutines return the complex conjugate value.

color_content Subroutine

Purpose

Returns the current intensity of the red, green, and blue (RGB) components of a color.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
color_content(Color,  R, G,
B)
short   Color;
short  *R, * G, * B;
```

Description

The **color_content** subroutine, given a color number, returns the current intensity of its red, green, and blue (RGB) components. This subroutine stores the information in the address specified by the *R*, *G*, and *B* arguments. If successful, this returns OK. Otherwise, this subroutine returns ERR if the color does not exist, is outside the valid range, or the terminal cannot change its color definitions.

To determine if you can change the color definitions for a terminal, use the **can_change_color** subroutine. You must call the **start_color** subroutine before you can call the **color_content** subroutine.

Note: The values stored at the addresses pointed to by *R*, *G*, and *B* are between 0 (no component) and 1000 (maximum amount of component) inclusive.

Return Values

Item	Description
OK	Indicates the subroutine was successful.
ERR	Indicates the color does not exist, is outside the valid range, or the terminal cannot change its color definitions.

Parameters

Item	Description
B	Points to the address that stores the intensity value of the blue component.
Color	Specifies the color number. The color parameter must be a value between **0** and **COLORS-1** inclusive.
R	Points to the address that stores the intensity value of the red component.
G	Points to the address that stores the intensity value of the green component.

Example

To obtain the RGB component information for color 10 (assuming the terminal supports at least 11 colors), use:

```
short *r, *g, *b; color_content(10,r,g,b);
```

conv Subroutines

Purpose

Translates characters.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <ctype.h>

int toupper ( Character)
int Character;

int tolower (Character)
int Character;

int _toupper (Character)
int Character;

int _tolower (Character)
int Character;

int toascii (Character)
int Character;

int NCesc ( Pointer,  CharacterPointer)
NLchar *Pointer;
char *CharacterPointer;

int NCtoupper ( Xcharacter)
int Xcharacter;

int NCtolower (Xcharacter)
int Xcharacter;

int _NCtoupper (Xcharacter)
int Xcharacter;

int _NCtolower (Xcharacter)
int Xcharacter;

int NCtoNLchar (Xcharacter)
int Xcharacter;

int NCunesc (CharacterPointer, Pointer)
char *CharacterPointer;
NLchar *Pointer;

int NCflatchr (Xcharacter)
int Xcharacter;
```

Description

The **toupper** and the **tolower** subroutines have as domain an **int**, which is representable as an unsigned **char** or the value of **EOF**: -1 through 255.

If the parameter of the **toupper** subroutine represents a lowercase letter and there is a corresponding uppercase letter (as defined by **LC_CTYPE**), the result is the corresponding uppercase letter. If the parameter of the **tolower** subroutine represents an uppercase letter, and there is a corresponding lowercase letter (as defined by **LC_CTYPE**), the result is the corresponding lowercase letter. All other values in the domain are returned unchanged. If case-conversion information is not defined in the current locale, these subroutines determine character case according to the "C" locale.

The **_toupper** and **_tolower** subroutines accomplish the same thing as the **toupper** and **tolower** subroutines, but they have restricted domains. The **_toupper** routine requires a lowercase letter as its parameter; its result is the corresponding uppercase letter. The **_tolower** routine requires an uppercase letter as its parameter; its result is the corresponding lowercase letter. Values outside the domain cause undefined results.

The **NC***xxxxxx* subroutines translate all characters, including extended characters, as code points. The other subroutines translate traditional ASCII characters only. The **NC***xxxxxx* subroutines are obsolete and should not be used if portability and future compatibility are a concern.

The value of the *Xcharacter* parameter is in the domain of any legal **NLchar** data type. It can also have a special value of -1, which represents the end of file **(EOF)**.

If the parameter of the **NCtoupper** subroutine represents a lowercase letter according to the current collating sequence configuration, the result is the corresponding uppercase letter. If the parameter of the **NCtolower** subroutine represents an uppercase letter according to the current collating sequence configuration, the result is the corresponding lowercase letter. All other values in the domain are returned unchanged.

The **_NCtoupper** and **_NCtolower** routines are macros that perform the same function as the **NCtoupper** and **NCtolower** subroutines, but have restricted domains and are faster. The **_NCtoupper** macro requires a lowercase letter as its parameter; its result is the corresponding uppercase letter. The **_NCtolower** macro requires an uppercase letter as its parameter; its result is the corresponding lowercase letter. Values outside the domain cause undefined results.

The **NCtoNLchar** subroutine yields the value of its parameter with all bits turned off that are not part of an **NLchar** data type.

The **NCesc** subroutine converts the **NLchar** value of the *Pointer* parameter into one or more ASCII bytes stored in the character array pointed to by the *CharacterPointer* parameter. If the **NLchar** data type represents an extended character, it is converted into a printable ASCII escape sequence that uniquely identifies the extended character. **NCesc** returns the number of bytes it wrote. The display symbol table lists the escape sequence for each character.

The opposite conversion is performed by the **NCunesc** macro, which translates an ordinary ASCII byte or escape sequence starting at *CharacterPointer* into a single **NLchar** at *Pointer*. **NCunesc** returns the number of bytes it read.

The **NCflatchr** subroutine converts its parameter value into the single ASCII byte that most closely resembles the parameter character in appearance. If no ASCII equivalent exists, it converts the parameter value to a ? (question mark).

Note: The **setlocale** subroutine may affect the conversion of the decimal point symbol and the thousands separator.

Parameters

Item	Description
Character	Specifies the character to be converted.
Xcharacter	Specifies an **NLchar** value to be converted.

Item	Description
CharacterPointer	Specifies a pointer to a single-byte character array.
Pointer	Specifies a pointer to an escape sequence.

copysign, copysignf, copysignl , copysignd32, copysignd64, and copysignd128 Subroutines

Purpose

Perform number manipulation.

Syntax

```
#include <math.h>

double copysign (x, y)
double x, double y;

float copysignf (x, y)
float x, float y;

long double copysignl (x, y)
long double x, long double y;

_Decimal32 copysignd32(x, y)
_Decimal32 x;
_Decimal32 y;

_Decimal64 copysignd64(x, y)
_Decimal64 x;
_Decimal64 y;

_Decimal128 copysignd128(x, y)
_Decimal128 x;
_Decimal128 y;
```

Description

The **copysign**, **copysignf**, **copysignl**, **copysignd32**, **copysignd64**, and **copysignd128** subroutines produce a value with the magnitude of *x* and the sign of *y*.

Parameters

Item	Description
x	Specifies the magnitude.
y	Specifies the sign.

Return Values

Upon successful completion, the **copysign**, **copysignf**, **copysignl**, **copysignd32**, **copysignd64**, and **copysignd128** subroutines return a value with a magnitude of *x* and a sign of *y*.

copywin Subroutine

Purpose

Copies a region of a window.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

int copywin(const WINDOW  *scrwin,
WINDOW  *dstwin,
int  sminrow,
int  smincol,
int  dminrow,
int  dmincol,
int  dmaxrow,
int  dmaxcol,
int  overlay);
```

Description

The **copywin** subroutine provides a finer granularity of control over the **overlay** and **overwrite** subroutines. As in the **prefresh** subroutine, a rectangle is specified in the destination window, (*dimrow*, *dimincol*) and (*dmaxrow*, *dmaxcol*), and the upper-left-corner coordinates of the source window, (*sminrow*, *smincol*). If the **overlay** subroutine is TRUE, then copying is non-destructive, as in the **overlay** subroutine. If the **overlay** subroutine is FALSE, then copying is destructive, as in the **overwrite** subroutine.

Parameters

Item	Description
**srcwin*	Points to the source window containing the region to copy.
**dstwin*	Points to the destination window to copy into.
sminrow	Specifies the upper left row coordinate of the source region.
smincol	Specifies the upper left column coordinate of the source region.
dminrow	Specifies the upper left row coordinate of the destination region.
dmincol	Specifies the upper left column coordinate for the destination region.
dmaxrow	Specifies the lower right row coordinate for the destination region.
dmaxcol	Specifies the lower right column coordinate for the destination region.
overlay	Sets the type of copy. If set to TRUE the copy is nondestructive. Otherwise, if set to FALSE, the copy is destructive.

Return Values

Upon successful completion, the **copywin** subroutine returns OK. Otherwise, it returns ERR.

Examples

To copy to an area in the destination window defined by coordinates (30,40), (30,49), (39,40), and (39,49) beginning with coordinates (0,0) in the source window, enter the following:

```
WINDOW *srcwin, *dstwin;

copywin(srcwin, dstwin,
```

```
 0, 0, 30,40, 39, 49,
  TRUE);
```

The example copies ten rows and ten columns from the source window beginning with coordinates (0,0) to the region in the destination window defined by the upper left coordinates (30, 40) and lower right coordinates (39, 49). Because the Overlay parameter is set to TRUE, the copy is nondestructive and blanks from the source window are not copied.

coredump Subroutine

Purpose

Creates a **core** file without terminating the calling process.

Library

Standard C library (**libc.a**)

Syntax

```
#include <core.h>

int coredump( coredumpinfop)
struct coredumpinfo *coredumpinfop ;
```

Description

The **coredump** subroutine creates a **core** file of the calling process without terminating the calling process. The created **core** file contains the memory image of the process, and this can be used with the **dbx** command for debugging purposes. In multithreaded processes, only one thread at a time should attempt to call this subroutine. Subsequent calls to **coredump** while a core dump (initiated by another thread) is in progress will fail.

Applications expected to use this facility need to be built with the **-bM:UR binder** flag, otherwise the routine will fail with an error code of **ENOTSUP**.

The **coredumpinfo** structure has the following fields:

Member Type	Member Name	Description
unsigned int	length	Length of the **core** file name
char *	name	Points to a character string that contains the name of the **core** file
int	reserved[8]	Reserved fields for future use

Parameters

Item	Description
coredumpinfop	Points to the **coredumpinfo** structure

If a NULL pointer is passed as an argument, the default file named **core** in the current directory is used.

Return Values

Upon successful completion, the **coredump** subroutine returns a value of 0. If the **coredump** subroutine is not successful, a value of -1 is returned and the **errno** global variable is set to indicate the error

Error Codes

Item	Description
EINVAL	Invalid argument.
EACCES	Search permission is denied on a component of the path prefix, the file exists and the pwrite permission is denied, or the file does not exist and write permission is denied for the parent directory of the file to be created.
EINPROGRESS	A core dump is already in progress.
ENOMEM	Not enough memory.
ENOTSUP	Routine not supported.
EFAULT	Invalid user address.

cosf, cosl, cos, cosd32, cosd64, and cosd128 Subroutines

Purpose

Computes the cosine.

Syntax

```
#include <math.h>

float cosf (x)
float x;

long double cosl (x)
long double x;

double cos (x)
double x;
_Decimal32 cosd32 (x)
_Decimal32 x;

_Decimal64 cosd64 (x)
_Decimal64 x;

_Decimal128 cosd128 (x)
_Decimal128 x;
```

Description

The **cosf**, **cosl**, **cos**, **cosd32**, **cosd64**, and **cosd218** subroutines compute the cosine of the *x*, parameter (measured in radians).

An application wishing to check for error situations should set **errno** to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **cosf**, **cosl**, **cos**, **cosd32**, **cosd64**, and **cosd128** subroutines return the cosine of *x*.

If *x* is NaN, a NaN is returned.

If *x* is ±0, the value 1.0 is returned.

If *x* is ±Inf, a domain error occurs, and a NaN is returned.

cosh, coshf, coshl, coshd32, coshd64, and coshd128 Subroutines

Purpose

Computes the hyperbolic cosine.

Syntax

```
#include <math.h>

float coshf (x)
float x;

long double coshl (x)
long double x;

double cosh (x)
double x;
_Decimal32 coshd32 (x)
_Decimal32 x;

_Decimal64 coshd64 (x)
_Decimal64 x;

_Decimal128 coshd128 (x)
_Decimal128 x;
```

Description

The **coshf**, **coshl**, **cosh**, **coshd32**, **coshd64**, and **coshd128** subroutines compute the hyperbolic cosine of the *x* parameter.

An application wishing to check for error situations should set **errno** to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these functions. On return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **coshf**, **coshl**, **cosh**, **coshd32**, **coshd64**, and **coshd128** subroutines return the hyperbolic cosine of *x*.

If the correct value would cause overflow, a range error occurs and the **coshf**, **coshl**, **cosh**, **coshd32**, **coshd64**, and **coshd128** subroutines return the value of the macro **HUGE_VALF**, **HUGE_VALL**, **HUGE_VAL**, **HUGE_VAL_D32**, **HUGE_VAL_D64**, and **HUGE_VAL_D128** respectively.

If *x* is NaN, a NaN is returned.

If *x* is ±0, the value 1.0 is returned.

If *x* is ±Inf, +Inf is returned.

cpfile Subroutine

Purpose

Optimized copy operation of contents from the source file to the destination file.

Library

Standard C Library (`libc.a`)

Syntax

```
#include <unistd.h>

int cpfile(sfd, dfd, offset, nbytesp, flags)
int        sfd;
int        dfd;
off64_t    offset;
size64_t  *nbytesp;
uint64_t   flags;
```

Description

The **cpfile** subroutine copies `nbytes` data from the opened source file (ID specified in the *sfd* parameter) to the opened destination file (ID specified by the *dfd* parameter). The **cpfile** subroutine copies only regular files. The **cpfile** subroutine can copy files from one local file system, network file system (NFS) or, mounted file system to other file systems. If this function is used for any other type of file or file system, an error is returned.

The `offset` argument specifies where to begin the read operation from the source file and it starts writing to the same `offset` value in the destination file unless the destination file is opened in the append mode (by using **O_APPEND** flag). If the `offset` value is negative or indicates a position that is beyond the end of source file, an error is returned.

The *nbytesp* argument is an input and output argument. Basically this argument is used to pass the value also to return a value. For an input operation the address points to the number of bytes to be copied from the specified `offset` value. The value 0 copies the entire file (or until end of file, if the offset value is nonzero). Fewer bytes might be copied than requested because of the following reasons:

- Insufficient space to write in the destination file.
- Insufficient memory to allocate temporary buffers.
- Upper limit is reached or a pending signal is detected.

The error value of -1 is returned and the `errno` global variable is set to indicate the failure of copy operation. On return, the *nbytesp* value specifies how many bytes are successfully copied before the subroutine returned from the call.

If the **cpfile** subroutine is interrupted by any signal, it returns from kernel space to user space to handle the signal. The error number points to the EINTR value and the *nbytesp* value indicates the number of bytes copied before the **cpfile** subroutine was interrupted. If you want the application to continue copying bytes of data from the source file after the signal is handled, call the **cpfile** subroutine again with a new offset value and length.

Note: If the application restarts the operation where it stopped, it might need to specify the NO_DEST_FSIZE_CHECK flag because the destination file size might not be zero after the application returns from the first call.

The **flags** argument is used to control the behavior of the call to **cpfile** subroutine. Specify the value as 0 provided, if you do not want to use the flag. Any other value indicates a valid flag. Multiple flag values can be passed together as bits.

Supported options for flag values are as follows:

SPARSE_DEST_FILE
Source file blocks that have all zero strings are set by using the `fclear` operation instead of the write operation on the destination file. If source file is sparse then destination file also becomes sparse after the copy operation.

NO_DEST_FSIZE_CHECK
The `cpfile` subroutine must not check the size of any destination file. If this flag is set the **cpfile** subroutine overwrites the contents of destination file.

Consider the following information about the **cpfile** subroutine:

- The **cpfile** subroutine is used for one of the following purposes:
  - The **cpfile** subroutine is used to create identical copy of the source file. Destination file size must be zero, less than, or equal to source file size.

    Note: If destination file size is non-zero then **NO_DEST_FSIZE_CHECK** flag must be turned on. The **cpfile** subroutine does not explicitly truncate the destination file. Therefore the application must truncate the destination file to zero, less than, or equal to the source file size before the call. A non-zero sized destination file that is opened in append mode does not create an identical copy of the source file after the copy operation is complete.
  - The **cpfile** subroutine is used to replace the portion of the destination file at the offset value that is specified by the `offset` parameter by the portion of the source file at the same offset value. Therefore, the destination file size can be nonzero. In this case, the application must turn on the **NO_DEST_FSIZE_CHECK** flag.
  - The **cpfile** subroutine is used to concatenate the content of source file with the content of destination file. In this case, the application must open destination file in append mode (by using the **O_APPEND** flag) and the **NO_DEST_FSIZE_CHECK** flag must be turned on because the destination file size is nonzero. The **cpfile** subroutine starts appending data from the source file to the end of the destination file.
- The **cpfile** subroutine can be used in a multi-threaded environment.
- When the subroutine is copying data, a parallel write operation on the source file, or the destination file might result in an unexpected result.
- If the **SPARSE_DEST_FILE** flag is specified, the **cpfile** subroutine optimizes the copy operation of the source file by skipping the block that has all zero strings in the source file by using the **fclear** flag instead of performing the write operation on the destination file.
- The **cpfile** subroutine does not copy any attributes, extended attributes, access control lists (ACLs) from the source file to the destination file. You must manually copy these attributes, if required.
- If system call detects any pending signal, the **cpfile** subroutine returns from kernel space to user space to handle the signal for an application. If application continues the copy operation after the pending signal is processed, application must call the **cpfile** subroutine again with a new offset value and length. New offset value indicates that from where to continue the copy operation and new length indicates the bytes to be copied from the specified offset.

  Note: The application might need to specify the **NO_DEST_FSIZE_CHECK** flag for consecutive calls because the destination file size might be non-zero after the previous call to the **cpfile** subroutine.
- By default, the **cpfile** subroutine expects the destination file size to be zero. If the application wants to work with the destination file of size non-zero, the application must pass the **NO_DEST_FSIZE_CHECK** flag to avoid failure. If application wants to concatenate the source file with the destination file, it must open the destination file in append mode (by using the**O_APPEND** flag) and call the **cpfile** subroutine with the **NO_DEST_FSIZE_CHECK** flag turned on.

  Note: If the application specifies the **NO_DEST_FSIZE_CHECK** flag, the destination file size is not checked. Hence, if the destination file is larger than source file, data in the destination file, which is located after an offset equal to the source file size is not modified by the **cpfile** subroutine.

Parameters

sfd
Specifies the file descriptor for the source file.

dfd
Specifies the file descriptor for the destination file.

Offset
Specifies the position in the source file from where to read the data and the position in the destination file where to start writing the data.

nbytesp
Specifies the input value or output value. This argument specifies the number of bytes to be copied. The value 0 copies the entire file. This argument returns the number of bytes that are copied.

flags
Specifies flag values as defined by parameters of the subroutine in the description section.

Return values

Upon successful completion, the call to the **cpfile** subroutine returns 0. The number of bytes that is copied to the destination file is must not be greater than the value specified by the *nbytes* parameter. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate an error. In both the cases, the *nbytesp* variable has the value of number of bytes that was copied to the destination file.

Error codes

The **cpfile** subroutine is unsuccessful when one or more of the following error codes are true. File system can generate errors other than the errors specified in the following list:

EBADF
The file descriptor parameter is not valid.

EINTR
The operation was interrupted by a signal.

EINVAL
The offset, length, or flags parameter is invalid or the *nbytesp* parameter is null. If destination file size is nonzero and if the **NO_DEST_FSIZE_CHECK** flag is not set, the **EINVAL** error code is returned.

ENOMEM
No memory is available in the system to perform the I/O operation.

EFBIG
An offset value greater than the **MAX_FILESIZE** value was requested.

EAGAIN
The source or destination file was changed unexpectedly. Error code indicates that the `cpfile` subroutine must be called again.

Example

The following code fragment shows the optimized method to copy file by using the **cpfile** subroutine:

```
#include <unistd.h>
int main (int argc, char **argv)
{
       int sfd, dfd;
       size64_t  nbytes = 0;
       uint64_t  flags = 0;
       off64_t   offset = 0;

       /* Open source file */
       sfd = open(argv[0], O_RDONLY, 0);
       if (sfd < 0)
       {
             perror("open");
```

```
                exit(-1);
        }
        /* Open destination file. Create if not exist and truncate to zero size. */
        dfd = open(argv[1],O_RDWR|O_CREAT|O_TRUNC, 0644);
        if (dfd < 0)
        {
                perror("open");
                exit(-1);
        }

        /* Perform any other tasks like copying attributes */
        /* Call cpfile to copy whole file. */
        rc = cpfile(sfd, dfd, offset, &nbytes, flags);
        {
                perror("cpfile");
                exit(-1);
        }
        close(sfd);
        close(dfd);
}
```

cpow, cpowf, or cpowl Subroutine

Purpose

Computes the complex power.

Syntax

```
#include <complex.h>

double complex cpow (x, y)
double complex x;
double complex y;

float complex cpowf (x, y)
float complex x;
float complex y;

long double complex cpowl (x, y)
long double complex x;
long double complex y;
```

Description

The **cpow**, **cpowf**, and **cpowl** subroutines compute the complex power function x^y, with a branch cut for the first parameter along the negative real axis.

Parameters

Item	Description
x	Specifies the base value.
y	Specifies the power the base value is raised to.

Return Values

The **cpow**, **cpowf**, and **cpowl** subroutines return the complex power function value.

cproj, cprojf, or cprojl Subroutine

Purpose

Computes the complex projection functions.

Syntax

```
#include <complex.h>

double complex cproj (z)
double complex z;

float complex cprojf (z)
float complex z;

long double complex cprojl (z)
long double complex z;
```

Description

The **cproj**, **cprojf**, and **cprojl** subroutines compute a projection of *z* onto the Riemann sphere: *z* projects to *z*, except that all complex infinities (even those with one infinite part and one NaN part) project to positive infinity on the real axis. If *z* has an infinite part, **cproj**(*z*) shall be equivalent to:

```
INFINITY + I * copysign(0.0, cimag(z))
```

Parameters

Item	Description
z	Specifies the value to be projected.

Return Values

The **cproj**, **cprojf**, and **cprojl** subroutines return the value of the projection onto the Riemann sphere.

cpu_context_barrier and cpu_speculation_barrier Subroutines

Purpose

Provides protection against speculative execution side-channel attacks.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/processor.h>
```

void cpu_context_barrier (int *value*)

void cpu_speculation_barrier (*void*)

Description

The **cpu_context_barrier** and **cpu_speculation_barrier** subroutines provide applications with processor-model-dependent mitigation against known speculative-execution vulnerabilities. These subroutines can be used by both 32-bit and 64-bit applications to protect applications against data-dependent storage access and to provide isolation between the trusted and untrusted segments of an application.

Note: Application performance might reduce when the **cpu_context_barrier** or **cpu_speculation_barrier** subroutine is used.

The **cpu_context_barrier** subroutine must be called from within the trusted domain and must be executed at each transition between the trusted domain and the untrusted domain. This subroutine accepts a single parameter that specifies the method in which the subroutine is used. Alternatively, a comprehensive variation of the barrier kernel subroutine can be used for scenarios where it is difficult to distinguish the method in which the subroutine must be used.

The **cpu_speculation_barrier** subroutine must be called from within the trusted domain before storage is accessed by using addresses that are computed from an untrusted source.

Parameters

Item	Description
value	Specifies the method in which the barrier subroutine is being invoked.

CPU context barrier values

Item	Description
CCB_ENTRY	Specify this value when transitioning into a trusted context domain.
CCB_EXIT	Specify this value when transitioning out of a trusted context domain.
CCB_ALL	Specify this value when transitioning into a trusted context domain or transitioning out of a trusted context domain.

Example

The following example shows how the trusted domain of an application calls an untrusted domain:

```
int                index;
char               val,
                   udata[];
extern int         max_tdata_index;
extern char        tdata[];

/* Fetch index from untrusted user */
cpu_context_barrier(CCB_EXIT);
index = get_index_from_user(...);
cpu_context_barrier(CCB_ENTRY);

/* Select trusted data from user input */
if (index < max_tdata_index) {
        cpu_speculation_barrier();
        val = tdata[index];
        udata[val]++;
}
```

cpuextintr_ctl Subroutine

Purpose

Performs Central Processing Unit (CPU) external interrupt control related operations on CPUs.

Library

Standard C library (**libc.a**)

Syntax

```
#include <sys/intr.h>

int cpuextintr_ctl(command,cpuset,flags)
```

```
extintrctl_t command;
rsethandle_t cpuset;
uint flags;
```

Description

The **cpuextintr_ctl** subroutine provides means of enabling, disabling, and querying the external interrupt state on the CPUs described by the CPU resource set. If you enable or disable a CPU's external interrupt, it affects the external interrupt delivery to the CPU. Typically, on multiple CPU system, external interrupts can be delivered to any running CPU, and the distribution among the CPUs is determined by a predefined method. Any external interrupt can only be delivered to a CPU if its interrupt priority is more favored than the current external interrupt priority of the CPU. When external interrupts are disabled through this interface, any external interrupt priority that is less favored than INTMAX is blocked until interrupts are enabled again. The **cpuextintr_ctl** subroutine is applicable only on selective hardware types.

Note: Because this subroutine changes the way external interrupt is delivered, system performance can be affected. This service guarantees at least one online CPU is available to handle all the external interrupts. Any CPU DLPAR removal fails if the operation breaks such rule. On an I/O bound system, one CPU might not be enough to handle all the external interrupts. Performance suffers due to insufficient CPU available to handle external interrupts.

Parameters

Item	Description
command	Specifies the operation to the CPUs specified by CPU resource set. One of the following values that are defined in **<sys/intr.h>** file can be used: **EXTINTDISABLE** Disable external interrupt on the CPUs specified by the CPU resource set. **EXTINTENABLE** Enable external interrupt on the CPUs specified by the CPU resource set. **QUERYEXTINTDISABLE** Returns a CPU resource set that have the CPUs with external interrupt as disabled. **QUERYEXTINTENABLE** Returns a CPU resource set that have the CPUs with external interrupt as enabled.
cpuset	Reference to a CPU resource set. Upon successful return from this kernel service, the CPUs, for which the external interrupt control operation is complete are set in the CPU resource set. The CPUs specified by the **cpuset** parameter are logical CPU IDs.
flags	Always set to 0 or EINVAL is returned.

Security

The caller must have root authority with the **CAP_NUMA_ATTACH** capability or **PV_KER_CONF** privilege in the RBAC environment.

Return Values

Upon successful completion, the **cpuextintr_ctl** subroutine returns the number of CPUs on which the command successfully completed. If unsuccessful, -1 is returned and the errno global variable is set to indicate the error.

Error Codes

Item	Description
EINVAL	The command is not valid, the **cpuset** references NULL, the **cpuset** is empty, or the flags value is unknown.
EFAULT	The **cpuset** buffer passed in is not valid.
ENOSYS	This function is not implemented on the platform.
EPERM	Caller does not have enough privilege to perform the requested operation.

Note: A return value of success does not necessarily indicate that external interrupts have been enabled or disabled on all of the specified CPUs. For example, if a CPU is not online, the enable or disable operation will not be performed on that CPU. The caller must check the returned cpuset to verify the completion of this operation on the CPUs. The **k_cpuextintr_ctl** kernel service does not block DR CPU add or remove operation during the entire period of system call.

creal, crealf, or creall Subroutine

Purpose

Computes the real part of a specified value.

Syntax

```
#include <complex.h>

double creal (z)
double complex z;

float crealf (z)
float complex z;

long double creall (z)
long double complex z;
```

Description

The **creal**, **crealf**, and **creall** subroutines compute the real part of the value specified by the *z* parameter.

Parameters

Item	Description
z	Specifies the real to be computed.

Return Values

These subroutines return the real part value.

crypt, encrypt, or setkey Subroutine

Purpose

Encrypts or decrypts data.

Library

Standard C Library (**libc.a**)

Syntax

```
char *crypt (PW, Salt)
const char * PW, * Salt;

void encrypt (Block, EdFlag)
char Block[64];
int EdFlag;

void setkey (Key)
const char * Key;
```

Description

The **crypt** and **encrypt** subroutines encrypt or decrypt data. The **crypt** subroutine performs a one-way encryption of a fixed data array with the supplied *PW* parameter. The subroutine uses the *Salt* parameter to vary the encryption algorithm.

The **encrypt** subroutine encrypts or decrypts the data supplied in the *Block* parameter using the key supplied by an earlier call to the **setkey** subroutine. The data in the *Block* parameter on input must be an array of 64 characters. Each character must be an char 0 or char 1.

If you need to statically bind functions from **libc.a** for **crypt** do the following:

1. Create a file and add the following:

   ```
   #!
   ___setkey
   ___encrypt
   ___crypt
   ```

2. Perform the linking.
3. Add the following to the make file:

   ```
   -bI:YourFileName
   ```

   where *YourFileName* is the name of the file you created in step 1. It should look like the following:

   ```
   LDFLAGS=bnoautoimp -bI:/lib/syscalls.exp -bI:YourFileName -lc
   ```

These subroutines are provided for compatibility with UNIX system implementations.

Parameters

Item	Description
Block	Identifies a 64-character array containing the values (**char**) 0 and (**char**) 1. Upon return, this buffer contains the encrypted or decrypted data.
EdFlag	Determines whether the subroutine encrypts or decrypts the data. If this parameter is 0, the data is encrypted. If this parameter is a nonzero value, the data is decrypted. If the **/usr/lib/libdes** or **/usr/lib/libdes_64** file does not exist and if the *EdFlag* parameter is set to a nonzero value, the **encrypt** subroutine returns the **ENOSYS** error code. The **/usr/lib/libdes** and **/usr/lib/libdes_64** files are part of the **des** fileset, which is located in the AIX Expansion Pack.
Key	Specifies an 64-element array of 0's and 1's cast as a **const char** data type. The *Key* parameter is used to encrypt or decrypt data.

Item	Description
PW	Specifies the string to be encrypted.
Salt	Determines the algorithm that the *PW* parameter applies to generate the returned output string. If the left brace ({) is not the first character of the value that the *Salt* parameter specifies, then the subroutine uses the Data Encryption Standard (DES) algorithm. For the DES algorithm, use the *Salt* parameter to vary the hashing algorithm in the one of 4096 ways. The *Salt* parameter must be a 2-character string that is from the following character types: **A-Z** Uppercase alpha characters **a-z** Lowercase alpha characters **0-9** Numeric characters **.** Period **/** Slash If the left brace ({) is the first character of the value that the *Salt* parameter specifies, then the Loadable Password Algorithm (LPA) uses the name that is specified within the braces ({}). A set of salt characters follows the LPA name and ends with a dollar sign ($). The length of the salt character depends on the specified LPA. The following example shows a possible value for the SMD5 LPA that the *Salt* parameter specifies: `{SMD5}JVDbGx8K$`

Return Values

The **crypt** subroutine returns a pointer to the encrypted password. The static area this pointer indicates may be overwritten by subsequent calls.

If the **crypt** subroutine is unsuccessful, a null pointer is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **encrypt** subroutine returns the following error codes:

Item	Description
ENOSYS	The **encrypt** subroutine was called by using the *EdFlag* parameter that was set to a nonzero value. Also, the **/usr/lib/libdes** or **/usr/lib/libdes_64** file does not exist. The **/usr/lib/libdes** and **/usr/lib/libdes_64** files are part of the **des** fileset, which is located in the AIX Expansion Pack.

csid Subroutine

Purpose

Returns the character set ID (charsetID) of a multibyte character.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdlib.h>

int csid ( String)
const char *String;
```

Description

The **csid** subroutine returns the charsetID of the multibyte character pointed to by the *String* parameter. No validation of the character is performed. The parameter must point to a value in the character range of the current code set defined in the current locale.

Parameters

Item	Description
String	Specifies the character to be tested.

Return Values

Successful completion returns an integer value representing the charsetID of the character. This integer can be a number from 0 through *n*, where *n* is the maximum character set defined in the CHARSETID field of the **charmap**.

csin, csinf, or csinl Subroutine

Purpose

Computes the complex sine.

Syntax

```
#include <complex.h>

double complex csin (z)
double complex z;

float complex csinf (z)
float complex z;

long double complex csinl (z)
long double complex z;
```

Description

The **csin**, **csinf**, and **csinl** subroutines compute the complex sine of the value specified by the *z* parameter.

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

The **csin**, **csinf**, and **csinl** subroutines return the complex sine value.

csinh, csinhf, or csinhl Subroutine

Purpose

Computes the complex hyperbolic sine.

Syntax

```
#include <complex.h>

double complex csinh (z)
double complex z;

float complex csinhf (z)
float complex z;

long double complex csinhl (z)
long double complex z;
```

Description

The **csinh**, **csinhf**, and **csinhl** subroutines compute the complex hyperbolic sine of the value specified by the *z* parameter.

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

The **csinh**, **csinhf**, and **csinhl** subroutines return the complex hyperbolic sine value.

csqrt, csqrtf, or csqrtl Subroutine

Purpose

Computes complex square roots.

Syntax

```
#include <complex.h>
double complex csqrt (z)
double complex z;

float complex csqrtf (z)
float complex z;

long double complex csqrtl (z)
long double complex z;
```

Description

The **csqrt**, **csqrtf**, and **csqrtl** subroutines compute the complex square root of the value specified by the *z* parameter, with a branch cut along the negative real axis.

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

The **csqrt**, **csqrtf**, and **csqrtl** subroutines return the complex square root value, in the range of the right half-plane (including the imaginary axis).

CT_HOOKx and CT_GEN macros

Purpose

Record a trace event into Component Trace, LMT or system trace buffers.

Syntax

The following set of macros is provided to record a trace entry:

```
#include <sys/ras_trace.h>
CT_HOOK0(ras_block_t cb, int level, int mem_dest,long hkwd);
CT_HOOK1(ras_block_t cb, int level, int mem_dest, long hkwd, long d1);
CT_HOOK2(ras_block_t cb, int level, int mem_dest, long hkwd, long d1, long d2);
CT_HOOK3(ras_block_t cb, int level, int mem_dest, long hkwd, long d1, long d2, long d3);
CT_HOOK4(ras_block_t cb, int level, \
int mem_dest, long hkwd, long d1, long d2, \
long d3, long d4);
CT_HOOK5(ras_block_t cb, int level, int mem_dest, \
long hkwd, long d1, long d2, long d3, \
long d4, long d5);
CT_GEN (ras_block_t cb, int level, long hkwd, long data, long len, void *buf);
```

Description

The CT_HOOKx macros allow you to record a trace hook. The "x" is the number of data words you want in this trace event.

The CT_GEN macro is used to record a generic trace hook.

All traces are timestamped.

Restriction: If the *cb* input parameter has a value of RAS_BLOCK_NULL, no tracing will be performed.

Parameters

Item	Description
`ras_block_t` *cb*	The *cb* parameter in the RAS control block that refers to the component that this trace entry belongs to.

Item	Description
`int` *level*	The *level* parameter allows filtering of different trace entries. The higher this level is, the more this trace will be considered as debug or detail information. In other words, this trace entry will appear only if the level of the trace entry is less than or equal to the level of trace chosen for memory or system trace mode. Ten levels of trace are available (**CT_LEVEL_0** to **CT_LEVEL_9**, corresponding to value 0 to 9) with four special levels: • minimal (CT_LVL_MINIMAL (=CT_LEVEL_1)) • normal (CT_LVL_NORMAL (=CT_LEVEL_3)) • detail (CT_LVL_DETAIL (=CT_LEVEL_7)) • default (CT_LVL_DEFAULT = CT_LVL_NORMAL in AIX 6.1 and above and CT_LVL_MINIMAL otherwise) When you are porting an existing driver or subsystem from the existing system trace to component trace, trace existing entries at **CT_LVL_DEFAULT**.
`int` *mem_dest*	For `CT_HOOKx` macros, the *mem_dest* parameter indicates the memory destination for this trace entry. It is an ORed value with the following possible settings: • `MT_RARE`: the trace entry is saved in the rare buffer of lightweight memory trace if the level condition of the memory trace mode for this control block is satisfied, meaning that the current level of trace for the memory trace mode is greater than or equal to the level of this trace entry. • `MT_COMMON`: the trace entry is saved in the common buffer of the lightweight memory trace if the level condition of the memory trace mode for this control block is satisfied. • `MT_PRIV`: the trace entry is saved in the private memory buffer of the component if the level condition of the memory trace mode for this control block is satisfied. • `MT_SYSTEM`: the trace entry is saved in the existing system trace if the level condition of the *system trace mode* for this control block is satisfied, if the system trace is running, and if the hook meets any additional criteria specified as part of the system trace. For example, if `MT_SYSTEM` is not set, the trace entry is not saved in the existing system trace. Only one of the `MT_RARE`, `MT_COMMON` and `MT_PRIV` values should be used, but you can combine ORed with `MT_SYSTEM`. Otherwise, the trace entry will be duplicated in several memory buffers. The *mem_dest* parameter is not needed for the `CT_GEN` macro because lightweight memory trace cannot accommodate generic entries. `CT_GEN` checks the memory trace and system trace levels to determine whether the generic entry should enter the private memory buffer and system trace buffers respectively.

The *hkwd*, *d1*, *d2*, *d3*, *d4*, *d5*, *len* and *buf* parameters are the same as those used for the existing TRCHKx or TRCGEN macros. The TRCHKx refers to the TRCHKLnT macros where *n* is from 0 to 5. For example, TRCHKL1T (hkwd, d1). The TRCGEN macros refer to the TRCGEN and TRCGENT macros.

For the hookword, OR the hookID with a subhookID if needed. For the `CT_HOOKx` macro, the subhook is ORed into the hookword. For the `CT_GEN` macro, the subhook is the *d1* parameter.

CT_HOOKx_PRIV, CTCS_HOOKx_PRIV, CT_HOOKx_COMMON, CT_HOOKx_RARE, and CT_HOOKx_SYSTEM Macros

Purpose

Record a trace event into Component Trace (CT), Lightweight Memory Trace (LMT), or system trace buffers.

Syntax

```
#include <sys/ras_trace.h>
CT_HOOK0_PRIV(ras_block_t cb, ulong hw);
CT_HOOK1_PRIV(ras_block_t cb, ulong hw, ulong d1);
CT_HOOK2_PRIV(ras_block_t cb, ulong hw, ulong d1, ulong d2);
CT_HOOK3_PRIV(ras_block_t cb, ulong hw, ulong d1, ulong d2, ulong d3);
CT_HOOK4_PRIV(ras_block_t cb, ulong hw, ulong d1, ulong d2, ulong d3, ulong d4);
CT_HOOK5_PRIV(ras_block_t cb, ulong hw, ulong d1, ulong d2, ulong d3, ulong d4, ulong d5);
```

```
#include <sys/ras_trace.h>
CTCS_HOOK0_PRIV(ras_block_t cb, ulong hw);
CTCS_HOOK1_PRIV(ras_block_t cb, ulong hw, ulong d1);
CTCS_HOOK2_PRIV(ras_block_t cb, ulong hw, ulong d1, ulong d2);
CTCS_HOOK3_PRIV(ras_block_t cb, ulong hw, ulong d1, ulong d2, ulong d3);
CTCS_HOOK4_PRIV(ras_block_t cb, ulong hw, ulong d1, ulong d2, ulong d3, ulong d4);
CTCS_HOOK5_PRIV(ras_block_t cb, ulong hw, ulong d1, ulong d2, ulong d3, ulong d4, ulong d5);
```

```
#include <sys/ras_trace.h>
CT_HOOK0_COMMON(ulong hw);
CT_HOOK1_COMMON(ulong hw, ulong d1);
CT_HOOK2_COMMON(ulong hw, ulong d1, ulong d2);
CT_HOOK3_COMMON(ulong hw, ulong d1, ulong d2, ulong d3);
CT_HOOK4_COMMON(ulong hw, ulong d1, ulong d2, ulong d3, ulong d4);
CT_HOOK5_COMMON(ulong hw, ulong d1, ulong d2, ulong d3, ulong d4, ulong d5);
```

```
#include <sys/ras_trace.h>
CT_HOOK0_RARE(ulong hw);
CT_HOOK1_RARE(ulong hw, ulong d1);
CT_HOOK2_RARE(ulong hw, ulong d1, ulong d2);
CT_HOOK3_RARE(ulong hw, ulong d1, ulong d2, ulong d3);
CT_HOOK4_RARE(ulong hw, ulong d1, ulong d2, ulong d3, ulong d4);
CT_HOOK5_RARE(ulong hw, ulong d1, ulong d2, ulong d3, ulong d4, ulong d5);
```

```
#include <sys/ras_trace.h>
CT_HOOK0_SYSTEM(ulong hw);
CT_HOOK1_SYSTEM(ulong hw, ulong d1);
CT_HOOK2_SYSTEM(ulong hw, ulong d1, ulong d2);
CT_HOOK3_SYSTEM(ulong hw, ulong d1, ulong d2, ulong d3);
CT_HOOK4_SYSTEM(ulong hw, ulong d1, ulong d2, ulong d3, ulong d4);
CT_HOOK5_SYSTEM(ulong hw, ulong d1, ulong d2, ulong d3, ulong d4, ulong d5);
```

Description

The CT_HOOKx_PRIV, CTCS_HOOKx_PRIV, CT_HOOKx_COMMON, CT_HOOKx_RARE, and CT_HOOKx_SYSTEM macros trace a trace event in to a specific trace facility. These macros are optimized for performance. Due to this optimization, no explicit checking is done to ensure the availability of a trace facility. In general, it is always safe to trace to either of the LMT buffer types or system source. Callers should use the **rasrb_trace_privlevel()** service to ensure that the selected Component Trace private buffer is available. Before calling routines that write to the private buffer of a Component Trace, checks should be made to ensure that the return value is not -1, and that the buffer is at the appropriate level required for tracing. Race conditions for infrastructure-serialized Component Trace macros are handled by the infrastructure. Component-serialized traces must ensure proper serialization between tracing and state changes made in the corresponding RAS callback.

The following table describes how macros are associated with a specific trace facility and includes notes about the macros.

Item	**Description**	
Trace Facility	**Macro**	**Notes**
Component Trace private buffer	CT_HOOKx_PRIV	Can be used with both infrastructure and component serialized traces.
Component Trace private buffer	CTCS_HOOKx_PRIV	Can only be used with component serialized traces.
Lightweight Memory Trace common buffer	CT_HOOKx_COMMON	
Lightweight Memory Trace rare buffer	CT_HOOKx_RARE	
System Trace buffer	CT_HOOKx_SYSTEM	

All traces are recorded with time stamps.

If the *cb* input parameter has a value of RAS_BLOCK_NULL, no tracing is performed.

Parameters

Item	**Description**
ras_block_t *cb*	The *cb* parameter is the RAS control block that refers to the component that this trace entry belongs to.

The *hkwd*, *d1*, *d2*, *d3*, *d4*, and *d5* parameters are the same as those used for the existing TRCHKx macros. The TRCHKx refers to the TRCHKLnT macros where *n* is from 0 to 5. For example, TRCHKL1T (hkwd, d1).

Example

In the following example, the **foo()** function uses Component Trace private buffers with system trace in a performance optimized way. The **foo()** function uses component-serialization and traces only when the detail level is at or above the CT_LEVEL_NORMAL level (defined in **sys/ras_trace.h**).

```
void foo() {
    long ipl;
    char memtrc, systrc;

    ipl = disable_lock(INTMAX, <Component Trace lock>);
    memtrc = rasrb_trace_privlevel(rasb) >= CT_LVL_NORMAL ? 1 : 0;
    systrc = rasrb_trace_syslevel(rasb) >= CT_LVL_NORMAL ? 1 : 0;
    …
    if (memtrc) {
        CTCS_HOOK5_PRIV(…)
    }
    if (systrc) {
        __INFREQUENT();
        CT_HOOK5_SYSTEM(…)
    }
    …
    unlock_enable(ipl, <Component Trace lock>)
    return;
}
```

CT_TRCON macro

Purpose

Return information on whether any trace is active at a certain level for a component.

Syntax

```
#include <sys/ras_trace.h>
CT_TRCON(cb, level)
```

Description

The CT_TRCON macro allows you to ascertain whether any type of trace (Component Trace, lightweight memory trace or system trace) will record events for the component specified at the trace detail level specified.

Note: If the *cb* input parameter has a value of RAS_BLOCK_NULL, the **CT_TRCON** macro indicates that the trace is off.

Parameters

Item	Description
`ras_block_t` *cb*	The *cb* parameter is the RAS control block pointer that refers to the component that this trace entry belongs to.
`int` *level*	Specifies the trace detail level.

ctan, ctanf, or ctanl Subroutine

Purpose

Computes complex tangents.

Syntax

```
#include <complex.h>

double complex ctan (z)
double complex z;

float complex ctanf (z)
float complex z;

long double complex ctanl (z)
long double complex z;
```

Description

The **ctan**, **ctanf**, and **ctanl** subroutines compute the complex tangent of the value specified by the *z* parameter.

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

The **ctan**, **ctanf**, and **ctanl** subroutines return the complex tangent value.

ctanh, ctanhf, or ctanhl Subroutine

Purpose

Computes the complex hyperbolic tangent.

Syntax

```
#include <complex.h>

double complex ctanh (z)
double complex z;

float complex ctanhf (z)
float complex z;

long double complex ctanhl (z)
long double complex z;
```

Description

The **ctanh**, **ctanhf**, and **ctanhl** subroutines compute the complex hyperbolic tangent of *z*.

Parameters

Item	Description
z	Specifies the value to be computed.

Return Values

The **ctanh**, **ctanhf**, and **ctanhl** subroutines return the complex hyperbolic tangent value.

CTCS_HOOKx Macros

Purpose

Record a trace event into component serialized Component Trace, Lightweight Memory Trace (LMT), or system trace buffers.

Syntax

The following set of macros is provided to record a trace entry:

```
#include <sys/ras_trace.h>
CTCS_HOOK0(ras_block_t cb, int level, int mem_dest, long hkwd);
CTCS_HOOK1(ras_block_t cb, int level, int mem_dest, long hkwd, long d1);
CTCS_HOOK2(ras_block_t cb, int level, int mem_dest, long hkwd, long d1, long d2);
CTCS_HOOK3(ras_block_t cb, int level, int mem_dest, long hkwd, long d1, long d2, long d3);
CTCS_HOOK4(ras_block_t cb, int level, int mem_dest, long hkwd, long d1, long d2, long d3, long
d4);
CTCS_HOOK5(ras_block_t cb, int level, int mem_dest, long hkwd, long d1, long d2, long d3, long
d4,
long d5);
```

Description

The **CTCS_HOOKx** macros record a trace hook in to a Component Trace buffer that is component-serialized. These macros cannot be used with buffers that are not component-serialized. The **x** in **CTCS_HOOKx** is the number of data words you want in this trace event.

All of the traces that are recorded are time-stamped.

If the *cb* input parameter contains a value of RAS_BLOCK_NULL, no tracing is performed.

Parameters

Item	Description
ras_block_t *cb*	The *cb* parameter is the RAS control block that links to the component that this trace entry belongs to.
int *level*	The *level* parameter allows filtering of different trace entries. The higher this level is, the more this trace is considered as debug or detail information. This trace entry is displayed only if the level of the trace entry is less than or equal to the level of the trace chosen for memory or system trace mode. Ten levels of trace are available (CT_LEVEL_0 to CT_LEVEL_9, corresponding to value 0 to 9) with the following special levels: • Minimal (CT_LVL_MINIMAL (=CT_LEVEL_1)) • Normal (CT_LVL_NORMAL (=CT_LEVEL_3)) • Detail (CT_LVL_DETAIL (=CT_LEVEL_7)) • Default (CT_LVL_DEFAULT = CT_LVL_NORMAL in AIX 6.1 and above. Otherwise, it is CT_LVL_MINIMAL) When you are porting an existing driver or subsystem from the existing system trace to a component trace, existing entries should be traced at the CT_LVL_DEFAULT level.

Item	Description
int *mem_dest*	The *mem_dest* parameter indicates the memory destination for this trace entry. It is an ORed value with the following possible settings: **MT_RARE** The trace entry is saved in the rare buffer of lightweight memory. In this case, the current level of trace for the memory trace mode is greater than or equal to the level of this trace entry. **MT_COMMON** The trace entry is saved in the common buffer of the lightweight memory trace. **MT_PRIV** The trace entry is saved in the private memory buffer of the component. **MT_SYSTEM** The trace entry is saved in the existing system trace if all of the following conditions are true: • The level condition of the system trace mode for this control block is satisfied • The system trace is running • The hook meets any additional criteria specified as part of the system trace If MT_SYSTEM is not set, the trace entry is not saved in the existing system trace. Only one of the **MT_RARE**, **MT_COMMON**, and **MT_PRIV** values should be used, but you can combine ORed with **MT_SYSTEM**. Otherwise, the trace entry will be duplicated in several memory buffers. The *mem_dest* parameter is not necessary for the **CT_GEN** macro because Lightweight Memory Trace cannot accommodate generic entries. The **CT_GEN** macro checks the memory trace and system trace levels to determine whether the generic entry should enter the private memory buffer and the system trace buffers respectively.

The *hkwd*, *d1*, *d2*, *d3*, *d4*, and *d5* parameters are the same as those used for the existing TRCHKx macros. The TRCHKx macros link to the TRCHKLnT macros where *n* is from 0 to 5. For example, TRCHKL1T (hkwd, d1).

ctermid Subroutine

Purpose

Generates the path name of the controlling terminal.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdio.h>
char *ctermid ( String)
char *String;
```

Description

The **ctermid** subroutine generates the path name of the controlling terminal for the current process and stores it in a string.

Note: File access permissions depend on user access. Access to a file whose path name the **ctermid** subroutine has returned is not guaranteed.

The difference between the **ctermid** and **ttyname** subroutines is that the **ttyname** subroutine must be handed a file descriptor and returns the actual name of the terminal associated with that file descriptor. The **ctermid** subroutine returns a string (the **/dev/tty** file) that refers to the terminal if used as a file name. Thus, the **ttyname** subroutine is useful only if the process already has at least one file open to a terminal.

Parameters

Item	Description
String	If the *String* parameter is a null pointer, the string is stored in an internal static area and the address is returned. The next call to the **ctermid** subroutine overwrites the contents of the internal static area. If the *String* parameter is not a null pointer, it points to a character array of at least `L_ctermid` elements as defined in the **stdio.h** file. The path name is placed in this array and the value of the *String* parameter is returned.

CTFUNC_HOOKx Macros

Purpose

Record a trace event, which is infrequently recorded, into Component Trace (CT), Lightweight Memory Trace (LMT), or system trace buffers.

Syntax

```
#include <sys/ras_trace.h>
CTFUNC_HOOK0(ras_block_t cb, char level, int mem_dest, ulong hw);
CTFUNC_HOOK1(ras_block_t cb, char level, int mem_dest, ulong hw, ulong d1);
CTFUNC_HOOK2(ras_block_t cb, char level, int mem_dest, ulong hw, ulong d1, ulong d2);
CTFUNC_HOOK3(ras_block_t cb, char level, int mem_dest, ulong hw, ulong d1, ulong d2, ulong d3);
CTFUNC_HOOK4(ras_block_t cb, char level, int mem_dest, ulong hw, ulong d1, ulong d2, ulong d3, ulong d4);
CTFUNC_HOOK5(ras_block_t cb, char level, int mem_dest, ulong hw, ulong d1, ulong d2, ulong d3, ulong d4,
ulong d5);
```

Description

The **CTFUNC_HOOKx** macros record a trace hook. Theses macros are optimized to record events that are rarely recorded, such as error path tracing. The **CTFUNC_HOOKx** macros can be used with any types of trace serialization. Besides their optimization for rare events, the **CTFUNC_HOOKx** macros are equivalent to the **CT_HOOKx** macros.

All of the traces that the **CTFUNC_HOOKx** macros record are time-stamped.

If the *cb* input parameter contains a value of RAS_BLOCK_NULL, no tracing will be performed.

Parameters

Item	Description
ras_block_t *cb*	The *cb* parameter is the RAS control block that refers to the component that this trace entry belongs to.

Item	Description
char *level*	The *level* parameter allows filtering of different trace entries. The higher this level is, the more this trace is considered as debug or detail information. This trace entry appears only if the level of the trace entry is less than or equal to the level of trace chosen for memory or system trace mode. Ten levels of trace are available (CT_LEVEL_0 to CT_LEVEL_9, corresponding to value 0 to 9) with the following four special levels: • Minimal (CT_LVL_MINIMAL (=CT_LEVEL_1)) • Normal (CT_LVL_NORMAL (=CT_LEVEL_3)) • Detail (CT_LVL_DETAIL (=CT_LEVEL_7)) • Default (CT_LVL_DEFAULT = CT_LVL_NORMAL in AIX 6.1. Otherwise, it is CT_LVL_MINIMAL) When you are porting an existing driver or subsystem from the existing system trace to component trace, existing entries should be traced at CT_LVL_DEFAULT.
int *mem_dest*	The *mem_dest* parameter indicates the memory destination for this trace entry. It is an ORed value with the following possible settings: **MT_RARE** The trace entry is saved in the rare buffer of lightweight memory trace if the level condition of the memory trace mode for this control block is satisfied, which means the current level of trace for the memory trace mode is greater than or equal to the level of this trace entry. **MT_COMMON** The trace entry is saved in the common buffer of the lightweight memory trace if the level condition of the memory trace mode for this control block is satisfied. **MT_PRIV** The trace entry is saved in the private memory buffer of the component if the level condition of the memory trace mode for this control block is satisfied. **MT_SYSTEM** The trace entry is saved in the existing system trace if all of the following conditions are true: • The level condition of the system trace mode for this control block is satisfied. • The system trace is running. • The hook meets any additional criteria specified as part of the system trace. If MT_SYSTEM is not set, the trace entry is not saved in the existing system trace. Only one of the **MT_RARE**, **MT_COMMON**, and **MT_PRIV** values can be used, but you can combine ORed with **MT_SYSTEM**. Otherwise, the trace entry duplicates in several memory buffers. The *mem_dest* parameter is not necessary for the **CT_GEN** macro because lightweight memory trace cannot accommodate generic entries. The **CT_GEN** macro checks the memory trace and system trace levels to determine whether the generic entry should enter the private memory buffer and the system trace buffers respectively.

The *hkwd*, *d1*, *d2*, *d3*, *d4*, and *d5* parameters are the same as those used for the existing TRCHKx macros. The TRCHKx macros link to the TRCHKLnT macros where *n* is from 0 to 5. For example, TRCHKL1T (hkwd, d1).

ctime, localtime, gmtime, mktime, difftime, asctime, or tzset Subroutine

Purpose

Converts the formats of date and time representations.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <time.h>
```

```
char *ctime ( Clock)
const time_t *Clock;
```

```
struct tm *localtime (Clock)
const time_t *Clock;
```

```
struct tm *gmtime (Clock)
const time_t *Clock;
```

```
time_t mktime( Timeptr)
struct tm *Timeptr;
```

```
double difftime( Time1,  Time0)
time_t Time0, Time1;
```

```
char *asctime ( Tm)
const struct tm *Tm;
```

```
void tzset ( )
extern long int timezone;
extern int daylight;
extern char *tzname[];
```

Description

Attention: Do not use the **tzset** subroutine when linking with both **libc.a** and **libbsd.a**. The **tzset** subroutine sets the global external variable called **timezone**, which conflicts with the **timezone** subroutine in **libbsd.a**. This name collision may cause unpredictable results.

Attention: Do not use the **ctime**, **localtime**, **gmtime**, or **asctime** subroutine in a multithreaded environment. See the multithread alternatives in the **ctime_r**, **localtime_r**, **gmtime_r**, or **asctime_r** subroutine article.

The **ctime** subroutine converts a time value pointed to by the *Clock* parameter, which represents the time in seconds since 00:00:00 Coordinated Universal Time (UTC), January 1, 1970, into a 26-character string in the following form:

```
Sun Sept 16 01:03:52 1973\n\0
```

The width of each field is always the same as shown here.

The **ctime** subroutine adjusts for the time zone and daylight saving time, if it is in effect.

The **localtime** subroutine converts the long integer pointed to by the *Clock* parameter, which contains the time in seconds since 00:00:00 UTC, 1 January 1970, into a **tm** structure. The **localtime** subroutine adjusts for the time zone and for daylight-saving time, if it is in effect. Use the time-zone information as though **localtime** called **tzset**.

The **gmtime** subroutine converts the long integer pointed to by the *Clock* parameter into a **tm** structure containing the Coordinated Universal Time (UTC), which is the time standard the operating system uses.

Note: UTC is the international time standard intended to replace GMT.

The **tm** structure is defined in the **time.h** file, and it contains the following members:

```
int tm_sec;     /* Seconds (0 - 59) */
int tm_min;     /* Minutes (0 - 59) */
int tm_hour;    /* Hours (0 - 23) */
int tm_mday;    /* Day of month (1 - 31) */
int tm_mon;     /* Month of year (0 - 11) */
int tm_year;    /* Year - 1900 */
int tm_wday;    /* Day of week (Sunday = 0) */
int tm_yday;    /* Day of year (0 - 365) */
int tm_isdst;   /* Nonzero = Daylight saving time */
```

The **mktime** subroutine is the reverse function of the **localtime** subroutine. The **mktime** subroutine converts the **tm** structure into the time in seconds since 00:00:00 UTC, 1 January 1970. The `tm_wday` and `tm_yday` fields are ignored, and the other components of the **tm** structure are not restricted to the ranges specified in the **/usr/include/time.h** file. The value of the `tm_isdst` field determines the following actions of the **mktime** subroutine:

Item	Description
0	Initially presumes that Daylight Saving Time (DST) is not in effect.
>0	Initially presumes that DST is in effect.
-1	Actively determines whether DST is in effect from the specified time and the local time zone. Local time zone information is set by the **tzset** subroutine.

Upon successful completion, the **mktime** subroutine sets the values of the `tm_wday` and `tm_yday` fields appropriately. Other fields are set to represent the specified time since January 1, 1970. However, the values are forced to the ranges specified in the **/usr/include/time.h** file. The final value of the `tm_mday` field is not set until the values of the `tm_mon` and `tm_year` fields are determined.

Note: The **mktime** subroutine cannot convert time values before 00:00:00 UTC, January 1, 1970 and after 03:14:07 UTC, January 19, 2038.

The **difftime** subroutine computes the difference between two calendar times: the *Time1* and -*Time0* parameters.

The **asctime** subroutine converts a **tm** structure to a 26-character string of the same format as **ctime**.

If the **TZ** environment variable is defined, then its value overrides the default time zone, which is the U.S. Eastern time zone. The **environment** facility contains the format of the time zone information specified by **TZ**. **TZ** is usually set when the system is started with the value that is defined in either the **/etc/environment** or **/etc/profile** files. However, it can also be set by the user as a regular environment variable for performing alternate time zone conversions.

The **tzset** subroutine sets the **timezone**, **daylight**, and **tzname** external variables to reflect the setting of **TZ**. The **tzset** subroutine is called by **ctime** and **localtime**, and it can also be called explicitly by an application program.

The **timezone** external variable contains the difference, in seconds, between UTC and local standard time. For example, the value of **timezone** is 5 * 60 * 60 for U.S. Eastern Standard Time.

The **daylight** external variable is nonzero when a daylight-saving time conversion should be applied. By default, this conversion follows the standard U.S. conventions; other conventions can be specified. The default conversion algorithm adjusts for the peculiarities of U.S. daylight saving time in 1974 and 1975.

The **tzname** external variable contains the name of the standard time zone (**tzname[0]**) and of the time zone when Daylight Saving Time is in effect (**tzname[1]**). For example:

```
char *tzname[2] = {"EST", "EDT"};
```

The **time.h** file contains declarations of all these subroutines and externals and the **tm** structure.

Parameters

Item	Description
Clock	Specifies the pointer to the time value in seconds.
Timeptr	Specifies the pointer to a **tm** structure.
Time1	Specifies the pointer to a **time_t** structure.
Time0	Specifies the pointer to a **time_t** structure.
Tm	Specifies the pointer to a **tm** structure.

Return Values

Attention: The return values point to static data that is overwritten by each call.

The **tzset** subroutine returns no value.

The **mktime** subroutine returns the specified time in seconds encoded as a value of type **time_t**. If the time cannot be represented, the function returns the value (**time_t**)-1.

The **localtime** and **gmtime** subroutines return a pointer to the **struct tm**.

The **ctime** and **asctime** subroutines return a pointer to a 26-character string.

The **difftime** subroutine returns the difference expressed in seconds as a value of type **double**.

ctime64, localtime64, gmtime64, mktime64, difftime64, or asctime64 Subroutine

Purpose

Converts the formats of date and time representations.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <time.h>

char *ctime64 (Clock)
const time64_t *Clock;

struct tm *localtime64 (Clock)
const time64_t *Clock;

struct tm *gmtime64 (Clock)
const time64_t *Clock;
```

```
time64_t mktime64(Timeptr)
struct tm *Timeptr;

double difftime64(Time1, Time0)
time64_t Time0, Time1;

char *asctime64 (Tm)
const struct tm *Tm;
```

Description

Attention: Do not use the **ctime**, **localtime**, **gmtime**, or **asctime** subroutine in a multithreaded environment.

The **ctime64** subroutine converts a time value pointed to by the *Clock* parameter, which represents the time in seconds since 00:00:00 Coordinated Universal Time (UTC), January 1, 1970, into a 26-character string in the following form:

```
Sun Sept 16 01:03:52 1973\n\0
```

The width of each field is always the same as shown here.

The **ctime64** subroutine adjusts for the time zone and daylight saving time, if it is in effect.

The **localtime64** subroutine converts the 64 bit long pointed to by the *Clock* parameter, which contains the time in seconds since 00:00:00 UTC, 1 January 1970, into a *tm* structure. The **localtime64** subroutine adjusts for the time zone and for daylight saving time, if it is in effect. Use the time-zone information as though **localtime64** called **tzset**.

The **gmtime64** subroutine converts the 64 bit long pointed to by the *Clock* parameter into a *tm* structure containing the Coordinated Universal Time (UTC), which is the time standard that the operating system uses.

Note: UTC is the international time standard intended to replace GMT.

The **mktime64** subroutine is the reverse function of the **localtime64** subroutine. The **mktime64** subroutine converts the *tm* structure into the time in seconds since 00:00:00 UTC, 1 January 1970. The **tm_wday** and **tm_yday** fields are ignored, and the other components of the *tm* structure are not restricted to the ranges specified in the **/usr/include/time.h** file. The value of the **tm_isdst** field determines the following actions of the **mktime64** subroutine:

Item	Description
0	Initially presumes that Daylight Saving Time (DST) is not in effect.
>0	Initially presumes that DST is in effect.
-1	Actively determines whether DST is in effect from the specified time and the local time zone. Local time zone information is set by the **tzset** subroutine.

Upon successful completion, the **mktime64** subroutine sets the values of the **tm_wday** and **tm_yday** fields appropriately. Other fields are set to represent the specified time since January 1, 1970. However, the values are forced to the ranges specified in the **/usr/include/time.h** file. The final value of the **tm_mday** field is not set until the values of the **tm_mon** and **tm_year** fields are determined.

Note: The **mktime64** subroutine cannot convert time values before 00:00:00 UTC, January 1, 1970 and after 23:59:59 UTC, December 31, 9999.

Note: The **difftime64** subroutine computes the difference between two calendar times: the *Time1* and *Time0* parameters.

Note: The **asctime64** subroutine converts a *tm* structure to a 26-character string of the same format as **ctime64**.

Parameters

Item	Description
Clock	Specifies the pointer to the time value in seconds.
Timeptr	Specifies the pointer to a **tm** structure.
Time1	Specifies the pointer to a **time64_t** structure.
Time0	Specifies the pointer to a **time64_t** structure.
Tm	Specifies the pointer to a **tm** structure.

Return Values

Attention: The return values point to static data that is overwritten by each call.

The **mktime64** subroutine returns the specified time in seconds encoded as a value of type **time64_t**. If the time cannot be represented, the function returns the value **(time64_t)-1**.

The **localtime64** and **gmtime64** subroutines return a pointer to the **tm** struct .

The **ctime64** and **asctime64** subroutines return a pointer to a 26-character string.

The **difftime64** subroutine returns the difference expressed in seconds as a value of type long double.

ctime64_r, localtime64_r, gmtime64_r, or asctime64_r Subroutine

Purpose

Converts the formats of date and time representations.

Library

Thread-Safe C Library (**libc_r.a**)

Syntax

```
#include <time.h>

char *ctime64_r(Timer, BufferPointer)
const time64_t * Timer;
char * BufferPointer;

struct tm *localtime64_r(Timer, CurrentTime)
const time64_t * Timer;
struct tm * CurrentTime;

struct tm *gmtime64_r (Timer, XTime)
const time64_t * Timer;
struct tm * XTime;

char *asctime64_r (TimePointer, BufferPointer)
const struct tm * TimePointer;
char * BufferPointer;
```

Description

The **ctime64_r** subroutine converts a time value pointed to by the *Timer* parameter, which represents the time in seconds since 00:00:00 Coordinated Universal Time (UTC), January 1, 1970, into the character array pointed to by the *BufferPointer* parameter. The character array should have a length of at least 26

characters so the converted time value fits without truncation. The converted time value string takes the form of the following example:

```
Sun Sept 16 01:03:52 1973\n\0
```

The width of each field is always the same as shown here. Thus, *ctime* will only return dates up to December 31, 9999.

The **ctime64_r** subroutine adjusts for the time zone and daylight saving time, if it is in effect.

The **localtime64_r** subroutine converts the **time64_t** structure pointed to by the *Timer* parameter, which contains the time in seconds since 00:00:00 UTC, January 1, 1970, into the **tm** structure pointed to by the *CurrentTime* parameter. The **localtime64_r** subroutine adjusts for the time zone and for daylight saving time, if it is in effect.

The **gmtime64_r** subroutine converts the **time64_t** structure pointed to by the *Timer* parameter into the **tm** structure pointed to by the *XTime* parameter.

The **tm** structure is defined in the **time.h** header file. The **time.h** file contains declarations of these subroutines, externals, and the **tm** structure.

The **asctime64_r** subroutine converts the **tm** structure pointed to by the *TimePointer* parameter into a 26-character string in the same format as the **ctime64_r** subroutine. The results are placed into the character array, *BufferPointer*. The *BufferPointer* parameter points to the resulting character array, which takes the form of the following example:

```
Sun Sept 16 01:03:52 1973\n\0
```

Programs using this subroutine must link to the **libpthreads.a** library.

Parameters

Item	Description
Timer	Points to a **time64_t** structure, which contains the number of seconds since 00:00:00 UTC, January 1, 1970.
BufferPointer	Points to a character array at least 26 characters long.
CurrentTime	Points to a **tm** structure. The result of the **localtime64_r** subroutine is placed here.
XTime	Points to a **tm** structure used for the results of the **gmtime64_r** subroutine.
TimePointer	Points to a **tm** structure used as input to the **asctime64_r** subroutine.

Return Values

The **localtime64_r** and **gmtime64_r** subroutines return a pointer to the **tm** structure. The **asctime64_r** returns NULL if either *TimePointer* or *BufferPointer* is NULL.

The **ctime64_r** and **asctime64_r** subroutines return a pointer to a 26-character string. The **ctime64_r** subroutine returns NULL if the *BufferPointer* is NULL.

The **difftime64** subroutine returns the difference expressed in seconds as a value of type long double.

Files

Item	Description
/usr/include/time.h	Defines time macros, data types, and structures.

ctime_r, localtime_r, gmtime_r, or asctime_r Subroutine

Purpose

Converts the formats of date and time representations.

Library

Thread-Safe C Library (**libc_r.a**)

Syntax

```
#include <time.h>

char *ctime_r(Timer, BufferPointer)
const time_t * Timer;
char * BufferPointer;

struct tm *localtime_r(Timer, CurrentTime)
const time_t * Timer;
struct tm * CurrentTime;

struct tm *gmtime_r(Timer, XTime)
const time_t * Timer;
struct tm * XTime;

char *asctime_r(TimePointer, BufferPointer)
const struct tm * TimePointer;
char * BufferPointer;
```

Description

The **ctime_r** subroutine converts a time value pointed to by the *Timer* parameter, which represents the time in seconds since 00:00:00 Coordinated Universal Time (UTC), January 1, 1970, into the character array pointed to by the *BufferPointer* parameter. The character array should have a length of at least 26 characters so the converted time value fits without truncation. The converted time value string takes the form of the following example:

```
Sun Sep 16 01:03:52 1973\n\0
```

The width of each field is always the same as shown here.

The **ctime_r** subroutine adjusts for the time zone and daylight saving time, if it is in effect.

The **localtime_r** subroutine converts the **time_t** structure pointed to by the *Timer* parameter, which contains the time in seconds since 00:00:00 UTC, January 1, 1970, into the **tm** structure pointed to by the *CurrentTime* parameter. The **localtime_r** subroutine adjusts for the time zone and for daylight saving time, if it is in effect.

The **gmtime_r** subroutine converts the **time_t** structure pointed to by the *Timer* parameter into the **tm** structure pointed to by the *XTime* parameter.

The **tm** structure is defined in the **time.h** header file. The **time.h** file contains declarations of these subroutines, externals, and the **tm** structure.

The **asctime_r** subroutine converts the **tm** structure pointed to by the *TimePointer* parameter into a 26-character string in the same format as the **ctime_r** subroutine. The results are placed into the character array, *BufferPointer*. The *BufferPointer* parameter points to the resulting character array, which takes the form of the following example:

```
Sun Sep 16 01:03:52 1973\n\0
```

Programs using this subroutine must link to the **libpthreads.a** library.

Parameters

Item	Description
Timer	Points to a **time_t** structure, which contains the number of seconds since 00:00:00 UTC, January 1, 1970.
BufferPointer	Points to a character array at least 26 characters long.
CurrentTime	Points to a **tm** structure. The result of the **localtime_r** subroutine is placed here.
XTime	Points to a **tm** structure used for the results of the **gmtime_r** subroutine.
TimePointer	Points to a **tm** structure used as input to the **asctime_r** subroutine.

Return Values

The **localtime_r** and **gmtime_r** subroutines return a pointer to the **tm** structure. The **asctime_r** returns NULL if either TimePointer or BufferPointer are NULL.

The **ctime_r** and **asctime_r** subroutines return a pointer to a 26-character string. The **ctime_r** subroutine returns NULL if the BufferPointer is NULL.

Files

Item	Description
/usr/include/time.h	Defines time macros, data types, and structures.

ctype, isalpha, isupper, islower, isdigit, isxdigit, isalnum, isspace, ispunct, isprint, isgraph, iscntrl, or isascii Subroutines

Purpose

Classifies characters.

Library

Standard Character Library (**libc.a**)

Syntax

```
#include <ctype.h>
```

int isalpha (*Character*)
int *Character*;

```
int isupper (Character)
int Character;
```

```
int islower (Character)
int Character;
```

```
int isdigit (Character)
int Character;
```

```
int isxdigit (Character)
int Character;
```

```
int isalnum (Character)
int Character;
```

```
int isspace (Character)
int Character;
```

```
int ispunct (Character)
int Character;
```

```
int isprint (Character)
int Character;
```

```
int isgraph (Character)
int Character;
```

```
int iscntrl (Character)
int Character;
```

```
int isascii (Character)
int Character;
```

Description

The **ctype** subroutines classify character-coded integer values specified in a table. Each of these subroutines returns a nonzero value for True and 0 for False.

Note: The **ctype** subroutines should only be used on character data that can be represented by a single byte value (0 through 255). Attempting to use the **ctype** subroutines on multi-byte locale data may give inconsistent results. Wide character classification routines (such as **iswprint**, **iswlower**, etc.) should be used with dealing with multi-byte character data.

Locale Dependent Character Tests

The following subroutines return nonzero (True) based upon the character class definitions for the current locale.

Item	Description
isalnum	Returns nonzero for any character for which the **isalpha** or **isdigit** subroutine would return nonzero. The **isalnum** subroutine tests whether the character is of the **alpha** or **digit** class.
isalpha	Returns nonzero for any character for which the **isupper** or **islower** subroutines would return nonzero. The **isalpha** subroutine also returns nonzero for any character defined as an alphabetic character in the current locale, or for a character for which *none* of the **iscntrl**, **isdigit**, **ispunct**, or **isspace** subroutines would return nonzero. The **isalpha** subroutine tests whether the character is of the **alpha** class.
isupper	Returns nonzero for any uppercase letter [A through Z]. The **isupper** subroutine also returns nonzero for any character defined to be uppercase in the current locale. The **isupper** subroutine tests whether the character is of the **upper** class.
islower	Returns nonzero for any lowercase letter [a through z]. The **islower** subroutine also returns nonzero for any character defined to be lowercase in the current locale. The **islower** subroutine tests whether the character is of the **lower** class.
isspace	Returns nonzero for any white-space character (space, form feed, new line, carriage return, horizontal tab or vertical tab). The **isspace** subroutine tests whether the character is of the **space** class.

Item	Description
ispunct	Returns nonzero for any character for which the **isprint** subroutine returns nonzero, except the space character and any character for which the **isalnum** subroutine would return nonzero. The **ispunct** subroutine also returns nonzero for any locale-defined character specified as a punctuation character. The **ispunct** subroutine tests whether the character is of the **punct** class.
isprint	Returns nonzero for any printing character. Returns nonzero for any locale-defined character that is designated a printing character. This routine tests whether the character is of the **print** class.
isgraph	Returns nonzero for any character for which the **isprint** character returns nonzero, except the space character. The **isgraph** subroutine tests whether the character is of the **graph** class.
iscntrl	Returns nonzero for any character for which the **isprint** subroutine returns a value of False (0) and any character that is designated a control character in the current locale. For the C locale, control characters are the ASCII delete character (0127 or 0x7F), or an ordinary control character (less than 040 or 0x20). The **iscntrl** subroutine tests whether the character is of the **cntrl** class.

Locale Independent Character Tests

The following subroutines return nonzero for the same characters, regardless of the locale:

Item	Description
isdigit	*Character* is a digit in the range [0 through 9].
isxdigit	*Character* is a hexadecimal digit in the range [0 through 9], [A through F], or [a through f].
isascii	*Character* is an ASCII character with a value in the range [0 through 0x7F].

Parameter

Item	Description
Character	Indicates the character to be tested (integer value).

Return Codes

The **ctype** subroutines return nonzero (True) if the character specified by the *Character* parameter is a member of the selected character class; otherwise, a 0 (False) is returned.

cuserid Subroutine

Purpose

Gets the alphanumeric user name associated with the current process.

Library

Standard C Library (**libc.a**)

Use the **libc_r.a** library to access the thread-safe version of this subroutine.

Syntax

```
#include <stdio.h>
```

```
char *cuserid ( Name)
char *Name;
```

Description

The **cuserid** subroutine gets the alphanumeric user name associated with the current process. This subroutine generates a character string representing the name of a process's owner.

Note: The **cuserid** subroutine duplicates functionality available with the **getpwuid** and **getuid** subroutines. Present applications should use the **getpwuid** and **getuid** subroutines.

If the *Name* parameter is a null pointer, then a character string of size `L_cuserid` is dynamically allocated with **malloc**, and the character string representing the name of the process owner is stored in this area. The **cuserid** subroutine then returns the address of this area. Multithreaded application programs should use this functionality to obtain thread specific data, and then continue to use this pointer in subsequent calls to the **curserid** subroutine. In any case, the application program must deallocate any dynamically allocated space with the **free** subroutine when the data is no longer needed.

If the *Name* parameter is not a null pointer, the character string is stored into the array pointed to by the *Name* parameter. This array must contain at least the number of characters specified by the constant `L_cuserid`. This constant is defined in the **stdio.h** file.

If the user name cannot be found, the **cuserid** subroutine returns a null pointer; if the *Name* parameter is not a null pointer, a null character ('\0') is stored in *Name* [0].

Parameter

Item	Description
Name	Points to a character string representing a user name.

curs_set Subroutine

Purpose

Sets the cursor visibility.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
int curs_set(int  visibility);
```

Description

The **curs_set** subroutine sets the appearance of the cursor based on the value of visibility:

```
Value of visibility   Appearance of Cursor
```

Item	Description
0	invisible
1	terminal-specific normal mode

Item	Description
2	terminal-specific high visibility mode

The terminal does not necessarily support all the above values.

Parameters

Item	Description
Visibility	Sets the cursor state. You can set the cursor state to one of the following: **0** Invisible **1** Visible **2** Very visible

Return Values

If the terminal supports the cursor mode specified by *visibility*, then the **cur_set** subroutine returns the previous cursor state. Otherwise, the subroutine returns ERR.

Examples

To set the cursor state to invisible, use:

```
curs_set(0);
```

c16rtomb, c32rtomb Subroutine

Purpose

The **c16rtomb** and **c32rtomb** subroutines convert a 16-bit wide character (UTF-16) and a 32-bit wide character (UTF-32) to the corresponding multibyte character of the current locale.

Library

Standard C library (**libc.a**)

Syntax

```
#include <uchar.h>
size_t c16rtomb (char * restrict s,  char16_t c16,
 mbstate_t * restrict ps);

size_t c32rtomb (char * restrict s,  char32_t c32,
 mbstate_t * restrict ps);
```

Description

If the value of the **s** parameter is a null pointer, the **c16rtomb** subroutine is equivalent to the following call, where **buf** is an internal buffer.

```
c16rtomb(buf, L'\0', ps)
```

If the value of the **s** parameter is not a null pointer, the **c16rtomb** subroutine determines the number of bytes needed to represent the multibyte character that corresponds to the wide character specified by the **c16** parameter, including any shift sequences, and stores the multibyte character representation in an array, in which the first element is specified by the **s** parameter.

The value greater than the value of **MB_CUR_MAX** bytes is stored.

If the value of the **c16** parameter is a null wide character, a null byte is stored, preceded by any shift sequence that is needed to restore the initial shift state and the resulting state is described is the initial conversion state.

If the value of the **s** parameter is a null pointer, the **c32rtomb** subroutine is equivalent to the following call, where **buf** is an internal buffer.

```
c32rtomb(buf, L'\0', ps)
```

If the value of the **s** parameter is not a null pointer, the **c32rtomb** subroutine determines the number of bytes needed to represent the multibyte character that corresponds to the wide character specified by the **c32** parameter, including any shift sequences, and stores the multibyte character representation in an array, in which the first element is specified by the **s** parameter.

The value greater than the value of **MB_CUR_MAX** bytes is stored. If the value of the **c32** parameter is a null wide character, a null byte is stored, preceded by any shift sequence that is needed to restore the initial shift state and the resulting state is described is the initial conversion state.

Note: The **c16rtomb** and **c32rtomb** subroutines include the **ps** parameter which is of the type pointer to **mbstate_t** value that points to an object which describes the current conversion state of the associated multibyte character sequence, which the subroutines alter as necessary. If the **ps** parameter is a null pointer, each subroutine uses its own internal **mbstate_t** object. The **c16rtomb** and **c32rtomb** subroutines do not avoid data races with other calls to the same subroutine.

Parameters

Item	Description
s	Specifies the first element of an array where the multibyte character representation is stored.
c16, c32	Represents the wide character sequence.
ps	Specifies the state of the multibyte conversion.

Example

- The **mbstate_t** pointer can be used as follows:

```
 mbstate_t ss = 0;
```

```
int x = c16rtomb(out, in, &ss);
```

Return Values

The **c16rtomb** subroutine returns the number of bytes stored in an array object, including any shift sequences.

When the value of the **c16** parameter is not a valid wide character, an encoding error occurs. The function stores the value of the **EILSEQ** macro in the **errno** variable and returns the *(size_t)(-1)*. The conversion state is unspecified.

The **c32rtomb** subroutine returns the number of bytes stored in an array object, including any shift sequences.

When the value of the **c32** parameter is not a valid wide character, an encoding error occurs. The function stores the value of the **EILSEQ** macro in the **errno** variable and returns *(size_t)(-1)*. The conversion state is unspecified.

Error codes

The **c16rtomb** and **c32rtomb** subroutine is unsuccessful if the following error code is set.

Item	Description
EILSEQ	Indicates an invalid multibyte character sequence.

Files

The **uchar.h** file defines standard macros, data types, and subroutines.

d

The following Base Operating System (BOS) runtime services begin with the letter *d*.

def_prog_mode, def_shell_mode, reset_prog_mode or reset_shell_mode Subroutine

Purpose

Saves/restores the program or shell terminal modes.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

int def_prog_mode
(void);

int def_shell_mode
(void);

int reset_prog_mode
(void);

int reset_shell_mode
(void);
```

Description

The **def_prog_mode** subroutine saves the current terminal modes as the "program" (in Curses) state for use by the **reset_prog_mode** subroutine.

The **def_shell_mode** subroutine saves the current terminal modes as the "shell" (not in Curses) state for use by the **reset_shell_mode** subroutine.

The **reset_prog_mode** subroutine restores the terminal to the "program" (in Curses) state.

The **reset_shell_mode** subroutine restores the terminal to the "shell" (not in Curses) state.

These subroutines affect the mode of the terminal associated with the current screen.

Return Values

Upon successful completion, these subroutines return OK. Otherwise, they return ERR.

Examples

For the **def_prog_mode** subroutine:

To save the "**in curses**" state, enter:

```
def_prog_mode();
```

For the **def_shell_mode** subroutine:

To save the "**out of curses**" state, enter:

```
def_shell_mode();
```

This routine saves the "**out of curses**" state.

def_shell_mode Subroutine

Purpose

Saves the current terminal modes as shell mode ("out of curses").

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
def_shell_mode( )
```

Description

The **def_shell_mode** subroutine saves the current terminal driver line discipline modes in the current terminal structure for later use by **reset_shell_mode()**. The **def_shell_mode** subroutine is called automatically by the **setupterm** subroutine.

This routine would normally not be called except by a library routine.

Example

To save the "**out of curses**" state, enter:

```
def_shell_mode();
```

This routine saves the "**out of curses**" state.

defssys Subroutine

Purpose

Initializes the **SRCsubsys** structure with default values.

Library

System Resource Controller Library (**libsrc.a**)

Syntax

```
#include <sys/srcobj.h>
#include <spc.h>
```

void defssys(*SRCSubsystem***)**
struct SRCsubsys ****SRCSubsystem*;**

Description

The **defssys** subroutine initializes the **SRCsubsys** structure of the **/usr/include/sys/srcobj.h** file with the following default values:

Field	Value
display	SRCYES
multi	SRCNO
contact	SRCSOCKET
waittime	TIMELIMIT
priority	20
action	ONCE
standerr	**/dev/console**
standin	**/dev/console**
standout	**/dev/console**

All other numeric fields are set to 0, and all other alphabetic fields are set to an empty string.

This function must be called to initialize the **SRCsubsys** structure before an application program uses this structure to add records to the subsystem object class.

Parameters

Item	Description
SRCSubsystem	Points to the **SRCsubsys** structure.

del_curterm, restartterm, set_curterm, or setupterm Subroutine

Purpose

Interfaces to the **terminfo** database.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <term.h>

int del_curterm(TERMINAL *oterm);

int restartterm(char *term,
int fildes,
int *erret);

TERMINAL *set_curterm(TERMINAL *nterm);

int setupterm(char *term,
int fildes,
int *erret);
```

Description

The **del_curterm, restartterm**, **set_curterm**, **setupterm** subroutines retrieve information from the **terminfo** database.

To gain access to the **terminfo** database, the **setupterm** subroutine must be called first. It is automatically called by the **initscr** and **newterm** subroutines. The **setupterm** subroutine initialises the other subroutines to use the **terminfo** record for a specified terminal (which depends on whether the **use_env** subroutine was called). It sets the dur_term external variable to a TERMINAL structure that contains the record from the terminfo database for the specified terminal.

The terminal type is the character string term; if term is a null pointer, the environment variable TERM is used. If TERM is not set or if its value is an empty string, the "unknown" is used as the terminal type. The application must set the *fildes* parameter to a file descriptor, open for output, to the terminal device, before calling the **setupterm** subroutine. If the *erret* parameter is not null, the integer it points to is set to one of the following values to report the function outcome:

Item	Description
-1	The terminfo database was not found (function fails).
0	The entry for the terminal was not found in **terminfo** (function fails).
1	Success.

A simple call to the **setupterm** subroutine that uses all the defaults and sends the output to stdout is:

```
setupterm(char *)0, fileno(stdout), (int *)0);
```

The **set_curterm** subroutine sets the variable **cur_term** to *nterm*, and makes all of the terminfo boolean, numeric, and string variables use the values from *nterm*.

The **del_curterm** subroutine frees the space pointed to by oterm and makes it available for further use. If *oterm* is the same as **cur_term**, references to any of the terminfo boolean, numeric, and string variables thereafter may refer to invalid memory locations until the **setupterm** subroutine is called again.

The **restartterm** subroutine assumes a previous call to the **setupterm** subroutine (perhaps from the **initscr** or **newterm** subroutine). It lets the application specify a different terminal type in *term* and updates the information returned by the **baudrate** subroutine based on the *fildes* parameter, but does not destroy other information created by the **initscr**, **newterm**, or **setupterm** subroutines.

Parameters

Item	Description
**oterm*	
**term*	
fildes	
**erret*	
**nterm*	

Return Values

Upon successful completion, the **set_curterm** subroutine returns the previous value of cur_term. Otherwise, it returns a null pointer.

Upon successful completion, the other subroutines return OK. Otherwise, they return ERR.

Examples

To free the space occupied by a **TERMINAL** structure called `my_term`, use:

```
TERMINAL *my_term; del_curterm(my_term);
```

For the **restartterm** subroutine:

To restart an **aixterm** after a previous memory save and exit on error with a message, enter:

```
restartterm("aixterm", 1, (int*)0);
```

For the **set_curterm** subroutine:

To set the **cur_term** variable to point to the `my_term` terminal, use:

```
TERMINAL *newterm; set_curterm(newterm);
```

For the **setupterm** subroutine:

To determine the current terminal's capabilities using **$TERM** as the terminal name, standard output as output, and returning no error codes, enter:

```
setupterm((char*) 0, 1, (int*) 0);
```

delay_output Subroutine

Purpose

Sets the delay output.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

int delay_output(int *ms*);

Description

On terminals that support pad characters, the **delay_output** subroutine pauses the output for at least *ms* milliseconds. Otherwise, the length of the delay is unspecified.

Parameters

Item	Description
ms	Specifies the number of milliseconds to delay output.

Return Values

Upon successful completion, the **delay_output** subroutine returns OK. Otherwise, it returns ERR.

Examples

To set the output to delay 250 milliseconds, enter:

```
delay_output(250);
```

delch, mvdelch, mvwdelch or wdelch Subroutine

Purpose

Deletes the character from a window.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
int delch(void);
```

```
int mvdelch
(int y
int x);
```

```
mvwdelch
(WINDOW  *win;
int y
int x);
```

```
wdelch
(WINDOW *win);
```

Description

The **delch**, **mvdelch**, **mvwdelch**, and **wdelch** subroutines delete the character at the current or specified position in the current or specified window. This subroutine does not change the cursor position.

Parameters

Item	Description
x	
y	
**win*	Identifies the window from which to delete the character.

Return Values

Upon successful completion, these subroutines return OK. Otherwise, they return ERR.

Examples

1. To delete the character at the current cursor location in the standard screen structure, enter:

   ```
   mvdelch();
   ```

2. To delete the character at cursor position y=20 and x=30 in the standard screen structure, enter:

```
mvwdelch(20, 30);
```

3. To delete the character at cursor position y=20 and x=30 in the user-defined window my_window, enter:

```
wdelch(my_window, 20, 30);
```

deleteln or wdeleteln Subroutine

Purpose

Deletes lines in a window.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
int deleteln(void);
```

int wdeleteln(WINDOW **win*);

Description

The **deleteln** and **wdeleteln** subroutines delete the line containing the cursor in the current or specified window and move all lines following the current line one line toward the cursor. The last line of the window is cleared. The cursor position does not change.

Parameters

Item	Description
**win*	Specifies the window in which to delete the line.

Return Values

Upon successful completion, these subroutines return OK. Otherwise, they return ERR.

Examples

1. To delete the current line in stdscr, enter:

```
deleteln();
```

2. To delete the current line in the user-defined window my_window, enter:

```
WINDOW *my_window;
wdeleteln(my_window);
```

delwin Subroutine

Purpose

Deletes a window.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

int delwin(WINDOW  *win);
```

Description

The **delwin** subroutine deletes *win*, freeing all memory associated with it. The application must delete subwindows before deleting the main window.

Parameters

Item	Description
**win*	Specifies the window to delete.

Return Values

Upon successful completion, the **delwin** subroutine returns OK. Otherwise, it returns ERR.

Examples

To delete the user-defined window `my_window` and its subwindow `my_sub_window`, enter:

```
WINDOW *my_sub_window, *my_window;
delwin(my_sub_window);

delwin(my_window);
```

delssys Subroutine

Purpose

Removes the subsystem objects associated with the *SubsystemName* parameter.

Library

System Resource Controller Library (**libsrc.a**)

Syntax

```
#include <sys/srcobj.h>
#include <spc.h>
```

```
int delssys ( SubsystemName)
char *SubsystemName;
```

Description

The **delssys** subroutine removes the subsystem objects associated with the specified subsystem. This removes all objects associated with that subsystem from the following object classes:

- Subsystem
- Subserver Type
- Notify

The program running with this subroutine must be running with the group **system**.

Parameter

Item	Description
SubsystemName	Specifies the name of the subsystem.

Return Values

Upon successful completion, the **delssys** subroutine returns a positive value. If no record is found, a value of 0 is returned. Otherwise, -1 is returned and the **odmerrno** variable is set to indicate the error. See "Appendix B. ODM Error Codes" for a description of possible **odmerrno** values.

Security

Privilege Control:

SET_PROC_AUDIT kernel privilege

Files Accessed:

Mode	File
644	**/etc/objrepos/SRCsubsys**
644	**/etc/objrepos/SRCsubsvr**
644	**/etc/objrepos/SRCnotify**

Auditing Events:

Event	Information
SRC_Delssys	Lists in an audit log the name of the subsystem being removed.

Files

Item	Description
/etc/objrepos/SRCsubsys	SRC Subsystem Configuration object class.
/etc/objrepos/SRCsubsvr	SRC Subsystem Configuration object class.
/etc/objrepos/SRCnotify	SRC Notify Method object class.
/dev/SRC	Specifies the **AF_UNIX** socket file.
/dev/.SRC-unix	Specifies the location for temporary socket files.
/usr/include/sys/srcobj.h	Defines object structures used by the SRC.
/usr/include/spc.h	Defines external interfaces provided by the SRC subroutines.

derwin, newwin, or subwin Subroutine

Purpose

Window creation subroutines.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

WINDOW *derwin(WINDOW *orig,
int nlines,
int ncols,
int begin_y,
int begin_x);

WINDOW *newwin(int nlines,
int ncols,
int begin_y,
 int begin_x);

WINDOW *subwin(WINDOW *orig,
int nlines,
int ncols,
int begin_y,
int begin_x);
```

Description

The **derwin** subroutine is the same as the **subwin** subroutine except that *begin_y* and *begin_x* are relative to the origin of the window *orig* rather than absolute screen positions.

The **newwin** subroutine creates a new window with *nlines* lines and *ncols* columns, positioned so that the origin is at (*begin_y*, *begin_x*). If *nlines* is zero, it defaults to LINES - *begin_y*; if *ncols* is zero, it defaults to COLS - *begin_x*.

The **subwin** subroutine creates a new window with *nlines* lines and *ncols* columns, positioned so that the origin is at (*begin_y*, *begin_x*). (This position is an absolute screen position, not a position relative to the window orig.) If any part of the new window is outside *orig*, the subroutine fails and the window is not created.

Parameters

Item	Description
ncols	
nlines	
begin_y	
begin_x	

Return Values

Upon successful completion, these subroutines return a pointer to the new window. Otherwise, they return a null pointer.

Examples

For the **derwin** and **newwin** subroutines:

1. To create a new window, enter:

```
WINDOW *my_window;

my_window = newwin(5, 10, 20, 30);
```

   my_window is now a window 5 lines deep, 10 columns wide, starting at the coordinates y = 20, x = 30. That is, the upper left corner is at coordinates y = 20, x = 30, and the lower right corner is at coordinates y = 24, x = 39.

2. To create a window that is flush with the right side of the terminal, enter:

```
WINDOW *my_window;

my_window = newwin(5, 0, 20, 30);
```

   my_window is now a window 5 lines deep, extending all the way to the right side of the terminal, starting at the coordinates y = 20, x = 30. The upper left corner is at coordinates y = 20, x = 30, and the lower right corner is at coordinates y = 24, x = lastcolumn.

3. To create a window that fills the entire terminal, enter:

```
WINDOW *my_window;

my_window = newwin(0, 0, 0, 0);
```

   my_window is now a screen that is a window that fills the entire terminal's display.

For the **subwin** subroutine:

1. To create a subwindow, use:

```
WINDOW *my_window, *my_sub_window;
my_window = newwin (“derwin, newwin, or subwin Subroutine” on page 246)
            (5, 10, 20, 30);
```

   my_sub_window is now a subwindow 2 lines deep, 5 columns wide, starting at the same coordinates of its parent window my_window. That is, the subwindow's upper-left corner is at coordinates y = 20, x = 30 and lower-right corner is at coordinates y = 21, x = 34.

2. To create a subwindow that is flush with the right side of its parent, use

```
WINDOW *my_window, *my_sub_window;
my_window =
newwin (“derwin, newwin, or subwin Subroutine” on page 246)(5, 10, 20, 30);
my_sub_window = subwin(my_window, 2, 0, 20, 30);
```

   my_sub_window is now a subwindow 2 lines deep, extending all the way to the right side of its parent window my_window, and starting at the same coordinates. That is, the subwindow's upper-left corner is at coordinates y = 20, x = 30 and lower-right corner is at coordinates y = 21, x = 39.

3. To create a subwindow in the lower-right corner of its parent, use:

```
WINDOW *my_window, *my_sub_window
my_window = newwwin (“derwin, newwin, or subwin Subroutine” on page 246)
            (5, 10, 20, 30);
my_sub_window = subwin(my_window, 0, 0, 22, 35);
```

   my_sub_window is now a subwindow that fills the bottom right corner of its parent window, my_window, starting at the coordinates y = 22, x = 35. That is, the subwindow's upper-left corner is at coordinates y = 22, x = 35 and lower-right corner is at coordinates y = 24, x = 39.

dirname Subroutine

Purpose

Report the parent directory name of a file path name.

Library

Standard C Library **(libc.a)**

Syntax

#include <libgen.h>

char *dirname (*path*) **char ***path*

Description

Given a pointer to a character string that contains a file system path name, the **dirname** subroutine returns a pointer to a string that is the parent directory of that file. Trailing "/" characters in the path are not counted as part of the path.

If *path* is a null pointer or points to an empty string, a pointer to a static constant "." is returned.

The **dirname** and **basename** subroutines together yield a complete path name. **dirname** (*path*) is the directory where **basename** (*path*) is found.

Parameters

Item	Description
path	Character string containing a file system path name.

Return Values

The **dirname** subroutine returns a pointer to a string that is the parent directory of *path.* If *path* or **path* is a null pointer or points to an empty string, a pointer to a string "." is returned. The **dirname** subroutine may modify the string pointed to by *path* and may return a pointer to static storage that may then be overwritten by sequent calls to the **dirname** subroutine.

Examples

A simple file name and the strings "." and ".." all have "." as their return value.

Input string	Output string
/usr/lib	/usr
/usr/	/
usr	.
/	/
.	.
..	.

The following code reads a path name, changes directory to the appropriate directory, and opens the file.

```
char path [MAXPATHEN],   *pathcopy;
int fd;
fgets (path, MAXPATHEN, stdin);
```

```
pathcopy = strdup (path);
chdir (dirname (pathcopy) );
fd = open (basename (path), O_RDONLY);
```

disclaim and disclaim64 Subroutines

Purpose

Disclaim the content of a memory address range.

Syntax

```
#include <sys/shm.h>
int disclaim ( Address,  Length, Flag)
char *Address;
unsigned int Length, Flag;

int disclaim64( Address, Length, Flag)
void *Address;
size_t Length;
unsigned long Flag;
```

Description

The **disclaim** and **disclaim64** subroutines mark an area of memory having content that is no longer needed. The system then stops paging the memory area. These subroutines cannot be used on memory that is mapped to a file by the **shmat** subroutine.

Parameters

Item	Description
Address	Points to the beginning of the memory area.
Length	Specifies the length of the memory area in bytes.
Flag	Must be the **DISCLAIM_ZEROMEM** value, which indicates that each memory location in the address range should be set to zero.

Return Values

When successful, the **disclaim** and **disclaim64** subroutines return a value of 0.

Error Codes

If the **disclaim** and **disclaim64** subroutines are not successful, they returns a value of -1 and set the **errno** global variable to indicate the error. The **disclaim** and **disclaim64** subroutines are not successful if one or more of the following are true:

Item	Description
EFAULT	The calling process does not have write access to the area of memory that begins at the *Address* parameter and extends for the number of bytes specified by the *Length* parameter.
EINVAL	The value of the *Flag* parameter is not valid.
EINVAL	The memory area is mapped to a file.

dlclose Subroutine

Purpose

Closes and unloads a module loaded by the **dlopen** subroutine.

Syntax

```
#include <dlfcn.h>
```

```
int dlclose(Data);
void *Data;
```

Description

The **dlclose** subroutine is used to remove access to a module loaded with the **dlopen** subroutine. In addition, access to dependent modules of the module being unloaded is removed as well.

The `dlclose` subroutine performs C++ termination, like the **terminateAndUnload** subroutine does.

Modules being unloaded with the **dlclose** subroutine will not be removed from the process's address space if they are still required by other modules. Nevertheless, subsequent uses of *Data* are invalid, and further uses of symbols that were exported by the module being unloaded result in undefined behavior.

Parameters

Item	Description
Data	A loaded module reference returned from a previous call to **dlopen**.

Return Values

Upon successful completion, `0` (zero) is returned. Otherwise, **errno** is set to **EINVAL**, and the return value is also **EINVAL**. Even if the **dlclose** subroutine succeeds, the specified module may still be part of the process's address space if the module is still needed by other modules.

Error Codes

Item	Description
EINVAL	The *Data* parameter does not refer to a module opened by **dlopen** that is still open. The parameter may be corrupt or the module may have been unloaded by a previous call to **dlclose**.

dlerror Subroutine

Purpose

Returns a pointer to information about the last **dlopen**, **dlsym**, or **dlclose** error.

Syntax

```
#include <dlfcn.h>
```

```
char *dlerror(void);
```

Description

The **dlerror** subroutine is used to obtain information about the last error that occurred in a dynamic loading routine (that is, **dlopen** , **dlsym** , or **dlclose**). The returned value is a pointer to a null-terminated string without a final newline. Once a call is made to this function, subsequent calls without any intervening dynamic loading errors will return NULL.

Applications can avoid calling the **dlerror** subroutine, in many cases, by examining **errno** after a failed call to a dynamic loading routine. If **errno** is **ENOEXEC**, the **dlerror** subroutine will return additional information. In all other cases, **dlerror** will return the string corresponding to the value of **errno**.

The **dlerror** function may invoke **loadquery** to ascertain reasons for a failure. If a call is made to l**oad** or **unload** between calls to **dlopen** and **dlerror**, incorrect information may be returned.

Return Values

A pointer to a static buffer is returned; a NULL value is returned if there has been no error since the last call to **dlerror**. Applications should not write to this buffer; they should make a copy of the buffer if they wish to preserve the buffer's contents.

dlopen Subroutine

Purpose

Dynamically loads a module into the calling process.

Syntax

```
#include <dlfcn.h>
```

```
void *dlopen (FilePath, Flags);
const char *FilePath;
int Flags;
```

Description

The **dlopen** subroutine loads the module specified by *FilePath* into the executing process's address space. Dependents of the module are automatically loaded as well. If the module is already loaded, it is not loaded again, but a new, unique value will be returned by the **dlopen** subroutine.

The **dlopen** subroutine is a portable way of dynamically loading shared libraries. It performs C++ static initialization of the modules that it loads, like the **loadAndInit** subroutine does.

The value returned by the **dlopen** might be used in subsequent calls to **dlsym** and **dlclose**. If an error occurs during the operation, **dlopen** returns NULL.

If the main application was linked with the **-brtl** option, then the runtime linker is invoked by **dlopen**. If the module being loaded was linked with runtime linking enabled, both intra-module and inter-module references are overridden by any symbols available in the main application. If runtime linking was enabled, but the module was not built enabled, then all inter-module references will be overridden, but some intra-module references will not be overridden.

If the module being opened with **dlopen** or any of its dependents is being loaded for the first time, initialization routines for these newly-loaded routines are called (after runtime linking, if applicable) before **dlopen** returns. Initialization routines are the functions specified with the **-binitfini:** linker option when the module was built. (See the **ld** command for more information about this option.)

After calling the initialization functions for all newly-loaded modules, C++ static initialization is performed. If you call the **dlopen** subroutine from within an initialization function or a C++ static initialization function, modules loaded by the nested **dlopen** subroutine might be initialized before completely initializing the originally loaded modules.

If a **dlopen** subroutine is called from within a **binitfini** function, the initialization of the current module is abandoned for other modules.

Note: If the module being loaded has read-other permission, the module is loaded into the global shared library segment. Modules loaded into the global shared library segment are not unloaded even if they are no longer being used. Use the **slibclean** command to remove unused modules from the global shared library segment. To load the module in the process private region, unload the module completely using the **slibclean** command, and then unset its read-other permission.

The LIBPATH or LD_LIBRARY_PATH environment variables can be used to specify a list of directories in which the **dlopen** subroutine searches for the named module. The running application also contains a set of library search paths that were specified when the application was linked. The **dlopen** subroutine searches the modules based on the mechanism that the **load** subroutine defines, because the **dlopen** subroutine internally calls the **load** subroutine with the **L_LIBPATH_EXEC** flag.

Item	Description
FilePath	Specifies the name of a file containing the loadable module. This parameter can be contain an absolute path, a relative path, or no path component. If *FilePath* contains a slash character, *FilePath* is used directly, and no directories are searched. If the *FilePath* parameter is /unix, **dlopen** returns a value that can be used to look up symbols in the current kernel image, including those symbols found in any kernel extension that was available at the time the process began execution. If the value of *FilePath* is NULL, a value for the main application is returned. This allows dynamically loaded objects to look up symbols in the main executable, or for an application to examine symbols available within itself.

Flags

Specifies variations of the behavior of **dlopen**. Either **RTLD_NOW** or **RTLD_LAZY** must always be specified. Other flags may be OR'ed with **RTLD_NOW** or **RTLD_LAZY**.

Item	Description
RTLD_NOW	Load all dependents of the module being loaded and resolve all symbols.
RTLD_LAZY	Specifies the same behavior as **RTLD_NOW**. In a future release of the operating system, the behavior of the **RTLD_LAZY** may change so that loading of dependent modules is deferred of resolution of some symbols is deferred.
RTLD_GLOBAL	Allows symbols in the module being loaded to be visible when resolving symbols used by other **dlopen** calls. These symbols will also be visible when the main application is opened with **dlopen**(NULL, *mode*).
RTLD_LOCAL	Prevent symbols in the module being loaded from being used when resolving symbols used by other **dlopen** calls. Symbols in the module being loaded can only be accessed by calling **dlsym** subroutine. If neither **RTLD_GLOBAL** nor **RTLD_LOCAL** is specified, the default is **RTLD_LOCAL**. If both flags are specified, **RTLD_LOCAL** is ignored.
RTLD_MEMBER	The **dlopen** subroutine can be used to load a module that is a member of an archive. The **L_LOADMEMBER** flag is used when the **load** subroutine is called. The module name *FilePath* names the archive and archive member according to the rules outlined in the **load** subroutine.

Item	Description
RTLD_NOAUTODEFER	Prevents deferred imports in the module being loaded from being automatically resolved by subsequent loads. The **L_NOAUTODEFER** flag is used when the **load** subroutine is called. Ordinarily, modules built for use by the **dlopen** and **dlsym** sub routines will not contain deferred imports. However, deferred imports can be still used. A module opened with **dlopen** may provide definitions for deferred imports in the main application, for modules loaded with the **load** subroutine (if the **L_NOAUTODEFER** flag was not used), and for other modules loaded with the **dlopen** subroutine (if the **RTLD_NOAUTODEFER** flag was not used).

Return Values

Upon successful completion, **dlopen** returns a value that can be used in calls to the **dlsym** and **dlclose** subroutines. The value is not valid for use with the **loadbind** and **unload** subroutines.

If the **dlopen** call fails, NULL (a value of 0) is returned and the global variable **errno** is set. If **errno** contains the value ENOEXEC, further information is available via the **dlerror** function.

Error Codes

See the **load** subroutine for a list of possible **errno** values and their meanings.

dlsym Subroutine

Purpose

Looks up the location of a symbol in a module that is loaded with **dlopen**.

Syntax

```
#include <dlfcn.h>
```

```
void *dlsym(Handle, Symbol);
void *Handle;
const char *Symbol;
```

Description

The **dlsym** subroutine looks up a named symbol exported from a module loaded by a previous call to the **dlopen** subroutine. Only exported symbols are found by **dlsym**. See the **ld** command to see how to export symbols from a module.

Item	Description
Handle	Specifies a value returned by a previous call to **dlopen** or one of the special handles **RTLD_DEFAULT**, **RTLD_NEXT** or **RTLD_MYSELF**.
Symbol	Specifies the name of a symbol exported from the referenced module in the form of a NULL-terminated string or the special symbol name **RTLD_ENTRY**.

Note: C++ symbol names should be passed to **dlsym** in mangled form; **dlsym** does not perform any name demangling on behalf of the calling application.

In case of the special handle **RTLD_DEFAULT**, **dlsym** searches for the named symbol starting with the first module loaded. It then proceeds through the list of initial loaded modules and any global modules

obtained with **dlopen** until a match is found. This search follows the default model employed to relocate all modules within the process.

In case of the special handle **RTLD_NEXT**, **dlsym** searches for the named symbol in the modules that were loaded following the module from which the **dlsym** call is being made.

In case of the special handle **RTLD_MYSELF**, **dlsym** searches for the named symbol in the modules that were loaded starting with the module from which the **dlsym** call is being made.

In case of the special symbol name **RTLD_ENTRY**, **dlsym** returns the module's entry point. The entry point, if present, is the value of the module's loader section symbol marked as entry point.

In case of **RTLD_DEFAULT**, **RTLD_NEXT**, and **RTLD_MYSELF**, if the modules being searched have been loaded from **dlopen** calls, **dlsym** searches the module only if the caller is part of the same **dlopen** dependency hierarchy, or if the module was given global search access. See **dlopen** for a discussion of the **RTLD_GLOBAL** mode.

A search for the named symbol is based upon breadth-first ordering of the module and its dependants. If the module was constructed using the **-G** or **-brtl** linker option, the module's dependants will include all modules named on the **ld** command line, in the original order. The dependants of a module that was not linked with the **-G** or **-brtl** linker option will be listed in an unspecified order.

Return Values

If the named symbol is found, its address is returned. If the named symbol is not found, NULL is returned and **errno** is set to 0. If *Handle* or *Symbol* is invalid, NULL is returned and **errno** is set to **EINVAL** .

If the first definition found is an export of an imported symbol, this definition will satisfy the search. The address of the imported symbol is returned. If the first definition is a deferred import, the definition is ignored and the search continues.

If the named symbol refers to a BSS symbol (uninitialized data structure), the search continues until an initialized instance of the symbol is found or the module and all of its dependants have been searched. If an initialized instance is found, its address is returned; otherwise, the address of the first uninitialized instance is returned.

Error Codes

Item	Description
EINVAL	If the *Handle* parameter does not refer to a module opened by **dlopen** that is still loaded or if the *Symbol* parameter points to an invalid address, the **dlsym** subroutine returns NULL and **errno** is set to **EINVAL**.

dirfd Subroutine

Purpose

Extracts the file descriptor used by a DIR stream.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <dirent.h>
```

```
int dirfd(dirp);
DIR *dirp;
```

Description

The **dirfd** subroutine returns a file descriptor that refers to the directory pointed to by the *dirp* argument. This file descriptor is closed by a call to the **closedir** subroutine. If an attempt is made to close the file descriptor, and to modify the state of the associated description, other than through the **closedir**, **readdir**, **readdir_r**, or **rewinddir** subroutines, the behavior is undefined.

Return Values

If successful, the **dirfd** subroutine returns an integer that contains a file descriptor for the stream pointed to by *dirp* argument. Otherwise, the **dirfd** subroutine returns -1 and sets the **errno** global variable to indicate the error.

Error Codes

The **dirfd** subroutine might fail if the following is true:

Item	Description
EINVAL	The *dirp* argument does not refer to a valid directory stream.
ENOTSUP	The implementation does not support the association of a file descriptor with a directory.

doupdate, refresh, wnoutrefresh, or wrefresh Subroutines

Purpose

Refreshes windows and lines.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

int doupdate(void);

int refresh(void);

int wnoutrefresh(WINDOW  *win);

int wrefresh(WINDOW *win);
```

Description

The **refresh** and **wrefresh** subroutines refresh the current or specified window. The subroutines position the terminal's cursor at the cursor position of the window, except that, if the leaveok mode has been enabled, they may leave the cursor at an arbitrary position.

The **wnoutrefresh** subroutine determines which parts of the terminal may need updating.

The **doupdate** subroutine sends to the terminal the commands to perform any required changes.

Parameters

Item	Description
**win*	Specifies the window to be refreshed.

Return Values

Upon successful completion, these subroutines return OK. Otherwise, they return ERR.

Examples

For the **doupdate** or **wnoutrefresh** subroutine:

To update the user-defined windows `my_window1` and `my_window2`, enter:

```
WINDOW *my_window1, my_window2;
wnoutrefresh(my_window1);
wnoutrefresh(my_window2);
doupdate();
```

For the **refresh** or **wrefresh** subroutine:

1. To update the terminal's display and the current screen structure to reflect changes made to the standard screen structure, use:

   ```
   refresh();
   ```

2. To update the terminal and the current screen structure to reflect changes made to a user-defined window called `my_window`, use:

   ```
   WINDOW *my_window;
   wrefresh(my_window);
   ```

3. To restore the terminal to its state at the last refresh, use:

   ```
   wrefresh(curscr);
   ```

This subroutine is useful if the terminal becomes garbled for any reason.

drand48, erand48, jrand48, lcong48, lrand48, mrand48, nrand48, seed48, or srand48 Subroutine

Purpose

Generate uniformly distributed pseudo-random number sequences.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdlib.h>
```

```
double drand48 (void)
```

```
double erand48 ( xsubi)
unsigned short int xsubi[3];
```

```
long int jrand48 (xsubi)
unsigned short int xsubi[3];
```

```
void lcong48 ( Parameter)
unsigned short int Parameter[7];
```

```
long int lrand48 (void)
```

```
long int mrand48 (void)
```

```
long int nrand48 (xsubi)
unsigned short int xsubi[3];
```

```
unsigned short int *seed48 ( Seed16v)
unsigned short int Seed16v[3];
```

```
void srand48 ( SeedValue)
long int SeedValue;
```

Description

> **Attention:** Do not use the **drand48**, **erand48**, **jrand48**, **lcong48**, **lrand48**, **mrand48**, **nrand48**, **seed48**, or **srand48** subroutine in a multithreaded environment.

This family of subroutines generates pseudo-random numbers using the linear congruential algorithm and 48-bit integer arithmetic.

The **drand48** subroutine and the **erand48** subroutine return positive double-precision floating-point values uniformly distributed over the interval [0.0, 1.0).

The **lrand48** subroutine and the **nrand48** subroutine return positive long integers uniformly distributed over the interval [0,2**31).

The **mrand48** subroutine and the **jrand48** subroutine return signed long integers uniformly distributed over the interval [-2**31, 2**31).

The **srand48** subroutine, **seed48** subroutine, and **lcong48** subroutine initialize the random-number generator. Programs must call one of them before calling the **drand48**, **lrand48** or **mrand48** subroutines. (Although it is not recommended, constant default initializer values are supplied if the **drand48**, **lrand48** or **mrand48** subroutines are called without first calling an initialization subroutine.) The **erand48**, **nrand48**, and **jrand48** subroutines do not require that an initialization subroutine be called first.

The previous value pointed to by the **seed48** subroutine is stored in a 48-bit internal buffer, and a pointer to the buffer is returned by the **seed48** subroutine. This pointer can be ignored if it is not needed, or it can be used to allow a program to restart from a given point at a later time. In this case, the pointer is accessed to retrieve and store the last value pointed to by the **seed48** subroutine, and this value is then used to reinitialize, by means of the **seed48** subroutine, when the program is restarted.

All the subroutines work by generating a sequence of 48-bit integer values, *x*[*i*], according to the linear congruential formula:

```
x[n+1] = (ax[n] + c)mod m, n is > = 0
```

The parameter *m* = 248; hence 48-bit integer arithmetic is performed. Unless the **lcong48** subroutine has been called, the multiplier value *a* and the addend value *c* are:

```
a = 5DEECE66D base 16 = 273673163155 base 8
```

```
c = B base 16 = 13 base 8
```

Parameters

Item	Description
xsubi	Specifies an array of three shorts, which, when concatenated together, form a 48-bit integer.
SeedValue	Specifies the initialization value to begin randomization. Changing this value changes the randomization pattern.
Seed16v	Specifies another seed value; an array of three unsigned shorts that form a 48-bit seed value.
Parameter	Specifies an array of seven shorts, which specifies the initial *xsubi* value, the multiplier value *a* and the add-in value *c*.

Return Values

The value returned by the **drand48**, **erand48**, **jrand48, lrand48**, **nrand48**, and **mrand48** subroutines is computed by first generating the next 48-bit *x*[*i*] in the sequence. Then the appropriate number of bits, according to the type of data item to be returned, are copied from the high-order (most significant) bits of *x*[*i*] and transformed into the returned value.

The **drand48**, **lrand48**, and **mrand48** subroutines store the last 48-bit *x*[*i*] generated into an internal buffer; this is why they must be initialized prior to being invoked.

The **erand48**, **jrand48**, and **nrand48** subroutines require the calling program to provide storage for the successive *x*[*i*] values in the array pointed to by the *xsubi* parameter. This is why these routines do not have to be initialized; the calling program places the desired initial value of *x*[*i*] into the array and pass it as a parameter.

By using different parameters, the **erand48**, **jrand48**, and **nrand48** subroutines allow separate modules of a large program to generate independent sequences of pseudo-random numbers. In other words, the sequence of numbers that one module generates does not depend upon how many times the subroutines are called by other modules.

The **lcong48** subroutine specifies the initial *x*[*i*] value, the multiplier value *a*, and the addend value *c*. The *Parameter* array elements *Parameter*[0-2] specify *x*[*i*], *Parameter*[3-5] specify the multiplier *a*, and *Parameter*[6] specifies the 16-bit addend *c*. After **lcong48** has been called, a subsequent call to either the **srand48** or **seed48** subroutine restores the standard *a* and *c* specified before.

The initializer subroutine **seed48** sets the value of *x*[*i*] to the 48-bit value specified in the array pointed to by the *Seed16v* parameter. In addition, **seed48** returns a pointer to a 48-bit internal buffer that contains the previous value of *x*[*i*] that is used only by **seed48**. The returned pointer allows you to restart the pseudo-random sequence at a given point. Use the pointer to copy the previous *x*[*i*] value into a temporary array. Then call **seed48** with a pointer to this array to resume processing where the original sequence stopped.

The initializer subroutine **srand48** sets the high-order 32 bits of *x*[*i*] to the 32 bits contained in its parameter. The low order 16 bits of *x*[*i*] are set to the arbitrary value 330E16.

drem Subroutine

Purpose

Computes the IEEE Remainder as defined in the IEEE Floating-Point Standard.

Libraries

IEEE Math Library (**libm.a**) or System V Math Library (**libmsaa.a**)

Syntax

```
#include <math.h>
```

double drem (*x*, *y*)
double *x*, *y*;

Description

The **drem** subroutine calculates the remainder r equal to x minus n to the x power multiplied by y (*r = x - n* * y), where the n parameter is the integer nearest the exact value of x divided by y (x/y). If |n -x/y| = 1/2, then the *n* parameter is an even value. Therefore, the remainder is computed exactly, and the absolute value of r (|r|) is less than or equal to the absolute value of y divided by 2 (|y|/2).

The IEEE Remainder differs from the **fmod** subroutine in that the IEEE Remainder always returns an *r* parameter such that |r| is less than or equal to |y|/2, while FMOD returns an *r* such that |r| is less than or equal to |y|. The IEEE Remainder is useful for argument reduction for transcendental functions.

Note: Compile any routine that uses subroutines from the **libm.a** library with the **-lm** flag. For example: compile the **drem.c** file:

```
cc drem.c -lm
```

Note: For new development, the **remainder** subroutine is the preferred interface.

Parameters

Item	Description
x	Specifies double-precision floating-point value.
y	Specifies a double-precision floating-point value.

Return Values

The **drem** subroutine returns a NaNQ value for (x, 0) and (+/-INF, y).

drw_lock_done Kernel Service

Purpose

Unlock a disabled read-write lock.

Syntax

```
#include <sys/lock_def.h>
```

void drw_lock_done(*lock_addr***)**
drw_lock_t *lock_addr* **;**

Parameters

Item	Description
lock_addr	Specifies the address of the lock word to unlock.

Description

The **drw_lock_done** service unlocks the specified read-write lock. The calling thread or interrupt handler must own the lock either in read shared or write exclusive mode. The **drw_lock_done** service has no return values.

Execution Environment

The **drw_lock_done** kernel service may be called from either the process environment or the interrupt environment. However, if called from the process environment, interrupts must be disabled to some interrupt priority other than **INTBASE**.

Return Values

Done

drw_lock_free Kernel Service

Purpose

Frees resources associated with a disabled read-write lock.

Syntax

```
#include <sys/lock_def.h>
```

void drw_lock_free(*lock_addr***)**
drw_lock_t *lock_addr* **;**

Parameters

Item	Description
lock_addr	Specifies the address of the lock word to free.

Description

The **drw_lock_free** service frees the specified read-write lock and all internal resources that might be associated with the lock.

Execution Environment

The **drw_lock_free()** kernel service may be called from either the process environment or the interrupt environment.

Return Values

None

drw_lock_init Kernel Service

Purpose

Initialize a disabled read-write lock.

Syntax

```
#include <sys/lock_def.h>
```

void drw_lock_init(*lock_addr*)
drw_lock_t *lock_addr* **;**

Parameters

Item	Description
lock_addr	Specifies the address of the lock word to initialize.

Description

The **drw_lock_init** service initializes the specified read-write lock. The **drw_lock_init** service has no return values.

Execution Environment

The **drw_lock_init()** kernel service must be called from the process environment only.

Return Values

None

drw_lock_islocked Kernel Service

Purpose

Determine whether a **drw_lock** is held in either read or write mode.

Syntax

```
#include <sys/lock_def.h>
```

boolean_t drw_lock_islocked (*lock_addr*)
)drw_lock_t *lock_addr* **;**

Parameters

Item	Description
lock_addr	Specifies the address of the lock word.

Description

The **drw_lock_islocked** kernel services returns FALSE if the specified lock is not held in read or write mode. It returns TRUE if the lock is locked at the time of the call.

Execution Environment

The **drw_lock_islocked** kernel service may be called from either the process environment or the interrupt environment. However, if called from the process environment, interrupts must be disabled to some interrupt priority other than **INTBASE**.

Return Values

The following only apply to drw_lock_read_to_write:

Return value	Description
TRUE	Indicates that the lock is not currently held.
FALSE	Indicates that the lock is held.

drw_lock_read Kernel Service

Purpose

Lock a disabled read-write lock in read-shared mode.

Syntax

```
#include <sys/lock_def.h>
```

void drw_lock_read(*lock_addr***)**
drw_lock_t *lock_addr* **;**

Parameters

Item	Description
lock_addr	Specifies the address of the lock word to lock.

Description

The **drw_lock_read** service locks the specified read-write lock in read shared mode. The lock must have been previously initialized with the **lock_init** kernel service. The **drw_lock_read** service has no return values.

Execution Environment

The **drw_lock_read** kernel service may be called from either the process environment or the interrupt environment. However, if called from the process environment, interrupts must be disabled to some interrupt priority other than **INTBASE**.

Return Values

None

drw_lock_read_to_write Kernel Service

Purpose

Upgrades a disabled read-write from read-shared to write exclusive mode.

Syntax

```
#include <sys/lock_def.h>
```

boolean drw_lock read_to_write (*lock_addr***)**
boolean drw_lock try_read_to_write (*lock_addr***)drw_lock_t** *lock_addr* **;**

Parameters

Item	Description
lock_addr	Specifies the address of the lock word to lock.

Description

The **drw_lock_read_to_write** and **drw_lock_try_read_to_write** kernel services try to upgrade the specified read-write lock from read-shared to write-exclusive mode. The caller must hold the lock in read mode. The lock is successfully upgraded if no other thread has already requested write-exclusive access for this lock. If the lock cannot be upgraded, it is no longer held on return from the **drw_lock_read_to_write** kernel service; it is still held in shared-read mode on return from the **drw_lock_try_read_to_write** kernel service.

The calling kernel thread must hold the lock in shared-read mode.

Execution Environment

The **drw_lock_read_to_write** and **drw_lock_try_read_to_write** kernel services may be called from either the process environment or the interrupt environment. However, if called from the process environment, interrupts must be disabled to some interrupt priority other than INTBASE.

Return Values

The following only apply to **drw_lock_read_to_write**:

Item	Description
TRUE	Indicates that the lock was successfully upgraded to exclusive-write mode.
FALSE	Indicates that the lock was not upgraded to exclusive-write mode and the lock is no longer held by the caller.

The following only apply to **lock_try_read_to_write**:

Item	Description
TRUE	Indicates that the lock was successfully upgraded to exclusive-write mode.
FALSE	Indicates that the lock was not upgraded and is held in read mode.

drw_lock_try_write Kernel Service

Purpose

Immediately acquire a disabled read-write lock in write-exclusive mode if available.

Syntax

```
#include <sys/lock_def.h>
```

boolean_t drw_lock try_write (*lock_addr***)**
drw_lock_t *lock_addr* **;**

Parameters

lock_addr
Specifies the address of the lock word to lock.

Description

The **drw_lock_try_write** kernel service acquires an available **drw_lock** in write mode and returns TRUE. It returns FALSE if the lock is not available.

Execution Environment

The **drw_lock_try_write** kernel service may be called from either the process environment or the interrupt environment. However, if called from the process environment, interrupts must be disabled to some interrupt priority other than **INTBASE**.

Return Values

The following only apply to **drw_lock_try_write**:

TRUE
Indicates that the lock was acquired.

FALSE
Indicates that the lock was not acquired.

drw_lock_write Kernel Service

Purpose

Lock a disabled read-write lock in write-exclusive mode.

Syntax

```
#include <sys/lock_def.h>
```

void drw_lock_write(*lock_addr***)**
drw_lock_t *lock_addr* **;**

Parameters

Item	Description
lock_addr	Specifies the address of the lock word to lock.

Description

The **drw_lock_write** service locks the specified read-write lock in write-exclusive mode. The lock must have been previously initialized with the **lock_init** kernel service. The **drw_lock_write** service has no return values.

Execution Environment

The **drw_lock_write** kernel service may be called from either the process environment or the interrupt environment. However, if called from the process environment, interrupts must be disabled to some interrupt priority other than **INTBASE**.

Return Values

None

drw_lock_write_to_read Kernel Service

Purpose

Downgrades a disabled read-write lock from write exclusive mode to read-shared mode.

Syntax

```
#include <sys/lock_def.h>
```

void drw_lock_write_to_read(*lock_addr***)**
drw_lock_t *lock_addr* **;**

Parameters

Item	Description
lock_addr	Specifies the address of the lock word to lock.

Description

The **drw_lock_write_to_read** kernel service downgrades the specified complex lock from exclusive-write mode to shared-read mode. The calling kernel thread must hold the lock in exclusive-write mode.

Once the lock has been downgraded to shared-read mode, other kernel threads will also be able to acquire it in read-shared mode.

Execution Environment

The **drw_lock_write_to_read** kernel service may be called from either the process environment or the interrupt environment. However, if called from the process environment, interrupts must be disabled to some interrupt priority other than **INTBASE**.

Return Values

None

dscr_ctl Subroutine

Purpose

Allows applications to read the current settings of the hardware streams mechanism and to set the system-wide or per-process values for the Data Streams Control Register (DSCR).

Note: The DSCR is privileged. It can be read or written only by the operating system. Beginning with POWER8, per-thread problem-state (user) access to the DSCR is allowed through Special Purpose Register (SPR) 3, as defined by the PowerISA.

Syntax

```
#include <sys/machine.h>
```

```
int dscr_ctl(int operation, void * buf_p, int size);
```

Description

The DSCR register consists of several bit fields:

Bit Position	Name	Description
39	SWTE (Software Transient Enable)	Applies the transient attribute to software defined streams.
40	HWTE (Hardware Transient Enable)	Applies the transient attribute to hardware detected streams.
41	STE (Store Transient Enable)	Applies the transient attribute to store streams.
42	LTE (Load Transient Enable)	Applies the transient attribute to load streams.
43	SWUE (Software Unit Count Enable)	Applies the unit count to software defined streams.
44	HWUE (Hardware Unit Count Enable)	Applies the unit count to hardware defined streams.
45-54	UNITCNT (Unit Count)	Number of units in a data stream.
55-57	URG (Depth Attainment Urgency)	Indicates the time of prefetch depth that can be reached for the hardware-detected streams.
58	LSD (Load Stream Disable)	Disables the hardware detection and the initiation of load streams.
59	SNSE (Stride-N Stream Enable)	Enables the hardware detection and initiation of load and store streams that have a stride greater than a single cache block. The load streams are detected only when the **LSD** bit is zero. The store streams are detected only when the **SSE** bit is one.
60	SSE (Store Stream Enable)	Enables the hardware detection and the initiation of store streams.
61-63	DPFD (Default Prefetch Depth)	Applies the depth value for the hardware-detected streams and software-defined streams for which a **dcbt** instruction with the TH value as 1010 is not used.

The firmware provides a platform default value for the DSCR register. When the prefetch depth is set to **0** in the DSCR register, the processor uses this default value implicitly.

The **dscr_ctl** system call allows a privileged application to set an operating system default value for the DSCR, which overrides the platform default.

The **dscr_ctl** system call allows any application to set a per-process value for the DSCR register, which overrides the operating system default value for this process.

When a thread issues the **dscr_ctl** system call to change the prefetch depth for the process, the new value is written into the AIX process context and the DSCR of the thread that runs the system call. If another

thread in the process is simultaneously running on another processor, it starts using the new DSCR value only after the new value is reloaded from the process context.

When a thread starts running on a processor, the value of the DSCR for the owning process is written in the DSCR register. If the process has not set its DSCR value with the **dscr_ctl** system call, the operating system default value is used.

When the **fork** subroutine is called, the new process inherits the DSCR value from its parent process. This value gets reset to the system default value when the **exec** subroutine is called.

On systems which support programmatic setting of the DSCR through problem-state (user) access, such as POWER8, the value set by such access is thread-specific and overrides any other values, even the ones that are written through this service. In other words, problem-state manipulation of the DSCR provides for the finest granularity of access (per-thread) to the hardware streams functionality.

The following symbolic values for the various fields are defined in the <sys/machine.h> file:

```
DPFD_DEFAULT            0
DPFD_NONE               1
DPFD_SHALLOWEST         2
DPFD_SHALLOW            3
DPFD_MEDIUM             4
DPFD_DEEP               5
DPFD_DEEPER             6
DPFD_DEEPEST            7

DSCR_SSE                1<<3
DSCR_SNSE               1<<4
DSCR_LSD                1<<5

URG_DEFAULT             0<<6
URG_NOT_URGENT          1<<6
URG_LEAST_URGENT        2<<6
URG_LEAST_URGENT        3<<6
URG_LESS_URGENT         4<<6
URG_MEDIUM              5<<6
URG_MORE_URGENT         6<<6
URG_MOST_URGENT         7<<6
```

```
DSCR_HWUE (1<<19)
DSCR_SWUE (1<<20)
DSCR_LTE  (1<<21)
DSCR_STE  (1<<22)
DSCR_HWTE (1<<23)
DSCR_SWTE (1<<24)
```

The following is the description of the **dscr_properties** structure in the <sys/machine.h> file:

```
struct dscr_properties {
      uint        version;             /* Properties struct version                  */
      uint        number_of_streams;   /* Number of hardware streams                 */
      long long   platform_default_pd; /* PFW default DSCR value                     */
      long long   os_default_pd;       /* AIX default DSCR value                     */
      int         dscr_version;        /* Architecture version, such as PowerISA 2.07 */
      uint        dscr_control;        /* System-wide DSCR control (read only)       */
      long long   dscr_smt[5];         /* DSCR/SMT Matrix                            */
      long long   dscr_mask;           /* Mask of valid bits per architecture version */
};
```

Depending on the version of the Instruction Set Architecture (ISA) for Power Systems servers supported by a specific AIX level on a specified hardware platform, only a subset of the bits previously shown might be supported.

Refer to the <sys/machine.h> header file for the definitions for the **dscr_version** field and the corresponding bits supported for each version.

The following is the sample code setting of the DSCR value of the process:

```
#include <sys/machine.h>
int rc;
long long dscr = DSCR_SSE | DPFD_DEEPER;
rc = dscr_ctl(DSCR_WRITE, &dscr);
```

Parameters

Parameter	Description
Operation	Specifies the operation to perform. It has the following flags: **DSCR_WRITE** Stores the new value from the input buffer into the process context and in the DSCR. **DSCR_READ** Reads the current value of the DSCR and returns it to the output buffer. **DSCR_GET_PROPERTIES** Reads the number of hardware streams supported by the platform, the platform default prefetch depth used by the firmware, the operating system default prefetch depth, and the supported version of the ISA for Power Systems servers from the kernel memory. It returns values in the output buffer (struct `dscr_properties` defined in the `sys/machine.h` file). **DSCR_SET_DEFAULT** Sets the 64-bit DSCR value in the buffer that is pointed to by the **buf_p** parameter as the operating system default. Returns the previous default value in the buffer that is pointed to by the **buf_p** parameter. It requires the root authority. The new default value is used by all the processes that do not explicitly set a DSCR value by using the **DSCR_WRITE** flag. The new default value is not permanent across reboot operations. To permanently set the default prefetch depth for an operating system across reboot operations, use the **dscrtl** command.
buf_p	When this parameter is used with the **DSCR_WRITE**, **DSCR_READ** and **DSCR_GET_PROPERTIES** values, the **buf_p** parameter specifies the pointer to an area of memory, that is the input buffer from where the values are copied from or the output buffer to which the data is copied. The **buf_p** parameter must be a pointer to a 64-bit data area for the **DSCR_WRITE**, **DSCR_READ** and **DSCR_SET_DEFAULT** operations. The **buf_p** parameter must be a pointer to a struct **dscr_properties** defined in the `sys/machine.h` file for the **DSCR_GET_PROPERTIES** operation.
size	Specifies the size in bytes of the area pointed to by the **buf_p** parameter.

Return Values

Value	Description
0	Returns 0 when the **dscr_ctl** subroutine is successful.
-1	Returns -1 if an error is detected. In this case, **errno** is set to indicate the error.

Error Codes

When the **dscr_ctl** subroutine fails, **errno** is set to one of the following values:

Value of errno	Description
EFAULT	The address passed to the function is not valid.
EINVAL	The operation is **DSCR_WRITE** or **DSCR_SET_DEFAULT** and the value passed for DSCR is not valid.
ENOTSUP	Data streams are not supported by platform hardware.

Value of errno	Description
EPERM	Operation is not permitted. The **DSCR_SET_DEFAULT** operation is used by a nonroot user.

duplocale Subroutine

Purpose

Duplicates a locale object.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <locale.h>
```

```
locale_t duplocale(locobj);
locale_t locobj;
```

Description

The **duplocale** subroutine creates a duplicate copy of the locale object that is referenced by the *locobj* argument.

If the *locobj* argument value is LC_GLOBAL_LOCALE, the **duplocale** subroutine creates a new locale object that contains a copy of the global locale that is determined by the **setlocale** subroutine.

If the *locobj* argument is not a valid handle for a locale object, the behavior of the **duplocale** subroutine is undefined.

Return Values

If successful, the **duplocale** subroutine returns a handle for a new locale object. Otherwise, the **duplocale** subroutine returns **(locale_t) 0** and sets the **errno** global variable to indicate the error.

Error Codes

The **duplocale** subroutine fails if the following is true:

Item	Description
ENOMEM	There is not enough memory available to create the locale object or load the locale data.

The **duplocale** subroutine might fail if the following is true:

Item	Description
EINVAL	The *locobj* argument is not a handle for a locale object.

e

The following Base Operating System (BOS) runtime services begin with the letter *e*.

_end, _etext, or _edata Identifier

Purpose

Define the first addresses following the program, initialized data, and all data.

Syntax

```
extern _end;
```

```
extern _etext;
```

```
extern _edata;
```

Description

The external names **_end**, **_etext**, and **_edata** are defined by the loader for all programs. They are not subroutines but identifiers associated with the following addresses:

Item	Description
_etext	The first address following the program text.
_edata	The first address following the initialized data region.
_end	The first address following the data region that is not initialized. The name **end** (with no underscore) defines the same address as does **_end** (with underscore).

The break value of the program is the first location beyond the data. When a program begins running, this location coincides with **end**. However, many factors can change the break value, including:

- The **brk** or **sbrk** subroutine
- The **malloc** subroutine
- The standard I/O subroutines
- The **-p** flag with the **cc** command

Therefore, use the **brk** or **sbrk(0)** subroutine, not the **end** address, to determine the break value of the program.

echo or noecho Subroutine

Purpose

Enables/disables terminal echo.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
int echo(void);
```

```
int noecho(void);
```

Description

The **echo** subroutine enables Echo mode for the current screen. The **noecho** subroutine disables Echo mode for the current screen. Initially, curses software echo mode is enabled and hardware echo mode of the tty driver is disabled. The **echo** and **noecho** subroutines control software echo only. Hardware echo must remain disabled for the duration of the application, else the behaviour is undefined.

Return Values

Upon successful completion, these subroutines return OK. Otherwise, they return ERR.

Examples

1. To turn echoing on, use:

   ```
   echo();
   ```

2. To turn echoing off, use:

   ```
   noecho();
   ```

echochar or wechochar Subroutines

Purpose

Echos single-byte character and rendition to a window and refreshes the window.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
int echochar(const chtype ch);
```

```
int wechochar(WINDOW *win,
const chtype ch);
```

Description

The **echochar** subroutine is equivalent to a call to the **addch** soubroutine followed by a call to the **refresh** subroutine.

The **wechochar** subroutine is equivalent to a call to the **waddch** subroutine followed by a call to the **wrefresh** subroutine.

Return Values

Upon successful completion, these subroutines return OK. Otherwise, they return ERR.

Example

To output the character `I` to the stdscr at the present cursor location and to update the physical screen, do the following:

```
echochar('I');
```

ecvt, fcvt, or gcvt Subroutine

Purpose

Converts a floating-point number to a string.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdlib.h>
```

```
char *ecvt ( Value,  NumberOfDigits,  DecimalPointer,  Sign;)
double Value;
int  NumberOfDigits, *DecimalPointer, *Sign;
```

```
char *fcvt (Value, NumberOfDigits, DecimalPointer, Sign;)
double Value;
int  NumberOfDigits, *DecimalPointer, *Sign;
```

```
char *gcvt (Value, NumberOfDigits,  Buffer;)
double Value;
int NumberOfDigits;
char *Buffer;
```

Description

The **ecvt**, **fcvt**, and **gcvt** subroutines convert floating-point numbers to strings.

The **ecvt** subroutine converts the *Value* parameter to a null-terminated string and returns a pointer to it. The *NumberOfDigits* parameter specifies the number of digits in the string. The low-order digit is rounded according to the current rounding mode. The **ecvt** subroutine sets the integer pointed to by the *DecimalPointer* parameter to the position of the decimal point relative to the beginning of the string. (A negative number means the decimal point is to the left of the digits given in the string.) The decimal point itself is not included in the string. The **ecvt** subroutine also sets the integer pointed to by the *Sign* parameter to a nonzero value if the *Value* parameter is negative and sets a value of 0 otherwise.

The **fcvt** subroutine operates identically to the **ecvt** subroutine, except that the correct digit is rounded for C or FORTRAN F-format output of the number of digits specified by the *NumberOfDigits* parameter.

Note: In the F-format, the *NumberOfDigits* parameter is the number of digits desired after the decimal point. Large numbers produce a long string of digits before the decimal point, and then *NumberOfDigits* digits after the decimal point. Generally, the **gcvt** and **ecvt** subroutines are more useful for large numbers.

The **gcvt** subroutine converts the *Value* parameter to a null-terminated string, stores it in the array pointed to by the *Buffer* parameter, and then returns the *Buffer* parameter. The **gcvt** subroutine attempts

to produce a string of the *NumberOfDigits* parameter significant digits in FORTRAN F-format. If this is not possible, the E-format is used. The **gcvt** subroutine suppresses trailing zeros. The string is ready for printing, complete with minus sign, decimal point, or exponent, as appropriate. The radix character is determined by the current locale (see **setlocale** subroutine). If the **setlocale** subroutine has not been called successfully, the default locale, POSIX, is used. The default locale specifies a **.** (period) as the radix character. The **LC_NUMERIC** category determines the value of the radix character within the current locale.

The **ecvt**, **fcvt**, and **gcvt** subroutines represent the following special values that are specified in ANSI/IEEE standards 754-1985 and 854-1987 for floating-point arithmetic:

Item	Description
Quiet NaN	Indicates a quiet not-a-number (NaNQ)
Signalling NaN	Indicates a signaling NaNS
Infinity	Indicates a INF value

The sign associated with each of these values is stored in the *Sign* parameter.

Note: A value of 0 can be positive or negative. In the IEEE floating-point, zeros also have signs and set the *Sign* parameter appropriately.

Attention: All three subroutines store the strings in a static area of memory whose contents are overwritten each time one of the subroutines is called.

Parameters

Item	Description
Value	Specifies some double-precision floating-point value.
NumberOfDigits	Specifies the number of digits in the string.
DecimalPointer	Specifies the position of the decimal point relative to the beginning of the string.
Sign	Specifies that the sign associated with the return value is placed in the *Sign* parameter. In IEEE floating-point, since 0 can be signed, the *Sign* parameter is set appropriately for signed 0.
Buffer	Specifies a character array for the string.

efs_closeKS Subroutine

Purpose

Disassociates the processes with open keystores.

Library

EFS Library (**libefs.a**)

Syntax

```
#include <libefs.h>

int efs_closeKS(void)
```

Description

The **efs_closeKS** subroutine disassociates an open keystore with a process. Therefore, the process does not have access to the EFS keys and is not to encrypt or decrypt files. Opening an encrypted file produces the error **ENOATTR**.

If a keystore is open using the **efskeymgr** command or using the login process, the keys within the keystore are associated to user's process and child processes. These keys are used within an Encrypted File System (EFS) to encrypt and decrypt files. If the **efs_closeKS** subroutine is called, the process is disassociated with the keystores, and is no longer able to open, decrypt or read EFS files. The process is not be able to open, encrypt or write EFS files. If the process has previously opened EFS files, those file operations maintain the ability to encrypt and decrypt.

Return Values

If successful, the **efs_closeKS** subroutine returns a value of zero. If it fails, it returns a value of -1 and sets the **errno** error code.

Errors

No error code is defined.

Files

The**/etc/security/group** File and the **user** File in *Files Reference*.

EnableCriticalSections, BeginCriticalSection, and EndCriticalSection Subroutine

Purpose

Enables a thread to be exempted from timeslicing and signal suspension, and protects critical sections.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/thread_ctl.h>

int EnableCriticalSections(void);
void BeginCriticalSection(void);
void EndCriticalSection(void);
```

Description

When called, the **EnableCriticalSections** subroutine enables the thread to be exempted from timeslicing and signal suspension. Once that is done, the thread can call the **BeginCriticalSection** and **EndCriticalSection** subroutines to protect critical sections. Calling the **BeginCriticalSection** and **EndCriticalSection** subroutines with exemption disabled has no effect. The subroutines are safe for use by multithreaded applications.

Once the service is enabled, the thread can protect critical sections by calling the **BeginCriticalSection** and **EndCriticalSection** subroutines. Calling the **BeginCriticalSection** subroutine will exempt the thread from timeslicing and suspension. Calling the **EndCriticalSection** subroutine will clear exemption for the thread.

The **BeginCriticalSection** subroutine will not make a system call. The **EndCriticalSection** subroutine might make a system call if the thread was granted a benefit during the critical section. The purpose of the system call would be to notify the kernel that any posted but undelivered stop signals can be delivered, and any postponed timeslice can now be completed.

Return Values

The **EnableCriticalSections** subroutine returns a zero.

endwin Subroutine

Purpose

Suspends curses session.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

int endwin(void)
```

Description

The **endwin** subroutine restores the terminal after Curses activity by at least restoring the saved shell terminal mode, flushing any output to the terminal and moving the cursor to the first column of the last line of the screen. Refreshing a window resumes program mode. The application must call the **endwin** subroutine for each terminal being used before exiting. If the **newterm** subroutine is called more than once for the same terminal, the first screen created must be the last one for which the **endwin** subroutine is called.

Return Values

Upon successful completion, the **endwin** subroutine returns OK. Otherwise, it returns ERR.

Examples

To terminate curses permanently or temporarily, enter:

```
endwin();
```

erase or werase Subroutine

Purpose

Copies blank spaces to every position in a window.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
erase( )
```

werase(*Window*)
WINDOW ***Window**;

Description

The **erase** and **werase** subroutines copy blank spaces to every position in the specified window. Use the **erase** subroutine with the stdscr and the **werase** subroutine with user-defined windows.

Parameters

Item	Description
Window	Specifies the window to erase.

Examples

1. To erase the standard screen structure, enter:

   ```
   erase();
   ```

2. To erase the user-defined window `my_window`, enter:

   ```
   WINDOW *my_window;
   werase(my_window);
   ```

erasechar, erasewchar, killchar, and killwchar Subroutine

Purpose

Terminal environment query functions.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

char erasechar(void);

int erasewchar(wchar_t *ch);

char killchar(void);
```

```
int killwchar(wchar_t
*ch);
```

Description

The **erasechar** subroutine returns the current character. chosen by the user. The **erasechar** subroutine stores the current erase character in the object pointed to by the *ch* parameter. If no erase character has been defined, the subroutine will fail and the object pointed to by *ch* will not be changed.

The **killchar** subroutine returns the current line.

The **killchar** subroutine stores the current line kill character in the object pointed to by *ch*. If no line kill character has been defined, the subroutine will fail and the object pointed to by *ch* will not be changed.

Return Values

The **erasechar** subroutine returns the erase character and the **killchar** subroutine returns the line kill character. The return value is unspecified when these characters are multi-byte characters.

Upon successful completion, the **erasechar** subroutine and the **killchar** subroutine return OK. Otherwise, they return ERR.

Examples

To retrieve a user's erase character and return it to the user-defined variable `myerase`, enter:

```
myerase = erasechar();
```

erf, erff, erfl, erfd32, erfd64, and erfd128 Subroutines

Purpose

Computes the error and complementary error functions.

Libraries

IEEE Math Library (**libm.a**) or System V Math Library (**libmsaa.a**)

Syntax

```
#include <math.h>
```

double erf (*x*)
double *x*;

```
float erff (x)
float x;
```

```
long double erfl (x)
long double x;
_Decimal32 erfd32 (x)
_Decimal32 x;

_Decimal64 erfd64 (x)
_Decimal64 x;

_Decimal128 erfd128 (x)
_Decimal128 x;
```

Description

The **erf**, **erff**, **erfl**, **erfd32**, **erfd64**, and **erfd128** subroutines return the error function of the *x* parameter, defined for the **erf** subroutine as the following:

```
erf(x) = (2/sqrt(pi) * (integral [0 to x] of exp(-(t**2)) dt)
```

```
erfc(x) = 1.0 - erf(x)
```

Note: Compile any routine that uses subroutines from the **libm.a** library with the **-lm** flag. To compile the **erf.c** file, for example, enter:

```
cc erf.c -lm
```

An application wishing to check for error situations should set **errno** to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these functions. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies a double-precision floating-point value.

Return Values

Upon successful completion, the **erf**, **erff**, **erfl**, **erfd32**, **erfd64**, and **erfd128** subroutines return the value of the error function.

If *x* is NaN, a NaN is returned.

If *x* is ±0, ±0 is returned.

If *x* is ±Inf, ±1 is returned.

If *x* is subnormal, a range error may occur, and 2 * *x*/**sqrt**(pi) should be returned.

erfc, erfcf, erfcl, erfcd32, erfcd64, and erfcd128 Subroutines

Purpose

Computes the complementary error function.

Syntax

```
#include <math.h>

float erfcf (x)
float x;

long double erfcl (x)
long double x;

double erfc (x)
double x;
_Decimal32 erfcd32 (x)
_Decimal32 x;
_Decimal64 erfcd64 (x)
_Decimal64 x;

_Decimal128 erfcd128 (x)
_Decimal128 x;
```

Description

The **erfcf**, **erfcl**, **erfc**, **erfcd32**, **erfcd64**, and **erfcd128** subroutines compute the complementary error function 1.0 **-** **erf**(*x*).

An application wishing to check for error situations should set **errno** to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these functions. Upon return, if **errno** is nonzero or

fetestexcept(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **erfcf**, **erfcl**, **erfc**, **erfcd32**, **erfcd64**, and **erfcd128** subroutines return the value of the complementary error function.

If the correct value would cause underflow and is not representable, a range error may occur. Either 0.0 (if representable), or an implementation-defined value is returned.

If *x* is NaN, a NaN is returned.

If *x* is ±0, +1 is returned.

If *x* is -Inf, +2 is returned.

If *x* is +Inf, +0 is returned.

If the correct value would cause underflow and is representable, a range error may occur and the correct value is returned.

errlog Subroutine

Purpose

Logs an application error to the system error log.

Library

Run-Time Services Library (**librts.a**)

Syntax

```
#include <sys/errids.h>
int errlog ( ErrorStructure,  Length)
void *ErrorStructure;
unsigned int Length;
```

Description

The **errlog** subroutine writes an error log entry to the **/dev/error** file. The **errlog** subroutine is used by application programs.

The transfer from the **err_rec** structure to the error log is by a **write** subroutine to the **/dev/error** special file.

The **errdemon** process reads from the **/dev/error** file and writes the error log entry to the system error log. The timestamp, machine ID, node ID, and Software Vital Product Data associated with the resource name (if any) are added to the entry before going to the log.

Parameters

Item	Description

ErrorStructure	Points to an error record structure containing an error record. Valid error record structures are typed in the **/usr/include/sys/err_rec.h** file. The two error record structures available are **err_rec** and **err_rec0**. The **err_rec** structure is used when the `detail_data` field is required. When the `detail_data` field is not required, the **err_rec0** structure is used.
	
	`struct err_rec0 {`
	`  unsigned int  error_id;`
	`  char  resource_name[ERR_NAMESIZE];`
	`};`
	`struct err_rec {`
	`  unsigned int error_id;`
	`  char resource_name[ERR_NAMESIZE];`
	`  char  detail_data[1];`
	`};`
	
	The fields of the structures **err_rec** and **err_rec0** are:
	
	`error_id`
	Specifies an index for the system error template database, and is assigned by the **errupdate** command when adding an error template. Use the **errupdate** command with the **-h** flag to get a #`define` statement for this 8-digit hexadecimal index.
	
	`resource_name`
	Specifies the name of the resource that has detected the error. For software errors, this is the name of a software component or an executable program. For hardware errors, this is the name of a device or system component. It does not indicate that the component is faulty or needs replacement instead, it is used to determine the appropriate diagnostic modules to be used to analyze the error.
	
	`detail_data`
	Specifies an array from 0 to **ERR_REC_MAX** bytes of user-supplied data. This data may be displayed by the **errpt** command in hexadecimal, alphanumeric, or binary form, according to the `data_encoding` fields in the error log template for this `error_id` field.

Length	Specifies the length in bytes of the **err_rec** structure, which is equal to the size of the `error_id` and `resource_name` fields plus the length in bytes of the `detail_data` field.

Return Values

Item	Description
0	The entry was logged successfully.
-1	The entry was not logged.

Files

Item	Description
/dev/error	Provides standard device driver interfaces required by the error log component.

Item	Description
/usr/include/sys/errids.h	Contains definitions for error IDs.
/usr/include/sys/err_rec.h	Contains structures defined as arguments to the **errsave** kernel service and the **errlog** subroutine.
/var/adm/ras/errlog	Maintains the system error log.

errlog_close Subroutine

Purpose

Closes an open error log file.

Syntax

```
library liberrlog.a

#include <sys/errlog.h>

int errlog_close(handle)
errlog_handle_t handle;
```

Description

The error log specified by the handle argument is closed. The handle must have been returned from a previous **errlog_open** call.

Return Values

Upon successful completion, the **errlog_close** subroutine returns 0.

If an error occurs, the **errlog_close** subroutine returns **LE_ERR_INVARG**.

errlog_find_first, errlog_find_next, and errlog_find_sequence Subroutines

Purpose

Retrieves an error log entry using supplied criteria.

Syntax

```
library liberrlog.a

#include <sys/errlog.h>

int errlog_find_first(handle, filter, result)
errlog_handle_t handle;
errlog_match_t *filter;
errlog_entry_t *result;

int errlog_find_next(handle, result)
errlog_handle_t handle;
errlog_entry_t *result;

int errlog_find_sequence(handle, sequence, result)
errlog_handle_t handle;
int sequence;
errlog_entry_t *result;
```

Description

The **errlog_find_first** subroutine finds the first occurrence of the search argument specified by filter using the direction specified by the **errlog_set_direction** subroutine. The reverse direction is used if none was specified. In other words, by default, entries are searched starting with the most recent entry.

The **errlog_match_t** structure, pointed to by the filter parameter, defines a test expression or set of expressions to be applied to each errlog entry.

If the value passed in the filter parameter is null, the **errlog_find_first** subroutine returns the first entry in the log, and the **errlog_find_next** subroutine can then be used to return subsequent entries. To read all log entries in the desired direction, open the log, then issue **errlog_find_next** calls.

To define a basic expression, **em_field** must be set to the field in the errlog entry to be tested, **em_op** must be set to the relational operator to be applied to that field, and either **em_intvalue** or **em_strvalue** must be set to the value to test against. Basic expressions may be combined by attaching them to **em_left** and **em_right** of another **errlog_match_t** structure and setting **em_op** of that structure to a binary or unary operator. These complex expressions may then be combined with other basic or complex expressions in the same fashion to build a tree that can define a filter of arbitrary complexity.

The **errlog_find_next** subroutine finds the next error log entry matching the criteria specified by a previous **errlog_find_first** call. The search continues in the direction specified by the **errlog_set_direction** subroutine or the reverse direction by default.

The **errlog_find_sequence** subroutine returns the entry matching the specified error log sequence number, found in the **el_sequence** field of the **errlog_entry** structure.

Parameters

The handle contains the handle returned by a prior call to errlog_open.

The filter parameter points to an **errlog_match_t** element defining the search argument, or the first of an argument tree.

The sequence parameter contains the sequence number of the entry to be retrieved.

The result parameter must point to the area to contain the returned error log entry.

Return Values

Upon successful completion, the **errlog_find_first**, **errlog_find_next**, and **errlog_find_sequence** subroutines return 0, and the memory referenced by result contains the found entry.

The following errors may be returned:

Item	Description
LE_ERR_INVARG	A parameter error was detected.
LE_ERR_NOMEM	Memory could not be allocated.
LE_ERR_IO	An i/o error occurred.
LE_ERR_DONE	No more entries were found.

Examples

The code below demonstrates how to search for all errlog entries in a date range and with a class of **H** (hardware) or **S** (software).

```
{
    extern int        begintime, endtime;

    errlog_match_t    beginstamp, endstamp, andstamp;
    errlog_match_t    hardclass, softclass, orclass;
    errlog_match_t    andtop;
    int               ret;
```

```
    errlog_entry_t    result;

    /*
     *  Select begin and end times
     */
    beginstamp.em_op = LE_OP_GT;                /* Expression 'A' */
    beginstamp.em_field = LE_MATCH_TIMESTAMP;
    beginstamp.em_intvalue=begintime;

    endstamp.em_op = LE_OP_LT;                  /* Expression 'B' */
    endstamp.em_field = LE_MATCH_TIMESTAMP;
    endstamp.em_intvalue=endtime;

    andstamp.em_op = LE_OP_AND;                 /* 'A' and 'B' */
    andstamp.em_left = &beginstamp;
    andstamp.em_right = &endstamp;

    /*
     * Select the classes we're interested in.
     */
    hardclass.em_op = LE_OP_EQUAL;                /* Expression 'C' */
    hardclass.em_field = LE_MATCH_CLASS;
    hardclass.em_strvalue = "H";

    softclass.em_op = LE_OP_EQUAL;                /* Expression 'D' */
    softclass.em_field = LE_MATCH_CLASS;
    softclass.em_strvalue = "S";

    orclass.em_op = LE_OP_OR;                  /* 'C' or 'D' */
    orclass.em_left = &hardclass;
    orclass.em_right = &softclass;

    andtop.em_op = LE_OP_AND;                  /* ('A' and 'B') and ('C' or 'D') */
    andtop.em_left = &andstamp;
    andtop.em_right = &orclass;

    ret = errlog_find_first(handle, &andtop, &result);
}
```

The **errlog_find_first** function will return the first entry matching filter. Successive calls to the **errlog_find_next** function will return successive entries that match the filter specified in the most recent call to the **errlog_find_first** function. When no more matching entries are found, the **errlog_find_first** and **errlog_find_next** functions will return the value **LE_ERR_DONE**.

errlog_open Subroutine

Purpose

Opens an error log and returns a handle for use with other **liberrlog.a** functions.

Syntax

```
library liberrlog.a

#include <fcntl.h>
#include <sys/errlog.h>

int errlog_open(path, mode, magic, handle)
char            *path;
int              mode;
unsigned int     magic;
errlog_handle_t *handle;
```

Description

The error log specified by the path argument will be opened using mode. The handle pointed to by the handle parameter must be used with subsequent operations.

Parameters

The path parameter specifies the path to the log file to be opened. If path is NULL, the default errlog file will be opened. The valid values for mode are the same as they are for the open system subroutine. They can be found in the **fcntl.h** files.

The **magic** argument takes the **LE_MAGIC** value, indicating which version of the **errlog_entry_t** structure this application was compiled with.

Return Values

Upon successful completion, the **errlog_open** subroutine returns a 0 and sets the memory pointed to by handle to a handle used by subsequent **liberrlog** operations.

Upon error, the **errlog_open** subroutine returns one of the following:

Item	Description
LE_ERR_INVARG	A parameter error was detected.
LE_ERR_NOFILE	The log file does not exist.
LE_ERR_NOMEM	Memory could not be allocated.
LE_ERR_IO	An i/o error occurred.
LE_ERR_INVFILE	The file is not a valid error log.

errlog_set_direction Subroutine

Purpose

Sets the direction for the error log find functions.

Syntax

```
library liberrlog.a

#include <sys/errlog.h>

int errlog_set_direction(handle, direction)
errlog_handle_t handle;
int direction;
```

Description

The **errlog_find_next** and **errlog_find_sequence** subroutines search the error log starting with the most recent log entry and going backward in time, by default. The **errlog_set_direction** subroutine is used to alter this direction.

Parameters

The handle parameter must contain a handle returned by a previous **errlog_open** call.

The direction parameter must be **LE_FORWARD** or **LE_REVERSE**. **LE_REVERSE** is the default if the **errlog_set_direction** subroutine is not used.

Return Values

Upon successful completion, the **errlog_set_direction** subroutine returns 0.

If a parameter is invalid, the **errlog_set_direction** subroutine returns **LE_ERR_INVARG**.

errlog_write Subroutine

Purpose

Changes the previously read error log entry.

Syntax

```
library liberrlog.a

#include <sys/errlog.h>

int errlog_write(handle, entry)
errlog_handle_t handle;
errlog_entry_t *entry;
```

Description

The **errlog_write** subroutine is used to update the most recently read log entry. Neither the length nor the sequence number of the entry may be changed. The entry is simply updated in place.

If the **errlog_write** subroutine is used in a multi-threaded application, the program should obtain a lock around the read/write pair to avoid conflict.

Parameters

The handle parameter must contain a handle returned by a previous **errlog_open** call.

The entry parameter must point to an entry returned by the previous error log find function.

Return Values

Upon successful completion, the **errlog_write** subroutine returns 0.

If a parameter is invalid, the **errlog_write** subroutine returns **LE_ERR_INVARG**.

The **errlog_write** subroutine may also return one of the following:

Item	Description
LE_ERR_INVFILE	The data on file is invalid.
LE_ERR_IO	An i/o error occurred.
LE_ERR_NOWRITE	The entry to be written didn't match the entry being updated.

exec, execl, execle, execlp, execv, execve, execvp, exect, or fexecve Subroutine

Purpose

Executes a file.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <unistd.h>
```

```
extern
char **environ;
```

```
int execl (
 Path,
 Argument0 [, Argument1, ...], 0)
const char *Path, *Argument0, *Argument
1, ...;
```

```
int execle (
 Path,
 Argument0 [, Argument1, ...], 0,

 EnvironmentPointer)
const
char *Path, *Argument0, *Argum
ent
1, ...;
char *const EnvironmentPointer[ ];
```

```
int execlp (
 File,
 Argument0 [, Argument1
, ...], 0)
const char *File, *Argument0, *Argument
1, ...;
```

```
int execv (
 Path,
 ArgumentV)
const char *Path;
char *const ArgumentV[ ];
```

```
int execve (
 Path,
 ArgumentV,

 EnvironmentPointer)
const char *Path;
char
*const ArgumentV[ ], *EnvironmentPointer
[ ];
```

```
int execvp (
 File,
 ArgumentV)
const char *File;
char *const ArgumentV[ ];
```

```
int exect (
 Path,
 ArgumentV,
 EnvironmentPointer)
char *Path, *ArgumentV, *EnvironmentPointer [ ];
```

```
int fexecve (FileDescriptor, ArgumentV, EnvironmentPointer)
int FileDescriptor;
char *const ArgumentV[ ], *EnvironmentPointer[ ];
```

Description

The **exec** subroutine, in all its forms, executes a new program in the calling process. The **exec** subroutine does not create a new process, but overlays the current program with a new one, which is called the *new-process image*. The new-process image file can be one of three file types:

- An executable binary file in XCOFF file format.
- An executable text file that contains a shell procedure (only the **execlp** and **execvp** subroutines allow this type of new-process image file).
- A file that names an executable binary file or shell procedure to be run.

The **fexecve** subroutine is equivalent to the **execve** subroutine, except that the fexecve subroutine takes the file descriptor of an open file to be executed as a first parameter, instead of a pathname. However, the following apply:

Note:

- If the file is a shell procedure that is deleted after the open operation, the **fexecve** subroutine starts the shell, but the shell cannot find the file.
- If the file is a shell procedure and the parent directory of the file is deleted after the file open operation, the **fexecve** subroutine returns an **ENOENT** error code.
- The **fexecve** subroutine does not check the Role Based Access Control (RBAC) execute permission.

The new-process image inherits the following attributes from the calling process image: session membership, supplementary group IDs, process signal mask, and pending signals.

The last of the types mentioned is recognized by a header with the following syntax:

```
#! Path [String]
```

The **#!** is the file *magic number*, which identifies the file type. The path name of the file to be executed is specified by the *Path* parameter. The *String* parameter is an optional character string that contains no tab or space characters. If specified, this string is passed to the new process as an argument in front of the name of the new-process image file. The header must be terminated with a new-line character. When called, the new process passes the *Path* parameter as *ArgumentV*[0]. If a *String* parameter is specified in the new process image file, the **exec** subroutine sets *ArgumentV*[0] to the *String* and *Path* parameter values concatenated together. The rest of the arguments passed are the same as those passed to the **exec** subroutine.

The **exec** subroutine attempts to cancel outstanding **asynchronous I/O requests** by this process. If the asynchronous I/O requests cannot be canceled, the application is blocked until the requests have completed.

The **exec** subroutine is similar to the **load** subroutine, except that the **exec** subroutine does not have an explicit library path parameter. Instead, the **exec** subroutine uses either the **LIBPATH** or LD_LIBRARY_PATH environment variable. The **LIBPATH** variable, when set, is used in favor of LD_LIBRARY_PATH; otherwise, LD_LIBRARY_PATH is used. These library path variables are ignored when the program that the **exec** subroutine is run on has more privilege than the calling program (for example, an **suid** program).

The **exect** subroutine is included for compatibility with older programs being traced with the **ptrace** command. The program being executed is forced into hardware single-step mode.

Note: exect is not supported in 64-bit mode.

Note: Currently, a Graphics Library program cannot be overlaid with another Graphics Library program. The overlaying program can be a nongraphics program. For additional information, see the **/usr/lpp/GL/README** file.

Parameters

Item	Description
Path	Specifies a pointer to the path name of the new-process image file. If Network File System (NFS) is installed on your system, this path can cross into another node. Data is copied into local virtual memory before proceeding.

Item	Description
File	Specifies a pointer to the name of the new-process image file. Unless the *File* parameter is a full path name, the path prefix for the file is obtained by searching the directories named in the **PATH** environment variable. The initial environment is supplied by the shell. **Note:** The **execlp** subroutine and the **execvp** subroutine take *File* parameters, but the rest of the **exec** subroutines take *Path* parameters. (For information about the environment, see the **environment** miscellaneous facility and the **sh** command.)
Argument0 [, *Argument1*, ...]	Point to null-terminated character strings. The strings constitute the argument list available to the new process. By convention, at least the *Argument0* parameter must be present, and it must point to a string that is the same as the *Path* parameter or its last component.
ArgumentV	Specifies an array of pointers to null-terminated character strings. These strings constitute the argument list available to the new process. By convention, the *ArgumentV* parameter must have at least one element, and it must point to a string that is the same as the *Path* parameter or its last component. The last element of the *ArgumentV* parameter is a null pointer.
EnvironmentPointer	An array of pointers to null-terminated character strings. These strings constitute the environment for the new process. The last element of the *EnvironmentPointer* parameter is a null pointer.
FileDescriptor	Specifies the file descriptor of an open file to be executed.

When a C program is run, it receives the following parameters:

```
main (ArgumentCount, ArgumentV, EnvironmentPointer)
int ArgumentCount;
char *ArgumentV[ ], *EnvironmentPointer[
];
```

In this example, the *ArgumentCount* parameter is the argument count, and the *ArgumentV* parameter is an array of character pointers to the arguments themselves. By convention, the value of the *ArgumentCount* parameter is at least 1, and the *ArgumentV*[0] parameter points to a string containing the name of the new-process image file.

The **main** routine of a C language program automatically begins with a runtime start-off routine. This routine sets the **environ** global variable so that it points to the environment array passed to the program in *EnvironmentPointer*. You can access this global variable by including the following declaration in your program:

```
extern char **environ;
```

The **execl**, **execv**, **execlp**, and **execvp** subroutines use the **environ** global variable to pass the calling process current environment to the new process.

File descriptors open in the calling process remain open, except for those whose **close-on-exec** flag is set. For those file descriptors that remain open, the file pointer is unchanged. (For information about file control, see the **fcntl.h** file.)

The state-of-conversion descriptors and message-catalog descriptors in the new process image are undefined. For the new process, an equivalent of the **setlocale** subroutine, specifying the **LC_ALL** value for its category and the **"C"** value for its locale, is run at startup.

If the new program requires shared libraries, the **exec** subroutine finds, opens, and loads each of them into the new-process address space. The referenced counts for shared libraries in use by the issuer of the **exec** are decremented. Shared libraries are searched for in the directories listed in the **LIBPATH** environment variable. If any of these files is remote, the data is copied into local virtual memory.

The **exec** subroutines reset all caught signals to the default action. Signals that cause the default action continue to do so after the **exec** subroutines. Ignored signals remain ignored, the signal mask remains the same, and the signal stack state is reset. (For information about signals, see the **sigaction** subroutine.)

If the *SetUserID* mode bit of the new-process image file is set, the **exec** subroutine sets the effective user ID of the new process to the owner ID of the new-process image file. Similarly, if the *SetGroupID* mode bit of the new-process image file is set, the effective group ID of the new process is set to the group ID of the new-process image file. The real user ID and real group ID of the new process remain the same as those of the calling process. (For information about the *SetID* modes, see the **chmod** subroutine.)

At the end of the **exec** operation the saved user ID and saved group ID of the process are always set to the effective user ID and effective group ID, respectively, of the process.

When one or both of the set ID mode bits is set and the file to be executed is a remote file, the file user and group IDs go through outbound translation at the server. Then they are transmitted to the client node where they are translated according to the inbound translation table. These translated IDs become the user and group IDs of the new process.

Note: setuid and **setgid** bids on shell scripts do not affect user or group IDs of the process finally executed.

Profiling is disabled for the new process.

The new process inherits the following attributes from the calling process:

- Nice value (see the **getpriority** subroutine, **setpriority** subroutine, **nice** subroutine)
- Process ID
- Parent process ID
- Process group ID
- **semadj** values (see the **semop** subroutine)
- tty group ID (see the **exit**, **atexit**, or **_exit** subroutine, **sigaction** subroutine)
- **trace** flag (see request 0 of the **ptrace** subroutine)
- Time left until an alarm clock signal (see the **incinterval** subroutine, **setitimer** subroutine, and **alarm** subroutine)
- Current directory
- Root directory
- File-mode creation mask (see the **umask** subroutine)
- File size limit (see the **ulimit** subroutine)
- Resource limits (see the **getrlimit** subroutine, **setrlimit** subroutine, and **vlimit** subroutine)
- `tms_utime`, `tms_stime`, `tms_cutime`, and `tms_ctime` fields of the **tms** structure (see the **times** subroutine)
- Login user ID

Upon successful completion, the **exec** subroutines mark for update the `st_atime` field of the file.

Examples

1. To run a command and pass it a parameter, enter:

   ```
   execlp("ls", "ls", "-al", 0);
   ```

   The **execlp** subroutine searches each of the directories listed in the **PATH** environment variable for the **ls** command, and then it overlays the current process image with this command. The **execlp** subroutine is not returned, unless the **ls** command cannot be executed.

   Note: This example does not run the shell command processor, so operations interpreted by the shell, such as using wildcard characters in file names, are not valid.

2. To run the shell to interpret a command, enter:

   ```
   execl("/usr/bin/sh", "sh", "-c", "ls -l *.c",
   0);
   ```

   This runs the **sh** command with the **-c** flag, which indicates that the following parameter is the command to be interpreted. This example uses the **execl** subroutine instead of the **execlp** subroutine because the full path name **/usr/bin/sh** is specified, making a path search unnecessary.

   Running a shell command in a child process is generally more useful than simply using the **exec** subroutine, as shown in this example. The simplest way to do this is to use the **system** subroutine.

3. The following is an example of a new-process file that names a program to be run:

   ```
   #! /usr/bin/awk -f
   { for (i = NF; i > 0; --i) print $i }
   ```

   If this file is named `reverse`, entering the following command on the command line:

   ```
   reverse chapter1 chapter2
   ```

   This command runs the following command:

   ```
   /usr/bin/awk -f reverse chapter1 chapter2
   ```

   Note: The **exec** subroutines use only the first line of the new-process image file and ignore the rest of it. Also, the **awk** command interprets the text that follows a # (pound sign) as a comment.

Return Values

Upon successful completion, the **exec** subroutines do not return because the calling process image is overlaid by the new-process image. If the **exec** subroutines return to the calling process, the value of -1 is returned and the **errno** global variable is set to identify the error.

Error Codes

If the **exec** subroutine is unsuccessful, it returns one or more of the following error codes:

Item	Description
EACCES	The new-process image file is not an ordinary file.
EACCES	The mode of the new-process image file denies execution permission.
ENOEXEC	The **exec** subroutine is neither an **execlp** subroutine nor an **execvp** subroutine. The new-process image file has the appropriate access permission, but the magic number in its header is not valid.
ENOEXEC	The new-process image file has a valid magic number in its header, but the header is damaged or is incorrect for the machine on which the file is to be run.

Item	Description
ETXTBSY	The new-process image file is a pure procedure (shared text) file that is currently open for writing by some process.
ENOMEM	The new process requires more memory than is allowed by the system-imposed maximum, the **MAXMEM** compiler option.
E2BIG	The number of bytes in the new-process argument list is greater than the system-imposed limit. This limit is a system configurable value that can be set by superusers or system group users using SMIT. Refer to **Kernel Tunable Parameters** for details.
EFAULT	The *Path*, *ArgumentV*, or *EnvironmentPointer* parameter points outside of the process address space.
EPERM	The *SetUserID* or *SetGroupID* mode bit is set on the process image file. The translation tables at the server or client do not allow translation of this user or group ID.

If the **exec** subroutine is unsuccessful because of a condition requiring path name resolution, it returns one or more of the following error codes:

Item	Description
EACCES	Search permission is denied on a component of the path prefix. Access could be denied due to a secure mount.
EFAULT	The *Path* parameter points outside of the allocated address space of the process.
EIO	An input/output (I/O) error occurred during the operation.
ELOOP	Too many symbolic links were encountered in translating the *Path* parameter.
ENAMETOOLONG	A component of a path name exceeded 255 characters and the process has the **disallow truncation** attribute (see the **ulimit** subroutine), or an entire path name exceeded 1023 characters.
ENOENT	A component of the path prefix does not exist.
ENOENT	A symbolic link was named, but the file to which it refers does not exist.
ENOENT	The path name is null.
ENOTDIR	A component of the path prefix is not a directory.
ESTALE	The root or current directory of the process is located in a virtual file system that has been unmounted.

In addition, some errors can occur when using the new-process file after the old process image has been overwritten. These errors include problems in setting up new data and stack registers, problems in mapping a shared library, or problems in reading the new-process file. Because returning to the calling process is not possible, the system sends the **SIGKILL** signal to the process when one of these errors occurs.

If an error occurred while mapping a shared library, an error message describing the reason for error is written to standard error before the signal **SIGKILL** is sent to the process. If a shared library cannot be mapped, the subroutine returns one of the following error codes:

Item	Description
ENOENT	One or more components of the path name of the shared library file do not exist.
ENOTDIR	A component of the path prefix of the shared library file is not a directory.

Item	Description
ENAMETOOLONG	A component of a path name prefix of a shared library file exceeded 255 characters, or an entire path name exceeded 1023 characters.
EACCES	Search permission is denied for a directory listed in the path prefix of the shared library file.
EACCES	The shared library file mode denies execution permission.
ENOEXEC	The shared library file has the appropriate access permission, but a magic number in its header is not valid.
ETXTBSY	The shared library file is currently open for writing by some other process.
ENOMEM	The shared library requires more memory than is allowed by the system-imposed maximum.
ESTALE	The process root or current directory is located in a virtual file system that has been unmounted.
EPROCLIM	If WLM is running, the limit on the number of processes, threads, or logins in the class may have been met.

If the **fexecve** subroutine is unsuccessful, it might also return one of the following error codes:

Item	Description
EBADF	The *FileDescriptor* argument does not specify a valid open file descriptor.
ENOENT	The *FileDescriptor* argument points to a shell procedure, but the original parent directory of the file has been deleted.

If NFS is installed on the system, the **exec** subroutine can also fail if the following is true:

Item	Description
ETIMEDOUT	The connection timed out.

exit, atexit, unatexit, _exit, or _Exit Subroutine

Purpose

Terminates a process.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdlib.h>
```

void exit (*Status*)
int *Status*;

void _exit (*Status*)
int *Status*;

```
void _Exit (Status)
int Status;
```

```
#include <sys/limits.h>
```

int atexit (*Function*)
void (Function*) (void);**

```
int unatexit (Function)
void (*Function)(void);
```

Description

The **exit** subroutine terminates the calling process after calling the standard I/O library **_cleanup** function to flush any buffered output. Also, it calls any functions registered previously for the process by the **atexit** subroutine. The **atexit** subroutine registers functions called at normal process termination for cleanup processing. Normal termination occurs as a result of either a call to the **exit** subroutine or a **return** statement in the **main** function.

Each function a call to the **atexit** subroutine registers must return. This action ensures that all registered functions are called.

Finally, the **exit** subroutine calls the **_exit** subroutine, which completes process termination and does not return. The **_exit** subroutine terminates the calling process and causes the following to occur:

The **_Exit** subroutine is functionally equivalent to the **_exit** subroutine. The **_Exit** subroutine does not call functions registered with **atexit** or any registered signal handlers. The way the subroutine is implemented determines whether open streams are flushed or closed, and whether temporary files are removed. The calling process is terminated with the consequences described below.

- All of the file descriptors, directory streams, conversion descriptors, and message catalog descriptors open in the calling process are closed.
- If the parent process of the calling process is executing a **wait** or **waitpid**, and has not set its SA_NOCLDWAIT flag nor set SIGCHLD to SIG_IGN, it is notified of the calling process' termination and the low order eight bits (that is, bits 0377) of *status* are made available to it. If the parent is not waiting, the child's status is made available to it when the parent subsequently executes **wait** or **waitpid**.
- If the parent process of the calling process is not executing a **wait** or **waitpid**, and has neither set its SA_NOCLDWAIT flag nor set SIGCHLD to SIG_IGN, the calling process is transformed into a zombie process. A zombie process is an inactive process that is deleted at some later time when its parent process executes **wait** or **waitpid**.
- Termination of a process does not directly terminate its children. The sending of a SIGHUP signal indirectly terminates children in some circumstances. This can be accomplished in one of two ways. If the implementation supports the SIGCHLD signal, a SIGCHLD is sent to the parent process. If the parent process has set its SA_NOCLDWAIT flag, or set SIGCHLD to SIG_IGN, the status is discarded, and the lifetime of the calling process ends immediately. If SA_NOCLDWAIT is set, it is implementation defined whether a SIGCHLD signal is sent to the parent process.
- The parent process ID of all of the calling process' existing child processes and zombie processes are set to the process ID of an implementation defined system process.
- Each attached shared memory segment is detached and the value of *shm_nattch* (see **shmget**) in the data structure associated with its shared memory ID is decremented by 1.
- For each semaphore for which the calling process has set a *semadj* value (see **semop**), that value is added to the *semval* of the specified semaphore.
- If the process is a controlling process, the SIGHUP signal is sent to each process in the foreground process group of the controlling terminal belonging to the calling process.
- If the process is a controlling process, the controlling terminal associated with the session is disassociated from the session, allowing it to be acquired by a new controlling process.
- If the exit of the process causes a process group to become orphaned, and if any member of the newly orphaned process group is stopped, a SIGHUP signal followed by a SIGCONT signal is sent to each process in the newly orphaned process group.

- All open named semaphores in the calling process are closed as if by appropriate calls to **sem_close**.
- Memory mappings that were created in the process are unmapped before the process is destroyed.
- Any blocks of typed memory that were mapped in the calling process are unmapped, as if the **munmap** subroutine was implicitly called to unmap them.
- All open message queue descriptors in the calling process are closed.
- Any outstanding cancelable asynchronous I/O operations may be canceled. Those asynchronous I/O operations that are not canceled complete as if the **_Exit** subroutine had not yet occurred, but any associated signal notifications are suppressed.

  The **_Exit** subroutine may block awaiting such I/O completion. The implementation defines whether any I/O is canceled, and which I/O may be canceled upon **_Exit**.
- Threads terminated by a call to **_Exit** do not invoke their cancelation cleanup handlers or per thread data destructors.
- If the calling process is a trace controller process, any trace streams that were created by the calling process are shut down.

The **unatexit** subroutine is used to unregister functions that are previously registered by the **atexit** subroutine. If the referenced function is found, it is removed from the list of functions that are called at normal program termination.

Parameters

Item	Description
Status	Indicates the status of the process. May be set to 0, EXIT_SUCCESS, EXIT_FAILURE, or any other value, though only the least significant 8 bits are available to a waiting parent process.
Function	Specifies a function to be called at normal process termination for cleanup processing. You may specify a number of functions to the limit set by the **ATEXIT_MAX** function, which is defined in the **sys/limits.h** file. A pushdown stack of functions is kept so that the last function registered is the first function called.

Return Values

Upon successful completion, the **atexit** subroutine returns a value of 0. Otherwise, a nonzero value is returned. The **exit** and **_exit** subroutines do not return a value.

The **unatexit()** subroutine returns a value of 0 if the function referenced by *Function* is found and removed from the **atexit** list. Otherwise, a nonzero value is returned.

exp, expf, expl, expd32, expd64, and expd128 Subroutines

Purpose

Computes exponential, logarithm, and power functions.

Libraries

IEEE Math Library (**libm.a**) or System V Math Library (**libmsaa.a**)

Syntax

```
#include <math.h>
```

```
double exp ( x)
double x;
```

```
float expf (x)
float x;
```

```
long double expl (x)
long double x;
```

```
_Decimal32 expd32 (x)
_Decimal32 x;
_Decimal64 expd64 (x)
_Decimal64 x;

_Decimal128 expd128 (x)
_Decimal128 x;
```

Description

These subroutines are used to compute exponential, logarithm, and power functions.

The **exp**, **expf**, **expl**, **expd32**, **expd64**, and **expd128** subroutines returns `exp (x)`.

An application wishing to check for error situations should set the **errno** global variable to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies some double-precision floating-point value.
y	Specifies some double-precision floating-point value.

Return Values

Upon successful completion, the **exp**, **expf**, **expl**, **expd32**, **expd64**, and **expd128** subroutines return the exponential value of *x*.

If the correct value would cause overflow, a range error occurs and the **exp**, **expf**, **expl**, **expd32**, **expd64**, and **expd128** subroutine returns the value of the macro **HUGE_VAL**, **HUGE_VALF**, **HUGE_VALL**, **HUGE_VAL_D32**, **HUGE_VAL_D64**, and **HUGE_VAL_D128** respectively.

If the correct value would cause underflow, and is not representable, a range error may occur, and either 0.0 (if supported), or an implementation-defined value is returned.

If *x* is NaN, a NaN is returned.

If *x* is ±0, 1 is returned.

If *x* is -Inf, +0 is returned.

If *x* is +Inf, *x* is returned.

If the correct value would cause underflow, and is representable, a range error may occur and the correct value is returned.

Error Codes

When using the **libm.a** library:

Item	Description
exp	If the correct value would overflow, the **exp** subroutine returns a **HUGE_VAL** value and the **errno** global variable is set to a **ERANGE** value.

When using **libmsaa.a**(**-lmsaa**):

Item	Description
exp	If the correct value would overflow, the **exp** subroutine returns a **HUGE_VAL** value. If the correct value would underflow, the **exp** subroutine returns 0. In both cases **errno** is set to **ERANGE**.
expl	If the correct value would overflow, the **expl** subroutine returns a **HUGE_VAL** value. If the correct value would underflow, the **expl** subroutine returns 0. In both cases **errno** is set to **ERANGE**.
expl	If the correct value overflows, the **expl** subroutine returns a **HUGE_VAL** value and **errno** is set to **ERANGE**.

These error-handling procedures may be changed with the **matherr** subroutine when using the **libmsaa.a** library.

exp2, exp2f, exp2l, exp2d32, exp2d64, and exp2d128 Subroutines

Purpose

Computes the base 2 exponential.

Syntax

```
#include <math.h>

double exp2 (x)
double x;

float exp2f (x)
float x;

long double exp2l (x)
long double x;
_Decimal32 exp2d32 (x)
_Decimal32 x;

_Decimal64 exp2d64 (x)
_Decimal64 x;

_Decimal128 exp2d128 (x)
_Decimal128 x;
```

Description

The **exp2**, **exp2f**, **exp2l**, **exp2d32**, **exp2d64**, and **exp2d128** subroutines compute the base 2 exponential of the *x* parameter.

An application wishing to check for error situations should set the **errno** global variable to zero and call **feclearexcept (FE_ALL_EXCEPT)** before calling these subroutines. On return, if **errno** is nonzero or **fetestexcept (FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW)** is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the base 2 exponential to be computed.

Return Values

Upon successful completion, the **exp2**, **exp2f**, **exp2l**, **exp2d32**, **exp2d64**, or **exp2d128** subroutine returns 2^x .

If the correct value causes overflow, a range error occurs and the **exp2**, **exp2f**, **exp2l**, **exp2d32**, **exp2d64**, and **exp2d128** subroutines return the value of the macro (**HUGE_VAL**, **HUGE_VALF**, **HUGE_VALL**, **HUGE_VAL_D32**, **HUGE_VAL_D64**, and **HUGE_VAL_D128** respectively).

If the correct value causes underflow and is not representable, a range error occurs, and 0.0 is returned.

If *x* is NaN, NaN is returned.

If *x* is ±0, 1 is returned.

If *x* is -Inf, 0 is returned.

If *x* is +Inf, *x* is returned.

If the correct value would cause underflow, and is representable, a range error may occur and the correct value is returned.

expm1, expm1f, expm1l, expm1d32, expm1d64, and expm1d128 Subroutine

Purpose

Computes exponential functions.

Syntax

```
#include <math.h>

float expm1f (x)
float x;

long double expm1l (x)
long double x;

double expm1 (x)
double x;
_Decimal32 expm1d32 (x)
_Decimal32 x;

_Decimal64 expm1d64 (x)
_Decimal64 x;
_Decimal128 expm1d128 (x)
_Decimal128 x;
```

Description

The **expm1f**, **expm1l**, **expm1**, **expm1d32**, **expm1d64**, and **expm1d128** subroutines compute e^x- 1.0.

An application wishing to check for error situations should set the **errno** global variable to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these functions. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **expm1f**, **expm1l**, **expm1**, **expm1d32**, **expm1d64**, and **expm1d128** subroutines return e^x- 1.0.

If the correct value would cause overflow, a range error occurs and the **expm1f**, **expm1l**, **expm1**, **expm1d32**, **expm1d64**, and **expm1d128** subroutines return the value of the macro **HUGE_VALF**, **HUGE_VALL**, **HUGE_VAL**, **HUGE_VAL_D32**, **HUGE_VAL_D64**, and **HUGE_VAL_D128** respectively.

If *x* is NaN, a NaN is returned.

If *x* is ±0, ±0 is returned.

If *x* is -Inf, -1 is returned.

If *x* is +Inf, *x* is returned.

If *x* is subnormal, a range error may occur and *x* is returned.

f

The following Base Operating System (BOS) runtime services begin with the letter *f*.

fabsf, fabsl, fabs, fabsd32, fabsd64, and fabsd128 Subroutines

Purpose

Determines the absolute value.

Syntax

```
#include <math.h>

float fabsf (x)
float x;

long double fabsl (x)
long double x;

double fabs (x)
double x;

_Decimal32 fabsd32 (x)
_Decimal32 x;

_Decimal64 fabsd64 (x)
_Decimal64 x;

_Decimal128 fabsd128 (x)
_Decimal128 x;
```

Description

The **fabsf**, **fabsl**, **fabs**, **fabsd32**, **fabsd64**, and **fabsd128** subroutines compute the absolute value of the *x* parameter, |*x*|.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **fabsf**, **fabsl**, **fabs**, **fabsd32**, **fabsd64**, and **fabsd128** subroutines return the absolute value of *x*.

If *x* is NaN, a NaN is returned.

If *x* is ±0, +0 is returned.

If *x* is ±Inf, +Inf is returned.

fattach Subroutine

Purpose

Attaches a STREAMS-based file descriptor to a file.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stropts.h>
int fattach(int fildes, const char *path);
```

Description

The **fattach** subroutine attaches a STREAMS-based file descriptor to a file, effectively associating a pathname with *fildes*. The *fildes* argument must be a valid open file descriptor associated with a STREAMS file. The *path* argument points to a pathname of an existing file. The process must have appropriate privileges, or must be the owner of the file named by *path* and have write permission. A successful call to **fattach** subroutine causes all pathnames that name the file named by *path* to name the STREAMS file associated with *fildes*, until the STEAMS file is detached from the file. A STREAMS file can be attached to more than one file and can have several pathnames associated with it.

The attributes of the named STREAMS file are initialized as follows: the permissions, user ID, group ID, and times are set to those of the file named by *path*, the number of links is set to 1, and the size and device identifier are set to those of the STREAMS file associated with *fildes*. If any attributes of the named STREAMS file are subsequently changed (for example, by **chmod** subroutine), neither the attributes of the underlying file nor the attributes of the STREAMS file to which *fildes* refers are affected.

File descriptors referring to the underlying file, opened prior to an **fattach** subroutine, continue to refer to the underlying file.

Parameters

Item	Description
fildes	A file descriptor identifying an open STREAMS-based object.
path	An existing pathname which will be associated with *fildes*.

Return Value

Item	Description
0	Successful completion.
-1	Not successful and *errno* set to one of the following.

Errno Value

Item	Description
EACCES	Search permission is denied for a component of the path prefix, or the process is the owner of *path* but does not have write permission on the file named by *path*.
EBADF	The file referred to by *fildes* is not an open file descriptor.
ENOENT	A component of *path* does not name an existing file or *path* is an empty string.
ENOTDIR	A component of the path prefix is not a directory.
EPERM	The effective user ID of the process is not the owner of the file named by *path* and the process does not have appropriate privilege.

Item	Description
EBUSY	The file named by *path* is currently a mount point or has a STREAMS file attached to it.
ENAMETOOLONG	The size of *path* exceeds {**PATH_MAX**}, or a component of *path* is longer than {**NAME_MAX**}.
ELOOP	Too many symbolic links wer encountered in resolving *path*.
EINVAL	The *fildes* argument does not refer to a STREAMS file.
ENOMEM	Insufficient storage space is available.

fchdir Subroutine

Purpose

Directory pointed to by the file descriptor becomes the current working directory.

Library

Standard C Library **(libc.a)**

Syntax

#include <unistd.h>

int fchdir (int *Fildes***)**

Description

The **fchdir** subroutine causes the directory specified by the *Fildes* parameter to become the current working directory.

Parameter

Item	Description
Fildes	A file descriptor identifying an open directory obtained from a call to the **open** subroutine.

Return Values

Item	Description
0	Successful completion
-1	Not successful and **errno** set to one of the following.

Error Codes

Item	Description
EACCES	Search access if denied.
EBADF	The file referred to by *Fildes* is not an open file descriptor.
ENOTDIR	The open file descriptor does not refer to a directory.

fclear or fclear64 Subroutine

Purpose

Makes a hole in a file.

Library

Standard C Library (**libc.a**)

Syntax

```
off_t fclear ( FileDescriptor,  NumberOfBytes)
int FileDescriptor;
off_t NumberOfBytes;

off64_t fclear64 ( FileDescriptor,  NumberOfBytes)
int FileDescriptor;
off64_t NumberOfBytes;
```

Description

The **fclear** and **fclear64** subroutines zero the number of bytes specified by the *NumberOfBytes* parameter starting at the current file pointer for the file specified in the *FileDescriptor* parameter. If Network File System (NFS) is installed on your system, this file can reside on another node.

The **fclear** subroutine can only clear up to **OFF_MAX** bytes of the file while **fclear64** can clear up to the maximum file size.

The **fclear** and **fclear64** subroutines cannot be applied to a file that a process has opened with the **O_DEFER** mode.

Successful completion of the **fclear** and **fclear64** subroutines clear the SetUserID bit (**S_ISUID**) of the file if any of the following are true:

- The calling process does not have root user authority.
- The effective user ID of the calling process does not match the user ID of the file.
- The file is executable by the group (**S_IXGRP**) or others (**S_IXOTH**).

This subroutine also clears the SetGroupID bit (**S_ISGID**) if:

- The file does not match the effective group ID or one of the supplementary group IDs of the process,

  OR
- The file is executable by the owner (**S_IXUSR**) or others (**S_IXOTH**).

  Note: Clearing of the SetUserID and SetGroupID bits can occur even if the subroutine fails because the data in the file was modified before the error was detected.

In the large file enabled programming environment, **fclear** is redefined to be **fclear64**.

Parameters

Item	Description
FileDescriptor	Indicates the file specified by the *FileDescriptor* parameter must be open for writing. The FileDescriptor is a small positive integer used instead of the file name to identify a file. This function differs from the logically equivalent write operation in that it returns full blocks of binary zeros to the file system, constructing holes in the file.

Item	Description
NumberOfBytes	Indicates the number of bytes that the seek pointer is advanced. If you use the **fclear** and **fclear64** subroutines past the end of a file, the rest of the file is cleared and the seek pointer is advanced by *NumberOfBytes*. The file size is updated to include this new hole, which leaves the current file position at the byte immediately beyond the new end-of-file pointer.

Return Values

Upon successful completion, a value of *NumberOfBytes* is returned. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **fclear** and **fclear64** subroutines fail if one or more of the following are true:

Item	Description
EIO	I/O error.
EBADF	The *FileDescriptor* value is not a valid file descriptor open for writing.
EINVAL	The file is not a regular file.
EMFILE	The file is mapped **O_DEFER** by one or more processes.
EAGAIN	The write operation in the **fclear** subroutine failed due to an enforced write lock on the file.

Item	Description
EFBIG	The current offset plus *NumberOfBytes* is exceeds the offset maximum established in the open file description associated with *FileDescriptor*.

Item	Description
EFBIG	An attempt was made to write a file that exceeds the process' file size limit or the maximum file size. If the user has set the environment variable **XPG_SUS_ENV=ON** prior to execution of the process, then the **SIGXFSZ** signal is posted to the process when exceeding the process' file size limit.

If NFS is installed on the system the **fclear** and **fclear64** subroutines can also fail if the following is true:

Item	Description
ETIMEDOUT	The connection timed out.

fclose or fflush Subroutine

Purpose

Closes or flushes a stream.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdio.h>
```

int fclose (*Stream*)
FILE ***Stream*;

int fflush (*Stream*)
FILE ***Stream*;

Description

The **fclose** subroutine writes buffered data to the stream specified by the *Stream* parameter, and then closes the stream. The **fclose** subroutine is automatically called for all open files when the **exit** subroutine is invoked.

The **fflush** subroutine writes any buffered data for the stream specified by the *Stream* parameter and leaves the stream open. The **fflush** subroutine marks the `st_ctime` and `st_mtime` fields of the underlying file for update.

If the *Stream* parameter is a null pointer, the **fflush** subroutine performs this flushing action on all streams for which the behavior is defined.

Parameters

Item	Description
Stream	Specifies the output stream.

Return Values

Upon successful completion, the **fclose** and **fflush** subroutines return a value of 0. Otherwise, a value of EOF is returned.

Error Codes

If the **fclose** and **fflush** subroutines are unsuccessful, the following errors are returned through the **errno** global variable:

Item	Description
EAGAIN	The **O_NONBLOCK** or `O_NDELAY` flag is set for the file descriptor underlying the *Stream* parameter and the process would be delayed in the write operation.
EBADF	The file descriptor underlying *Stream* is not valid.
EFBIG	An attempt was made to write a file that exceeds the process' file size limit or the maximum file size. See the **ulimit** subroutine.
EFBIG	The file is a regular file and an attempt was made to write at or beyond the offset maximum associated with the corresponding stream.
EINTR	The **fflush** subroutine was interrupted by a signal.
EIO	The process is a member of a background process group attempting to write to its controlling terminal, the **TOSTOP** signal is set, the process is neither ignoring nor blocking the **SIGTTOU** signal and the process group of the process is orphaned. This error may also be returned under implementation-dependent conditions.
ENOMEM	The underlying stream was created by open_memstream() or open_wmemstream( ) and insufficient memory is available.

Item	Description
ENOSPC	No free space remained on the device containing the file or in the buffer used by the fmemopen( ) function.
EPIPE	An attempt is made to write to a pipe or FIFO that is not open for reading by any process. A **SIGPIPE** signal is sent to the process.
ENXIO	A request was made of a non-existent device, or the request was outside the capabilities of the device

fcntl, dup, or dup2 Subroutine

Purpose

Controls open file descriptors.

Library

Standard C Library (**libc.a**)

Berkeley compatibility library (`libbsd.a`) (for the **fcntl** subroutine)

Syntax

#include <fcntl.h>

int fcntl (*FileDescriptor*, *Command*, *Argument*) **int** *FileDescriptor*, *Command*, *Argument*;

#include <unistd.h>

int dup2(*Old*, *New*) **int** *Old*, *New*;

int dup(*FileDescriptor*) **int** *FileDescriptor*;

Description

The **fcntl** subroutine performs controlling operations on the open file specified by the *FileDescriptor* parameter. If Network File System (NFS) is installed on your system, the open file can reside on another node. The **fcntl** subroutine is used to:

- Duplicate open file descriptors.
- Set and get the file-descriptor flags.
- Set and get the file-status flags.
- Manage record locks.
- Manage asynchronous I/O ownership.
- Close multiple files.

The **fcntl** subroutine can provide the same functions as the **dup** and **dup2** subroutines.

If *FileDescriptor* refers to a terminal device or socket, then asynchronous I/O facilities can be used. These facilities are normally enabled by using the **ioctl** subroutine with the **FIOASYNC**, **FIOSETOWN**, and **FIOGETOWN** commands. However, a BSD-compatible mechanism is also available if the application is linked with the **libbsd.a** library.

When the *FileDescriptor* parameter refers to a shared memory object, the **fcntl** subroutine manages only the **F_DUPFD**, **F_DUP2FD**, **F_GETFD**, **F_SETFD**, **F_GETFL**, and **F_CLOSEM** commands.

When using the **libbsd.a** library, asynchronous I/O is enabled by using the **F_SETFL** command with the **FASYNC** flag set in the *Argument* parameter. The **F_GETOWN** and **F_SETOWN** commands get the current

asynchronous I/O owner and set the asynchronous I/O owner. However, these commands are valid only when the file descriptor refers to a terminal device or a socket.

All applications containing the **fcntl** subroutine must be complied with **_BSD** set to a specific value. Acceptable values are 43 and 44. In addition, all socket applications must include the BSD **libbsd.a** library.

General Record Locking Information

A lock is either an *enforced* or *advisory lock* and either a *read* or a *write lock*.

> **Attention:** Buffered I/O does not work properly when used with file locking. Do not use the standard I/O package routines on files that are going to be locked.

For a lock to be an enforced lock, the Enforced Locking attribute of the file must be set; for example, the **S_ENFMT** bit must be set, but the **S_IXGRP**, **S_IXUSR**, and **S_IXOTH** bits must be clear. Otherwise, the lock is an advisory lock. A given file can have advisory or enforced locks, but not both. The description of the **sys/mode.h** file includes a description of file attributes.

When a process holds an enforced lock on a section of a file, no other process can access that section of the file with the **read** or **write** subroutine. In addition, the **open** and **ftruncate** subroutines cannot truncate the locked section of the file, and the **fclear** subroutine cannot modify the locked section of the file. If another process attempts to read or modify the locked section of the file, the process either sleeps until the section is unlocked or returns with an error indication.

When a process holds an advisory lock on a section of a file, no other process can lock that section of the file (or an overlapping section) with the **fcntl** subroutine. (No other subroutines are affected.) As a result, processes must voluntarily call the **fcntl** subroutine in order to make advisory locks effective.

When a process holds a read lock on a section of a file, other processes can also set read locks on that section or on subsets of it. Read locks are also called *shared* locks.

A read lock prevents any other process from setting a write lock on any part of the protected area. If the read lock is also an enforced lock, no other process can modify the protected area.

The file descriptor on which a read lock is being placed must have been opened with read access.

When a process holds a write lock on a section of a file, no other process can set a read lock or a write lock on that section. Write locks are also called *exclusive* locks. Only one write lock and no read locks can exist for a specific section of a file at any time.

If the lock is also an enforced lock, no other process can read or modify the protected area.

The following general rules about file locking apply:

- Changing or unlocking part of a file in the middle of a locked section leaves two smaller sections locked at each end of the originally locked section.
- If the calling process holds a lock on a file, that lock can be replaced by later calls to the **fcntl** subroutine.
- All locks associated with a file for a given process are removed when the process closes *any* file descriptor for that file.
- Locks are not inherited by a child process after a **fork** subroutine is run.

  Note: Deadlocks due to file locks in a distributed system are not always detected. When such deadlocks can possibly occur, the programs requesting the locks should set time-out timers.

Locks can start and extend beyond the current end of a file but cannot be negative relative to the beginning of the file. A lock can be set to extend to the end of the file by setting the `l_len` field to 0. If such a lock also has the `l_start` and `l_whence` fields set to 0, the whole file is locked. The `l_len`, `l_start`, and `l_whence` locking fields are part of the **flock** structure.

When an application locks a region of a file using the 32 bit locking interface (F_SETLK), and the last byte of the lock range includes MAX_OFF (2 Gb - 1), then the lock range for the unlock request will be extended to include MAX_END (2 ^ ^ 63 - 1).

Parameters

Item	Description
FileDescriptor	Specifies an open file descriptor obtained from a successful call to the **open** subroutine, **fcntl** subroutine, **pipe** subroutine, or **shm_open** subroutine. File descriptors are small positive integers used (instead offile names) to identify files or a shared memory object.
Argument	Specifies a variable whose value sets the function specified by the *Command* parameter. When dealing with file locks, the *Argument* parameter must be a pointer to the **FLOCK** structure.
Command	Specifies the operation performed by the **fcntl** subroutine. The **fcntl** subroutine can duplicate open file descriptors, set file-descriptor flags, set file descriptor locks, set process IDs, and close open file descriptors.

Duplicating File Descriptors

Item	Description
F_DUPFD	Returns a new file descriptor as follows: • Lowest-numbered available file descriptor greater than or equal to the *Argument* parameter • Same object references as the original file • Same file pointer as the original file (that is, both file descriptors share one file pointer if the object is a file) • Same access mode (read, write, or read-write) • Same file status flags (That is, both file descriptors share the same file status flags.) • The **close-on-exec** flag (**FD_CLOEXEC** bit) associated with the new file descriptor is cleared

Setting File-Descriptor Flags

Item	Description
F_GETFD	Gets the **close-on-exec** flag (**FD_CLOEXEC** bit) that is associated with the file descriptor specified by the *FileDescriptor* parameter. The *Argument* parameter is ignored. File descriptor flags are associated with a single file descriptor, and do not affect others associated with the same file.
F_SETFD	Assigns the value of the *Argument* parameter to the **close-on-exec** flag (**FD_CLOEXEC** bit) that is associated with the *FileDescriptor* parameter. If the **FD_CLOEXEC** flag value is 0, the file remains open across any calls to **exec** subroutines; otherwise, the file will close upon the successful execution of an **exec** subroutine.

Item	Description
F_GETFL	Gets the file-status flags and file-access modes for the open file description associated with the file descriptor specified by the *FileDescriptor* parameter. The open file description is set at the time the file is opened and applies only to those file descriptors associated with that particular call to the file. This open file descriptor does not affect other file descriptors that refer to the same file with different open file descriptions. The file-status flags have the following values: **O_APPEND** Set append mode. **O_NONBLOCK** No delay. The file-access modes have the following values: **O_RDONLY** Open for reading only. **O_RDWR** Open for reading and writing. **O_WRONLY** Open for writing only. The file access flags can be extracted from the return value using the **O_ACCMODE** mask, which is defined in the **fcntl.h** file.
F_SETFL	Sets the file status flags from the corresponding bits specified by the *Argument* parameter. The file-status flags are set for the open file description associated with the file descriptor specified by the *FileDescriptor* parameter. The following flags may be set: • **O_APPEND** or **FAPPEND** • **O_NDELAY** or **FNDELAY** • **O_NONBLOCK** or **FNONBLOCK** • **O_SYNC** or **FSYNC** • **FASYNC** The **O_NDELAY** and **O_NONBLOCK** flags affect only operations against file descriptors derived from the same **open** subroutine. In BSD, these operations apply to all file descriptors that refer to the object.

Setting File Locks

Item	Description
F_GETLK	Gets information on the first lock that blocks the lock described in the **flock** structure. The *Argument* parameter should be a pointer to a type **struct flock**, as defined in the **flock.h** file. The information retrieved by the **fcntl** subroutine overwrites the information in the **struct flock** pointed to by the *Argument* parameter. If no lock is found that would prevent this lock from being created, the structure is left unchanged, except for lock type (`l_type`) which is set to **F_UNLCK**.
F_SETLK	Sets or clears a file-segment lock according to the lock description pointed to by the *Argument* parameter. The *Argument* parameter should be a pointer to a type **struct flock**, which is defined in the **flock.h** file. The **F_SETLK** option is used to establish read (or shared) locks (**F_RDLCK**), or write (or exclusive) locks (**F_WRLCK**), as well as to remove either type of lock (**F_UNLCK**). The lock types are defined by the **fcntl.h** file. If a shared or exclusive lock cannot be set, the **fcntl** subroutine returns immediately.

Item	Description
F_SETLKW	Performs the same function as the **F_SETLK** option unless a read or write lock is blocked by existing locks, in which case the process sleeps until the section of the file is free to be locked. If a signal that is to be caught is received while the **fcntl** subroutine is waiting for a region, the **fcntl** subroutine is interrupted, returns a -1, sets the **errno** global variable to **EINTR**. The lock operation is not done.

Item	Description
F_GETLK64	Gets information on the first lock that blocks the lock described in the **flock64** structure. The *Argument* parameter should be a pointer to an object of the type **struct flock64**, as defined in the **flock.h** file. The information retrieved by the **fcntl** subroutine overwrites the information in the **struct flock64** pointed to by the *Argument* parameter. If no lock is found that would prevent this lock from being created, the structure is left unchanged, except for lock type (`l_type`) which is set to **F_UNLCK**.
F_SETLK64	Sets or clears a file-segment lock according to the lock description pointed to by the *Argument* parameter. The *Argument* parameter should be a pointer to a type **struct flock64**, which is defined in the **flock.h** file. The **F_SETLK** option is used to establish read (or shared) locks (**F_RDLCK**), or write (or exclusive) locks (**F_WRLCK**), as well as to remove either type of lock (**F_UNLCK**). The lock types are defined by the **fcntl.h** file. If a shared or exclusive lock cannot be set, the **fcntl** subroutine returns immediately.
F_SETLKW64	Performs the same function as the **F_SETLK** option unless a read or write lock is blocked by existing locks, in which case the process sleeps until the section of the file is free to be locked. If a signal that is to be caught is received while the **fcntl** subroutine is waiting for a region, the **fcntl** subroutine is interrupted, returns a -1, sets the **errno** global variable to **EINTR**. The lock operation is not done.

Setting Process ID

Item	Description
F_GETOWN	Gets the process ID or process group currently receiving **SIGIO** and **SIGURG** signals. Process groups are returned as negative values.
F_SETOWN	Sets the process or process group to receive **SIGIO** and **SIGURG** signals. Process groups are specified by supplying a negative *Argument* value. Otherwise, the *Argument* parameter is interpreted as a process ID.

Closing File Descriptors

Item	Description
F_CLOSEM	Closes all file descriptors from *FileDescriptor* up to the highest currently open file descriptor (*U_maxofile*).
Old	Specifies an open file descriptor.
New	Specifies an open file descriptor that is returned by the **dup2** subroutine.

Compatibility Interfaces

The lockfx Subroutine

The **fcntl** subroutine functions similar to the **lockfx** subroutine, when the *Command* parameter is **F_SETLK**, **F_SETLKW**, or **F_GETLK**, and when used in the following way:

fcntl (*FileDescriptor***,** *Command***,** *Argument***)**

is equivalent to:

lockfx (*FileDescriptor***,** *Command***,** *Argument***)**

The dup and dup2 Subroutines

The **fcntl** subroutine functions similar to the **dup** and **dup2** subroutines, when used in the following way:

```
dup (FileDescriptor)
```

is equivalent to:

```
fcntl (FileDescriptor, F_DUPFD, 0)
```

```
dup2 (Old, New)
```

is equivalent to:

```
close (New);
fcntl(Old, F_DUPFD, New)
```

The **dup** and **dup2** subroutines differ from the **fcntl** subroutine in the following ways:

- If the file descriptor specified by the *New* parameter is greater than or equal to **OPEN_MAX**, the **dup2** subroutine returns a -1 and sets the **errno** variable to **EBADF**.
- If the file descriptor specified by the *Old* parameter is valid and equal to the file descriptor specified by the *New* parameter, the **dup2** subroutine will return the file descriptor specified by the *New* parameter, without closing it.
- If the file descriptor specified by the *Old* parameter is not valid, the **dup2** subroutine will be unsuccessful and will not close the file descriptor specified by the *New* parameter.
- The value returned by the **dup** and **dup2** subroutines is equal to the *New* parameter upon successful completion; otherwise, the return value is -1.

Return Values

Upon successful completion, the value returned depends on the value of the *Command* parameter, as follows:

Item	Description
Command	Return Value
F_DUPFD	A new file descriptor
F_GETFD	The value of the flag (only the **FD_CLOEXEC** bit is defined)
F_SETFD	A value other than -1
F_GETFL	The value of file flags
F_SETFL	A value other than -1
F_GETOWN	The value of descriptor owner
F_SETOWN	A value other than -1
F_GETLK	A value other than -1
F_SETLK	A value other than -1
F_SETLKW	A value other than -1
F_CLOSEM	A value other than -1.

If the **fcntl** subroutine fails, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **fcntl** subroutine is unsuccessful if one or more of the following are true:

Item	Description
EACCES	The *Command* argument is **F_SETLK**; the type of lock is a shared or exclusive lock and the segment of a file to be locked is already exclusively-locked by another process, or the type is an exclusive lock and some portion of the segment of a file to be locked is already shared-locked or exclusive-locked by another process.
EBADF	The *FileDescriptor* parameter is not a valid open file descriptor.
EDEADLK	The *Command* argument is **F_SETLKW**; the lock is blocked by some lock from another process and putting the calling process to sleep, waiting for that lock to become free would cause a deadlock.
ENOTTY	The file descriptor does not refer to a terminal device or socket.
EMFILE	The *Command* parameter is **F_DUPFD**, and the maximum number of file descriptors are currently open (**OPEN_MAX**).
EINVAL	The *Command* parameter is **F_DUPFD**, and the *Argument* parameter is negative or greater than or equal to **OPEN_MAX**.
EINVAL	An illegal value was provided for the *Command* parameter.
EINVAL	An attempt was made to lock a fifo or pipe.
ESRCH	The value of the *Command* parameter is **F_SETOWN**, and the process ID specified as the *Argument* parameter is not in use.
EINTR	The *Command* parameter was **F_SETLKW** and the process received a signal while waiting to acquire the lock.
EOVERFLOW	The *Command* parameter was **F_GETLK** and the block lock could not be represented in the **flock** structure.

The **dup** and **dup2** subroutines fail if one or both of the following are true:

Item	Description
EBADF	The *Old* parameter specifies an invalid open file descriptor or the *New* parameter specifies a file descriptor that is out of range.
EMFILE	The number of file descriptors exceeds the **OPEN_MAX** value or there is no file descriptor above the value of the *New* parameter.

If NFS is installed on the system, the **fcntl** subroutine can fail if the following is true:

Item	Description
ETIMEDOUT	The connection timed out.

fdetach Subroutine

Purpose

Detaches STREAMS-based file from the file to which it was attached.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stropts.h>
int fdetach(const char *path);
```

Parameters

Item	Description
path	Pathname of a file previous associated with a STREAMS-based object using the **fattach** subroutine.

Description

The **fdetach** subroutine detaches a STREAMS-based file from the file to which it was attached by a previous call to **fattach** subroutine. The *path* argument points to the pathname of the attached STREAMS file. The process must have appropriate privileges or be the owner of the file. A successful call to **fdetach** subroutine causes all pathnames that named the attached STREAMS file to again name the file to which the STREAMS file was attached. All subsequent operations on *path* will operate on the underlying file and not on the STREAMS file.

All open file descriptors established while the STREAMS file was attached to the file referenced by *path* will still refer to the STREAMS file after the **fdetach** subroutine has taken effect.

If there are no open file descriptors or other references to the STREAMS file, then a successful call to **fdetach** subroutine has the same effect as performing the last **close** subroutine on the attached file.

The **umount** command may be used to detach a file name if an | application exits before performing **fdetach** subroutine.

Return Value

Item	Description
0	Successful completion.
-1	Not successful and **errno** set to one of the following.

Errno Value

Item	Description
EACCES	Search permission is denied on a component of the path prefix.
EPERM	The effective user ID is not the owner of *path* and the process does not have appropriate privileges.
ENOTDIR	A component of the path prefix is not a directory.
ENOENT	A component of *path* parameter does not name an existing file or *path* is an empty string.
EINVAL	The *path* parameter names a file that is not currently attached.
ENAMETOOLONG	The size of *path* parameter exceeds {**PATH_MAX**}, or a component of *path* is longer than {**NAME_MAX**}.
ELOOP	Too many symbolic links were encountered in resolving the *path* parameter.
ENOMEM	Insufficient storage space is available.

fdim, fdimf, fdiml, fdimd32, fdimd64, and fdimd128 Subroutines

Purpose

Computes the positive difference between two floating-point numbers.

Syntax

```
#include <math.h>

double fdim (x, y)
double x;
double y;

float fdimf (x, y)
float x;
float y;

long double fdiml (x, y)
long double x;
long double y;

_Decimal32 fdimd32 (x, y);
_Decimal32 x;
_Decimal32 y;

_Decimal64 fdimd64 (x, y);
_Decimal64 x;
_Decimal64 y;

_Decimal128 fdimd128 (x, y);
_Decimal128 x;
_Decimal128 y;
```

Description

The **fdim**, **fdimf**, **fdiml**, **fdimd32**, **fdimd64**, and **fdimd128** subroutines determine the positive difference between their arguments. If the value of the *x* parameter is greater than that of the *y* parameter, *x* - *y* is returned. If *x* is less than or equal to *y*, +0 is returned.

An application that wants to check for error situations should set the **errno** global variable to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. On return, if the **errno** is a value of non-zero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is a value of non-zero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.
y	Specifies the value to be computed.

Return Values

Upon successful completion, the **fdim**, **fdimf**, **fdiml**, **fdimd32**, **fdimd64**, and **fdimd128** subroutines return the positive difference value.

If *x*-*y* is positive and overflows, a range error occurs and the **fdim**, **fdimf**, **fdiml**, **fdimd32**, **fdimd64**, and **fdimd128** subroutines return the value of the **HUGE_VAL**, **HUGE_VALF**, **HUGE_VALL**, **HUGE_VAL_D32**, **HUGE_VAL_D64** and **HUGE_VAL_D128** macro respectively.

If *x*-*y* is positive and underflows, a range error might occur, and 0.0 is returned.

If *x* or *y* is NaN, a NaN is returned.

fe_dec_getround and fe_dec_setround Subroutines

Purpose

Reads and sets the IEEE decimal floating-point rounding mode.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <fenv.h>
int fe_dec_getround ();
int fe_dec_setround (RoundMode);
int RoundMode
```

Description

The **fe_dec_getround** subroutine returns the current rounding mode. The **fe_dec_setround** subroutine changes the rounding mode to the *RoundMode* parameter and returns the value of zero if it successfully completes.

Decimal floating-point rounding occurs when the infinitely precise result of a decimal floating-point operation cannot be represented exactly in the destination decimal floating-point format. The IEEE Standard for decimal floating-point arithmetic defines five modes that round the floating-point numbers: **round toward zero**, **round to nearest**, **round toward +INF**, **round toward -INF**, and **round to nearest ties away from zero**. Once a rounding mode is selected, it affects all subsequent decimal floating-point operations until another rounding mode is selected.

Tip: The default decimal floating-point rounding mode is the **round to nearest** mode. All C main programs begin with the rounding mode that is set to **round to nearest**.

The encodings of the rounding modes are defined in the ANSI C Standard. The **fenv.h** file contains definitions for the rounding modes. The following table shows the **fenv.h** definition, the ANSI C Standard value, and a description of each rounding mode.

fenv.h definition	ANSI value	Description
FE_DEC_TONEAREST	0	Round to nearest
FE_DEC_TOWARDZERO	1	Round toward zero
FE_DEC_UPWARD	2	Round toward +INF
FE_DEC_DOWNWARD	3	Round toward -INF
FE_DEC_TONEARESTFROMZERO	4	Round to nearest ties away from zero

Parameters

Item	Description
RoundMode	Specifies one of the following modes: FE_DEC_TOWARDZERO, FE_DEC_TONEAREST, FE_DEC_UPWARD, FE_DEC_DOWNWARD, FE_DEC_TONEARESTFROMZERO.

Return Values

On successful completion, the **fe_dec_getround** subroutine returns the current rounding mode. Otherwise , it returns -1.

On successful completion, the **fe_dec_setround** subroutine returns the value of zero. Otherwise, it returns -1.

feclearexcept Subroutine

Purpose

Clears floating-point exceptions.

Syntax

```
#include <fenv.h>

int feclearexcept (excepts)
int excepts;
```

Description

The **feclearexcept** subroutine attempts to clear the supported floating-point exceptions represented by the *excepts* parameter.

Parameters

Item	Description
excepts	Specifies the supported floating-point exception to be cleared.

Return Values

If the *excepts* parameter is zero or if all the specified exceptions were successfully cleared, the **feclearexcept** subroutine returns zero. Otherwise, it returns a nonzero value.

fegetenv or fesetenv Subroutine

Purpose

Gets and sets the current floating-point environment.

Syntax

```
#include <fenv.h>

int fegetenv (envp)
fenv_t *envp;

int fesetenv (envp)
const fenv_t *envp;
```

Description

The **fegetenv** subroutine stores the current floating-point environment in the object pointed to by the *envp* parameter.

The **fesetenv** subroutine attempts to establish the floating-point environment represented by the object pointed to by the *envp* parameter. The *envp* parameter points to an object set by a call to the **fegetenv** or **feholdexcept** subroutines, or equal a floating-point environment macro. The **fesetenv** subroutine does not raise floating-point exceptions. It only installs the state of the floating-point status flags represented through its argument.

Parameters

Item	Description
envp	Points to an object set by a call to the **fegetenv** or **feholdexcept** subroutines, or equal a floating-point environment macro.

Return Values

If the representation was successfully stored, the **fegetenv** subroutine returns zero. Otherwise, it returns a nonzero value. If the environment was successfully established, the **fesetenv** subroutine returns zero. Otherwise, it returns a nonzero value.

fegetexceptflag or fesetexceptflag Subroutine

Purpose

Gets and sets floating-point status flags.

Syntax

```
#include <fenv.h>

int fegetexceptflag (flagp, excepts)
feexcept_t *flagp;
int excepts;

int fesetexceptflag (flagp, excepts)
const fexcept_t *flagp;
int excepts;
```

Description

The **fegetexceptflag** subroutine attempts to store an implementation-defined representation of the states of the floating-point status flags indicated by the *excepts* parameter in the object pointed to by the *flagp* parameter.

The **fesetexceptflag** subroutine attempts to set the floating-point status flags indicated by the *excepts* parameter to the states stored in the object pointed to by the *flagp* parameter. The value pointed to by the *flagp* parameter shall have been set by a previous call to the **fegetexceptflag** subroutine whose second argument represented at least those floating-point exceptions represented by the *excepts* parameter. This subroutine does not raise floating-point exceptions. It only sets the state of the flags.

Parameters

Item	Description
flagp	Points to the object that holds the implementation-defined representation of the states of the floating-point status flags.
excepts	Points to an implementation-defined representation of the states of the floating-point status flags.

Return Values

If the representation was successfully stored, the **fegetexceptflag** parameter returns zero. Otherwise, it returns a nonzero value. If the *excepts* parameter is zero or if all the specified exceptions were successfully set, the **fesetexceptflag** subroutine returns zero. Otherwise, it returns a nonzero value.

fegetround or fesetround Subroutine

Purpose

Gets and sets the current rounding direction.

Syntax

```
#include <fenv.h>

int fegetround (void)

int fesetround (round)
int round;
```

Description

The **fegetround** subroutine gets the current rounding direction.

The **fesetround** subroutine establishes the rounding direction represented by the *round* parameter. If the *round* parameter is not equal to the value of a rounding direction macro, the rounding direction is not changed.

Parameters

Item	Description
round	Specifies the rounding direction.

Return Values

The **fegetround** subroutine returns the value of the rounding direction macro representing the current rounding direction or a negative value if there is no such rounding direction macro or the current rounding direction is not determinable.

The **fesetround** subroutine returns a zero value if the requested rounding direction was established.

feholdexcept Subroutine

The **feholdexcept** subroutine returns zero if non-stop floating-point exception handling was successfully installed.

Purpose

Saves current floating-point environment.

Syntax

```
#include <fenv.h>

int feholdexcept (envp)
fenv_t *envp;
```

Description

The **feholdexcept** subroutine saves the current floating-point environment in the object pointed to by *envp*, clears the floating-point status flags, and installs a non-stop (continue on floating-point exceptions) mode for all floating-point exceptions.

Parameters

Item	Description
envp	Points to the current floating-point environment.

Return Values

fence Subroutine

Purpose

Allows you to request and change the virtual shared disk fence map.

Syntax

```
#include <vsd_ioctl.h>
int ioctl(FileDescriptor, Command, Argument)
int FileDescriptor, Command;
void *Argument;
```

Description

Use this subroutine to request and change the virtual shared disk fence map. The fence map, which controls whether virtual shared disks can send or satisfy requests from virtual shared disks at remote nodes, is defined as:

```
struct  vsd_FenceMap             /* This is the argument to the VSD fence ioctl. */
{
   ulong                  flags;
   vsd_minorBitmap_t      minornoBitmap; /* Bitmap of minor numbers to fence
                                            (supports 10000 vsds)              */
   vsd_Fence_Bitmap_t     nodesBitmap;   /* Nodes to (un)fence these vsds from
                                            (supports node numbers 1-2048)     */

}vsd_FenceMap_t
```

The flags **VSD_FENCE** and **VSD_UNFENCE** are mutually exclusive — an ioctl can either fence a set of virtual shared disks or unfence a set of virtual shared disks, but not both. The *minornoBitmap* denotes which virtual shared disks are to be fenced/unfenced from the nodes specified in the *nodesBitmap*.

Parameters

FileDescriptor
Specifies the open file descriptor for which the control operation is to be performed.

Command
Specifies the control function to be performed. The value of this parameter is always `GIOCFENCE`.

Argument
Specifies a pointer to a `vsd_fence_map` structure.

The *flags* field of the `vsd_fence_map` structure determines the type of operation that is performed. The flags could be set with one or more options using the OR operator. These options are as follows:

VSD_FENCE_FORCE
If this option is specified, a node can unfence itself.

VSD_FENCE_GET
Denotes a query request.

VSD_FENCE
Denotes a fence request.

VSD_UNFENCE
Denotes an unfence request.

Examples

The following example fences a virtual shared disk with a minor number of 7 from node 4 and 5, and unfences a virtual shared disk with a minor number of 5 from node 1:

```
int fd;
vsd_FenceMap_t FenceMap;

/* Clear the FenceMap */
bzero(FenceMap, sizeof(vsd_FenceMap_t));

/* fence nodes 4,5 from minor 7 */
FenceMap.flags = VSD_FENCE;
MAP_SET(7, FenceMap.minornoBitmap);
MAP_SET(4, FenceMap.nodesBitmap);
MAP_SET(5, FenceMap.nodesBitmap);

/* Issue the fence request */
ioctl(fd,GIOCFENCE,&FenceMap);

/* Unfence node 1 from minor 5*/
bzero(FenceMap, sizeof(vsd_FenceMap_t));
FenceMap.flags = VSD_UNFENCE | VSD_FENCE_FORCE;
MAP_SET(5, FenceMap.minornoBitmap);
MAP_SET(1, FenceMap.nodesBitmap);

/* Issue the fence request */
ioctl(fd,GIOCFENCE,&FenceMap);
```

Return Values

If the request succeeds, the ioctl returns 0. In the case of an error, a value of -1 is returned with the global variable `errno` set to identify the error.

Error Values

The `fence` ioctl subroutine can return the following error codes:

EACCES
Indicates that an unfence was requested from a fenced node without the VSD_FENCE_FORCE option.

EINVAL
Indicates an invalid request (ambiguous flags or unidentified virtual shared disks).

ENOCONNECT
Indicates that either the primary or the secondary node for a virtual shared disk to be fenced is not a member of the virtual shared disk group, or the virtual shared disk in question is in the **stopped** state.

ENOTREADY
Indicates that the group is not active or the Recoverable virtual shared disk subsystem is not available.

ENXIO
Indicates that the Virtual shared disk driver is being unloaded.

feof, ferror, clearerr, or fileno Macro

Purpose

Checks the status of a stream.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdio.h>
```

int feof (*Stream*)
**FILE ****Stream*;

```
int ferror (Stream)
FILE *Stream;
```

```
void clearerr (Stream)
FILE *Stream;
```

```
int fileno (Stream)
FILE *Stream;
```

Description

The **feof** macro inquires about the end-of-file character (EOF). If EOF has previously been detected reading the input stream specified by the *Stream* parameter, a nonzero value is returned. Otherwise, a value of 0 is returned.

The **ferror** macro inquires about input or output errors. If an I/O error has previously occurred when reading from or writing to the stream specified by the *Stream* parameter, a nonzero value is returned. Otherwise, a value of 0 is returned.

The **clearerr** macro inquires about the status of a stream. The **clearerr** macro resets the error indicator and the EOF indicator to a value of 0 for the stream specified by the *Stream* parameter.

The **fileno** macro inquires about the status of a stream. The **fileno** macro returns the integer file descriptor associated with the stream pointed to by the *Stream* parameter. Otherwise a value of -1 is returned.

Parameters

Item	Description
Stream	Specifies the input or output stream.

feraiseexcept Subroutine

If the argument is zero or if all the specified exceptions were successfully raised, the **feraiseexcept** subroutine returns a zero. Otherwise, it returns a nonzero value.

Purpose

Raises the floating-point exception.

Syntax

```
#include <fenv.h>

int feraiseexcept (excepts)
int excepts;
```

Description

The **feraiseexcept** subroutine attempts to raise the supported floating-point exceptions represented by the *excepts* parameter. The order in which these floating-point exceptions are raised is unspecified.

Parameters

Item	Description
excepts	Points to the floating-point exceptions.

Return Values

fetch_and_add and fetch_and_addlp Subroutines

Purpose

Updates a variable atomically.

Library

Standard C library (**libc.a**)

Syntax

```
#include <sys/atomic_op.h>
int fetch_and_add ( addr,  value)
atomic_p addr;
int value;

long fetch_and_addlp ( addr,  value)
atomic_l addr;
ulong value;
```

Description

The **fetch_and_add** and **fetch_and_addlp** subroutines increment one word in a single atomic operation. This operation is useful when a counter variable is shared between several threads or processes. When updating such a counter variable, it is important to make sure that the fetch, update, and store operations occur atomically (are not interruptible). For example, consider the sequence of events which could occur if the operations were interruptible:

1. A process fetches the counter value and adds one to it.
2. A second process fetches the counter value, adds one, and stores it.
3. The first process stores its value.

The result of this is that the update made by the second process is lost.

Traditionally, atomic access to a shared variable would be controlled by a mechanism such as semaphores. Compared to such mechanisms, the **fetch_and_add** and **fetch_and_addlp** subroutines require very little increase in processor usage.

For 32-bit applications, the **fetch_and_add** and **fetch_and_addlp** subroutines are identical and operate on a word aligned single word (32-bit variable aligned on a 4-byte boundary).

For 64-bit applications, the **fetch_and_add** subroutine operates on a word aligned single word (32-bit variable aligned on a 4-byte boundary) and the **fetch_and_addlp** subroutine operates on a double word aligned double word (64-bit variable aligned on an 8-byte boundary).

Parameters

Item	Description
addr	Specifies the address of the variable to be incremented.
value	Specifies the value to be added to the variable.

Return Values

This subroutine returns the original value of the variable.

fetch_and_and, fetch_and_or, fetch_and_andlp, and fetch_and_orlp Subroutines

Purpose

Sets or clears bits in a variable atomically.

Library

Standard C library (**libc.a**)

Syntax

```
#include <sys/atomic_op.h>
uint fetch_and_and ( addr, mask)
atomic_p addr;
unit mask;

ulong fetch_and_andlp ( addr, mask)
atomic_l addr;
ulong mask;

uint fetch_and_or ( addr,mask)
atomic_p addr;
intunit mask;

ulong fetch_and_orlp ( addr, mask)
atomic_l addr;
ulong mask;
```

Description

The **fetch_and_and**, **fetch_and_andlp**, **fetch_and_or**, and **fetch_and_orlp** subroutines respectively clear and set bits in a variable, according to a bit *mask*, as a single atomic operation.

The **fetch_and_and** and **fetch_and_andlp** subroutines clear bits in the variable that correspond to clear bits in the bit mask.

The **fetch_and_or** and **fetch_and_orlp** subroutines sets bits in the variable that correspond to set bits in the bit mask.

For 32-bit applications, the **fetch_and_and** and **fetch_and_andlp** subroutines are identical and operate on a word aligned single word (32-bit variable aligned on a 4-byte boundary). The **fetch_and_or** and

fetch_and_orlp subroutines are identical and operate on a word aligned single word (32-bit variable aligned on a 4-byte boundary).

For 64-bit applications, the **fetch_and_and** and **fetch_and_or** operate on a word aligned single word (32-bit variable aligned on a 4-byte boundary). The **fetch_and_addlp** and **fetch_and_orlp** subroutines operate on a double word aligned double word (64-bit variable aligned on an 8 -byte boundary).

These operations are useful when a variable containing bit flags is shared between several threads or processes. When updating such a variable, it is important that the fetch, bit clear or set, and store operations occur atomically (are not interruptible). For example, consider the sequence of events which could occur if the operations were interruptible:

1. A process fetches the flags variable and sets a bit in it.
2. A second process fetches the flags variable, sets a different bit, and stores it.
3. The first process stores its value.

The result is that the update made by the second process is lost.

Traditionally, atomic access to a shared variable would be controlled by a mechanism such as semaphores. Compared to such mechanisms, the **fetch_and_and**, **fetch_and_andlp**, **fetch_and_or**, and **fetch_and_orlp** subroutines require very little overhead.

Parameters

Item	Description
addr	Specifies the address of the variable whose bits are to be cleared or set.
mask	Specifies the bit mask which is to be applied to the variable.

Return Values

These subroutines return the original value of the variable.

fetestexcept Subroutine

The **fetestexcept** subroutine determines which of a specified subset of the floating-point exception flags are currently set. The *excepts* parameter specifies the floating-point status flags to be queried.

The **fetestexcept** subroutine returns the value of the bitwise-inclusive OR of the floating-point exception macros corresponding to the currently set floating-point exceptions included in *excepts*.

Purpose

Tests floating-point exception flags.

Syntax

```
#include <fenv.h>

int fetestexcept (excepts)
int excepts;
```

Description

Parameters

Item	Description
excepts	Specifies the floating-point status flags to be queried.

Return Values

feupdateenv Subroutine

Purpose

Updates floating-point environment.

Syntax

```
#include <fenv.h>

int feupdateenv (envp)
const fenv_t *envp;
```

Description

The **feupdateenv** subroutine attempts to save the currently raised floating-point exceptions in its automatic storage, attempts to install the floating-point environment represented by the object pointed to by the *envp* parameter, and attempts to raise the saved floating-point exceptions. The *envp* parameter point to an object set by a call to **feholdexcept** or **fegetenv**, or equal a floating-point environment macro.

Parameters

Item	Description
envp	Points to an object set by a call to the **feholdexcept** or the **fegetenv** subroutine, or equal a floating-point environment macro.

Return Values

The **feupdateenv** subroutine returns a zero value if all the required actions were successfully carried out.

finfo or ffinfo Subroutine

Purpose

Returns file information.

Library

Standard C library (**libc.a**)

Syntax

```
#include <sys/finfo.h>
```

```
int finfo(Path1, cmd, buffer, length)
const char *Path1;
int cmd;
void  *buffer;
int length;
```

```
int ffinfo (fd, cmd, buffer, length)
int fd;
int cmd;
void  *buffer;
int length;
```

Description

The **finfo** and **ffinfo** subroutines return specific file information for the specified file.

Parameters

Item	Description
Path1	Path name of a file system object to query.
fd	File descriptor for an open file to query.
cmd	Specifies the type of file information to be returned.
buffer	User supplied buffer which contains the file information upon successful return. **/usr/include/sys/finfo.h** describes the buffer.
length	Length of the query buffer.

Commands

Item	Description
FI_PATHCONF	When the **FI_PATHCONF** command is specified, a file's implementation information is returned. **Note:** The operating system provides another subroutine that retrieves file implementation characteristics, **pathconf** command. While the **finfo** and **ffinfo** subroutines can be used to retrieve file information, it is preferred that programs use the **pathconf** interface.
FI_DIOCAP	When the **FI_DIOCAP** command is specified, the file's direct I/O capability information is returned. The buffer supplied by the application is of type **struct diocapbuf *** .

Return Values

Upon successful completion, the **finfo** and **ffinfo** subroutines return a value of 0 and the user supplied buffer is correctly filled in with the file information requested. If the **finfo** or **ffinfo** subroutines were unsuccessful, a value of **-1** is returned and the global **errno** variable is set to indicate the error.

Error Codes

Item	Description
EACCES	Search permission is denied for a component of the path prefix.
EINVAL	If the length specified for the user buffer is greater than **MAX_FINFO_BUF**. If the command argument is not supported. If **FI_DIOCAP** command is specified and the file object does not support Direct I/O.
ENAMETOOLONG	The length of the Path parameter string exceeds the **PATH_MAX** value.
ENOENT	The named file does not exist or the Path parameter points to an empty string.

Item	Description
ENOTDIR	A component of the path prefix is not a directory.
EBADF	File descriptor provided is not valid.

filter Subroutine

Purpose

Disables use of certain terminal capabilities.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
void filter(void);
```

Description

The **filter** subroutine changes the algorithm for initialising terminal capabilities that assume that the terminal has more than one line. A subsequent call to the **initscr** or **newterm** subroutine performs the following actions:

- Disables use of clear, cud, cud1, cup, cuu1, and vpa.
- Sets the value of the home string to the value of the cr. string.
- Sets lines equal to 1.

Any call to the **filter** subroutine must precede the call to the **initscr** or **newterm** subroutine.

flash Subroutine

Purpose

Flashes the screen.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
int flash(void);
```

Description

The **flash** subroutine alerts the user. It flashes the screen, or if that is not possible, it sounds the audible alarm on the terminal. If neither signal is possible, nothing happens.

Return Values

The **flash** subroutine always returns OK.

Examples

To cause the terminal to flash, enter:

```
flash();
```

flockfile, ftrylockfile, funlockfile Subroutine

Purpose

Provides for explicit application-level locking of stdio (FILE*) objects.

Library

Standard Library (**libc.a**)

Syntax

```
#include <stdio.h>
void flockfile (FILE * file)
int ftrylockfile (FILE * file)
void funlockfile (FILE * file)
```

Description

The **flockfile**, **ftrylockfile** and **funlockfile** functions provide for explicit application-level locking of stdio (**FILE***) objects. These functions can be used by a thread to delineate a sequence of I/O statements that are to be executed as a unit.

The **flockfile** function is used by a thread to acquire ownership of a (**FILE***) object.

The **ftrylockfile** function is used by a thread to acquire ownership of a (**FILE***) object if the object is available; **ftrylockfile** is a non-blocking version of **flockfile**.

The **funlockfile** function is used to relinquish the ownership granted to the thread. The behavior is undefined if a thread other than the current owner calls the **funlockfile** function.

Logically, there is a lock count associated with each (**FILE***) object. This count is implicitly initialised to zero when the (**FILE***) object is created. The (**FILE***) object is unlocked when the count is zero. When the count is positive, a single thread owns the (**FILE***) object. When the **flockfile** function is called, if the count is zero or if the count is positive and the caller owns the (**FILE***) object, the count is incremented. Otherwise, the calling thread is suspended, waiting for the count to return to zero. Each call to **funlockfile** decrements the count. This allows matching calls to **flockfile** (or successful calls to **ftrylockfile**) and **funlockfile** to be nested.

All functions that reference (**FILE***) objects behave as if they use **flockfile** and **funlockfile** internally to obtain ownership of these (**FILE***) objects.

Return Values

None for **flockfile** and **funlockfile**. The function ftrylock returns zero for success and non-zero to indicate that the lock cannot be acquired.

Implementation Specifics

These subroutines are part of Base Operating System (BOS) subroutines.

Realtime applications may encounter priority inversion when using FILE locks. The problem occurs when a high priority thread locks a file that is about to be unlocked by a low priority thread, but the low priority thread is preempted by a medium priority thread. This scenario leads to priority inversion; a high priority thread is blocked by lower priority threads for an unlimited period of time. During system design, realtime programmers must take into account the possibility of this kind of priority inversion. They can deal with it in a number of 7434 ways, such as by having critical sections that are guarded by file locks execute at a high priority, so that a thread cannot be preempted while executing in its critical section.

floor, floorf, floorl, floord32, floord64, floord128, nearest, trunc, itrunc, and uitrunc Subroutines

Purpose

The **floor** subroutine, **floorf** subroutine, **floorl** subroutine, **nearest** subroutine, **trunc** subroutine, **floord32** subroutine, **floord64** subroutine, and **floord128** subroutine, round floating-point numbers to floating-point integer values.

The **itrunc** subroutine and **uitrunc** subroutine round floating-point numbers to signed and unsigned integers, respectively.

Libraries

IEEE Math Library (**libm.a**) or System V Math Library (**libmsaa.a**) Standard C Library (**libc.a**) (separate syntax follows)

Syntax

```
#include <math.h>
```

```
double floor ( x)
double x;
```

```
float floorf (x)
float x;
```

```
long double floorl (x)
long double x;
```

```
_Decimal32 floord32(x)
_Decimal32 x;

_Decimal64 floord64(x)
_Decimal64 x;

_Decimal128 floord128(x)
_Decimal128 x;
```

```
double nearest (x)
double x;
```

```
double trunc (x)
double x;
```

Standard C Library (**libc.a**)

```
#include <stdlib.h>
#include <limits.h>
```

```
int itrunc (x)
double x;
```

```
unsigned int uitrunc (x)
double x;
```

Description

The **floor**, **floorf**, **floorl**, **floord32**, **floord64**, and **floord128** subroutines return the largest floating-point integer value that is not greater than the *x* parameter.

An application wishing to check for error situations should set **errno** to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

The **nearest** subroutine returns the nearest floating-point integer value to the *x* parameter. If *x* lies exactly halfway between the two nearest floating-point integer values, an even floating-point integer is returned.

The **trunc** subroutine returns the nearest floating-point integer value to the *x* parameter in the direction of 0. This is equivalent to truncating off the fraction bits of the *x* parameter.

Note: The default floating-point rounding mode is *round to nearest.* All C main programs begin with the rounding mode set to *round to nearest.*

The **itrunc** subroutine returns the nearest signed integer to the *x* parameter in the direction of 0. This is equivalent to truncating the fraction bits from the *x* parameter and then converting *x* to a signed integer.

The **uitrunc** subroutine returns the nearest unsigned integer to the *x* parameter in the direction of 0. This action is equivalent to truncating off the fraction bits of the *x* parameter and then converting *x* to an unsigned integer.

Note: Compile any routine that uses subroutines from the **libm.a** library with the **-lm** flag. To compile the `floor.c` file, for example, enter:

```
cc floor.c -lm
```

The **itrunc**, **uitrunc**, **trunc**, and **nearest** subroutines are not part of the ANSI C Library.

Parameters

Item	Description
x	Specifies a double-precision floating-point value. For the **floorl** subroutine, specifies a long double-precision floating-point value.

Item	Description
y	Specifies a double-precision floating-point value. For the **floorl** subroutine, specifies some long double-precision floating-point value.

Return Values

Upon successful completion, the **floor**, **floorf**, **floorl**, **floord32**, **floord64**, and **floord128** subroutines return the largest integral value that is not greater than *x*, expressed as a **double**, **float**, **long double**, **_Decimal32**, **_Decimal64**, or **_Decimal128**, as appropriate for the return type of the function.

If *x* is NaN, a NaN is returned.

If *x* is ±0 or ±Inf, *x* is returned.

If the correct value would cause overflow, a range error occurs and the**floor**, **floorf**, **floorl**, **floord32**, **floord64**, and **floord128** subroutines return the value of the macro **-HUGE_VAL**, **-HUGE_VALF**, **-HUGE_VALL**, **-HUGE_VAL_D32**, **-HUGE_VAL_D64**, and **-HUGE_VAL_D128**, respectively.

Error Codes

The **itrunc** and **uitrunc** subroutines return the **INT_MAX** value if *x* is greater than or equal to the **INT_MAX** value and the **INT_MIN** value if *x* is equal to or less than the **INT_MIN** value. The **itrunc** subroutine returns the **INT_MIN** value if *x* is a Quiet NaN(not-a-number) or Silent NaN. The **uitrunc** subroutine returns 0 if *x* is a Quiet NaN or Silent NaN. (The **INT_MAX** and **INT_MIN** values are defined in the **limits.h** file.) The **uitrunc** subroutine **INT_MAX** if *x* is greater than **INT_MAX** and 0 if *x* is less than or equal 0.0

Files

Item	Description
float.h	Contains the ANSI C **FLT_ROUNDS** macro.

flushinp Subroutine

Purpose

Discards input.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
int flushinp(void);
```

Description

The **flushinp** subroutine discards (flushes) any characters in the input buffers associated with the current screen.

Return Values

The **flushinp** subroutine always returns OK.

Examples

To flush all type-ahead characters typed by the user but not yet read by the program, enter:

```
flushinp();
```

fma, fmaf, fmal, and fmad128 Subroutines

Purpose

Floating-point multiply-add.

Syntax

```
#include <math.h>

double fma (x, y, z)
double x;
double y;
double z;

float fmaf (x, y, z)
float x;
float y;
float z;

long double fmal (x, y, z)
long double x;
long double y;
long double z;

_Decimal128 fmad128 (x, y, z)
_Decimal128 x;
_Decimal128 y;
_Decimal128 z;
```

Description

The **fma**, **fmaf**, **fmal**, and **fmad128** subroutines compute (*x* * *y*) + *z*, rounded as one ternary operation. They compute the value (as if) to infinite precision and round once to the result format, according to the rounding mode characterized by the value of FLT_ROUNDS.

An application wishing to check for error situations should set the **errno** global variable to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be multiplied by the *y* parameter.
y	Specifies the value to be multiplied by the *x* parameter.
z	Specifies the value to be added to the product of the *x* and *y* parameters.

Return Values

Upon successful completion, the **fma**, **fmaf**, **fmal**, and **fmad128** subroutines return (*x* * *y*) + *z*, rounded as one ternary operation.

If *x* or *y* are NaN, a NaN is returned.

If *x* multiplied by *y* is an exact infinity and *z* is also an infinity but with the opposite sign, a domain error occurs, and a NaN is returned.

If one of the *x* and *y* parameters is infinite, the other is zero, and the *z* parameter is not a NaN, a domain error occurs, and a NaN is returned.

If one of the *x* and *y* parameters is infinite, the other is zero, and *z* is a NaN, a NaN is returned and a domain error may occur.

If *x***y* is not 0*Inf nor Inf*0 and *z* is a NaN, a NaN is returned.

fmax, fmaxf, fmaxl, fmaxd32, fmaxd64, and fmaxd128 Subroutines

Purpose

Determines the maximum numeric value of two floating-point numbers.

Syntax

```
#include <math.h>

double fmax (x, y)
double x;
double y;

float fmaxf (x, y)
float x;
float y;

long double fmaxl (x, y)
long double x;
long double y;

_Decimal32 fmaxd32 (x, y);
_Decimal32 x;
_Decimal32 y;

_Decimal64 fmaxd64 (x, y);
_Decimal64 x;
_Decimal64 y;

_Decimal128 fmaxd128 (x, y);
_Decimal128 x;
_Decimal128 y;
```

Description

The **fmax**, **fmaxf**, **fmaxl**, **fmaxd32**, **fmaxd64**, and **fmaxd128** subroutines determine the maximum numeric value of their arguments. NaN arguments are treated as missing data. If one argument is a NaN and the other numeric, the **fmax**, **fmaxf**, **fmaxl**, **fmaxd32**, **fmaxd64**, and **fmaxd128** subroutines choose the numeric value.

Parameters

Item	Description
x	Specifies the value to be computed.
y	Specifies the value to be computed.

Return Values

Upon successful completion, the **fmaxl**, **fmaxf**, **fmaxl**, **fmaxd32**, **fmaxd64**, and **fmaxd128** subroutines return the maximum numeric value of their arguments.

If one argument is a NaN, the other argument is returned.

If *x* and *y* are NaN, a NaN is returned.

fmemopen Subroutine

Purpose

Opens a memory buffer stream.

Library

Standard Library (**libc.a**)

Syntax

```
#include <stdio.h>
FILE *fmemopen (void *restrict buf, size_t size, const char *restrict mode);
```

Description

The **fmemopen** subroutine associates the buffer given by the *buf* and *size* arguments with a stream. The *buf* argument must be either a null pointer or point to a buffer that contains the value specified by the *size* parameter in bytes.

The *mode* argument is a character string having one of the following values:

- *r* or *rb* to open the stream for reading.
- *w* or *wb* to open the stream for writing.
- *a* or *ab* Append to pen the stream for writing at the first null byte.
- *r+* or *rb+* or *r+b* to open the stream for update (reading and writing).
- *w+* or *wb+* or *w+b* to open the stream for update (reading and writing). Truncates the buffer contents.
- *a+* or *ab+* or *a+b* Append to open the stream for update (reading and writing) and the initial position is at the first null byte.

The character *b* does not have any effect.

If a null pointer is specified as the *buf* argument, the **fmemopen** subroutine allocates the number of bytes specified by the *size* parameter to the memory by a call to the **malloc** subroutine. This buffer is automatically released when the stream is closed. Because this feature is only useful when the stream is opened for updating since there is no way to get a pointer to the buffer, the **fmemopen** subroutine call fails if the *mode* argument does not include a **+** character.

The stream maintains a current position in the buffer. This position is initially set to either the beginning of the buffer (for *r* and *w* modes) or to the first null byte in the buffer (for *a* modes). If no null byte is found in the append mode, the initial position is set to one byte after the end of the buffer.

If *buf* is a null pointer, the initial position is always set to the beginning of the buffer.

The stream also maintains the size of the current buffer contents. For modes *r* and *r+* the size is set to the value given by the *size* argument. For modes *w* and *w+* the initial size is zero and for modes *a* and *a+* the initial size is either the position of the first null byte in the buffer or the value of the size argument if no null byte is found.

A read operation on the stream does not advance the current buffer position behind the current buffer size. Reaching the buffer size in a read operation counts as end of file. Null bytes in the buffer have no special meaning for reads. The read operation starts at the current buffer position of the stream.

A write operation starts either at the current position of the stream (if mode does not contain *a* as the first character) or at the current size of the stream (if mode does not contain *a* as the first character). If the current position at the end of the write is larger than the current buffer size, the current buffer size is set to the current position. A write operation on the stream doesl not advance the current buffer size behind the size given in the size argument.

When a stream opened for writing is flushed or closed, a null byte is written at the current position or at the end of the buffer, depending on the size of the contents. If a stream open for update is flushed or closed and the last write has advanced the current buffer size, a null byte is written at the end of the buffer if it fits.

An attempt to seek a memory buffer stream to a negative position or to a position larger than the buffer size given in the size argument fails.

Return Values

Upon successful completion, the **fmemopen** subroutine returns a pointer to the object controlling the stream. Otherwise, a null pointer is returned, and the *errno* variable is set to indicate the error.

Error Codes

The **fmemopen** function returns the following error code:

Table 1. Error codes

Item	Description
EINVAL	The *size* argument specifies a buffer size of zero or the value of the *mode* argument is not valid or the *buf* argument is a null pointer and the *mode* argument does not include a **+** character.
EMFILE	**FOPEN_MAX** streams are currently open in the calling process.
ENOMEM	The *buf* argument is a null pointer and the allocation of a buffer of length specified by the *size* parameter has failed.

Examples

```
#include <stdio.h>
static char buffer[] = "foobar";
int
main (void)
{
int ch;
FILE *stream;
stream = fmemopen(buffer, strlen (buffer), "r");
if (stream == NULL)
/* handle error */;
while ((ch = fgetc(stream)) != EOF)
printf("Got %c\n", ch);
fclose(stream);
return (0);
}
```

The above program produces the following output:

Got f

Got o

Got o

Got b

Got a

Got r

fminf, fminl, fmind32, fmind64, and fmind128 Subroutines

Purpose

Determines the minimum numeric value of two floating-point numbers.

Syntax

```
#include <math.h>

float fminf (x, y)
float x;
float y;

long double fminl (x, y)
long double x;
long double y;

_Decimal32 fmind32 (x, y)
_Decimal32 x;
_Decimal32 y;

_Decimal64 fmind64 (x, y)
_Decimal64 x;
_Decimal64 y;

_Decimal128 fmind128 (x, y)
_Decimal128 x;
_Decimal128 y;
```

Description

The **fminf**, **fminl**, **fmind32**, **fmind64**, and **fmind128** subroutines determine the minimum numeric value of their arguments. NaN arguments are treated as missing data. If one argument is a NaN and the other numeric, the **fminf**, **fminl**, **fmind32**, **fmind64**, and **fmind128** subroutines choose the numeric value.

Parameters

Item	Description
x	Specifies the value to be computed.
y	Specifies the value to be computed.

Return Values

Upon successful completion, the **fminf**, **fminl**, **fmind32**, **fmind64**, and **fmind128** subroutines return the minimum numeric value of their arguments.

If one argument is a NaN, the other argument is returned.

If *x* and *y* are NaN, a NaN is returned.

fmod, fmodf, fmodl, fmodd32, fmodd64, and fmodd128 Subroutines

Purpose

Computes the floating-point remainder value.

Syntax

```
#include <math.h>

float fmodf (x, y)
float x;
float y;

long double fmodl (x, y)
long double x, y;

double fmod (x, y)
double x, y;
_Decimal32 fmodd32 (x, y)
_Decimal32 x, y;

_Decimal64 fmodd64 (x, y)
_Decimal64 x, y;

_Decimal128 fmodd128 (x, y)
_Decimal128 x, y;
```

Description

The **fmodf**, **fmodl**, **fmod**, **fmodd32**, **fmodd64**, and **fmodd128** subroutines return the floating-point remainder of the division of *x* by *y*.

An application that wants to check for error situations must set the **errno** global variable to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. On return, if **errno** is the value of non-zero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is the value of non-zero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.
y	Specifies the value to be computed.

Return Values

The **fmodf**, **fmodl**, **fmod**, **fmodd32**, **fmodd64**, and **fmodd128** subroutines return the value *x*- *i* **y*. For the integer *i* such that, if *y* is nonzero, the result has the same sign as *x* and the magnitude is less than the magnitude of *y*.

If the correct value will cause underflow, and is not representable, a range error might occur, and 0.0 is returned.

If *x* or *y* is NaN, a NaN is returned.

If *y* is zero, a domain error occurs, and a NaN is returned.

If *x* is infinite, a domain error occurs, and a NaN is returned.

If *x* is ±0 and *y* is not zero, ±0 is returned.

If *x* is not infinite and *y* is ±Inf, *x* is returned.

If the correct value will cause underflow, and is representable, a range error might occur and the correct value is returned.

If the correct value is zero, rounding error might cause the return value to differ from 0.0. Depending on the values of *x* and *y*, and the rounding mode, the magnitude of the return value in this case might be near 0.0 or near the magnitude of y. This case can be avoided by using the decimal floating-point subroutines (**fmodd32**, **fmodd64**, and **fmodd128**).

fmtmsg Subroutine

Purpose

Display a message in the specified format on standard error, the console, or both.

Library

Standard C Library **(libc.a)**

Syntax

```
#include <fmtmsg.h>

int fmtmsg (long Classification,
const char *Label,
int Severity,
cont char *Text;
cont char *Action,
cont char *Tag)
```

Description

The **fmtmsg** subroutine can be used to display messages in a specified format instead of the traditional **printf** subroutine interface.

Base on a message's classification component, the **fmtmsg** subroutine either writes a formatted message to standard error, the console, or both.

A formatted message consists of up to five parameters. The *Classification* parameter is not part of a message displayed to the user, but defines the source of the message and directs the display of the formatted message.

Parameters

Item	Description
Classification	Contains identifiers from the following groups of major classifications and subclassifications. Any one identifier from a subclass may be used in combination with a single identifier from a different subclass. Two or more identifiers from the same subclass should not be used together, with the exception of identifiers from the display subclass. (Both display subclass identifiers may be used so that messages can be displayed to both standard error and system console). **major classifications** Identifies the source of the condition. Identifiers are: **MM_HARD** (hardware), **MM_SOFT** (software), and **MM_FIRM** (firmware). **message source subclassifications** Identifies the type of software in which the problem is detected. Identifiers are: **MM_APPL** (application), **MM_UTIL** (utility), and **MM_OPSYS** (operating system). **display subclassification** Indicates where the message is to be displayed. Identifiers are: **MM_PRINT** to display the message on the standard error stream, **MM_CONSOLE** to display the message on the system console. One or both identifiers may be used. **status subclassifications** Indicates whether the application will recover from the condition. Identifiers are:**MM_RECOVER** (recoverable) and **MM_RECOV** (non-recoverable). An additional identifier, **MM_NULLMC**, identifies that no classification component is supplied for the message.
Label	Identifies the source to the message. The format is two fields separated by a colon. The first field is up to 10 bytes, the second field is up to 14 bytes.
Severity	
Text	Describes the error condition that produced the message. The character string is not limited to a specific size. If the character string is null then a message will be issued stating that no text has been provided.
Action	Describes the first step to be taken in the error-recovery process. The **fmtmsg** subroutine precedes the action string with the prefix: `TO FIX:`. The *Action* string is not limited to a specific size.
Tag	An identifier which references online documentation for the message. Suggested usage is that *tag* includes the *Label* and a unique identifying number. A sample *tag* is `UX:cat:146`.

Environment Variables

The **MSGVERB** (message verbosity) environment variable controls the behavior of the **fmtmsg** subroutine.

MSGVERB tells the **fmtmsg** subroutine which message components it is to select when writing messages to standard error. The value of **MSGVERB** is a colon-separated list of optional keywords. **MSGVERB** can be set as follows:

```
MSGVERB=[keyword[:keyword[:...]]]
export  MSGVERB
```

Valid keywords are: *Label, Severity, Text, Action,* and *Tag*. If **MSGVERB** contains a keyword for a component and the component's value is not the component's null value, **fmtmsg** subroutine includes that component in the message when writing the message to standard error. If **MSGVERB** does not include a keyword for a message component, that component is not included in the display of the message. The keywords may appear in any order. If **MSGVERB** is not defined, if its value is the null string, if its value is not of the correct format, of if it contains keywords other than the valid ones listed previously, the **fmtmsg** subroutine selects all components.

MSGVERB affects only which components are selected for display to standard error. All message components are included in console messages.

Application Usage

One or more message components may be systematically omitted from messages generated by an application by using the null value of the parameter for that component. The table below indicates the null values and identifiers for **fmtmsg** subroutine parameters. The parameters are of type `char*` unless otherwise indicated.

Parameter	Null-Value	Identifier
label	(char*)0	MM_NULLLBL
severity (type `int`)	0	MM_NULLSEV
class (type `long`)	0L	MM_NULLMC
text	(char*)0	MM_NULLTXT
action	(char*)0	MM_NULLACT
tag	(char*)0	MM_NULLTAG

Another means of systematically omitting a component is by omitting the component keywords when defining the MSGVERB environment variable.

Return Values

The exit codes for the **fmtmsg** subroutine are the following:

Item	Description
MM_OK	The function succeeded.
MM_NOTOK	The function failed completely.
MM_MOMSG	The function was unable to generate a message on standard error.
MM_NOCON	The function was unable to generate a console message.

Examples

1. The following example of the **fmtmsg** subroutine:

```
fmtmsg(MM_PRINT, "UX:cat", MM_ERROR, "illegal option",
"refer tp cat in user's reference manual", "UX:cat:001")
```

   produces a complete message in the specified message format:

```
UX:cat ERROR: illegal option
TO FIX: refer to cat in user's reference manual UX:cat:001
```

2. When the environment variable MSGVERB is set as follows:

```
MSGVERB=severity:text:action
```

and the Example 1 is used, the **fmtmsg** subroutine produces:

```
ERROR: illegal option
TO FIX: refer to cat in user's reference manual UX:cat:001
```

fnmatch Subroutine

Purpose

Matches file name patterns.

Library

Standard C Library (**libc. a**)

Syntax

```
#include <fnmatch.h>
```

```
int fnmatch ( Pattern,  String,  Flags);
int Flags;
const char *Pattern, *String;
```

Description

The **fnmatch** subroutine checks the string specified by the *String* parameter to see if it matches the pattern specified by the *Pattern* parameter.

The **fnmatch** subroutine can be used by an application or command that needs to read a dictionary and apply a pattern against each entry; the **find**command is an example of this. It can also be used by the **pax** command to process its *Pattern* variables, or by applications that need to match strings in a similar manner.

Parameters

Item	Description
Pattern	Contains the pattern to which the *String* parameter is to be compared. The *Pattern* parameter can include the following special characters: *** (asterisk)** Matches zero, one, or more characters. **? (question mark)** Matches any single character, but will not match 0 (zero) characters. **[ ] (brackets)** Matches any one of the characters enclosed within the brackets. If a pair of characters separated by a dash are contained within the brackets, the pattern matches any character that lexically falls between the two characters in the current locale.
String	Contains the string to be compared against the *Pattern* parameter.

Item	Description
Flags	Contains a bit flag specifying the configurable attributes of the comparison to be performed by the **fnmatch** subroutine. The *Flags* parameter modifies the interpretation of the *Pattern* and *String* parameters. It is the bitwise inclusive OR of zero or more of the following flags (defined in the **fnmatch.h** file): **FNM_PATHNAME** Indicates the / (slash) in the *String* parameter matches a / in the *Pattern* parameter. **FNM_PERIOD** Indicates a leading period in the *String* parameter matches a period in the *Pattern* parameter. **FNM_NOESCAPE** Enables quoting of special characters using the \ (backslash).

If the **FNM_ PATHNAME** flag is set in the *Flags* parameter, a / (slash) in the *String* parameter is explicitly matched by a / in the *Pattern* parameter. It is not matched by either the * (asterisk) or ? (question-mark) special characters, nor by a bracket expression. If the **FNM_PATHNAME** flag is not set, the / is treated as an ordinary character.

If the **FNM_PERIOD** flag is set in the *Flags* parameter, then a leading period in the *String* parameter only matches a period in the *Pattern* parameter; it is not matched by either the asterisk or question-mark special characters, nor by a bracket expression. The setting of the **FNM_PATHNAME** flag determines a period to be leading, according to the following rules:

- If the **FNM_PATHNAME** flag is set, a . (period) is leading only if it is the first character in the *String* parameter or if it immediately follows a /.
- If the **FNM_PATHNAME** flag is not set, a . (period) is leading only if it is the first character of the *String* parameter. If **FNM_PERIOD** is not set, no special restrictions are placed on matching a period.

If the **FNM_NOESCAPE** flag is not set in the *Flags* parameter, a \ (backslash) character in the *Pattern* parameter, followed by any other character, will match that second character in the *String* parameter. For example, \\ will match a backslash in the *String* parameter. If the **FNM_NOESCAPE** flag is set, a \ (backslash) will be treated as an ordinary character.

Return Values

If the value in the *String* parameter matches the pattern specified by the *Pattern* parameter, the **fnmatch** subroutine returns 0. If there is no match, the **fnmatch** subroutine returns the **FNM_NOMATCH** constant, which is defined in the **fnmatch.h** file. If an error occurs, the **fnmatch** subroutine returns a nonzero value.

Files

Item	Description
/usr/include/fnmatch.h	Contains system-defined flags and constants.

fopen, fopen64, freopen, freopen64, fopen_s or fdopen Subroutine

Purpose

Opens a stream and handles runtime constraint violations.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdio.h>
#define STDC_WANT_LIB_EXT1 1
FILE  *fopen ( Path,  Type)
const char *Path, *Type;

FILE  *fopen64 ( Path,  Type)
char  *Path, *Type;

FILE  *freopen (Path, Type,  Stream)
const char *Path, *Type;
FILE  *Stream;

FILE  *freopen64 (Path, Type,  Stream)
char  *Path, *Type;
FILE  *Stream;

FILE  *fdopen ( FileDescriptor, Type)
int   FileDescriptor;
const char *Type;

errno_t fopen_s ( streamptr, filename, mode)
FILE * *streamptr ;
const char * filename ;
const char * mode ;
```

Description

The **fopen** and **fopen64** subroutines open the file named by the *Path* parameter and associate a stream with it and return a pointer to the **FILE** structure of this stream.

When you open a file for update, you can perform both input and output operations on the resulting stream. However, an output operation cannot be directly followed by an input operation without an intervening **fflush** subroutine call or a file positioning operation (**fseek**, **fseeko**, **fseeko64**, **fsetpos**, **fsetpos64** or **rewind** subroutine). Also, an input operation cannot be directly followed by an output operation without an intervening flush or file positioning operation, unless the input operation encounters the end of the file.

When you open a file for appending (that is, when the *Type* parameter is set to **a**), it is impossible to overwrite information already in the file.

If two separate processes open the same file for append, each process can write freely to the file without destroying the output being written by the other. The output from the two processes is intermixed in the order in which it is written to the file.

Note: If the data is buffered, it is not actually written until it is flushed.

The **freopen** and **freopen64** subroutines first attempt to flush the stream and close any file descriptor associated with the *Stream* parameter. Failure to flush the stream or close the file descriptor is ignored.

The **freopen** and **freopen64** subroutines substitute the named file in place of the open stream. The original stream is closed regardless of whether the subsequent open succeeds. The **freopen** and **freopen64** subroutines returns a pointer to the **FILE** structure associated with the *Stream* parameter. The **freopen** and **freopen64** subroutines is typically used to attach the pre-opened streams associated with standard input (**stdin**), standard output (**stdout**), and standard error (**stderr**) streams to other files.

The **fdopen** subroutine associates a stream with a file descriptor obtained from an **openx** subroutine, **dup** subroutine, **creat** subroutine, or **pipe** subroutine. These subroutines open files but do not return pointers to **FILE** structures. Many of the standard I/O package subroutines require pointers to **FILE** structures.

The *Type* parameter for the **fdopen** subroutine specifies the mode of the stream, such as **r** to open a file for reading, or **a** to open a file for appending (writing at the end of the file). The mode value of the *Type* parameter specified with the **fdopen** subroutine must agree with the mode of the file specified when the file was originally opened or created.

Note: Using the **fdopen** subroutine with a file descriptor obtained from a call to the **shm_open** subroutine must be avoided and might result in an error on the next **fread**, **fwrite** or **fflush** call.

The largest value that can be represented correctly in an object of type off_t will be established as the offset maximum in the open file description.

The **fopen_s** subroutine opens the file by using the name of the string pointed to by the **filename** parameter, and associates a stream with the file.

Files are opened for writing with exclusive (also known as non shared) access. If the file is created, and the first character of the **mode** parameter is not **u**, and if the underlying system supports exclusive mode concept, the file has a permission that prevents other users on the system from accessing the file.

If the file is created and the first character of the **mode** parameter is **u**, the file retains the system default file access permissions until the file is closed.

If the file is opened successfully, the pointer to the **FILE** structure that is pointed to by the *streamptr* parameter is set to the pointer that points to the object controlling the opened file. Otherwise, the pointer to the **FILE** structure pointed to by the *streamptr* parameter is set to a null pointer, and the file retains the system default file access permissions until the file is closed.

Runtime Constraints

1. For the **fopen_s** subroutine, the *streamptr*, *filename* or *mode* parameters must not be a null pointer.
2. If there is a runtime constraint violation, the **fopen_s** subroutine does not attempt to open a file. If the *streamptr* parameter is not a null pointer, the **fopen_s** subroutine sets the *streamptr* parameter to the null pointer.

Parameters

Item	Description
Path	Points to a character string that contains the name of the file to be opened.

Item	Description
Type	Points to a character string that has one of the following values: **r** Opens a text file for reading. **w** Creates a new text file for writing, or opens and truncates a file to 0 length. **a** Appends (opens a text file for writing at the end of the file, or creates a file for writing). **rb** Opens a binary file for reading. **wb** Creates a binary file for writing, or opens and truncates a file to 0. **ab** Appends (opens a binary file for writing at the end of the file, or creates a file for writing). **r+** Opens a file for update (reading and writing). **w+** Truncates or creates a file for update. **a+** Appends (opens a text file for writing at end of file, or creates a file for writing). **r+b , rb+** Opens a binary file for update (reading and writing). **w+b , wb+** Creates a binary file for update, or opens and truncates a file to 0 length. **a+b , ab+** Appends (opens a binary file for update, writing at the end of the file, or creates a file for writing). **wx** Creates a text file for writing. **wbx** Creates a binary file for writing. **w+x** Creates a text file for updating. **w+bx or wb+x** Creates a binary file for updating. **Note:** • The operating system does not distinguish between text and binary files. • The **b** value in the *Type* parameter is ignored. • Opening a file with exclusive mode (**x** as the last character in the mode argument) fails, if the file already exists or cannot be created. Otherwise, the file is created with exclusive (also known as non shared) access if the underlying system supports exclusive access. • The **fdopen** subroutine has no impact on exclusive mode.
Stream	Specifies the input stream.
FileDescriptor	Specifies a valid open file descriptor.

Item	Description
streamptr	Specifies the stream that is associated with the file name, and the value cannot be null.
filename	Specifies the file name to be opened, and the value cannot be null.
mode	The value cannot be null. The mode parameter is the same as the **Type** parameter described for **fopen** subroutine, with the addition that the modes starting with the character **w** or **a** can be preceded by the character **u** as shown below: **uw** Truncates to 0 or creates a text file for writing and has default permissions. **uwx** Creates a text file for writing and has default permissions. **ua** Opens or creates a text file for writing at the end of the file and has default permissions. **uwb** Truncates to 0 or creates a binary file for writing and has default permissions. **uwbx** Creates a binary file for writing and has default permissions. **uab** Opens or creates a binary file for writing at the end of the file and has default permissions. **uw+** Truncates to 0 or creates a text file for update and has default permissions. **uw+x** Creates a text file for update and has default permissions. **ua+ append** Opens or creates a text file for update and writing at the end-of-file and has default permissions. **uw+b or uwb+** Truncates to 0 or creates a binary file for update and has default permissions. **uw+bx or uwb+x** Creates a binary file for update and has default permissions. **ua+b or uab+ append** Opens or creates a binary file for update and writing at the end-of-file and has default permissions. **Note:** If the **mode** parameter is not preceded with **u**, the file permissions are user only.

Return Values

If the **fdopen**, **fopen**, **fopen64**, **freopen** or **freopen64** subroutine is unsuccessful, a null pointer is returned and the **errno** global variable is set to indicate the error.

The **fopen_s** subroutine returns a zero if it opens the file. If the file is not opened or if there is a runtime constraint violation, the **fopen_s** subroutine returns a nonzero value.

Error Codes

The **fopen**, **fopen64**, **freopen** and **freopen64** subroutines are unsuccessful if the following is true:

Item	Description
EACCES	Search permission is denied on a component of the path prefix, the file exists and the permissions specified by the mode are denied, or the file does not exist and write permission is denied for the parent directory of the file to be created.
ELOOP	Too many symbolic links were encountered in resolving path.
EINTR	A signal was received during the process.
EISDIR	The named file is a directory and the process does not have write access to it.
ENAMETOOLONG	The length of the filename exceeds **PATH_MAX** or a pathname component is longer than **NAME_MAX**.
EMFILE	The maximum number of files allowed are currently open.
ENOENT	The named file does not exist or the *File Descriptor* parameter points to an empty string.
ENOSPC	The file is not yet created and the directory or file system to contain the new file cannot be expanded.
ENOTDIR	A component of the path prefix is not a directory.
ENXIO	The named file is a character- or block-special file, and the device associated with this special file does not exist.
EOVERFLOW	The named file is a regular file and the size of the file cannot be represented correctly in an object of type off_t.
EROFS	The named file resides on a read-only file system and does not have write access.
ETXTBSY	The file is a pure-procedure (shared-text) file that is being executed and the process does not have write access.

The **fdopen**, **fopen**, **fopen64**, **freopen** and **freopen64** subroutines are unsuccessful if the following is true:

Item	Description
EINVAL	The value of the *Type* argument is not valid.
EINVAL	The value of the *mode* argument is not valid.
EMFILE	**FOPEN_MAX** streams are currently open in the calling process.
EMFILE	**STREAM_MAX** streams are currently open in the calling process.
ENAMETOOLONG	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds **PATH_MAX**.
ENOMEM	Insufficient storage space is available.

The **freopen** and **fopen** subroutines are unsuccessful if the following is true:

Item	Description
EOVERFLOW	The named file is a size larger than 2 Gigabytes.

The **fdopen** subroutine is unsuccessful if the following is true:

Item	Description
EBADF	The value of the *File Descriptor* parameter is not valid.

POSIX

Item	Description
w	Truncates to 0 length or creates text file for writing.
w+	Truncates to 0 length or creates text file for update.
a	Opens or creates text file for writing at end of file.
a+	Opens or creates text file for update, writing at end of file.

SAA

At least eight streams, including three standard text streams, can open simultaneously. Both binary and text modes are supported.

fork, f_fork, or vfork Subroutine

Purpose

Creates a new process.

Libraries

fork, **f_fork**, and **vfork**: Standard C Library (**libc.a**)

Syntax

```
#include <unistd.h>
```

```
pid_t fork(void)
```

```
pid_t f_fork(void)
```

```
int vfork(void)
```

Description

The **fork** subroutine creates a new process. The new process (child process) is an almost exact copy of the calling process (parent process). The child process inherits the following attributes from the parent process:

- Environment
- Close-on-exec flags (described in the **exec** subroutine)
- Signal handling settings (such as the **SIG_DFL** value, the **SIG_IGN** value, and the *Function Address* parameter)
- Set user ID mode bit
- Set group ID mode bit
- Profiling on and off status
- Nice value
- All attached shared libraries

- Process group ID
- **tty** group ID (described in the **exit**, **atexit**, or **_exit** subroutine, **signal** subroutine, and **raise** subroutine)
- Current directory
- Root directory
- File-mode creation mask (described in the **umask** subroutine)
- File size limit (described in the **ulimit** subroutine)
- Attached shared memory segments (described in the **shmat** subroutine)
- Attached mapped file segments (described in the **shmat** subroutine)
- Debugger process ID and multiprocess flag if the parent process has multiprocess debugging enabled (described in the **ptrace** subroutine).

The child process differs from the parent process in the following ways:

- The child process has only one user thread; it is the one that called the **fork** subroutine.
- The child process has a unique process ID.
- The child process ID does not match any active process group ID.
- The child process has a different parent process ID.
- The child process has its own copy of the file descriptors for the parent process. However, each file descriptor of the child process shares a common file pointer with the corresponding file descriptor of the parent process.
- All **semadj** values are cleared. For information about **semadj** values, see the **semop** subroutine.
- Process locks, text locks, and data locks are not inherited by the child process. For information about locks, see the **plock** subroutine.
- If multiprocess debugging is turned on, the **trace** flags are inherited from the parent; otherwise, the **trace** flags are reset. For information about request 0, see the **ptrace** subroutine.
- The child process **utime**, **stime**, **cutime**, and **cstime** subroutines are set to 0. (For more information, see the **getrusage** , **times**, and **vtimes** subroutines.)
- Any pending alarms are cleared in the child process. (For more information, see the **incinterval**, **setitimer**, and **alarm** subroutines.)
- The set of signals pending for the child process is initialized to an empty set.
- The child process can have its own copy of the message catalogue for the parent process.

Attention: If you are using the **fork** or **vfork** subroutines with an X Window System, X Toolkit, or Motif application, open a separate display connection (socket) for the forked process. If the child process uses the same display connection as the parent, the X Server will not be able to interpret the resulting data.

The **f_fork** subroutine is similar to **fork**, except for:

- It is required that the child process calls one of the **exec** functions immediately after it is created. Since the **fork** handlers are never called, the application data, mutexes and the locks are all undefined in the child process.

The **vfork** subroutine is supported as a compatibility interface for older Berkeley Software Distribution (BSD) system programs and can be used by compiling with the Berkeley Compatibility Library (**libbsd.a**).

In the Version 4 of the operating system, the parent process does not have to wait until the child either exits or executes, as it does in BSD systems. The child process is given a new address space, as in the **fork** subroutine. The child process does not share any parent address space.

Attention: When using the **fork** or **vfork** subroutines with an Enhanced X-Windows, X Toolkit, or Motif application, a separate display connection (socket) should be opened for the forked process. The child process should never use the same display connection as the parent. Display connections are embodied with sockets, and sockets are inherited by the child process. Any attempt to have multiple processes writing to the same display connection results in the random

interleaving of X protocol packets at the word level. The resulting data written to the socket will not be valid or undefined X protocol packets, and the X Server will not be able to interpret it.

Attention: Although the **fork** and **vfork** subroutine may be used with Graphics Library applications, the child process must not make any additional Graphics Library subroutine calls. The child application inherits some, but not all of the graphics hardware resources of the parent. Drawing by the child process may hang the graphics adapter, the Enhanced X Server, or may cause unpredictable results and place the system into an unpredictable state.

For additional information, see the **/usr/lpp/GL/README** file.

Return Values

Upon successful completion, the **fork** subroutine returns a value of 0 to the child process and returns the process ID of the child process to the parent process. Otherwise, a value of -1 is returned to the parent process, no child process is created, and the **errno** global variable is set to indicate the error.

Error Codes

The **fork** subroutine is unsuccessful if one or more of the following are true:

Item	Description
EAGAIN	Exceeds the limit on the total number of processes running either systemwide or by a single user, or the system does not have the resources necessary to create another process.
ENOMEM	Not enough space exists for this process.
EPROCLIM	If WLM is running, the limit on the number of processes or threads in the class may have been met.

fp_any_enable, fp_is_enabled, fp_enable_all, fp_enable, fp_disable_all, or fp_disable Subroutine

Purpose

These subroutines allow operations on the floating-point trap control.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <fptrap.h>
```

```
int fp_any_enable()
int fp_is_enabled( Mask)
fptrap_t Mask;
```

```
void fp_enable_all()
void fp_enable(Mask)
fptrap_t Mask;
```

```
void fp_disable_all()
void fp_disable(Mask)
fptrap_t Mask;
```

Description

Floating point traps must be enabled before traps can be generated. These subroutines aid in manipulating floating-point traps and identifying the trap state and type.

In order to take traps on floating point exceptions, the **fp_trap** subroutine must first be called to put the process in serialized state, and the **fp_enable** subroutine or **fp_enable_all** subroutine must be called to enable the appropriate traps.

The header file **fptrap.h** defines the following names for the individual bits in the floating-point trap control:

Item	Description
TRP_INVALID	Invalid Operation Summary
TRP_DIV_BY_ZERO	Divide by Zero
TRP_OVERFLOW	Overflow
TRP_UNDERFLOW	Underflow
TRP_INEXACT	Inexact Result

Parameters

Item	Description
Mask	A 32-bit pattern that identifies floating-point traps.

Return Values

The **fp_any_enable** subroutine returns 1 if any floating-point traps are enabled. Otherwise, 0 is returned.

The **fp_is_enabled** subroutine returns 1 if the floating-point traps specified by the *Mask* parameter are enabled. Otherwise, 0 is returned.

The **fp_enable_all** subroutine enables all floating-point traps.

The **fp_enable** subroutine enables all floating-point traps specified by the *Mask* parameter.

The **fp_disable_all** subroutine disables all floating-point traps.

The **fp_disable** subroutine disables all floating-point traps specified by the *Mask* parameter.

fp_clr_flag, fp_set_flag, fp_read_flag, or fp_swap_flag Subroutine

Purpose

Allows operations on the floating-point exception flags.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <float.h>
#include <fpxcp.h>
```

```
void fp_clr_flag( Mask)
fpflag_t Mask;
```

```
void fp_set_flag(Mask)
fpflag_t Mask;
```

```
fpflag_t fp_read_flag( )
```

```
fpflag_t fp_swap_flag(Mask)
fpflag_t Mask;
```

Description

These subroutines aid in determining both when an exception has occurred and the exception type. These subroutines can be called explicitly around blocks of code that may cause a floating-point exception.

According to the *IEEE Standard for Binary Floating-Point Arithmetic*, the following types of floating-point operations must be signaled when detected in a floating-point operation:

- Invalid operation
- Division by zero
- Overflow
- Underflow
- Inexact

An invalid operation occurs when the result cannot be represented (for example, a **sqrt** operation on a number less than 0).

The *IEEE Standard for Binary Floating-Point Arithmetic* states: "For each type of exception, the implementation shall provide a status flag that shall be set on any occurrence of the corresponding exception when no corresponding trap occurs. It shall be reset only at the user's request. The user shall be able to test and to alter the status flags individually, and should further be able to save and restore all five at one time."

Floating-point operations can set flags in the floating-point exception status but cannot clear them. Users can clear a flag in the floating-point exception status using an explicit software action such as the **fp_swap_flag (**0**)** subroutine.

The **fpxcp.h** file defines the following names for the flags indicating floating-point exception status:

Item	Description
FP_INVALID	Invalid operation summary
FP_OVERFLOW	Overflow
FP_UNDERFLOW	Underflow
FP_DIV_BY_ZERO	Division by 0
FP_INEXACT	Inexact result

In addition to these flags, the operating system supports additional information about the cause of an invalid operation exception. The following flags also indicate floating-point exception status and defined in the **fpxcp.h** file. The flag number for each exception type varies, but the mnemonics are the same for all ports. The following invalid operation detail flags are not required for conformance to the IEEE floating-point exceptions standard:

Item	Description
FP_INV_SNAN	Signaling NaN
FP_INV_ISI	INF - INF

Item	Description
FP_INV_IDI	INF / INF
FP_INV_ZDZ	0 / 0
FP_INV_IMZ	INF x 0
FP_INV_CMP	Unordered compare
FP_INV_SQRT	Square root of a negative number
FP_INV_CVI	Conversion to integer error
FP_INV_VXSOFT	Software request

Parameters

Item	Description
Mask	A 32-bit pattern that identifies floating-point exception flags.

Return Values

The **fp_clr_flag** subroutine resets the exception status flags defined by the *Mask* parameter to 0 (false). The remaining flags in the exception status are unchanged.

The **fp_set_flag** subroutine sets the exception status flags defined by the *Mask* parameter to 1 (true). The remaining flags in the exception status are unchanged.

The **fp_read_flag** subroutine returns the current floating-point exception status. The flags in the returned exception status can be tested using the flag definitions above. You can test individual flags or sets of flags.

The **fp_swap_flag** subroutine writes the *Mask* parameter into the floating-point status and returns the floating-point exception status from before the write.

Users set or reset multiple exception flags using **fp_set_flag** and **fp_clr_flag** by ANDing or ORing definitions for individual flags. For example, the following resets both the overflow and inexact flags:

```
fp_clr_flag (FP_OVERFLOW | FP_INEXACT)
```

fp_cpusync Subroutine

Purpose

Queries or changes the floating-point exception enable (FE) bit in the Machine Status register (MSR).

Note: This subroutine has been replaced by the **fp_trapstate** subroutine. The **fp_cpusync** subroutine is supported for compatibility, but the **fp_trapstate** subroutine should be used for development.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <fptrap.h>
```

```
int fp_cpusync ( Flag);
int Flag;
```

Description

The **fp_cpusync** subroutine is a service routine used to query, set, or reset the Machine Status Register (MSR) floating-point exception enable (FE) bit. The MSR FE bit determines whether a processor runs in pipeline or serial mode. Floating-point traps can only be generated by the hardware when the processor is in synchronous mode.

The **fp_cpusync** subroutine changes only the MSR FE bit. It is a service routine for use in developing custom floating-point exception-handling software. If you are using the **fp_enable** or **fp_enable_all** subroutine or the **fp_sh_trap_info** or **fp_sh_set_stat** subroutine, you must use the **fp_trap** subroutine to place the process in serial mode.

Parameters

Item	Description
Flag	Specifies to query or modify the MSR FE bit: **FP_SYNC_OFF** Sets the FE bit in the MSR to Off, which disables floating-point exception processing immediately. **FP_SYNC_ON** Sets the FE bit in the MSR to On, which enables floating-exception processing for the next floating-point operation. **FP_SYNC_QUERY** Returns the current state of the process (either **FP_SYNC_ON** or **FP_SYNC_OFF**) without modifying it.

If called with any other value, the **fp_cpusync** subroutine returns **FP_SYNC_ERROR**.

Return Values

If called with the **FP_SYNC_OFF** or **FP_SYNC_ON** flag, the **fp_cpusync** subroutine returns a value indicating which flag was in the previous state of the process.

If called with the **FP_SYNC _QUERY** flag, the **fp_cpusync** subroutine returns a value indicating the current state of the process, either the **FP_SYNC_OFF** or **FP_SYNC_ON** flag.

Error Codes

If the **fp_cpusync** subroutine is called with an invalid parameter, the subroutine returns **FP_SYNC_ERROR**. No other errors are reported.

fp_flush_imprecise Subroutine

Purpose

Forces imprecise signal delivery.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <fptrap.h>
```

```
void fp_flush_imprecise ()
```

Description

The **fp_flush_imprecise** subroutine forces any imprecise interrupts to be reported. To ensure that no signals are lost when a program voluntarily exits, use this subroutine in combination with the **atexit** subroutine.

Example

The following example illustrates using the **atexit** subroutine to run the **fp_flush_imprecise** subroutine before a program exits:

```
#include <fptrap.h>
#include <stdlib.h>
#include <stdio.h>
  if (0!=atexit(fp_flush_imprecise))
           puts ("Failure in atexit(fp_flush_imprecise) ");
```

fp_invalid_op, fp_divbyzero, fp_overflow, fp_underflow, fp_inexact, fp_any_xcp Subroutine

Purpose

Tests to see if a floating-point exception has occurred.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <float.h>
#include <fpxcp.h>
```

```
int
fp_invalid_op()
int fp_divbyzero()
```

```
int fp_overflow()
int fp_underflow()
```

```
int
fp_inexact()
int fp_any_xcp()
```

Description

These subroutines aid in determining when an exception has occurred and the exception type. These subroutines can be called explicitly after blocks of code that may cause a floating-point exception.

Return Values

The **fp_invalid_op** subroutine returns a value of 1 if a floating-point invalid-operation exception status flag is set. Otherwise, a value of 0 is returned.

The **fp_divbyzero** subroutine returns a value of 1 if a floating-point divide-by-zero exception status flag is set. Otherwise, a value of 0 is returned.

The **fp_overflow** subroutine returns a value of 1 if a floating-point overflow exception status flag is set. Otherwise, a value of 0 is returned.

The **fp_underflow** subroutine returns a value of 1 if a floating-point underflow exception status flag is set. Otherwise, a value of 0 is returned.

The **fp_inexact** subroutine returns a value of 1 if a floating-point inexact exception status flag is set. Otherwise, a value of 0 is returned.

The **fp_any_xcp** subroutine returns a value of 1 if a floating-point invalid operation, divide-by-zero, overflow, underflow, or inexact exception status flag is set. Otherwise, a value of 0 is returned.

fp_iop_snan, fp_iop_infsinf, fp_iop_infdinf, fp_iop_zrdzr, fp_iop_infmzr, fp_iop_invcmp, fp_iop_sqrt, fp_iop_convert, or fp_iop_vxsoft Subroutines

Purpose

Tests to see if a floating-point exception has occurred.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <float.h>
#include <fpxcp.h>
```

```
int fp_iop_snan()
int fp_iop_infsinf()
```

```
int
fp_iop_infdinf()
int fp_iop_zrdzr()
```

```
int
fp_iop_infmzr()
int fp_iop_invcmp()
```

```
int
fp_iop_sqrt()
int fp_iop_convert()
```

```
int
fp_iop_vxsoft ();
```

Description

These subroutines aid in determining when an exception has occurred and the exception type. These subroutines can be called explicitly after blocks of code that may cause a floating-point exception.

Return Values

The **fp_iop_snan** subroutine returns a value of 1 if a floating-point invalid-operation exception status flag is set due to a signaling NaN (NaNS) flag. Otherwise, a value of 0 is returned.

The **fp_iop_infsinf** subroutine returns a value of 1 if a floating-point invalid-operation exception status flag is set due to an INF-INF flag. Otherwise, a value of 0 is returned.

The **fp_iop_infdinf** subroutine returns a value of 1 if a floating-point invalid-operation exception status flag is set due to an INF/INF flag. Otherwise, a value of 0 is returned.

The **fp_iop_zrdzr** subroutine returns a value of 1 if a floating-point invalid-operation exception status flag is set due to a 0.0/0.0 flag. Otherwise, a value of 0 is returned.

The **fp_iop_infmzr** subroutine returns a value of 1 if a floating-point invalid-operation exception status flag is set due to an INF*0.0 flag. Otherwise, a value of 0 is returned.

The **fp_iop_invcmp** subroutine returns a value of 1 if a floating-point invalid-operation exception status flag is set due to a compare involving a NaN. Otherwise, a value of 0 is returned.

The **fp_iop_sqrt** subroutine returns a value of 1 if a floating-point invalid-operation exception status flag is set due to the calculation of a square root of a negative number. Otherwise, a value of 0 is returned.

The **fp_iop_convert** subroutine returns a value of 1 if a floating-point invalid-operation exception status flag is set due to the conversion of a floating-point number to an integer, where the floating-point number was a NaN, an INF, or was outside the range of the integer. Otherwise, a value of 0 is returned.

The **fp_iop_vxsoft** subroutine returns a value of 1 if the VXSOFT detail bit is on. Otherwise, a value of 0 is returned.

fp_raise_xcp Subroutine

Purpose

Generates a floating-point exception.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <fpxcp.h>

int fp_raise_xcp( mask)
fpflag_t mask;
```

Description

The **fp_raise_xcp** subroutine causes any floating-point exceptions defined by the *mask* parameter to be raised immediately. If the exceptions defined by the *mask* parameter are enabled and the program is running in serial mode, the signal for floating-point exceptions, **SIGFPE**, is raised.

If more than one exception is included in the *mask* variable, the exceptions are raised in the following order:

1. Invalid
2. Dividebyzero
3. Underflow
4. Overflow
5. Inexact

Thus, if the user exception handler does not disable further exceptions, one call to the **fp_raise_xcp** subroutine can cause the exception handler to be entered many times.

Parameters

Item	Description
mask	Specifies a 32-bit pattern that identifies floating-point traps.

Return Values

The **fp_raise_xcp** subroutine returns 0 for normal completion and returns a nonzero value if an error occurs.

fp_read_rnd or fp_swap_rnd Subroutine

Purpose

Read and set the IEEE floating-point rounding mode.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <float.h>
```

```
fprnd_t fp_read_rnd()
fprnd_t fp_swap_rnd( RoundMode)
fprnd_t RoundMode;
```

Description

The **fp_read_rnd** subroutine returns the current rounding mode. The **fp_swap_rnd** subroutine changes the rounding mode to the *RoundMode* parameter and returns the value of the rounding mode before the change.

Floating-point rounding occurs when the infinitely precise result of a floating-point operation cannot be represented exactly in the destination floating-point format (such as double-precision format).

The *IEEE Standard for Binary Floating-Point Arithmetic* allows floating-point numbers to be rounded in four different ways: round toward zero, round to nearest, round toward +INF, and round toward -INF. Once a rounding mode is selected it affects all subsequent floating-point operations until another rounding mode is selected.

Note: The default floating-point rounding mode is round to nearest. All C main programs begin with the rounding mode set to round to nearest.

The encodings of the rounding modes are those defined in the *ANSI C Standard*. The **float.h** file contains definitions for the rounding modes. Below is the **float.h** definition, the *ANSI C Standard* value, and a description of each rounding mode.

float.h Definition	ANSI Value	Description
FP_RND_RZ	0	Round toward 0
FP_RND_RN	1	Round to nearest
FP_RND_RP	2	Round toward +INF
FP_RND_RM	3	Round toward -INF

The **fp_swap_rnd** subroutine can be used to swap rounding modes by saving the return value from **fp_swap_rnd**(*RoundMode*). This can be useful in functions that need to force a specific rounding mode for use during the function but wish to restore the caller's rounding mode on exit. Below is a code fragment that accomplishes this action:

```
save_mode = fp_swap_rnd (new_mode);
....desired code using new_mode
(void) fp_swap_rnd(save_mode); /*restore caller's mode*/
```

Parameters

Item	Description
RoundMode	Specifies one of the following modes: **FP_RND_RZ**, **FP_RND_RN**, **FP_RND_RP**, or **FP_RND_RM**.

fp_sh_info, fp_sh_trap_info, or fp_sh_set_stat Subroutine

Purpose

From within a floating-point signal handler, determines any floating-point exception that caused the trap in the process and changes the state of the Floating-Point Status and Control register (FPSCR) in the user process.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <fpxcp.h>
#include <fptrap.h>
#include <signal.h>
```

```
void fp_sh_info( scp,  fcp,  struct_size)
struct sigcontext *scp;
struct fp_sh_info *fcp;
size_t struct_size;
```

```
void fp_sh_trap_info( scp,  fcp)
struct sigcontext *scp;
struct fp_ctx *fcp;
```

```
void fp_sh_set_stat( scp,  fpscr)
struct sigcontext *scp;
fpstat_t fpscr;
```

Description

These subroutines are for use within a user-written signal handler. They return information about the process that was running at the time the signal occurred, and they update the Floating-Point Status and Control register for the process.

Note: The **fp_sh_trap_info** subroutine is maintained for compatibility only. It has been replaced by the **fp_sh_info** subroutine, which should be used for development.

These subroutines operate only on the state of the user process that was running at the time the signal was delivered. They read and write the **sigcontext** structure. They do not change the state of the signal handler process itself.

The state of the signal handler process can be modified by the **fp_any_enable**, **fp_is_enabled**, **fp_enable_all**, **fp_enable**, **fp_disable_all**, or **fp_disable** subroutine.

fp_sh_info

The **fp_sh_info** subroutine returns information about the process that caused the trap by means of a floating-point context (**fp_sh_info**) structure. This structure contains the following information:

```
typedef struct fp_sh_info {
fpstat_t       fpscr;
fpflag_t       trap;
short          trap_mode;
char           flags;
char           extra;
} fp_sh_info_t;
```

The fields are:

Item	Description
fpscr	The Floating-Point Status and Control register (FPSCR) in the user process at the time the interrupt occurred.
trap	A mask indicating the trap or traps that caused the signal handler to be entered. This mask is the logical OR operator of the enabled floating-point exceptions that occurred to cause the trap. This mask can have up to two exceptions; if there are two, the **INEXACT** signal must be one of them. If the mask is 0, the **SIGFPE** signal was raised not by a floating-point operation, but by the **kill** or **raise** subroutine or the **kill** command.
trap_mode	The trap mode in effect in the process at the time the signal handler was entered. The values returned in the **fp_sh_info.trap_mode** file use the following argument definitions: **FP_TRAP_OFF** Trapping off **FP_TRAP_SYNC** Precise trapping on **FP_TRAP_IMP_REC** Recoverable imprecise trapping on **FP_TRAP_IMP** Non-recoverable imprecise trapping on
flags	This field is interpreted as an array of bits and should be accessed with masks. The following mask is defined: **FP_IAR_STAT** If the value of the bit at this mask is 1, the exception was precise and the IAR points to the instruction that caused the exception. If the value bit at this mask is 0, the exception was imprecise.

fp_sh_trap_info

The **fp_sh_trap_info** subroutine is maintained for compatibility only. The **fp_sh_trap_info** subroutine returns information about the process that caused the trap by means of a floating-point context (**fp_ctx**) structure. This structure contains the following information:

```
fpstat_t fpscr;
fpflag_t trap;
```

The fields are:

Item	Description
fpscr	The Floating-Point Status and Control register (FPSCR) in the user process at the time the interrupt occurred.

Item	Description
`trap`	A mask indicating the trap or traps that caused the signal handler to be entered. This mask is the logical OR operator of the enabled floating-point exceptions that occurred to cause the trap. This mask can have up to two exceptions; if there are two, the **INEXACT** signal must be one of them. If the mask is 0, the **SIGFPE** signal was raised not by a floating-point operation, but by the **kill** or **raise** subroutine or the **kill** command.

fp_sh_set_stat

The **fp_sh_set_stat** subroutine updates the Floating-Point Status and Control register (FPSCR) in the user process with the value in the `fpscr` field.

The signal handler must either clear the exception bit that caused the trap to occur or disable the trap to prevent a recurrence. If the instruction generated more than one exception, and the signal handler clears only one of these exceptions, a signal is raised for the remaining exception when the next floating-point instruction is executed in the user process.

Parameters

Item	Description
fcp	Specifies a floating-point context structure.
scp	Specifies a **sigcontext** structure for the interrupt.
struct_size	Specifies the size of the **fp_sh_info** structure.
fpscr	Specifies which Floating-Point Status and Control register to update.

fp_trap Subroutine

Purpose

Queries or changes the mode of the user process to allow floating-point exceptions to generate traps.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <fptrap.h>

int fp_trap( flag)
int flag;
```

Description

The **fp_trap** subroutine queries and changes the mode of the user process to allow or disallow floating-point exception trapping. Floating-point traps can only be generated when a process is executing in a traps-enabled mode.

The default state is to execute in pipelined mode and not to generate floating-point traps.

Note: The **fp_trap** routines only change the execution state of the process. To generate floating-point traps, you must also enable traps. Use the **fp_enable** and **fp_enable_all** subroutines to enable traps.

Before calling the **fp_trap(FP_TRAP_SYNC)** routine, previous floating-point operations can set to True certain exception bits in the Floating-Point Status and Control register (FPSCR). Enabling these

Cexceptions and calling the **fp_trap(FP_TRAP_SYNC)** routine does not cause an immediate trap to occur. That is, the operation of these traps is edge-sensitive, not level-sensitive.

The **fp_trap** subroutine does not clear the exception history. You can query this history by using any of the following subroutines:

- **fp_any_xcp**
- **fp_divbyzero**
- **fp_iop_convert**
- **fp_iop_infdinf**
- **fp_iop_infmzr**
- **fp_iop_infsinf**
- **fp_iop_invcmp**
- **fp_iop_snan**
- **fp_iop_sqrt**
- **fp_iop_vxsoft**
- **fp_iop_zrdzr**
- **fp_inexact**
- **fp_invalid_op**
- **fp_overflow**
- **fp_underflow**

Parameters

Item	Description
flag	Specifies a query of or change in the mode of the user process: **FP_TRAP_OFF** Puts the user process into trapping-off mode and returns the previous mode of the process, either **FP_TRAP_SYNC**, **FP_TRAP_IMP**, **FP_TRAP_IMP_REC**, or **FP_TRAP_OFF**. **FP_TRAP_QUERY** Returns the current mode of the user process. **FP_TRAP_SYNC** Puts the user process into precise trapping mode and returns the previous mode of the process. **FP_TRAP_IMP** Puts the user process into non-recoverable imprecise trapping mode and returns the previous mode. **FP_TRAP_IMP_REC** Puts the user process into recoverable imprecise trapping mode and returns the previous mode. **FP_TRAP_FASTMODE** Puts the user process into the fastest trapping mode available on the hardware platform. **Note:** Some hardware models do not support all modes. If an unsupported mode is requested, the **fp_trap** subroutine returns **FP_TRAP_UNIMPL**.

Return Values

If called with the **FP_TRAP_OFF**, **FP_TRAP_IMP**, **FP_TRAP_IMP_REC**, or **FP_TRAP_SYNC** flag, the **fp_trap** subroutine returns a value indicating which flag was in the previous mode of the process if the hardware

supports the requested mode. If the hardware does not support the requested mode, the **fp_trap** subroutine returns **FP_TRAP_UNIMPL**.

If called with the **FP_TRAP_QUERY** flag, the **fp_trap** subroutine returns a value indicating the current mode of the process, either the **FP_TRAP_OFF**, **FP_TRAP_IMP**, **FP_TRAP_IMP_REC**, or **FP_TRAP_SYNC** flag.

If called with **FP_TRAP_FASTMODE**, the **fp_trap** subroutine sets the fastest mode available and returns the mode selected.

Error Codes

If the **fp_trap** subroutine is called with an invalid parameter, the subroutine returns **FP_TRAP_ERROR**.

If the requested mode is not supported on the hardware platform, the subroutine returns **FP_TRAP_UNIMPL**.

fp_trapstate Subroutine

Purpose

Queries or changes the trapping mode in the Machine Status register (MSR).

Note: This subroutine replaces the **fp_cpusync** subroutine. The **fp_cpusync** subroutine is supported for compatibility, but the **fp_trapstate** subroutine should be used for development.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <fptrap.h>
```

```
int fp_trapstate (int)
```

Description

The **fp_trapstate** subroutine is a service routine used to query or set the trapping mode. The trapping mode determines whether floating-point exceptions can generate traps, and can affect execution speed. See **Floating-Point Exceptions Overview** in *General Programming Concepts: Writing and Debugging Programs* for a description of precise and imprecise trapping modes. Floating-point traps can be generated by the hardware only when the processor is in a traps-enabled mode.

The **fp_trapstate** subroutine changes only the trapping mode. It is a service routine for use in developing custom floating-point exception-handling software. If you are using the **fp_enable** or **fp_enable_all** subroutine or the **fp_sh_info** or **fp_sh_set_stat** subroutine, you must use the **fp_trap** subroutine to change the process' trapping mode.

Parameters

Item	Description
flag	Specifies a query of, or change in, the trap mode: **FP_TRAPSTATE_OFF** Sets the trapping mode to Off and returns the previous mode. **FP_TRAPSTATE_QUERY** Returns the current trapping mode without modifying it. **FP_TRAPSTATE_IMP** Puts the process in non-recoverable imprecise trapping mode and returns the previous state. **FP_TRAPSTATE_IMP_REC** Puts the process in recoverable imprecise trapping mode and returns the previous state. **FP_TRAPSTATE_PRECISE** Puts the process in precise trapping mode and returns the previous state. **FP_TRAPSTATE_FASTMODE** Puts the process in the fastest trap-generating mode available on the hardware platform and returns the state selected. **Note:** Some hardware models do not support all modes. If an unsupported mode is requested, the **fp_trapstate** subroutine returns **FP_TRAP_UNIMPL** and the trapping mode is not changed.

Return Values

If called with the **FP_TRAPSTATE_OFF**, **FP_TRAPSTATE_IMP**, **FP_TRAPSTATE_IMP_REC**, or **FP_TRAPSTATE_PRECISE** flag, the **fp_trapstate** subroutine returns a value indicating the previous mode of the process. The value may be **FP_TRAPSTATE_OFF**, **FP_TRAPSTATE_IMP**, **FP_TRAPSTATE_IMP_REC**, or **FP_TRAPSTATE_PRECISE**. If the hardware does not support the requested mode, the **fp_trapstate** subroutine returns **FP_TRAP_UNIMPL**.

If called with the FP_TRAPSTATE_QUERY flag, the **fp_trapstate** subroutine returns a value indicating the current mode of the process. The value may be **FP_TRAPSTATE_OFF**, **FP_TRAPSTATE_IMP**, **FP_TRAPSTATE_IMP_REC**, or **FP_TRAPSTATE_PRECISE**.

If called with the **FP_TRAPSTATE_FASTMODE** flag, the **fp_trapstate** subroutine returns a value indicating which mode was selected. The value may be **FP_TRAPSTATE_OFF**, **FP_TRAPSTATE_IMP**, **FP_TRAPSTATE_IMP_REC**, or **FP_TRAPSTATE_PRECISE**.

fpclassify Macro

Purpose

Classifies real floating type.

Syntax

```
#include <math.h>

int fpclassify(x)
real-floating x;
```

Description

The **fpclassify** macro classifies the *x* parameter as NaN, infinite, normal, subnormal, zero, or into another implementation-defined category. An argument represented in a format wider than its semantic type is converted to its semantic type. Classification is based on the type of the argument.

Parameters

Item	Description
x	Specifies the value to be classified.

Return Values

The **fpclassify** macro returns the value of the number classification macro appropriate to the value of its argument.

fread or fwrite Subroutine

Purpose

Reads and writes binary files.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdio.h>
size_t fread (Pointer, Size, NumberOfItems, Stream)
void *Pointer;
size_tSize, NumberOfItems;
FILE *Stream;
size_t fwrite (Pointer, Size, NumberOfItems, Stream)
const void *Pointer;
size_t Size, NumberOfItems;
FILE *Stream;
```

Description

The **fread** subroutine copies the number of data items specified by the *NumberOfItems* parameter from the input stream into an array beginning at the location pointed to by the *Pointer* parameter. Each data item has the form ***Pointer*.

The **fread** subroutine stops copying bytes if an end-of-file (EOF) or error condition is encountered while reading from the input specified by the *Stream* parameter, or when the number of data items specified by the *NumberOfItems* parameter have been copied. This subroutine leaves the file pointer of the *Stream* parameter, if defined, pointing to the byte following the last byte read. The **fread** subroutine does not change the contents of the *Stream* parameter.

The `st_atime` field will be marked for update by the first successful run of the **fgetc**, **fgets**, **fgetwc**, **fgetws**, **fread**, **fscanf**, **getc**, **getchar**, **gets**, or **scanf** subroutine using a stream that returns data not supplied by a prior call to the **ungetc**or **ungetwc** subroutine.

Note: The **fread** subroutine is a buffered **read** subroutine library call. It reads data in 4KB blocks. For tape block sizes greater than 4KB, use the **open** subroutine and **read** subroutine.

The **fwrite** subroutine writes items from the array pointed to by the *Pointer* parameter to the stream pointed to by the *Stream* parameter. Each item's size is specified by the *Size* parameter. The **fwrite** subroutine writes the number of items specified by the *NumberOfItems* parameter. The file-position

indicator for the stream is advanced by the number of bytes successfully written. If an error occurs, the resulting value of the file-position indicator for the stream is indeterminate.

The **fwrite** subroutine appends items to the output stream from the array pointed to by the *Pointer* parameter. The **fwrite** subroutine appends as many items as specified in the *NumberOfItems* parameter.

The **fwrite** subroutine stops writing bytes if an error condition is encountered on the stream, or when the number of items of data specified by the *NumberOfItems* parameter have been written. The **fwrite** subroutine does not change the contents of the array pointed to by the *Pointer* parameter.

The `st_ctime` and `st_mtime` fields will be marked for update between the successful run of the **fwrite** subroutine and the next completion of a call to the **fflush** or **fclose** subroutine on the same stream, the next call to the **exit** subroutine, or the next call to the **abort** subroutine.

Parameters

Item	Description
Pointer	Points to an array.
Size	Specifies the size of the variable type of the array pointed to by the *Pointer* parameter. The *Size* parameter can be considered the same as a call to **sizeof** subroutine.
NumberOfItems	Specifies the number of items of data.
Stream	Specifies the input or output stream.

Return Values

The **fread** and **fwrite** subroutines return the number of items actually transferred. If the *NumberOfItems* parameter contains a 0, no characters are transferred, and a value of 0 is returned. If the *NumberOfItems* parameter contains a negative number, it is translated to a positive number, since the *NumberOfItems* parameter is of the unsigned type.

Error Codes

If the **fread** subroutine is unsuccessful because the I/O stream is unbuffered or data needs to be read into the I/O stream's buffer, it returns one or more of the following error codes:

Item	Description
EAGAIN	Indicates that the **O_NONBLOCK** flag is set for the file descriptor specified by the *Stream* parameter, and the process would be delayed in the **fread** operation.
EBADF	Indicates that the file descriptor specified by the *Stream* parameter is not a valid file descriptor open for reading.
EINTR	Indicates that the read operation was terminated due to receipt of a signal, and no data was transferred.

Note: Depending upon which library routine the application binds to, this subroutine may return **EINTR**. Refer to the **signal** subroutine regarding **sa_restart**.

Item	Description
EIO	Indicates that the process is a member of a background process group attempting to perform a read from its controlling terminal, and either the process is ignoring or blocking the **SIGTTIN** signal or the process group has no parent process.
ENOMEM	Indicates that insufficient storage space is available.
ENXIO	Indicates that a request was made of a nonexistent device.

If the **fwrite** subroutine is unsuccessful because the I/O stream is unbuffered or the I/O stream's buffer needs to be flushed, it returns one or more of the following error codes:

Item	Description
EAGAIN	Indicates that the **O_NONBLOCK** or O_NDELAY flag is set for the file descriptor specified by the *Stream* parameter, and the process is delayed in the write operation.
EBADF	Indicates that the file descriptor specified by the *Stream* parameter is not a valid file descriptor open for writing.
EFBIG	Indicates that an attempt was made to write a file that exceeds the file size of the process limit or the systemwide maximum file size.
EINTR	Indicates that the write operation was terminated due to the receipt of a signal, and no data was transferred.
EIO	Indicates that the process is a member of a background process group attempting to perform a write to its controlling terminal, the **TOSTOP** signal is set, the process is neither ignoring nor blocking the **SIGTTOU** signal, and the process group of the process is orphaned.
ENOSPC	Indicates that there was no free space remaining on the device containing the file.
EPIPE	Indicates that an attempt is made to write to a pipe or first-in-first-out (FIFO) process that is not open for reading by any process. A **SIGPIPE** signal is sent to the process.

The **fwrite** subroutine is also unsuccessful due to the following error conditions:

Item	Description
ENOMEM	Indicates that insufficient storage space is available.
ENXIO	Indicates that a request was made of a nonexistent device, or the request was outside the capabilities of the device.

freehostent Subroutine

Purpose

To free memory allocated by getipnodebyname and getipnodebyaddr.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <netdb.h>
void freehostent (ptr)
struct hostent * ptr;
```

Description

The **freehostent** subroutine frees any dynamic storage pointed to by elements of *ptr*. This includes the **hostent** structure and the data areas pointed to by the h_name, h_addr_list, and h_aliases members of the **hostent** structure.

freelocale Subroutine

Purpose

Frees resources allocated for a locale object.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <locale.h>

void freelocale(locobj);
locale_t locobj;
```

Return Value

None

Errors

None

Description

The **freelocale** subroutine releases the resources allocated for a locale object that is returned by a call to the **newlocale** or **duplocale** subroutines.

Any use of a locale object that has been freed results in undefined behavior.

Example

The following example shows a code snippets to free a locale object created by the **newlocale** subroutine:

```
#include <locale.h>

...
/* Every locale object allocated with newlocale() should be
* freed using freelocale():
*/

locale_t loc;
/* Get the locale. */

loc = newlocale (LC_CTYPE_MASK | LC_TIME_MASK, "locname", NULL);
/* ... Use the locale object ... */
...
/* Free the locale object resources. */
freelocale (loc);
```

freelmb Subroutine

Purpose

Returns a block of memory allocated by **alloclmb()** to the system.

Syntax

```
#include <sys/dr.h>
int freelmb(long long laddr
```

Description

The **freelmb()** subroutine returns a block of memory, allocated by **allocmb()**, for general system use.

Parameters

Item	Description
laddr	A previously allocated LMB address.

Execution Environment

This **freelmb()** interface should only be called from the process environment.

Return Values

Item	Description
0	The LMB is successfully freed.

Error Codes

Item	Description
ENOTSUP	LMB allocation not supported on this system.
EINVAL	*laddr* does not describe a previously allocated LMB.
EINVAL	Not in the process environment.

frevoke Subroutine

Purpose

Revokes access to a file by other processes.

Library

Standard C Library (**libc.a**)

Syntax

```
int frevoke ( FileDescriptor)
int FileDescriptor;
```

Description

The **frevoke** subroutine revokes access to a file by other processes.

All accesses to the file are revoked, except through the file descriptor specified by the *FileDescriptor* parameter to the **frevoke** subroutine. Subsequent attempts to access the file, using another file descriptor established before the **frevoke** subroutine was called, fail and cause the process to receive a return value of -1, and the **errno** global variable is set to **EBADF** .

A process can revoke access to a file only if its effective user ID is the same as the file owner ID or if the invoker has root user authority.

Note: The **frevoke** subroutine has no affect on subsequent attempts to open the file. To ensure exclusive access to the file, the caller should change the mode of the file before issuing the **frevoke** subroutine. Currently the **frevoke** subroutine works only on terminal devices.

Parameters

Item	Description
FileDescriptor	A file descriptor returned by a successful **open** subroutine.

Return Values

Upon successful completion, the **frevoke** subroutine returns a value of 0.

If the **frevoke** subroutine fails, it returns a value of -1 and the **errno** global variable is set to indicate the error.

Error Codes

The **frevoke** subroutine fails if the following is true:

Item	Description
EBADF	The *FileDescriptor* value is not the valid file descriptor of a terminal.
EPERM	The effective user ID of the calling process is not the same as the file owner ID.
EINVAL	Revocation of access rights is not implemented for this file.

frexpd32, frexpd64, and frexpd128 Subroutines

Purpose

Extracts the mantissa and exponent from a decimal floating-point number.

Syntax

```
#include <math.h>

_Decimal32 frexpd32 (num, exp)
_Decimal32 num;
int *exp;

_Decimal64 frexpd64 (num, exp)
_Decimal64 num;
int *exp;

_Decimal128 frexpd128 (num, exp)
_Decimal128 num;
int *exp;
```

Description

The **frexpd32**, **frexpd64**, and **frexpd128** subroutines divide a decimal floating-point number into a mantissa and an integral power of 10. The integer exponent is stored in the **int** object pointed to by the **exp** parameter.

Parameters

Item	Description
num	Specifies the decimal floating-point number to be divided into a mantissa and an integral power of 10.
exp	Points to where the integer exponent is stored.

Return Values

For finite arguments, the **frexpd32**, **frexpd64**, and **frexpd128** subroutines return the mantissa value in the **x** parameter. Therefore, the **num** parameter equals the **x** parameter times 10 raised to the power *exp* parameter.

If *num* is NaN, a NaN is returned, and the value of the **exp* is not specified.

If *num* is ±0, ±0 is returned, and the value of the **exp* is 0.

If *num* is ±Inf, *num* is returned, and the value of the **exp* is not specified.

frexpf, frexpl, or frexp Subroutine

Purpose

Extracts the mantissa and exponent from a double precision number.

Syntax

```
#include <math.h>

float frexpf (num, exp)
float num;
int *exp;

long double frexpl (num, exp)
long double num;
int *exp;

double frexp (num, exp)
double num;
int *exp;
```

Description

The **frexpf**, **frexpl**, and **frexp** subroutines break a floating-point number *num* into a normalized fraction and an integral power of 2. The integer exponent is stored in the **int** object pointed to by *exp*.

Parameters

Item	Description
num	Specifies the floating-point number to be broken into a normalized fraction and an integral power of 2.
exp	Points to where the integer exponent is stored.

Return Values

For finite arguments, the **frexpf**, **frexpl**, and **frexp** subroutines return the value *x*, such that *x* has a magnitude in the interval [½ ,1) or 0, and *num* equals *x* times 2 raised to the power *exp*.

If *num* is NaN, a NaN is returned, and the value of **exp* is unspecified.

If *num* is ±0, ±0 is returned, and the value of **exp* is 0.

If *num* is ±Inf, *num* is returned, and the value of **exp* is unspecified.

fscntl Subroutine

Purpose

Controls file system control operations.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/types.h>
#include <j2/j2_cntl.h>
#include <sys/vmount.h>
```

```
int fscntl ( vfs_id,  Command,  Argument,   ArgumentSize)
int vfs_id;
int Command;
char *Argument;
int ArgumentSize;
```

Description

The **fscntl** subroutine performs a variety of file system-specific functions. These functions typically require root user authority.

The Enhanced Journaled File System (JFS2) supports several *Command* values that can be used by applications. Each of these *Command* values requires root authority.

FSCNTL_FREEZE
The file system specified by *vfs_id* is "frozen" for a specified amount of time. The act of freezing a file system produces a nearly consistent on-disk image of the file system, and writes all dirty file system metadata and user data to the disk. In its frozen state, the file system is read-only, and anything that attempts to modify the file system or its contents must wait for the freeze to end. The *Argument* is treated as an integral timeout value in seconds (instead of a pointer). The file system is thawed by FSCNTL_THAW or when the timeout expires. The timeout, which must be a positive value, can be renewed using FSCNTL_REFREEZE. The *ArgumentSize* must be 0.

Note: For all applications using this interface, use FSCNTL_THAW to thaw the file system rather than waiting for the timeout to expire. If the timeout expires, an error log entry is generated as an advisory.

FSCNTL_REFREEZE
The file system specified by *vfs_id*, which must be already frozen, has its timeout value reset. If the command is used on a file system that is not frozen, an error is returned. The *Argument* is treated as an integral timeout value in seconds (instead of a pointer). The file system is thawed by FSCNTL_THAW or when the new timeout expires. The timeout must be a positive value. The *ArgumentSize* must be 0.

FSCNTL_THAW
The file system specified by *vfs_id* is thawed. Modifications to the file system are still allowed after it is thawed, and the file system image might no longer be consistent after the thaw occurs. If the file

system is not frozen at the time of the call, an error is returned. The *Argument* and *ArgumentSize* must both be 0.

The Journaled File System (JFS) supports only internal **fscntl** interfaces. Application programs should not call this function on a JFS file system, because **fscntl** is reserved for system management commands, such as the **chfs** command.

Parameters

Item	Description
vfs_id	Identifies the file system to be acted upon. This information is returned by the **stat** subroutine in the `st_vfs` field of the **stat.h** file.
Command	Identifies the operation to be performed.
Argument	Specifies a pointer to a block of file system specific information that defines how the operation is to be performed.
ArgumentSize	Defines the size of the buffer pointed to by the *Argument* parameter.

Return Values

Upon successful completion, the **fscntl** subroutine returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **fscntl** subroutine fails if any of the following errors are true:

Item	Description
EINVAL	The *vfs_id* parameter does not identify a valid file system.
EINVAL	The *Command* parameter is not recognized by the file system.
EINVAL	The timeout specified to `FSCNTL_FREEZE` or `FSCNTL_REFREEZE` is invalid.
EALREADY	The *Command* parameter was `FSCNTL_FREEZE` and the file system specified was already frozen.
EALREADY	The *Command* parameter was `FSCNTL_REFREEZE` or `FSCNTL_THAW` and the file system specified was not frozen.

fseek, fseeko, fseeko64, rewind, ftell, ftello, ftello64, fgetpos, fgetpos64, fsetpos, or fsetpos64 Subroutine

Purpose

Repositions the file pointer of a stream.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdio.h>

int fseek ( Stream,  Offset,  Whence)
FILE *Stream;
```

```
long int Offset;
int Whence;
```

```
void rewind (Stream)
FILE *Stream;
```

```
long int ftell (Stream)
FILE *Stream;
```

```
int fgetpos (Stream, Position)
FILE *Stream;
fpos_t *Position;
```

```
int fsetpos (Stream,  Position)
FILE *Stream;
const fpos_t *Position;
```

```
int fseeko ( Stream,  Offset,  Whence)
FILE *Stream;
off_t Offset;
int Whence;
```

```
int fseeko64 ( Stream,  Offset,  Whence)
FILE *Stream;
off64_t Offset;
int Whence;
```

```
off_t int ftello (Stream)
FILE *Stream;
```

```
off64_t int ftello64 (Stream)
FILE *Stream;
```

```
int fgetpos64 (Stream, Position)
FILE *Stream;
fpos64_t *Position;
```

```
int fsetpos64 (Stream,  Position)
FILE *Stream;
const fpos64_t *Position;
```

Description

The **fseek**, **fseeko** and **fseeko64** subroutines set the position of the next input or output operation on the I/O stream specified by the Stream parameter. The position if the next operation is determined by the *Offset* parameter, which can be either positive or negative.

The **fseek**, **fseeko** and **fseeko64** subroutines set the file pointer associated with the specified *Stream* as follows:

- If the *Whence* parameter is set to the **SEEK_SET** value, the pointer is set to the value of the *Offset* parameter.
- If the *Whence* parameter is set to the **SEEK_CUR** value, the pointer is set to its current location plus the value of the *Offset* parameter.
- If the *Whence* parameter is set to the **SEEK_END** value, the pointer is set to the size of the file plus the value of the *Offset* parameter.

The **fseek**, **fseeko**, and **fseeko64** subroutine are unsuccessful if attempted on a file that has not been opened using the **fopen** subroutine. In particular, the **fseek** subroutine cannot be used on a terminal or on a file opened with the **popen** subroutine. The **fseek** and **fseeko** subroutines will also fail when the resulting offset is larger than can be properly returned.

The **rewind** subroutine is equivalent to calling the **fseek** subroutine using parameter values of (*Stream*,**SEEK_SET,SEEK_SET**), except that the **rewind** subroutine does not return a value. Do not use the **rewind** subroutine in situations where the **fseek** subroutine might fail (for example, when the **fseek** subroutine is used with buffered I/O streams). In this case, use the **fseek** subroutine, so error conditions can be checked.

The **fseek**, **fseeko**, **fseeko64** and **rewind** subroutines undo any effects of the **ungetc** and **ungetwc** subroutines and clear the end-of-file (EOF) indicator on the same stream.

The **fseek**, **fseeko**, and **fseeko64** function allows the file-position indicator to be set beyond the end of existing data in the file. If data is written later at this point, subsequent reads of data in the gap will return bytes of the value 0 until data is actually written into the gap.

A successful calls to the **fsetpos** or **fsetpos64** subroutines clear the **EOF** indicator and undoes any effects of the **ungetc** and **ungetwc** subroutines.

After an **fseek**, **fseeko**, **fseeko64** or a **rewind** subroutine, the next operation on a file opened for update can be either input or output.

ftell, **ftello** and **ftello64** subroutines return the position current value of the file-position indicator for the stream pointed to by the *Stream* parameter. **ftell** and **ftello** will fail if the resulting offset is larger than can be properly returned.

The **fgetpos** and **fgetpos64** subroutines store the current value of the file-position indicator for the stream pointed to by the *Stream* parameter in the object pointed to by the *Position* parameter. The **fsetpos** and **fsetpos64** set the file-position indicator for *Stream* according to the value of the *Position* parameter, which must be the result of a prior call to **fgetpos** or **fgetpos64** subroutine. **fgetpos** and **fsetpos** will fail if the resulting offset is larger than can be properly returned.

Parameters

Item	Description
Stream	Specifies the input/output (I/O) stream.
Offset	Determines the position of the next operation.
Whence	Determines the value for the file pointer associated with the *Stream* parameter.
Position	Specifies the value of the file-position indicator.

Return Values

Upon successful completion, the **fseek**, **fseeko** and **fseeko64** subroutine return a value of 0. Otherwise, it returns a value of -1.

Upon successful completion, the **ftell**, **ftello** and **ftello64** subroutine return the offset of the current byte relative to the beginning of the file associated with the named stream. Otherwise, a **long int** value of -1 is returned and the **errno** global variable is set.

Upon successful completion, the **fgetpos**, **fgetpos64**, **fsetpos** and **fsetpos64** subroutines return a value of 0. Otherwise, a nonzero value is returned and the **errno** global variable is set to the specific error.

Error Codes

If the **fseek**, **fseeko**, **fseeko64**, **ftell**, **ftello**, or **ftello64** subroutines are unsuccessful because the stream is unbuffered or the stream buffer needs to be flushed and the call to the subroutine causes an underlying **lseek** or **write** subroutine to be invoked, it returns one or more of the following error codes:

Item	Description
EAGAIN	Indicates that the **O_NONBLOCK** flag is set for the file descriptor, delaying the process in the write operation.

Item	Description
EBADF	Indicates that the file descriptor underlying the *Stream* parameter is not open for writing.
EFBIG	Indicates that an attempt has been made to write to a file that exceeds the file-size limit of the process or the maximum file size.
EFBIG	Indicates that the file is a regular file and that an attempt was made to write at or beyond the offset maximum associated with the corresponding stream.
EINTR	Indicates that the write operation has been terminated because the process has received a signal, and either no data was transferred, or the implementation does not report partial transfers for this file.
EIO	Indicates that the process is a member of a background process group attempting to perform a **write** subroutine to its controlling terminal, the **TOSTOP** flag is set, the process is not ignoring or blocking the **SIGTTOU** signal, and the process group of the process is orphaned. This error may also be returned under implementation-dependent conditions.
ENOSPC	Indicates that no remaining free space exists on the device containing the file.
EPIPE	Indicates that an attempt has been made to write to a pipe or FIFO that is not open for reading by any process. A **SIGPIPE** signal will also be sent to the process.
EINVAL	Indicates that the *Whence* parameter is not valid. The resulting file-position indicator will be set to a negative value. The **EINVAL** error code does not apply to the **ftell** and **rewind** subroutines.
ESPIPE	Indicates that the file descriptor underlying the *Stream* parameter is associated with a pipe, FIFO, or socket.
EOVERFLOW	Indicates that for *fseek*, the resulting file offset would be a value that cannot be represented correctly in an object of type *long*.
EOVERFLOW	Indicates that for *fseeko*, the resulting file offset would be a value that cannot be represented correctly in an object of type *off_t*.
ENXIO	Indicates that a request was made of a non-existent device, or the request was outside the capabilities of the device.

The **fgetpos** and **fsetpos** subroutines are unsuccessful due to the following conditions:

Item	Description
EINVAL	Indicates that either the *Stream* or the *Position* parameter is not valid. The **EINVAL** error code does not apply to the **fgetpos** subroutine.
EBADF	Indicates that the file descriptor underlying the *Stream* parameter is not open for writing.
ESPIPE	Indicates that the file descriptor underlying the *Stream* parameter is associated with a pipe, FIFO, or socket.

The **fseek**, **fseeko**, **ftell**, **ftello**, **fgetpos**, and **fsetpos** subroutines are unsuccessful under the following condition:

Item	Description
EOVERFLOW	The resulting could not be returned properly.

fsync or fsync_range Subroutine

Purpose

Writes changes in a file to permanent storage.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <unistd.h>

int fsync ( FileDescriptor)
int FileDescriptor;

int fsync_range (FileDescriptor, how, start, length)
int FileDescriptor;
int how;
off_t start;
off_t length;
```

Description

The **fsync** subroutine causes all modified data in the open file specified by the *FileDescriptor* parameter to be saved to permanent storage. On return from the **fsync** subroutine, all updates have been saved on permanent storage.

The **fsync_range** subroutine causes all modified data in the specified range of the open file specified by the *FileDescriptor* parameter to be saved to permanent storage. On return from the **fsync_range** subroutine, all updates in the specified range have been saved on permanent storage.

This paragraph refers to deprecated function available only in the JFS file system. Data written to a file that a process has opened for deferred update (with the **O_DEFER** flag) is not written to permanent storage until another process issues an **fsync_range** or **fsync** call against this file or runs a synchronous **write** subroutine (with the **O_SYNC** flag) on this file. See the **fcntl.h** file and the **open** subroutine for descriptions of the **O_DEFER** and **O_SYNC** flags respectively.

Note: The file identified by the *FileDescriptor* parameter must be open for writing when the **fsync** subroutine is issued or the call is unsuccessful. This restriction was not enforced in BSD systems. The **fsync_range** subroutine does not require write access.

Parameters

Item	Description
FileDescriptor	A valid, open file descriptor.

Item	Description
how	Specify the handling characteristics of the operation. **O_SYNC** The modified data in the range specified by the <*start, length*> parameters is written to storage. If any metadata is modified then all modified user data is written to storage. Any metadata changes and the file attributes including timestamps are also written to storage. **O_DSYNC** The modified data in the range specified by the <*start, length*> parameters is written to storage. If there is modified metadata for the file then the metadata is also written if it is required to read the data. Otherwise, no metadata updates occur. **O_NOCACHE** The modified data is written as with the **O_DSYNC** parameter. The full pages in the range specified by the <*start, length*> parameters are removed from the memory cache. The pages are removed from the cache even if they are not modified. The operation also works on files that are open only for reading.
start	Starting file offset.
length	Length, or zero for all cache data.

Return Values

Upon successful completion, the **fsync** subroutine returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Upon successful completion, the **fsync_range** subroutine returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **fsync** or **fsync_range** subroutine is unsuccessful if one or more of the following are true:

Item	Description
EIO	An I/O error occurred while reading from or writing to the file system.
EBADF	The *FileDescriptor* parameter is not a valid file descriptor open for writing.
EINVAL	The file is not a regular file.
EINTR	The subroutine was interrupted by a signal.

ftok Subroutine

Purpose

Generates a standard interprocess communication key.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/types.h>
#include <sys/ipc.h>
```

key_t ftok (*Path*, *ID*)
char **Path*;
int *ID*;

Description

Attention: If the *Path* parameter of the **ftok** subroutine names a file that has been removed while keys still refer to it, the **ftok** subroutine returns an error. If that file is then re-created, the **ftok** subroutine will probably return a key different from the original one.

Attention: Each installation should define standards for forming keys. If standards are not adhered to, unrelated processes may interfere with each other's operation.

Attention: The **ftok** subroutine does not guarantee unique key generation. However, the occurrence of key duplication is very rare and mostly for across file systems.

The **ftok** subroutine returns a key, based on the *Path* and *ID* parameters, to be used to obtain interprocess communication identifiers. The **ftok** subroutine returns the same key for linked files if called with the same *ID* parameter. Different keys are returned for the same file if different *ID* parameters are used.

All interprocess communication facilities require you to supply a key to the **msgget**, **semget**, and **shmget** subroutines in order to obtain interprocess communication identifiers. The **ftok** subroutine provides one method for creating keys, but other methods are possible. For example, you can use the project ID as the most significant byte of the key, and use the remaining portion as a sequence number.

Parameters

Item	Description
Path	Specifies the path name of an existing file that is accessible to the process.
ID	Specifies a character that uniquely identifies a project.

Return Values

When successful, the **ftok** subroutine returns a key that can be passed to the **msgget**, **semget**, or **shmget** subroutine.

Error Codes

The **ftok** subroutine returns the value **(key_t)-1** if one or more of the following are true:

- The file named by the *Path* parameter does not exist.
- The file named by the *Path* parameter is not accessible to the process.
- The *ID* parameter has a value of 0.

ftw or ftw64 Subroutine

Purpose

Walks a file tree.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <ftw.h>

int ftw ( Path,  Function,  Depth)
char *Path;
int (*Function(const char*, const struct stat*, int);
int Depth;

int ftw64 ( Path,  Function,  Depth)
char *Path;
int (*Function(const char*, const struct stat64*, int);
int Depth;
```

Description

The **ftw** and **ftw64** subroutines recursively searches the directory hierarchy that descends from the directory specified by the *Path* parameter.

For each file in the hierarchy, the **ftw** and **ftw64** subroutines call the function specified by the *Function* parameter. **ftw** passes it a pointer to a null-terminated character string containing the name of the file, a pointer to a stat structure containing information about the file, and an integer. **ftw64** passes it a pointer to a null-terminated character string containing the name of the file, a pointer to a **stat64** structure containing information about the file, and an integer.

The integer passed to the *Function* parameter identifies the file type with one of the following values:

Item	Description
FTW_F	Regular file
FTW_D	Directory
FTW_DNR	Directory that cannot be read
FTW_SL	Symbolic Link
FTW_NS	File for which the **stat** structure could not be executed successfully

If the integer is **FTW-DNR**, the files and subdirectories contained in that directory are not processed.

If the integer is **FTW-NS**, the **stat** structure contents are meaningless. An example of a file that causes **FTW-NS** to be passed to the *Function* parameter is a file in a directory for which you have read permission but not execute (search) permission.

The **ftw** and **ftw64** subroutines finish processing a directory before processing any of its files or subdirectories.

The **ftw** and **ftw64** subroutines continue the search until the directory hierarchy specified by the *Path* parameter is completed, an invocation of the function specified by the *Function* parameter returns a nonzero value, or an error is detected within the **ftw** and **ftw64** subroutines, such as an I/O error.

The **ftw** and **ftw64** subroutines traverse symbolic links encountered in the resolution of the *Path* parameter, including the final component. Symbolic links encountered while walking the directory tree rooted at the *Path* parameter are not traversed.

The **ftw** and **ftw64** subroutines use one file descriptor for each level in the tree. The *Depth* parameter specifies the maximum number of file descriptors to be used. In general, the **ftw** and **ftw64** subroutines runs faster if the value of the *Depth* parameter is at least as large as the number of levels in the tree. However, the value of the *Depth* parameter must not be greater than the number of file descriptors currently available for use. If the value of the *Depth* parameter is 0 or a negative number, the effect is the same as if it were 1.

Because the **ftw** and **ftw64** subroutines are recursive, it is possible for it to terminate with a memory fault due to stack overflow when applied to very deep file structures.

The **ftw** and **ftw64** subroutines use the **malloc** subroutine to allocate dynamic storage during its operation. If the **ftw** and **ftw64** subroutined is terminated prior to its completion, such as by the **longjmp** subroutine being executed by the function specified by the *Function* parameter or by an interrupt routine, the **ftw** and **ftw64** subroutines cannot free that storage. The storage remains allocated. A safe way to handle interrupts is to store the fact that an interrupt has occurred, and arrange to have the function specified by the *Function* parameter return a nonzero value the next time it is called.

Parameters

Item	Description
Path	Specifies the directory hierarchy to be searched.
Function	Specifies the file type.
Depth	Specifies the maximum number of file descriptors to be used. *Depth* cannot be greater than OPEN_MAX which is described in the sys/limits.h header file.

Return Values

If the tree is exhausted, the **ftw** and **ftw64** subroutines returns a value of 0. If the subroutine pointed to by **fn** returns a nonzero value, **ftw** and **ftw64** subroutines stops its tree traversal and returns whatever value was returned by the subroutine pointed to by **fn**. If the **ftw** and **ftw64** subroutines detects an error, it returns a -1 and sets the **errno** global variable to indicate the error.

Error Codes

If the **ftw** or **ftw64** subroutines detect an error, a value of -1 is returned and the **errno** global variable is set to indicate the error.

The **ftw** and **ftw64** subroutine are unsuccessful if:

Item	Description
EACCES	Search permission is denied for any component of the *Path* parameter or read permission is denied for *Path*.
ENAMETOOLONG	The length of the path exceeds **PATH_MAX** while **_POSIX_NO_TRUNC** is in effect.
ENOENT	The *Path* parameter points to the name of a file that does not exist or points to an empty string.
ENOTDIR	A component of the *Path* parameter is not a directory.

The **ftw** subroutine is unsuccessful if:

Item	Description
EOVERFLOW	A file in *Path* is of a size larger than 2 Gigabytes.

fwide Subroutine

Purpose

Set stream orientation.

Library

Standard Library (**libc.a**)

Syntax

```
#include <stdio.h>
#include <wchar.h>
```

```
int fwid (FILE * stream, int mode),
```

Description

The **fwide** function determines the orientation of the stream pointed to by stream. If mode is greater than zero, the function first attempts to make the stream wide-oriented. If mode is less than zero, the function first attempts to make the stream byte-oriented. Otherwise, mode is zero and the function does not alter the orientation of the stream.

If the orientation of the stream has already been determined, **fwide** does not change it.

Because no return value is reserved to indicate an error, an application wishing to check for error situations should set errno to 0, then call **fwide**, then check errno and if it is non-zero, assume an error has occurred.

A call to **fwide** with mode set to zero can be used to determine the current orientation of a stream.

Return Values

The **fwide** function returns a value greater than zero if, after the call, the stream has wide-orientation, a value less than zero if the stream has byte-orientation, or zero if the stream has no orientation.

Errors

The **fwide** function may fail if:

Item	Description
EBADF	The stream argument is not a valid stream.

fwprintf, wprintf, swprintf Subroutines

Purpose

Print formatted wide-character output.

Library

Standard Library (**libc.a**)

Syntax

```
#include <stdio.h>
#include <wchar.h>
```

```
int fwprintf ( FILE * stream, const wchar_t * format, . . .)
int wprintf (const wchar_t * format, . .)
int swprintf (wchar_t *s, size_t n, const wchar_t * format, . . .)
```

Description

The **fwprintf** function places output on the named output stream. The **wprintf** function places output on the standard output stream **stdout**. The **swprintf** function places output followed by the null wide-

character in consecutive wide-characters starting at ***s**; no more than **n** wide-characters are written, including a terminating null wide-character, which is always added (unless **n** is zero).

Each of these functions converts, formats and prints its arguments under control of the **format** wide-character string. The **format** is composed of zero or more directives: **ordinary wide-characters**, which are simply copied to the output stream and **conversion specifications** , each of which results in the fetching of zero or more arguments. The results are undefined if there are insufficient arguments for the **format.** If the **format** is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.

EX Conversions can be applied to the **nth** argument after the **format** in the argument list, rather than to the next unused argument. In this case, the conversion wide-character % (see below) is replaced by the sequence **%n$**, where n is a decimal integer in the range [1, {NL_ARGMAX}], giving the position of the argument in the argument list. This feature provides for the definition of format wide-character strings that select arguments in an order appropriate to specific languages (see the EXAMPLES section).

In format wide-character strings containing the **%n$** form of conversion specifications, numbered arguments in the argument list can be referenced from the format wide-character string as many times as required.

In format wide-character strings containing the % form of conversion specifications, each argument in the argument list is used exactly once.

All forms of the **fwprintf** functions allow for the insertion of a language-dependent radix character in the output string, output as a wide-character value. The radix character is defined in the program's locale (category LC_NUMERIC). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (.).

EX Each conversion specification is introduced by the % wide-character or by the wide-character sequence %n$,after which the following appear in sequence:

- Zero or more **flags** (in any order), which modify the meaning of the conversion specification.
- An optional minimum **field width**. If the converted value has fewer wide-characters than the field width, it will be padded with spaces by default on the left; it will be padded on the right, if the left-adjustment flag (-), described below, is given to the field width. The field width takes the form of an asterisk (*), described below, or a decimal integer.
- An optional **precision** that gives the minimum number of digits to appear for the d, i, o, u, **x** and **X** conversions; the number of digits to appear after the radix character for the e, E and f conversions; the maximum number of significant digits for the g and G conversions; or the maximum number of wide-characters to be printed from a string in s conversions. The precision takes the form of a period (.) followed either by an asterisk (*), described below, or an optional decimal digit string, where a null digit string is treated as 0. If a precision appears with any other conversion wide-character, the behaviour is undefined.
- An optional **l** (lowercase *L*), **L**, **h**, **H**, **D** or **DD** specifies one of the following conversions:
  - An optional **l** specifying that a following **c** conversion wide-character applies to a **wint_t** argument.
  - An optional **l** specifying that a following **s** conversion wide-character applies to a **wchar_t** argument.
  - An optional **l** specifying that a following **d**, **i**, **o**, **u**, **x** or **X** conversion wide-character applies to a type **long int** or **unsigned long int** argument.
  - An optional **l** specifying that a following **n** conversion wide-character applies to a pointer to a type **long int** argument.
  - An optional **L** specifying that a following **e**, **E**, **f**, **g** or **G** conversion wide-character applies to a type **long double** argument.
  - An optional **h** specifying that a following **d**, **i**, **o**, **u**, **x** or **X** conversion wide-character applies to a type **short int** or type **unsigned short int** argument (the argument that will be promoted according to the integral promotions, and its value will be converted to type **short int** or **unsigned short int** before printing).
  - An optional **h** specifying that a following **n** conversion wide-character applies to a pointer to a type **short int** argument.

- An optional **H** specifying that a following **e**, **E**, **f**, **g**, or **G** conversion wide-character applies to a **_Decimal32** parameter.
- An optional **D** specifying that a following **e**, **E**, **f**, **g**, or **G** conversion wide-character applies to a **_Decimal64** parameter.
- An optional **DD** specifying that a following **e**, **E**, **f**, **g**, or **G** conversion wide-character applies to a **_Decimal128** parameter.

If an **l**, **L** , **h**, **H**, **D**, or **DD** appears with any other conversion wide-character, the behavior is undefined.

- A **conversion wide-character** that indicates the type of conversion to be applied.

A field width, or precision, or both, may be indicated by an asterisk (*). In this case an argument of type int supplies the field width or precision. Arguments specifying field width, or precision, or both must appear in that order before the argument, if any, to be converted. A negative field width is taken as a - flag followed by a positive field width. A negative precision is taken as if EX the precision were omitted. In format wide-character strings containing the %n$ form of a conversion specification, a field width or precision may be indicated by the sequence *m$, where m is a decimal integer in the range [1, {NL_ARGMAX}] giving the position in the argument list (after the format argument) of an integer argument containing the field width or precision, for example:

```
wprintf(L"%1$d:%2$.*3$d:%4$.*3$d\n", hour, min, precision, sec);
```

The **format** can contain either numbered argument specifications (that is, **%n$** and ***m$),** or unnumbered argument specifications (that is, % and *), but normally not both. The only exception to this is that %% can be mixed with the **%n$** form. The results of mixing numbered and unnumbered argument specifications in a **format** wide-character string are undefined. When numbered argument specifications are used, specifying the Nth argument requires that all the leading arguments, from the first to the (N-1)th, are specified in the format wide-character string.

The flag wide-characters and their meanings are:

Item	Description
'	The integer portion of the result of a decimal conversion (%i, %d, %u, %f, %g or %G) will be formatted with thousands' grouping wide-characters. For other conversions the behaviour is undefined. The non-monetary grouping wide-character is used.
-	The result of the conversion will be left-justified within the field. The conversion will be right-justified if this flag is not specified.
+	The result of a signed conversion will always begin with a sign (+ or -). The conversion will begin with a sign only when a negative value is converted if this flag is not specified.
space	If the first wide-character of a signed conversion is not a sign or if a signed conversion results in no wide-characters, a space will be prefixed to the result. This means that if the space and + flags both appear, the space flag will be ignored.
#	This flag specifies that the value is to be converted to an alternative form. For o conversion, it increases the precision (if necessary) to force the first digit of the result to be 0. For x or X conversions, a non-zero result will have 0x (or 0X) prefixed to it. For e, E, f, g or G conversions, the result will always contain a radix character, even if no digits follow it. Without this flag, a radix character appears in the result of these conversions only if a digit follows it. For g and G conversions, trailing zeros will **not** be removed from the result as they normally are. For other conversions, the behavior is undefined.
0	For d, i, o, u, x, X, e, E, f, g and G conversions, leading zeros (following any indication of sign or base) are used to pad to the field width; no space padding is performed. If the 0 and - flags both appear, the 0 flag will be ignored. For d, i, o, u, x and X conversions, if a precision is specified, the 0 flag will be ignored. If the 0 and ' flags both appear, the grouping wide-characters are inserted before zero padding. For other conversions, the behavior is undefined.

The conversion wide-characters and their meanings are:

Item	Description
d,i	The **int** argument is converted to a signed decimal in the style [-] **dddd**. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
o	The **unsigned int** argument is converted to unsigned octal format in the style **dddd**. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
u	The **unsigned int** argument is converted to unsigned decimal format in the style **dddd**. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
x	The **unsigned int** argument is converted to unsigned hexadecimal format in the style **dddd**; the letters abcdef are used. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
X	Behaves the same as the x conversion wide-character except that letters ABCDEF are used instead of abcdef.
f	The **double** argument is converted to decimal notation in the style [-] **ddd.ddd**, where the number of digits after the radix character is equal to the precision specification. If the precision is missing, it is taken as 6; if the precision is explicitly 0 and no # flag is present, no radix character appears. If a radix character appears, at least one digit appears before it. The value is rounded to the appropriate number of digits. The **fwprintf** family of functions may make available wide-character string representations for infinity and NaN.
e, E	The **double** argument is converted in the style [-] **d.ddde +/- dd**, where there is one digit before the radix character (which is non-zero if the argument is non-zero) and the number of digits after it is equal to the precision; if the precision is missing, it is taken as 6; if the precision is 0 and no # flag is present, no radix character appears. The value is rounded to the appropriate number of digits. The E conversion wide-character will produce a number with E instead of e introducing the exponent. The exponent always contains at least two digits. If the value is 0, the exponent is 0. The **fwprintf** family of functions may make available wide-character string representations for infinity and NaN.
g, G	The **double** argument is converted in the style f or e (or in the style E in the case of a G conversion wide-character), with the precision specifying the number of significant digits. If an explicit precision is 0, it is taken as 1. The style used depends on the value converted; style e (or E) will be used only if the exponent resulting from such a conversion is less than -4 or greater than or equal to the precision. Trailing zeros are removed from the fractional portion of the result; a radix character appears only if it is followed by a digit. The **fwprintf** family of functions may make available wide-character string representations for infinity and NaN.
c	If no l (ell) qualifier is present, the **int** argument is converted to a wide-character as if by calling the **btowc** function and the resulting wide-character is written. Otherwise the **wint_t** argument is converted to **wchar_t,** and written.

Item	Description
s	If no l (ell) qualifier is present, the argument must be a pointer to a character array containing a character sequence beginning in the initial shift state. Characters from the array are converted as if by repeated calls to the **mbrtowc** function, with the conversion state described by an **mbstate_t** object initialised to zero before the first character is converted, and written up to (but not including) the terminating null wide-character. If the precision is specified, no more than that many wide-characters are written. If the precision is not specified or is greater than the size of the array, the array must contain a null wide-character. If an l (ell) qualifier is present, the argument must be a pointer to an array of type **wchar_t.** Wide characters from the array are written up to (but not including) a terminating null wide-character. If no precision is specified or is greater than the size of the array, the array must contain a null wide-character. If a precision is specified, no more than that many wide-characters are written.
p	The argument must be a pointer to void. The value of the pointer is converted to a sequence of printable wide-characters, in an implementation-dependent manner. The argument must be a pointer to an integer into which is written the number of wide-characters written to the output so far by this call to one of the **fwprintf** functions. No argument is converted.
C	Same as lc.
S	Same as ls.
%	Output a % wide-character; no argument is converted. The entire conversion specification must be %%.

If a conversion specification does not match one of the above forms, the behavior is undefined.

In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Characters generated by **fwprintf** and **wprintf** are printed as if **fputwc** had been called.

The **st_ctime** and **st_mtime** fields of the file will be marked for update between the call to a successful execution of **fwprintf** or **wprintf** and the next successful completion of a call to **fflush** or **fclose** on the same stream or a call to exit or abort.

Return Values

Upon successful completion, these functions return the number of wide-characters transmitted excluding the terminating null wide-character in the case of **swprintf** or a negative value if an output error was encountered.

Error Codes

For the conditions under which **fwprintf** and **wprintf** will fail and may fail, refer to **fputwc**. In addition, all forms of **fwprintf** may fail if:

Item	Description
EILSEQ	A wide-character code that does not correspond to a valid character has been detected
EINVAL	There are insufficient arguments.
	In addition, **wprintf** and **fwprintf** may fail if:
ENOMEM	Insufficient storage space is available.

The **swprintf** will fail if:

Item	Description
EOVERFLOW	The value of *n* is greater than {INT_MAX} or the number of bytes needed to hold the output excluding the terminating null is greater than {INT_MAX}.

Examples

To print the language-independent date and time format, the following statement could be used:

```
wprintf (format, weekday, month, day, hour, min);
```

For American usage, format could be a pointer to the wide-character string:

```
L"%s, %s %d, %d:%.2d\n"
```

producing the message:

```
Sunday, July 3, 10:02
```

whereas for German usage, format could be a pointer to the wide-character string:

```
L"%1$s, %3$d. %2$s, %4$d:%5$.2d\n"
```

producing the message:

```
Sonntag, 3. July, 10:02
```

fwscanf, wscanf, swscanf Subroutines

Purpose

Convert formatted wide-character input.

Library

Standard Library (**libc.a**)

Syntax

```
#include <stdio.h>
#include <wchar.h>
```

```
int fwscanf (FILE * stream, const wchar_t * format, ...);
int wscanf (const wchar_t * format, ...);
int swscanf (const wchar_t * s, const wchar_t * format, ...);
```

Description

The **fwscanf** function reads from the named input stream. The **wscanf** function reads from the standard input stream stdin. The **swscanf** function reads from the wide-character string s. Each function reads wide-characters, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control wide-character string format described below, and a set of pointer arguments indicating where the converted input should be stored. The result is undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.

Conversions can be applied to the **nth** argument after the **format** in the argument list, rather than to the next unused argument. In this case, the conversion wide-character % (see below) is replaced by the sequence **%n$,** where **n** is a decimal integer in the range [1, {NL_ARGMAX}]. This feature provides for

the definition of format wide-character strings that select arguments in an order appropriate to specific languages. In format wide-character strings containing the **%n$** form of conversion specifications, it is unspecified whether numbered arguments in the argument list can be referenced from the format wide-character string more than once.

The format can contain either form of a conversion specification, that is, % or **%n$,** but the two forms cannot normally be mixed within a single format wide-character string. The only exception to this is that %% or %* can be mixed with the **%n$** form.

The **fwscanf** function in all its forms allows for detection of a language-dependent radix character in the input string, encoded as a wide-character value. The radix character is defined in the program's locale (category LC_NUMERIC). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (.).

The format is a wide-character string composed of zero or more directives. Each directive is composed of one of the following: one or more white-space wide-characters (space, tab, newline, vertical-tab or form-feed characters); an ordinary wide-character (neither % nor a white-space character); or a conversion specification. Each conversion specification is introduced by a % or the sequence **%n$** after which the following appear in sequence:

- An optional assignment-suppressing character *.
- An optional non-zero decimal integer that specifies the maximum field width.
- An optional size modifier **h**, **H**, **l** (lowercase *L*), **L**, **D**, or **DD** indicating the size of the receiving object.
  - Must precede the **c**, **s** and **[** conversion wide-characters with the **l** (lowercase *L*) if the corresponding argument is a pointer to **wchar_t**.
  - Must precede the **d**, **i** and **n** conversion wide-characters with the **h** if the corresponding argument is a pointer to **short int** or with the **l** (lowercase *L*) if it is a pointer to **long int**.
  - Must precede the **o**, **u** and **x** conversion wide-characters with the **h** if the corresponding argument is a pointer to **unsigned short int** or with **l** (lowercase *L*) if it is a pointer to **unsigned long int**.
  - Must precede the **e**, **f** and **g** conversion wide-characters with **l** (lowercase *L*) if the corresponding argument is a pointer to **double** or with the **L** if it is a pointer to long double.
  - Must precede the **e**, **f** and **g** conversion wide-characters with the **H** if the corresponding argument is a pointer to**_Decimal32**.
  - Must precede the **e**, **f** and **g** conversion wide-characters with the **D** if the corresponding argument is a pointer to**_Decimal64**.
  - Must precede the **e**, **f** and **g** conversion wide-characters with the **DD** if the corresponding argument is a pointer to**_Decimal128**.

  If an **l** (lowercase *L*), **L**, **h**, **H**, **D**, or **DD** appears with any other conversion wide-character, the behavior is undefined.
- A conversion wide-character that specifies the type of conversion to be applied. The valid conversion wide-characters are described below.

The **fwscanf** functions execute each directive of the format in turn. If a directive fails, as detailed below, the function returns. Failures are described as input failures (due to the unavailability of input bytes) or matching failures (due to inappropriate input).

A directive composed of one or more white-space wide-characters is executed by reading input until no more valid input can be read, or up to the first wide-character which is not a white-space wide-character, which remains unread.

A directive that is an ordinary wide-character is executed as follows. The next wide-character is read from the input and compared with the wide-character that comprises the directive; if the comparison shows that they are not equivalent, the directive fails, and the differing and subsequent wide-characters remain unread.

A directive that is a conversion specification defines a set of matching input sequences, as described below for each conversion wide-character. A conversion specification is executed in the following steps:

Input white-space wide-characters (as specified by **iswspace**) are skipped, unless the conversion specification includes a [, c or n conversion character.

An item is read from the input, unless the conversion specification includes an n conversion wide-character. An input item is defined as the longest sequence of input wide-characters, not exceeding any specified field width, which is an initial subsequence of a matching sequence. The first wide-character, if any, after the input item remains unread. If the length of the input item is 0, the execution of the conversion specification fails; this condition is a matching failure, unless end-of-file, an encoding error, or a read error prevented input from the stream, in which case it is an input failure.

Except in the case of a % conversion wide-character, the input item (or, in the case of a %n conversion specification, the count of input wide-characters) is converted to a type appropriate to the conversion wide-character. If the input item is not a matching sequence, the execution of the conversion specification fails; this condition is a matching failure. Unless assignment suppression was indicated by a *, the result of the conversion is placed in the object pointed to by the first argument following the **format** argument that has not already received a conversion result if the conversion specification is introduced by %, or in the nth argument if introduced by the wide-character sequence %n$. If this object does not have an appropriate type, or if the result of the conversion cannot be represented in the space provided, the behavior is undefined.

The following conversion wide-characters are valid:

Item	Description
d	Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of **wcstol** with the value 10 for the base argument. In the absence of a size modifier, the corresponding argument must be a pointer to **int**.
i	Matches an optionally signed integer, whose format is the same as expected for the subject sequence of **wcstol** with 0 for the base argument. In the absence of a size modifier, the corresponding argument must be a pointer to **int**.
o	Matches an optionally signed octal integer, whose format is the same as expected for the subject sequence of **wcstoul** with the value 8 for the base argument. In the absence of a size modifier, the corresponding argument must be a pointer to **unsigned int**.
u	Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of **wcstoul** with the value 10 for the base argument. In the absence of a size modifier, the corresponding argument must be a pointer to **unsigned int**.
x	Matches an optionally signed hexadecimal integer, whose format is the same as expected for the subject sequence of **wcstoul** with the value 16 for the base argument. In the absence of a size modifier, the corresponding argument must be a pointer to **unsigned int**.
e, f, g	Matches an optionally signed floating-point number, whose format is the same as expected for the subject sequence of **wcstod** . In the absence of a size modifier, the corresponding argument must be a pointer to float. If the **fwprintf** family of functions generates character string representations for infinity and NaN (a 7858 symbolic entity encoded in floating-point format) to support the ANSI/IEEE Std 754:1985 standard, the **fwscanf**5 family of functions will recognise them as input.
s	Matches a sequence of non white-space wide-characters. If no l (ell) qualifier is present, characters from the input field are converted as if by repeated calls to the **wcrtomb** function, with the conversion state described by an **mbstate_t** object initialised to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence and the terminating null character, which will be added automatically. Otherwise, the corresponding argument must be a pointer to an array of **wchar_t** large enough to accept the sequence and the terminating null wide-character, which will be added automatically.

Item	Description
[	Matches a non-empty sequence of wide-characters from a set of expected wide-characters (the **scanset**). If no l (ell) qualifier is present, wide-characters from the input field are converted as if by repeated calls to the **wcrtomb** function, with the conversion state described by an **mbstate_t** object initialised to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence and the terminating null character, which will be added automatically. If an l (ell) qualifier is present, the corresponding argument must be a pointer to an array of **wchar_t** large enough to accept the sequence and the terminating null wide-character, which will be added automatically The conversion specification includes all subsequent wide characters in the **format** string up to and including the matching right square bracket (]). The wide-characters between the square brackets (the **scanlist**) comprise the scanset, unless the wide-character after the left square bracket is a circumflex (^), in which case the scanset contains all wide-characters that do not appear in the scanlist between the circumflex and the right square bracket. If the conversion specification begins with [ ] or [^], the right square bracket is included in the scanlist and the next right square bracket is the matching right square bracket that ends the conversion specification; otherwise the first right square bracket is the one that ends the conversion specification. If a - is in the scanlist and is not the first wide-character, nor the second where the first wide-character is a ^;, nor the last wide-character, the behavior is implementation-dependent.
c	Matches a sequence of wide-characters of the number specified by the field width (1 if no field width is present in the conversion specification). If no l (ell) qualifier is present, wide-characters from the input field are converted as if by repeated calls to the **wcrtomb** function, with the conversion state described by an **mbstate_t** object initialised to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence. No null character is added. Otherwise, the corresponding argument must be a pointer to an array of **wchar_t** large enough to accept the sequence. No null wide-character is added.
p	Matches an implementation-dependent set of sequences, which must be the same as the set of sequences that is produced by the %p conversion of the corresponding **fwprintf** functions. The corresponding argument must be a pointer to a pointer to void. The interpretation of the input item is implementation-dependent. If the input item is a value converted earlier during the same program execution, the pointer that results will compare equal to that value; otherwise the behavior of the %p conversion is undefined.
n	No input is consumed. The corresponding argument must be a pointer to the integer into which is to be written the number of wide-characters read from the input so far by this call to the **fwscanf** functions. Execution of a %n conversion specification does not increment the assignment count returned at the completion of execution of the function.
C	Same as lc.
S	Same as ls.
%	Matches a single %; no conversion or assignment occurs. The complete conversion specification must be %%.

If a conversion specification is invalid, the behavior is undefined.

The conversion characters E, G and X are also valid and behave the same as, respectively, e, g and x.

If end-of-file is encountered during input, conversion is terminated. If end-of-file occurs before any wide-characters matching the current conversion specification (except for %n) have been read (other than leading white-space, where permitted), execution of the current conversion specification terminates with an input failure. Otherwise, unless execution of the current conversion specification is terminated

with a matching failure, execution of the following conversion specification (if any) is terminated with an input failure.

Reaching the end of the string in **swscanf** is equivalent to encountering end-of-file for **fwscanf**.

If conversion terminates on a conflicting input, the offending input is left unread in the input. Any trailing white space (including newline) is left unread unless matched by a conversion specification. The success of literal matches and suppressed assignments is only directly determinable via the %n conversion specification.

The **fwscanf** and **wscanf** functions may mark the **st_atime** field of the file associated with stream for update. The **st_atime** field will be marked for update by the first successful execution of **fgetc**, **fgetwc**, **fgets**, **fgetws**, **fread**, **getc**, **getwc**, **getchar**, **getwchar**, **gets**, **fscanf** or **fwscanf** using stream that returns data not supplied by a prior call to **ungetc**.

In format strings containing the % form of conversion specifications, each argument in the argument list is used exactly once.

Return Values

Upon successful completion, these functions return the number of successfully matched and assigned input items; this number can be 0 in the event of an early matching failure. If the input ends before the first matching failure or conversion, EOF is returned. If a read error occurs the error indicator for the stream is set, EOF is returned, and errno is set to indicate the error.

Error Codes

For the conditions under which the **fwscanf** functions will fail and may fail, refer to **fgetwc**. In addition, **fwscanf** may fail if:

Item	Description
EILSEQ	Input byte sequence does not form a valid character.
EINVAL	There are insufficient arguments.

Examples

The call:

```
int i, n; float x; char name[50];
n = wscanf(L"%d%f%s", &i, &x, name);
```

with the input line:

```
25 54.32E-1 Hamster
```

will assign to n the value 3, to i the value 25, to x the value 5.432, and name will contain the string Hamster.

The call:

```
int i; float x; char name[50];
(void) wscanf(L"%2d%f%*d %[0123456789]", &i, &x, name);
```

with input:

```
56789 0123 56a72
```

will assign 56 to **i**, 789.0 to x, skip 0123, and place the string 56\0 in **name**. The next call to **getchar** will return the character a.

g

The following Base Operating System (BOS) runtime services begin with the letter *g*.

gai_strerror Subroutine

Purpose

Facilitates consistent error information from EAI_* values returned by the getaddrinfo subroutine.

Library

Library (**libc.a**)

Syntax

```
#include <sys/socket.h>
#include <netdb.h>
char *
gai_strerror (ecode)
int ecode;
int
gai_strerror_r (ecode, buf, buflen)
int ecode;
char *buf;
int buflen;
```

Description

For multithreaded environments, the second version should be used. In **gai_strerror_r**, *buf* is a pointer to a data area to be filled in. *buflen* is the length (in bytes) available in *buf*.

It is the caller's responsibility to insure that *buf* is sufficiently large to store the requested information, including a trailing null character. It is the responsibility of the function to insure that no more than *buflen* bytes are written into *buf*.

Return Values

If successful, a pointer to a string containing an error message appropriate for the EAI_* errors is returned. If ecode is not one of the EAI_* values, a pointer to a string indicating an unknown error is returned.

gamma Subroutine

Purpose

Computes the natural logarithm of the gamma function.

Libraries

The **gamma**: IEEE Math Library (**libm.a**) or System V Math Library (**libmsaa.a**)

Syntax

```
#include <math.h>
```

```
extern int signgam;
```

```
double gamma (x)
double x;
```

Description

The **gamma** subroutine computes the logarithm of the gamma function.

The sign of gamma(*x*) is returned in the external integer **signgam**.

Note: Compile any routine that uses subroutines from the **libm.a** with the **-lm** flag. To compile the **lgamma.c** file, enter:

```
cc lgamma.c -lm
```

Parameters

Item	Description
x	Specifies the value to be computed.

garbagedlines Subroutine

Purpose

Discards and replaces a number of lines in a window.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
garbagedlines(Window,  BegLine, NumLines)
WINDOW * Window;
int BegLine,  NumLines;
```

Description

The **garbagedlines** subroutine discards and replaces lines in a window. The *Begline* parameter specifies the beginning line number and the *Numlines* parameter specifies the number of lines to discard. Curses discards and replaces the specified lines before adding more data.

Uses this subroutine for applications that need to redraw a line that is garbled. Lines may become garbled as the result of noisy communication lines. Instead of refreshing the entire display, use the **garbagedlines** subroutine to refresh a portion of the display and to avoid even more communication noise.

Parameters

Item	Description
Window	Points to a window.
BegLine	Identifies the beginning line in a range of lines to discard.

Item	Description
NumLines	Specifies the total number of lines in a range of lines to discard and replace.

Examples

To discard and replace 5 lines in the `mywin` window starting with line `10`, use:

```
WINDOW *mywin; garbagedlines(mywin, 10, 5);
```

gencore or coredump Subroutine

Purpose

Creates a core file without terminating the process.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <core.h>

int gencore (coredumpinfop)
struct coredumpinfo *coredumpinfop;

int coredump (coredumpinfop)
struct coredumpinfo *coredumpinfop;
```

Description

The **gencore** and **coredump** subroutines create a core file of a process without terminating it. The core file contains the snapshot of the process at the time the call is made and can be used with the **dbx** command for debugging purposes.

If any thread of the process is in a system call when its snapshot core file is generated, the register information returned may not be reliable (except for the stack pointer). To save all user register contents when a system call is made so that they are available to the **gencore** and **coredump** subroutines, the application should be built using the `"-bM:UR"` flags.

If any thread of the process is sleeping inside the kernel or stopped (possibly for job control), the caller of the **gencore** and **coredump** subroutines will also be blocked until the thread becomes runnable again. Thus, these subroutines may take a long time to complete depending upon the target process state.

The **coredump** subroutine always generates a core file for the process from which it is called. This subroutine has been replaced by the **gencore** subroutine and is being provided for compatibility reasons only.

The **gencore** subroutine creates a core file for the process whose process ID is specified in the *pid* field of the **coredumpinfo** structure. For security measures, the user ID (uid) and group ID (gid) of the core file are set to the uid and gid of the process.

Both these subroutines return success even if the core file cannot be created completely because of filesystem space constraints. When using the **dbx** command with an incomplete core file, **dbx** may warn that the core file is truncated.

In the **"Change / Show Characteristics of Operating System"** smitty screen, there are two options regarding the creation of the core file. The core file will always be created in the default core format and will ignore the value specified in the **"Use pre-430 style CORE dump"** option. However, the value

specified for the **"Enable full CORE dump"** option will be considered when creating the core file. Resource limits of the target process for **file** and **coredump** will be enforced.

The **coredumpinfo** structure contains the following fields:

Member Type	Member Name	Description
unsigned int	*length*	Length of the core file name.
char *	*name*	Name of the core file.
pid_t	*pid*	ID of the process to be coredumped.
int	*flags*	Flags-version flag. Set this to **GENCORE_VERSION_1**.

Note: The *pid* and *flags* fields are required for the **gencore** subroutine, but are ignored for the **coredump** subroutine

Parameters

Item	Description
coredumpinfop	Specifies the address of the **coredumpinfo** structure that provides the file name to save the core snapshot and its length. For the **gencore** subroutine, it also provides the process id of the process whose core is to be dumped and a flag which includes version flag bits. The version flag value must be set to **GENCORE_VERSION_1**.

Return Values

Upon successful completion, the **gencore** and **coredump** subroutines return a 0. If unsuccessful, a -1 is returned, and the **errno** global variable is set to indicate the error

Error Codes

Item	Description
EACCES	Search permission is denied on a component of the path prefix, the file exists and permissions specified by the mode are denied, or the file does not exist and write permission is denied for the parent directory of the file to be created.
ENOENT	The *name* field in the *coredumpinfo* parameter points to an empty string.
EINTR	The subroutine was interrupted by a signal before it could complete.
ENAMETOOLONG	The value of the *length* field in the **coredumpinfop** structure or the length of the absolute path of the specified core file name is greater than **MAXPATHLEN** (as defined in the **sys/param.h** file).
EINVAL	The value of the *length* field in the **coredumpinfop** structure is 0.
EAGAIN	The target process is already in the middle of another **gencore** or **coredump** subroutine.
ENOMEM	Unable to allocate memory resources to complete the subroutine.

In addition to the above, the following **errno** values can be set when the **gencore** subroutine is unsuccessful:

Item	Description
EPERM	The real or effective user ID of the calling process does not match the real or effective user ID of target process or the calling process does not have root user authority.
ESRCH	There is no process whose ID matches the value specified in the *pid* field of the *coredumpinfop* parameter or the process is exiting.
EINVAL	The *flags* field in the *coredumpinfop* parameter is not set to a valid version value.

genpagvalue Subroutine

Purpose

Sets the current process credentials.

Library

Security Library (libc.a)

Syntax

```
#include <pag.h>
int  genpagvalue(pag_name, pag_value,pag_flags);
char *       pag_name;
uint64_t *   pag_value;
int           pag_flags;
```

Description

The **genpagvalue** subroutine generates a new PAG value for a given PAG name. For this function to succeed, the PAG name must be registered with the operating system before calling the **genpagvalue** subroutine. The **genpagvalue** subroutine is limited to maintaining information about the last generated PAG number and accordingly generating a new number. This service can optionally store the PAG value in the process's **cred** structure. It does not monitor the PAG values stored in the **cred** structure by other means.

The PAG value returned is of size 64 bits. The number of significant bits is determined by the requested PAG type. 32-bit PAGs have 32 significant bits. 64-bit PAGs have 62 significant bits.

A process must have root authority to invoke this function for 32-bit PAG types. Any process may invoke this function for 64-bit PAG types.

The *pag_flags* parameter with the value **PAG_SET_VALUE** causes the generated value to be atomically stored in the process's credentials. The *pag_flags* parameter with both the **PAG_SET_VALUE** and **PAG_COPY_CRED** values set causes the current process's credentials to be duplicated before the generated value is stored.

Parameters

Item	Description
pag_name	The name parameter is a 1 to 4 character, NULL terminated name for the PAG type. Typical values include `afs`, `dfs`, `pki` and `krb5`.
pag_value	This pointer points to a buffer where the OS will return the newly generated PAG value.

Item	Description
pag_flags	These flags control the behavior of the **getpagvalue** subroutine. This must be set to 0 or one or more of the values **PAG_SET_VALUE** or **PAG_COPY_CRED**.

Return Values

A value of 0 is returned upon successful completion. If the **genpagvalue** subroutine fails a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **genpagvalue** subroutine fails if one or more of the following are true:

Item	Description
EINVAL	The PAG value cannot be generated because the named PAG type does not exist as part of the table.
EPERM	The process does not have the correct authority to use the service.

Other errors might be set by subroutines invoked by the **genpagvalue** subroutine.

get_ipc_info Subroutine

Purpose

Get IPC information for a requested workload partition.

Syntax

```
#include <sys/ipc_info.h>

int get_ipc_info(cid, cmd, version, buffer, size)
cid_t cid;
int cmd;
int version;
char * buffer;
int * size;
```

Description

The **get_ipc_info** subroutine returns IPC information for the associated workload partition ID and copies it to the address specified for the *buffer* parameter. If *cid* parameter is zero, then the IPC information of the workload partition that is associated to the current process is returned. Based on the command specified for *cmd* that is requested, an array of corresponding structures will be copied to the address starting at the address specified for *buffer*. The number of array structures depends on the number of IPC objects of the requested type that are present.

The value specified for the *cid* parameter is not used as input to the **GET_IPCINFO_SHM_ALL**, **GET_IPCINFO_MSG_ALL**, and **GET_IPCINFO_SEM_ALL** commands. These commands are useful from the global workload partition to return IPC information for all workload partitions on the system.

If the value for the *size* parameter on input is smaller than the data to be returned, then **ENOSPC** is returned and the value for the *size* parameter is set to the actual size needed.

Parameters

Item	Description
cid	Specifies the workload partition ID.

Item	Description
cmd	Specifies which request command to perform. See **cmd types** for a list of possible commands.
version	Specifies which version of the request structure to return. Valid versions are specified in the **sys/ipc_info.h** header file.
buffer	Specifies the starting address for the requested IPC structures.
size	Specifies the maximum number of bytes to return.

Cmd types

The *cmd* parameter is supplied on input and describes the type of IPC information to return. The following *cmd* types are supported:

Item	Description
GET_IPCINFO_SHM	Returns System V shared memory structures *ipcinfo_shm_t* for the requested workload partition.
GET_IPCINFO_MSG	Returns System V message queue structures *ipcinfo_msg_t* for the requested workload partition.
GET_IPCINFO_SEM	Returns System V semaphore structures *ipcinfo_sem_t* for the requested workload partition.
GET_IPCINFO_RTSHM	Returns POSIX real-time shared memory structures *ipcinfo_rtshm_t* for the requested workload partition.
GET_IPCINFO_RTMSG	Returns POSIX real-time message queue structures *ipcinfo_rtmq_t* for the requested workload partition.
GET_IPCINFO_RTSEM	Returns POSIX real-time semaphore structures *ipcinfo_rtsem_t* for the requested workload partition.
GET_IPCINFO_SHM_ALL	Returns all System V shared memory structures *ipcinfo_shm_t* that are accessible by the current process.
GET_IPCINFO_MSG_ALL	Returns all System V message queue structures *ipcinfo_msg_t* that are accessible by the current process.
GET_IPCINFO_SEM_ALL	Returns all System V semaphore structures *ipcinfo_sem_t* that are accessible by the current process.

Execution Environment

Process environment only.

Return Values

Item	Description
0	The command completed successfully.
EPERM	Error indicating the current process does not have permission to retrieve workload partition information for the WPAR ID specified for the *cid* parameter.
EINVAL	Invalid value specified for the *cmd*, *version*, or *cid* parameters.
EFAULT	Error during the **copyout** to user space.
ENOSPC	Size for the *buffer* parameter that is indicated by the *size* parameter is smaller than the data to be returned.

get_malloc_log Subroutine

Purpose

Retrieves information about the malloc subsystem.

Syntax

```
#include <malloc.h>
size_t get_malloc_log (addr, buf, bufsize)
void *addr;
void *buf;
size_t bufsize;
```

Description

The **get_malloc_log** subroutine retrieves a record of currently active malloc allocations. These records are stored as an array of **malloc_log** structures, which are copied from the process heap into the buffer specified by the *buf* parameter. No more than *bufsize* bytes are copied into the buffer. Only records corresponding to the heap of which *addr* is a member are copied, unless *addr* is NULL, in which case records from all heaps are copied. The *addr* parameter must be either a pointer to space allocated previously by the malloc subsystem or NULL.

Parameters

Item	Description
addr	Pointer to a space allocated by the malloc subsystem.
buf	Specifies into which buffer the **malloc_log** structures are stored.
bufsize	Specifies the number of bytes that can be copied into the buffer.

Return Values

The **get_malloc_log** subroutine returns the number of bytes actually transferred into the *bufsize* parameter. If Malloc Log is not enabled, 0 is returned. If *addr* is not a pointer allocated by the malloc subsystem, 0 is returned and the **errno** global variable is set to **EINVAL**.

get_malloc_log_live Subroutine

Purpose

Provides information about the malloc subsystem.

Syntax

```
#include <malloc.h>
struct malloc_log* get_malloc_log_live (addr)
void *addr;
```

Description

The **get_malloc_log_live** subroutine provides access to a record of currently active malloc allocations. The information is stored as an array of **malloc_log** structures, which are located in the process heap. This data is volatile and subject to update. The *addr* parameter must be either a pointer to space allocated previously by the malloc subsystem or NULL.

Parameters

Item	Description
addr	Pointer to space allocated previously by the malloc subsystem

Return Values

The **get_malloc_log_live** subroutine returns a pointer to the process heap at which the records of current malloc allocations are stored. If the *addr* parameter is NULL, a pointer to the beginning of the array is returned. If *addr* is a pointer to space allocated previously by the malloc subsystem, the pointer returned corresponds to records of the same heap as *addr*. If Malloc Log is not enabled, NULL is returned. If *addr* is not a pointer allocated by the malloc subsystem, NULL is returned and the **errno** global variable is set to **EINVAL**.

get_speed, set_speed, or reset_speed Subroutines

Purpose

Set and get the terminal baud rate.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/str_tty.h>
```

```
int get_speed (FileDescriptor)
int FileDescriptor;
```

```
int set_speed (FileDescriptor, Speed)
int FileDescriptor;
int Speed;
```

```
int reset_speed (FileDescriptor)
int FileDescriptor;
```

Description

The baud rate functions **set_speed** subroutine and **get_speed** subroutine are provided top allow the user applications to program any value of the baud rate that is supported by the asynchronous adapter, but that cannot be expressed using the termios subroutines **cfsetospeed**, **cfsetispeed**, **cfgetospeed**, and **cfsgetispeed**. Those subroutines are indeed limited to the set values {BO, B50, ..., B38400} described in <**termios.h**>.

Interaction with the termios Baud flags:

If the terminal's device driver supports these subroutines, it has two interfaces for baud rate manipulation.

Operation for Baud Rate:

normal mode: This is the default mode, in which a termios supported speed is in use.

speed-extended mode: This mode is entered either by calling **set_speed** subroutine a non-termios supported speed at the configuration of the line.

In this mode, all the calls to **tcgetattr** subroutine or **TCGETS ioctl** subroutine will have B50 in the returned termios structure.

If **tcsetatt** subroutine or **TCSETS**, **TCSETAF**, or **TCSETAW ioctl** subroutines is called and attempt to set B50, the actual baud rate is not changed. If is attempts to set any other termios-supported speed, the driver will switch back to the normal mode and the requested baud rate is set. Calling **reset_speed** subroutine is another way to switch back to the normal mode.

Parameters

Item	Description
FileDescriptor	Specifies an open file descriptor.
Speed	The integer value of the requested speed.

Return Values

Upon successful completion, **set_speed** and **reset_speed** return a value of 0, and **get_speed** returns a positive integer specifying the current speed of the line. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

Item	Description
EINVAL	The *FileDescriptor* parameter does not specify a valid file descriptor for a **tty** the recognizes the **set_speed**, **get_speed** and **reset_speed** subroutines, or the *Speed* parameter of **set_speed** is not supported by the terminal.

Plus all the **errno** codes that may be set in case of failure in an **ioctl** subroutine issued to a streams based **tty**.

getargs Subroutine

Purpose

Gets arguments of a process.

Library

Standard C library (**libc.a)**

Syntax

```
#include <procinfo.h>
#include <sys/types.h>

int getargs (processBuffer, bufferLen, argsBuffer, argsLen)
struct procsinfo  *processBuffer
or struct procentry64  *processBuffer;
int  bufferLen;
char  *argsBuffer;
int  argsLen;
```

Description

The **getargs** subroutine returns a list of parameters that were passed to a command when it was started. Only one process can be examined per call to **getargs**.

The **getargs** subroutine uses the pi_pid field of *processBuffer* to determine which process to look for. *bufferLen* should be set to the size of **struct procsinfo** or **struct procentry64**. Parameters are returned in *argsBuffer*, which should be allocated by the caller. The size of this array must be given in *argsLen*.

On return, *argsBuffer* consists of a succession of strings, each terminated with a null character (ascii `\0'). Hence, two consecutive NULLs indicate the end of the list.

Note: The arguments may be changed asynchronously by the process, but results are not guaranteed to be consistent.

Parameters

processBuffer
Specifies the address of a **procsinfo** or **procentry64** structure, whose pi_pid field should contain the pid of the process that is to be looked for.

bufferLen
Specifies the size of a single **procsinfo** or **procentry64** structure.

argsBuffer
Specifies the address of an array of characters to be filled with a series of strings representing the parameters that are needed. An extra NULL character marks the end of the list. This array must be allocated by the caller.

argsLen
Specifies the size of the *argsBuffer* array. No more than *argsLen* characters are returned.

Return Values

If successful, the **getargs** subroutine returns zero. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **getargs** subroutine does not succeed if the following are true:

Item	Description
ESRCH	The specified process does not exist.
EFAULT	The copy operation to the buffer was not successful or the *processBuffer* or *argsBuffer* parameters are invalid.
EINVAL	The *bufferLen* parameter does not contain the size of a single **procsinfo** or **procentry64** structure.
ENOMEM	There is no memory available in the address space.

getaudithostattr, IDtohost, hosttoID, nexthost or putaudithostattr Subroutine

Purpose

Accesses the host information in the audit host database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>

int  getaudithostattr (Hostname, Attribute, Value, Type)
char *Hostname;
char *Attribute;
void *Value;
int Type;

char *IDtohost (ID);
char *ID;

char *hosttoID (Hostname, Count);
char *Hostname;
int Count;

char *nexthost (void);

int putaudithostattr (Hostname, Attribute, Value, Type);
char *Hostname;
char *Attribute;
void *Value;
int Type;
```

Description

These subroutines access the audit host information.

The **getaudithostattr** subroutine reads a specified attribute from the host database. If the database is not already open, this subroutine does an implicit open for reading.

Similarly the **putaudithostattr** subroutine writes a specified attribute into the host database. If the database is not already open, this subroutine does an implicit open for reading and writing. Data changed by the **putaudithostattr** must be explicitly committed by calling the **putaudithostattr** subroutine with a Type of **SEC_COMMIT**. Until all the data is committed, only these subroutines within the process return written data.

New entries in the host database must first be created by invoking **putaudithostattr** with the **SEC_NEW** type.

The **IDtohost** subroutine converts an 8 byte host identifier into a hostname.

The **hosttoID** subroutine converts a hostname to a pointer to an array of valid 8 byte host identifiers. A pointer to the array of identifiers is returned on success. A **NULL** pointer is returned on failure. The number of known host identifiers is returned in ***Count**.

The **nexthost** subroutine returns a pointer to the name of the next host in the audit host database.

Parameters

Item	Description
Attribute	Specifies which attribute is read. The following possible attributes are defined in the **usersec.h** file: **S_AUD_CPUID** Host identifier list. The attribute type is **SEC_LIST**.
Count	Specifies the number of 8 byte host identifier entries that are available in the *IDarray* parameter or that have been returned in the *IDarray* parameter.
Hostname	Specifies the name of the host for the operation.

Item	Description
ID	An 8 byte host identifier.
IDarray	Specifies a pointer to an array of 1 or more 8 byte host identifiers.
Type	Specifies the type of attribute expected. Valid types are defined in **usersec.h**. The only valid Type value is **SEC_LIST**.
Value	The return value for read operations and the new value for write operations.

Return Values

On successful completion, the **getaudithostattr**, **IDtohost**, **hosttoID**, **nexthost**, or **putaudithostattr** subroutine returns 0. If unsuccessful, the subroutine returns non-zero.

Error Codes

The **getaudithostattr**, **IDtohost**, **hosttoID**, **nexthost**, or **putaudithostattr** subroutine fails if the following is true:

Item	Description
EINVAL	If invalid attribute *Name* or if *Count* is equal to zero for the **hosttoID** subroutine.
ENOENT	If there is no matching *Hostname* entry in the database.

getauthattr Subroutine

Purpose

Queries the authorizations that are defined in the authorization database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>

int getauthattr(Auth, Attribute, Value, Type)
    char *Auth;
    char *Attribute;
    void *Value;
    int Type;
```

Description

The **getauthattr** subroutine reads a specified attribute from the authorization database. The **getauthattr** subroutine can retrieve authorization definitions from both the user-defined authorization database and the system-defined authorization table. For attributes of the **SEC_CHAR** and **SEC_LIST** types, the **getauthattr** subroutine returns the value in allocated memory. The caller needs to free this memory.

Parameters

Item	Description
Auth	The authorization name. This parameter must be specified unless the *Type* parameter is **SEC_COMMIT**.
Attribute	Specifies which attribute is read. The following possible attributes are defined in the **usersec.h** file: **S_AUTHORIZATIONS** A list of all available authorizations on the system. This attribute is read-only and is only available to the **getauthattr** subroutine when **ALL** is specified for the *Auth* parameter. The attribute type is **SEC_LIST**. **S_AUTH_CHILDREN** A list of all authorizations that exist in the authorization hierarchy below the authorization specified by the *Auth* parameter. This attribute is read-only and is available only to the **getauthattr** subroutine. The attribute type is **SEC_LIST**. **S_DFLTMSG** Specifies the default authorization description to use if message catalogs are not in use. The attribute type is **SEC_CHAR**. **S_ID** Specifies a unique integer that is used to identify the authorization. The attribute type is **SEC_INT**. **Note:** Do not modify this value after it is set initially when the authorization is created. Modifying the value might compromise the security of the system. **S_MSGCAT** Specifies the message catalog file name that contains the description of the authorization. The attribute type is **SEC_CHAR**. **S_MSGSET** Specifies the message set that contains the description of the authorization in the file that the **S_MSGCAT** attribute specifies. The attribute type is **SEC_INT**. **S_MSGNUMBER** Specifies the message number for the description of the authorization in the file that the **S_MSGCAT** attribute specifies and the message set that the **S_MSGSET** attribute specifies. The attribute type is **SEC_INT**. **S_ROLES** A list of roles using this authorization. This attribute is read-only. The attribute type is **SEC_LIST**.
Value	Specifies a buffer, a pointer to a buffer, or a pointer to a pointer depending on the *Attribute* and *Type* parameters. See the *Type* parameter for more details.

Item	Description
Type	Specifies the type of attribute expected. Valid types are defined in the **usersec.h** file and include: **SEC_INT** The format of the attribute is an integer. The user should supply a pointer to a defined integer variable. **SEC_CHAR** The format of the attribute is a null-terminated character string. The user should supply a pointer to a defined character pointer variable. The value is returned as allocated memory. The caller needs to free this memory. **SEC_LIST** The format of the attribute is a series of concatenated strings, each null-terminated. The last string in the series is terminated by two successive null characters. The user should supply a pointer to a defined character pointer variable. The value is returned as allocated memory. The caller needs to free this memory.

Security

Files Accessed:

File	Mode
/etc/security/ authorizations	rw

Return Values

If successful, the **getauthattr** subroutine returns 0. Otherwise, a value of -1 is returned and the **errno** global value is set to indicate the error.

Error Codes

If the **getauthattr** subroutine fails, one of the following **errno** values can be set:

Item	Description
EINVAL	The *Auth* parameter is **NULL** or one of the reserved authorization names (**default, ALLOW_OWNER, ALLOW_GROUP, ALLOW_ALL**).
EINVAL	The *Attribute* or *Type* parameter is **NULL** or does not contain one of the defined values.
EINVAL	The *Auth* parameter is **ALL** and the *Attribute* parameter is not **S_AUTHORIZATIONS**.
EINVAL	The *Value* parameter does not point to a valid buffer for this type of attribute.
ENOATTR	The *Attribute* parameter is **S_AUTHORIZATIONS**, but the *Auth* parameter is not **ALL**.
ENOATTR	The attribute specified in the *Attribute* parameter is valid but no value is defined for the authorization.
ENOENT	The authorization specified in the *Auth* parameter does not exist.
ENOMEM	Memory cannot be allocated.
EPERM	The operation is not permitted.
EACCES	Access permission is denied for the data request.

getauthattrs Subroutine

Purpose

Retrieves multiple authorization attributes from the authorization database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>

int getauthattrs(Auth, Attributes, Count)
    char *Auth;
    dbattr_t *Attributes;
    int Count;
```

Description

The **getauthattrs** subroutine reads one or more attributes from the authorization database. The **getauthattrs** subroutine can retrieve authorization definitions from both the user-defined authorization database and the system-defined authorization table.

The *Attributes* array contains information about each attribute that is to be read. Each element in the *Attributes* array must be examined upon a successful call to the **getauthattrs** subroutine, to determine whether the *Attributes* array was successfully retrieved. The attributes of the **SEC_CHAR** or **SEC_LIST** type will have their values returned to allocated memory. The caller need to free this memory. The **dbattr_t data** structure contains the following fields:

Item	Description
attr_name	The name of the target authorization attribute.
attr_idx	This attribute is used internally by the **getauthattrs** subroutine.
attr_type	The type of a target attribute.
attr _flag	The result of the request to read the target attribute. On successful completion, a value of zero is returned. Otherwise, a value of nonzero is returned.
attr_un	A union that contains the returned values for the requested query.
attr_domain	The **getauthattrs** subroutine ignores any input to this field. If this field is set to null, the subroutine sets this field to the name of the domain where the authorization is found.

The following valid authorization attributes for the **getauthattrs** subroutine are defined in the **usersec.h** file:

Name	Description	Type
S_AUTHORIZATIONS	A list of all available authorizations on the system. It is valid only when the *Auth* parameter is set to the **ALL** variable.	**SEC_LIST**
S_AUTH_CHILDREN	A list of all authorizations that exist in the authorization hierarchy under the authorization that is specified by the *Auth* parameter.	**SEC_LIST**

Name	Description	Type
S_DFLTMSG	The default authorization description that is used when catalogs are not in use.	**SEC_CHAR**
S_ID	A unique integer that is used to identify the authorization.	**SEC_INT**
S_MSGCAT	The message catalog name that contains the authorization description.	**SEC_CHAR**
S_MSGSET	The message catalog set number of the authorization description.	**SEC_INT**
S_MSGNUMBER	The message number of the authorization description.	**SEC_INT**
S_ROLES	A list of roles that contain the authorization in their authorization set.	**SEC_LIST**

The following union members correspond to the definitions of the **attr_char**, **attr_int**, **attr_long** and **attr_llong** macros in the **usersec.h** file:

Item	Description
au_char	Attributes of the **SEC_CHAR** and **SEC_LIST** types store a pointer to the returned value in this member when the attributes are successfully retrieved. The caller is responsible for freeing this memory.
au_int	The storage location for attributes of the **SEC_INT** type.
au_long	The storage location for attributes of the **SEC_LONG** type.
au_llong	The storage location for attributes of the **SEC_LLONG** type.

If **ALL** is specified for the *Auth* parameter, the only valid attribute that can be displayed in the *Attribute* array is the **S_AUTHORIZATIONS** attribute. Specifying any other attribute with an authorization name of **ALL** causes the **getauthattrs** subroutine to fail.

Parameters

Item	Description
Auth	Specifies the authorization name for the *Attributes* array to read.
Attributes	A pointer to an array of zero or more elements of the **dbattr_t** type. The list of authorization attributes is defined in the **usersec.h** header file.
Count	The number of array elements in the *Attributes* array.

Security

Files Accessed:

File	Mode
/etc/security/ authorizations	r

Return Values

If the authorization that is specified by the *Auth* parameter exists in the authorization database, the **getauthattrs** subroutine returns the value of zero. On successful completion, the **attr_flag** attribute of each element in the *Attributes* array must be examined to determine whether it was successfully retrieved. If the specified authorization does not exist, a value of -1 is returned and the **errno** value is set to indicate the error.

Error Codes

If the **getauthattrs** subroutine returns -1, one of the following **errno** values is set:

Item	Description
EINVAL	The *Auth* parameter is **NULL, default, ALLOW_OWNER, ALLOW_GROUP**, or **ALLOW_ALL**.
EINVAL	The *Count* parameter is less than zero.
EINVAL	The *Attributes* array is **NULL** and the *Count* parameter is greater than zero.
EINVAL	The *Auth* parameter is **ALL** but the Attributes entry contains an attribute other than **S_AUTHORIZATIONS**.
ENOENT	The authorization specified in the *Auth* parameter does not exist.
ENOMEM	Memory cannot be allocated.
EPERM	Operation is not permitted.
EACCES	Access permission is denied for the data request.

If the **getauthattrs** subroutine fails to query an attribute, one of the following errors is returned to the **attr_flag** field of the corresponding *Attributes* element:

Item	Description
EACCES	The invoker does not have access to the attribute specified in the **attr_name** field.
EINVAL	The **attr_name** field in the *Attributes* entry is not a recognized authorization attribute.
EINVAL	The **attr_type** field in the *Attributes* entry contains a type that is not valid.
EINVAL	The **attr_un** field in the *Attributes* entry does not point to a valid buffer.
ENOATTR	The **attr_name** field in the *Attributes* entry specifies a valid attribute, but no value is defined for this authorization.

getauthdb or getauthdb_r Subroutine

Purpose

Finds the current administrative domain.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <usersec.h>

int getauthdb (Value)
authdb_t *Value;

int getauthdb_r (Value)
authdb_t *Value;
```

Description

The **getauthdb** and **getauthdb_r** subroutines return the value of the current authentication domain in the *Value* parameter. The **getauthdb** subroutine returns the value of the current process-wide authentication domain. The **getauthdb_r** subroutine returns the authentication domain for the current thread if one has been set. The subroutines return -1 if no administrative domain has been set.

Parameters

Item	Description
Value	A pointer to a variable of type **authdb_t**. The **authdb_t** type is a 16-character array that contains the name of a loadable authentication module.

Return Values

Item	Description
1	The value returned is from the process-wide data.
0	The value returned is from the thread-specific data. An authentication database module has been specified by an earlier call to the **setauthdb** subroutine. The name of the current database module has been copied to the *Value* parameter.
-1	The subroutine failed. An authentication database module has not been specified by an earlier call to the **setauthdb** subroutine.

getbegyx, getmaxyx, getparyx, or getyx Subroutine

Purpose

Gets the cursor and window coordinates.

Library

Curses Library (**libcurses.a**)

Syntax

```
include <curses.h>
```

```
void getbegyx(WINDOW  *win,
int  y,
int  x);
```

```
void getmaxyx(WINDOW *win,
int y,
int x);
```

```
void getparyx(WINDOW *win,
int y,
int x);
```

```
void getyx(WINDOW *win,
int y,
int x);
```

Description

The **getbegyx** macro stores the absolute screen coordinates of the specified window's origin in *y* and *x*.

The **getmaxyx** macro stores the number of rows of the specified window in *y* and *x* and stores the window's number of columns in *x*.

The **getparyx** macro, if the specified window is a subwindow, stores in *y* and *x* the coordinates of the window's origin relative to its parent window. Otherwise, -1 is stored in *y* and *x*.

The **getyx** macro stores the cursor position of the specified window in *y* and *x*.

Parameters

Item	Description
**win*	Identifies the window to get the coordinates from.
Y	Returns the row coordinate.
X	Returns the column coordinate.

Examples

For the **getbegyx** subroutine:

To obtain the beginning coordinates for the `my_win` window and store in integers *y* and *x*, use:

```
WINDOW *my_win;
int y, x;
getbegyx(my_win, y, x);
```

For the **getmaxyx** subroutine:

To obtain the size of the `my_win` window, use:

```
WINDOW *my_win;

int y,x;
getmaxyx(my_win, y, x);
```

Integers *y* and *x* will contain the size of the window.

getc, getchar, fgetc, or getw Subroutine

Purpose

Gets a character or word from an input stream.

Library

Standard I/O Package (**libc.a**)

Syntax

```
#include <stdio.h>
```

int getc (*Stream***)**
FILE ****Stream*;**

```
int fgetc (Stream)
FILE *Stream;
```

```
int getchar (void)
```

```
int getw (Stream)
FILE *Stream;
```

Description

The **getc** macro returns the next byte as an **unsigned char** data type converted to an **int** data type from the input specified by the *Stream* parameter and moves the file pointer, if defined, ahead one byte in the *Stream* parameter. The **getc** macro cannot be used where a subroutine is necessary; for example, a subroutine pointer cannot point to it.

Because it is implemented as a macro, the **getc** macro does not work correctly with a *Stream* parameter value that has side effects. In particular, the following does not work:

```
getc(*f++)
```

In such cases, use the **fgetc** subroutine.

The **fgetc** subroutine performs the same function as the **getc** macro, but **fgetc** is a true subroutine, not a macro. The **fgetc** subroutine runs more slowly than **getc** but takes less disk space.

The **getchar** macro returns the next byte from **stdin** (the standard input stream). The **getchar** macro is equivalent to **getc(stdin)**.

The first successful run of the **fgetc**, **fgets**, **fgetwc**, **fgetws**, **fread**, **fscanf**, **getc**, **getchar**, **gets** or **scanf** subroutine using a stream that returns data not supplied by a prior call to the **ungetc** or **ungetwc** subroutine marks the `st_atime` field for update.

The **getc** and **getchar** macros have also been implemented as subroutines for ANSI compatibility. To access the subroutines instead of the macros, insert **#undef getc** or **#undef getchar** at the beginning of the source file.

The **getw** subroutine returns the next word (**int**) from the input specified by the *Stream* parameter and increments the associated file pointer, if defined, to point to the next word. The size of a word varies from one machine architecture to another. The **getw** subroutine returns the constant **EOF** at the end of the file or when an error occurs. Since **EOF** is a valid integer value, the **feof** and **ferror** subroutines should be used to check the success of **getw**. The **getw** subroutine assumes no special alignment in the file.

Because of additional differences in word length and byte ordering from one machine architecture to another, files written using the **putw** subroutine are machine-dependent and may not be readable using the **getw** macro on a different type of processor.

Parameters

Item	Description
Stream	Points to the file structure of an open file.

Return Values

Upon successful completion, the **getc**, **fgetc**, **getchar**, and **getw** subroutines return the next byte or **int** data type from the input stream pointed by the *Stream* parameter. If the stream is at the end of the file, an end-of-file indicator is set for the stream and the integer constant **EOF** is returned. If a read error occurs, the **errno** global variable is set to reflect the error, and a value of **EOF** is returned. The **ferror** and **feof** subroutines should be used to distinguish between the end of the file and an error condition.

Error Codes

If the stream specified by the *Stream* parameter is unbuffered or data needs to be read into the stream's buffer, the **getc**, **getchar**, **fgetc**, or **getw** subroutine is unsuccessful under the following error conditions:

Item	Description
EAGAIN	Indicates that the **O_NONBLOCK** flag is set for the file descriptor underlying the stream specified by the *Stream* parameter. The process would be delayed in the **fgetc** subroutine operation.
EBADF	Indicates that the file descriptor underlying the stream specified by the *Stream* parameter is not a valid file descriptor opened for reading.
EFBIG	Indicates that an attempt was made to read a file that exceeds the process' file-size limit or the maximum file size. See the **ulimit** subroutine.
EINTR	Indicates that the read operation was terminated due to the receipt of a signal, and either no data was transferred, or the implementation does not report partial transfer for this file. **Note:** Depending upon which library routine the application binds to, this subroutine may return **EINTR**. Refer to the **signal** subroutine regarding **sa_restart**.
EIO	Indicates that a physical error has occurred, or the process is in a background process group attempting to perform a **read** subroutine call from its controlling terminal, and either the process is ignoring (or blocking) the **SIGTTIN** signal or the process group is orphaned.
EPIPE	Indicates that an attempt is made to read from a pipe or first-in-first-out (FIFO) that is not open for reading by any process. A **SIGPIPE** signal will also be sent to the process.
EOVERFLOW	Indicates that the file is a regular file and an attempt was made to read at or beyond the offset maximum associated with the corresponding stream.

The **getc**, **getchar**, **fgetc**, or **getw** subroutine is also unsuccessful under the following error conditions:

Item	Description
ENOMEM	Indicates insufficient storage space is available.
ENXIO	Indicates either a request was made of a nonexistent device or the request was outside the capabilities of the device.

getc_unlocked, getchar_unlocked, putc_unlocked, putchar_unlocked Subroutines

Purpose

stdio with explicit client locking.

Library

Standard Library (**libc.a**)

Syntax

```
#include <stdio.h>
```

```
int getc_unlocked (FILE * stream);
int getchar_unlocked (void);
int putc_unlocked (int c, FILE * stream);
int putchar_unlocked (int c);
```

Description

Versions of the functions **getc**, **getchar**, **putc**, and **putchar** respectively named **getc_unlocked**, **getchar_unlocked**, **putc_unlocked**, and **putchar_unlocked** are provided which are functionally identical to the original versions with the exception that they are not required to be implemented in a thread-safe manner. They may only safely be used within a scope protected by **flockfile** (or **ftrylockfile**) and **funlockfile**. These functions may safely be used in a multi-threaded program if and only if they are called while the invoking thread owns the (FILE*) object, as is the case after a successful call of the **flockfile** or **ftrylockfile** functions.

Return Values

See **getc**, **getchar**, **putc**, and **putchar**.

getch, mvgetch, mvwgetch, or wgetch Subroutine

Purpose

Gets a single-byte character from the terminal.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

int getch(void)

int mvgetch(int y,
int x);
```

```
int mvwgetch(WINDOW *win,
int y,
int x);

int wgetch(WINDOW *win);
```

Description

The **getch**, **wgetch**, **mvgetch**, and **mvwgetch** subroutines read a single-byte character from the terminal associated with the current or specified window. The results are unspecified if the input is not a single-byte character. If the **keypad** subroutine is enabled, these subroutines respond to the corresponding KEY_ value defined in <curses.h>.

Processing of terminal input is subject to the general rules described in Section 3.5 on page 34.

If echoing is enabled, then the character is echoed as though it were provided as an input argument to the **addch** subroutine, except for the following characters:

```
<backspace>,
```

```
<left-arrow> and
```

```
the current erase character:
```

The input is interpreted as specified in Section 3.4.3 on page 31 and then the character at the resulting cursor position is deleted as though the **delch** subroutine was called, except that if the cursor was originally in the first column of the line, then the user is alerted as though the **beep** subroutine was called.

The user is alerted as though the **beep** subroutine was called. Information concerning the function keys is not returned to the caller.

Function Keys

If the current or specified window is not a pad, and it has been moved or modified since the last refresh operation, then it will be refreshed before another character is read.

The Importance of Terminal Modes

The output of the **getch** subroutines is, in part, determined by the mode of the terminal. The following describes the action of the **getch** subroutines in each type of terminal mode:

Mode	Action of getch Subroutines
NODELAY	Returns a value of ERR if there is no input waiting.
DELAY	Halts execution until the system passes text through the program. If CBREAK mode is also set, the program stops after receiving one character. If **NOCBREAK** mode is set, the **getch** subroutine stops reading after the first new line character.
HALF-DELAY	Halts execution until a character is typed or a specified time out is reached. If **echo** is set, the character is also echoed to the window.

Note: When using the **getch** subroutines do not set both the **NOCBREAK** mode and the **ECHO** mode at the same time. This can cause undesirable results depending on the state of the tty driver when each character is typed.

Getting Function Keys

If your program enables the keyboard with the **keypad** subroutine, and the user presses a function key, the token for that function key is returned instead of raw characters. The possible function keys are defined in the **/usr/include/curses.h** file. Each **#define** macro begins with a **KEY_** prefix.

If a character is received that could be the beginning of a function key (such as an Escape character) curses sets a timer. If the remainder of the sequence is not received before the timer expires, the

character is passed through. Otherwise, the function key's value is returned. For this reason, after a user presses the Esc key there is a delay before the escape is returned to the program. Programmers should not use the Esc key for a single character routine.

Within the **getch** subroutine, a structure of type timeval, defined in the **/usr/include/sys/time.h** file, indicates the maximum number of microseconds to wait for the key response to complete.

The **ESCDELAY** environment variable sets the length of time to wait before timing out and treating the ESC keystroke as the ESC character rather than combining it with other characters in the buffer to create a key sequence. The **ESCDELAY** environment variable is measured in fifths of a millisecond. If **ESCDELAY** is 0, the system immediately composes the **ESCAPE** response without waiting for more information from the buffer. The user may choose any value between 0 and 99,999, inclusive. The default setting for the **ESCDELAY** environment variable is 500 (one tenth of a second).

Programs that do not want the **getch** subroutines to set a timer can call the **notimeout** subroutine. If notimeout is set to TRUE, curses does not distinguish between function keys and characters when retrieving data.

The **getch** subroutines might not be able to return all function keys because they are not defined in the **terminfo** database or because the terminal does not transmit a unique code when the key is pressed. The following function keys may be returned by the **getch** subroutines:

Item	Description
KEY_MIN	Minimum curses key.
KEY_BREAK	Break key (unreliable).
KEY_DOWN	Down Arrow key.
KEY_UP	Up Arrow key.
KEY_LEFT	Left Arrow key.
KEY_RIGHT	Right Arrow key.
KEY_HOME	Home key.
KEY_BACKSPACE	Backspace.
KEY_F(*n*)	Function key F*n*, where *n* is an integer from 0 to 64.
KEY_DL	Delete line.
KEY_IL	Insert line.
KEY_DC	Delete character.
KEY_IC	Insert character or enter insert mode.
KEY_EIC	Exit insert character mode.
KEY_CLEAR	Clear screen.
KEY_EOS	Clear to end of screen.
KEY_EOL	Clear to end of line.
KEY_SF	Scroll 1 line forward.
KEY_SR	Scroll 1 line backwards (reverse).
KEY_NPAGE	Next page.
KEY_PPAGE	Previous page.
KEY_STAB	Set tab.
KEY_CTAB	Clear tab.
KEY_CATAB	Clear all tabs.

Item	Description
KEY_ENTER	Enter or send (unreliable).
KEY_SRESET	Soft (partial) reset (unreliable).
KEY_RESET	Reset or hard reset (unreliable).
KEY_PRINT	Print or copy.
KEY_LL	Home down or bottom (lower left).
KEY_A1	Upper-left key of keypad.
KEY_A3	Upper-right key of keypad.
KEY_B2	Center-key of keypad.
KEY_C1	Lower-left key of keypad.
KEY_C3	Lower-right key of keypad.
KEY_BTAB	Back tab key.
KEY_BEG	beg(inning) key
KEY_CANCEL	cancel key
KEY_CLOSE	close key
KEY_COMMAND	cmd (command) key
KEY_COPY	copy key
KEY_CREATE	create key
KEY_END	end key
KEY_EXIT	exit key
KEY_FIND	find key
KEY_HELP	help key

Item	Description
KEY_MARK	mark key
KEY_MESSAGE	message key
KEY_MOVE	move key
KEY_NEXT	next object key
KEY_OPEN	open key
KEY_OPTIONS	options key
KEY_PREVIOUS	previous object key
KEY_REDO	redo key
KEY_REFERENCE	ref(erence) key
KEY_REFRESH	refresh key
KEY_REPLACE	replace key
KEY_RESTART	restart key
KEY_RESUME	resume key
KEY_SAVE	save key
KEY_SBEG	shifted beginning key

Item	Description
KEY_SCANCEL	shifted cancel key
KEY_SCOMMAND	shifted command key
KEY_SCOPY	shifted copy key
KEY_SCREATE	shifted create key
KEY_SDC	shifted delete char key
KEY_SDL	shifted delete line key
KEY_SELECT	select key
KEY_SEND	shifted end key
KEY_SEOL	shifted clear line key
KEY_SEXIT	shifted exit key
KEY_SFIND	shifted find key
KEY_SHELP	shifted help key
KEY_SHOME	shifted home key
KEY_SIC	shifted input key
KEY_SLEFT	shifted left arrow key
KEY_SMESSAGE	shifted message key
KEY_SMOVE	shifted move key
KEY_SNEXT	shifted next key
KEY_SOPTIONS	shifted options key
KEY_SPREVIOUS	shifted prev key
KEY_SPRINT	shifted print key
KEY_SREDO	shifted redo key
KEY_SREPLACE	shifted replace key
KEY_SRIGHT	shifted right arrow
KEY_SRSUME	shifted resume key
KEY_SSAVE	shifted save key
KEY_SSUSPEND	shifted suspend key
KEY_SUNDO	shifted undo key
KEY_SUSPEND	suspend key
KEY_UNDO	undo key

Parameters

Item	Description
Column	Specifies the horizontal position to move the logical cursor to before getting the character.
Line	Specifies the vertical position to move the logical cursor to before getting the character.
Window	Identifies the window to get the character from and echo it into.

Return Values

Upon successful completion, the **getch, mvwgetch,** and **wgetch** subroutines, CURSES, and Curses Interface return the single-byte character, KEY_ value, or ERR. When in the nodelay mode and no data is available, ERR is returned.

Examples

1. To get a character and echo it to the stdscr, use:

```
mvgetch();
```

2. To get a character and echo it into stdscr at the coordinates y=20, x=30, use:

```
mvgetch(20, 30);
```

3. To get a character and echo it into the user-defined window `my_window` at coordinates y=20, x=30, use:

```
WINDOW *my_window;
mvwgetch(my_window, 20, 30);
```

getcmdattr Subroutine

Purpose

Queries the command security information in the privileged command database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>

int getcmdattr (Command, Attribute, Value, Type)
    char *Command;
    char *Attribute;
    void *Value;
    int Type;
```

Description

The **getcmdattr** subroutine reads a specified attribute from the command database. If the database is not open, this subroutine does an implicit open for reading. For attributes of the **SEC_CHAR** and **SEC_LIST** types, the **getcmdattr** subroutine returns the value to the allocated memory. Caller needs to free this memory.

Parameters

Item	Description
Command	Specifies the command name. The value should be the full path to the command on the system.

Item	Description
Attribute	Specifies the attribute to read. The following possible attributes are defined in the **usersec.h** file: **S_ACCESSAUTHS** Access authorizations. The attribute type is **SEC_LIST** and is a null-separated list of authorization names. Sixteen authorizations can be specified. A user with one of the authorizations is allowed to run the command. In addition to the user-defined and system-defined authorizations available on the system, the following three special values are allowed: **ALLOW_OWNER** Allows the command owner to run the command without checking for access authorizations. **ALLOW_GROUP** Allows the command group to run the command without checking for access authorizations. **ALLOW_ALL** Allows every user to run the command without checking for access authorizations. **S_AUTHPRIVS** Authorized privileges. The attribute type is **SEC_LIST**. Privilege authorization and authorized privileges pairs indicate process privileges during the execution of the command corresponding to the authorization that the parent process possesses. The authorization and its corresponding privileges are separated by an equal sign (=); individual privileges are separated by a plus sign (+); the authorization and privileges pairs are separated by a comma (,) as shown in the following illustration: `auth=priv+priv+...,auth=priv+priv...,...` The number of authorization and privileges pairs is limited to sixteen. **S_AUTHROLES** The role or list of roles, users having these have to be authenticated to allow execution of the command. The attribute type is **SEC_LIST**. **S_INNATEPRIVS** Innate privileges. This is a null-separated list of privileges that are assigned to the process when running the command. The attribute type is **SEC_LIST**. **S_INHERITPRIVS** Inheritable privileges. This is a null-separated list of privileges that are passed to child process privileges. The attribute type is **SEC_LIST**. **S_EUID** The effective user ID to be assumed when running the command. The attribute type is **SEC_INT**. **S_EGID** The effective group ID to be assumed when running the command. The attribute type is **SEC_INT**. **S_RUID** The real user ID to be assumed when running the command. The attribute type is **SEC_INT**.
Value	Specifies a pointer, or a pointer to a pointer according to the value specified in the *Attribute* and *Type* parameters. See the *Type* parameter for more details.

Item	Description
Type	Specifies the type of attribute. The following valid types are defined in the **usersec.h** file: **SEC_INT** The format of the attribute is an integer. For the subroutine, the user should supply a pointer to a defined integer variable. **SEC_CHAR** The format of the attribute is a null-terminated character string. For the subroutine, the user should supply a pointer to a defined character pointer variable. Caller needs to free this memory. **SEC_LIST** The format of the attribute is a series of concatenated strings that each of which is null-terminated. The last string in the series is terminated by two successive null characters. For the subroutine, the user should supply a pointer to a defined character pointer variable. Caller needs to free this memory.

Security

Files Accessed:

File	Mode
/etc/security/privcmds	rw

Return Values

If successful, the **getcmdattr** subroutine returns zero. Otherwise, a value of -1 is returned and the **errno** global value is set to indicate the error.

Error Codes

If the **getcmdattr** subroutine fails, one of the following **errno** values is set:

Item	Description
EINVAL	The *Command* parameter is **NULL** or **default**.
EINVAL	The *Attribute* array or the *Type* parameter is **NULL** or does not contain one of the defined values.
ENOATTR	The *Attribute* array is **S_PRIVCMDS**, but the *Command* parameter is not **ALL**.
ENOENT	The command specified in the *Command* parameter does not exist.
ENOATTR	The attribute specified in the *Attribute* array is valid, but no value is defined for the command.
EPERM	The operation is not permitted.
EIO	Failed to access remote command database.

getcmdattrs Subroutine

Purpose

Retrieves multiple command attributes from the privileged command database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>

int getcmdattrs(Command, Attributes, Count)
    char *Command;
    dbattr_t *Attributes;
    int Count;
```

Description

The **getcmdattrs** subroutine reads one or more attributes from the privileged command database. The command specified with the *Command* parameter must include the full path to the command and exist in the privileged command database. If the database is not open, this subroutine does an implicit open for reading.

The *Attributes* array contains information about each attribute that is to be read. Each element in the *Attributes* array must be examined upon a successful call to the **getcmdattrs** subroutine to determine whether the *Attributes* array was successfully retrieved. The values of the **SEC_CHAR** or **SEC_LIST** attributes successfully returned are in the allocated memory. Caller need to free this memory after use. The **dbattr_t data** structure contains the following fields:

Item	Description
attr_name	The name of the target command attribute.
attr_idx	This attribute is used internally by the **getcmdattrs** subroutine.
attr_type	The type of the target attribute.
attr _flag	The result of the request to read the target attribute. On successful completion, a value of zero is returned. Otherwise, it returns a nonzero value.
attr_un	A union that contains the returned values for the requested query.
attr_domain	The subroutine ignores any input to this field. If this field is set to null, the subroutine sets this field to the name of the domain where the command is found.

The following valid privileged command attributes for the subroutine are defined in the **usersec.h** file:

Name	Description	Type
S_PRIVCMDS	Retrieves all the commands in the privileged command database. It is valid only when the *Command* parameter is **ALL**.	**SEC_LIST**
S_ACCESSAUTHS	Access authorizations. This is a null-separated list of authorization names. Sixteen authorizations can be specified. A user with any one of the authorizations is allowed to run the command. In addition to the user-defined and system-defined authorizations available on the system, the following three special values are allowed: **ALLOW_OWNER** Allows the command owner to run the command without checking for access authorizations. **ALLOW_GROUP** Allows the command group to run the command without checking for access authorizations. **ALLOW_ALL** Allows every user to run the command without checking for access authorizations.	**SEC_LIST**

Name	Description	Type

S_AUTHPRIVS	Authorized privileges. Privilege authorization and authorized privileges pairs indicate process privileges during the execution of the command corresponding to the authorization that the parent process possesses. The authorization and its corresponding privileges are separated by an equal sign (=); individual privileges are separated by a plus sign (+). The attribute is of the **SEC_LIST** type and the value is a null-separated list, so authorization and privileges pairs are separated by a NULL character (\0), as shown in the following illustration:
	`auth=priv+priv+...`
	`\0auth=priv+priv+...\0...\0\0`
	The number of authorization and privileges pairs is limited to sixteen.
		SEC_LIST

S_AUTHROLES	The role or list of roles, users having these have to be authenticated to allow execution of the command.	**SEC_LIST**
S_INNATEPRIVS	Innate privileges. This is a null-separated list of privileges that are assigned to the process when running the command.	**SEC_LIST**
S_INHERITPRIVS	Inheritable privileges. This is a null-separated list of privileges that are assigned to child processes.	**SEC_LIST**
S_EUID	The effective user ID to be assumed when running the command.	**SEC_INT**
S_EGID	The effective group ID to be assumed when running the command.	**SEC_INT**
S_RUID	The real user ID to be assumed when running the command.	**SEC_INT**

The following union members correspond to the definitions of the **attr_char**, **attr_char**, **attr_int**, **attr_long** and **attr_llong** macros in the **usersec.h** file:

Item	Description
au_char	Attributes of the **SEC_CHAR** and **SEC_LIST** types store a pointer to the returned value in this member when the attributes are successfully retrieved. Caller need to free this memory.
au_int	Storage location for attributes of the **SEC_INT** type.
au_long	Storage location for attributes of the **SEC_LONG** type.
au_llong	Storage location for attributes of the **SEC_LLONG** type.

If **ALL** is specified for the *Command* parameter, the **S_PRIVCMDS** attribute is the only valid attribute that is displayed in the *Attribute* array. Specifying any other attribute with a command name of **ALL** causes the **getcmdattrs** subroutine to fail.

Parameters

Item	Description
Command	Specifies the command for the attributes to be read.
Attributes	A pointer to an array of zero or more elements of the **dbattr_t** type. The list of command attributes is defined in the **usersec.h** header file.
Count	The number of array elements in the *Attributes* array.

Security

Files Accessed:

File	Mode
/etc/security/privcmds	r

Return Values

If the command specified by the *Command* parameter exists in the privileged command database, the **getcmdattrs** subroutine returns zero. On successful completion, the **attr_flag** attribute of each element in the *Attributes* array must be examined to determine whether it was successfully retrieved. On failure, a value of -1 is returned and the **errno** value is set to indicate the error.

Error Codes

If the **getcmdattrs** subroutine returns -1, one of the following **errno** values is set:

Item	Description
EINVAL	The *Command* parameter is **NULL** or **default**.
EINVAL	The *Command* parameter is **ALL** but the Attributes entry contains an attribute other than **S_PRIVCMDS**.
EINVAL	The *Count* parameter is less than zero.
ENOENT	The command specified in the *Command* parameter does not exist.
ENOMEM	Memory cannot be allocated.
EPERM	The operation is not permitted.

If the **getcmdattrs** subroutine fails to query an attribute, one of the following errors is returned in the **attr_flag** field of the corresponding attributes element:

Item	Description
EACCES	The invoker does not have access to the attribute that is specified in the **attr_name** field.
EINVAL	The **attr_name** field in the *Attributes* array is not a recognized command attribute.
EINVAL	The **attr_type** field in the *Attributes* array contains a type that is not valid.
EINVAL	The **attr_un** field in the *Attributes* array does not point to a valid buffer.
ENOATTR	The **attr_name** field in the *Attributes* array specifies a valid attribute, but no value is defined for this privileged command.
ENOMEM	Memory cannot be allocated to store the return value.
EIO	Failed to access remote command database.

getconfattr or putconfattr Subroutine

Purpose

Accesses the system information in the user database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
#include <userconf.h>
```

int getconfattr (*sys*, *Attribute*, *Value*, *Type*)
char * *sys*;
char * *Attribute*;
**void ***Value;
int *Type*;

int putconfattr (*sys*, *Attribute*, *Value*, *Type*)
char * *sys*;
char * *Attribute*;
**void ***Value;
int *Type*;

Description

The **getconfattr** subroutine reads a specified attribute from the system information database. The **putconfattr** subroutine writes a specified attribute to the system information database.

Parameters

sys
System attribute. The following possible attributes are defined in the **userconf.h** file.

- SC_SYS_LOGIN
- SC_SYS_USER
- SC_SYS_ADMUSER
- SC_SYS_AUDIT SEC_LIST
- SC_SYS_AUSERS SEC_LIST
- SC_SYS_ASYS SEC_LIST
- SC_SYS_ABIN SEC_LIST
- SC_SYS_ASTREAM SEC_LIST

Users can define the system attribute parameter. In this case, the parameter value is used as a stanza name. The stanza name contains the specified attribute and value in the *Attribute* and *Value* parameters. The `putconfattr` subroutine creates this stanza in the file associated with the attribute. The `getconfattr` subroutine retrieves the value for the specified attribute and user defined stanza.

Attribute
Specifies which attribute is read. The following possible attributes are defined in the **usersec.h** file:

S_CORECOMP
Core compression status. The attribute type is **SEC_CHAR**.

S_COREPATH
Core path specification status. The attribute type is **SEC_CHAR**.

S_COREPNAME
Core path specification location. The attribute type is **SEC_CHAR**.

S_CORENAMING
Core naming status. The attribute type is **SEC_CHAR**.

S_PGRP
Principle group name.

If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file, the Lightweight Directory Access Protocol (LDAP) group can be assigned to LOCAL user as primary group and vice versa.

The attribute type is **SEC_CHAR**.

S_GROUPS
Groups to which the user belongs.

If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file, the LDAP group can be assigned to LOCAL user and vice versa.

The attribute type is **SEC_LIST**.

S_ADMGROUPS
Groups for which the user is an administrator.

If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file, the LDAP group can be assigned to LOCAL user and vice versa.

The attribute type is **SEC_LIST**.

S_ADMIN
Administrative status of a user. The attribute type is **SEC_BOOL**.

S_AUDITCLASSES
Audit classes to which the user belongs. The attribute type is **SEC_LIST**.

S_AUTHSYSTEM
Defines the user's authentication method. The attribute type is **SEC_CHAR.**

S_HOME
Home directory. The attribute type is **SEC_CHAR**.

S_SHELL
Initial program run by a user. The attribute type is **SEC_CHAR**.

S_GECOS
Personal information for a user. The attribute type is **SEC_CHAR**.

S_USRENV
User-state environment variables. The attribute type is **SEC_LIST**.

S_SYSENV
Protected-state environment variables. The attribute type is **SEC_LIST**.

S_LOGINCHK
Specifies whether the user account can be used for local logins. The attribute type is **SEC_BOOL**.

S_HISTEXPIRE
Defines the period of time (in weeks) that a user cannot reuse a password. The attribute type is **SEC_INT**.

S_HISTSIZE
Specifies the number of previous passwords that the user cannot reuse. The attribute type is **SEC_INT**.

S_MAXREPEAT
Defines the maximum number of times a user can repeat a character in a new password. The attribute type is **SEC_INT**.

S_MINAGE
Defines the minimum age in weeks that the user's password must exist before the user can change it. The attribute type is **SEC_INT**.

S_PWDCHECKS
Defines the password restriction methods for this account. The attribute type is **SEC_LIST**.

S_MINALPHA
Defines the minimum number of alphabetic characters required in a new user's password. The attribute type is **SEC_INT**.

S_MINDIFF
Defines the minimum number of characters required in a new password that were not in the old password. The attribute type is **SEC_INT**.

S_MINLEN
Defines the minimum length of a user's password. The attribute type is **SEC_INT**.

S_MINOTHER
Defines the minimum number of non-alphabetic characters required in a new user's password. The attribute type is **SEC_INT**.

S_DICTIONLIST
Defines the password dictionaries for this account. The attribute type is **SEC_LIST**.

S_SUCHK
Specifies whether the user account can be accessed with the **su** command. Type **SEC_BOOL**.

S_REGISTRY
Defines the user's authentication registry. The attribute type is **SEC_CHAR**.

S_RLOGINCHK
Specifies whether the user account can be used for remote logins using the **telnet** or **rlogin** commands. The attribute type is **SEC_BOOL**.

S_DAEMONCHK
Specifies whether the user account can be used for daemon execution of programs and subsystems using the **cron** daemon or **src**. The attribute type is **SEC_BOOL**.

S_TPATH
Defines how the account may be used on the trusted path. The attribute type is **SEC_CHAR**. This attribute must be one of the following values:

nosak
The secure attention key is not enabled for this account.

notsh
The trusted shell cannot be accessed from this account.

always
This account may only run trusted programs.

on
Normal trusted-path processing applies.

S_MINLOWERALPHA
Defines the minimum number of lowercase alphabetic characters required in a new user password. The attribute type is **SEC_INT**.

S_MINUPPERALPHA
Defines the minimum number of uppercase alphabetic characters required in a new user password. The attribute type is **SEC_INT**.

S_MINDIGIT
Defines the minimum number of digits required in a new user password. The attribute type is **SEC_INT**.

S_MINSPECIALCHAR
Defines the minimum number of special characters required in a new user password. The attribute type is **SEC_INT**.

S_TTYS
List of ttys that can or cannot be used to access this account. The attribute type is **SEC_LIST**.

S_SUGROUPS
Groups that can or cannot access this account.

If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file, the LDAP group can be assigned to LOCAL user and vice versa.

The attribute type is **SEC_LIST**.

S_EXPIRATION
Expiration date for this account, in seconds since the epoch. The attribute type is **SEC_CHAR**.

S_AUTH1
Primary authentication methods for this account. The attribute type is **SEC_LIST**.

S_AUTH2
Secondary authentication methods for this account. The attribute type is **SEC_LIST**.

S_UFSIZE
Process file size soft limit. The attribute type is **SEC_INT**.

S_UCPU
Process CPU time soft limit. The attribute type is **SEC_INT**.

S_UDATA
Process data segment size soft limit. The attribute type is **SEC_INT**.

S_USTACK
Process stack segment size soft limit. Type: **SEC_INT**.

S_URSS
Process real memory size soft limit. Type: **SEC_INT**.

S_UCORE
Process core file size soft limit. The attribute type is **SEC_INT**.

S_PWD
Specifies the value of the passwd field in the **/etc/passwd** file. The attribute type is **SEC_CHAR**.

S_UMASK
File creation mask for a user. The attribute type is **SEC_INT**.

S_LOCKED
Specifies whether the user's account can be logged into. The attribute type is **SEC_BOOL**.

S_UFSIZE_HARD
Process file size hard limit. The attribute type is **SEC_INT**.

S_UCPU_HARD
Process CPU time hard limit. The attribute type is **SEC_INT**.

S_UDATA_HARD
Process data segment size hard limit. The attribute type is **SEC_INT**.

S_USTACK_HARD
Process stack segment size hard limit. Type: **SEC_INT**.

S_URSS_HARD
Process real memory size hard limit. Type: **SEC_INT**.

S_UCORE_HARD
Process core file size hard limit. The attribute type is **SEC_INT**.

Note: These values are string constants that should be used by applications both for convenience and to permit optimization in latter implementations.

Type
Specifies the type of attribute expected. Valid types are defined in the **usersec.h** file and include:

SEC_INT
The format of the attribute is an integer.

For the **getconfattr** subroutine, the user should supply a pointer to a defined integer variable. For the **putconfattr** subroutine, the user should supply an integer.

SEC_CHAR
The format of the attribute is a null-terminated character string.

SEC_LIST
The format of the attribute is a series of concatenated strings, each null-terminated. The last string in the series is terminated by two successive null characters.

SEC_BOOL
The format of the attribute from the **getconfattr** subroutine is an integer with the value of either 0 (false) or 1 (true). The format of the attribute for the **putconfattr** subroutine is a null-terminated string containing one of the following strings: true, false, yes, no, always, or never.

SEC_COMMIT
For the **putconfattr** subroutine, this value specified by itself indicates that the changes to the named *sys* value or stanza are to be committed to permanent storage. The *Attribute* and *Value* parameters are ignored. If no stanza name is specified, all outstanding changes to the system information databases are committed to permanent storage.

SEC_DELETE
The corresponding attribute is deleted from the database.

Security

Item	Description

Files Accessed:

Mode	File
rw	**/etc/security/user**
rw	**/etc/security/limits**
rw	**/etc/security/login.cfg**
rw	**/usr/lib/security/mkuser.default**
rw	**/etc/security/audit/config**

Return Values

If successful, the **getconfattr** subroutine returns a value of zero.

If unsuccessful, the **getconfattr** subroutine returns a value of -1.

Error Codes

Item	Description
ENOENT	The value that the *Sys* parameter specifies does not exist.
ENOATTR	The specified *Attribute* variable is not defined for this *Sys* parameter.
EINVAL	The *Attribute* or *Type* variable for the specified *Sys* parameter is not valid.
EACCESS	The user does not have access to the specified *Attribute* variable.
EIO	Failed to access remote system information database.

Files

Item	Description
/etc/passwd	Contains user IDs.

getconfattrs Subroutine

Purpose

Accesses system information in the system information database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
#include <userconf.h>
```

int getconfattrs (*Sys*, *Attributes*, *Count*)
char * *Sys*;
dbattr_t * *Attributes*;
int *Count*

Description

The **getconfattrs** subroutine accesses system configuration information.

The **getconfattrs** subroutine reads one or more attributes from the system configuration database. If the database is not already open, this subroutine does an implicit open for reading.

The *Attributes* array contains information about each attribute that is to be written. The **dbattr_t** data structure contains the following fields:

attr_name
The name of the desired attribute.

attr_idx
Used internally by the **getconfattrs** subroutine.

attr_type
The type of the desired attribute. The list of attribute types is defined in the **usersec.h** header file.

attr_flag
The results of the request to read the desired attribute.

attr_un
A union containing the values to be written. Its union members that follow correspond to the definitions of the **attr_char**, **attr_int**, **attr_long**, and **attr_llong** macros, respectively:

au_char
Attributes of type **SEC_CHAR** and **SEC_LIST** store a pointer to the value to be written.

au_int
Attributes of type **SEC_INT** and **SEC_BOOL** contain the value of the attribute to be written.

au_long
Attributes of type **SEC_LONG** contain the value of the attribute to be written.

au_llong
Attributes of type **SEC_LLONG** contain the value of the attribute to be written.

attr_domain
The authentication domain containing the attribute. The **getconfattrs** subroutine is responsible for managing the memory referenced by this pointer.

Use the **setuserdb** and **enduserdb** subroutines to open and close the system configuration database. Failure to explicitly open and close the system database can result in loss of memory and performance.

Parameters

Item	Description
Sys	Specifies the name of the subsystem for which the attributes are to be read.
Attributes	A pointer to an array of one or more elements of type **dbattr_t**. The list of system attributes is defined in the **usersec.h** header file.
Count	The number of array elements in *Attributes*.

Security

Files accessed:

Item	Description
Mode	**File**
r	**/etc/security/.ids**
r	**/etc/security/audit/config**
r	**/etc/security/audit/events**
r	**/etc/security/audit/objects**
r	**/etc/security/login.cfg**
r	**/etc/security/portlog**
r	**/etc/security/roles**
r	**/usr/lib/security/methods.cfg**
r	**/usr/lib/security/mkuser.default**

Return Values

If the value of the *Sys* or *Attributes* parameter is NULL, or the value of the *Count* parameter is less than 1, the **getconfattrs** subroutine returns a value of -1, and sets the **errno** global variable to indicate the error. Otherwise, the subroutine returns a value of zero. The **getconfattrs** subroutine does not check the validity of the *Sys* parameter. Each element in the *Attributes* array must be examined on a successful call to the **getconfattrs** subroutine to determine whether the *Attributes* array entry is successfully retrieved.

Error Codes

The **getconfattrs** subroutine returns an error that indicates that the system attribute does or does not exist. Additional errors can indicate an error querying the information databases for the requested attributes.

Item	Description
EINVAL	The *Attributes* parameter is NULL.
EINVAL	The *Count* parameter is less than 1.
ENOENT	The specified *Sys* does not exist.
EIO	Failed to access remote system information database.

If the **getconfattrs** subroutine fails to query an attribute, one or more of the following errors is returned in the **attr_flag** field of the corresponding *Attributes* element:

Item	Description
EACCES	The user does not have access to the attribute specified in the **attr_name** field.

Item	Description
EINVAL	The **attr_type** field in the *Attributes* entry contains an invalid type.
EINVAL	The **attr_un** field in the *Attributes* entry does not point to a valid buffer or to valid data for this type of attribute. Limited testing is possible and all errors might not be detected.
ENOMEM	Memory could not be allocated to store the return value.
ENOATTR	The **attr_name** field in the *Attributes* entry specifies an attribute that is not defined for this system table.

Files

Item	Description
/etc/security/.ids	The next available user and group ID values.
/etc/security/audit/config	Bin and stream mode audit configuration parameters.
/etc/security/audit/events	Format strings for audit event records.
/etc/security/audit/objects	File system objects that are explicitly audited.
/etc/security/login.cfg	Miscellaneous login relation parameters.
/etc/security/portlog	Port login failure and locking history.
/etc/security/roles	Definitions of administrative roles.
/usr/lib/security/methods.cfg	Definitions of loadable authentication modules.
/usr/lib/security/mkuser.default	Default user attributes for administrative and non administrative users.

getcontext or setcontext Subroutine

Purpose

Initializes the structure pointed to by *ucp* to the context of the calling process.

Library

(**libc.a**)

Syntax

#include <ucontext.h>

int getcontext (ucontext_t ****ucp*);**

**int setcontext (const uncontext_t ****ucp*);

Description

The **getcontext** subroutine initalizes the structure pointed to by *ucp* to the current user context of the calling process. The **ucontext_t** type that *ucp* points to defines the user context and includes the contents of the calling process' machine registers, the signal mask, and the current execution stack.

The setcontext subroutine restores the user context pointed to by *ucp*. A successful call to setcontext subroutine does not return; program execution resumes at the point specified by the *ucp* argument passed to setcontext subroutine. The *ucp* argument should be created either by a prior call to getcontext subroutine, or by being passed as an argument to a signal handler. If the *ucp* argument was created with

getcontext subroutine, program execution continues as if the corresponding call of getcontext subroutine had just returned. If the *ucp* argument was created with makecontext subroutine, program execution continues with the function passed to makecontext subroutine. When that function returns, the process continues as if after a call to setcontext subroutine with the *ucp* argument that was input to makecontext subroutine. If the *ucp* argument was passed to a signal handler, program execution continues with the program instruction following the instruction interrupted by the signal. If the uc_link member of the ucontext_t structure pointed to by the *ucp* arguement is equal to 0, then this context is the main context, and the process will exit when this context returns.

Parameters

Item	Description
ucp	A pointer to a user stucture.

Return Values

If successful, a value of 0 is returned. If unsuccessful, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **getcontext** and **setcontext** subroutines are unsuccessful if one of the following is true:

Item	Description
EINVAL	NULL *ucp* address
EFAULT	Invalid *ucp* address

getcwd Subroutine

Purpose

Gets the path name of the current directory.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <unistd.h>

char *getcwd ( Buffer,  Size)
char *Buffer;
size_t Size;
```

Description

The **getcwd** subroutine places the absolute path name of the current working directory in the array pointed to by the *Buffer* parameter, and returns that path name. The *size* parameter specifies the size in bytes of the character array pointed to by the *Buffer* parameter.

Parameters

Item	Description
Buffer	Points to string space that will contain the path name. If the *Buffer* parameter value is a null pointer, the **getcwd** subroutine, using the **malloc** subroutine, obtains the number of bytes of free space as specified by the *Size* parameter. In this case, the pointer returned by the **getcwd** subroutine can be used as the parameter in a subsequent call to the **free** subroutine. Starting the **getcwd** subroutine with a null pointer as the *Buffer* parameter value is not recommended.

Item	Description
Size	Specifies the length of the string space. The value of the *Size* parameter must be at least 1 greater than the length of the path name to be returned.

Return Values

If the **getcwd** subroutine is unsuccessful, a null value is returned and the **errno** global variable is set to indicate the error. The **getcwd** subroutine is unsuccessful if the *Size* parameter is not large enough or if an error occurs in a lower-level function.

Error Codes

If the **getcwd** subroutine is unsuccessful, it returns one or more of the following error codes:

Item	Description
EACCES	Indicates that read or search permission was denied for a component of the path name
EINVAL	Indicates that the *Size* parameter is 0 or a negative number.
ENOMEM	Indicates that insufficient storage space is available.
ERANGE	Indicates that the *Size* parameter is greater than 0, but is smaller than the length of the path name plus 1.

getdate Subroutine

Purpose

Convert user format date and time.

Library

Standard C Library **(libc.a)**

Syntax

```
#include <time.h>

struct tm *getdate (const char *string)
extern int getdate_err
```

Description

The **getdate** subroutine converts user definable date and/or time specifications pointed to by *string*, into a **struct tm**. The structure declaration is in the **time.h** header file (see **ctime** subroutine).

User supplied templates are used to parse and interpret the input string. The templates are contained in text files created by the user and identified by the environment variable **DATEMSK**. The **DATEMSK** variable should be set to indicate the full pathname of the file that contains the templates. The first line in the template that matches the input specification is used for interpretation and conversation into the internal time format.

The templates should follow a format where complex field descriptors are preceded by simpler ones. For example:

```
%M
%H:%M
%m/%d/%y
%m/%d/%y %H:%M:%S
```

The following field descriptors are supported:

Item	Description
%%	Same as %.
%a	Abbreviated weekday name.
%A	Full weekday name.
%b	Abbreviated month name.
%B	Full month name.
%c	Locale's appropriate date and time representation.
%C	Century number (00-99; leading zeros are permitted but not required)
%d	Day of month (01 - 31: the leading zero is optional.
%e	Same as %d.
%D	Date as %m/%d/%y.
%h	Abbreviated month name.
%H	Hour (00 - 23)
%I	Hour (01 - 12)
%m	Month number (01 - 12)
%M	Minute (00 - 59)
%n	Same as \n.
%p	Locale's equivalent of either AM or PM.
%r	Time as %I:%M:%S %p
%R	Time as %H: %M
%S	Seconds (00 - 61) Leap seconds are allowed but are not predictable through use of algorithms.
%t	Same as tab.
%T	Time as %H: %M:%S
%w	Weekday number (Sunday = 0 - 6)
%x	Locale's appropriate date representation.
%X	Locale's appropriate time representation.

Item	Description
%y	Year within century. **Note:** When the environment variable **XPG_TIME_FMT=ON**, **%y** is the year within the century. When a century is not otherwise specified, values in the range 69-99 refer to years in the twentieth century (1969 to 1999, inclusive); values in the range 00-68 refer to 2000 to 2068, inclusive.
%Y	Year as ccyy (such as 1986)
%Z	Time zone name or no characters if no time zone exists. If the time zone supplied by %Z is not the same as the time zone **getdate** subroutine expects, an invalid input specification error will result. The **getdate** subroutine calculates an expected time zone based on information supplied to the interface (such as hour, day, and month).

The match between the template and input specification performed by the **getdate** subroutine is case sensitive.

The month and weekday names can consist of any combination of upper and lower case letters. The used can request that the input date or time specification be in a specific language by setting the LC_TIME category (See the **setlocale** subroutine).

Leading zero's are not necessary for the descriptors that allow leading zero's. However, at most two digits are allowed for those descriptors, including leading zero's. Extra whitespace in either the template file or in *string* is ignored.

The field descriptors %c, %x, and %X will not be supported if they include unsupported field descriptors.

Example 1 is an example of a template. Example 2 contains valid input specifications for the template. Example 3 shows how local date and time specifications can be defined in the template.

The following rules apply for converting the input specification into the internal format:

- If only the weekday is given, today is assumed if the given month is equal to the current day and next week if it is less.
- If only the month is given, the current month is assumed if the given month is equal to the current month and next year if it is less and no year is given (the first day of month is assumed if no day is given).
- If no hour, minute, and second are given, the current hour, minute and second are assumed.
- If no date is given, today is assumed if the given hour is greater than the current hour and tomorrow is assumed if it is less.

Return Values

Upon successful completion, the **getdate** subroutine returns a pointer to **struct tm;** otherwise, it returns a null pointer and the external variable **getdate_err** is set to indicate the error.

Error Codes

Upon failure, a null pointer is returned and the variable **getdate_err** is set to indicate the error.

The following is a complete list of the **getdate_err** settings and their corresponding descriptions:

Item	Description
1	The **DATEMSK** environment variable is null or undefined.
2	The template file cannot be opened for reading.
3	Failed to get file status information.
4	The template file is not a regular file.

Item	Description
5	An error is encountered while reading the template file.
6	Memory allocation failed (not enough memory available.
7	There is no line in the template that matches the input.
8	Invalid input specification, Example: February 31 or a time is specified that can not be represented in a time_t (representing the time in seconds since 00:00:00 UTC, January 1, 1970).

Examples

1. The following example shows the possible contents of a template:

```
%m
%A %B %d, %Y, %H:%M:%S
%A
%B
%m/%d/%y %I %p
%d, %m, %Y %H:%M
at %A the %dst of %B in %Y
run job at %I %p, %B %dnd
&A den %d. %B %Y %H.%M Uhr
```

2. The following are examples of valid input specifications for the template in Example 1:

```
getdate ("10/1/87 4 PM")
getdate ("Friday")
getdate ("Friday September 18, 1987, 10:30:30")
getdate ("24,9,1986 10:30")
getdate ("at monday the 1st of december in 1986")
getdate ("run job at 3 PM. december 2nd")
```

   If the LC_TIME category is set to a German locale that includes `freitag` as a weekday name and `oktober` as a month name, the following would be valid:

```
getdate ("freitag den 10. oktober 1986 10.30 Uhr")
```

3. The following examples shows how local date and time specification can be defined in the template.

Invocation	Line in Template
getdate ("11/27/86")	%m/%d/%y
getdate ("27.11.86"0	%d.%m.%y
getdate ("86-11-27")	%y-%m-%d
getdate ("Friday 12:00:00")	%A %H:%M:%S

4. The following examples help to illustrate the above rules assuming that the current date Mon Sep 22 12:19:47 EDT 1986 and the LC_TIME category is set to the default "C" locale.

Input	Line in Template	Date
Mon	%a	Mon Sep 22 12:19:47 EDT 1986
Sun	%a	Sun Sep 28 12:19:47 EDT 1986
Fri	%a	Fri Sep 26 12:19:47 EDT 1986
September	%B	Mon Sep1 12:19:47 EDT 1986
January	%B	Thu Jan 1 12:19:47 EDT 1986
December	%B	Mon Dec 1 12:19:47 EDT 1986
Sep Mon	%b %a	Mon Sep 1 12:19:47 EDT 1986

Input	Line in Template	Date
Jan Fri	%b %a	Fri Jan 2 12:19:47 EDT 1986
Dec Mon	%b %a	Mon Dec 1 12:19:47 EDT 1986
Jan Wed 1989	%b %a %Y	Wed Jan 4 12:19:47 EDT 1986
Fri 9	%a %H	Fri Sep 26 12:19:47 EDT 1986
Feb 10:30	%b %H: %S	Sun Feb 1 12:19:47 EDT 1986
10:30	%H: %M	Tue Sep 23 12:19:47 EDT 1986
13:30	%H: %M	Mon Sep 22 12:19:47 EDT 1986

getdevattr Subroutine

Purpose

Retrieves the device security information in the privileged device database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>

int getdevattr (Device, Attribute, Value, Type)
    char *Device;
    char *Attribute;
    void *Value;
    int Type;
```

Description

The **getdevattr** subroutine reads a specified attribute from the device database. If the database is not open, this subroutine does an implicit open for reading. For attributes of the **SEC_CHAR** and **SEC_LIST** types, the **getdevattr** subroutine returns the value to the allocated memory. Caller needs to free this memory.

Parameters

Item	Description
Device	Specifies the device name. The value should be the full path to the device on the system. This parameter must be specified unless the *Type* parameter is **SEC_COMMIT**.
Attribute	Specifies the attribute that is read. The following possible attributes are defined in the **usersec.h** file: **S_READPRIVS** Privileges required to read from the device. Eight privileges can be defined. A process with any of the read privileges is allowed to read from the device. The attribute type is **SEC_LIST**. **S_WRITEPRIVS** Privileges required to write to the device. Eight privileges can be defined. A process with any of the write privileges is allowed to write to the device.

Item	Description
Value	Specifies a pointer or a pointer to a pointer according to the *Attribute* array and the *Type* parameters. See the *Type* parameter for more details.
Type	Specifies the type of attribute. The following valid types are defined in the **usersec.h** file: **SEC_INT** The format of the attribute is an integer. For the **getdevattr** subroutine, the user should supply a pointer to a defined integer variable. **SEC_CHAR** The format of the attribute is a null-terminated character string. For the **getdevattr** subroutine, the user should supply a pointer to a defined character pointer variable. The value is returned as allocated memory for the **getdevattr** subroutine. Caller need to free this memory. **SEC_LIST** The format of the attribute is a series of concatenated strings, each of which is null-terminated. The last string in the series is terminated by two successive null characters. For the **getdevattr** subroutine, the user should supply a pointer to a defined character pointer variable. Caller need to free this memory.

Security

Files Accessed:

File	Mode
/etc/security/privdevs	rw

Return Values

On successful completion, the **getdevattr** subroutine returns a value of zero. Otherwise, a value of -1 is returned and the **errno** global value is set to indicate the error.

Error Codes

If the **getdevattr** subroutine fails, one of the following **errno** values is set:

Item	Description
EINVAL	The *Device* parameter is **NULL** or **default**.
EINVAL	The *Attribute* or *Type* parameter is **NULL** or does not contain one of the defined values.
EINVAL	The *Attribute* parameter is **S_PRIVDEVS**, but the *Device* parameter is not **ALL**.
ENOENT	The device specified in the *Device* parameter does not exist.
ENOATTR	The attribute specified in the *Attribute* parameter is valid, but no value is defined for the device.
EPERM	The operation is not permitted.

getdevattrs Subroutine

Purpose

Retrieves multiple device attributes from the privileged device database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>

int getdevattrs(Device, Attributes, Count)
    char *Device;
    dbattr_t *Attributes;
    int Count;
```

Description

The **getdevattrs** subroutine reads one or more attributes from the privileged device database. The device specified with the *Device* parameter must include the full path to the device and exist in the privileged device database. If the database is not open, this subroutine does an implicit open for reading.

The *Attributes* parameter contains information about each attribute that is to be read. Each element in the *Attributes* parameter must be examined on a successful call to the **getdevattrs** subroutine to determine whether the *Attributes* parameter was successfully retrieved. The values of the **SEC_CHAR** or **SEC_LIST** attributes that are successfully returned are in the allocated memory. Caller need to free this memory after use. The **dbattr_t data** structure contains the following fields:

Item	Description
attr_name	The name of the target device attribute.
attr_idx	This attribute is used internally by the **getdevattrs** subroutine.
attr_type	The type of the target attribute.
attr _flag	The result of the request to read the target attribute. On successful completion, the value of zero is returned. Otherwise, a nonzero value is returned.
attr_un	A union that contains the returned values for the requested query.
attr_domain	The subroutine ignores any input to this field. If this field is set to null, the subroutine sets this field to the name of the domain where the device is found.

The following valid privileged device attributes for the **getdevattrs** subroutine are defined in the **usersec.h** file:

Name	Description	Type
S_PRIVDEVS	Retrieves all the devices in the privileged device database. It is valid only when the *Device* parameter is set to **ALL**.	**SEC_LIST**
S_READPRIVS	The privileges that are required to read from the device. Eight privileges can be defined. A process with any of the read privileges is allowed to read from the device.	**SEC_LIST**

Name	Description	Type
S_WRITEPRIVS	The privileges that are required to write to the device. Eight privileges can be defined. A process with any of the write privileges is allowed to write to the device.	**SEC_LIST**

The following union members correspond to the definitions of the **attr_char**, **attr_init**, **attr_long** and the **attr_llong** macros in the **usersec.h** file respectively.

Item	Description
au_char	The attributes of the **SEC_CHAR** and **SEC_LIST** types store a pointer to the returned value in this member when the attributes are successfully retrieved. Caller need to free this memory.
au_int	The storage location for attributes of the **SEC_INT** type.
au_long	The storage location for attributes of the **SEC_LONG** type.
au_llong	The storage location for attributes of the **SEC_LLONG** type.

If **ALL** is specified for the *Device* parameter, the **S_PRIVDEVS** attribute is the only valid attribute that is displayed in the *Attribute* parameter. Specifying any other attribute with a device name of **ALL** causes the **getdevattrs** subroutine to fail.

Parameters

Item	Description
Device	Specifies the device for which the attributes are to be read.
Attributes	A pointer to an array of zero or more elements of the **dbattr_t** type. The list of device attributes is defined in the **usersec.h** header file.
Count	The number of array elements in the *Attributes* parameter.

Security

Files Accessed:

File	Mode
/etc/security/privdevs	r

Return Values

If the device that is specified by the *Device* parameter exists in the privileged device database, the **getdevattrs** subroutine returns zero. On successful completion, the **attr_flag** attribute of each element in the *Attributes* parameter must be examined to determine whether it was successfully retrieved. On failure, a value of -1 is returned and the **errno** value is set to indicate the error.

Error Codes

If the **getdevattrs** subroutine returns -1, one of the following **errno** values is set:

Item	Description
EINVAL	The *Device* parameter is **NULL** or **default**.
EINVAL	The *Device* parameter is **ALL**, but the *Attributes* parameter contains an attribute other than **S_PRIVDEVS**.
EINVAL	The *Count* parameter is less than zero.
EINVAL	The *Device* parameter is **NULL** and the *Count* parameter is greater than zero.
ENOENT	The device specified in the *Device* parameter does not exist.
EPERM	The operation is not permitted.

If the **getdevattrs** subroutine fails to query an attribute, one of the following errors is returned to the **attr_flag** field of the corresponding *Attributes* element:

Item	Description
EACCES	The invoker does not have access to the attribute specified in the **attr_name** field.
EINVAL	The **attr_name** field in the *Attributes* parameter is not a recognized device attribute.
EINVAL	The **attr_type** field in the *Attributes* parameter contains a type that is not valid.
EINVAL	The **attr_un** field in the *Attributes* parameter does not point to a valid buffer.
ENOATTR	The **attr_name** field in the *Attributes* parameter specifies a valid attribute, but no value is defined for this device.
ENOMEM	Memory cannot be allocated to store the return value.

getdomattr Subroutine

Purpose

Queries the domains that are defined in the domain database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
int getdomattr ( Dom, Attribute, Value, Type)
char * Domain;
char * Attribute;

void *Value;
int Type;
```

Description

The **getdomattr** subroutine reads a specified attribute from the domain database. If the database is not open, this subroutine does an implicit open for reading. For the attributes of the SEC_CHAR and SEC_LIST types, the **getdomattr** subroutine returns the value to the allocated memory. The caller must free this memory.

Parameters

Item	Description
Dom	Specifies the domain name.
Attribute	Specifies the attribute to read. The following possible attributes are defined in the **usersec.h** file: S_DOMAINS A list of all available domains on the system. This attribute is read only and is only available to the **getdomattr** subroutine when ALL is specified for the Dom parameter. The attribute type is SEC_LIST. S_ID Specifies a unique integer that is used to identify the domains. The attribute type is SEC_INT. S_DFLTMSG Specifies the default domain description to use if message catalogs are not in use. The attribute type is SEC_CHAR. S_MSGCAT Specifies the message catalog file name that contains the description of the domain . The attribute type is SEC_CHAR. S_MSGSET Specifies the message set that contains the description of the domain in the file that the S_MSGCAT attribute specifies. The attribute type is SEC_INT. S_MSGNUMBER Specifies the message number for the description of the domain in the file that the S_MSGCAT attribute specifies and the message set that the S_MSGSET attribute specifies. The attribute type is SEC_INT.
Value	Specifies a pointer, or a pointer to a pointer according to the value specified in the *Attribute* and *Type* parameters. See the *Type* parameter for more details. Specifies the type of attribute. The following valid types are defined in the **usersec.h** file: SEC_INT The format of the attribute is an integer. For the subroutine, the user should supply a pointer to a defined integer variable.
Type	SEC_LIST The format of the attribute is a series of concatenated strings that each of which is null-terminated. The last string in the series is terminated by two successive null characters. For the subroutine, the user should supply a pointer to a defined character pointer variable. Caller needs to free this memory.

Item	Description
File	**Mode**

Item	Description
/etc/security/domains	R

Return Values

If successful, the **getdomattr** subroutine returns zero. Otherwise, a value of -1 is returned and the **errno** global value is set to indicate the error.

Error Codes

Item	Description
EINVAL	The *Dom* parameter is NULL. The *Attribute* or *Type* parameter is NULL or does not contain one of the defined values. The *Dom* parameter is ALL and the *Attribute* parameter is not S_DOMAINS. The *Value* parameter does not point to a valid buffer for this type of attribute.
ENOATTR	The *Attribute* parameter is S_DOMAINS, but the *Dom* parameter is not ALL The attribute specified in the Attribute parameter is valid but no value is defined for the domain. .
ENOENT	The domain specified in the *Dom* parameter does not exist.
ENOMEM	Memory cannot be allocated.
EPERM	The operation is not permitted.
EACCES	Access permission is denied for the data request.

getdomattrs Subroutine

Purpose

Retrieves multiple domain attributes from the domain-assigned object database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
int getdomattrs ( Dom, Attributes, Count)
char * Dom;
dbattr_t * Attributes;
int Count;
```

Description

The **getdomattrs** subroutine reads one or more attributes from the domain-assigned object database. The *Attributes* array contains information about each attribute that is to be read. Each element in the Attributes array must be examined upon a successful call to the **getdomattrs** subroutine, to determine

whether the *Attributes* array was successfully retrieved. The attributes of the SEC_CHAR or SEC_LIST type will have their values returned to the allocated memory. The caller need to free this memory. The **dbattr_t** data structure contains the following fields:

Item	Description
attr_name	The name of the target domain attribute.
attr_idx	This attribute is used internally by the **getdomattrs** subroutine.
attr_type	The type of a target attribute.
attr _flag	The result of the request to read the target attribute. On successful completion, a value of zero is returned. Otherwise, a value of nonzero is returned.
attr_un	A union that contains the returned values for the requested query.
attr_domain	The **getdomattrs** subroutine ignores any input to this field. If this field is set to null, the subroutine sets this field to the name of the domain where the domain is found.

The following valid domain attributes for the **getdomattrs** subroutine are defined in the **usersec.h** file:

Name	Description	Type
S_DOMAINS	A list of all available domains on the system. It is valid only when the *Dom* parameter is set to the ALL variable.	SEC_LIST
S_DFLTMSG	The default domain description that is used when catalogs are not in use.	SEC_CHAR
S_ID	A unique integer that is used to identify the domain.	SEC_INT
S_MSGCAT	The message catalog name that contains the domain description.	SEC_CHAR
S_MSGSET	The message catalog set number of the domain description.	SEC_INT
S_MSGNUMBER	The message number of the domain description.	SEC_INT

The following union members correspond to the definitions of the ATTR_CHAR, ATTR_INT, ATTR_LONG and ATTR_LLONG macros in the **usersec.h** file:

Item	Description
au_char	Attributes of the SEC_CHAR and SEC_LIST types store a pointer to the returned value in this member when the attributes are successfully retrieved. The caller is responsible for freeing this memory.
au_int	The storage location for attributes of the SEC_INT type.

Item	Description
au_long	The storage location for attributes of the SEC_LONG type.
au_llong	The storage location for attributes of the SEC_LLONG type.

If ALL is specified for the *Dom* parameter, the only valid attribute that can be displayed in the Attribute array is the S_DOMAINS attribute. Specifying any other attribute with an domain name of ALL causes the **getdomattrs** subroutine to fail.

Parameters

Item	Description
Dom	Specifies the domain name for the *Attributes* array to read.
Attribute	A pointer to an array of zero or more elements of the **dbattr_t** type. The list of domain attributes is defined in the **usersec.h** header file.
Count	The number of array elements in the *Attributes* array.

Security

Files Accessed:

Item	Description
File	**Mode**
`/etc/security/domains`	`r`

Return Values

If the domain that is specified by the *Dom* parameter exists in the domain database, the **getdomattrs** subroutine returns the value of zero. On successful completion, the **attr_flag** attribute of each element in the *Attributes* array must be examined to determine whether it was successfully retrieved. If the specified domain does not exist, a value of -1 is returned and the **errno** value is set to indicate the error.

Error Codes

Item	Description
EINVAL	The *Dom* parameter is NULL. The *Count* parameter is less than zero. The *Attributes* array is NULL and the Count parameter is greater than zero. The *Dom* parameter is ALL but the Attributes entry contains an attribute other than S_DOMAINS.
ENOENT	The domain specified in the *Dom* parameter does not exist.
ENOMEM	Memory cannot be allocated.
EPERM	The operation is not permitted.
EACCES	Access permission is denied for the data request.

If the **getdomattrs** subroutine fails to query an attribute, one of the following errors is returned to the **attr_flag** field of the corresponding *Attributes* element:

Item	Description
EACCES	The invoker does not have access to the attribute specified in the **attr_name** field.
EINVAL	The **attr_name** field in the *Attributes* entry is not a recognized domain attribute. The **attr_type** field in the *Attributes* entry contains a type that is not valid. The **attr_un** field in the *Attributes* entry does not point to a valid buffer.
ENOATTR	The **attr_name** field in the *Attributes* entry specifies a valid attribute, but no value is defined for this domain.

getdtablesize Subroutine

Purpose

Gets the descriptor table size.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <unistd.h>

int getdtablesize (void)
```

Description

The **getdtablesize** subroutine is used to determine the size of the file descriptor table.

The size of the file descriptor table for a process is set by the **ulimit** command or by the **setrlimit** subroutine. The **getdtablesize** subroutine returns the current size of the table as reported by the **getrlimit** subroutine. If **getrlimit** reports that the table size is unlimited, **getdtablesize** instead returns the value of OPEN_MAX, which is the largest possible size of the table.

Note: The **getdtablesize** subroutine returns a runtime value that is specific to the version of the operating system on which the application is running. The **getdtablesize** returns a value that is set in the **limits** file, which can be different from system to system.

Return Values

The **getdtablesize** subroutine returns the size of the descriptor table.

getea Subroutine

Purpose

Reads the value of an extended attribute.

Syntax

```
#include <sys/ea.h>

ssize_t getea(const char *path, const char *name,
        void *value, size_t size);
ssize_t fgetea(int filedes, const char *name, void *value, size_t size);
ssize_t lgetea(const char *path, const char *name,
        void *value, size_t size);
```

Description

Extended attributes are name:value pairs associated with the file system objects (such as files, directories, and symlinks). They are extensions to the normal attributes that are associated with all objects in the file system (that is, the **stat(2)** data).

Do not define an extended attribute name with the eight characters prefix "(0xF8)SYSTEM(0xF8)". Prefix "(0xF8)SYSTEM(0xF8)" is reserved for system use only.

Note: The 0xF8 prefix represents a non-printable character.

The **getea** subroutine retrieves the value of the extended attribute identified by *name* and associated with the given *path* in the file system. The length of the attribute *value* is returned. The **fgetea** subroutine is identical to **getea**, except that it takes a file descriptor instead of a path. The **lgetea** subroutine is identical to **getea**, except, in the case of a symbolic link, the link itself is interrogated rather than the file that it refers to.

Parameters

Item	Description
path	The path name of the file.
name	The name of the extended attribute. An extended attribute name is a NULL-terminated string.
value	A pointer to a buffer in which the attribute will be stored. The value of an extended attribute is an opaque byte stream of specified length.
size	The size of the buffer. If size is 0, **getea** returns the current size of the named extended attribute, which can be used to estimate whether the size of a buffer is sufficiently large enough to hold the value associated with the extended attribute.
filedes	A file descriptor for the file.

Return Values

If the **getea** subroutine succeeds, a nonnegative number is returned that indicates the size of the extended attribute value. Upon failure, -1 is returned and **errno** is set appropriately.

Error Codes

Item	Description
EACCES	Caller lacks read permission on the base file, or lacks the appropriate ACL privileges for named attribute **read**.
EFAULT	A bad address was passed for *path*, *name*, or *value*.
EFORMAT	File system is capable of supporting EAs, but EAs are disabled.
EINVAL	A path-like name should not be used (such as **zml/file**, **.** and **..**).
ENAMETOOLONG	The *path* or *name* value is too long.

Item	Description
ENOATTR	The named attribute does not exist, or the process has no access to this attribute.
ERANGE	The size of the value buffer is too small to hold the result.
ENOTSUP	Extended attributes are not supported by the file system.

The errors documented for the **stat(2)** system call are also applicable here.

getenv Subroutine

Purpose

Returns the value of an environment variable.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdlib.h>
```

char *getenv (*Name*)
const char *Name;

Description

The **getenv** subroutine searches the environment list for a string of the form *Name*=*Value*. Environment variables are sometimes called shell variables because they are frequently set with shell commands.

Parameters

Item	Description
Name	Specifies the name of an environment variable. If a string of the proper form is not present in the current environment, the **getenv** subroutine returns a null pointer.

Return Values

The **getenv** subroutine returns a pointer to the value in the current environment, if such a string is present. If such a string is not present, a null pointer is returned. The **getenv** subroutine normally does not modify the returned string. The **putenv** subroutine, however, may overwrite or change the returned string. Do not attempt to free the returned pointer. The **getenv** subroutine returns a pointer to the user's copy of the environment (which is static), until the first invocation of the **putenv** subroutine that adds a new environment variable. The **putenv** subroutine allocates an area of memory large enough to hold both the user's environment and the new variable. The next call to the **getenv** subroutine returns a pointer to this newly allocated space that is not static. Subsequent calls by the **putenv** subroutine use the **realloc** subroutine to make space for new variables. Unsuccessful completion returns a null pointer.

getevars Subroutine

Purpose

Gets environment of a process.

Library

Standard C library (**libc.a)**

Syntax

```
#include <procinfo.h>
#include <sys/types.h>

int getevars (processBuffer, bufferLen, argsBuffer, argsLen)
struct procsinfo  *processBuffer
or struct procentry64  *processBuffer;
int  bufferLen;
char  *argsBuffer;
int  argsLen;
```

Description

The **getevars** subroutine returns the environment that was passed to a command when it was started. Only one process can be examined per call to **getevars**.

The **getevars** subroutine uses the pi_pid field of *processBuffer* to determine which process to look for. *bufferLen* should be set to size of **struct procsinfo** or **struct procentry64**. Parameters are returned in *argsBuffer*, which should be allocated by the caller. The size of this array must be given in *argsLen*.

On return, *argsBuffer* consists of a succession of strings, each terminated with a null character (ascii `\0'). Hence, two consecutive NULLs indicate the end of the list.

Note: The arguments may be changed asynchronously by the process, but results are not guaranteed to be consistent.

Parameters

processBuffer
Specifies the address of a **procsinfo** or **procentry64** structure, whose pi_pid field should contain the pid of the process that is to be looked for.

bufferLen
Specifies the size of a single **procsinfo** or **procentry64** structure.

argsBuffer
Specifies the address of an array of characters to be filled with a series of strings representing the parameters that are needed. An extra NULL character marks the end of the list. This array must be allocated by the caller.

argsLen
Specifies the size of the *argsBuffer* array. No more than *argsLen* characters are returned.

Return Values

If successful, the **getevars** subroutine returns zero. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **getevars** subroutine does not succeed if the following are true:

Item	Description
ESRCH	The specified process does not exist.

Item	Description
EFAULT	The copy operation to the buffer was not successful or the *processBuffer* or *argsBuffer* parameters are invalid.
EINVAL	The *bufferLen* parameter does not contain the size of a single **procsinfo** or **procentry64** structure.
ENOMEM	There is no memory available in the address space.

getfilehdr Subroutine

Purpose

Retrieves the header details of the advanced accounting data file.

Library

The `libaacct.a` library.

Syntax

```
#define <sys/aacct.h>
getfilehdr(filename, hdrinfo)
char *filename;
struct aacct_file_header *hdrinfo;
```

Description

The `getfilehdr` subroutine retrieves the advanced accounting data file header information in a structure of type `aacct_file_header` and returns it to the caller through the structure pointer passed to it. The data file header contains the system details such as the name of the host, the partition number, and the system model.

Parameters

Item	Description
filename	Name of the advanced accounting data file.
hdrinfo	Pointer to the `aacct_file_header` structure in which the header information is returned.

Security

No restrictions. Any user can call this function.

Return Values

Item	Description
0	The call to the subroutine was successful.
-1	The call to the subroutine failed.

Error Codes

Item	Description
EINVAL	The passed pointer is NULL.

Item	Description
ENOENT	Specified data file does not exist.
EPERM	Permission denied. Unable to read the data file.

getfirstprojdb Subroutine

Purpose

Retrieves details of the first project from the specified project database.

Library

The **libaacct.a** library.

Syntax

```
<sys/aacct.h>
getfirstprojdb(void *handle, struct project *project, char *comm)
```

Description

The **getfirstprojdb** subroutine retrieves the first project definitions from the project database, which is controlled through the *handle* parameter. The caller must initialize the project database prior to calling this routine with the **projdballoc** routine. Upon successful completion, the project information is copied to the project structure specified by the caller. In addition, the associated project comment, if present, is copied to the buffer pointed to by the *comm* parameter. The comment buffer is allocated by the caller and must have a length of 1024 bytes.

There is an internal state (that is, the current project) associated with the project database. When the project database is initialized, the current project is the first project in the database. The **getnextprojdb** subroutine returns the current project and advances the current project assignment to the next project in the database so that successive calls read each project entry in the database. The **getfirstprojdb** subroutine can be used to reset the database, so that the initial project is the current project assignment.

Parameters

Item	Description
handle	Pointer to the **projdb** handle.
project	Pointer to project structure where the retrieved data is stored.
comm	Pointer to the comment buffer.

Security

No restriction. Any user can call this function.

Return Values

Item	Description
0	Success
-1	Failure

Error Codes

Item	Description
EINVAL	Invalid arguments, if passed pointer is NULL.
ENOENT	No projects available.

getfsent, getfsspec, getfsfile, getfstype, setfsent, or endfsent Subroutine

Purpose

Gets information about a file system.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <fstab.h>
```

```
struct fstab *getfsent( )
```

struct fstab *getfsspec (*Special*)
char *Special;

struct fstab *getfsfile(*File*)
char *File;

struct fstab *getfstype(*Type*)
char *Type;

```
void setfsent( )
```

```
void endfsent( )
```

Description

The **getfsent** subroutine reads the next line of the **/etc/filesystems** file, opening the file if necessary.

The **setfsent** subroutine opens the **/etc/filesystems** file and positions to the first record.

The **endfsent** subroutine closes the **/etc/filesystems** file.

The **getfsspec** and **getfsfile** subroutines sequentially search from the beginning of the file until a matching special file name or file-system file name is found, or until the end of the file is encountered. The **getfstype** subroutine does likewise, matching on the file-system type field.

Note: All information is contained in a static area, which must be copied to be saved.

Parameters

Item	Description
Special	Specifies the file-system file name.
File	Specifies the file name.

Item	Description
Type	Specifies the file-system type.

Return Values

The **getfsent**, **getfsspec**, **getfstype**, and **getfsfile** subroutines return a pointer to a structure that contains information about a file system. The header file **fstab.h** describes the structure. A null pointer is returned when the end of file (EOF) is reached or if an error occurs.

Files

Item	Description
/etc/filesystems	Centralizes file system characteristics.

getfsfbitindex and getfsfbitstring Subroutines

Purpose

Retrieve file security flag indices and strings.

Library

Trusted AIX Library (**libmls.a**)

Syntax

```
#include <mls/mls.h>

int getfsfbitindex (fsfname)
const char *fsfname;

int getfsfstring (buff, size, index)
char *buff;
int *size;
int index;
```

Description

The **getfsfbitindex** subroutine searches in the file security flags table for the file security flag that the *fsfname* parameter specifies. The file security flag name that the *fsfname* parameter specified is used as a string.

The **getfsfstring** subroutine converts the specified file security flag index into a string and stores the result in the *buff* parameter. The length of the *buff* parameter is specified by the *size* parameter. If the length specified by the *size* parameter is less than that of the string, the **getfsfstring** subroutine fails and returns the required length into the *size* parameter for the index that is specified by the *index* parameter.

Parameters

Item	Description
buff	Specifies the buffer that the file security flag is copied to.
fsfname	Specifies the file security flag to be searched for.
index	Specifies the file security flag index that is to be converted to a string.
size	Specifies the size of the buffer that the *buff* parameter specifies.

Return Values

If successful, the **getfsfbitindex** subroutine returns a value that is equal to or greater than zero. Otherwise, it returns a value of -1.

If successful, the **getfsfstring** subroutine returns a value of zero. Otherwise, it returns a value of -1.

Error Codes

If these subroutines fail, they set one of the following error codes:

Item	Description
EINVAL	The parameters specified NULL value or the index is not valid.
ENOSPC	The size of the buffer is not large enough to store the file security flag string.

getgid, getegid or gegidx Subroutine

Purpose

Gets the process group IDs.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <unistd.h>
#include <sys/types.h>
```

```
gid_t getgid (void);
```

```
gid_t getegid (void);
```

```
#include <id.h>
```

```
gid_t getgidx (int type);
```

Description

The **getgid** subroutine returns the real group ID of the calling process.

The **getegid** subroutine returns the effective group ID of the calling process.

The **getgidx** subroutine returns the group ID indicated by the *type* parameter of the calling process.

These subroutines are part of Base Operating System (BOS) Runtime.

Return Values

The **getgid**, **getegid**and **getgidx** subroutines return the requested group ID. The **getgid** and **getegid** subroutines are always successful.

The **getgidx** subroutine will return -1 and set the global **errno** variable to EINVAL if the type parameter is not one of ID_REAL, ID_EFFECTIVE or ID_SAVED.

Parameters

Item	Description
type	Specifies the group ID to get. Must be one of `ID_REAL` (real group ID), `ID_EFFECTIVE` (effective group ID) or `ID_SAVED` (saved set-group ID).

Error Codes

If the **getgidx** subroutine fails the following is returned:

Item	Description
`EINVAL`	Indicates the value of the type parameter is invalid.

getgrent, getgrgid, getgrnam, setgrent, or endgrent Subroutine

Purpose

Accesses the basic group information in the user database.

Library

Standard C Library (**libc.a)**

Syntax

```
#include <sys/types.h>
#include <grp.h>
```

```
struct group *getgrent ( );
```

```
struct group *getgrgid (GID)
gid_t  GID;
```

```
struct group *getgrnam (Name)
const char * Name;
```

```
void setgrent ( );
```

```
void endgrent ( );
```

Description

Attention: The information returned by the **getgrent**, **getgrnam**, and **getgrgid** subroutines is stored in a static area and is overwritten on subsequent calls. You must copy this information to save it.

Attention: These subroutines should not be used with the **getgroupattr** subroutine. The results are unpredictable.

The **setgrent** subroutine opens the user database if it is not already open. Then, this subroutine sets the cursor to point to the first group entry in the database.

Attention: The **getgrent** subroutine is only supported by LOCAL and NIS load modules, not any other LAM authentication module.

The **getgrent**, **getgrnam**, and **getgrgid** subroutines return information about the requested group. The **getgrent** subroutine returns the next group in the sequential search. The **getgrnam** subroutine returns the first group in the database whose name matches that of the *Name* parameter. The **getgrgid**

subroutine returns the first group in the database whose group ID matches the *GID* parameter. The **endgrent** subroutine closes the user database.

Note: An ! (exclamation mark) is written into the `gr_passwd` field. This field is ignored and is present only for compatibility with older versions of UNIX operating systems.

Note: If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file, the **getgrnam** or **getgrgid** subroutine gets group information from the Lightweight Directory Access Protocol (LDAP) and files domains, if the group name or group ID belongs to any one of these domains.

These subroutines also return the list of user members for the group. Currently, the list is limited to 2000 entries (this could change in the future to where all the entries for the group are returned).

The Group Structure

The **group** structure is defined in the **grp.h** file and has the following fields:

Item	Description
`gr_name`	Contains the name of the group.
`gr_passwd`	Contains the password of the group. **Note:** This field is no longer used.
`gr_gid`	Contains the ID of the group.
`gr_mem`	Contains the members of the group.

If the Network Information Service (NIS) is enabled on the system, these subroutines attempt to retrieve the group information from the NIS authentication server.

Parameters

Item	Description
GID	Specifies the group ID.
Name	Specifies the group name.

Item	Description
Group	Specifies the basic group information to enter into the user database.

Return Values

If successful, the **getgrent**, **getgrnam**, and **getgrgid** subroutines return a pointer to a valid group structure. Otherwise, a null pointer is returned.

Error Codes

These subroutines fail if one or more of the following are returned:

Item	Description
EIO	Indicates that an input/output (I/O) error has occurred.
EINTR	Indicates that a signal was caught during the **getgrnam** or **getgrgid** subroutine.
EMFILE	Indicates that the maximum number of file descriptors specified by the **OPEN_MAX** value are currently open in the calling process.
ENFILE	Indicates that the maximum allowable number of files is currently open in the system.

To check an application for error situations, set the **errno** global variable to a value of 0 before calling the **getgrgid** subroutine. If the **errno** global variable is set on return, an error occurred.

File

Item	Description
/etc/group	Contains basic group attributes.

getgrgid_r Subroutine

Purpose

Gets a group database entry for a group ID.

Library

Thread-safe C Library (**libc_r.a**)

Syntax

```
#include <sys/types.h>
#include <grp.h>

int getgrgid_r(gid_t gid,
struct group *grp,
char *buffer,
size_t bufsize,
struct group **result);
```

Description

The **getgrgid_r** subroutine updates the **group** structure pointed to by *grp* and stores a pointer to that structure at the location pointed to by *result*. The structure contains an entry from the group database with a matching *gid*. Storage referenced by the group structure is allocated from the memory provided with the *buffer* parameter, which is *bufsize* characters in size. The maximum size needed for this buffer can be determined with the {_SC_GETGR_R_SIZE_MAX} *sysconf* parameter. A NULL pointer is returned at the location pointed to by *result* on error or if the requested entry is not found.

Note: If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file, the **getgrgid_r** subroutine gets group information from the Lightweight Directory Access Protocol and files domains, if the group ID belongs to any one of these domains.

Return Values

Upon successful completion, **getgrgid_r** returns a pointer to a **struct group** with the structure defined in **<grp.h>** with a matching entry if one is found. The **getgrgid_r** function returns a null pointer if either the requested entry was not found, or an error occurred. On error, *errno* will be set to indicate the error.

The return value points to a static area that is overwritten by a subsequent call to the **getgrent**, **getgrgid**, or **getgrnam** subroutine.

If successful, the **getgrgid_r** function returns zero. Otherwise, an error number is returned to indicate the error.

Error Codes

The **getgrgid_r** function fails if:

Item	Description
ERANGE	Insufficient storage was supplied via *buffer* and *bufsize* to contain the data to be referenced by the resulting **group** structure.

Applications wishing to check for error situations should set *errno* to 0 before calling **getgrgid_r**. If *errno* is set on return, an error occurred.

getgrnam_r Subroutine

Purpose

Search a group database for a name.

Library

Thread-Safe C Library (**libc_r.a**)

Syntax

```
#include <sys/types.h>
#include <grp.h>

int getgrnam_r (const char **name,
struct group *grp,
char *buffer,
size_t bufsize,
struct group **result);
```

Description

The **getgrnam_r** function updates the **group** structure pointed to by *grp* and stores pointer to that structure at the location pointed to by *result.* The structure contains an entry from the group database with a matching *gid* or *name*. Storage referenced by the group structure is allocated from the memory provided with the *buffer* parameter, which is *bufsize* characters in size. The maximum size needed for this buffer can be determined with the {_SC_GETGR_R_SIZE_MAX} *sysconf* parameter. A NULL pointer is returned at the location pointed to by *result* on error or if the requested entry is not found.

Note: If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file then the **getgrnam_r** subroutine gets group information from the Lightweight Directory Access Protocol (LDAP) and files, if the group name belongs to any one of these domains.

Return Values

The **getgrnam_r** function returns a pointer to a **struct group** with the structure defined in **<grp.h>** with a matching entry if one is found. The **getgrnam_r** function returns a null pointer if either the requested entry was not found, or an error occurred. On error, *errno* will be set to indicate the error.

The return value points to a static area that is overwritten by a subsequent call to the **getgrent**, **getgrgid**, or **getgrnam** subroutine.

If successful, the **getgrnam_r** function returns zero. Otherwise, an error number is returned to indicate the error.

Error Codes

The **getgrnam_r** function fails if:

Item	Description
ERANGE	Insufficient storage was supplied via *buffer* and *bufsize* to contain the data to be referenced by the resulting **group** structure.

Applications wishing to check for error situations should set *errno* to 0 before calling **getgrnam_r**. If *errno* is set on return, an error occurred.

getgroupattr, IDtogroup, nextgroup, or putgroupattr Subroutine

Purpose

Accesses the group information in the user database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
```

```
int getgroupattr (Group, Attribute, Value, Type)
char * Group;
char * Attribute;
void * Value;
int  Type;
```

```
int putgroupattr (Group, Attribute, Value, Type)
char *Group;
char *Attribute;
void *Value;
int Type;
```

```
char *IDtogroup ( GID)
gid_t GID;
```

```
char *nextgroup ( Mode,  Argument)
int Mode, Argument;
```

Description

Attention: These subroutines and the **setpwent** and **setgrent** subroutines should not be used simultaneously. The results can be unpredictable.

These subroutines access group information. Because of their greater granularity and extensibility, you should use them instead of the **getgrent**, **putgrent**, **getgrnam**, **getgrgid**, **setgrent**, and **endgrent** subroutines.

The **getgroupattr** subroutine reads a specified attribute from the group database. If the database is not already open, the subroutine will do an implicit open for reading.

Similarly, the **putgroupattr** subroutine writes a specified attribute into the group database. If the database is not already open, the subroutine does an implicit open for reading and writing. Data changed by **putgroupattr** must be explicitly committed by calling the **putgroupattr** subroutine with a *Type* parameter specifying the **SEC_COMMIT** value. Until the data is committed, only **get** subroutine calls within the process will return the written data.

New entries in the user and group databases must first be created by invoking **putgroupattr** with the **SEC_NEW** type.

The **IDtogroup** subroutine translates a group ID into a group name.

The **nextgroup** subroutine returns the next group in a linear search of the group database. The consistency of consecutive searches depends upon the underlying storage-access mechanism and is not guaranteed by this subroutine.

The **setuserdb** and **enduserdb** subroutines should be used to open and close the user database.

Parameters

Item	Description
Argument	Presently unused and must be specified as null.
Attribute	Specifies which attribute is read. The following possible values are defined in the **usersec.h** file: **S_ID** Group ID. The attribute type is **SEC_INT**. **S_USERS** Members of the group. The attribute type is **SEC_LIST**. **S_ADMS** Administrators of the group. The attribute type is **SEC_LIST**. **S_ADMIN** Administrative status of a group. Type: **SEC_BOOL**. **S_GRPEXPORT** Specifies if the DCE registry can overwrite the local group information with the DCE group information during a DCE export operation. The attribute type is **SEC_BOOL**. Additional user-defined attributes may be used and will be stored in the format specified by the *Type* parameter.
GID	Specifies the group ID to be translated into a group name.
Group	Specifies the name of the group for which an attribute is to be read.
Mode	Specifies the search mode. Also can be used to delimit the search to one or more user credential databases. Specifying a non-null *Mode* value implicitly rewinds the search. A null mode continues the search sequentially through the database. This parameter specifies one of the following values as a bit mask (defined in the **usersec.h** file): **S_LOCAL** The local database of groups are included in the search. **S_SYSTEM** All credentials servers for the system are searched.

Item	Description
Type	Specifies the type of attribute expected. Valid values are defined in the **usersec.h** file and include: **SEC_INT** The format of the attribute is an integer. The buffer returned by the **getgroupattr** subroutine and the buffer supplied by the **putgroupattr** subroutine are defined to contain an integer. **SEC_CHAR** The format of the attribute is a null-terminated character string. **SEC_LIST** The format of the attribute is a series of concatenated strings, each null-terminated. The last string in the series is terminated by two successive null characters. **SEC_BOOL** A pointer to an integer (**int ***) that has been cast to a null pointer. **SEC_COMMIT** For the **putgroupattr** subroutine, this value specified by itself indicates that changes to the named group are committed to permanent storage. The *Attribute* and *Value* parameters are ignored. If no group is specified, changes to all modified groups are committed to permanent storage. **SEC_DELETE** The corresponding attribute is deleted from the database. **SEC_NEW** If using the **putgroupattr** subroutine, updates all the group database files with the new group name.
Value	Specifies the address of a pointer for the **getgroupattr** subroutine. The **getgroupattr** subroutine will return the address of a buffer in the pointer. For the **putgroupattr** subroutine, the *Value* parameter specifies the address of a buffer in which the attribute is stored. See the *Type* parameter for more details.

Security

Item	Description
Files Accessed:	

Mode	File
rw	**/etc/group** (write access for **putgroupattr**)
rw	**/etc/security/group** (write access for **putgroupattr**)

Return Values

The **getgroupattr** and **putgroupattr** subroutines, when successfully completed, return a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

The **IDtogroup** and **nextgroup** subroutines return a character pointer to a buffer containing the requested group name, if successfully completed. Otherwise, a null pointer is returned and the **errno** global variable is set to indicate the error.

Error Codes

Note: All of these subroutines return errors from other subroutines.

These subroutines fail if the following is true:

Item	Description
EACCES	Access permission is denied for the data request.

The **getgroupattr** subroutine fails if the following is returned:

Item	Description
EIO	Failed to access remote group database.

The **getgroupattr** and **putgroupattr** subroutines fail if one or more of the following are true:

Item	Description
EINVAL	The *Value* parameter does not point to a valid buffer or to valid data for this type of attribute. Limited testing is possible and all errors may not be detected.
EINVAL	The *Type* parameter contains more than one of the **SEC_INT**, **SEC_BOOL**, **SEC_CHAR**, **SEC_LIST**, or **SEC_COMMIT** attributes.
EINVAL	The *Type* parameter specifies that an individual attribute is to be committed, and the *Group* parameter is null.
ENOENT	The specified *Group* parameter does not exist or the attribute is not defined for this group.
EPERM	Operation is not permitted.

The **IDtogroup** subroutine fails if the following is true:

Item	Description
ENOENT	The *GID* parameter could not be translated into a valid group name on the system.

The **nextgroup** subroutine fails if one or more of the following are true:

Item	Description
EINVAL	The *Mode* parameter is not null, and does not specify either **S_LOCAL** or **S_SYSTEM**.
EINVAL	The *Argument* parameter is not null.
ENOENT	The end of the search was reached.

getgroupattrs Subroutine

Purpose

Retrieves multiple group attributes in the group database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>

int getgroupattrs (Group, Attributes, Count)
char * Group;
```

```
dbattr_t * Attributes;
int Count
```

Description

Attention: Do not use this subroutine and the **setpwent** and **setgrent** subroutines simultaneously. The results can be unpredictable.

The **getgroupattrs** subroutine accesses group information. Because of its greater granularity and extensibility, use it instead of the **getgrent** routines.

The **getgroupattrs** subroutine reads one or more attributes from the group database. If the database is not already open, this subroutine does an implicit open for reading. A call to the **getgroupattrs** subroutine with an *Attributes* parameter of null and *Count* parameter of 0 for every new group verifies that the group exists.

The *Attributes* array contains information about each attribute that is to be read. The **dbattr_t** data structure contains the following fields:

attr_name
The name of the desired attribute.

attr_idx
Used internally by the **getgroupattrs** subroutine.

attr_type
The type of the desired attribute. The list of attribute types is defined in the **usersec.h** header file.

attr_flag
The results of the request to read the desired attribute.

attr_un
A union containing the returned values. Its union members that follow correspond to the definitions of the **attr_char**, **attr_int**, **attr_long**, and **attr_llong** macros, respectively:

au_char
Attributes of type **SEC_CHAR** and **SEC_LIST** store a pointer to the returned attribute in this member when the requested attribute is successfully read. The caller is responsible for freeing this memory.

au_int
Attributes of type **SEC_INT** and **SEC_BOOL** store the value of the attribute in this member when the requested attribute is successfully read.

au_long
Attributes of type **SEC_LONG** store the value of the attribute in this member when the requested attribute is successfully read.

au_llong
Attributes of type **SEC_LLONG** store the value of the attribute in this member when the requested attribute is successfully read.

attr_domain
The authentication domain containing the attribute. The **getgroupattrs** subroutine is responsible for managing the memory referenced by this pointer. If **attr_domain** is specified for an attribute, the get request is sent only to that domain. If **attr_domain** is not specified (that is, set to NULL), **getgroupattrs** searches the domains in a predetermined order. The search starts with the local file system and continues with the domains specified in the **/usr/lib/security/methods.cfg** file. This search space can be restricted with the **setauthdb** subroutine so that only the domain specified in the **setauthdb** call is searched. If **attr_domain** is not specified, the **getgroupattrs** subroutine sets this field to the name of the domain from which the value is retrieved. If the request for a NULL domain was not satisfied, the request is tried from the local files using the default stanza.

Use the **setuserdb** and **enduserdb** subroutines to open and close the group database. Failure to explicitly open and close the group database can result in loss of memory and performance.

Parameters

Item	Description
Group	Specifies the name of the group for which the attributes are to be read.
Attributes	A pointer to an array of 0 or more elements of type **dbattr_t**. The list of group attributes is defined in the **usersec.h** header file.
Count	The number of array elements in *Attributes*. A *Count* parameter of 0 can be used to determine if the group exists.

Security

Files accessed:

Item	Description
Mode	**File**
rw	**/etc/group**
rw	**/etc/security/group**

Return Values

If *Group* exists, the **getgroupattrs** subroutine returns 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error. Each element in the *Attributes* array must be examined on a successful call to **getgroupattrs** to determine if the *Attributes* array entry was successfully retrieved.

Error Codes

The **getgroupattrs** subroutine returns an error that indicates that the group does or does not exist. Additional errors can indicate an error querying the information databases for the requested attributes.

Item	Description
EINVAL	The *Count* parameter is less than zero.
EINVAL	The *Attributes* parameter is null and the *Count* parameter is greater than 0.
ENOENT	The specified *Group* parameter does not exist.
EIO	Failed to access the remote group database.

If the **getgroupattrs** subroutine fails to query an attribute, one or more of the following errors is returned in the **attr_flag** field of the corresponding *Attributes* element:

Item	Description
EACCES	The user does not have access to the attribute specified in the *attr_name* field.
EINVAL	The **attr_type** field in the *Attributes* entry contains an invalid type.
EINVAL	The **attr_un** field in the *Attributes* entry does not point to a valid buffer or to valid data for this type of attribute. Limited testing is possible and all errors might not be detected.
ENOATTR	The **attr_name** field in the *Attributes* entry specifies an attribute that is not defined for this user or group.
ENOMEM	Memory could not be allocated to store the return value.

Examples

The following sample test program displays the output to a call to **getgroupattrs**. In this example, the system has a user named foo.

```
    attribute name   : id
    attribute flag   : 0
    attribute domain : files
    attribute value  : 204

    attribute name   : admin
    attribute flag   : 0
    attribute domain : files
    attribute value  : 0

    attribute name   : adms
    attribute flag   : 0
    attribute domain : files
    attribute value  :

    attribute name   : registry
    attribute flag   : 0
    attribute domain :
    attribute value  : compat

 */
#include <stdio.h>
#include <usersec.h>

            /*
```

```
             * No attribute value. Continue.
             */
            printf("\n");
            continue;
        }
        /*
         * We have a value.
         */
        printf("attribute domain : %s \n", attributes[i].attr_domain);
        printf("attribute value  : ");

        switch (attributes[i].attr_type)
        {
            case SEC_CHAR:
                if (attributes[i].attr_char) {
                                printf("%s\n", attributes[i].attr_char);
                    free(attributes[i].attr_char);
                }
                break;
            case SEC_LIST:
                if (attributes[i].attr_char) {
                                printf("%s\n", ConvertToComma(
                            attributes[i].attr_char));
                    free(attributes[i].attr_char);
                }
                                break;
            case SEC_INT:
            case SEC_BOOL:
                                printf("%d\n", attributes[i].attr_int);
                                break;
            default:
                break;
                }
        printf("\n");
    }
    exit(0);
}

/*
 * ConvertToComme:
 * replaces NULLs in str with commas.
 */
char *
ConvertToComma(char *str)
{
        char *s = str;

        if (! str || ! *str)
                return(s);

        for (; *str; str++) {
                while(*(++str));
                *str = ',';
        }

        *(str-1) = 0;
        return(s);
}
```

The following output for the call is expected:

```
    attribute name   : id
    attribute flag   : 0
    attribute domain : files
    attribute value  : 204

    attribute name   : admin
    attribute flag   : 0

    attribute flag   : 0
    attribute domain : files
    attribute value  :

    attribute name   : registry
    attribute flag   : 0
    attribute domain :
    attribute value  : compat
```

Files

Item	Description
/etc/group	Contains group IDs.

getgroups Subroutine

Purpose

Gets the supplementary group ID of the current process.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/types.h>
#include <unistd.h>

int getgroups (NGroups, GIDSet)
int  NGroups;
gid_t  GIDSet [ ];
```

Description

The **getgroups** subroutine gets the supplementary group ID of the process. The list is stored in the array pointed to by the *GIDSet* parameter. The *NGroups* parameter indicates the number of entries that can be stored in this array. The **getgroups** subroutine never returns more than the number of entries specified by the **NGROUPS_MAX** constant. (The **NGROUPS_MAX** constant is defined in the **limits.h** file.) If the value in the *NGroups* parameter is 0, the **getgroups** subroutine returns the number of groups in the supplementary group.

Parameters

Item	Description
GIDSet	Points to the array in which the supplementary group ID of the user's process is stored.
NGroups	Indicates the number of entries that can be stored in the array pointed to by the *GIDSet* parameter.

Return Values

Upon successful completion, the **getgroups** subroutine returns the number of elements stored into the array pointed to by the *GIDSet* parameter. If the **getgroups** subroutine is unsuccessful, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **getgroups** subroutine is unsuccessful if either of the following error codes is true:

Item	Description
EFAULT	The *NGroups* and *GIDSet* parameters specify an array that is partially or completely outside of the allocated address space of the process.

Item	Description
EINVAL	The *NGroups* parameter is smaller than the number of groups in the supplementary group.

getgrpaclattr, nextgrpacl, or putgrpaclattr Subroutine

Purpose

Accesses the group screen information in the SMIT ACL database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
```

```
int getgrpaclattr (Group, Attribute, Value, Type)
char *User;
char *Attribute;
void *Value;
int Type;
```

```
char *nextgrpacl(void)
```

```
int putgrpaclattr (Group, Attribute, Value, Type)
char *User;
char *Attribute;
void *Value;
int Type;
```

Description

The **getgrpaclattr** subroutine reads a specified group attribute from the SMIT ACL database. If the database is not already open, this subroutine does an implicit open for reading.

Similarly, the **putgrpaclattr** subroutine writes a specified attribute into the user SMIT ACL database. If the database is not already open, this subroutine does an implicit open for reading and writing. Data changed by the **putgrpaclattr** subroutine must be explicitly committed by calling the **putgrpaclattr** subroutine with a *Type* parameter specifying **SEC_COMMIT**. Until all the data is committed, only the **getgrpaclattr** subroutine within the process returns written data.

The **nextgrpacl** subroutine returns the next group in a linear search of the group SMIT ACL database. The consistency of consecutive searches depends upon the underlying storage-access mechanism and is not guaranteed by this subroutine.

The **setacldb** and **endacldb** subroutines should be used to open and close the database.

Parameters

Item	Description
Attribute	Specifies which attribute is read. The following possible attributes are defined in the **usersec.h** file: **S_SCREENS** String of SMIT screens. The attribute type is **SEC_LIST**.

Item	Description
Type	Specifies the type of attribute expected. Valid types are defined in the **usersec.h** file and include: **SEC_LIST** The format of the attribute is a series of concatenated strings, each null-terminated. The last string in the series must be an empty (zero character count) string. For the **getgrpaclattr** subroutine, the user should supply a pointer to a defined character pointer variable. For the **putgrpaclattr** subroutine, the user should supply a character pointer. **SEC_COMMIT** For the **putgrpaclattr** subroutine, this value specified by itself indicates that changes to the named group are to be committed to permanent storage. The *Attribute* and *Value* parameters are ignored. If no group is specified, the changes to all modified groups are committed to permanent storage. **SEC_DELETE** The corresponding attribute is deleted from the group SMIT ACL database. **SEC_NEW** Updates the group SMIT ACL database file with the new group name when using the **putgrpaclattr** subroutine.
Value	Specifies a buffer, a pointer to a buffer, or a pointer to a pointer depending on the *Attribute* and *Type* parameters. See the *Type* parameter for more details.

Return Values

If successful, the **getgrpaclattr** returns 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

Possible return codes are:

Item	Description
EACCES	Access permission is denied for the data request.
ENOENT	The specified *Group* parameter does not exist or the attribute is not defined for this group.
ENOATTR	The specified user attribute does not exist for this group.
EINVAL	The *Attribute* parameter does not contain one of the defined attributes or null.
EINVAL	The *Value* parameter does not point to a valid buffer or to valid data for this type of attribute.
EPERM	Operation is not permitted.

getgrset Subroutine

Purpose

Accesses the concurrent group set information in the user database.

Library

Standard C Library (**libc.a)**

Syntax

```
char *getgrset (User)
const char * User;
```

Description

The **getgrset** subroutine returns a pointer to the comma separated list of concurrent group identifiers for the named user.

If the Network Information Service (NIS) is enabled on the system, these subroutines attempt to retrieve the user information from the NIS authentication server.

Notes:

- If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file, all the group IDs are fetched from the Lightweight Directory Access Protocol (LDAP) and the files domains, if the user belongs to any one of these domains.
- The **getgrset** subroutine is not a threadsafe subroutine. For information about the threadsafe subroutine, see the **getgrset_r** subroutine.

Parameters

Item	Description
User	Specifies the user name.

Return Values

If successful, the **getgrset** subroutine returns a pointer to a list of supplementary groups. This pointer must be freed by the user.

Error Codes

A **NULL** pointer is returned on error. The value of the **errno** global variable is undefined on error.

File

Item	Description
/etc/group	Contains basic group attributes.

getgrset_r Subroutine

Purpose

Obtains group set information in the user database.

Library

Threadsafe C Library (**libc.a)**

Syntax

#include <sys/types.h>

#include <grp.h>

#define _THREAD_SAFE

int **getgrset_r** (char *nam, struct _grjunk * grp)

Description

The **getgrset_r** subroutine populates group data into the structure pointed by group for the named user. It returns TS_SUCCESS if the group information is populated.

If the Network Information Service (NIS) is enabled on the system, these subroutines attempt to retrieve the user information from the NIS authentication server.

Note: If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file, all the group IDs are fetched from the Lightweight Directory Access Protocol (LDAP) and files domains, if the user belongs to any one of these domains.

Parameters

Item	Description
User	Specifies the user name.

Return Values

If successful, the **getgrset_r** subroutine fills the group-related information into the second parameter and returns 0.

Error Codes

The **getgrset_r** subroutine returns -1 when it is unable to populate the **struct_grjunk *grp** structure.

File

Item	Description
/etc/group	Contains basic group attributes.

getinterval, incinterval, absinterval, resinc, resabs, alarm, ualarm, getitimer or setitimer Subroutine

Purpose

Manipulates the expiration time of interval timers.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/time.h>

int getinterval ( timerID,  value)
timer_t timerID;
struct itimerstruc_t *value;

int incinterval (timerID, value,  ovalue)
timer_t timerID;
struct itimerstruc_t *value, *ovalue;
```

```
int absinterval (timerID, value, ovalue)
timer_t timerID;
struct itimerstruc_t *value, *ovalue;

int resabs (timerID,  resolution,  maximum)
timer_t timerID;
struct timestruc_t *resolution, *maximum;

int resinc (timerID, resolution, maximum)
timer_t timerID;
struct timestruc_t *resolution, *maximum;
```

```
#include <unistd.h>
```

```
unsigned int alarm ( seconds)
unsigned int seconds;

useconds_t ualarm (value,  interval)
useconds_t value, interval;

int setitimer ( which, value, ovalue)
int which;
struct itimerval *value, *ovalue;

int getitimer (which, value)
int which;
struct itimerval *value;
```

Description

The **getinterval**, **incinterval**, and **absinterval** subroutines manipulate the expiration time of interval timers. These functions use a timer value defined by the **struct itimerstruc_t** structure, which includes the following fields:

```
struct timestruc_t it_interval;   /* timer interval period      */
struct timestruc_t it_value;      /* timer interval expiration  */
```

If the `it_value` field is nonzero, it indicates the time to the next timer expiration. If `it_value` is 0, the per-process timer is disabled. If the `it_interval` member is nonzero, it specifies a value to be used in reloading the `it_value` field when the timer expires. If `it_interval` is 0, the timer is to be disabled after its next expiration (assuming `it_value` is nonzero).

The **getinterval** subroutine returns a value from the **struct itimerstruc_t** structure to the *value* parameter. The `it_value` field of this structure represents the amount of time in the current interval before the timer expires, should one exist for the per-process timer specified in the *timerID* parameter. The `it_interval` field has the value last set by the **incinterval** or **absinterval** subroutine. The fields of the *value* parameter are subject to the resolution of the timer.

The **incinterval** subroutine sets the value of a per-process timer to a given offset from the current timer setting. The **absinterval** subroutine sets the value of the per-process timer to a given absolute value. If the specified absolute time has already expired, the **absinterval** subroutine will succeed and the expiration notification will be made. Both subroutines update the interval timer period. Time values smaller than the resolution of the specified timer are rounded up to this resolution. Time values larger than the maximum value of the specified timer are rounded down to the maximum value.

The **resinc** and **resabs** subroutines return the resolution and maximum value of the interval timer contained in the *timerID* parameter. The resolution of the interval timer is contained in the *resolution* parameter, and the maximum value is contained in the *maximum* parameter. These values might not be

the same as the values returned by the corresponding system timer, the **gettimer** subroutine. In addition, it is likely that the maximum values returned by the **resinc** and **resabs** subroutines will be different.

Note: If a nonprivileged user attempts to submit a fine granularity timer (that is, a timer request of less than 10 milliseconds), the timer request is raised to 10 milliseconds.

The **alarm** subroutine causes the system to send the calling thread's process a **SIGALRM** signal after the number of real-time seconds specified by the *seconds* parameter have elapsed. Since the signal is sent to the process, in a multi-threaded process another thread than the one that called the **alarm** subroutine may receive the **SIGALRM** signal. Processor scheduling delays may prevent the process from handling the signal as soon as it is generated. If the value of the *seconds* parameter is 0, a pending alarm request, if any, is canceled. Alarm requests are not stacked. Only one **SIGALRM** generation can be scheduled in this manner. If the **SIGALRM** signal has not yet been generated, the call results in rescheduling the time at which the **SIGALRM** signal is generated. If several threads in a process call the **alarm** subroutine, only the last call will be effective.

The **ualarm** subroutine sends a **SIGALRM** signal to the invoking process in a specified number of seconds. The **getitimer** subroutine gets the value of an interval timer. The **setitimer** subroutine sets the value of an interval timer.

Parameters

Item	Description
timerID	Specifies the ID of the interval timer.
value	Points to a **struct itimerstruc_t** structure.
ovalue	Represents the previous time-out period.
resolution	Resolution of the timer.
maximum	Indicates the maximum value of the interval timer.
seconds	Specifies the number of real-time seconds to elapse before the first **SIGALRM** signal.
interval	Specifies the number of microseconds between subsequent periodic **SIGALRM** signals. If a nonprivileged user attempts to submit a fine granularity timer (that is, a timer request of less than 10 milliseconds), the timer request interval is automatically raised to 10 milliseconds.
which	Identifies the type of timer. Valid values are: **ITIMER_PROF** Decrements in process virtual time and when the system runs on behalf of the process. It is designed for use by interpreters in statistically profiling the execution of interpreted programs. Each time the **ITIMER_PROF** timer expires, the **SIGPROF** signal occurs. Because this signal may interrupt in-progress system calls, programs using this timer must be prepared to restart interrupted system calls. **ITIMER_REAL** Decrements in real time. A **SIGALRM** signal occurs when this timer expires. **ITMER_REAL_TH** Real-time, per-thread timer. Decrements in real time and delivers a **SIGTALRM** signal when it expires. The **SIGTALRM** is sent to the thread that sets the timer. Each thread has its own timer and can manipulate its own timer. This timer is only supported with the 1:1 thread model. If the timer is used in M:N thread model, undefined results might occur. **ITIMER_VIRTUAL** Decrements in process virtual time. It runs only during process execution. A **SIGVTALRM** signal occurs when it expires.

Return Values

If these subroutines are successful, a value of 0 is returned. If an error occurs, a value of -1 is returned and the **errno** global variable is set.

The **alarm** subroutine returns the amount of time (in seconds) remaining before the system is scheduled to generate the **SIGALARM** signal from the previous call to **alarm**. It returns a 0 if there was no previous **alarm** request.

The **ualarm** subroutine returns the number of microseconds previously remaining in the alarm clock.

Error Codes

If the **getinterval**, **incinterval**, **absinterval**, **resinc**, **resabs**, **setitimer**, **getitimer**, or **setitimer** subroutine is unsuccessful , a value of -1 is returned and the **errno** global variable is set to one of the following error codes:

Item	Description
EINVAL	Indicates that the *timerID* parameter does not correspond to an ID returned by the **gettimerid** subroutine, or a value structure specified a nanosecond value less than 0 or greater than or equal to one thousand million (1,000,000,000).
EIO	Indicates that an error occurred while accessing the timer device.
EFAULT	Indicates that a parameter address has referenced invalid memory.

The **alarm** subroutine is always successful. No return value is reserved to indicate an error for it.

getiopri Subroutine

Purpose

Enables the getting of a process I/O priority.

Syntax

```
short getiopri (ProcessID);
pid_t ProcessID;
```

Description

The `getiopri` subroutine returns the I/O scheduling priority of a process. If the target process ID does not match the process ID of the caller, the caller must either be running as root, or have an effective and real user ID that matches the target process.

Parameters

Item	Description
ProcessID	Specifies the process ID. If this value is `-1`, the current process scheduling priority is returned.

Return Values

Upon successful completion, the `getiopri` subroutine returns the I/O scheduling priority of a thread in the process. A returned value of `IOPRIORITY_UNSET` indicates that the I/O priority was not set. Otherwise, a value of `-1` is returned and the `errno` global variable is set to indicate the error.

Errors

Item	Description
EPERM	The calling process is not root. It does not have the same process ID as the target process, and does not have the same real effective user ID as the target process.
ESRCH	No process can be found corresponding to the specified *ProcessID*.

Implementation Specifics

1. Implementation requires an additional field in the `proc` structure.
2. The default setting for process I/O priority is `IOPRIORITY_UNSET`.
3. Once set, process I/O priorities should be inherited across a `fork`. I/O priorities should not be inherited across an `exec`.
4. The `setiopri` system call generates an auditing event using *audit_svcstart* if auditing is enabled on the system (*audit_flag* is true).

getipnodebyaddr Subroutine

Purpose

Address-to-nodename translation.

Library

Standard C Library (**libc.a**)

(**libaixinet**)

Syntax

```
#include <sys/socket.h>
#include <netdb.h>
struct hostent *getipnodebyaddr(src, len, af, error_num)
const void *src;
size_t len;
int af;
int *error_num;
```

Description

The **getipnodebyaddr** subroutine has the same arguments as the **gethostbyaddr** subroutine but adds an error number. It is thread-safe.

The **getipnodebyaddr** subroutine is similar in its name query to the **gethostbyaddr** subroutine except in one case. If *af* equals AF_INET6 and the IPv6 address is an IPv4-mapped IPv6 address or an IPv4-compatible address, then the first 12 bytes are skipped over and the last 4 bytes are used as an IPv4 address with af equal to AF_INET to lookup the name.

If the **getipnodebyaddr** subroutine is returning success, then the single address that is returned in the **hostent** structure is a copy of the first argument to the function with the same address family and length that was passed as arguments to this function.

All of the information returned by **getipnodebyaddr** is dynamically allocated: the **hostent** structure and the data areas pointed to by the `h_name`, `h_addr_lisy`, and `h_aliases` members of the **hostent** structure. To return this information to the system the function **freehostent** is called.

Parameters

Item	Description
src	Specifies a node address. It is a pointer to either a 4-byte (IPv4) or 16-byte (IPv6) binary format address.
af	Specifies the address family which is either AF_INET or AF_INET6.
len	Specifies the length of the node binary format address.
error_num	Returns argument to the caller with the appropriate error code.

Return Values

The **getipnodebyaddr** subroutine returns a pointer to a **hostent** structure on success.

The **getipnodebyaddr** subroutine returns a null pointer if an error occurs. The *error_num* parameter is set to indicate the error.

Error Codes

Item	Description
HOST_NOT_FOUND	The host specified by the *name* parameter was not found.
TRY_AGAIN	The local server did not receive a response from an authoritative server. Try again later.
NO_RECOVERY	This error code indicates an unrecoverable error.
NO_ADDRESS	The requested *name* is valid but does not have an Internet address at the name server.

getipnodebyname Subroutine

Purpose

Nodename-to-address translation.

Library

Standard C Library (**libc.a**)

(**libaixinet**)

Syntax

```
#include <libc.a>
#include <netdb.h>
struct hostent *getipnodebyname(name, af, flags, error_num)
const char *name;
int af;
int flags;
int *error_num;
```

Description

The commonly used functions **gethostbyname** and **gethostbyname2** are inadequate for many applications. You could not specify the type of addresses desired in **gethostbyname**. In **gethostbyname2**, a global option (RES_USE_INET6) is required when IPV6 addresses are used. Also, **gethostbyname2** needed more control over the type of addresses required.

The **getipnodebyname** subroutine gives the caller more control over the types of addresses required and is thread safe. It also does not need a global option like RES_USE_INET6.

The name argument can be either a node name or a numeric (either a dotted-decimal IPv4 or colon-seperated IPv6) address.

The *flags* parameter values include AI_DEFAULT, AI_V4MAPPED, AI_ALL and AI_ADDRCONFIG. The special flags value AI_DEFAULT is designed to handle most applications. Its definition is:

```
#define AI_DEFAULT (AI_V4MAPPED | AI_ADDRCONFIG)
```

When porting simple applications to use IPv6, simply replace the call:

```
hp = gethostbyname(name);
```

with

```
hp = getipnodebyname(name, AF_INET6, AI_DEFAULT, &error_num);
```

To modify the behavior of the **getipnodebyname** subroutine, constant values can be logically-ORed into the *flags* parameter.

A *flags* value of 0 implies a strict interpretation of the *af* parameter. If *af* is AF_INET then only IPv4 addresses are searched for and returned. If *af* is AF_INET6 then only IPv6 addresses are searched for and returned.

If the AI_V4MAPPED flag is specified along with an *af* of AF_INET6, then the caller accepts IPv4-mapped IPv6 addresses. That is, if a query for IPv6 addresses fails, then a query for IPv4 addresses is made and if any are found, then they are returned as IPv4-mapped IPv6 addresses. The AI_V4MAPPED flag is only valid with an *af* of AF_INET6.

If the AI_ALL flag is used in conjunction the AI_V4MAPPED flag and *af* is AF_INET6, then the caller wants all addresses. The addresses returned are IPv6 addresses and/or IPv4-mapped IPv6 addresses. Only if both queries (IPv6 and IPv4) fail does **getipnodebyname** return NULL. Again, the AI_ALL flag is only valid with an *af* of AF_INET6.

The AI_ADDRCONFIG flag is used to specify that a query for IPv6 addresses should only occur if the node has at least one IPv6 source address configured and a query for IPv4 addresses should only occur if the node has at least one IPv4 source address configured. For example, if the node only has IPv4 addresses configured, af equals AF_INET6, and the node name being looked up has both IPv4 and IPv6 addresses, then if only the AI_ADDRCONFIG flag is specified, getipnodebyname will return NULL. If the AI_V4MAPPED flag is specified with the AI_ADDRCONFIG flag (AI_DEFAULT), then any IPv4 addresses found will be returned as IPv4-mapped IPv6 addresses.

There are 4 different situations when the name argument is a literal address string:

1. *name* is a dotted-decimal IPv4 address and *af* is AF_INET. If the query is successful, then `h_name` points to a copy of *name*, `h_addrtype` is the *af* argument, `h_length` is 4, `h_aliases` is a NULL pointer, `h_addr_list[0]` points to the 4-byte binary address and `h_addr_list[1]` is a NULL pointer.
2. *name* is a colon-separated IPv6 address and *af* is AF_INET6. If the query is successful, then `h_name` points to a copy of *name*, `h_addrtype` is the *af* parameter, `h_length` is 16, `h_aliases` is a NULL pointer, `h_addr_list[0]` points to the 16-byte binary address and `h_addr_list[1]` is a NULL pointer.
3. *name* is a dotted-decimal IPv4 address and *af* is AF_INET6. If the AI_V4MAPPED flag is specified and the query is successful, then `h_name` points to an IPv4-mapped IPv6 address string, `h_addrtype` is the *af* argument, `h_length` is 16, `h_aliases` is a NULL pointer, `h_addr_list[0]` points to the 16-byte binary address and `h_addr_list[1]` is a NULL pointer.
4. *name* is a colon-separated IPv6 address and af is AF_INET. This is an error, **getipnodebyname** returns a NULL pointer and *error_num* equals HOST_NOT_FOUND.

Parameters

Item	Description
name	Specifies either a node name or a numeric (either a dotted-decimal IPv4 or colon-separated IPv6) address.
af	Specifies the address family which is either AF_INET or AF_INET6.
flags	Controls the types of addresses searched for and the types of addresses returned.
error_num	Returns argument to the caller with the appropriate error code.

Return Values

The **getipnodebyname** subroutine returns a pointer to a **hostent** structure on success.

The **getipnodebyname** subroutine returns a null pointer if an error occurs. The *error_num* parameter is set to indicate the error.

Error Codes

Item	Description
HOST_NOT_FOUND	The host specified by the *name* parameter was not found.
TRY_AGAIN	The local server did not receive a response from an authoritative server. Try again later.
NO_RECOVERY	The host specified by the *name*parameter was not found. This error code indicates an unrecoverable error.
NO_ADDRESS	The requested *name* is valid but does not have an Internet address at the name server.

getline, getdelim Subroutines

Purpose

Reads a delimited record from a stream.

Library

Standard Library (**libc.a**)

Syntax

```
#include <stdio.h>
ssize_t getdelim(char **lineptr, size_t *n, int delimiter, FILE *stream);
ssize_t getline(char **lineptr, size_t *n, FILE *stream);
```

Description

The **getdelim** function reads from stream until it encounters a character matching the delimiter character. The delimiter argument is an int, the value of which the application will ensure is a character representable as an unsigned char of equal value that terminates the read process. If the delimiter argument has any other value, the behavior is undefined.

The application will ensure that *lineptr is a valid argument that could be passed to the free() function. If *n is non-zero, the application shall ensure that *lineptr points to an object of at least *n bytes.

The **getline()** function is equivalent to the **getdelim()** function with delimiter character equal to the '\n' character.

Return Values

Upon successful completion, the **getdelim()** function will return the number of characters written into the buffer, including the delimiter character if one was encountered before EOF. Otherwise, it returns -1 and set the errno to indicate the error.

Error Codes

The function may fail if:

Item	Description
[EINVAL]	lineptr or n are null pointers
[ENOMEM]	Insufficient memory is available.
[EINVAL]	Stream is not a valid file descriptor.
[EOVERFLOW]	More than {SSIZE_MAX} characters were read without encountering the delimiter character.

getlogin Subroutine

Purpose

Gets a user's login name.

Library

Standard C Library (**libc.a**)

Syntax

```
include <sys/types.h>
include <unistd.h>
include <limits.h>
```

```
char *getlogin (void)
```

Description

Attention: Do not use the **getlogin** subroutine in a multithreaded environment. To access the thread-safe version of this subroutines, see the **getlogin_r** (“getlogin_r Subroutine” on page 482) subroutine.

Attention: The **getlogin** subroutine returns a pointer to an area that may be overwritten by successive calls.

The **getlogin** subroutine returns a pointer to the login name in the /**etc**/**utmp** file. You can use the **getlogin** subroutine with the **getpwnam** (“getpwent, getpwuid, getpwnam, putpwent, setpwent, or endpwent Subroutine” on page 524) subroutine to locate the correct password file entry when the same user ID is shared by several login names.

If the **getlogin** subroutine cannot find the login name in the /**etc**/**utmp** file, it returns the process **LOGNAME** environment variable. If the **getlogin** subroutine is called within a process that is not attached

to a terminal, it returns the value of the **LOGNAME** environment variable. If the **LOGNAME** environment variable does not exist, a null pointer is returned.

In UNIX03 mode, if the login name cannot be found in the `/etc/utmp` file or if there is no controlling terminal for the process, the **getlogin** subroutine does not return the **LOGNAME** environment variable, it returns a null pointer and sets the error code **ENXIO**. This behavior is enabled by setting the environment variable **XPG_SUS_ENV=ON** (which enables all UNIX03 functionality) or by setting the variable **XPG_GETLOGIN=ON** (which just enables UNIX03 mode for the **getlogin** and **getlogin_r** subroutines).

Return Values

The return value can point to static data whose content is overwritten by each call. If the login name is not found, the **getlogin** subroutine returns a null pointer.

Error Codes

If the **getlogin** function is unsuccessful, it returns one or more of the following error codes:

Item	Description
EMFILE	Indicates that the **OPEN_MAX** file descriptors are currently open in the calling process.
ENFILE	Indicates that the maximum allowable number of files is currently open in the system.
ENXIO	Indicates that the calling process has no controlling terminal.

Files

Item	Description
/etc/utmp	Contains a record of users logged into the system.

getlogin_r Subroutine

Purpose

Gets a user's login name.

Library

Thread-Safe C Library (**libc_r.a**)

Syntax

```
int getlogin_r (Name, Length)
char * Name;
size_t  Length;
```

Description

The **getlogin_r** subroutine gets a user's login name from the **/etc/utmp** file and places it in the *Name* parameter. Only the number of bytes specified by the *Length* parameter (including the ending null value) are placed in the *Name* parameter.

Applications that call the **getlogin_r** subroutine must allocate memory for the login name before calling the subroutine. The name buffer must be the length of the *Name* parameter plus an ending null value.

If the **getlogin_r** subroutine cannot find the login name in the **utmp** file or the process is not attached to a terminal, it places the **LOGNAME** environment variable in the name buffer. If the **LOGNAME** environment variable does not exist, the *Name* parameter is set to null and the **getlogin_r** subroutine returns a -1.

In UNIX03 mode, if the login name cannot be found in the `/etc/utmp` file or if there is no controlling terminal for the process, the **getlogin_r** subroutine does not place the **LOGNAME** environment variable in the name buffer, it just returns the error code **ENXIO**. This behavior is enabled by setting the environment variable **XPG_SUS_ENV=ON** (which enables all UNIX03 functionality) or by setting the variable **XPG_GETLOGIN=ON** (which just enables UNIX03 mode for the **getlogin** and **getlogin_r** subroutines).

Parameters

Item	Description
Name	Specifies a buffer for the login name. This buffer should be the length of the *Length* parameter plus an ending null value.
Length	Specifies the total length in bytes of the *Name* parameter. No more bytes than the number specified by the *Length* parameter are placed in the *Name* parameter, including the ending null value.

Return Values

If successful, the `getlogin_r` function returns `0`. Otherwise, an error number is returned to indicate the error.

Error Codes

If the **getlogin_r** subroutine does not succeed, it returns one of the following error codes:

Item	Description
EINVAL	Indicates that the *Name* parameter is not valid.
EMFILE	Indicates that the **OPEN_MAX** file descriptors are currently open in the calling process.
ENFILE	Indicates that the maximum allowable number of files are currently open in the system.
ENXIO	Indicates that the calling process has no controlling terminal.
ERANGE	Indicates that the value of *Length* is smaller than the length of the string to be returned, including the terminating null character.

File

Item	Description
/etc/utmp	Contains a record of users logged into the system.

getmax_sl, getmax_tl, getmin_sl, and getmin_tl Subroutines

Purpose

Retrieve maximum and minimum sensitivity label (SL) and integrity label (TL) from the initialized label encodings file.

Library

Trusted AIX Library (**libmls.a**)

Syntax

```
#include <mls/mls.h>
int getmax_sl (sl)
sl_t *sl;

int getmax_tl (tl)
tl_t *tl;

int getmin_sl(sl)
sl_t *sl;

int getmin_tl(tl)
sl_t *tl;
```

Description

The **getmax_sl** subroutine retrieves the maximum SL that is defined in the initialized label encodings file and copies the result to the *sl* parameter.

The **getmax_tl** subroutine retrieves the maximum TL that is defined in the initialized label encodings file and copies the result to the *tl* parameter.

The **getmin_sl** subroutine retrieves the minimum SL that is defined in the initialized label encodings file and copies the result to the *sl* parameter.

The **getmax_tl** subroutine retrieves the minimum TL that is defined in the initialized label encodings file and copies the result to the *tl* parameter.

Requirement: Must initialize the database before running these subroutines.

Parameters

Item	Description
sl	Specifies the sensitivity label to be copied to.
tl	Specifies the integrity label to be copied to.

Files Access

Mode	File
r	**/etc/security/enc/LabelEncodings**

Return Values

If successful, these subroutines return a value of zero. Otherwise, they return a value of -1.

Error Codes

If these subroutines fail, they return one of the following error codes:

Item	Description
ENIVAL	The parameter specifies a value that is null.
ENOTREADY	The database is not initialized.

getmaxyx Subroutine

Purpose

Returns the size of a window.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
getmaxyx( Window, Y, X);
WINDOW *Window;
int  Y,  X;
```

Description

The **getmaxyx** subroutine returns the size of a window. The size is returned as the number of rows and columns in the window. The values are stored in integers *Y* and *X*.

Parameters

Item	Description
Window	Identifies the window whose size to get.
Y	Contains the number of rows in the window.
X	Contains the number of columns in the window.

Example

To obtain the size of the `my_win` window, use:

```
WINDOW *my_win;

int y,x;
getmaxyx(my_win, y, x);
```

Integers *y* and *x* will contain the size of the window.

getnextprojdb Subroutine

Purpose

Retrieves the next project from the specified project database.

Library

The **libaacct.a** library.

Syntax

```
<sys/aacct.h>

getnextprojdb(void *handle, struct project *project, char *comm)
```

Description

The **getnextprojdb** subroutine retrieves the next project definitions from the project database named through the *handle* parameter. The caller must initialize the project database prior to calling this routine with the **projdballoc** routine. Upon successful completion, the project information is copied to the project structure specified by the caller. In addition, the associated project comment, if present, is copied to the buffer pointed to by the *comm* parameter. The comment buffer is allocated by the caller and must have a length of 1024 bytes.

There is an internal state (that is, the current project) associated with the project database. When the project database is initialized, the current project is the first project in the database. The **getnextprojdb** subroutine returns the current project and advances the current project assignment to the next project in the database so that successive calls read each project entry in the database. When the last project is read, the current project assignment is advanced to the end of the database. Any attempt to read beyond the end of the project database results in a failure.

Parameters

Item	Description
handle	Pointer to the **projdb** handle.
project	Pointer to project structure where the retrieved data is stored.
comm	Comment associated with the project in the database.

Security

No restriction. Any user can call this function.

Return Values

Item	Description
0	Success
-1	Failure

Error Codes

Item	Description
EINVAL	Invalid arguments, if passed pointer is NULL.
ENOENT	End of the project database.
ENOENT	No projects available.

getnstr, getstr, mvgetnstr, mvgetstr, mvwgetnstr, mvwgetstr, wgetnstr, or wgetstr Subroutine

Purpose

Gets a multi-byte character string from the terminal.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

int getnstr(char  *str,
int n);

int getstr(char *str);

int mvgetnstr(int y,
int x,
char *st,
int n);

int mvgetstr(int y,
int x,
char *str);

int mvwgetnstr(WINDOW  *win,
int y,
int x,
char *str,
int n);

int mvwgetstr(WINDOW *win,
int y,
int x,
char *str);

int wgetnstr(WINDOW *win,
char *str,
int n);

int wgetstr(WINDOW *win,
char *str);
```

Description

The effect of the **getstr** subroutine is as though a series of calls to the **getch** subroutine was made, until a **newline** subroutine, carriage return, or end-of-file is received. The resulting value is placed in the area pointed to by *str*. The string is then terminated with a null byte. The **getnstr**, **mvgetnstr**, **mvwgetnstr**, and **wgetnstr** subroutines read at most *n* bytes, thus preventing a possible overflow of the input buffer. The user's erase and kill characters are interpreted, as well as any special keys (such as function keys, home key, clear key, and so on).

The **mvgetstr** subroutines is identical to the **getstr** subroutine except that it is as though it is a call to the **move** subroutine and then a series of calls to the **getch** subroutine. The **mvwgetstr** subroutine is identical to the **getstr** subroutine except that it is as though it is a call to the **wmove** subroutine and then a series of calls to the **wgetch** subroutine.

The **mvgetnstr** subroutines is identical to the **getstr** subroutine except that it is as though it is a call to the **move** subroutine and then a series of calls to the **getch** subroutine. The **mvwgetnstr** subroutine is identical to the **getstr** subroutine except that it is as though it is a call to the **wmove** subroutine and then a series of calls to the **wgetch** subroutine.

The **getstr**, **wgetstr**, **mvgetstr**, and **mvwgetstr** subroutines will only return the entire multi-byte sequence associated with a character. If the array is large enough to contain at least one character, the subroutines fill the array with complete characters. If the array is not large enough to contain any complete characters, the function fails.

Parameters

Item	Description
n	Specifies the upper boundary on the number of bytes to read.
x	Holds the column coordinate of the logical cursor.
y	Holds the line or row coordinate of the logical cursor.
**str*	Identifies where to store the string.
**win*	Identifies the window to get the string from and echo it into.

Return Values

Upon successful completion, these subroutines return OK. Otherwise, they return ERR.

Examples

1. To get a string, store it in the user-defined variable `my_string`, and echo it into the stdscr, enter:

```
char *my_string;
getstr(my_string);
```

2. To get a string, echo it into the user-defined window `my_window`, and store it in the user-defined variable `my_string`, enter:

```
WINDOW *my_window;
char *my_string;
wgetstr(my_window, my_string);
```

3. To get a string in the stdscr at coordinates `y=20`, `x=30`, and store it in the user-defined variable `my_string`, enter:

```
char *string;
mvgetstr(20, 30, string);
```

4. To get a string in the user-defined window `my_window` at coordinates `y=20`, `x=30`, and store it in the user-defined variable `my_string`, enter:

```
WINDOW *my_window;
char *my_string;
mvwgetstr(my_window, 20, 30, my_string);
```

getobjattr Subroutine

Purpose

Queries the object security information defined in the domain-assigned object database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
int getobjattr ( Obj, Attribute, Value, Type)
char * Obj;
char * Attribute;
void *Value;
int Type;
```

Description

The **getobjattr** subroutine reads a specified attribute from the domain-assigned object database. If the database is not open, this subroutine does an implicit open for reading. For attributes of the SEC_CHAR and SEC_LIST types, the **getobjattr** subroutine returns the value to the allocated memory. The caller must free this allocated memory.

Parameters

Item	Description
Obj	Specifies the object name.
Attribute	Specifies the attribute to read. The following possible attributes are defined in the **usersec.h** file: • **S_DOMAINS** The list of domains to which the object belongs. The attribute type is **SEC_LIST**. • **S_CONFSETS** The list of domains that are excluded from accessing the object. The attribute type is **SEC_LIST** • S_TYPE The type of the object. Valid values are: – S_NETINT For Network interfaces – S_FILE For file based objects. The object name should be the absolute path – S_DEVICE For Devices. The absolute path should be specified. – S_NETPORT For port and port ranges The attribute type is SEC_CHAR. • S_SECFLAGS The security flags for the object. The valid values are FSF_DOM_ALL and FSF_DOM_ANY. The attribute type is SEC_INT.
Value	Specifies a pointer, or a pointer to a pointer according to the value specified in the *Attribute* and *Type* parameters. See the *Type* parameter for more details.

Item	Description
Type	The *Type* parameter specifies the type of the attribute. The following valid types are defined in the **usersec.h** file: SEC_INT The format of the attribute is an integer. For the subroutine, you must provide a pointer to a defined integer variable. SEC_LIST The format of the attribute is a series of concatenated strings each of which is null-terminated. The last string in the series is terminated by two successive null characters. For the subroutine, you must supply a pointer to a defined character pointer variable. The caller must free this memory.

Security

Files Accessed:

Item	Description
File	**Mode**
`/etc/security/domobjs`	`rw`

Return Values

If successful, the **getobjattr** subroutine returns zero. Otherwise, a value of -1 is returned and the **errno** global value is set to indicate the error.

Error Codes

Item	Description
EINVAL	The *Obj* parameter is NULL. The *Attribute* or *Type* parameter is NULL or does not contain one of the defined values. The *Obj* parameter is ALL and the *Attribute* parameter is not S_DOMAINS. The *Value* parameter does not point to a valid buffer for this type of attribute.
ENOATTR	The *Attribute* parameter is S_DOMAINS, but the *Obj* parameter is not ALL. The attribute specified in the *Attribute* parameter is valid but no value is defined for the object.
ENOENT	The object specified in the *Obj* parameter does not exist.
ENOMEM	Memory cannot be allocated.
EPERM	The operation is not permitted.
EACCES	Access permission is denied for the data request.

getobjattrs Subroutine

Purpose

Retrieves multiple object security attributes from the domain-assigned object database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
int getobjattrs ( Obj, Attributes, Count)
char * Obj;
dbattr_t *Attributes;
int Count;
```

Description

The **getobjattrs** subroutine reads one or more attributes from the domain-assigned object database. The **Attributes** array contains information about each attribute that is to be read. Each element in the **Attributes** array must be examined upon a successful call to the **getobjattrs** subroutine, to determine whether the **Attributes** array was successfully retrieved. The attributes of the SEC_CHAR or SEC_LIST type will have their values returned to the allocated memory. The caller must free this memory. The **dbattr_t** data structure contains the following fields:

The name of the target object attribute. The following valid object attributes for the **getobjattrs** subroutine are defined in the **usersec.h** file:

attr_name
Specifies the name.

attr_idx
This attribute is used internally by the **getobjattrs** subroutine.

attr_type
The type of a target attribute.

attr _flag
The result of the request is to read the target attribute. On successful completion, a value of zero is returned. Otherwise, a nonzero value is returned.

attr_un
A union that contains the returned values for the requested query.

The following table lists the different vales for *attr_name* attribute:

Name	Description	Type
S_DOMAINS	A list domains of the object.	SEC_LIST
S_CONFSETS	The list of domains defined in the conflict set of the object.	SEC_LIST
S_TYPE	The type of the object. Valid values are: S_DEVICE, S_FILE, S_NETPORT, S_NETINT	SEC_CHAR
S_SECFLAGS	The security flag associated with the object. The valid values are: FSF_DOM_ALL and FSF_DOM_ANY.	SEC_INT

The following union members correspond to the definitions of the **attr_char**, **attr_int**, **attr_long** and **attr_llong** macros in the **usersec.h** file:

au_char
Attributes of the SEC_CHAR and SEC_LIST types store a pointer to the returned value in this member when the attributes are successfully retrieved. The caller is responsible for freeing this memory.

au_int
The storage location for attributes of the SEC_INT type.

au_long
The storage location for attributes of the SEC_LONG type.

au_llong
The storage location for attributes of the SEC_LLONG type.

If ALL is specified for the *Obj* parameter, the only valid attribute that can be displayed in the **Attributes** array is the S_DOMAINS attribute. Specifying any other attribute with a domain name of ALL causes the **getobjattrs** subroutine to fail.

Parameters

Obj
Specifies the object name for the **Attributes** array to read.

Attributes
A pointer to an array of zero or more elements of the type **dbattr_t**. The list of domain-assigned object attributes is defined in the **usersec.h** header file.

Count
The number of array elements in the **Attributes** array.

Security

Files Accessed:

/etc/security/domains
mode: r

Return Values

If the object specified by the *Obj* parameter exists in the domain-assigned object database, the **getobjattrs** subroutine returns the value of zero. On successful completion, the **attr_flag** attribute of each element in the **Attributes** array must be examined to determine whether it was successfully retrieved. If the specified object does not exist, a value of -1 is returned and the **errno** value is set to indicate the error.

Error Codes

If the **getobjattrs** subroutine returns -1, one of the following **errno** values is set:

EINVAL

The *Obj* parameter is NULL.

The *Count* parameter is less than zero.

The **Attributes** array is NULL and the *Count* parameter is greater than zero.

The *Obj* parameter is ALL but the **Attributes** entry contains an attribute other than S_DOMAINS.

ENOENT
The object specified in the *Obj* parameter does not exist.

ENOMEM
Memory cannot be allocated.

EPERM
The operation is not permitted.

EACCES
Access permission is denied for the data request.

If the **getobjattrs** subroutine fails to query an attribute, one of the following errors is returned to the **attr_flag** field of the corresponding **Attributes** element:

EACCES
The invoker does not have access to the attribute specified in the **attr_name** field.

EINVAL

The **attr_name** field in the **Attributes** entry is not a recognized object attribute.

The **attr_type** field in the **Attributes** entry contains a type that is not valid.

The **attr_un** field in the **Attributes** entry does not point to a valid buffer.

ENOATTR

The **attr_name** field in the **Attributes** entry specifies a valid attribute, but no value is defined for this object.

getopt Subroutine

Purpose

Returns the next flag letter specified on the command line.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <unistd.h>

int getopt (ArgumentC,  ArgumentV,  OptionString)
int ArgumentC;
char *const ArgumentV [ ];
const char *OptionString;

extern int  optind;
extern int  optopt;
extern int  opterr;
extern char * optarg;
```

Description

The *optind* parameter indexes the next element of the *ArgumentV* parameter to be processed. It is initialized to 1 and the **getopt** subroutine updates it after calling each element of the *ArgumentV* parameter.

The **getopt** subroutine returns the next flag letter in the *ArgumentV* parameter list that matches a letter in the *OptionString* parameter. If the flag takes an argument, the **getopt** subroutine sets the *optarg* parameter to point to the argument as follows:

- If the flag was the last letter in the string pointed to by an element of the *ArgumentV* parameter, the *optarg* parameter contains the next element of the *ArgumentV* parameter and the *optind* parameter is incremented by 2. If the resulting value of the *optind* parameter is not less than the *ArgumentC* parameter, this indicates a missing flag argument, and the **getopt** subroutine returns an error message.

- Otherwise, the *optarg* parameter points to the string following the flag letter in that element of the *ArgumentV* parameter and the *optind* parameter is incremented by 1.

Note: The user who wants to scan the same *ArgumentV* parameter again or scan multiple *ArgumentV* sets in the same program, need to reinitialize the **getopt()** subroutine by setting the *optind* parameter to 0.

Parameters

Item	Description
ArgumentC	Specifies the number of parameters passed to the routine.
ArgumentV	Specifies the list of parameters passed to the routine.
OptionString	Specifies a string of recognized flag letters. If a letter is followed by a : (colon), the flag is expected to take a parameter that may or may not be separated from it by white space.
optind	Specifies the next element of the *ArgumentV* array to be processed.
optopt	Specifies any erroneous character in the *OptionString* parameter.
opterr	Indicates that an error has occurred when set to a value other than 0.
optarg	Points to the next option flag argument.

Return Values

The **getopt** subroutine returns the next flag letter specified on the command line. A value of -1 is returned when all command line flags have been parsed. When the value of the *ArgumentV* **[***optind***]** parameter is null, ***ArgumentV* [*optind*]** is not the **-** (minus) character, or *ArgumentV* **[***optind***]** points to the "**-**" (minus) string, the **getopt** subroutine returns a value of -1 without changing the value. If *ArgumentV* **[***optind***]** points to the "**- -**" (double minus) string, the **getopt** subroutine returns a value of -1 after incrementing the value of the *optind* parameter.

Error Codes

If the **getopt** subroutine encounters an option character that is not specified by the *OptionString* parameter, a **?** (question mark) character is returned. If it detects a missing option argument and the first character of *OptionString* is a **:** (colon), then a **:** (colon) character is returned. If this subroutine detects a missing option argument and the first character of *OptionString* is not a colon, it returns a **?** (question mark). In either case, the **getopt** subroutine sets the *optopt* parameter to the option character that caused the error. If the application has not set the *opterr* parameter to 0 and the first character of *OptionString* is not a **:** (colon), the **getopt** subroutine also prints a diagnostic message to standard error.

Examples

The following code fragment processes the flags for a command that can take the mutually exclusive flags **a** and **b**, and the flags **f** and **o**, both of which require parameters.

```
#include <unistd.h>    /*Needed for access subroutine constants*/
main (argc, argv)
int argc;
char **argv;
{
   int c;
   extern int optind;
   extern char *optarg;
   .
   .
   .
   while ((c = getopt(argc, argv, "abf:o:")) != EOF)

   {
      switch (c)
```

```
      {
         case 'a':
            if (bflg)
               errflg++;
            else
               aflg++;
            break;

         case 'b':
            if (aflg)
               errflg++;
            else
               bflg++;
            break;

         case 'f':
            ifile = optarg;
            break;

         case 'o':
            ofile = optarg;
            break;

         case '?':
            errflg++;
      } /* case */

      if (errflg)
      {
         fprintf(stderr, "usage: . . . ");
         exit(2);
      }
   } /* while */

   for ( ; optind < argc; optind++)
   {
      if (access(argv[optind], R_OK))
      {
         .
         .
         .
      }
   } /* for */
}   /* main */
```

getosuuid Subroutine

Purpose

Retrieves the operating system Universal Unique Identifier (UUID).

Library

Standard C Library (**libc.a**)

Syntax

```
#include <uuid.h>
int getosuuid (uuid,uuid_type)
uuid_t * uuid;
int uuid_type;
```

Description

Retrieves the operating system UUID saved in the AIX kernel. If in a WPAR, the WPAR UUID is returned instead.

Note:

The UUID of the AIX operating system can be retrieved using the **lsattr** command:

```
lsattr -l sys0 -a os_uuid -E
```

Parameters

Item	Description
uuid	Points to the location used to return the operating system UUID.
uuid_type	Specifies the type of UUID to retrieve. Must be **GETOSUUID_AIX**.

Return Values

Upon successful completion the **getosuuid** subroutine returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

Item	Description
EINVAL	Indicates the value of the *uuid_type* parameter is invalid.
EFAULT	Invalid address in parameter *uuid*.

getpagesize Subroutine

Purpose

Gets the system page size.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <unistd.h>

int getpagesize( )
```

Description

The **getpagesize** subroutine returns the number of bytes in a page. Page granularity is the granularity for many of the memory management calls.

The page size is determined by the system and may not be the same as the underlying hardware page size.

getpaginfo Subroutine

Purpose

Retrieves a Process Authentication Group (PAG) flags for a given PAG type.

Library

Security Library (`libc.a`)

Syntax

```
#include <pag.h>

int getpaginfo ( name, infop, infosz )
char * name;
struct paginfo * infop;
int infosz;
```

Description

The `getpaginfo` subroutine retrieves the PAG flags for a given PAG name. For this function to succeed, the PAG name must be registered with the operating system before this subroutine is called. The *infop* parameter must be a valid, referenced PAG info structure of the size specified by *infosz*.

Parameters

Item	Description
name	A 1-character to 4-character, NULL-terminated name for the PAG type. Typical values include `afs`, `dfs`, `pki`, and `krb5`.
infop	Points to a `paginfo struct` where the operating system returns the PAG flags.
infosz	Indicates the size of the PAG info structure.

Return Values

A value of `0` is returned upon successful completion. If the `getpaginfo` subroutine fails a value of `-1` is returned and the `errno` global variable is set to indicate the error.

Error Codes

The `getpaginfo` subroutine fails if the following condition is true:

Item	Description
`EINVAL`	The named PAG type does not exist as part of the table.

Other errors might be set by subroutines invoked by the `getpaginfo` subroutine.

getpagvalue or getpagvalue64 Subroutine

Purpose

Returns the Process Authentication Group (PAG) value for a given PAG type.

Library

Security Library (`libc.a`)

Syntax

```
#include <pag.h>

int getpagvalue ( name )
char * name;

uint64_t getpagvalue64( name );
char * name;
```

Description

The `getpagvalue` and `getpagvalue64` subroutines retrieve the PAG value for a given PAG name. For these functions to succeed, the PAG name must be registered with the operating system before these subroutines are called.

Parameters

Item	Description
name	A 1-character to 4-character, NULL-terminated name for the PAG type. Typical values include `afs`, `dfs`, `pki`, and `krb5`.

Return Values

The `getpagvalue` and `getpagvalue64` subroutines return a PAG value upon successful completion. Upon a failure, a value of `-1` is returned and the `errno` global variable is set to indicate the error.

Error Codes

The `getpagvalue` and `getpagvalue64` subroutines fail if the following condition is true:

Item	Description
`EINVAL`	The named PAG type does not exist as part of the table.

Other errors might be set by subroutines invoked by the `getpagvalue` and `getpagvalue64` subroutines.

getpass Subroutine

Purpose

Reads a password.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdlib.h>

char *getpass ( Prompt)
char *Prompt;
```

Description

Attention: The characters are returned in a static data area. Subsequent calls to this subroutine overwrite the static data area.

The **getpass** subroutine does the following:

- Opens the controlling terminal of the current process.
- Writes the characters specified by the *Prompt* parameter to that device.
- Reads from that device the number of characters up to the value of the **PASS_MAX** constant until a new-line or end-of-file (EOF) character is detected.
- Restores the terminal state and closes the controlling terminal.

During the read operation, character echoing is disabled.

The **getpass** subroutine is not safe in a multithreaded environment. To use the **getpass** subroutine in a threaded application, the application must keep the integrity of each thread.

Parameters

Item	Description
Prompt	Specifies a prompt to display on the terminal.

Return Values

If this subroutine is successful, it returns a pointer to the string. If an error occurs, the subroutine returns a null pointer and sets the **errno** global variable to indicate the error.

Error Codes

If the **getpass** subroutine is unsuccessful, it returns one or more of the following error codes:

Item	Description
EINTR	Indicates that an interrupt occurred while the **getpass** subroutine was reading the terminal device. If a **SIGINT** or **SIGQUIT** signal is received, the **getpass** subroutine terminates input and sends the signal to the calling process.
ENXIO	Indicates that the process does not have a controlling terminal.

Note: Any subroutines called by the **getpass** subroutine may set other error codes.

getpcred Subroutine

Purpose

Reads the current process credentials.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>

char **getpcred ( Which)
int Which;
```

Description

The **getpcred** subroutine reads the specified process security credentials and returns a pointer to a NULL terminated array of pointers in allocated memory. Each pointer in the array points to a string containing an attribute/value pair in allocated memory. It's the responsibility of the caller to free each individual string as well as the array of pointers.

Parameters

Item	Description
Which	Specifies which credentials are read. This parameter is a bit mask and can contain one or more of the following values, as defined in the **usersec.h** file: **CRED_RUID** Real user name **CRED_LUID** Login user name **CRED_RGID** Real group name **CRED_GROUPS** Supplementary group ID **CRED_AUDIT** Audit class of the current process **Note:** A process must have root user authority to retrieve this credential. Otherwise, the **getpcred** subroutine returns a null pointer and the **errno** global variable is set to **EPERM**. **CRED_RLIMITS** BSD resource limits **Note:** Use the **getrlimit** (“getrlimit, getrlimit64, setrlimit, setrlimit64, or vlimit Subroutine” on page 526) subroutine to control resource consumption. **CRED_UMASK** The umask. If the *Which* parameter is null, all credentials are returned.

Return Values

When successful, the **getpcred** subroutine returns a pointer to a NULL terminated array of string pointers containing the requested values. If the **getpcred** subroutine is unsuccessful, a NULL pointer is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **getpcred** subroutine fails if either of the following are true:

Item	Description
EINVAL	The *Which* parameter contains invalid credentials requests.
EPERM	The process does not have the proper authority to retrieve the requested credentials.

Other errors can also be set by any subroutines invoked by the **getpcred** subroutine.

getpeereid Subroutine

Note: The **getpeerid** technology used to support this function in AIX was originally published by D. J. Bernstein, Associate Professor, Department of Mathematics, Statistics, and Computer Science, University of Illinois at Chicago. In addition, the specific **getpeerid** syntax reflected originated with William Erik Baxter. All the aforementioned are used by AIX with permission.

Purpose

Gets the effective user ID and effective group ID of a peer on a connected UNIX domain socket.

Syntax

```
#include <sys/types.h>
    int getpeereid (int socket, uid_t *euid, gid_t *egid)
```

Description

The **getpeereid** subroutine returns the effective user and group IDs of the peer connected to a stream socket in the UNIX domain. The effective user and group IDs are saved in the socket, to be returned, when the peer calls **connect** or **listen**.

Parameters

Item	Description
socket	Specifies the descriptor number of a connected socket.
euid	The effective user ID of the peer socket.
egid	The effective group ID of the peer socket.

Return Values

When the **getpeereid** subroutine successfully completes, a value of 0 is returned and the *euid* and *egid* parameters hold the effective user ID and group ID, respectively.

If the **getpeereid** subroutine is unsuccessful, the system handler returns a value of -1 to the calling program and sets the **errno** global variable to an error code that indicates the specific error.

Error Codes

The **getpeereid** subroutine is unsuccessful if any of the following errors occurs:

Item	Description
EBADF	The *socket* parameter is not valid.
ENOTSOCK	The *socket* parameter refers to a file, not a socket.
ENOTCONN	The socket is not connected.
ENOBUFS	Insufficient resources were available in the system to complete the call.
EFAULT	The *address* parameter is not in a writable part of the user address space.

getpenv Subroutine

Purpose

Reads the current process environment.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>

char **getpenv ( Which)
int Which;
```

Description

The **getpenv** subroutine reads the specified environment variables and returns them in a character buffer.

Parameters

Item	Description
Which	Specifies which environment variables are to be returned. This parameter is a bit mask and may contain one or more of the following values, as defined in the **usersec.h** file: **PENV_USR** The normal user-state environment. Typically, the shell variables are contained here. **PENV_SYS** The system-state environment. This data is located in system space and protected from unauthorized access. All variables are returned by setting the *Which* parameter to logically OR the **PENV_USER** and **PENV_SYSTEM** values. The variables are returned in a null-terminated array of character pointers in the form `var=val`. The user-state environment variables are prefaced by the string **USRENVIRON:**, and the system-state variables are prefaced with **SYSENVIRON:**. If a user-state environment is requested, the current directory is always returned in the **PWD** variable. If this variable is not present in the existing environment, the **getpenv** subroutine adds it to the returned string.

Return Values

Upon successful return, the **getpenv** subroutine returns the environment values. If the **getpenv** subroutine fails, a null value is returned and the **errno** global variable is set to indicate the error.

Note: This subroutine can partially succeed, returning only the values that the process permits it to read.

Error Codes

The **getpenv** subroutine fails if one or more of the following are true:

Item	Description
EINVAL	The *Which* parameter contains values other than **PENV_USR** or **PENV_SYS**.

Other errors can also be set by subroutines invoked by the **getpenv** subroutine.

getpfileattr Subroutine

Purpose

Accesses the privileged file security information in the privileged file database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>

int getpfileattr (File, Attribute, Value, Type)
    char *File;
    char *Attribute;
    void *Value;
    int Type;
```

Description

The **getpfileattr** subroutine reads a specified attribute from the privileged file database. If the database is not open, this subroutine does an implicit open for reading.

Parameters

Item	Description
File	Specifies the file name. The value must be the full path to the file on the system. This parameter must be specified unless the value of the *Type* parameter is **SEC_COMMIT**.
Attribute	Specifies which attribute is read. The following possible attributes are defined in the **usersec.h** file: **S_READAUTHS** Authorizations required to read the file using the **pvi** command. A total of eight authorizations can be defined. The attribute type is **SEC_LIST**. **S_WRITEAUTHS** Authorizations required to write to the file using the **pvi** command. A total of eight authorizations can be defined. The attribute type is **SEC_LIST**.
Value	Specifies a buffer, a pointer to a buffer, or a pointer to a pointer depending on the *Attribute* and *Type* parameters. See the *Type* parameter for more details.
Type	Specifies the type of attribute expected. The **usersec.h** file defines and includes the following valid types: **SEC_LIST** The format of the attribute is a series of concatenated strings, each null-terminated. The last string in the series is terminated by two successive null characters. For the **getpfileattr** subroutine, you must supply a pointer to a defined character pointer variable. It is the caller's responsibility to free this memory. **SEC_DELETE** If the *Attribute* parameter is specified, the corresponding attribute is deleted from the privileged file database. If no *Attribute* parameter is specified, the entire privileged file definition is deleted from the privileged file database.

Security

Files Accessed:

File	Mode
/etc/security/privfiles	rw

Return Values

If successful, the **getpfileattr** subroutine returns a value of zero. Otherwise, a value of -1 is returned and the **errno** global value is set to indicate the error.

Error Codes

If the **getpfileattr** subroutine fails, one of the following **errno** values can be set:

Item	Description
EINVAL	The *File* parameter is **NULL** or **default**.
EINVAL	The *Attribute* or *Type* parameter is **NULL** or does not contain one of the defined values.
EINVAL	The *Attribute* parameter is **S_PRIVFILES**, but the *File* parameter is not **ALL**.
EINVAL	The *Value* parameter does not point to a valid buffer for this type of attribute.
ENOENT	The file specified in the *File* parameter does not exist.
ENOATTR	The attribute specified in the *Attribute* parameter is valid, but no value is defined for the file.
EPERM	Operation is not permitted.

getpfileattrs Subroutine

Purpose

Retrieves multiple file attributes from the privileged file database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>

int getpfileattrs(File, Attributes, Count)
    char *File;
    dbattr_t *Attributes;
    int Count;
```

Description

The **getpfileattrs** subroutine reads one or more attributes from the privileged file database (**/etc/security/privfiles**). The file specified with the *File* parameter must include the full path to the file and exist in the privileged file database. If the database is not open, this subroutine does an implicit open for reading.

The Attributes array contains information about each attribute that is to be read. Each element in the Attributes array must be examined upon a successful call to the **getpfileattrs** subroutine to determine

whether the Attributes array was successfully retrieved. The **dbattr_t data** structure contains the following fields:

Item	Description
attr_name	The name of the desired file attribute.
attr_idx	This attribute is used internally by the **getpfileattrs** subroutine.
attr_type	The type of the target attribute.
attr _flag	The result of the request to read the target attribute. A value of zero is returned on success; a nonzero value is returned otherwise.
attr_un	A union containing the returned values for the requested query.

Valid privileged file attributes for the **getpfileattrs** subroutine defined in the **usersec.h** file are:

Name	Description	Type
S_PRIVFILES	Retrieves all the files in the privileged file database. It is valid only when the *File* parameter is **ALL**.	**SEC_LIST**
S_READAUTHS	Read authorization. It is a null separated list of authorization names. A total of eight authorizations can be specified. A user with any one of the authorizations is allowed to read the file using the privileged editor **/usr/bin/pvi**.	**Steeliest**
S_WRITEAUTHS	Write authorization. It is a null separated list of authorization names. A total of eight authorizations can be specified. A user with any one of the authorizations is allowed to write the file using the privileged editor **/usr/bin/pvi**.	**SEC_LIST**

The union members that follow correspond to the definitions of the **attr_char, attr_int, attr_long** and **attr_llong** macros in the **usersec.h** file respectively.

Item	Description
au_char	Attributes of the **SEC_CHAR** and **SEC_LIST** types store a pointer to the returned value in this member when the attributes are successfully retrieved. The caller is responsible for freeing this memory.
au_int	Storage location for attributes of the **SEC_INT** type.
au_long	Storage location for attributes of the **SEC_LONG** type.
au_llong	Storage location for attributes of the **SEC_LLONG** type.

If **ALL** is specified for the *File* parameter, the only valid attribute that can appear in the Attribute array is the **S_PRIVFILES** attribute. Specifying any other attribute with a file name of **ALL** causes the **getpfileattrs** subroutine to fail.

Parameters

Item	Description
File	Specifies the file name for which the attributes are to be read.
Attributes	A pointer to an array of zero or more elements of the **dbattr_t** type. The list of file attributes is defined in the **usersec.h** header file.
Count	The number of array elements in the Attributes array.

Security

Files Accessed:

File	Mode
/etc/security/privfiles	r

Return Values

If the file specified by the *File* parameter exists in the privileged file database, the **getpfileattrs** subroutine returns zero. On success, the **attr_flag** attribute of each element in the Attributes array must be examined to determine whether it was successfully retrieved. If the specified file does not exist, a value of -1 is returned and the **errno** value is set to indicate the error.

Error Codes

If the **getpfileattrs** subroutine returns -1, one of the following **errno** values can be set:

Item	Description
EINVAL	The *File* parameter is **NULL** or **default**.
EINVAL	The *File* parameter is **ALL** but the Attributes entry contains an attribute other than **S_PRIVFILES**.
EINVAL	The *Count* parameter is less than zero.
EINVAL	The *File* parameter is **NULL** and the *Count* parameter is greater than zero.
ENOENT	The file specified in the *File* parameter does not exist in the database.
EPERM	Operation is not permitted.

If the **getpfileattrs** subroutine fails to query an attribute, one of the following errors is returned in the **attr_flag** field of the corresponding Attributes element:

Item	Description
EACCES	The invoker does not have access to the attribute specified in the **attr_name** field.
EINVAL	The **attr_name** field in the Attributes entry is not a recognized file attribute.
EINVAL	The **attr_type** field in the Attributes entry contains an invalid type.
EINVAL	The **attr_un** field in the Attributes entry does not point to a valid buffer.
ENOATTR	The **attr_name** field in the Attributes entry specifies a valid attribute, but no value is defined for this file.
ENOMEM	Memory cannot be allocated to store the return value.

getpgid Subroutine

Purpose

Returns the process group ID of the calling process.

Library

Standard C Library **(libc.a)**

Syntax

#include <unistd.h>

```
pid_t getpgid (Pid)
(pid_ Pid)
```

Description

The **getpgid** subroutine returns the process group ID of the process whose process ID is equal to that specified by the *Pid* parameter. If the value of the *Pid* parameter is equal to **(pid_t)0**, the **getpgid** subroutine returns the process group ID of the calling process.

Parameter

Item	Description
Pid	The process ID of the process to return the process group ID for.

Return Values

Item	Description
id	The process group ID of the requested process
-1	Not successful and **errno** set to one of the following.

Error Code

Item	Description
ESRCH	There is no process with a process ID equal to *Pid*.

Item	Description
EPERM	The process whose process ID is equal to *Pid* is not in the same session as the calling process.
EINVAL	The value of the *Pid* argument is invalid.

getpid, getpgrp, or getppid Subroutine

Purpose

Returns the process ID, process group ID, and parent process ID.

Syntax

```
#include <unistd.h>
```

```
pid_t getpid (void)
```

```
pid_t getpgrp (void)
```

```
pid_t getppid (void)
```

Description

The **getpid** subroutine returns the process ID of the calling process.

The **getpgrp** subroutine returns the process group ID of the calling process.

The **getppid** subroutine returns the process ID of the calling process' parent process.

getportattr or putportattr Subroutine

Purpose

Accesses the port information in the port database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
```

```
int getportattr (Port, Attribute, Value, Type)
char * Port;
char * Attribute;
void * Value;
int  Type;
```

```
int putportattr (Port, Attribute, Value, Type)
char *Port;
char *Attribute;
void *Value;
int Type;
```

Description

The **getportattr** or **putportattr** subroutine accesses port information. The **getportattr** subroutine reads a specified attribute from the port database. If the database is not already open, the **getportattr** subroutine implicitly opens the database for reading. The **putportattr** subroutine writes a specified attribute into the port database. If the database is not already open, the **putportattr** subroutine implicitly opens the database for reading and writing. The data changed by the **putportattr** subroutine must be explicitly committed by calling the **putportattr** subroutine with a *Type* parameter equal to the **SEC_COMMIT** value. Until all the data is committed, only these subroutines within the process return the written data.

Values returned by these subroutines are in dynamically allocated buffers. You do not need to move the values prior to the next call.

Use the **setuserdb** or **enduserdb** subroutine to open and close the port database.

Parameters

Item	Description
Port	Specifies the name of the port for which an attribute is read.
Attribute	Specifies the name of the attribute read. This attribute can be one of the following values defined in the **usersec.h** file: **S_HERALD** Defines the initial message printed when the **getty** or **login** command prompts for a login name. This value is of the type **SEC_CHAR**. **S_SAKENABLED** Indicates whether or not trusted path processing is allowed on this port. This value is of the type **SEC_BOOL**. **S_SYNONYM** Defines the set of ports that are **synonym** attributes for the given port. This value is of the type **SEC_LIST**. **S_LOGTIMES** Defines when the user can access the port. This value is of the type **SEC_LIST**. **S_LOGDISABLE** Defines the number of unsuccessful login attempts that result in the system locking the port. This value is of the type **SEC_INT**. **S_LOGINTERVAL** Defines the time interval in seconds within which **S_LOGDISABLE** number of unsuccessful login attempts must occur before the system locks the port. This value is of the type **SEC_INT**. **S_LOGREENABLE** Defines the time interval in minutes after which a system-locked port is unlocked. This value is of the type **SEC_INT**. **S_LOGDELAY** Defines the delay factor in seconds between unsuccessful login attempts. This value is of the type **SEC_INT**. **S_LOCKTIME** Defines the time in seconds since the epoch (zero time, January 1, 1970) that the port was locked. This value is of the type **SEC_INT**. **S_ULOGTIMES** Lists the times in seconds since the epoch (midnight, January 1, 1970) when unsuccessful login attempts occurred. This value is of the type **SEC_LIST**. **S_USERNAMEECHO** Indicates whether user name input echo and user name masking is enabled for the port. This value is of the type **SEC_BOOL**. **S_PWDPROMPT** Defines the password prompt message printed when requesting password input. This value is of the type **SEC_CHAR**.
Value	Specifies the address of a buffer in which the attribute is stored with **putportattr** or is to be read **getportattr**.

Item	Description
Type	Specifies the type of attribute expected. The following types are valid and defined in the **usersec.h** file: **SEC_INT** Indicates the format of the attribute is an integer. The buffer returned by the **getportattr** subroutine and the buffer supplied by the **putportattr** subroutine are defined to contain an integer. **SEC_CHAR** Indicates the format of the attribute is a null-terminated character string. **SEC_LIST** Indicates the format of the attribute is a list of null-terminated character strings. The list itself is null terminated. **SEC_BOOL** An integer with a value of either 0 or 1, or a pointer to a character pointing to one of the following strings: • True • Yes • Always • False • No • Never **SEC_COMMIT** Indicates that changes to the specified port are committed to permanent storage if specified alone for the **putportattr** subroutine. The *Attribute* and *Value* parameters are ignored. If no port is specified, changes to all modified ports are committed. **SEC_DELETE** Deletes the corresponding attribute from the database. **SEC_NEW** Updates all of the port database files with the new port name when using the **putportattr** subroutine.

Security

Access Control: The calling process must have access to the port information in the port database.

File Accessed:

Item	Description
rw	/etc/security/login.cfg
rw	/etc/security/portlog

Return Values

The **getportattr** and **putportattr** subroutines return a value of 0 if completed successfully. Otherwise, a value of -1 is returned and the **errno** global value is set to indicate the error.

Error Codes

These subroutines are unsuccessful if the following values are true:

Item	Description
EACCES	Indicates that access permission is denied for the data requested.
ENOENT	Indicates that the *Port* parameter does not exist or the attribute is not defined for the specified port.
ENOATTR	Indicates that the specified port attribute does not exist for the specified port.
EINVAL	Indicates that the *Attribute* parameter does not contain one of the defined attributes or is a null value.
EINVAL	Indicates that the *Value* parameter does not point to a valid buffer or to valid data for this type of attribute.

Item	Description
EPERM	Operation is not permitted.

getppriv Subroutine

Purpose

Gets a privilege set associated with a process.

Library

Security Library (**libc.a**)

Syntax

```
#include <sys/types.h>
#include <sys/priv.h>
int getppriv(pid, which, privset, privsize)
pid_t pid;
int which;
privg_t *privset;
int privsize;
```

Description

The **getppriv** subroutine returns the privilege set for the process specified by the *pid* parameter. If the value of the *pid* is negative, the calling process's privilege set is retrieved. The value of the *which* parameter is one of the PRIV_EFFECTIVE, PRIV_MAXIMUM, PRIV_INHERITED, PRIV_LIMITING or PRIV_USED values. The corresponding privilege set is copied to the *privset* parameter in the size specified by the *privsize* parameter. The PV_PROC_PRIV privilege is required in the effective set when a process wants to obtain privilege set from another process.

Parameters

Item	Description
Pid	Indicates the process that the privilege set is requested for.
Which	Specifies the privilege set to get.
Privset	Stores the privilege set.
Privsize	Specifies the size of the privilege set.

Return Values

The **getppriv** subroutine returns one of the following values:

Item	Description
0	The subroutine completes successfully.
-1	An error has occurred. An **errno** global variable is set to indicate the error.

Error Codes

The **getppriv** subroutine fails if any of the following values is true:

Item	Description
EFAULT	The *privset* parameter is pointing to an address that is not legal.
EINVAL	The value of the *privset* parameter is NULL, or the value of the *privsize* parameter is not valid.
EPERM	The process does not have the privilege (**PV_PROC_PRIV** or **MAC** read) to obtain another process' privilege set.
ESRCH	No process has a process ID that is equal to the value of the *Pid* parameter.

getpri Subroutine

Purpose

Returns the scheduling priority of a process.

Library

Standard C Library (**libc.a**)

Syntax

```
int getpri ( ProcessID)
pid_t ProcessID;
```

Description

The **getpri** subroutine returns the scheduling priority of a process.

Parameters

Item	Description
ProcessID	Specifies the process ID. If this value is 0, the current process scheduling priority is returned.

Return Values

Upon successful completion, the **getpri** subroutine returns the scheduling priority of a thread in the process. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **getpri** subroutine is unsuccessful if one of the following is true:

Item	Description
EPERM	A process was located, but its effective and real user ID did not match that of the process running the **getpri** subroutine, and the calling process did not have root user authority.
ESRCH	No process can be found corresponding to that specified by the *ProcessID* parameter.

getprivid Subroutine

Purpose

Converts a privilege name into a numeric value.

Library

Security Library (**libc.a**)

Syntax

```
#include <userpriv.h>
#include <sys/priv.h>

int getprivid(char *privname)
```

Description

The **getprivid** subroutine converts a given privilege name specified by the *privname* parameter into a numeric value of the privilege index that is defined in the <**sys/priv.h**> header file.

Parameters

Item	Description
privname	Specifies the privilege name that is in string format.

Return Values

The **getprivid** subroutine returns one of the following values:

Item	Description
privilege index	The subroutine successfully completes.
-1	The subroutine cannot find the privilege name specified by the *privname* parameter.

Errors

No **errno** value is set.

getprivname Subroutine

Purpose

Converts a privilege bit into a readable string.

Library

Security Library (**libc.a**)

Syntax

```
#include <userpriv.h>
#include <sys/priv.h>

char *getprivname(int priv)
```

Description

The **getprivname** subroutine converts a given privilege bit specified by the *priv* parameter into a readable string.

Parameters

Item	Description
priv	Specifies the privilege to be converted.

Return Values

The **getprivname** subroutine returns one of the following values:

Item	Description
character string	The privilege is valid.
NULL	The privilege is not valid.

Errors

No **errno** value is set.

getpriority, setpriority, or nice Subroutine

Purpose

Gets or sets the nice value.

Libraries

getpriority, **setpriority**: Standard C Library (**libc.a**)

nice: Standard C Library (**libc.a**)

Berkeley Compatibility Library (**libbsd.a**)

Syntax

```
#include <sys/resource.h>
```

```
int getpriority( Which,  Who)
int Which;
int Who;

int setpriority(Which, Who,  Priority)
int Which;
int Who;
int Priority;
```

```
#include <unistd.h>
```

```
int nice( Increment)
int Increment;
```

Description

The nice value of the process, process group, or user, as indicated by the *Which* and *Who* parameters is obtained with the **getpriority** subroutine and set with the **setpriority** subroutine.

The **getpriority** subroutine returns the highest priority nice value (lowest numerical value) pertaining to any of the specified processes. The **setpriority** subroutine sets the nice values of all of the specified processes to the specified value. If the specified value is less than -20, a value of -20 is used; if it is greater than 20, a value of 20 is used. Only processes that have root user authority can lower nice values.

The **nice** subroutine increments the nice value by the value of the *Increment* parameter.

Note: Nice values are only used for the scheduling policy **SCHED_OTHER**, where they are combined with a calculation of recent cpu usage to determine the priority value.

To provide upward compatibility with older programs, the **nice** interface, originally found in AT&T System V, is supported.

Note: Process priorities in AT&T System V are defined in the range of 0 to 39, rather than -20 to 20 as in BSD, and the **nice** library routine is supported by both. Accordingly, two versions of the **nice** are supported by AIX Version 3. The default version behaves like the AT&T System V version, with the *Increment* parameter treated as the modifier of a value in the range of 0 to 39 (0 corresponds to -20, 39 corresponds to 9, and priority 20 is not reachable with this interface).

If the behavior of the BSD version is desired, compile with the Berkeley Compatibility Library (**libbsd.a**). The *Increment* parameter is treated as the modifier of a value in the range -20 to 20.

Parameters

Item	Description
Which	Specifies one of **PRIO_PROCESS**, **PRIO_PGRP**, or **PRIO_USER**.
Who	Interpreted relative to the *Which* parameter (a process identifier, process group identifier, and a user ID, respectively). A zero value for the *Who* parameter denotes the current process, process group, or user.
Priority	Specifies a value in the range -20 to 20. Negative nice values cause more favorable scheduling.
Increment	Specifies a value that is added to the current process nice value. Negative values can be specified, although values exceeding either the high or low limit are truncated.

Return Values

On successful completion, the **getpriority** subroutine returns an integer in the range -20 to 20. A return value of -1 can also indicate an error, and in this case the **errno** global variable is set.

On successful completion, the **setpriority** subroutine returns 0. Otherwise, -1 is returned and the global variable **errno** is set to indicate the error.

On successful completion, the **nice** subroutine returns the new nice value minus {NZERO}. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Note: A value of -1 can also be returned. In that case, the calling process should also check the **errno** global variable.

Error Codes

The **getpriority** and **setpriority** subroutines are unsuccessful if one of the following is true:

Item	Description
ESRCH	No process was located using the *Which* and *Who* parameter values specified.
EINVAL	The *Which* parameter was not recognized.

In addition to the errors indicated above, the **setpriority** subroutine is unsuccessful if one of the following is true:

Item	Description
EPERM	A process was located, but neither the effective nor real user ID of the caller of the process executing the **setpriority** subroutine has root user authority.
EACCES	The call to **setpriority** would have changed the priority of a process to a value lower than its current value, and the effective user ID of the process executing the call did not have root user authority.

The **nice** subroutine is unsuccessful if the following is true:

Item	Description
EPERM	The *Increment* parameter is negative and the calling process does not have appropriate privileges.

getproclist, getlparlist, or getarmlist Subroutine

Purpose

Retrieve the transaction records from the advanced accounting data file.

Library

The `libaacct.a` library.

Syntax

```
#include <sys/aacct.h>
int getproclist(filename, begin_time, end_time, p_list);
int getlparlist(filename, begin_time, end_time, l_list);
int getarmlist(filename, begin_time, end_time, t_list);
char *filename;
long long begin_time;
long long end_time;
struct aacct_tran **p_list, **l_list, **t_list
```

Description

The `getproclist`, `getlparlist`, and `getarmlist` subroutines parse the specified advanced accounting data file and retrieve the process, LPAR, and ARM transaction records, respectively. The retrieved transaction records are returned in the form of a linked list of type `struct aacct_tran_rec`.

These APIs can be called multiple times with different accounting data file names in order to generate a consolidated list of transaction records from multiple data files. They append the new file data to the end of the linked list pointed to by the *p_list*, *l_list*, and *t_list* arguments. They also internally sort the transaction records based on the time of transaction, which gives users a time-sorted list of transaction records from these routines.

The `getproclist`, `getlparlist`, and `getarmlist` subroutines can also be used to retrieve the intended transaction records for a particular interval of time by passing the begin and end times of the interval as arguments to these routines. If these interval arguments are specified as `-1`, transaction records for all the intervals are retrieved.

Parameters

Item	Description
begin_time	Specifies the start timestamp for collecting records in a particular intervals. The input is in seconds since EPOCH. Specifying `-1` retrieves all the records.
end_time	Specifies the end timestamp for collecting records in a particular intervals. The input is in seconds since EPOCH. Specifying `-1` retrieves all the records.
filename	Name of the advanced accounting data file.
l_list	Pointers to the linked list of `aacct_tran_rec` structures, which hold the retrieved LPAR records.
p_list	Pointers to the linked list of `aacct_tran_rec` structures, which hold the retrieved process records.
t_list	Pointers to the linked list of `aacct_tran_rec` structures, which hold the retrieved ARM records.

Security

No restrictions. Any user can call this function.

Return Values

Item	Description
0	The call to the subroutine was successful.
-1	The call to the subroutine failed.

Error Codes

Item	Description
`EINVAL`	The passed pointer is NULL.
`ENOENT`	Specified data file does not exist.
`EPERM`	Permission denied. Unable to read the data file.
`ENOMEM`	Insufficient memory.

getprocs Subroutine

Purpose

Gets process table entries.

Library

Standard C library (**libc.a**)

Syntax

```
#include <procinfo.h>
#include <sys/types.h>
```

```
int
getprocs ( ProcessBuffer,  ProcessSize,  FileBuffer,  FileSize,  IndexPointer,  Count)
struct procsinfo *ProcessBuffer;
or struct procsinfo64 *ProcessBuffer;
int ProcessSize;
struct fdsinfo *FileBuffer;
int FileSize;
pid_t *IndexPointer;
int Count;
```

```
int
getprocs64 ( ProcessBuffer,  ProcessSize,  FileBuffer,  FileSize,  IndexPointer,  Count)
struct procentry64 *ProcessBuffer;
int ProcessSize;
struct fdsinfo64 *FileBuffer;
int FileSize;
pid_t *IndexPointer;
int Count;
```

Description

The **getprocs** subroutine returns information about processes, including process table information defined by the **procsinfo** structure, and information about the per-process file descriptors defined by the **fdsinfo** structure.

The **getprocs** subroutine retrieves up to *Count* process table entries, starting with the process table entry corresponding to the process identifier indicated by *IndexPointer*, and places them in the array of **procsinfo** structures indicated by the *ProcessBuffer* parameter. File descriptor information corresponding to the retrieved processes are stored in the array of **fdsinfo** structures indicated by the *FileBuffer* parameter.

On return, the process identifier referenced by *IndexPointer* is updated to indicate the next process table entry to be retrieved. The **getprocs** subroutine returns the number of process table entries retrieved.

The **getprocs** subroutine is normally called repeatedly in a loop, starting with a process identifier of zero, and looping until the return value is less than *Count*, indicating that there are no more entries to retrieve.

Note: The process table may change while the **getprocs** subroutine is accessing it. Returned entries will always be consistent, but since processes can be created or destroyed while the **getprocs** subroutine is running, there is no guarantee that retrieved entries will still exist, or that all existing processes have been retrieved.

When used in 32-bit mode, limits larger than can be represented in 32 bits are truncated to RLIM_INFINITY. Large **rusage** and other values are truncated to INT_MAX. Alternatively, the **struct procsinfo64** and *sizeof* (**struct procsinfo64**) can be used by 32-bit **getprocs** to return full 64-bit process information. Note that the **procsinfo** structure not only increases certain **procsinfo** fields from 32 to 64 bits, but that it contains additional information not present in **procsinfo**. The **struct procsinfo64** contains the same data as **struct procsinfo** when compiled in a 64-bit program.

The 64-bit applications are required to use **getprocs64()** and **procentry64**. Note that **struct procentry64** contains the same information as **struct procsinfo64**, with the addition of support for the 64-bit time_t and dev_t, and the 256-bit sigset_t. The **procentry64** structure also contains a new version of **struct ucred** (**struct ucred_ext**) and a new, expanded **struct rusage** (**struct trusage64**) as described in **<sys/cred.h>** and **<sys/resource.h>** respectively. Application developers are also encouraged to use **getprocs64()** in 32-bit applications to obtain 64-bit process information as this interface provides the new, larger types. The **getprocs()** interface will still be supported for 32-bit applications using **struct procsinfo** or **struct procsinfo64** but will not be available to 64-bit applications.

Parameters

ProcessBuffer
Specifies the starting address of an array of **procsinfo**, **procsinfo64**, or **procentry64** structures to be filled in with process table entries. If a value of **NULL** is passed for this parameter, the **getprocs** subroutine scans the process table and sets return values as normal, but no process entries are retrieved.

Note: The *ProcessBuffer* parameter of **getprocs** subroutine contains two struct rusage fields named **pi_ru** and **pi_cru**. Each of these fields contains two struct timeval fields named **ru_utime** and **ru_stime**. The **tv_usec** field in both of the struct timeval contain nanoseconds instead of microseconds. These values cone from the struct user fields named **U_ru** and **U_cru**. The **pi_cru_*** fields also contain the page faults for reaped child which roll back to parent. This field is updated before the child can become zombie.

ProcessSize
Specifies the size of a single **procsinfo**, **procsinfo64**, or **procentry64** structure.

FileBuffer
Specifies the starting address of an array of **fdsinfo**, or **fdsinfo64** structures to be filled in with per-process file descriptor information. If a value of **NULL** is passed for this parameter, the **getprocs** subroutine scans the process table and sets return values as normal, but no file descriptor entries are retrieved.

Note: Use **fdsinfo64_100K** when processes have more than 32 K file descriptors.

FileSize
Specifies the size of a single **fdsinfo**, or **fdsinfo64** structure.

Note: Use **fdsinfo64_100K** when processes have more than 32 K file descriptors.

IndexPointer
Specifies the address of a process identifier which indicates the required process table entry. A process identifier of zero selects the first entry in the table. The process identifier is updated to indicate the next entry to be retrieved.

Note: The *IndexPointer* does not have to correspond to an existing process, and may in fact correspond to a different process than the one you expect. There is no guarantee that the process slot pointed to by *IndexPointer* will contain the same process between successive calls to **getprocs()** or **getprocs64()**.

Count
Specifies the number of process table entries requested.

Return Values

If successful, the **getprocs** subroutine returns the number of process table entries retrieved; if this is less than the number requested, the end of the process table has been reached. A value of 0 is returned when the end of the process table has been reached. Otherwise, a value of -1 is returned, and the **errno** global variable is set to indicate the error.

Error Codes

The **getprocs** subroutine does not succeed if the following are true:

Item	Description
EINVAL	The *ProcessSize* or *FileSize* parameters are invalid, or the *IndexPointer* parameter does not point to a valid process identifier, or the *Count* parameter is not greater than zero.
EFAULT	The copy operation to one of the buffers was not successful.

getproj Subroutine

Purpose

Retrieves the project definition from the kernel project registry for the requested project name.

Library

The **libaacct.a** library.

Syntax

```
<sys/aacct.h>

getproj(struct project *, int flag)
```

Description

The **getproj** subroutine functions similar to the **getprojs** subroutine with the exception that the **getproj** subroutine retrieves the definition only for the project name or number, which is passed as its argument. The *flag* parameter indicates what is passed. The *flag* parameter has the following values:

- PROJ_NAME — Indicates that the supplied project definition only has the project name. The **getproj** subroutine queries the kernel to obtain a match for the supplied project name and returns the matching entry.
- PROJ_NUM — Indicates that the supplied project definition only has the project number. The **getproj** subroutine queries the kernel to obtain a match for the supplied project number and returns the matching entry.

Generally, the projects are loaded from the system project definition file or LDAP, or from both. When more than one of these project repositories are used, project name and project ID collisions are possible. These projects are differentiated by the kernel using an origin flag. This origin flag designates the project repository from where the project definition is obtained. If the caller wants to retrieve the project definition that belongs to a specific project repository, the specific origin value should be passed in the flags field of the project structure. Valid project origins values that can be passed are defined in the `sys/aacct.h` file. If the projects are currently loaded from the project repository represented by the origin value, `getproj` returns the specified project if it exists. If the origin value is not passed, the first project reference found in the kernel registry is returned. Regardless of whether the origin is passed or not, `getproj` always returns the project origin flags in the output project structure.

Parameters

Item	Description
project	Pointer holding the project whose information is required.
flag	An integer flag that indicates whether the match needs to be performed on the supplied project name or number.

Security

There are no restrictions. Any user can call this function.

Return Values

Item	Description
0	Success
-1	Failure

Error Codes

Item	Description
EINVAL	Invalid argument. The *flag* parameter is not valid or the passed pointer is NULL.
ENOENT	Project not found.

getprojdb Subroutine

Purpose

Retrieves the specified project record from the project database.

Library

The **libaacct.a** library.

Syntax

```
<sys/aacct.h>

getprojdb(void *handle, struct project *project,  int flag)
```

Description

The **getprojdb** subroutine searches the project database associated with the *handle* parameter for the specified project. The project database must be initialized before calling this subroutine. The routines **projdballoc** and **projdbfinit** are provided for this purpose. The *flag* parameter indicates the type of search. The following flags are defined:

- **PROJ_NAME** — Search by product name. The **getprojdb** subroutine scans the file to obtain a match for the supplied project name and returns the matching entry.
- **PROJ_NUM** — Search by product number. The **getprojdb** subroutine scans the file to obtain a match for the supplied project number and returns the matching entry.

The entire database is searched. If the specified record is found, the **getprojdb** subroutine stores the relevant project information into the `struct project` buffer, which is passed as an argument to this subroutine. The specified project is then made the current project in the database. If the specified project is not found, the database is reset so that the first project in the database is the current project.

Parameters

Item	Description
handle	Pointer to the handle allocated for the project database.
project	Pointer holding the project name whose information is required.

Item	Description
flag	Integer flag indicating what type of information is sent for matching; that is, whether the match needs to be performed by project name or number.

Security

No restrictions. Any user can call this function.

Return Values

Item	Description
0	Success
-1	Failure

Error Codes

Item	Description
ENOENT	Project definition not found.
EINVAL	Invalid arguments if flag is not valid or passed pointer is NULL.

getprojs Subroutine

Purpose

Retrieves the project details from the kernel project registry.

Library

The **libaacct.a** library.

Syntax

```
<sys/aacct.h>

getprojs(struct project *, int *)
```

Description

The **getprojs** subroutine retrieves the specified number of project definitions from the kernel project registry. The number of definitions to be retrieved is passed as an argument to this subroutine, and it is also passed with a buffer of type **struct *project***, where the retrieved project definitions are stored.

When the **getprojs** subroutine is called with a NULL value passed instead of a pointer to a **struct *project***, the **getprojs** subroutine returns the total number of defined projects in the kernel project registry. This number can be used by any subsequent calls to retrieve the project details.

If the integer value passed is smaller than the number of project definitions available, then the project buffer will be filled with as many entries as requested. If the value is greater than the number of available definitions, then the available records are filled in the structure and the integer value is updated with the number of records actually retrieved.

Generally, the projects are loaded from the system project definition file or LDAP, or from both. When more than one of these project repositories are used, project name and project ID collisions are possible. These projects are differentiated by the kernel using an origin flag. This origin flag designates the project repository from where the project definition is obtained. Valid project origins values that can be passed

are defined in the `sys/aacct.h` file. The `getproj` subroutine also returns this origin information in the `flags` field of the output project structures.

Parameters

Item	Description
pointer	Points to a project structure where the retrieved data is stored.
int	An integer that indicates the number of elements to be retrieved.

Security

There are no restrictions. Any user can call this function.

Return Values

Item	Description
0	Success
-1	Failure

Error Codes

Item	Description
EINVAL	Invalid arguments if passed *int* pointer is NULL
ENOENT	No projects available.

getpw Subroutine

Purpose

Retrieves a user's /etc/passwd file entry.

Library

Standard C Library **(libc.a)**

Syntax

int getpw (*UserID*, *Buffer*)

```
uid_t UserID
char *Buffer
```

Description

The **getpw** subroutine opens the **/etc/passwd** file and returns, in the *Buffer* parameter, the **/etc/passwd** file entry of the user specified by the *UserID* parameter.

Parameters

Item	Description
Buffer	Specifies a character buffer large enough to hold any **/etc/passwd** entry.
UserID	Specifies the ID of the user for which the entry is desired.

Return Values

The **getpw** subroutine returns:

Item	Description
0	Successful completion
-1	Not successful.

getpwent, getpwuid, getpwnam, putpwent, setpwent, or endpwent Subroutine

Purpose

Accesses the basic user information in the user database.

Library

Standard C Library **(libc.a)**

Syntax

```
#include <sys/types.h>
#include <pwd.h>
```

```
struct passwd *getpwent ( )
```

```
struct passwd *getpwuid ( UserID)
uid_t UserID;
```

```
struct passwd *getpwnam ( Name)
char *Name;
```

```
int putpwent ( Password,  File)
struct passwd *Password;
FILE *File;
```

```
void setpwent ( )
```

```
void endpwent ( )
```

Description

Attention: All information generated by the **getpwent**, **getpwnam**, and **getpwuid** subroutines is stored in a static area. Subsequent calls to these subroutines overwrite this static area. To save the information in the static area, applications should copy it.

Attention: The **getpwent** subroutine is only supported by LOCAL and NIS load modules, not any other LAM authentication module.

These subroutines access the basic user attributes.

The **setpwent** subroutine opens the user database if it is not already open. Then, this subroutine sets the cursor to point to the first user entry in the database. The **endpwent** subroutine closes the user database.

The **getpwent**, **getpwnam**, and **getpwuid** subroutines return information about a user. These subroutines do the following:

Item	Description
getpwent	Returns the next user entry in the sequential search.
getpwnam	Returns the first user entry in the database whose name matches the *Name* parameter.
getpwuid	Returns the first user entry in the database whose ID matches the *UserID* parameter.

The **putpwent** subroutine writes a password entry into a file in the colon-separated format of the **/etc/passwd** file.

The passwd structure

The **getpwent**, **getpwnam**, and **getpwuid** subroutines return a **passwd** structure. The **passwd** structure is defined in the **pwd.h** file and has the following fields:

Item	Description
pw_name	Contains the name of the user name.
pw_passwd	Contains the user's encrypted password.
	Note: If the password is not stored in the **/etc/passwd** file and the invoker does not have access to the shadow file that contains passwords, this field contains an undecryptable string, usually an * (asterisk).
pw_uid	Contains the user's ID.
pw_gid	Identifies the user's principal group ID.
pw_gecos	Contains general user information.
pw_dir	Identifies the user's home directory.
pw_shell	Identifies the user's login shell.

Note: If Network Information Services (NIS) is enabled on the system, these subroutines attempt to retrieve the information from the NIS authentication server before attempting to retrieve the information locally.

Parameters

Item	Description
File	Points to an open file whose format is similar to the **/etc/passwd** file format.
Name	Specifies the user name.
Password	Points to a password structure. This structure contains user attributes.
UserID	Specifies the user ID.

Security

Item	Description
Files Accessed:	

Mode	File
rw	**/etc/passwd** (write access for the **putpwent** subroutine only)
r	**/etc/security/passwd** (if the password is desired)

Return values

The **getpwent**, **getpwnam**, and **getpwuid** subroutines return a pointer to a valid password structure if successful. Otherwise, a null pointer is returned.

The **getpwent** subroutine will return a null pointer and an **errno** value of **ENOATTR** when it detects a corrupt entry. To get subsequent entries following the corrupt entry, call the **getpwent** subroutine again.

Error codes

If any of these subroutines fail, the following errors might be returned:

Item	Description
EACCES	Access permission is denied for the data request.
EINVAL	The parameter does not contain one of the defined attributes or null.
EIO	Failed to access remote user database.
ENOATTR	The specified attribute is not defined for the current user.
EPERM	Operation is not permitted.
ESRCH	The specified parameter does not exist.

Files

Item	Description
/etc/passwd	Contains user IDs and their passwords

getrlimit, getrlimit64, setrlimit, setrlimit64, or vlimit Subroutine

Purpose

Controls maximum system resource consumption.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/time.h>
#include <sys/resource.h>

int setrlimit( Resource1, RLP)
int Resource1;
struct rlimit *RLP;

int setrlimit64 ( Resource1, RLP)
int Resource1;
struct rlimit64 *RLP;

int getrlimit ( Resource1, RLP)
int Resource1;
struct rlimit *RLP;
```

```
int getrlimit64 ( Resource1, RLP)
int Resource1;
struct rlimit64 *RLP;

#include <sys/vlimit.h>

vlimit ( Resource2, Value)
int Resource2, Value;
```

Description

The **getrlimit** subroutine returns the values of limits on system resources used by the current process and its children processes. The **setrlimit** subroutine sets these limits. The **vlimit** subroutine is also supported, but the **getrlimit** subroutine replaces it.

A resource limit is specified as either a soft (current) or hard limit. A calling process can raise or lower its own soft limits, but it cannot raise its soft limits above its hard limits. A calling process must have root user authority to raise a hard limit.

Note: The initial values returned by the **getrlimit** subroutine are the **ulimit** values in effect when the process was started. For *maxdata* programs the initial value returned by **getrlimit** for the soft data limit is the lower of the hard data limit or the *maxdata* value. When a program is executing using the large address-space model, the operating system attempts to modify the soft limit on data size, if necessary, to increase it to match the *maxdata* value. If the *maxdata* value is larger than the current hard limit on data size, either the program will not execute if the *XPG_SUS_ENV* environment variable has the value set to ON, or the soft limit will be set to the current hard limit. If the *maxdata* value is smaller than the size of the program's static data, the program will not execute.

The **rlimit** structure specifies the hard and soft limits for a resource, as defined in the **sys/resource.h** file. The **RLIM_INFINITY** value defines an infinite value for a limit.

When compiled in 32-bit mode, RLIM_INFINITY is a 32-bit value; when compiled in 64-bit mode, it is a 64-bit value. 32-bit routines should use **RLIM64_INFINITY** when setting 64-bit limits with the **setrlimit64** routine, and recognize this value when returned by **getrlimit64**.

This information is stored as per-process information. This subroutine must be executed directly by the shell if it is to affect all future processes created by the shell.

Note: Raising the data limit does not raise the program break value. Use the **brk/sbrk** subroutines to raise the break value. If the proper memory segments are not initialized at program load time, raising your memory limit will not allow access to this memory. Use the **-bmaxdata** flag of the **ld** command to set up these segments at load time.

When compiled in 32-bit mode, the **struct rlimit** values may be returned as RLIM_SAVED_MAX or RLIM_SAVED_CUR when the actual resource limit is too large to represent as a 32-bit **rlim_t**.

These values can be used by library routines which set their own **rlimits** to save off potentially 64-bit **rlimit** values (and prevent them from being truncated by the 32-bit **struct rlimit**). Unless the library routine intends to permanently change the **rlimits**, the RLIM_SAVED_MAX and RLIM_SAVED_CUR values can be used to restore the 64-bit **rlimits**.

Application limits may be further constrained by available memory or implementation defined constants such as **OPEN_MAX** (maximum available open files).

Parameters

Item	Description
Resource1	Can be one of the following values: **RLIMIT_AS** The maximum size, in bytes, of the total available memory of a process. This limit is enforced by the kernel only if the *XPG_SUS_ENV=ON* environment variable is set in the user's environment before the process is executed. If the *XPG_SUS_ENV* environment variable is not set in the user's environment, the limit is not enforced. **RLIMIT_CORE** The largest size, in bytes, of a **core** file that can be created. This limit is enforced by the kernel. If the value of the **RLIMIT_FSIZE** limit is less than the value of the **RLIMIT_CORE** limit, the system uses the **RLIMIT_FSIZE** limit value as the soft limit. **RLIMIT_CPU** The maximum amount of central processing unit (processor) time, in seconds, to be used by each process. If a process exceeds its soft processor limit, the kernel will send a **SIGXCPU** signal to the process. After the hard limit is reached, the process will be killed with **SIGXCPU**, even if it handles, blocks, or ignores that signal. **RLIMIT_DATA** The maximum size, in bytes, of the data region for a process. This limit defines how far a program can extend its break value with the **sbrk** subroutine. This limit is enforced by the kernel. If the *XPG_SUS_ENV=ON* environment variable is set in the user's environment before the process is executed and a process attempts to set the limit lower than current usage, the operation fails with the value of *errno* global variable set to **EINVAL**. If the *XPG_SUS_ENV* environment variable is not set, the operation fails with the value of *errno* global variable set to **EFAULT**. **RLIMIT_FSIZE** The largest size, in bytes, of any single file that can be created. When a process attempts to write, truncate, or clear beyond its soft **RLIMIT_FSIZE** limit, the operation will fail with the value of *errno* global variable set to **EFBIG**. If the *XPG_SUS_ENV=ON* environment variable is set in the user's environment before the process is executed, the **SIGXFSZ** signal is also generated. **RLIMIT_NOFILE** This is a number one greater than the maximum value that the system may assign to a newly-created descriptor. **RLIMIT_STACK** The maximum size, in bytes, of the stack region for a process. This limit defines how far a program stack region can be extended. Stack extension is performed automatically by the system. This limit is enforced by the kernel. When the stack limit is reached, the process receives a **SIGSEGV** signal. If this signal is not caught by a handler by using the signal stack, the signal ends the process. **RLIMIT_RSS** The maximum size, in bytes, to which the resident set size of a process can grow. This limit is not enforced by the kernel. A process may exceed its soft limit size without being ended. **RLIMIT_THREADS** The maximum number of threads each process can create. This limit is enforced by the kernel and the pthread debug library. **RLIMIT_NPROC** The maximum number of processes each user can create.
RLP	Points to the **rlimit** or **rlimit64** structure, which contains the soft (current) and hard limits. For the **getrlimit** subroutine, the requested limits are returned in this structure. For the **setrlimit** subroutine, the desired new limits are specified here.
Resource2	The flags for this parameter are defined in the **sys/vlimit.h**, and are mapped to corresponding flags for the **setrlimit** subroutine.
Value	Specifies an integer used as a soft-limit parameter to the **vlimit** subroutine.

Return Values

On successful completion, a return value of 0 is returned, changing or returning the resource limit. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error. If the current limit specified is beyond the hard limit, the **setrlimit** subroutine sets the limit to max limit and returns successfully.

Error Codes

The **getrlimit**, **getrlimit64**, **setrlimit**, **setrlimit64**, or **vlimit** subroutine is unsuccessful if one of the following is true:

Item	Description
EFAULT	The address specified for the *RLP* parameter is not valid.

Item	Description
EINVAL	The *Resource1* parameter is not a valid resource, or the limit specified in the *RLP* parameter is invalid.
EPERM	The limit specified to the **setrlimit** subroutine would have raised the maximum limit value, and the caller does not have root user authority.

getrpcent, getrpcbyname, getrpcbynumber, setrpcent, or endrpcent Subroutine

Purpose

Accesses the **/etc/rpc** file.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <netdb.h>

struct rpcent *getrpcent ()
struct rpcent *getrpcbyname ( Name)
char *Name;
struct rpcent *getrpcbynumber ( Number)
int Number;
void setrpcent (StayOpen)
int  StayOpen
void endrpcent
```

Description

Attention: Do not use the **getrpcent**, **getrpcbyname**, **getrpcbynumber**, **setrpcent**, or **endrpcent** subroutine in a multithreaded environment.

Attention: The information returned by the **getrpcbyname**, and **getrpcbynumber** subroutines is stored in a static area and is overwritten on subsequent calls. Copy the information to save it.

The **getprcbyname** and **getrpcbynumber** subroutines each return a pointer to an object with the **rpcent** structure. This structure contains the broken-out fields of a line from the **/etc/rpc** file. The **getprcbyname** and **getrpcbynumber** subroutines searches the **rpc** file sequentially from the beginning of the file until it finds a matching RPC program name or number, or until it reaches the end of the file. The **getrpcent** subroutine reads the next line of the file, opening the file if necessary.

The **setrpcent** subroutine opens and rewinds the **/etc/rpc** file. If the *StayOpen* parameter does not equal 0, the **rpc** file is not closed after a call to the **getrpcent** subroutine.

The **setrpcent** subroutine rewinds the **rpc** file. The **endrpcent** subroutine closes it.

The **rpc** file contains information about Remote Procedure Call (RPC) programs. The **rpcent** structure is in the **/usr/include/netdb.h** file and contains the following fields:

Item	Description
`r_name`	Contains the name of the server for an RPC program
`r_aliases`	Contains an alternate list of names for RPC programs. This list ends with a 0.
`r_number`	Contains a number associated with an RPC program.

Parameters

Item	Description
Name	Specifies the name of a server for **rpc** program.
Number	Specifies the **rpc** program number for service.
StayOpen	Contains a value used to indicate whether to close the **rpc** file.

Return Values

These subroutines return a null pointer when they encounter the end of a file or an error.

Files

Item	Description
/etc/rpc	Contains information about Remote Procedure Call (RPC) programs.

getrusage, getrusage64, times, or vtimes Subroutine

Purpose

Displays information about resource use.

Libraries

getrusage, **getrusage64**, **times**: Standard C Library (**libc.a**)

Item	Description
vtimes:	Berkeley Compatibility Library (**libbsd.a**)

Syntax

```
#include <sys/times.h>
#include <sys/resource.h>
```

```
int getrusage ( Who,  RUsage)
int Who;
struct rusage *RUsage;
```

```
int getrusage64 ( Who,  RUsage)
int Who;
struct rusage64 *RUsage;
```

```
#include <sys/types.h>
#include <sys/times.h>
```

```
clock_t times ( Buffer)
struct tms *Buffer;
```

```
#include <sys/times.h>
```

```
vtimes ( ParentVM,  ChildVM)
struct vtimes *ParentVm, ChildVm;
```

Description

The **getrusage** subroutine displays information about how resources are used by the current process or all completed child processes.

When compiled in 64-bit mode, **rusage** counters are 64 bits. If **getrusage** is compiled in 32-bit mode, **rusage** counters are 32 bits. If the kernel's value of a **usage** counter has exceeded the capacity of the corresponding 32-bit **rusage** value being returned, the **rusage** value is set to INT_MAX.

The **getrusage64** subroutine can be called to make 64-bit **rusage** counters explicitly available in a 32-bit environment.

64-bit quantities are also available to 64-bit applications through the **getrusage()** interface in the ru_utime and ru_stime fields of **struct rusage**.

The **times** subroutine fills the structure pointed to by the *Buffer* parameter with time-accounting information. All time values reported by the **times** subroutine are measured in terms of the number of clock ticks used. Applications should use **sysconf** (**_SC_CLK_TCK**) to determine the number of clock ticks per second.

The **tms** structure defined in the **/usr/include/sys/times.h** file contains the following fields:

```
time_t   tms_utime;
```

```
time_t   tms_stime;
```

```
time_t   tms_cutime;
```

```
time_t   tms_cstime;
```

This information is read from the calling process as well as from each completed child process for which the calling process executed a **wait** subroutine.

Item	Description
`tms_utime`	The CPU time used for executing instructions in the user space of the calling process
`tms_stime`	The CPU time used by the system on behalf of the calling process.
`tms_cutime`	The sum of the `tms_utime` and the `tms_cutime` values for all the child processes.
`tms_cstime`	The sum of the `tms_stime` and the `tms_cstime` values for all the child processes.

Note: The system measures time by counting clock interrupts. The precision of the values reported by the **times** subroutine depends on the rate at which the clock interrupts occur.

The **vtimes** subroutine is supported to provide compatibility with earlier programs.

The **vtimes** subroutine returns accounting information for the current process and for the completed child processes of the current process. Either the *ParentVm* parameter, the *ChildVm* parameter, or both may be 0. In that case, only the information for the nonzero pointers is returned.

After a call to the **vtimes** subroutine, each buffer contains information as defined by the contents of the **/usr/include/sys/vtimes.h** file.

Parameters

Item	Description
Who	Specifies a value of **RUSAGE_THREAD**, **RUSAGE_SELF**, or **RUSAGE_CHILDREN**.

Item	Description
RUsage	Points to a buffer described in the **/usr/include/sys/resource.h** file. The fields are interpreted as follows: **ru_utime** The total amount of time running in user mode. **ru_stime** The total amount of time spent in the system executing on behalf of the processes. **ru_maxrss** The maximum size, in kilobytes, of the used resident set size. **ru_ixrss** An integral value indicating the amount of memory used by the text segment that was also shared among other processes. This value is expressed in units of kilobytes * seconds-of-execution and is calculated by adding the number of shared memory pages in use each time the internal system clock ticks, and then averaging over one-second intervals. **ru_idrss** An integral value of the amount of unshared memory in the data segment of a process (expressed in units of kilobytes * seconds-of-execution). **ru_minflt** The number of page faults serviced without any I/O activity. In this case, I/O activity is avoided by reclaiming a page frame from the list of pages awaiting reallocation. **ru_majflt** The number of page faults serviced that required I/O activity. **ru_nswap** The number of times a process was swapped out of main memory. **ru_inblock** The number of times the file system performed input. **ru_oublock** The number of times the file system performed output. **Note:** The numbers that the `ru_inblock` and `ru_oublock` fields display account for real I/O only; data supplied by the caching mechanism is charged only to the first process to read or write the data. **ru_msgsnd** The number of IPC messages sent. **ru_msgrcv** The number of IPC messages received. **ru_nsignals** The number of signals delivered. **ru_nvcsw** The number of times a context switch resulted because a process voluntarily gave up the processor before its time slice was completed. This usually occurs while the process waits for availability of a resource. **ru_nivcsw** The number of times a context switch resulted because a higher priority process ran or because the current process exceeded its time slice.
Buffer	Points to a **tms** structure.
ParentVm	Points to a **vtimes** structure that contains the accounting information for the current process.

Item	Description
ChildVm	Points to a **vtimes** structure that contains the accounting information for the terminated child processes of the current process.

Return Values

Upon successful completion, the **getrusage** and **getrusage64** subroutines return a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Upon successful completion, the **times** subroutine returns the elapsed real time in units of ticks, whether profiling is enabled or disabled. This reference time does not change from one call of the **times** subroutine to another. If the **times** subroutine fails, it returns a value of -1 and sets the **errno** global variable to indicate the error.

Error Codes

The **getrusage** and **getrusage64** subroutines do not run successfully if either of the following is true:

Item	Description
EINVAL	The *Who* parameter is not a valid value.
EFAULT	The address specified for *RUsage* is not valid.

The **times** subroutine does not run successfully if the following is true:

Item	Description
EFAULT	The address specified by the *buffer* parameter is not valid.

getroleattr, nextrole or putroleattr Subroutine

Purpose

Accesses the role information in the roles database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
```

```
int getroleattr(Role, Attribute, Value, Type)
char *Role;
char *Attribute;
void *Value;
int Type;
```

```
char *nextrole(void)
```

```
int putroleattr(Role, Attribute, Value, Type)
char *Role;
char *Attribute;
void *Value;
int Type;
```

Description

The **getroleattr** subroutine reads a specified attribute from the role database. If the database is not already open, this subroutine does an implicit open for reading.

Similarly, the **putroleattr** subroutine writes a specified attribute into the role database. If the database is not already open, this subroutine does an implicit open for reading and writing. Data changed by the **putroleattr** subroutine must be explicitly committed by calling the **putroleattr** subroutine with a Type parameter specifying SEC_COMMIT. Until all the data is committed, only the **getroleattr** subroutine within the process returns written data.

The **nextrole** subroutine returns the next role in a linear search of the role database. The consistency of consecutive searches depends upon the underlying storage-access mechanism and is not guaranteed by this subroutine.

The **setroledb** and **endroledb** subroutines should be used to open and close the role database.

Parameters

Item	Description
Attribute	Specifies which attribute is read. The following possible attributes are defined in the **usersec.h** file: **S_AUDITCLASSES** Audit classes to which the role belongs. The attribute type is **SEC_LIST**. **S_ROLELIST** List of roles included by this role. The attribute type is **SEC_LIST**. **S_AUTHORIZATIONS** List of authorizations included by this role. The attribute type is **SEC_LIST**. **S_GROUPS** List of groups required for this role. The attribute type is **SEC_LIST**. **S_HOSTSENABLEDROLE** List of hosts from where the role can be downloaded to the Kernel Role Table. The attribute type is **SEC_LIST**. **S_HOSTSDISABLEDROLE** List of hosts from where the role cannot be downloaded to the Kernel Role Table. The attribute type is **SEC_LIST**. **S_SCREENS** List of SMIT screens required for this role. The attribute type is **SEC_LIST**. **S_VISIBILITY** Number value stating the visibility of the role. The attribute type is **SEC_INT**. **S_MSGCAT** Message catalog file name. The attribute type is **SEC_CHAR**. **S_MSGNUMBER** Message number within the catalog. The attribute type is **SEC_INT**. **S_MSGSET** Message catalog set number. The attribute type is **SEC_INT**. **S_ID** Role identifier. The attribute type is **SEC_INT**. **S_DFLTMSG** Default role description string used when catalogs are not in use. The attribute type is **SEC_CHAR**. **S_USERS** List of users that have been assigned this role. This attribute is a read only attribute and cannot be modified through the **putroleattr** subroutine. The attribute type is **SEC_LIST**. **S_AUTH_MODE** The authentication to use when assuming the role through the **swrole** command. Valid values are **NONE** and **INVOKER**. The attribute type is **SEC_CHAR**.

Item	Description
Type	Specifies the type of attribute expected. Valid types are defined in the **usersec.h** file and include: **SEC_INT** The format of the attribute is an integer. For the **getroleattr** subroutine, the user should supply a pointer to a defined integer variable. For the **putroleattr** subroutine, the user should supply an integer. **SEC_CHAR** The format of the attribute is a null-terminated character string. For the **getroleattr** subroutine, the user should supply a pointer to a defined character pointer variable. For the **putroleattr** subroutine, the user should supply a character pointer. **SEC_LIST** The format of the attribute is a series of concatenated strings, each null-terminated. The last string in the series must be an empty (zero character count) string. For the **getroleattr** subroutine, the user should supply a pointer to a defined character pointer variable. For the **putroleattr** subroutine, the user should supply a character pointer. **SEC_COMMIT** For the **putroleattr** subroutine, this value specified by itself indicates that changes to the named role are to be committed to permanent storage. The *Attribute* and *Value* parameters are ignored. If no role is specified, the changes to all modified roles are committed to permanent storage. **SEC_DELETE** The corresponding attribute is deleted from the database. **SEC_NEW** Updates the role database file with the new role name when using the **putroleattr** subroutine.
Value	Specifies a buffer, a pointer to a buffer, or a pointer to a pointer depending on the *Attribute* and *Type* parameters. See the *Type* parameter for more details.

Return Values

If successful, the **getroleattr** returns 0. Otherwise, a value of -1 is returned and the **errno** global variables is set to indicate the error.

Error Codes

Possible return codes are:

Item	Description
EACCES	Access permission is denied for the data request.
ENOENT	The specified *Role* parameter does not exist.
ENOATTR	The specified role attribute does not exist for this role.
EINVAL	The *Attribute* parameter does not contain one of the defined attributes or null.
EINVAL	The *Value* parameter does not point to a valid buffer or to valid data for this type of attribute.

Item	Description
EPERM	Operation is not permitted.

getroleattrs Subroutine

Purpose

Retrieves multiple role attributes from the role database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>

int getroleattrs(Role, Attributes, Count)
    char *Role;
    dbattr_t *Attributes;
    int Count;
```

Description

The **getroleattrs** reads one or more attributes from the role database. The role specified with the *Role* parameter must already exist in the role database. The *Attributes* parameter contains information about each attribute that is to be read. All attributes specified by the *Attributes* parameter must be examined on a successful call to the **getroleattrs** subroutine to determine whether value of the *Attributes* parameter was successfully retrieved. Attributes of the **SEC_CHAR** or **SEC_LIST** type will have their values returned to the allocated memory. Caller need to free this memory. The **dbattr_t data** structure contains the following fields:

Item	Description
attr_name	The name of the target role attribute.
attr_idx	This attribute is used internally by the **getroleattrs** subroutine.
attr_type	The type of the target attribute.
attr _flag	The result of the request to read the target attribute. On successful completion, the value of zero is returned. Otherwise, it returns a value of nonzero.
attr_un	A union that contains the returned values for the requested query.
attr_domain	The subroutine ignores any input to this field. If this field is set to null, the subroutine sets this field to the name of the domain where the role is found.

The following valid role attributes for the **getroleattrs** subroutine are defined in the **usersec.h** file:

Name	Description	Type
S_AUDITCLASSES	Audit classes to which the role belongs.	**SEC_LIST**
S_AUTHORIZATIONS	Retrieves all the authorizations that are assigned to the role.	**SEC_LIST**

Name	Description	Type
S_AUTH_MODE	The authentication to perform when assuming the role through the **swrole** command. It contains the following possible values: **NONE** No authentication is required. **INVOKER** This is the default value. Invokers of the **swrole** command must enter their passwords to assume the role.	**SEC_CHAR**
S_DFLTMSG	The default role description that is used when catalogs are not in use.	**SEC_CHAR**
S_GROUPS	The groups that a user is suggested to become a member of. It is for informational purpose only.	**SEC_LIST**
S_HOSTSENABLEDROLE	The list of hosts from where the role can be downloaded to the Kernel Role Table.	**SEC_LIST**
S_HOSTSDISABLEDROLE	The list of hosts from where the role cannot be downloaded to the Kernel Role Table.	**SEC_LIST**
S_ID	The role identifier.	**SEC_INT**
S_MSGCAT	The message catalog name that contains the role description.	**SEC_CHAR**
S_MSGSET	The message catalog's set number for the role description.	**SEC_INT**
S_MSGNUMBER	The message number for the role description.	**SEC_INT**
S_ROLELIST	Lists of roles whose authorizations are included in this role.	**SEC_LIST**
S_ROLES	Retrieves all the roles that are available on the system. It is valid only when the *Role* parameter is set to **ALL**.	**SEC_LIST**
S_SCREENS	The SMIT screens that the role can access.	**SEC_LIST**

Name	Description	Type
S_VISIBILITY	An integer that determines whether the role is active or not. It contains the following possible values: **-1** The role is disabled. **0** The role is active but not visible from a GUI. **1** The role is active and visible. This is the default value.	**SEC_INT**
S_USERS	Lists of users that have been assigned this role.	**SEC_LIST**

The following union members correspond to the definitions of the **attr_char**, **attr_int**, **attr_long** and the **attr_llong** macros in the **usersec.h** file respectively.

Item	Description
au_char	The attributes of the **SEC_CHAR** and **SEC_LIST** types store a pointer to the returned value in this member when the attributes are successfully retrieved. The caller is responsible for freeing this memory.
au_int	The storage location for attributes of the **SEC_INT** type.
au_long	The storage location for attributes of the **SEC_LONG** type.
au_llong	The storage location for attributes of the **SEC_LLONG** type.

If **ALL** is specified for the *Role* parameter, the only valid attribute that can be displayed in the *Attribute* parameter is the **S_ROLES** attribute. Specifying any other attribute with a role name of **ALL** causes the **getroleattrs** subroutine to fail.

Parameters

Item	Description
Role	Specifies the role name for which the attributes are to be read.
Attributes	A pointer to an array of zero or more elements of the **dbattr_t** type. The list of role attributes is defined in the **usersec.h** header file.
Count	The number of attributes specified in the *Attributes* parameter.

Security

Files Accessed:

File	Mode
/etc/security/roles	r

Return Values

If the role specified by the *Role* parameter exists in the role database, the **getroleattrs** subroutine returns zero. On successful completion, the **attr_flag** attribute of each attribute that is specified in the *Attributes* parameter must be examined to determine whether it was successfully retrieved. If the specified role does not exist, a value of -1 is returned and the **errno** value is set to indicate the error.

Error Codes

If the **getroleattrs** subroutine returns -1, one of the following **errno** values is set:

Item	Description
EINVAL	The *Role* parameter is **NULL**.
EINVAL	The *Count* parameter is less than zero.
EINVAL	The *Role* parameter is **NULL** and the *Count* parameter is greater than zero.
EINVAL	The *Role* parameter is **ALL** but the *Attributes* parameter contains an attribute other than **S_ROLES**.
ENOENT	The role specified in the *Role* parameter does not exist.
ENOMEM	Memory cannot be allocated.
EPERM	The operation is not permitted.
EACCES	Access permission is denied for the data request.

If the **getroleattrs** subroutine fails to query an attribute, one of the following errors is returned in the **attr_flag** field of the corresponding value of the *Attributes* parameter:

Item	Description
EACCES	The invoker does not have access to the attribute specified in the **attr_name** field.
EINVAL	The **attr_name** field in the *Attributes* parameter is not a recognized role attribute.
EINVAL	The **attr_type** field in the *Attributes* parameter contains a type that is not valid.
EINVAL	The **attr_un** field in the *Attributes* parameter does not point to a valid buffer.
ENOATTR	The **attr_name** field in the *Attributes* parameter specifies a valid attribute, but no value is defined for this role.

gets or fgets Subroutine

Purpose

Gets a string from a stream.

Library

Standard I/O Library (**libc.a**)

Syntax

```
#include <stdio.h>
char *gets ( String)
char *String;
```

```
char *fgets (String,  Number,  Stream)
char *String;
int Number;
FILE *Stream;
```

Description

The **gets** subroutine reads bytes from the standard input stream, **stdin**, into the array pointed to by the *String* parameter. It reads data until it reaches a new-line character or an end-of-file condition. If a new-line character stops the reading process, the **gets** subroutine discards the new-line character and terminates the string with a null character.

The **fgets** subroutine reads bytes from the data pointed to by the *Stream* parameter into the array pointed to by the *String* parameter. The **fgets** subroutine reads data up to the number of bytes specified by the *Number* parameter minus 1, or until it reads a new-line character and transfers that character to the *String* parameter, or until it encounters an end-of-file condition. The **fgets** subroutine then terminates the data string with a null character.

The first successful run of the **fgetc**, **fgets**, **fgetwc**, **fgetws**, **fread**, **fscanf**, **getc**, **getchar**, **gets** or **scanf** subroutine using a stream that returns data not supplied by a prior call to the **ungetc**or **ungetwc** subroutine marks the `st_atime` field for update.

Parameters

Item	Description
String	Points to a string to receive bytes.
Stream	Points to the **FILE** structure of an open file.
Number	Specifies the upper bound on the number of bytes to read.

Return Values

If the **gets** or **fgets** subroutine encounters the end of the file without reading any bytes, it transfers no bytes to the *String* parameter and returns a null pointer. If a read error occurs, the **gets** or **fgets** subroutine returns a null pointer and sets the **errno** global variable (errors are the same as for the **fgetc** subroutine). Otherwise, the **gets** or **fgets** subroutine returns the value of the *String* parameter.

> **Note:** Depending upon which library routine the application binds to, this subroutine may return **EINTR**. Refer to the **signal** subroutine regarding the **SA_RESTART** value.

getsecconfig and setsecconfig Subroutines

Purpose

Retrieves and sets the kernel security configuration flags for system run mode.

Library

Trusted AIX Library (**libmls.a**)

Syntax

```
#include <mls/mls.h>

int getsecconfig (secconf)
uint32_t *secconf;

int setsecconfig(secconf, mode)
```

```
uint32_t secconf;
ushort mode;
```

Description

The **getsecconfig** subroutine retrieves the security configuration flags based on the current run mode. The flags are copied to kernel security configuration flag specified by the *secconf* parameter.

The **setsecconfig** subroutine sets the kernel security configuration for the specified mode according to flag that the *secconf* parameter specifies. The kernel configuration flags can only be changed in the CONFIGURATION runtime mode.

Parameters

Item	Description
secconf	Specifies the kernel security configuration flags.
Mode	Specifies the runtime mode to be updated. The valid values are CONFIGURATION_MODE and OPERATIONAL_MODE.

Security

Access Control: To set the configuration flags, the calling process invoking should have the PV_KER_SECCONFIG privilege.

Return Values

If successful, these subroutines return a value of zero. Otherwise, they return a value of -1.

Error Codes

If these subroutines fail, they set one of the following error codes:

Item	Description
EINVAL	The value that the parameter specifies is null.
EINVAL	The specified run time mode is not valid.
EINVAL	The configuration flags that are specified are not proper.
EPERM	The calling process either does not have permissions or privileges, or the system is not in the CONFIGURATION runtime mode.

getsecorder Subroutine

Purpose

Retrieves the ordering of domains for certain security databases.

Library

Standard C Library (**libc.a**)

Syntax

```
char * getsecorder (name)
       char *name;
```

Description

The **getsecorder** subroutine returns the value of the domain order for the database specified by the *name* parameter. When a previous call to the **setsecorder** subroutine with a valid value is successful, the **getsecorder** subroutine returns that value. Otherwise, the value of the **secorder** attribute of the name database in the **/etc/nscontrol.conf** file is returned. The returned value is a comma separated list of module names. The caller must free it after use. This subroutine is thread safe.

Parameters

Item	Description
name	Specifies the database name. The parameter can have one of the following valid values: • **authorizations** • **roles** • **privcmds** • **privdevs** • **privfiles**

Security

Files Accessed:

File	Mode
/etc/nscontrol.conf	r

Return Values

On successful completion, a comma-separated list of module names is returned. If the subroutine fails, it returns a value of NULL and sets the **errno** value to indicate the error.

Error Codes

Item	Description
EINVAL	The database name is not valid.
ENOMEM	Unable to allocate memory.

getfsent_r, getfsspec_r, getfsfile_r, getfstype_r, setfsent_r, or endfsent_r Subroutine

Purpose

Gets information about a file system.

Library

Thread-Safe C Library (**libc_r.a**)

Syntax

```
#include <fstab.h>
```

```
int getfsent_r (FSSent, FSFile, PassNo)
struct fstab * FSSent;
AFILE_t * FSFile;
int * PassNo;

int getfsspec_r (Special, FSSent, FSFile, PassNo)
const char * Special;
struct fstab *FSSent;
AFILE_t *FSFile;
int *PassNo;

int getfsfile_r (File, FSSent, FSFile, PassNo)
const char * File;
struct fstab *FSSent;
AFILE_t *FSFile;
int *PassNo;

int getfstype_r (Type, FSSent, FSFile, PassNo)
const char * Type;
struct fstab *FSSent;
AFILE_t *FSFile;
int *PassNo;
```

```
int setfsent_r (FSFile, PassNo)
AFILE_t * FSFile;
int *PassNo;
```

```
int endfsent_r (FSFile)
AFILE_t *FSFile;
```

Description

The **getfsent_r** subroutine reads the next line of the **/etc/filesystems** file, opening it necessary.

The **setfsent_r** subroutine opens the **filesystems** file and positions to the first record.

The **endfsent_r** subroutine closes the **filesystems** file.

The **getfsspec_r** and **getfsfile_r** subroutines search sequentially from the beginning of the file until a matching special file name or file-system file name is found, or until the end of the file is encountered. The **getfstype_r** subroutine behaves similarly, matching on the file-system type field.

Programs using this subroutine must link to the **libpthreads.a** library.

Parameters

Item	Description
FSSent	Points to a structure containing information about the file system. The *FSSent* parameter must be allocated by the caller. It cannot be a null value.
FSFile	Points to an attribute structure. The *FSFile* parameter is used to pass values between subroutines.
PassNo	Points to an integer. The **setfsent_r** subroutine initializes the *PassNo* parameter.
Special	Specifies a special file name to search for in the **filesystems** file.
File	Specifies a file name to search for in the **filesystems** file.
Type	Specifies a type to search for in the **filesystems** file.

Return Values

Item	Description
0	Indicates that the subroutine was successful.
-1	Indicates that the subroutine was not successful.

Files

Item	Description
/etc/filesystems	Centralizes file-system characteristics.

getroles Subroutine

Purpose

Gets the role ID of the current process.

Library

Security Library (**libc.a**)

Syntax

```
#include <unistd.h>
#include <sys/types.h>
#include <sys/cred.h>

int getroles (pid,roles, nroles)
pid_t pid;
rid_t *roles;
int nroles;
```

Description

The **getroles** subroutine gets the supplementary role ID of the process specified by the *pid* parameter. The list is stored in the array pointed to by the *roles* parameter. The *nroles* parameter indicates the number of entries that can be stored in this array. The **getroles** subroutine never returns more than the number of entries specified by the **MAX_ROLES** constant. (The **MAX_ROLES** constant is defined in the <**sys/cred.h**> header file.) If the value in the *nroles* parameter is 0, the **getroles** subroutine returns the number of roles in the given process.

Parameters

Item	Description
Pid	Indicates the process for which the role IDs are requested.
Roles	Points to the array in which the role IDs of the user's process is stored.
nroles	Indicates the number of entries that can be stored in the array pointed to by the *roles* parameter.

Return Values

The **getroles** subroutine returns one of the following values:

Item	Description
0	The subroutine completes successfully.
-1	An error has occurred. An **errno** global variable is set to indicate the error.

Error Codes

The **getroles** subroutine fails if any of the following value is true:

Item	Description
EFAULT	The *roles* and *nroles* parameters specify an array that is partially or completely outside of the process' allocated address space.
EINVAL	The value of the *nroles* parameter is smaller than that of the *roles* parameter in the current process.
EPERM	The invoker does not have the **PV_DAC_RID** privilege in its effective privilege set when the *Pid* is not the same as the current process ID.
ESRCH	No process has a process ID that equals to *Pid*.

getsid Subroutine

Purpose

Returns the session ID of the calling process.

Library

(**libc.a**)

Syntax

#include <unistd.h>

pid_t getsid (pid_ t *pid***)**

Description

The **getsid** subroutine returns the process group ID of the process that is the session leader of the process specified by *pid*. If *pid* is equal to **pid_t** subroutine, it specifies the calling process.

Parameters

Item	Description
pid	A process ID of the process being queried.

Return Values

Upon successful completion, **getsid** subroutine returns the process group ID of the session leaded of the specified process. Otherwise, it returns (**pid_t**)-1 and set **errno** to indicate the error.

Item	Description
id	The session ID of the requested process.
-1	Not successful and the **errno** global variable is set to one of the following error codes.

Error Codes

Item	Description
ESRCH	There is no process with a process ID equal to *pid.*

Item	Description
EPERM	The process specified by pid is not in the same session as the calling process.
ESRCH	There is no process with a process ID equal to *pid*.

getssys Subroutine

Purpose

Reads a subsystem record.

Library

System Resource Controller Library (**libsrc.a**)

Syntax

```
#include <sys/srcobj.h>
#include <spc.h>
```

```
int getssys( SubsystemName, SRCSubsystem)
char * SubsystemName;
struct SRCsubsys * SRCSubsystem;
```

Description

The **getssys** subroutine reads a subsystem record associated with the specified subsystem and returns the ODM record in the **SRCsubsys** structure.

The **SRCsubsys** structure is defined in the **sys/srcobj.h** file.

Parameters

Item	Description
SRCSubsystem	Points to the **SRCsubsys** structure.
SubsystemName	Specifies the name of the subsystem to be read.

Return Values

Upon successful completion, the **getssys** subroutine returns a value of 0. Otherwise, it returns a value of -1 and the **odmerrno** variable is set to indicate the error, or an SRC error code is returned.

Error Codes

If the **getssys** subroutine fails, the following is returned:

Item	Description
SRC_NOREC	Subsystem name does not exist.

Files

Item	Description
/etc/objrepos/SRCsubsys	SRC Subsystem Configuration object class.

getsubopt Subroutine

Purpose

Parse suboptions from a string.

Library

Standard C Library **(libc.a)**

Syntax

```
#include <stdlib.h>

int getsubopt (char **optionp,
char * const * tokens,
char ** valuep)
```

Description

The **getsubopt** subroutine parses suboptions in a flag parameter that were initially parsed by the **getopt** subroutine. These suboptions are separated by commas and may consist of either a single token, or a token-value pair separated by an equal sign. Because commas delimit suboptions in the option string, they are not allowed to be part of the suboption or the value of a suboption. similarly, because the equal sign separates a token from its value, a token must not contain an equal sign.

The **getsubopt** subroutine takes the address of a pointer to the option string, a vector of possible tokens, and the address of a value string pointer. It returns the index of the token that matched the suboption in the input string or -1 if there was no match. If the option string at **optionp* contains only one suboption, the **getsubopt** subroutine updates **optionp* to point to the start of the next suboption. It the suboption has an associated value, the **getsubopt** subroutine updates **valuep* to point to the value's first character. Otherwise it sets **valuep* to a NULL pointer.

The token vector is organized as a series of pointers to strings. The end of the token vector is identified by a NULL pointer.

When the **getsubopt** subroutine returns, if **valuep* is not a NULL pointer then the suboption processed included a value. The calling program may use this information to determine if the presence or lack of a value for this suboption is an error.

Additionally, when the **getsubopt** subroutine fails to match the suboption with the tokens in the *tokens* array, the calling program should decide if this is an error, or if the unrecognized option should be passed on to another program.

Return Values

The **getsubopt** subroutine returns the index of the matched token string, or -1 if no token strings were matched.

getsubsvr Subroutine

Purpose

Reads a subsystem record.

Library

System Resource Controller Library (**libsrc.a**)

Syntax

```
#include <sys/srcobj.h>
#include <spc.h>
```

int getsubsvr(*SubserverName*, *SRCSubserver***)**
char ***_SubserverName_;**
struct SRCSubsvr ***_SRCSubserver_;**

Description

The **getsubsvr** subroutine reads a subsystem record associated with the specified subserver and returns the ODM record in the **SRCsubsvr** structure.

The **SRCsubsvr** structure is defined in the **sys/srcobj.h** file and includes the following fields:

Item	Description
char	sub_type[30];
char	subsysname[30];
short	sub_code;

Parameters

Item	Description
SRCSubserver	Points to the **SRCsubsvr** structure.
SubserverName	Specifies the subserver to be read.

Return Values

Upon successful completion, the **getsubsvr** subroutine returns a value of 0. Otherwise, it returns a value of -1 and the **odmerrno** variable is set to indicate the error, or an SRC error code is returned.

Error Codes

If the **getsubsvr** subroutine fails, the following is returned:

Item	Description
SRC_NOREC	The specified **SRCsubsvr** record does not exist.

Files

Item	Description
/etc/objrepos/SRCsubsvr	SRC Subserver Configuration object class.

getsyx Subroutine

Purpose

Retrieves the current coordinates of the virtual screen cursor.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

getsyx(*Y***,** *X***)**
int * *Y***, *** *X***;**

Description

The **getsyx** subroutine retrieves the current coordinates of the virtual screen cursor and stores them in the location specified by Y and X. The current coordinates are those where the cursor was placed after the last call to the **wnoutrefresh**, **pnoutrefresh**, **or wrefresh**, subroutine. If the **leaveok** subroutine was TRUE for the last window refreshed, then the **getsyx** subroutine returns -1 for both X and Y.

If lines have been removed from the top of the screen using the **ripoffline** subroutine, *Y* and *X* include these lines. *Y* and *X* should only be used as arguments for the **setsyx** subroutine.

The **getsyx** subroutine, along with the **setsyx** subroutine, is meant to be used by a user-defined function that manipulates curses windows but wants the position of the cursor to remain the same. Such a function would do the following:

- Call the **getsyx** subroutine to obtain the current virtual cursor coordinates.
- Continue manipulating the windows.
- Call the **wnoutrefresh** subroutine on each window manipulated.
- Reset the current virtual cursor coordinates to the original values with the **setsyx** subroutine.
- Refresh the display with a call to the **doupdate** subroutine.

Parameters

Item	Description
X	Points to the current row position of the virtual screen cursor. A value of -1 indicates the **leaveok** subroutine was TRUE for the last window refreshed.
Y	Points to the current column position of the virtual screen cursor. A value of -1 indicates the **leaveok** subroutine was TRUE for the last window refreshed.

getsystemcfg Subroutine

Purpose

Displays the system configuration information.

Syntax

```
#include <systemcfg.h>
uint64_t getsystemcfg ( int name)
```

Description

Displays the system configuration information.

Parameters

Item	Description
name	Specifies the system variable setting to be returned. Valid values for the *name* parameter are defined in the **systemcfg.h** file.

Return Values

If the value specified by the *name* parameter is system-defined, the **getsystemcfg** subroutine returns the data that is associated with the structure member represented by the *input* parameter. Otherwise, the **getsystemcfg** subroutine will return **UINT64_MAX**, and **errno** will be set.

Error Codes

The **getsystemcfg** subroutine will fail if:

Item	Description
EINVAL	The value of the *name* parameter is invalid.

gettcbattr or puttcbattr Subroutine

Purpose

Accesses the TCB information in the user database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
```

```
int gettcbattr (Entry, Attribute, Value, Type)
char * Entry;
char * Attribute;
void * Value;
int  Type;
```

```
int puttcbattr (Entry, Attribute, Value, Type)
char *Entry;
char *Attribute;
void *Value;
int Type;
```

Description

These subroutines access Trusted Computing Base (TCB) information.

The **gettcbattr** subroutine reads a specified attribute from the `tcbck` database. If the database is not already open, the subroutine will do an implicit open for reading.

Similarly, the **puttcbattr** subroutine writes a specified attribute into the `tcbck` database. If the database is not already open, the subroutine does an implicit open for reading and writing. Data changed by **puttcbattr** must be explicitly committed by calling the **puttcbattr** subroutine with a *Type* parameter specifying the **SEC_COMMIT** value. Until the data is committed, only **get** subroutine calls within the process will return the written data.

New entries in the `tcbck` databases must first be created by invoking **puttcbattr** with the **SEC_NEW** type.

The `tcbck` database usually defines all the files and programs that are part of the TCB, but the root user or a member of the security group can choose to define only those files considered to be security-relevant.

Parameters

Item	Description
Attribute	Specifies which attribute is read. The following possible values are defined in the **sysck.h** file: **S_ACL** The access control list for the file. Type: **SEC_CHAR**. **S_CHECKSUM** The checksum of the file. Type: **SEC_CHAR**. **S_CLASS** The logical group of the file. The attribute type is **SEC_LIST**. **S_GROUP** The file group. The attribute type is **SEC_CHAR**. **S_LINKS** The hard links to this file. Type: **SEC_LIST**. **S_MODE** The File mode. Type: **SEC_CHAR**. **S_OWNER** The file owner. Type: **SEC_CHAR**. **S_PROGRAM** The associated checking program for the file. Type: **SEC_CHAR**. **S_SIZE** The size of the file in bytes. Type: **SEC_LONG**. **S_SOURCE** The source for the file. Type: **SEC_CHAR**. **S_SYMLINKS** The symbolic links to the file. Type: **SEC_LIST**. **S_TARGET** The target file (if file is a symbolic link). Type: **SEC_CHAR**. **S_TCB** The Trusted Computer Base. The attribute type is **SEC_BOOL**. **S_TYPE** The type of file. The attribute type is **SEC_CHAR**. Additional user-defined attributes may be used and will be stored in the format specified by the *Type* parameter.
Entry	Specifies the name of the file for which an attribute is to be read or written.
Type	Specifies the type of attribute expected. Valid values are defined in the **usersec.h** file and include: **SEC_BOOL** A pointer to an integer (**int ***) that has been cast to a null pointer. **SEC_CHAR** The format of the attribute is a null-terminated character string. **SEC_LIST** The format of the attribute is a series of concatenated strings, each null-terminated. The last string in the series is terminated by two successive null characters. **SEC_LONG** The format of the attribute is a 32-bit integer.

Item	Description
Value	Specifies the address of a pointer for the **gettcbattr** subroutine. The **gettcbattr** subroutine will return the address of a buffer in the pointer. For the **puttcbattr** subroutine, the *Value* parameter specifies the address of a buffer in which the attribute is stored. See the *Type* parameter for more details.

Security

Item	Description
Files Accessed:	

Mode	File
rw	**/etc/security/sysck.cfg** (write access for **puttcbattr**)

Return Values

The **gettcbattr** and **puttcbattr** subroutines, when successfully completed, return a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

Note: These subroutines return errors from other subroutines.

These subroutines fail if the following is true:

Item	Description
EACCES	Access permission is denied for the data request.

The **gettcbattr** and **puttcbattr** subroutines fail if one or more of the following are true:

Item	Description
EINVAL	The *Value* parameter does not point to a valid buffer or to valid data for this type of attribute. Limited testing is possible and all errors may not be detected.
EINVAL	The *Entry* parameter is null or contains a pointer to a null string.
EINVAL	The *Type* parameter contains more than one of the **SEC_BOOL**, **SEC_CHAR**, **SEC_LIST**, or **SEC_LONG** attributes.
EINVAL	The *Type* parameter specifies that an individual attribute is to be committed, and the *Entry* parameter is null.
ENOENT	The specified *Entry* parameter does not exist or the attribute is not defined for this entry.
EPERM	Operation is not permitted.

getthrds Subroutine

Purpose

Gets kernel thread table entries.

Library

Standard C library (**libc.a**)

Syntax

```
#include <procinfo.h>
#include <sys/types.h>
```

```
int
getthrds ( ProcessIdentifier,  ThreadBuffer,  ThreadSize,  IndexPointer,  Count)
pid_t ProcessIdentifier;
struct thrdsinfo *ThreadBuffer;
or struct thrdsinfo64 *ThreadBuffer;
int ThreadSize;
tid_t *IndexPointer;
int Count;
```

```
int
getthrds64 ( ProcessIdentifier,  ThreadBuffer,  ThreadSize,  IndexPointer,  Count)
pid_t ProcessIdentifier;
struct thrdentry64 *ThreadBuffer;
int ThreadSize;
tid64_t *IndexPointer;
int Count;
```

Description

The **getthrds** subroutine returns information about kernel threads, including kernel thread table information defined by the **thrdsinfo** or **thrdsinfo64** structure.

The **getthrds** subroutine retrieves up to *Count* kernel thread table entries, starting with the entry corresponding to the thread identifier indicated by *IndexPointer*, and places them in the array of **thrdsinfo** or **thrdsinfo64**, or **thrdentry64** structures indicated by the *ThreadBuffer* parameter.

On return, the kernel thread identifier referenced by *IndexPointer* is updated to indicate the next kernel thread table entry to be retrieved. The **getthrds** subroutine returns the number of kernel thread table entries retrieved.

If the *ProcessIdentifier* parameter indicates a process identifier, only kernel threads belonging to that process are considered. If this parameter is set to -1, all kernel threads are considered.

The **getthrds** subroutine is normally called repeatedly in a loop, starting with a kernel thread identifier of zero, and looping until the return value is less than *Count*, indicating that there are no more entries to retrieve.

1. Do not use information from the **procsinfo** structure (see the **getprocs** subroutine) to determine the value of the *Count* parameter; a process may create or destroy kernel threads in the interval between a call to **getprocs** and a subsequent call to **getthrds**.
2. The kernel thread table may change while the **getthrds** subroutine is accessing it. Returned entries will always be consistent, but since kernel threads can be created or destroyed while the **getthrds** subroutine is running, there is no guarantee that retrieved entries will still exist, or that all existing kernel threads have been retrieved.

When used in 32-bit mode, limits larger than can be represented in 32 bits are truncated to RLIM_INFINITY. Large values are truncated to INT_MAX. 64-bit applications are required to use **getthrds64()** and **struct thrdentry64.** Note that **struct thrdentry64** contains the same information as **struct thrdsinfo64** with the only difference being support for the 64-bit tid_t and the 256-bit sigset_t. Application developers are also encouraged to use **getthrds64()** in 32-bit applications to obtain 64-bit thread information as this interface provides the new, larger types. The **getthrds()** interface will still be supported for 32-bit applications using **struct thrdsinfo** or **struct thrdsinfo64**, but will not be available to 64-bit applications.

Parameters

ProcessIdentifier
Specifies the process identifier of the process whose kernel threads are to be retrieved. If this parameter is set to -1, all kernel threads in the kernel thread table are retrieved.

ThreadBuffer
Specifies the starting address of an array of **thrdsinfo** or **thrdsinfo64**, or **thrdentry64** structures which will be filled in with kernel thread table entries. If a value of **NULL** is passed for this parameter, the **getthrds** subroutine scans the kernel thread table and sets return values as normal, but no kernel thread table entries are retrieved.

ThreadSize
Specifies the size of a single **thrdsinfo**, **thrdsinfo64**, or **thrdentry64** structure.

IndexPointer
Specifies the address of a kernel thread identifier which indicates the required kernel thread table entry (this does not have to correspond to an existing kernel thread). A kernel thread identifier of zero selects the first entry in the table. The kernel thread identifier is updated to indicate the next entry to be retrieved.

Count
Specifies the number of kernel thread table entries requested.

Return Value

If successful, the **getthrds** subroutine returns the number of kernel thread table entries retrieved; if this is less than the number requested, the end of the kernel thread table has been reached. A value of 0 is returned when the end of the kernel thread table has been reached. Otherwise, a value of -1 is returned, and the **errno** global variable is set to indicate the error.

Error Codes

The **getthrds** subroutine fails if the following are true:

Item	Description
EINVAL	The *ThreadSize* is invalid, or the *IndexPointer* parameter does not point to a valid kernel thread identifier, or the *Count* parameter is not greater than zero.
ESRCH	The process specified by the *ProcessIdentifier* parameter does not exist.
EFAULT	The copy operation to one of the buffers failed.

gettimeofday, settimeofday, or ftime Subroutine

Purpose

Displays, gets and sets date and time.

Libraries

gettimeofday, **settimeofday**: Standard C Library (l**ibc.a**)

ftime: Berkeley Compatibility Library (**libbsd.a**)

Syntax

```
#include <sys/time.h>
int gettimeofday ( Tp,  Tzp)
struct timeval *Tp;
void *Tzp;
int settimeofday (Tp, Tzp)
```

struct timeval ****Tp*;**
struct timezone ****Tzp*;**

```
#include <sys/types.h>
#include <sys/timeb.h>
int ftime (Tp)
struct timeb *Tp;
```

Description

Current Greenwich time and the current time zone are displayed with the **gettimeofday** subroutine, and set with the **settimeofday** subroutine. The time is expressed in seconds and microseconds since midnight (0 hour), January 1, 1970. The resolution of the system clock is hardware-dependent, and the time may be updated either continuously or in "ticks." If the *Tzp* parameter has a value of 0, the time zone information is not returned or set.

If a recent `adjtime` subroutine call is causing the clock to be adjusted backwards, it is possible that two closely spaced `gettimeofday` calls will observe that time has moved backwards. You can set the `GETTOD_ADJ_MONOTONIC` environment value to cause the returned value to never decrease. After this environment variable is set, the returned value briefly remains constant as necessary to always report a nondecreasing time of day. This extra processing adds significant pathlength to `gettimeofday`. Although any setting of this environment variable requires this extra processing, setting it to 1 is recommended for future compatibility.

The *Tp* parameter returns a pointer to a **timeval** structure that contains the time since the epoch began in seconds and microseconds.

The **timezone** structure indicates both the local time zone (measured in minutes of time westward from Greenwich) and a flag that, if nonzero, indicates that daylight saving time applies locally during the appropriate part of the year.

In addition to the difference in timer granularity, the **timezone** structure distinguishes these subroutines from the POSIX **gettimer** and **settimer** subroutines, which deal strictly with Greenwich Mean Time.

The **ftime** subroutine fills in a structure pointed to by its argument, as defined by **<sys/timeb.h>**. The structure contains the time in seconds since 00:00:00 UTC (Coordinated Universal Time), January 1, 1970, up to 1000 milliseconds of more-precise interval, the local timezone (measured in minutes of time westward from UTC), and a flag that, if nonzero, indicates that Daylight Saving time is in effect, and the values stored in the timeb structure have been adjusted accordingly.

Parameters

Item	Description
Tp	Pointer to a **timeval** structure, defined in the **sys/time.h** file.
Tzp	Pointer to a **timezone** structure, defined in the **sys/time.h** file.

Return Values

If the subroutine succeeds, a value of 0 is returned. If an error occurs, a value of -1 is returned and **errno** is set to indicate the error.

Error Codes

If the **settimeofday** subroutine is unsuccessful, the **errno** value is set to **EPERM** to indicate that the process's effective user ID does not have root user authority.

No errors are defined for the **gettimeofday** or **ftime** subroutine.

gettimer, settimer, restimer, stime, or time Subroutine

Purpose

Gets or sets the current value for the specified systemwide timer.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/time.h>
#include <sys/types.h>
```

```
int gettimer( TimerType,  Value)
timer_t TimerType;
struct timestruc_t * Value;
```

```
#include <sys/timers.h>
#include <sys/types.h>
```

```
int gettimer( TimerType,  Value)
timer_t TimerType;
struct itimerspec * Value;
```

```
int settimer(TimerType,  TimePointer)
int TimerType;
const struct timestruc_t *TimePointer;
```

```
int restimer(TimerType,  Resolution,  MaximumValue)
int TimerType;
struct timestruc_t *Resolution, *MaximumValue;
```

```
int stime( Tp)
long *Tp;
```

```
#include <sys/types.h>
```

```
time_t time(Tp)
time_t *Tp;
```

Description

The **settimer** subroutine is used to set the current value of the *TimePointer* parameter for the systemwide timer, specified by the *TimerType* parameter.

When the **gettimer** subroutine is used with the function prototype in **sys/timers.h**, then except for the parameters, the **gettimer** subroutine is identical to the **getinterval** subroutine. Use of the **getinterval** subroutine is recommended, unless the **gettimer** subroutine is required for a standards-conformant application. The description and semantics of the **gettimer** subroutine are subject to change between releases, pending changes in the draft standard upon which the current **gettimer** subroutine description is based.

When the **gettimer** subroutine is used with the function prototype in **/sys/timers.h**, the **gettimer** subroutine returns an **itimerspec** structure to the pointer specified by the *Value* parameter. The **it_value** member of the **itimerspec** structure represents the amount of time in the current interval before the timer (specified by the *TimerType* parameter) expires, or a zero interval if the timer is disabled. The members of the pointer specified by the *Value* parameter are subject to the resolution of the timer.

When the **gettimer** subroutine is used with the function prototype in **sys/time.h**, the **gettimer** subroutine returns a **timestruc** structure to the pointer specified by the *Value* parameter. This structure holds the current value of the system wide timer specified by the *Value* parameter.

The resolution of any timer can be obtained by the **restimer** subroutine. The *Resolution* parameter represents the resolution of the specified timer. The *MaximumValue* parameter represents the maximum possible timer value. The value of these parameters are the resolution accepted by the **settimer** subroutine.

Note: If a nonprivileged user attempts to submit a fine granularity timer (that is, a timer request of less than 10 milliseconds), the timer request is raised to 10 milliseconds.

The **time** subroutine returns the time in seconds since the Epoch (that is, 00:00:00 GMT, January 1, 1970). The *Tp* parameter points to an area where the return value is also stored. If the *Tp* parameter is a null pointer, no value is stored.

The **stime** subroutine is implemented to provide compatibility with older AIX, AT&T System V, and BSD systems. It calls the **settimer** subroutine using the **TIMEOFDAY** timer.

Parameters

Item	Description
Value	Points to a structure of type **itimerspec**.
TimerType	Specifies the systemwide timer: **TIMEOFDAY** (POSIX system clock timer) This timer represents the time-of-day clock for the system. For this timer, the values returned by the **gettimer** subroutine and specified by the **settimer** subroutine represent the amount of time since 00:00:00 GMT, January 1, 1970.
TimePointer	Points to a structure of type **struct timestruc_t**.
Resolution	The resolution of a specified timer.
MaximumValue	The maximum possible timer value.
Tp	Points to a structure containing the time in seconds.

Return Values

The **gettimer**, **settimer**, **restimer**, and **stime** subroutines return a value of 0 (zero) if the call is successful. A return value of -1 indicates an error occurred, and **errno** is set.

The **time** subroutine returns the value of time in seconds since Epoch. Otherwise, a value of ((**time_t**) - 1) is returned and the **errno** global variable is set to indicate the error.

Error Codes

If an error occurs in the **gettimer**, **settimer**, **restimer**, or **stime** subroutine, a return value of - 1 is received and the **errno** global variable is set to one of the following error codes:

Item	Description
EINVAL	The *TimerType* parameter does not specify a known systemwide timer, or the *TimePointer* parameter of the **settimer** subroutine is outside the range for the specified systemwide timer.
EFAULT	A parameter address referenced memory that was not valid.
EIO	An error occurred while accessing the timer device.

Item	Description
EPERM	The requesting process does not have the appropriate privilege to set the specified timer.

If the **time** subroutine is unsuccessful, a return value of -1 is received and the **errno** global variable is set to the following:

Item	Description
EFAULT	A parameter address referenced memory that was not valid.

gettimerid Subroutine

Purpose

Allocates a per-process interval timer.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/time.h>
#include <sys/events.h>

timer_t gettimerid( timertype,  notifytype)
int timertype;
int notifytype;
```

Description

The **gettimerid** subroutine is used to allocate a per-process interval timer based on the timer with the given timer type. The unique ID is used to identify the interval timer in interval timer requests. (For more information, see **getinterval** subroutine). The particular timer type, the *timertype* parameter, is defined in the **sys/time.h** file and can identify either a system-wide timer or a per-process timer. The mechanism by which the process is to be notified of the expiration of the timer event is the *notifytype* parameter, which is defined in the **sys/events.h** file.

The *timertype* parameter represents one of the following timer types:

Item	Description
TIMEOFDAY	POSIX system clock timer. This timer represents the time-of-day clock for the system. For this timer, the values returned by the **gettimer** subroutine and specified by the **settimer** subroutine represent the amount of time since 00:00:00 GMT, January 1, 1970, in nanoseconds.
TIMERID_ALRM	Alarm timer. This timer schedules the delivery of a **SIGALRM** signal at a timer specified in the call to the **settimer** subroutine.
TIMERID_REAL	Real-time timer. The real-time timer decrements in real time. A **SIGALRM** signal is delivered when this timer expires.
TIMERID_REAL_TH	Real-time, per-thread timer. Decrements in real time and delivers a **SIGTALRM** signal when it expires. The **SIGTALRM** is sent to the thread that sets the timer. Each thread has its own timer and can manipulate its own timer. This timer is only supported with the 1:1 thread model. If the timer is used in M:N thread model, undefined results might occur.

Item	Description
TIMERID_VIRTUAL	Virtual timer. The virtual timer decrements in process virtual time. it runs only when the process is executing in user mode. A **SIGVTALRM** signal is delivered when it expires.
TIMERID_PROF	Profiling timer. The profiling timer decrements both when running in user mode and when the system is running for the process. It is designed to be used by processes to profile their execution statistically. A **SIGPROF** signal is delivered when the profiling timer expires.

Interval timers with a notification value of **DELIVERY_SIGNAL** are inherited across an **exec** subroutine.

Parameters

Item	Description
notifytype	Notifies the process of the expiration of the timer event.
timertype	Identifies either a system-wide timer or a per-process timer.

Return Values

If the **gettimerid** subroutine succeeds, it returns a **timer_t** structure that can be passed to the per-process interval timer subroutines, such as the **getinterval** subroutine. If an error occurs, the value -1 is returned and **errno** is set.

Error Codes

If the **gettimerid** subroutine fails, the value -1 is returned and **errno** is set to one of the following error codes:

Item	Description
EAGAIN	The calling process has already allocated all of the interval timers associated with the specified timer type for this implementation.
EINVAL	The specified timer type is not defined.

getttyent, getttynam, setttyent, or endttyent Subroutine

Purpose

Gets a tty description file entry.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <ttyent.h>

struct ttyent *getttyent()
struct ttyent *getttynam( Name)
char *Name;
void setttyent()
void endttyent()
```

Description

Attention: Do not use the **getttyent**, **getttynam**, **setttyent**, or **endttyent** subroutine in a multithreaded environment.

The **getttyent** and **getttynam** subroutines each return a pointer to an object with the **ttyent** structure. This structure contains the broken-out fields of a line from the tty description file. The **ttyent** structure is in the **/usr/include/sys/ttyent.h** file and contains the following fields:

Item	Description
`tty_name`	The name of the character special file in the **/dev** directory. The character special file must reside in the **/dev** directory.
`ty_getty`	The command that is called by the **init** process to initialize tty line characteristics. This is usually the **getty** command, but any arbitrary command can be used. A typical use is to initiate a terminal emulator in a window system.
`ty_type`	The name of the default terminal type connected to this tty line. This is typically a name from the **termcap** database. The **TERM** environment variable is initialized with this name by the **getty** or **login** command.
`ty_status`	A mask of bit fields that indicate various actions to be allowed on this tty line. The following is a description of each flag: **TTY_ON** Enables logins (that is, the **init** process starts the specified **getty** command on this entry). **TTY_SECURE** Allows a user with root user authority to log in to this terminal. The **TTY_ON** flag must be included.
`ty_window`	The command to execute for a window system associated with the line. The window system is started before the command specified in the `ty_getty` field is executed. If none is specified, this is null.
`ty_comment`	The trailing comment field. A leading delimiter and white space is removed.

The **getttyent** subroutine reads the next line from the tty file, opening the file if necessary. The **setttyent** subroutine rewinds the file. The **endttyent** subroutine closes it.

The **getttynam** subroutine searches from the beginning of the file until a matching name (specified by the *Name* parameter) is found (or until the EOF is encountered).

Parameters

Item	Description
Name	Specifies the name of a tty description file.

Return Values

These subroutines return a null pointer when they encounter an EOF (end-of-file) character or an error.

Files

Item	Description
/usr/lib/libodm.a	Specifies the ODM (Object Data Manager) library.
/usr/lib/libcfg.a	Archives device configuration subroutines.
/etc/termcap	Defines terminal capabilities.

getuid, geteuid, or getuidx Subroutine

Purpose

Gets the real or effective user ID of the current process.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/types.h>
#include <unistd.h>
```

```
uid_t getuid(void)
```

```
uid_t geteuid(void)
```

```
#include <id.h>
```

```
uid_t getuidx (int type);
```

Description

The **getuid** subroutine returns the real user ID of the current process. The **geteuid** subroutine returns the effective user ID of the current process.

The **getuidx** subroutine returns the user ID indicated by the *type* parameter of the calling process.

These subroutines are part of Base Operating System (BOS) Runtime.

Return Values

The **getuid**, **geteuid** and **getuidx** subroutines return the corresponding user ID. The **getuid** and **geteuid** subroutines always succeed.

The **getuidx** subroutine will return -1 and set the global **errno** variable to EINVAL if the *type* parameter is not one of ID_REAL, ID_EFFECTIVE, ID_SAVED or ID_LOGIN.

Parameters

Item	Description
type	Specifies the user ID to get. Must be one of ID_REAL (real user ID), ID_EFFECTIVE (effective user ID), ID_SAVED (saved set-user ID) or ID_LOGIN (login user ID).

Error Codes

If the **getuidx** subroutine fails the following is returned:

Item	Description
EINVAL	Indicates the value of the type parameter is invalid.

getuinfo Subroutine

Purpose

Finds a value associated with a user.

Library

Standard C Library (**libc.a**)

Syntax

```
char *getuinfo ( Name)
char *Name;
```

Description

The **getuinfo** subroutine finds a value associated with a user. This subroutine searches a user information buffer for a string of the form *Name*=*Value* and returns a pointer to the *Value* substring if the *Name* value is found. A null value is returned if the *Name* value is not found.

The **INuibp** global variable points to the user information buffer:

```
extern char *INuibp;
```

This variable is initialized to a null value.

If the **INuibp** global variable is null when the **getuinfo** subroutine is called, the **usrinfo** subroutine is called to read user information from the kernel into a local buffer. The **INUuibp** is set to the address of the local buffer. If the **INuibp** external variable is not set, the **usrinfo** subroutine is automatically called the first time the **getuinfo** subroutine is called.

Parameter

Item	Description
Name	Specifies a user name.

getuinfox Subroutine

Purpose

Finds a value associated with a user.

Library

Standard C Library (**libc.a**)

Syntax

```
char *getuinfox ( Name)
char *Name;
```

Description

The **getuinfox** subroutine finds a value associated with a user. This subroutine searches a privileged kernel buffer for a string of the form *Name*=*Value* and returns a pointer to the *Value* substring if the *Name*

value is found. A Null value is returned if the *Name* value is not found. The caller is responsible for freeing the memory returned by the **getuinfox** subroutine.

Parameters

Item	Description
Name	Specifies a name.

Return Values

Upon success, the **getuinfox** subroutine returns a pointer to the *Value* substring.

Error Codes

A Null value is returned if the *Name* value is not found.

getuserattr, IDtouser, nextuser, or putuserattr Subroutine

Purpose

Accesses the user information in the user database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>

int getuserattr (User, Attribute, Value, Type)
char * User;
char * Attribute;
void * Value;
int  Type;

char *IDtouser( UID)
uid_t UID;

char *nextuser ( Mode,  Argument)
int Mode, Argument;

int putuserattr (User, Attribute, Value, Type)
char *User;
char *Attribute;
void *Value;
int Type;
```

Description

Attention: These subroutines and the **setpwent** and **setgrent** subroutines should not be used simultaneously. The results can be unpredictable.

These subroutines access user information. Because of their greater granularity and extensibility, you should use them instead of the **getpwent** routines.

The **getuserattr** subroutine reads a specified attribute from the user database. If the database is not already open, this subroutine does an implicit open for reading. A call to the **getuserattr** subroutine for every new user verifies that the user exists.

Similarly, the **putuserattr** subroutine writes a specified attribute into the user database. If the database is not already open, this subroutine does an implicit open for reading and writing. Data changed by the **putuserattr** subroutine must be explicitly committed by calling the **putuserattr** subroutine with a *Type* parameter specifying **SEC_COMMIT**. Until all the data is committed, only these subroutines within the process return written data.

New entries in the user and group databases must first be created by invoking **putuserattr** with the **SEC_NEW** type.

The **IDtouser** subroutine translates a user ID into a user name.

The **nextuser** subroutine returns the next user in a linear search of the user database. The consistency of consecutive searches depends upon the underlying storage-access mechanism and is not guaranteed by this subroutine.

The **setuserdb** and **enduserdb** subroutines should be used to open and close the user database.

The **enduserdb** subroutine frees all memory allocated by the **getuserattr** subroutine.

Parameters

Argument
Presently unused and must be specified as null.

Attribute
Specifies which attribute is read. The following possible attributes are defined in the **usersec.h** file:

S_CORECOMP
Core compression status. The attribute type is **SEC_CHAR**.

S_COREPATH
Core path specification status. The attribute type is **SEC_CHAR**.

S_COREPNAME
Core path specification location. The attribute type is **SEC_CHAR**.

S_CORENAMING
Core naming status. The attribute type is **SEC_CHAR**.

S_ID
User ID. The attribute type is **SEC_INT**.

S_PGID
Principle group ID.

If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file, the Lightweight Directory Access Protocol (LDAP) group ID can be assigned to LOCAL user as primary group ID and vice versa.

The attribute type is **SEC_INT**.

S_PGRP
Principle group name.

If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file, the LDAP group can be assigned to LOCAL user as primary group and vice versa.

The attribute type is **SEC_CHAR**.

S_GROUPS
Groups to which the user belongs.

If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file, the LDAP group can be assigned to LOCAL user and vice versa.

The attribute type is **SEC_LIST**.

S_ADMGROUPS
Groups for which the user is an administrator.

If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file, the LDAP group can be assigned to LOCAL user and vice versa.

The attribute type is **SEC_LIST**.

S_ADMIN
Administrative status of a user. The attribute type is **SEC_BOOL**.

S_AUDITCLASSES
Audit classes to which the user belongs. The attribute type is **SEC_LIST**.

S_AUTHSYSTEM
Defines the user's authentication method. The attribute type is **SEC_CHAR.**

S_HOME
Home directory. The attribute type is **SEC_CHAR**.

S_SHELL
Initial program run by a user. The attribute type is **SEC_CHAR**.

S_GECOS
Personal information for a user. The attribute type is **SEC_CHAR**.

S_USRENV
User-state environment variables. The attribute type is **SEC_LIST**.

S_SYSENV
Protected-state environment variables. The attribute type is **SEC_LIST**.

S_LOGINCHK
Specifies whether the user account can be used for local logins. The attribute type is **SEC_BOOL**.

S_HISTEXPIRE
Defines the period of time (in weeks) that a user cannot reuse a password. The attribute type is **SEC_INT**.

S_HISTSIZE
Specifies the number of previous passwords that the user cannot reuse. The attribute type is **SEC_INT**.

S_MAXREPEAT
Defines the maximum number of times a user can repeat a character in a new password. The attribute type is **SEC_INT**.

S_MINAGE
Defines the minimum age in weeks that the user's password must exist before the user can change it. The attribute type is **SEC_INT**.

S_PWDCHECKS
Defines the password restriction methods for this account. The attribute type is **SEC_LIST**.

S_MINALPHA
Defines the minimum number of alphabetic characters required in a new user's password. The attribute type is **SEC_INT**.

S_MINDIFF
Defines the minimum number of characters required in a new password that were not in the old password. The attribute type is **SEC_INT**.

S_MINLEN
Defines the minimum length of a user's password. The attribute type is **SEC_INT**.

S_MINOTHER
Defines the minimum number of non-alphabetic characters required in a new user's password. The attribute type is **SEC_INT**.

S_DICTION
Defines the password dictionaries for this account. The attribute type is **SEC_LIST**.

S_SUCHK
Specifies whether the user account can be accessed with the **su** command. Type **SEC_BOOL**.

S_REGISTRY
Defines the user's authentication registry. The attribute type is **SEC_CHAR**.

S_RLOGINCHK
Specifies whether the user account can be used for remote logins using the **telnet** or **rlogin** commands. The attribute type is **SEC_BOOL**.

S_DAEMONCHK
Specifies whether the user account can be used for daemon execution of programs and subsystems using the **cron** daemon or **src**. The attribute type is **SEC_BOOL**.

S_TPATH
Defines how the account may be used on the trusted path. The attribute type is **SEC_CHAR**. This attribute must be one of the following values:

nosak
The secure attention key is not enabled for this account.

notsh
The trusted shell cannot be accessed from this account.

always
This account may only run trusted programs.

on
Normal trusted-path processing applies.

S_TTYS
List of ttys that can or cannot be used to access this account. The attribute type is **SEC_LIST**.

S_SUGROUPS
Groups that can or cannot access this account.

If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file, the LDAP group can be assigned to LOCAL user and vice versa.

The attribute type is **SEC_LIST**.

S_EXPIRATION
Expiration date for this account is a string in the form MMDDhhmmyy, where MM is the month, DD is the day, hh is the hour in 0 to 24 hour notation, mm is the minutes past the hour, and yy is the last two digits of the year. The attribute type is **SEC_CHAR**. For more information about the password expiration, see the **/etc/security/user** file.

S_AUTH1
Primary authentication methods for this account. The attribute type is **SEC_LIST**.

S_AUTH2
Secondary authentication methods for this account. The attribute type is **SEC_LIST**.

S_UFSIZE
Process file size soft limit. The attribute type is **SEC_INT**.

S_UCPU
Process CPU time soft limit. The attribute type is **SEC_INT**.

S_UDATA
Process data segment size soft limit. The attribute type is **SEC_INT**.

S_USTACK
Process stack segment size soft limit. Type: **SEC_INT**.

S_URSS
Process real memory size soft limit. Type: **SEC_INT**.

S_UCORE
Process core file size soft limit. The attribute type is **SEC_INT**.

S_UNOFILE
Process file descriptor table size soft limit. The attribute type is **SEC_INT**.

S_PWD
Specifies the value of the passwd field in the **/etc/passwd** file. The attribute type is **SEC_CHAR**.

S_UMASK
File creation mask for a user. The attribute type is **SEC_INT**.

S_LOCKED
Specifies whether the user's account can be logged into. The attribute type is **SEC_BOOL**.

S_ROLES
Defines the administrative roles for this account. The attribute type is **SEC_LIST**.

S_UFSIZE_HARD
Process file size hard limit. The attribute type is **SEC_INT**.

S_UCPU_HARD
Process CPU time hard limit. The attribute type is **SEC_INT**.

S_UDATA_HARD
Process data segment size hard limit. The attribute type is **SEC_INT**.

S_USREXPORT
Specifies if the DCE registry can overwrite the local user information with the DCE user information during a DCE export operation. The attribute type is **SEC_BOOL**.

S_USTACK_HARD
Process stack segment size hard limit. Type: **SEC_INT**.

S_URSS_HARD
Process real memory size hard limit. Type: **SEC_INT**.

S_UCORE_HARD
Process core file size hard limit. The attribute type is **SEC_INT**.

S_UNOFILE_HARD
Process file descriptor table size hard limit. The attribute type is **SEC_INT**.

S_DOMAINS
The domains for the user. It can be one or more. The attribute type is **SEC_LIST**.

S_DFLT_ROLES
The default roles for the user. It can be one or more roles. The attribute type is **SEC_LIST**.

S_MINLOWERALPHA
Defines the minimum number of lowercase alphabetic characters required in a new user password. The attribute type is **SEC_INT**.

S_MINUPPERALPHA
Defines the minimum number of uppercase alphabetic characters required in a new user password. The attribute type is **SEC_INT**.

S_MINDIGIT
Defines the minimum number of digits required in a new user password. The attribute type is **SEC_INT**.

S_MINSPECIALCHAR
Defines the minimum number of special characters required in a new user's password. The attribute type is **SEC_INT**.

Note: These values are string constants that should be used by applications both for convenience and to permit optimization in latter implementations. Additional user-defined attributes may be used and will be stored in the format specified by the *Type* parameter.

Mode
Specifies the search mode. This parameter can be used to delimit the search to one or more user credentials databases. Specifying a non-null *Mode* value also implicitly rewinds the search. A null *Mode* value continues the search sequentially through the database. This parameter must include one of the following values specified as a bit mask; these are defined in the **usersec.h** file:

S_LOCAL
Locally defined users are included in the search.

S_SYSTEM
All credentials servers for the system are searched.

Type
Specifies the type of attribute expected. Valid types are defined in the **usersec.h** file and include:

SEC_INT
The format of the attribute is an integer.

For the **getuserattr** subroutine, the user should supply a pointer to a defined integer variable. For the **putuserattr** subroutine, the user should supply an integer.

SEC_CHAR
The format of the attribute is a null-terminated character string.

For the **getuserattr** subroutine, the user should supply a pointer to a defined character pointer variable. For the **putuserattr** subroutine, the user should supply a character pointer.

SEC_LIST
The format of the attribute is a series of concatenated strings, each null-terminated. The last string in the series is terminated by two successive null characters.

For the **getuserattr** subroutine, the user should supply a pointer to a defined character pointer variable. For the **putuserattr** subroutine, the user should supply a character pointer.

SEC_BOOL
The format of the attribute from **getuserattr** is an integer with the value of either 0 (false) or 1 (true). The format of the attribute for **putuserattr** is a null-terminated string containing one of the following strings: true, false, yes, no, always, or never.

For the **getuserattr** subroutine, the user should supply a pointer to a defined integer variable. For the **putuserattr** subroutine, the user should supply a character pointer.

SEC_COMMIT
For the **putuserattr** subroutine, this value specified by itself indicates that changes to the named user are to be committed to permanent storage. The *Attribute* and *Value* parameters are ignored. If no user is specified, the changes to all modified users are committed to permanent storage.

SEC_DELETE
The corresponding attribute is deleted from the database.

SEC_NEW
Updates all the user database files with the new user name when using the **putuserattr** subroutine.

UID
Specifies the user ID to be translated into a user name.

User
Specifies the name of the user for which an attribute is to be read.

Value
Specifies a buffer, a pointer to a buffer, or a pointer to a pointer depending on the *Attribute* and *Type* parameters. See the *Type* parameter for more details.

Security

Item	Description
Files Accessed:	

Mode	File
rw	**/etc/passwd**
rw	**/etc/group**
rw	**/etc/security/user**
rw	**/etc/security/limits**
rw	**/etc/security/group**
rw	**/etc/security/environ**

Return Values

If successful, the **getuserattr** subroutine and the **putuserattr** subroutine return 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

If successful, the **IDtouser** and the **nextuser** subroutines return a character pointer to a buffer containing the requested user name. Otherwise, a null pointer is returned and the **errno** global variable is set to indicate the error.

Error Codes

If any of these subroutines fail, the following is returned:

Item	Description
EACCES	Access permission is denied for the data request.

If the **getuserattr** subroutine or the **getuserattrs** subroutine fail, the following is returned:

Item	Description
EIO	Failed to access remote user database.

If the **getuserattr** and **putuserattr** subroutines fail, one or more of the following is returned:

Item	Description
ENOENT	The specified *User* parameter does not exist.
EINVAL	The *Attribute* parameter does not contain one of the defined attributes or null.
EINVAL	The *Value* parameter does not point to a valid buffer or to valid data for this type of attribute. Limited testing is possible and all errors may not be detected.
EPERM	Operation is not permitted.
ENOATTR	The specified attribute is not defined for this user.

If the **IDtouser** subroutine fails, one or more of the following is returned:

Item	Description
ENOENT	The specified *User* parameter does not exist

If the **nextuser** subroutine fails, one or more of the following is returned:

Item	Description
EINVAL	The *Mode* parameter is not one of null, **S_LOCAL**, or **S_SYSTEM**.
EINVAL	The *Argument* parameter is not null.
ENOENT	The end of the search was reached.

Files

Item	Description
/etc/passwd	Contains user IDs.

getuserattrs Subroutine

Purpose

Retrieves multiple user attributes in the user database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>

int getuserattrs (User, Attributes, Count)
char * User;
dbattr_t * Attributes;
int Count
```

Description

Attention: Do not use this subroutine and the **setpwent** and **setgrent** subroutines simultaneously. The results can be unpredictable.

The **getuserattrs** subroutine accesses user information. Because of its greater granularity and extensibility, use it instead of the **getpwent** routines.

The **getuserattrs** subroutine reads one or more attributes from the user database. If the database is not already open, this subroutine does an implicit open for reading. A call to the **getuserattrs** subroutine with an *Attributes* parameter of null and the *Count* parameter of zero for every new user verifies that the user exists.

The *Attributes* array contains information about each attribute that is to be read. The **dbattr_t** data structure contains the following fields:

attr_name
The name of the desired attribute.

attr_idx
Used internally by the **getuserattrs** subroutine.

attr_type
The type of the desired attribute. The following possible attributes are defined in the **usersec.h** file:

S_CORECOMP
Core compression status. The attribute type is **SEC_CHAR**.

S_COREPATH
Core path specification status. The attribute type is **SEC_CHAR**.

S_COREPNAME
Core path specification location. The attribute type is **SEC_CHAR**.

S_CORENAMING
Core naming status. The attribute type is **SEC_CHAR**.

S_ID
User ID. The attribute type is **SEC_INT**.

S_PGID
Principle group ID.

If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file, the Lightweight Directory Access Protocol (LDAP) group ID can be assigned to LOCAL user as primary group ID and vice versa.

The attribute type is **SEC_INT**.

S_PGRP
Principle group name.

If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file, the LDAP group can be assigned to LOCAL user as primary group and vice versa.

The attribute type is **SEC_CHAR**.

S_GROUPS
Groups to which the user belongs.

If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file, the LDAP group can be assigned to LOCAL user and vice versa.

The attribute type is **SEC_LIST**.

S_ADMGROUPS
Groups for which the user is an administrator.

If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file, the LDAP group can be assigned to LOCAL user and vice versa.

The attribute type is **SEC_LIST**.

S_ADMIN
Administrative status of a user. The attribute type is **SEC_BOOL**.

S_AUDITCLASSES
Audit classes to which the user belongs. The attribute type is **SEC_LIST**.

S_AUTHSYSTEM
Defines the user's authentication method. The attribute type is **SEC_CHAR.**

S_HOME
Home directory. The attribute type is **SEC_CHAR**.

S_SHELL
Initial program run by a user. The attribute type is **SEC_CHAR**.

S_GECOS
Personal information for a user. The attribute type is **SEC_CHAR**.

S_USRENV
User-state environment variables. The attribute type is **SEC_LIST**.

S_SYSENV
Protected-state environment variables. The attribute type is **SEC_LIST**.

S_LOGINCHK
Specifies whether the user account can be used for local logins. The attribute type is **SEC_BOOL**.

S_HISTEXPIRE
Defines the period of time (in weeks) that a user cannot reuse a password. The attribute type is **SEC_INT**.

S_HISTSIZE
Specifies the number of previous passwords that the user cannot reuse. The attribute type is **SEC_INT**.

S_MAXREPEAT
Defines the maximum number of times a user can repeat a character in a new password. The attribute type is **SEC_INT**.

S_MINAGE
Defines the minimum age in weeks that the user's password must exist before the user can change it. The attribute type is **SEC_INT**.

S_PWDCHECKS
Defines the password restriction methods for this account. The attribute type is **SEC_LIST**.

S_MINALPHA
Defines the minimum number of alphabetic characters required in a new user's password. The attribute type is **SEC_INT**.

S_MINDIFF
Defines the minimum number of characters required in a new password that were not in the old password. The attribute type is **SEC_INT**.

S_MINLEN
Defines the minimum length of a user's password. The attribute type is **SEC_INT**.

S_MINOTHER
Defines the minimum number of non-alphabetic characters required in a new user's password. The attribute type is **SEC_INT**.

S_DICTIONLIST
Defines the password dictionaries for this account. The attribute type is **SEC_LIST**.

S_SUCHK
Specifies whether the user account can be accessed with the **su** command. Type **SEC_BOOL**.

S_REGISTRY
Defines the user's authentication registry. The attribute type is **SEC_CHAR**.

S_RLOGINCHK
Specifies whether the user account can be used for remote logins using the **telnet** or **rlogin** commands. The attribute type is **SEC_BOOL**.

S_DAEMONCHK
Specifies whether the user account can be used for daemon execution of programs and subsystems using the **cron** daemon or **src**. The attribute type is **SEC_BOOL**.

S_TPATH
Defines how the account might be used on the trusted path. The attribute type is **SEC_CHAR**. This attribute must be one of the following values:

nosak
The secure attention key is not enabled for this account.

notsh
The trusted shell cannot be accessed from this account.

always
This account may only run trusted programs.

on
Normal trusted-path processing applies.

S_TTYS
List of ttys that can or cannot be used to access this account. The attribute type is **SEC_LIST**.

S_SUGROUPS
Groups that can or cannot access this account.

If the *domainlessgroups* attribute is set in the **/etc/secvars.cfg** file, the LDAP group can be assigned to LOCAL user and vice versa.

The attribute type is **SEC_LIST**.

S_EXPIRATION
Expiration date for this account is a string in the form MMDDhhmmyy, where MM is the month, DD is the day, hh is the hour in 0 to 24 hour notation, mm is the minutes past the hour, and yy is the last two digits of the year. The attribute type is **SEC_CHAR**.

S_AUTH1
Primary authentication methods for this account. The attribute type is **SEC_LIST**.

S_AUTH2
Secondary authentication methods for this account. The attribute type is **SEC_LIST**.

S_UFSIZE
Process file size soft limit. The attribute type is **SEC_INT**.

S_UCPU
Process processor time soft limit. The attribute type is **SEC_INT**.

S_UDATA
Process data segment size soft limit. The attribute type is **SEC_INT**.

S_USTACK
Process stack segment size soft limit. Type: **SEC_INT**.

S_URSS
Process real memory size soft limit. Type: **SEC_INT**.

S_UCORE
Process core file size soft limit. The attribute type is **SEC_INT**.

S_UNOFILE
Process file descriptor table size soft limit. The attribute type is **SEC_INT**.

S_PWD
Specifies the value of the passwd field in the **/etc/passwd** file. The attribute type is **SEC_CHAR**.

S_UMASK
File creation mask for a user. The attribute type is **SEC_INT**.

S_LOCKED
Specifies whether the user's account can be logged into. The attribute type is **SEC_BOOL**.

S_ROLES
Defines the administrative roles for this account. The attribute type is **SEC_LIST**.

S_UFSIZE_HARD
Process file size hard limit. The attribute type is **SEC_INT**.

S_UCPU_HARD
Process processor time hard limit. The attribute type is **SEC_INT**.

S_UDATA_HARD
Process data segment size hard limit. The attribute type is **SEC_INT**.

S_USREXPORT
Specifies if the DCE registry can overwrite the local user information with the DCE user information during a DCE export operation. The attribute type is **SEC_BOOL**.

S_USTACK_HARD
Process stack segment size hard limit. Type: **SEC_INT**.

S_URSS_HARD
Process real memory size hard limit. Type: **SEC_INT**.

S_UCORE_HARD
Process core file size hard limit. The attribute type is **SEC_INT**.

S_UNOFILE_HARD
Process file descriptor table size hard limit. The attribute type is **SEC_INT**.

S_DFLT_ROLES
The default roles for the user. It can be one or more. The attribute type is **SEC_LIST**.

S_DOMAINS
The domains for the user. It can be one or more. The attribute type is **SEC_LIST**.

S_MINLOWERALPHA
Defines the minimum number of lowercase alphabetic characters required in a new user password. The attribute type is **SEC_INT**.

S_MINUPPERALPHA
Defines the minimum number of uppercase alphabetic characters required in a new user password. The attribute type is **SEC_INT**.

S_MINDIGIT
Defines the minimum number of digits required in a new user password. The attribute type is **SEC_INT**.

S_MINSPECIALCHAR
Defines the minimum number of special characters required in a new user password. The attribute type is **SEC_INT**.

attr_flag
The results of the request to read the desired attribute.

attr_un
A union containing the returned values. Its union members, which follows, correspond to the definitions of the **attr_char**, **attr_int**, **attr_long**, and **attr_llong** macros, respectively:

au_char
Attributes of type **SEC_CHAR** and **SEC_LIST** store a pointer to the returned attribute in this member when the requested attribute is successfully read. The caller is responsible for freeing this memory.

au_int
Attributes of type **SEC_INT** and **SEC_BOOL** store the value of the attribute in this member when the requested attribute is successfully read.

au_long
Attributes of type **SEC_LONG** store the value of the attribute in this member when the requested attribute is successfully read.

au_llong
Attributes of type **SEC_LLONG** store the value of the attribute in this member when the requested attribute is successfully read.

attr_domain
The authentication domain containing the attribute. The **getuserattrs** subroutine is responsible for managing the memory referenced by this pointer. If **attr_domain** is specified for an attribute, the get request is sent only to that domain. If **attr_domain** is not specified (that is, set to NULL), **getuserattrs** searches the domains known to the system and sets this field to the name of the domain from which the value is retrieved. This search space can be restricted with the **setauthdb** subroutine so that only the domain specified in the **setauthdb** call is searched. If the request for a NULL domain was not satisfied, the request is tried from the local files using the default stanza.

Use the **setuserdb** and **enduserdb** subroutines to open and close the user database. Failure to explicitly open and close the user database can result in loss of memory and performance.

Parameters

Item	Description
User	Specifies the name of the user for which the attributes are to be read.
Attributes	A pointer to an array of zero or more elements of type **dbattr_t**. The list of user attributes is defined in the **usersec.h** header file.
Count	The number of array elements in *Attributes*.

Security

Files accessed:

Item	Description
Mode	**File**
rw	**/etc/passwd**
rw	**/etc/group**
rw	**/etc/security/user**
rw	**/etc/security/limits**
rw	**/etc/security/group**
rw	**/etc/security/environ**

Return Values

If *User* exists, the **getuserattrs** subroutine returns zero. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error. Each element in the *Attributes* array must be examined on a successful call to **getuserattrs** to determine if the *Attributes* array entry was successfully retrieved.

Error Codes

The **getuserattrs** subroutine returns an error that indicates that the user does or does not exist. Additional errors can indicate an error querying the information databases for the requested attributes.

Item	Description
EINVAL	The *Count* parameter is less than zero.
EINVAL	The *Attributes* parameter is null and the *Count* parameter is greater than zero.
ENOENT	The specified *User* parameter does not exist.
EIO	Failed to access remote user database.

If the **getuserattrs** subroutine fails to query an attribute, one or more of the following errors is returned in the **attr_flag** field of the corresponding *Attributes* element:

Item	Description
EACCES	The user does not have access to the attribute specified in the *attr_name* field.
EINVAL	The **attr_type** field in the *Attributes* entry contains a type that is not valid.
EINVAL	The **attr_un** field in the *Attributes* entry does not point to a valid buffer or to valid data for this type of attribute. Limited testing is possible and all errors might not be detected.
ENOATTR	The **attr_name** field in the *Attributes* entry specifies an attribute that is not defined for this user or group.

Examples

The following sample test program displays the output to a call to **getuserattrs**. In this example, the system has a user named `foo`.

```
#include <stdio.h>
#include <usersec.h>

#define NATTR 3
#define USERNAME "foo"

main() {

    dbattr_t attributes[NATTR];
```

```
    int     i;
    int     rc;

    memset (&attributes, 0, sizeof(attributes));

    /*
     * Fill in the attributes array with "id", "expires" and
     * "SYSTEM" attributes.
     */

    attributes[0].attr_name = S_ID;
    attributes[0].attr_type = SEC_INT;;

    attributes[1].attr_name = S_ADMIN;
    attributes[1].attr_type = SEC_BOOL;

    attributes[2].attr_name = S_AUTHSYSTEM;
    attributes[2].attr_type = SEC_CHAR;

    /*
     * Make a call to getuserattrs.
     */

        setuserdb(S_READ);

    rc = getuserattrs(USERNAME, attributes, NATTR);

        enduserdb();

    if (rc) {
        printf("getuserattrs failed ....\n");
        exit(-1);
    }

    for (i = 0; i < NATTR; i++) {
        printf("attribute name   : %s \n", attributes[i].attr_name);
        printf("attribute flag   : %d \n", attributes[i].attr_flag);

        if (attributes[i].attr_flag) {

            /*
             * No attribute value. Continue.
             */
            printf("\n");
            continue;
        }
        /*
         * We have a value.
         */
        printf("attribute domain : %s \n", attributes[i].attr_domain);
        printf("attribute value  : ");

        switch (attributes[i].attr_type)
        {
            case SEC_CHAR:
                if (attributes[i].attr_char) {
                                    printf("%s\n", attributes[i].attr_char);
                    free(attributes[i].attr_char);
                }
                                break;
            case SEC_INT:
            case SEC_BOOL:
                                printf("%d\n", attributes[i].attr_int);
                                break;
            default:
                break;
                }
        printf("\n");
    }
    exit(0);
}
```

The following output for the call is expected:

```
    attribute name   : id
    attribute flag   : 0
    attribute domain : files
    attribute value  : 206
```

```
    attribute name   : admin
    attribute flag   : 0
    attribute domain : files
    attribute value  : 0

    attribute name   : SYSTEM
    attribute flag   : 0
    attribute domain : files
    attribute value  : compat
```

Files

Item	Description
/etc/passwd	Contains user IDs.

GetUserAuths Subroutine

Purpose

Accesses the set of authorizations of a user.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
```

```
char *GetUserAuths(void);
```

Description

The **GetUserAuths** subroutine returns the list of authorizations associated with the real user ID and group set of the process. By default, the ALL authorization is returned for the root user.

Return Values

If successful, the **GetUserAuths** subroutine returns a list of authorizations associated with the user. The format of the list is a series of concatenated strings, each null-terminated. A null string terminates the list. Otherwise, a null pointer is returned and the **errno** global variable is set to indicate the error.

getuserpw, putuserpw, or putuserpwhist Subroutine

Purpose

Accesses the user authentication data.

Library

Security Library (**libc.a**)

Syntax

```
#include <userpw.h>
```

```
struct userpw *getuserpw ( User)
char *User;

int putuserpw ( Password)
struct userpw *Password;

int putuserpwhist ( Password,  Message)
struct userpw *Password;
char **Message;
```

Description

These subroutines may be used to access user authentication information. Because of their greater granularity and extensibility, you should use them instead of the **getpwent** routines.

The **getuserpw** subroutine reads the user's locally defined password information. If the **setpwdb** subroutine has not been called, the **getuserpw** subroutine will call it as `setpwdb (S_READ)`. This can cause problems if the **putuserpw** subroutine is called later in the program.

The **putuserpw** subroutine updates or creates a locally defined password information stanza in the **/etc/security/passwd** file. The password entry created by the **putuserpw** subroutine is used only if there is an `!` (exclamation point) in the **/etc/passwd** file's `password` field. The user application can use the **putuserattr** subroutine to add an ! to this field.

The **putuserpw** subroutine will open the authentication database read/write if no other access has taken place, but the program should call `setpwdb (S_READ | S_WRITE)` before calling the **putuserpw** subroutine.

The **putuserpwhist** subroutine updates or creates a locally defined password information stanza in the **etc/security/passwd** file. The subroutine also manages a database of previous passwords used for password reuse restriction checking. It is recommended to use the **putuserpwhist** subroutine, rather than the **putuserpw** subroutine, to ensure the password is added to the password history database.

Parameters

Item	Description
Password	Specifies the password structure used to update the password information for this user. This structure is defined in the **userpw.h** file and contains the following members: **upw_name** Specifies the user's name. (The first eight characters must be unique, since longer names are truncated.) **upw_passwd** Specifies the user's password. **upw_lastupdate** Specifies the time, in seconds, since the epoch (that is, 00:00:00 GMT, January 1, 1970), when the password was last updated. **upw_flags** Specifies attributes of the password. This member is a bit mask of one or more of the following values, defined in the **userpw.h** file. **PW_NOCHECK** Specifies that new passwords need not meet password restrictions in effect for the system. **PW_ADMCHG** Specifies that the password was last set by an administrator and must be changed at the next successful use of the **login** or **su** command**.** **PW_ADMIN** Specifies that password information for this user may only be changed by the root user.
Message	Indicates a message that specifies an error occurred while updating the password history database. Upon return, the value is either a pointer to a valid string within the memory allocated storage or a null pointer.
User	Specifies the name of the user for which password information is read. (The first eight characters must be unique, since longer names are truncated.)

Security

Files Accessed:

Mode	File
rw	**/etc/security/passwd**

Return Values

If successful, the **getuserpw** subroutine returns a valid pointer to a **userpw** structure. Otherwise, a null pointer is returned and the **errno** global variable is set to indicate the error. If the user exists but there is no user entry in the **/etc/security/passwd** file, the **getuserpw** subroutine returns success with the name field set to user name, the password field set to NULL, the lastupdate field set to 0 and the flags field set to 0. If the user exists and there is an entry in the **/etc/security/passwd** file but one or more fields are missing, the **getuserpw** subroutine returns the fields that exist.

If the user exists but there is no user entry in the **/etc/security/passwd** file, the **putuserpw** subroutine creates a user stanza in the **/etc/security/passwd** file. If the user exists and there is an entry in the **/etc/security/passwd** file but one or more fields are missing, the **putuserpw** subroutine updates the fields that exist and creates the fields that are missing.

If successful, the **putuserpwhist** subroutine returns a value of 0. If the subroutine failed to update or create a locally defined password information stanza in the **/etc/security/passwd** file, the

putuserpwhist subroutine returns a nonzero value. If the subroutine was unable to update the password history database, a message is returned in the *Message* parameter and a return code of 0 is returned. If the user exists but there is no user entry in the **/etc/security/passwd** file, the **putuserpwhist** subroutine creates a user stanza in the **/etc/security/passwd** file and updates the password history. If the user exists and there is an entry in the **/etc/security/passwd** file but one or more fields are missing, the **putuserpwhist** subroutine updates the fields that exist, creates the fields that are missing and modifies the password history.

Error Codes

The **getuserpw, putuserpw,** and **putuserpwhist** subroutines fail if the following values are true:

Item	Description
EACCES	The user is not able to open the files that contain the password attributes.
ENOENT	The user does not exist in the **/etc/passwd** file.

Subroutines invoked by the **getuserpw, putuserpw,** or **putuserpwhist** subroutines can also set errors.

Files

Item	Description
/etc/security/passwd	Contains user passwords.

getuserpwx Subroutine

Purpose

Accesses the user authentication data.

Library

Security Library (**libc.a**)

Syntax

```
#include <userpw.h>

struct userpwx *getuserpwx (User)
char * User;
```

Description

The **getuserpwx** subroutine accesses user authentication information. Because of its greater granularity and extensibility, use it instead of the **getpwent** routines.

The **getuserpwx** subroutine reads the user's password information from the local administrative domain or from a loadable authentication module that supports the required user attributes.

The **getuserpw** subroutine opens the authentication database read-only if no other access has taken place, but the program should call **setpwdb** (**S_READ**) followed by **endpwdb** after access to the authentication database is no longer required.

The data returned by **getuserpwx** is stored in allocated memory and must be freed by the caller when the data is no longer required. The entire structure can be freed by invoking the **free** subroutine with the pointer returned by **getuserpwx**.

Parameters

Item	Description
User	Specifies the name of the user for which password information is read.

Security

Files accessed:

Item	Description
Mode	**File**
r	**/etc/passwd**
r	**/etc/security/passwd**

Return Values

If successful, the **getuserpwx** subroutine returns a valid pointer to a **userpwx** structure. Otherwise, a null pointer is returned and the **errno** global variable is set to indicate the error. The fields in a **userpwx** structure are defined in the **userpw.h** file, and they include the following members:

Item	Description
upw_name	Specifies the user's name.
upw_passwd	Specifies the user's encrypted password.
upw_lastupdate	Specifies the time, in seconds, since the epoch (that is, 00:00:00 GMT, 1 January 1970), when the password was last updated.
upw_flags	Specifies attributes of the password. This member is a bit mask of one or more of the following values, defined in the **userpw.h** file: **PW_NOCHECK** Specifies that new passwords need not meet password restrictions in effect for the system. **PW_ADMCHG** Specifies that the password was last set by an administrator and must be changed at the next successful use of the login or **su** command. **PW_ADMIN** Specifies that password information for this user can only be changed by the root user.
upw_authdb	Specifies the administrative domain containing the authentication data.

Error Codes

The **getuserpwx** subroutine fails if one of the following values is true:

Item	Description
EACCES	The user is not able to open the files that contain the password attributes.
ENOENT	The user does not have an entry in the **/etc/security/passwd** file or other administrative domain.

Subroutines invoked by the **getuserpwx** subroutine can also set errors.

Files

Item	Description
/etc/security/passwd	Contains user passwords.

getusraclattr, nextusracl or putusraclattr Subroutine

Purpose

Accesses the user screen information in the SMIT ACL database.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
```

```
int getusraclattr(User, Attribute, Value, Type)
char *User;
char *Attribute;
void *Value;
int Type;
```

```
char *nextusracl(void)
```

```
int putusraclattr(User, Attribute, Value, Type)
char *User;
char *Attribute;
void *Value;
int Type;
```

Description

The **getusraclattr** subroutine reads a specified user attribute from the SMIT ACL database. If the database is not already open, this subroutine does an implicit open for reading.

Similarly, the **putusraclattr** subroutine writes a specified attribute into the user SMIT ACL database. If the database is not already open, this subroutine does an implicit open for reading and writing. Data changed by the **putusraclattr** subroutine must be explicitly committed by calling the **putusraclattr** subroutine with a *Type* parameter specifying **SEC_COMMIT**. Until all the data is committed, only the **getusraclattr** subroutine within the process returns written data.

The **nextusracl** subroutine returns the next user in a linear search of the user SMIT ACL database. The consistency of consecutive searches depends upon the underlying storage-access mechanism and is not guaranteed by this subroutine.

The **setacldb** and **endacldb** subroutines should be used to open and close the database.

Parameters

Item	Description
Attribute	Specifies which attribute is read. The following possible attributes are defined in the **usersec.h** file: **S_SCREENS** String of SMIT screens. The attribute type is **SEC_LIST**. **S_ACLMODE** String specifying the SMIT ACL database search scope. The attribute type is **SEC_CHAR**. **S_FUNCMODE** String specifying the databases to be searched. The attribute type is **SEC_CHAR**.
Type	Specifies the type of attribute expected. Valid types are defined in the **usersec.h** file and include: **SEC_CHAR** The format of the attribute is a null-terminated character string. For the **getusraclattr** subroutine, the user should supply a pointer to a defined character pointer variable. For the **putusraclattr** subroutine, the user should supply a character pointer. **SEC_LIST** The format of the attribute is a series of concatenated strings, each null-terminated. The last string in the series must be an empty (zero character count) string. For the **getusraclattr** subroutine, the user should supply a pointer to a defined character pointer variable. For the **putusraclattr** subroutine, the user should supply a character pointer. **SEC_COMMIT** For the **putusraclattr** subroutine, this value specified by itself indicates that changes to the named user are to be committed to permanent storage. The *Attribute* and *Value* parameters are ignored. If no user is specified, the changes to all modified users are committed to permanent storage. **SEC_DELETE** The corresponding attribute is deleted from the user SMIT ACL database. **SEC_NEW** Updates the user SMIT ACL database file with the new user name when using the **putusraclattr** subroutine.
Value	Specifies a buffer, a pointer to a buffer, or a pointer to a pointer depending on the *Attribute* and *Type* parameters. See the *Type* parameter for more details.

Return Values

If successful, the **getusraclattr** returns 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

Possible return codes are:

Item	Description
EACCES	Access permission is denied for the data request.
ENOENT	The specified User parameter does not exist or the attribute is not defined for this user.

Item	Description
ENOATTR	The specified user attribute does not exist for this user.
EINVAL	The *Attribute* parameter does not contain one of the defined attributes or null.
EINVAL	The *Value* parameter does not point to a valid buffer or to valid data for this type of attribute.
EPERM	Operation is not permitted.

getutent, getutid, getutline, pututline, setutent, endutent, or utmpname Subroutine

Purpose

Accesses **utmp** file entries.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <utmp.h>

struct utmp *getutent ( )

struct utmp *getutid ( ID)
struct utmp *ID;

struct utmp *getutline ( Line)
struct utmp *Line;

void pututline ( Utmp)
struct utmp *Utmp;

void setutent ( )

void endutent ( )

void utmpname ( File)
char *File;
```

Description

The **getutent**, **getutid**, and **getutline** subroutines return a pointer to a structure of the following type:

```
struct utmp
> {
>     char ut_user[256];           /* User name */
>     char ut_id[14];              /* /etc/inittab ID */
>     char ut_line[64];            /* Device name (console, lnxx) */
>     pid_t ut_pid;                /* Process ID */
>     short ut_type;               /* Type of entry */
>         int __time_t_space;      /* for 32vs64-bit time_t PPC */
>         time_t ut_time;          /* time entry was made */
>         struct exit_status
>         {
>             short e_termination; /* Process termination status */
>             short e_exit;        /* Process exit status */
>         }
```

```
>         ut_exit;                /* The exit status of a process
>                                 /* marked as DEAD_PROCESS. */
>         char ut_host[256];      /* host name */
>         int __dbl_word_pad;     /* for double word alignment */
>         int __reservedA[2];
>         int __reservedV[6];
> };
```

The **getutent** subroutine reads the next entry from a **utmp**-like file. If the file is not open, this subroutine opens it. If the end of the file is reached, the **getutent** subroutine fails.

The **pututline** subroutine writes the supplied *Utmp* parameter structure into the **utmp** file. It is assumed that the user of the **pututline** subroutine has searched for the proper entry point using one of the **getut** subroutines. If not, the **pututline** subroutine calls **getutid** to search forward for the proper place. If so, **pututline** does not search. If the **pututline** subroutine does not find a matching slot for the entry, it adds a new entry to the end of the file.

The **setutent** subroutine resets the input stream to the beginning of the file. Issue a **setuid** call before each search for a new entry if you want to examine the entire file.

The **endutent** subroutine closes the file currently open.

The **utmpname** subroutine changes the name of a file to be examined from **/etc/utmp** to any other file. The name specified is usually **/var/adm/wtmp**. If the specified file does not exist, no indication is given. You are not aware of this fact until your first attempt to reference the file. The **utmpname** subroutine does not open the file. It closes the old file, if currently open, and saves the new file name.

The most current entry is saved in a static structure. To make multiple accesses, you must copy or use the structure between each access. The **getutid** and **getutline** subroutines examine the static structure first. If the contents of the static structure match what they are searching for, they do not read the **utmp** file. Therefore, you must fill the static structure with zeros after each use if you want to use these subroutines to search for multiple occurrences.

If the **pututline** subroutine finds that it is not already at the correct place in the file, the implicit read it performs does not overwrite the contents of the static structure returned by the **getutent** subroutine, the **getuid** subroutine, or the **getutline** subroutine. This allows you to get an entry with one of these subroutines, modify the structure, and pass the pointer back to the **pututline** subroutine for writing.

These subroutines use buffered standard I/O for input. However, the **pututline** subroutine uses an unbuffered nonstandard write to avoid race conditions between processes trying to modify the **utmp** and **wtmp** files.

Parameters

Item	Description
ID	If you specify a type of **RUN_LVL**, **BOOT_TIME**, **OLD_TIME**, or **NEW_TIME** in the *ID* parameter, the **getutid** subroutine searches forward from the current point in the **utmp** file until an entry with a `ut_type` matching `ID->ut_type` is found. If you specify a type of **INIT_PROCESS**, **LOGIN_PROCESS**, **USER_PROCESS**, or **DEAD_PROCESS** in the *ID* parameter, the **getutid** subroutine returns a pointer to the first entry whose type is one of these four and whose `ut_id` field matches `Id->ut_id`. If the end of the file is reached without a match, the **getutid** subroutine fails.
Line	The **getutline** subroutine searches forward from the current point in the **utmp** file until it finds an entry of type **LOGIN_PROCESS** or **USER_PROCESS** that also has a `ut_line` string matching the `Line->ut_line` parameter string. If the end of file is reached without a match, the **getutline** subroutine fails.
Utmp	Points to the **utmp** structure.
File	Specifies the name of the file to be examined.

Return Values

These subroutines fail and return a null pointer if a read or write fails due to a permission conflict or because the end of the file is reached.

Files

Item	Description
/etc/utmp	Path to the **utmp** file, which contains a record of users logged into the system.
/var/adm/wtmp	Path to the **wtmp** file, which contains accounting information about users logged in.

getvfsent, getvfsbytype, getvfsbyname, getvfsbyflag, setvfsent, or endvfsent Subroutine

Purpose

Gets a **vfs** file entry.

Library

Standard C Library(**libc.a**)

Syntax

```
#include <sys/vfs.h>
#include <sys/vmount.h>
```

```
struct vfs_ent *getvfsent( )
```

struct vfs_ent *getvfsbytype(*vfsType***)**
int *vfsType***;**

struct vfs_ent *getvfsbyname(*vfsName***)**
char **vfsName***;**

struct vfs_ent *getvfsbyflag(*vfsFlag***)**
int *vfsFlag***;**

```
void setvfsent( )
```

```
void endvfsent( )
```

Description

Attention: All information is contained in a static area and so must be copied to be saved.

The **getvfsent** subroutine, when first called, returns a pointer to the first **vfs_ent** structure in the file. On the next call, it returns a pointer to the next **vfs_ent** structure in the file. Successive calls are used to search the entire file.

The **vfs_ent** structure is defined in the **vfs.h** file and it contains the following fields:

```
char vfsent_name;
int vfsent_type;
```

```
int vfsent_flags;
char *vfsent_mnt_hlpr;
char *vfsent_fs_hlpr;
```

The **getvfsbytype** subroutine searches from the beginning of the file until it finds a **vfs** type matching the *vfsType* parameter. The subroutine then returns a pointer to the structure in which it was found.

The **getvfsbyname** subroutine searches from the beginning of the file until it finds a **vfs** name matching the *vfsName* parameter. The search is made using flattened names; the search-string uses ASCII equivalent characters.

The **getvfsbytype** subroutine searches from the beginning of the file until it finds a type matching the *vfsType* parameter.

The **getvfsbyflag** subroutine searches from the beginning of the file until it finds the entry whose flag corresponds flags defined in the **vfs.h** file. Currently, these are **VFS_DFLT_LOCAL** and **VFS_DFLT_REMOTE**.

The **setvfsent** subroutine rewinds the **vfs** file to allow repeated searches.

The **endvfsent** subroutine closes the **vfs** file when processing is complete.

Parameters

Item	Description
vfsType	Specifies a **vfs** type.
vfsName	Specifies a **vfs** name.
vfsFlag	Specifies either **VFS_DFLT_LOCAL** or **VFS_DFLT_REMOTE**.

Return Values

The **getvfsent**, **getvfsbytype**, **getvfsbyname**, and **getvfsbyflag** subroutines return a pointer to a **vfs_ent** structure containing the broken-out fields of a line in the **/etc/vfs** file. If an end-of-file character or an error is encountered on reading, a null pointer is returned.

Files

Item	Description
/etc/vfs	Describes the virtual file system (VFS) installed on the system.

getwc, fgetwc, or getwchar Subroutine

Purpose

Gets a wide character from an input stream.

Library

Standard I/O Package (**libc.a**)

Syntax

```
#include <stdio.h>
```

```
wint_t getwc ( Stream)
FILE *Stream;
```

```
wint_t fgetwc (Stream)
FILE *Stream;
```

```
wint_t getwchar (void)
```

Description

The **fgetwc** subroutine obtains the next wide character from the input stream specified by the *Stream* parameter, converts it to the corresponding wide character code, and advances the file position indicator the number of bytes corresponding to the obtained multibyte character. The **getwc** subroutine is equivalent to the **fgetwc** subroutine, except that when implemented as a macro, it may evaluate the *Stream* parameter more than once. The **getwchar** subroutine is equivalent to the **getwc** subroutine with **stdin** (the standard input stream).

The first successful run of the **fgetc**, **fgets**, **fgetwc**, **fgetws**, **fread**, **fscanf**, **getc**, **getchar**, **gets**, or **scanf** subroutine using a stream that returns data not supplied by a prior call to the **ungetc** or **ungetwc** subroutine marks the `st_atime` field for update.

Parameters

Item	Description
Stream	Specifies input data.

Return Values

Upon successful completion, the **getwc** and **fgetwc** subroutines return the next wide character from the input stream pointed to by the *Stream* parameter. The **getwchar** subroutine returns the next wide character from the input stream pointed to by stdin.

If the end of the file is reached, an indicator is set and **WEOF** is returned. If a read error occurs, an error indicator is set, **WEOF** is returned, and the **errno** global variable is set to indicate the error.

Error Codes

If the **getwc**, **fgetwc**, or **getwchar** subroutine is unsuccessful because the stream is not buffered or data needs to be read into the buffer, it returns one of the following error codes:

Item	Description
EAGAIN	Indicates that the **O_NONBLOCK** flag is set for the file descriptor underlying the *Stream* parameter, delaying the process.
EBADF	Indicates that the file descriptor underlying the *Stream* parameter is not valid and cannot be opened for reading.
EINTR	Indicates that the process has received a signal that terminates the read operation.
EIO	Indicates that a physical error has occurred, or the process is in a background process group attempting to read from the controlling terminal, and either the process is ignoring or blocking the **SIGTTIN** signal or the process group is orphaned.
EOVERFLOW	Indicates that the file is a regular file and an attempt has been made to read at or beyond the offset maximum associated with the corresponding stream.

The **getwc**, **fgetwc**, or **getwchar** subroutine is also unsuccessful due to the following error conditions:

Item	Description
ENOMEM	Indicates that storage space is insufficient.
ENXIO	Indicates that the process sent a request to a nonexistent device, or the device cannot handle the request.
EILSEQ	Indicates that the **wc** wide-character code does not correspond to a valid character.

getwd Subroutine

Purpose

Gets current directory path name.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <unistd.h>

char *getwd ( PathName)
char *PathName;
```

Description

The **getwd** subroutine determines the absolute path name of the current directory, then copies that path name into the area pointed to by the *PathName* parameter.

The maximum path-name length, in characters, is set by the **PATH_MAX** value, as specified in the **limits.h** file.

Parameters

Item	Description
PathName	Points to the full path name.

Return Values

If the call to the **getwd** subroutine is successful, a pointer to the absolute path name of the current directory is returned. If an error occurs, the **getwd** subroutine returns a null value and places an error message in the *PathName* parameter.

In UNIX03 mode, the getwd subroutine returns a null value if the actual path name is longer than the value defined by PATH_MAX. In the previous mode, the getwd subroutine returns a truncated path name if the path name is longer than PATH_MAX. The previous behavior can be disabled setting the environment variable XPG_SUS_ENV=ON.

getws or fgetws Subroutine

Purpose

Gets a string from a stream.

Library

Standard I/O Library (**libc.a**)

Syntax

```
#include <stdio.h>
```

```
wchar_t *fgetws ( WString,  Number,  Stream)
wchar_t *WString;
int Number;
FILE *Stream;
```

```
wchar_t *getws (WString)
wchar_t *WString;
```

Description

The **fgetws** subroutine reads characters from the input stream, converts them to the corresponding wide character codes, and places them in the array pointed to by the *WString* parameter. The subroutine continues until either the number of characters specified by the *Number* parameter minus 1 are read or the subroutine encounters a new-line or end-of-file character. The **fgetws** subroutine terminates the wide character string specified by the *WString* parameter with a null wide character.

The **getws** subroutine reads wide characters from the input stream pointed to by the standard input stream (**stdin**) into the array pointed to by the *WString* parameter. The subroutine continues until it encounters a new-line or the end-of-file character, then it discards any new-line character and places a null wide character after the last character read into the array.

Parameters

Item	Description
WString	Points to a string to receive characters.
Stream	Points to the **FILE** structure of an open file.
Number	Specifies the maximum number of characters to read.

Return Values

If the **getws** or **fgetws** subroutine reaches the end of the file without reading any characters, it transfers no characters to the *String* parameter and returns a null pointer. If a read error occurs, the **getws** or **fgetws** subroutine returns a null pointer and sets the **errno** global variable to indicate the error.

Error Codes

If the **getws** or **fgetws** subroutine is unsuccessful because the stream is not buffered or data needs to be read into the stream's buffer, it returns one or more of the following error codes:

Item	Description
EAGAIN	Indicates that the **O_NONBLOCK** flag is set for the file descriptor underlying the *Stream* parameter, and the process is delayed in the **fgetws** subroutine.
EBADF	Indicates that the file descriptor specifying the *Stream* parameter is not a read-access file.
EINTR	Indicates that the read operation is terminated due to the receipt of a signal, and either no data was transferred or the implementation does not report partial transfer for this file.

Item	Description
EIO	Indicates that insufficient storage space is available.
ENOMEM	Indicates that insufficient storage space is available.
EILSEQ	Indicates that the data read from the input stream does not form a valid character.

getyx Macro

Purpose

Returns the coordinates of the logical cursor in the specified window.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

getyx( Window,  Line,  Column)
WINDOW *Window;
int Line, Column;
```

Description

The **getyx** macro returns the coordinates of the logical cursor in the specified window.

Parameters

Item	Description
Window	Identifies the window to get the cursor location from.
Column	Holds the column coordinate of the logical cursor.
Line	Holds the line or row coordinate of the logical cursor.

Example

To get the location of the logical cursor in the user-defined window `my_window` and then put these coordinates in the user-defined integer variables `Line` and `Column`, enter:

```
WINDOW *my_window;
int line, column;
getyx(my_window, line, column);
```

glob Subroutine

Purpose

Generates path names.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <glob.h>

int glob (Pattern, Flags, (Errfunc)(), Pglob)
const char  *Pattern;
int  Flags;
int  *Errfunc (Epath, Eerrno)
const char  *Epath;
int  Eerrno;
glob_t  *Pglob;
```

Description

The **glob** subroutine constructs a list of accessible files that match the *Pattern* parameter.

The **glob** subroutine matches all accessible path names against this pattern and develops a list of all matching path names. To have access to a path name, the **glob** subroutine requires search permission on every component of a path except the last, and read permission on each directory of any file name component of the *Pattern* parameter that contains any of the special characters * (asterisk), ? (question mark), or [(left bracket). The **glob** subroutine stores the number of matched path names and a pointer to a list of pointers to path names in the *Pglob* parameter. The path names are in sort order, based on the setting of the **LC_COLLATE** category in the current locale. The first pointer after the last path name is a null character. If the pattern does not match any path names, the returned number of matched paths is zero.

Parameters

Pattern
Contains the file name pattern to compare against accessible path names.

Flags
Controls the customizable behavior of the **glob** subroutine.

The *Flags* parameter controls the behavior of the **glob** subroutine. The *Flags* value is the bitwise inclusive OR of any of the following constants, which are defined in the **glob.h** file:

GLOB_APPEND
Appends path names located with this call to any path names previously located. If the **GLOB_APPEND** constant is not set, new path names overwrite previous entries in the *Pglob* array. The **GLOB_APPEND** constant should not be set on the first call to the **glob** subroutine. It may, however, be set on subsequent calls.

The **GLOB_APPEND** flag can be used to append a new set of path names to those found in a previous call to the **glob** subroutine. If the **GLOB_APPEND** flag is specified in the *Flags* parameter, the following rules apply:

- If the application sets the **GLOB_DOOFFS** flag in the first call to the **glob** subroutine, it is also set in the second. The value of the *Pglob* parameter is not modified between the calls.
- If the application did not set the **GLOB_DOOFFS** flag in the first call to the **glob** subroutine, it is not set in the second.
- After the second call, the *Pglob* parameter points to a list containing the following:
  - Zero or more null characters, as specified by the **GLOB_DOOFFS** flag.
  - Pointers to the path names that were in the *Pglob* list before the call, in the same order as after the first call to the **glob** subroutine.
  - Pointers to the new path names generated by the second call, in the specified order.
- The count returned in the *Pglob* parameter is the total number of path names from the two calls.
- The application should not modify the *Pglob* parameter between the two calls.

It is the caller's responsibility to create the structure pointed to by the *Pglob* parameter. The **glob** subroutine allocates other space as needed.

GLOB_DOOFFS
Uses the **gl_offs** structure to specify the number of null pointers to add to the beginning of the **gl_pathv** component of the *Pglob* parameter.

GLOB_ERR
Causes the **glob** subroutine to return when it encounters a directory that it cannot open or read. If the **GLOB_ERR** flag is not set, the **glob** subroutine continues to find matches if it encounters a directory that it cannot open or read.

GLOB_MARK
Specifies that each path name that is a directory should have a / (slash) appended.

GLOB_NOCHECK
If the *Pattern* parameter does not match any path name, the **glob** subroutine returns a list consisting only of the *Pattern* parameter, and the number of matched patterns is one.

GLOB_NOSORT
Specifies that the list of path names need not be sorted. If the **GLOB_NOSORT** flag is not set, path names are collated according to the current locale.

GLOB_QUOTE
If the **GLOB_QUOTE** flag is set, a \ (backslash) can be used to escape metacharacters.

Errfunc
Specifies an optional subroutine that, if specified, is called when the **glob** subroutine detects an error condition.

Pglob
Contains a pointer to a **glob_t** structure. The structure is allocated by the caller. The array of structures containing the file names matching the *Pattern* parameter are defined by the **glob** subroutine. The last entry is a null pointer.

Epath
Specifies the path that failed because a directory could not be opened or read.

Eerrno
Specifies the **errno** value of the failure indicated by the *Epath* parameter. This value is set by the **opendir**, **readdir**, or **stat** subroutines.

Return Values

On successful completion, the **glob** subroutine returns a value of 0. The *Pglob* parameter returns the number of matched path names and a pointer to a null-terminated list of matched and sorted path names. If the number of matched path names in the *Pglob* parameter is zero, the pointer in the *Pglob* parameter is undefined.

Error Codes

If the **glob** subroutine terminates due to an error, it returns one of the nonzero constants below. These are defined in the **glob.h** file. In this case, the *Pglob* values are still set as defined in the Return Values section.

Item	Description
GLOB_ABORTED	Indicates the scan was stopped because the **GLOB_ERROR** flag was set or the subroutine specified by the **errfunc** parameter returned a nonzero value.
GLOB_NOSPACE	Indicates a failed attempt to allocate memory.

If, during the search, a directory is encountered that cannot be opened or read and the *Errfunc* parameter is not a null value, the **glob** subroutine calls the subroutine specified by the **errfunc** parameter with two arguments:

- The *Epath* parameter specifies the path that failed.
- The *Eerrno* parameter specifies the value of the **errno** global variable from the failure, as set by the **opendir**, **readdir**, or **stat** subroutine.

If the subroutine specified by the *Errfunc* parameter is called and returns nonzero, or if the **GLOB_ERR** flag is set in the *Flags* parameter, the **glob** subroutine stops the scan and returns **GLOB_ABORTED** after setting the *Pglob* parameter to reflect the paths already scanned. If **GLOB_ERR** is not set and either the *Errfunc* parameter is null or `*errfunc` returns zero, the error is ignored.

The *Pglob* parameter has meaning even if the **glob** subroutine fails. Therefore, the **glob** subroutine can report partial results in the event of an error. However, if the number of matched path names is 0, the pointer in the *Pglob* parameter is unspecified even if the **glob** subroutine did not return an error.

Examples

The **GLOB_NOCHECK** flag can be used with an application to expand any path name using wildcard characters. However, the **GLOB_NOCHECK** flag treats the pattern as just a string by default. The **sh** command can use this facility for option parameters, for example.

The **GLOB_DOOFFS** flag can be used by applications that build an argument list for use with the **execv**, **execve**, or **execvp** subroutine. For example, an application needs to do the equivalent of `ls -l *.c`, but for some reason cannot. The application could still obtain approximately the same result using the sequence:

```
globbuf.gl_offs = 2;
glob ("*.c", GLOB_DOOFFS, NULL, &globbuf);
globbuf.gl_pathv[0] = "ls";
globbuf.gl_pathv[1] ="-l";
execvp ("ls", &globbuf.gl_pathv[0]);
```

Using the same example, `ls -l *.c *.h` could be approximated using the **GLOB_APPEND** flag as follows:

```
globbuf.gl_offs = 2;
glob ("*.c", GLOB_DOOFFS, NULL, &globbuf);
glob ("*.h", GLOB_DOOFFS|GLOB_APPEND, NULL, &globbuf);
```

The new path names generated by a subsequent call with the **GLOB_APPEND** flag set are not sorted together with the previous path names. This is the same way the shell handles path name expansion when multiple expansions are done on a command line.

globfree Subroutine

Purpose

Frees all memory associated with the *pglob* parameter.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <glob.h>
```

void globfree (*pglob*)
glob_t *pglob;

Description

The **globfree** subroutine frees any memory associated with the *pglob* parameter due to a previous call to the **glob** subroutine.

Parameters

Item	Description
pglob	Structure containing the results of a previous call to the **glob** subroutine.

grantpt Subroutine

Purpose

Changes the mode and ownership of a pseudo-terminal device.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdlib.h>

int grantpt ( FileDescriptor)
int FileDescriptor;
```

Description

The **grantpt** subroutine changes the mode and the ownership of the worker pseudo-terminal associated with the controller pseudo-terminal device defined by the *FileDescriptor* parameter. The user ID of the worker pseudo-terminal is set to the real UID of the calling process. The group ID of the worker pseudo-terminal is set to an unspecified group ID. The permission mode of the worker pseudo-terminal is set to readable and writeable by the owner, and writeable by the group.

Parameters

Item	Description
FileDescriptor	Specifies the file descriptor of the controller pseudo-terminal device.

Return Value

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **grantpt** function may fail if:

Item	Description
EBADF	The *fildes* argument is not a valid open file descriptor.
EINVAL	The *fildes* argument is not associated with a controller pseudo-terminal device.
EACCES	The corresponding worker pseudo-terminal device could not be accessed.

h

The following Base Operating System (BOS) runtime services begin with the letter *h*.

halfdelay Subroutine

Purpose

Controls input character delay mode.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
int halfdelay(int tenths);
```

Description

The **halfdelay** subroutine sets the input mode for the current window to Half-Delay Mode and specifies tenths of seconds as the half-delay interval. The *tenths* argument must be in a range from 1 up to and including 255.

Flag

Item	Description
x	Instructs **wgetch** to wait *x* tenths of a second for input before timing out.

Parameters

Item	Description
tenths	

Return Values

Upon successful completion, the **halfdelay** subroutine returns OK. Otherwise, it returns ERR.

has_colors Subroutine

Purpose

Determines whether a terminal supports color.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
has_colors()
```

Description

The **has_colors** subroutine determines whether a terminal supports color. If the terminal supports color, the **has_colors** subroutine returns TRUE. Otherwise, it returns FALSE. Because this subroutine tests for color, you can call it before the **start_color** subroutine.

The **has_colors** routine makes writing terminal-independent programs easier because you can use the subroutine to determine whether to use color or another video attribute.

Use the **can_change_colors** subroutine to determine whether a terminal that supports colors also supports changing its color definitions.

Examples

To determine whether or not a terminal supports color, use:

```
has_colors();
```

has_ic and has_il Subroutine

Purpose

Query functions for terminal insert and delete capability.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
bool has_ic(void);
```

```
bool has_il(void);
```

Description

The **has_ic** subroutine indicates whether the terminal has insert- and delete-character capabilities.

The **has_il** subroutine indicates whether the terminal has insert- and delete-line capabilities, or can simulate them using scrolling regions.

Return Values

The **has_ic** subroutine returns a value of TRUE if the terminal has insert- and delete-character capabilities. Otherwise, it returns FALSE.

The **has_il** subroutine returns a value of TRUE if the terminal has insert- and delete-line capabilities. Otherwise, it returns FALSE.

Examples

For the **has_ic** subroutine:

To determine the insert capability of a terminal by returning TRUE or FALSE into the user-defined variable `insert_cap`, enter:

```
int insert_cap;
insert_cap = has_ic();
```

For the **has_il** subroutine:

To determine the insert capability of a terminal by returning TRUE or FALSE into the user-defined variable `insert_line`, enter:

```
int insert_line;
insert_line = has_il();
```

has_il Subroutine

Purpose

Determines whether the terminal has insert-line capability.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
has_il( )
```

Description

The **has_il** subroutine determines whether a terminal has insert-line capability.

Return Values

The **has_il** subroutine returns TRUE if terminal has insert-line capability and FALSE, if not.

Examples

To determine the insert capability of a terminal by returning TRUE or FALSE into the user-defined variable `insert_line`, enter:

```
int insert_line;
insert_line = has_il();
```

HBA_CloseAdapter Subroutine

Purpose

Closes the adapter opened by the **HBA_OpenAdapter** subroutine.

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

void HBA_CloseAdapter (handle)
HBA_HANDLE handle;
```

Description

The **HBA_CloseAdapter** subroutine closes the file associated with the file handle that was the result of a call to the **HBA_OpenAdapter** subroutine. The **HBA_CloseAdapter** subroutine calls the **close** subroutine, and applies it to the file handle. After performing the operation, the handle is set to NULL.

Parameters

Item	Description
handle	Specifies the open file descriptor obtained from a successful call to the **open** subroutine.

HBA_FreeLibrary Subroutine

Purpose

Frees all the resources allocated to build the Common HBA API Library.

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

HBA_STATUS HBA_FreeLibrary ()
```

Description

The **HBA_FreeLibrary** subroutine frees all resources allocated to build the Common HBA API library. This subroutine must be called after calling any other routine from the Common HBA API library.

Error Codes

The Storage Area Network Host Bus Adapter API subroutines return the following error codes:

Item	Description
HBA_STATUS_OK	A value of 0 on successful completion.
HBA_STATUS_ERROR	A value of 1 if an error occurred.

HBA_GetAdapterAttributes, HBA_GetPortAttributes, HBA_GetDiscoveredPortAttributes, HBA_GetPortAttributesByWWN Subroutine

Purpose

Gets the attributes of the end device's adapter, port, or remote port.

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

HBA_STATUS HBA_GetAdapterAttributes (handle, hbaattributes)
HBA_STATUS HBA_GetAdapterPortAttributes (handle, portindex, portattributes)
HBA_STATUS HBA_GetDiscoveredPortAttributes (handle, portindex, discoveredportindex,
portattributes)
HBA_STATUS HBA_GetPortAttributesByWWN (handle, PortWWN, portattributes)

HBA_HANDLE handle;
HBA_ADAPTERATTRIBUTES *hbaattributes;
HBA_UINT32 portindex;
HBA_PORTATTRIBUTES *portattributes;
HBA_UINT32 discoveredportindex;
HBA_WWN PortWWN;
```

Description

The **HBA_GetAdapterAttributes** subroutine queries the ODM and makes system calls to gather information pertaining to the adapter. This information is returned to the **HBA_ADAPTERATTRIBUTES** structure. This structure is defined in the **/usr/include/sys/hbaapi.h** file.

The **HBA_GetAdapterAttributes**, **HBA_GetAdapterPortAttributes**, **HBA_GetDiscoveredPortAttributes**, and **HBA_GetPortAttributesByWWN** subroutines return the attributes of the adapter, port or remote port.

These attributes include:

- Manufacturer
- SerialNumber
- Model
- ModelDescription
- NodeWWN
- NodeSymbolicName
- HardwareVersion
- DriverVersion
- OptionROMVersion
- FirmwareVersion
- VendorSpecificID
- NumberOfPorts
- Drivername

The **HBA_GetAdapterPortAttributes**, **HBA_GetDiscoveredPortAttributes**, and **HBA_GetPortAttributesByWWN** subroutines also query the ODM and make system calls to gather

information. The gathered information pertains to the port attached to the adapter or discovered on the network. The attributes are stored in the **HBA_PORTATTRIBUTES** structure. This structure is defined in the **/usr/include/sys/hbaapi.h** file.

These attributes include:

- NodeWWN
- PortWWN
- PortFcId
- PortType
- PortState
- PortSupportedClassofService
- PortSupportedFc4Types
- PortActiveFc4Types
- OSDeviceName
- PortSpeed
- NumberofDiscoveredPorts
- PortSymbolicName
- PortSupportedSpeed
- PortMaxFrameSize
- FabricName

The **HBA_GetAdapterPortAttributes** subroutine returns the attributes of the attached port.

The **HBA_GetDiscoveredPortAttributes**, and **HBA_GetPortAttributesByWWN** subroutines return the same information. However, these subroutines differ in the way they are called, and in the way they acquire the information.

Parameters

Item	Description
handle	Specifies the open file descriptor obtained from a successful call to the **open** subroutine.
hbaatributes	Points to an **HBA_AdapterAttributes** structure, which is used to store information pertaining to the Host Bus Adapter.
portindex	Specifies the index number of the port where the information was obtained.
portattributes	Points to an **HBA_PortAttributes** structure used to store information pertaining to the port attached to the Host Bus Adapter.
discoveredportindex	Specifies the index of the attached port discovered over the network.
PortWWN	Specifies the world wide name or port name of the target device.

Return Values

Upon successful completion, the attributes and a value of HBA_STATUS_OK, or 0 are returned.

If no information for a particular attribute is available, a null value is returned for that attribute. HBA_STATUS_ERROR or 1 is returned if certain ODM queries or system calls fail while trying to retrieve the attributes.

Error Codes

The Storage Area Network Host Bus Adapter API subroutines return the following error codes:

Item	Description
HBA_STATUS_OK	A value of 0 on successful completion.
HBA_STATUS_ERROR	A value of 1 if an error occurred.
HBA_STATUS_ERROR_INVALID_HANDLE	A value of 3 if there was an invalid file handle.
HBA_STATUS_ERROR_ARG	A value of 4 if there was a bad argument.
HBA_STATUS_ERROR_ILLEGAL_WWN	A value of 5 if the world wide name was not recognized.

HBA_GetAdapterName Subroutine

Purpose

Gets the name of a Common Host Bus Adapter.

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

HBA_STATUS HBA_GetAdapterName (adapterindex, adaptername)
HBA_UINT32 adapterindex;
char *adaptername;
```

Description

The **HBA_GetAdapterName** subroutine gets the name of a Common Host Bus Adapter. The *adapterindex* parameter is an index into an internal table containing all FCP adapters on the machine. The *adapterindex* parameter is used to search the table and obtain the adapter name. The name of the adapter is returned in the form of `mgfdomain-model-adapterindex`. The name of the adapter is used as an argument for the **HBA_OpenAdapter** subroutine. From the **HBA_OpenAdapter** subroutine, the file descriptor will be obtained where additional Common HBA API routines can then be called using the file descriptor as the argument.

Parameters

Item	Description
adapterindex	Specifies the index of the adapter held in the adapter table for which the name of the adapter is to be returned.
adaptername	Points to a character string that will be used to hold the name of the adapter.

Return Values

Upon successful completion, the **HBA_GetAdapterName** subroutine returns the name of the adapter and a 0, or a status code of HBA_STATUS_OK. If unsuccessful, a null value will be returned for *adaptername* and an value of 1, or a status code of HBA_STATUS_ERROR.

Error Codes

The Storage Area Network Host Bus Adapter API subroutines return the following error codes:

Item	Description
HBA_STATUS_OK	A value of 0 on successful completion.
HBA_STATUS_ERROR	A value of 1 if an error occurred.
HBA_STATUS_ERROR_NOT_SUPPORTED	A value of 2 if the function is not supported.
HBA_STATUS_ERROR_INVALID_HANDLE	A value of 3 if there was an invalid file handle.
HBA_STATUS_ERROR_ARG	A value of 4 if there was a bad argument.
HBA_STATUS_ERROR_ILLEGAL_WWN	A value of 5 if the world wide name was not recognized.
HBA_STATUS_ERROR_ILLEGAL_INDEX	A value of 6 if an index was not recognized.
HBA_STATUS_ERROR_MORE_DATA	A value of 7 if a larger buffer is required.
HBA_STATUS_ERROR_STALE_DATA	A value of 8 if information has changed since the last call to the **HBA_RefreshInformation** subroutine.
HBA_STATUS_SCSI_CHECK_CONDITION	A value of 9 if a SCSI Check Condition was reported.
HBA_STATUS_ERROR_BUSY	A value of 10 if the adapter was busy or reserved. Try again later.
HBA_STATUS_ERROR_TRY_AGAIN	A value of 11 if the request timed out. Try again later.
HBA_STATUS_ERROR_UNAVAILABLE	A value of 12 if the referenced HBA has been removed or deactivated.

HBA_GetEventBuffer Subroutine

Purpose

Removes and returns the next events from the HBA's event queue.

Syntax

```
HBA_STATUS HBA_GetEventBuffer(
        HBA_HANDLE handle,
        HBA_EVENTINFO *pEventBuffer,
        HBA_UINT32 *pEventCount,
);
```

Description

The **HBA_GetEventBuffer** function removes and returns the next events from the HBA's event queue. The number of events returned is the lesser of the value of the *EventCount* parameter at the time of the call and the number of entries available in the event queue.

Parameters

Item	Description
handle	A handle to an open HBA.

Item	Description
pEventBuffer	Pointer to a buffer to receive events.
pEventCount	Pointer to the number of event records that fit in the space allocated for the buffer to receive events. It is set to the size (in event records) of the buffer for receiving events on call, and is returned as the number of events actually delivered.

Return Values

The value of the **HBA_GetEventBuffer** function is a valid status return value that indicates the reason for completion of the requested function. **HBA_STATUS_OK** is returned to indicate that no errors were encountered and *pEventCount* indicates the number of event records returned. A valid status return value that most closely describes the result of the function should be returned to indicate a reason with no required value.

The return values for the following parameters are as follows:

Item	Description
pEventBuffer	Remains unchanged. The buffer to which it points contains event records representing previously undelivered events.
pEventCount	Remains unchanged. The value of the integer to which it points contains the number of event records that actually were delivered.

Error Codes

Item	Description
HBA_STATUS_ERROR	Returned to indicate any problem with no required value.

HBA_GetFC4Statistics Subroutine

Purpose

Returns traffic statistics for a specific FC-4 protocol through a specific local HBA and local end port.

Syntax

```
HBA_STATUS HBA_GetFC4Statistics(
        HBA_HANDLE handle,
        HBA_WWN hbaPortWWN,
        HBA_UINT8 FC4type,
        HBA_FC4STATISTICS *statistics
);
```

Description

The **HBA_GetFC4Statistics** function returns traffic statistics for a specific FC-4 protocol through a specific local HBA and local end port.

Note: Basic Link Service, Extended Link Service, and CT each have specific Data Structure **TYPE** values, so their traffic can be requested.

Parameters

Item	Description
handle	A handle to an open HBA containing the end port for which FC-4 statistics can return.
hbaPortWWN	The Port Name of the local HBA end port for which FC-4 statistics can return.
FC4type	The Data Structure **TYPE** assigned by FC-FS to the FC-4 protocol for which FC-4 statistics are requested.
statistics	A pointer to an FC-4 Statistics structure in which the statistics for the specified FC-4 protocol can be returned.

Return Values

The value of the **HBA_GetFC4Statistics** function is a valid status return value that indicates the reason for completion of the requested function. **HBA_STATUS_OK** is returned to indicate that the statistics for the specified FC-4 and end port have been returned. A valid status return value that most closely describes the result of the function should be returned to indicate a reason with no required value.

The return value for the following parameter is as follows:

Item	Description
statistics	Remains unchanged. The structure to which it points contains the statistics for the specified FC-4 protocol.

Error Codes

Item	Description
HBA_STATUS_ERROR_ILLEGAL_WWN	Indicates that the HBA referenced by *handle* does not contain an end port with Port Name *hbaPortWWN*.
HBA_STATUS_ERROR_UNSUPPORTED_FC4	Indicates that the specified HBA end port does not support the specified FC-4 protocol.
HBA_STATUS_ERROR	Returned to indicate any problem with no required value.

HBA_GetFcpPersistentBinding Subroutine

Purpose

Gets persistent binding information of SCSI LUNs.

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

HBA_STATUS HBA_GetFcpPersistentBinding (handle, binding)
HBA_HANDLE handle;
PHBA_FCPBinding binding;
```

Description

For the specified HBA_HANDLE, the **HBA_GetFcpPersistentBinding** subroutine returns the full binding information of local SCSI LUNs to FCP LUNs for each child of the specified HBA_HANDLE. Applications must allocate memory for the **HBA_FCPBINDING** structure, and also pass to the subroutine the number of entries allocated. If the subroutine determines that the structure is not large enough to represent the full binding information, it will set the *NumberOfEntries* variable to the correct value and return an error.

Parameters

Item	Description
handle	An HBA_HANDLE to an open adapter.

binding	A pointer to a structure containing the binding information of the handle's children. The **HBA_FCPBINDING** structure has the following form:
	`struct HBA_FCPBinding {`
	`  HBA_UINT32 NumberOfEntries;`
	`  HBA_FCPBINDINGENTRY entry[1]; /* Variable length array */`
	`  };`
	The size of the structure is determined by the calling application, and is passed in by the *NumberOfEntries* variable.

Return Values

Upon successful completion, HBA_STATUS_OK is returned, and the *binding* parameter points to the full binding structure. If the application has not allocated enough space for the full binding, HBA_STATUS_ERROR_MORE_DATA is returned and the *NumberOfEntries* field in the binding structure is set to the correct value.

Error Codes

If there is insufficient space allocated for the full binding. HBA_STATUS_ERROR_MORE_DATA is returned.

HBA_GetFCPStatistics Subroutine

Purpose

Returns traffic statistics for a specific OS SCSI logical unit provided by the FCP protocol on a specific local HBA.

Syntax

```
HBA_STATUS HBA_GetFCPStatistics(
        HBA_HANDLE handle,
        const HBA_SCSIID *lunit,
        HBA_FC4STATISTICS *statistics
);
```

Description

The **HBA_GetFCPStatistics** function returns traffic statistics for a specific OS SCSI logical unit provided by the FCP protocol on a specific local HBA.

Parameters

Item	Description
handle	A handle to an open HBA containing the end port for which FCP-2 statistics can be returned.
lunit	Pointer to a structure specifying the OS SCSI logical unit for which FCP-2 statistics are requested.
statistics	Pointer to a FC-4 Statistics structure in which the FCP-2 statistics for the specified logical unit can be returned.

Return Values

The value of the **HBA_GetFCPStatistics** function is a valid status return value that indicates the reason for completion of the requested function. **HBA_STATUS_OK** is returned to indicate that FCP-2 statistics have been returned for the specified HBA. A valid status return value that most closely describes the result of the function should be returned to indicate a reason with no required value.

The return value for the following parameter is as follows:

Item	Description
statistics	Remains unchanged. The structure to which it points contains the FCP-2 statistics for the specified HBA and logical unit.

Error Codes

Item	Description
HBA_STATUS_ERROR_INVALID_LUN	The HBA referenced by *handle* does not support the logical unit referenced by *lunit*.
HBA_STATUS_ERROR_UNSUPPORTED_FC4	The specified HBA end port does not support FCP-2.
HBA_STATUS_ERROR	Returned to indicate any problem with no required value.

HBA_GetFcpTargetMappingV2 Subroutine

Purpose

Returns the mapping between OS targets or logical units and FCP targets or logical units offered by the specified HBA end port at the time the function call is processed.

Syntax

```
HBA_STATUS HBA_GetFcpTargetMappingV2(
        HBA_HANDLE handle,
        HBA_WWN hbaPortWWN,
        HBA_FCPTARGETMAPPINGV2 *pMapping
);
```

Description

The **HBA_GetFcpTargetMappingV2** function returns the mapping between OS identification of SCSI targets or logical units and FCP identification of targets or logical units offered by the specified HBA end port at the time the function call is processed. Space in the *pMapping* structure permitting, one mapping

entry is returned for each FCP logical unit represented in the OS and one mapping entry is returned for each FCP target that is represented in the OS but for which no logical units are represented in the OS. No target mapping entries are returned to represent FCP objects that are not represented in the OS (that is, objects that are unmapped).

The mappings returned include a Logical Unit Unique Device Identifier (LUID) for each logical unit that provides one. For logical units that provide more than one LUID, the LUID returned is the type 3 (FC **Name_Identifier**) LUID with the smallest identifier value if any LUID of type 3 is provided; otherwise, the type 2 (IEEE EUI-64) LUID with the smallest identifier value if any LUID of type 2 is provided; otherwise, the type 1 (T10 vendor identification) LUID with the smallest identifier value if any LUID of type 1 is provided; otherwise, the type 0 (vendor specific) LUID with the smallest identifier value. If the logical unit provides no LUID, the value of the first four bytes of the LUID field are 0.

Parameters

Item	Description
handle	A handle to an open HBA containing the end port for which target mappings are requested.
hbaPortWWN	Port Name of the local HBA end port for which target mappings are requested.
pMapping	Pointer to an **HBA_FCPTARGETMAPPINGV2** structure. The size of this structure shall be limited by the *NumberOfEntries* value within the structure.

Return Values

The value of the **HBA_GetFcpTargetMappingV2** function is a valid status return value that indicates the reason for completion of the requested function. **HBA_STATUS_OK** is returned to indicate that all mapping entries have been returned for the specified end port. A valid status return value that most closely describes the result of the function should be returned to indicate a reason with no required value.

The return value for the following parameter is as follows:

Item	Description
pMapping	Remains unchanged. The structure to which it points contains mapping information from OS identifications of SCSI logical units to FCP identifications of logical units for the specified local HBA end port. The number of entries in the structure is the minimum of the number of entries specified at function call or the full mapping. The value of the *NumberOfEntries* field of the returned structure is the total number of mappings the end port has established. This is true even when the function returns an error stating that the buffer is too small to return all of the established mappings. An upper-level application can either allocate a sufficiently large buffer and check this value after a read, or do a read of the *NumberOfEntries* value separately and allocate a new buffer given the size to accommodate the entire mapping structure.

Error Codes

Item	Description
HBA_STATUS_ERROR_MORE_DATA	More space in the buffer is required to contain mapping information.
HBA_STATUS_ERROR_ILLEGAL_WWN	The HBA referenced by *handle* does not contain an end port with Port Name *hbaPortWWN*.
HBA_STATUS_ERROR_NOT_SUPPORTED	The HBA referenced by *handle* does not support target mapping.

Item	Description
HBA_STATUS_ERROR	Returned to indicate any problem with no required value.

HBA_GetFcpTargetMapping Subroutine

Purpose

Gets mapping of OS identification to FCP indentification for each child of the specified HBA_HANDLE.

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

HBA_STATUS HBA_GetFcpTargetMapping (handle, mapping)
HBA_HANDLE handle;
PHBA_FCPTARGETMAPPING mapping;
```

Description

For the specified HBA_HANDLE, the **HBA_GetFcpTargetMapping** subroutine maps OS identification of all its SCSI logical units to their FCP indentification. Applications must allocate memory for the **HBA_FCPTargetMapping** structure, and also pass to the subroutine the number of entries allocated. If the subroutine determines that the structure is not large enough to represent the entire mapping, it will set the *NumberOfEntries* variable to the correct value and return an error.

Parameters

Item	Description
handle	An HBA_HANDLE to an open adapter.

mapping	A pointer to a structure containing a mapping of the handle's children. The **HBA_FCPTARGETMAPPING** structure has the following form:
	`struct HBA_FCPTargetMapping (`
	`HBA_UINT32 NumberOfEntries;`
	`HBA_FCPSCSIENTRY entry[1] /* Variable length array containing mappings */`
	`);`
	The size of the structure is determined by the calling application, and is passed in by the *NumberOfEntries* variable.

Return Values

If successful, HBA_STATUS_OK is returned and the mapping parameter points to the full mapping structure. If the application has not allocated enough space for the full mapping, HBA_STATUS_ERROR_MORE_DATA is returned, and the *NumberOfEntries* field in the mapping structure is set to the correct value.

Error Codes

If there is insufficient space allocated for the full mapping, HBA_STATUS_ERROR_MORE_DATA is returned.

HBA_GetNumberOfAdapters Subroutine

Purpose

Returns the number of adapters discovered on the system.

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

HBA_UINT32 HBA_GetNumberOfAdapters ()
```

Description

The **HBA_GetNumberOfAdapters** subroutine returns the number of HBAs supported by the library. The value returned is the current number of HBAs and reflects dynamic change of the HBA inventory without requiring a restart of the system, driver, or library.

Return Values

The **HBA_GetNumberOfAdapters** subroutine returns an integer representing the number of adapters on the machine.

HBA_GetPersistentBindingV2 Subroutine

Purpose

Returns persistent bindings between an FCP target and a SCSI ID for a specified HBA end port.

Syntax

```
HBA_STATUS HBA_GetPersistentBindingV2(
        HBA_HANDLE handle,
        HBA_WWN hbaPortWWN,
        HBA_FCPTARGETMAPPINGV2 *binding
);
```

Description

The **HBA_GetFcpPersistentBindingV2** function returns persistent bindings between an FCP target and a SCSI ID for a specified HBA end port. The binding information can include bindings to Logical Unit Unique Device Identifiers (LUIDs).

Parameters

Item	Description
handle	A handle to an open HBA containing the end port for which persistent binding can be returned.
hbaPortWWN	The Port Name of the local HBA end port for which persistent binding can be returned.

Item	Description
binding	Pointer to an **HBA_FCPBINDING2** structure. The *NumberOfEntries* field in the structure limits the number of entries that are returned.

Return Values

The value of the **HBA_GetPersistentBindingV2** function is a valid status return value that indicates the reason for completion of the requested function. **HBA_STATUS_OK** is returned to indicate that all binding entries have been returned for the specified end port. A valid status return value that most closely describes the result of the function should be returned to indicate a reason with no required value.

The return value for the following parameter is as follows:

Item	Description
binding	Remains unchanged. The structure to which it points contains binding information from OS identifications of SCSI logical units to FCP and LUID identifications of logical units for the specified HBA end port. The number of entries in the structure is the minimum of the number of entries specified at function call or the full set of bindings. The *NumberOfEntries* field contains the total number of bindings established by the end port. An application can either call **HBA_GetPersistentBindingV2** with *NumberOfEntries* set to 0 to retrieve the number of entries available, or allocate a sufficiently large buffer to retrieve entries at first call. The **Status** field of each **HBA_FCPBINDINGENTRY2** substructure is 0.

Error Codes

Item	Description
HBA_STATUS_ERROR_MORE_DATA	More space in the buffer is required to contain binding information.
HBA_STATUS_ERROR_ILLEGAL_WWN	The HBA referenced by *handle* does not contain an end port with Port Name *hbaPortWWN*.
HBA_STATUS_ERROR_NOT_SUPPORTED	The HBA referenced by *handle* does not support persistent binding.
HBA_STATUS_ERROR	Returned to indicate any problem with no required value.

HBA_GetPortStatistics Subroutine

Purpose

Gets the statistics for a Host Bus Adapter (HBA).

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

HBA_STATUS HBA_GetPortStatistics (handle, portindex, portstatistics)
HBA_HANDLE handle;
```

```
HBA_UINT32 portindex;
HBA_PORTSTATISTICS *portstatistics;
```

Description

The **HBA_GetPortStatistics** subroutine retrieves the statistics for the specified adapter. Only single-port adapters are supported, and the *portindex* parameter is disregarded. The exact meaning of events being counted for each statistic is vendor specific. The **HBA_PORTSTATISTICS** structure includes the following fields:

- *SecondsSinceLastReset*
- *TxFrames*
- *TxWords*
- *RxFrames*
- *RxWords*
- *LIPCount*
- *NOSCount*
- *ErrorFrames*
- *DumpedFrames*
- *LinkFailureCount*
- *LossOfSyncCount*
- *LossOfSignalCount*
- *PrimitiveSeqProtocolErrCount*
- *InvalidTxWordCount*
- *InvalidCRCCount*

Parameters

Item	Description
handle	HBA_HANDLE to an open adapter.
portindex	Not used.
portstatistics	Pointer to an HBA_PORTSTATISTICS structure.

HBA_GetRNIDMgmtInfo Subroutine

Purpose

Sends a **SCSI GET RNID** command to a remote port of the end device.

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

HBA_STATUS HBA_GetRNIDMgmtInfo (handle, pInfo)
HBA_HANDLE handle;
HBA_MGMTINFO *pInfo;
```

Description

The **HBA_SetRNIDMgmtInfo** subroutine sends a **SCSI GET RNID** (Request Node Identification Data) command through a call to **ioctl** with the **SCIOLCHBA** operation as its argument. The *arg* parameter for the **SCIOLCHBA** operation is the address of a **scsi_chba** structure. This structure is defined in the **/usr/include/sys/scsi_buf.h** file. The *scsi_chba* parameter block allows the caller to select the **GET RNID** command to be sent to the adapter. The **pInfo** structure stores the RNID data returned from **SCIOLCHBA**. The **pInfo** structure is defined in the **/usr/include/sys/hbaapi.h** file. The structure includes:

- wwn
- unittype
- PortId
- NumberOfAttachedNodes
- IPVersion
- UDPort
- IPAddress
- reserved
- TopologyDiscoveryFlags

If successful, the GET RNID data in *pInfo* is returned from the adapter.

Parameters

Item	Description
handle	Specifies the open file descriptor obtained from a successful call to the **open** subroutine.
pInfo	Specifies the structure containing the information to get or set from the **RNID** command

Return Values

Upon successful completion, the **HBA_GetRNIDMgmtInfo** subroutine returns a pointer to a structure containing the data from the **GET RNID** command and a value of HBA_STATUS_OK, or a value of 0. If unsuccessful, a null value is returned along with a value of HBA_STATUS_ERROR, or a value of 1.

Upon successful completion, the **HBA_SetRNIDMgmtInfo** subroutine returns a value of HBA_STATUS_OK, or a value of 0. If unsuccessful, an HBA_STATUS_ERROR value, or a value of 1 is returned.

Error Codes

The Storage Area Network Host Bus Adapter API subroutines return the following error codes:

Item	Description
HBA_STATUS_OK	A value of 0 on successful completion.
HBA_STATUS_ERROR	A value of 1 if an error occurred.
HBA_STATUS_ERROR_INVALID_HANDLE	A value of 3 if there was an invalid file handle.

HBA_GetVersion Subroutine

Purpose

Returns the version number of the Common HBA API.

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

HBA_UINT32 HBA_GetVersion ()
```

Description

The **HBA_GetVersion** subroutine returns the version number representing the release of the Common HBA API.

Return Values

Upon successful completion, the **HBA_GetVersion** subroutine returns an integer value designating the version number of the Common HBA API.

HBA_LoadLibrary Subroutine

Purpose

Loads a vendor specific library from the Common HBA API.

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

HBA_STATUS HBA_LoadLibrary ()
```

Description

The **HBA_LoadLibrary** subroutine loads a vendor specific library from the Common HBA API. This library must be called first before calling any other routine from the Common HBA API.

Return Values

The **HBA_LoadLibrary** subroutine returns a value of 0, or **HBA_STATUS_OK**.

HBA_OpenAdapter Subroutine

Purpose

Opens the specified adapter for reading.

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

HBA_HANDLE HBA_OpenAdapter (adaptername)
char *adaptername;
```

Description

The **HBA_OpenAdapter** subroutine opens the adapter for reading for the purpose of getting it ready for additional calls from other subroutines in the Common HBA API.

The **HBA_OpenAdapter** subroutine allows an application to open a specified HBA device, giving the application access to the device through the HBA_HANDLE return value. The library ensures that all access to this HBA_HANDLE between **HBA_OpenAdapter** and **HBA_CloseAdapter** calls is to the same device.

Parameters

Item	Description
adaptername	Specifies a string that contains the description of the adapter as returned by the **HBA_GetAdapterName** subroutine.

Return Values

If successful, the **HBA_OpenAdapter** subroutine returns an HBA_HANDLE with a value greater than 0. If unsuccessful, the subroutine returns a 0.

HBA_OpenAdapterByWWN Subroutine

Purpose

Attempts to open a handle to the HBA that contains a **Node_Name** or **N_Port_Name** matching the *wwn* argument.

Syntax

```
HBA_STATUS HBA_OpenAdapterByWWN(
        HBA_HANDLE *pHandle,
        HBA_WWN wwn
);
```

Description

The **HBA_OpenAdapterByWWN** function attempts to open a handle to the HBA that contains a **Node_Name** or **N_Port_Name** matching the *wwn* argument. The specified **Name_Identifier** matches the **Node_Name** or **N_Port_Name** of the HBA. Discovered end ports (remote end ports) are *not* checked for a match.

Parameters

Item	Description
pHandle	Pointer to a handle. The value at entry is irrelevant.
wwn	**Name_Identifier** to match the **Node_Name** or **N_Port_Name** of the HBA to open.

Return Values

The value of the **HBA_OpenAdapterByWWN** function is a valid status return value that indicates the reason for completion of the requested function. **HBA_STATUS_OK** is returned to indicate that the handle contains a valid HBA handle.

The return values for the following parameter is as follows:

Item	Description
pHandle	Remains unchanged. If the open succeeds, the value to which it points is a handle to the requested HBA. On failure, the value is undefined.

Error Codes

Item	Description
HBA_STATUS_ERROR_ILLEGAL_WWN	There is no HBA with a **Node_Name** or **N_Port_Name** that matches *wwn*.
HBA_STATUS_ERROR_AMBIGUOUS_WWN	Multiple HBAs have a matching **Name_Identifier**. This can occur if the **Node_Name**s of multiple HBAs are identical.
HBA_STATUS_ERROR	Returned to indicate any other problem with opening the HBA.

HBA_RefreshInformation Subroutine

Purpose

Refreshes stale information from the Host Bus Adapter.

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

void HBA_RefreshInformation (handle)
HBA_HANDLE handle;
```

Description

The **HBA_RefreshInformation** subroutine refreshes stale information from the Host Bus Adapter. This would reflect changes to information obtained from calls to the **HBA_GetAdapterPortAttributes**, or **HBA_GetDiscoveredPortAttributes** subroutine. Once the application calls the **HBA_RefreshInformation** subroutine, it can proceed to the attributes's call to get the new data.

Parameters

Item	Description
handle	Specifies the open file descriptor obtained from a successful call to the **open** subroutine for which the refresh operation is to be performed.

HBA_ScsiInquiryV2 Subroutine

Purpose

Sends a SCSI INQUIRY command to a remote end port.

Syntax

```
HBA_STATUS HBA_ScsiInquiryV2 (
        HBA_HANDLE handle,
        HBA_WWN hbaPortWWN,
        HBA_WWN discoveredPortWWN,
        HBA_UINT64 fcLUN,
        HBA_UINT8 CDB_Byte1,
        HBA_UINT8 CDB_Byte2,
        void *pRspBuffer,
        HBA_UINT32 *pRspBufferSize,
        HBA_UINT8 *pScsiStatus,
        void *pSenseBuffer,
        HBA_UINT32 *pSenseBufferSize
);
```

Description

The **HBA_ScsiInquiryV2** function sends a **SCSI INQUIRY** command to a remote end port.

A SCSI command is never sent to an end port that does not have SCSI target functionality. If sending a SCSI command causes a SCSI overlapped command condition with a correctly operating target, the command does not get sent. Proper use of tagged commands is an acceptable means of avoiding a SCSI overlapped command condition with targets that support tagged commands.

Parameters

Item	Description
handle	Open HBA through which the **SCSI INQUIRY** command can be issued.
hbaPortWWN	The Port Name for a local HBA end port through which the **SCSI INQUIRY** command can be issued.
discoveredPortWWN	The Port Name for an end port to which the **SCSI INQUIRY** command can be sent.
fcLUN	The SCSI LUN to which the **SCSI INQUIRY** command can be sent.
CDB_Byte1	The second byte of the CDB for the **SCSI INQUIRY** command. This contains control flag bits. At the time this standard was written, the effects of the value of CDB_Byte1 on a SCSI INQUIRY command were as follows: • 0 – Requests the standard SCSI INQUIRY data. • 1 – Requests the vital product data (EVPD) specified by *CDB_Byte2*. • 2 – Requests command support data (**CmdDt**) for the command specified in *CDB_Byte2*. • Other values – Can cause SCSI Check Condition.

Item	Description
CDB_Byte2	The third byte of the CDB for the **SCSI INQUIRY** command. If *CDB_Byte1* is 1, *CDB_Byte2* is the Vital Product Data page code to request. If *CDB_Byte1* is 2, *CDB_Byte2* is the Operation Code of the command support data requested. For other values of *CDB_Byte1*, the value of *CDB_Byte2* is unspecified, and values other than 0 can cause a SCSI Check Condition.
pRspBuffer	A pointer to a buffer to receive the **SCSI INQUIRY** command response.
pRspBufferSize	A pointer to the size in bytes of the buffer to receive the **SCSI INQUIRY** command response.
pScsiStatus	A pointer to a buffer to receive SCSI status.
pSenseBuffer	A pointer to a buffer to receive SCSI sense data.
pSenseBufferSize	A pointer to the size in bytes of the buffer to receive SCSI sense data.

Return Values

The value of the **HBA_ScsiInquiryV2** function is a valid status return value that indicates the reason for completion of the requested function. **HBA_STATUS_OK** is returned to indicate that the complete payload of a reply to the **SCSI INQUIRY** command has been returned. A valid status return value that most closely describes the result of the function should be returned to indicate a reason with no required value.

The return values for the following parameters are as follows:

Item	Description
pRspBuffer	Remains unchanged. If the function value is **HBA_STATUS_OK**, the buffer to which it points contains the response to the **SCSI INQUIRY** command.
pRspBufferSize	Remains unchanged. The value of the integer to which it points is the size in bytes of the response returned by the command. This cannot exceed the size passed as an argument at this pointer.
pScsiStatus	Remains unchanged. The value of the byte to which it points is the SCSI status. If the function value is **HBA_STATUS_OK** or **HBA_STATUS_SCSI_CHECK_CONDITION**, the value of the SCSI status can be interpreted based on the SCSI spec. A SCSI status of **HBA_STATUS_OK** indicates that a SCSI response is in the response buffer. A SCSI status of **HBA_STATUS_SCSI_CHECK_CONDITION** indicates that no value is stored in the response, and the sense buffer contains failure information if available.
pSenseBuffer	Remains unchanged. If the function value is **HBA_STATUS_SCSI_CHECK_CONDITION**, the buffer to which it points contains the sense data for the command.
pSenseBufferSize	Remains unchanged. The value of the integer to which it points is the size in bytes of the sense information returned by the command. This cannot exceed the size passed as an argument at this pointer.

Error Codes

Item	Description
HBA_STATUS_ERROR_ILLEGAL_WWN	The HBA referenced by handle does not contain an end port with Port Name *hbaPortWWN*.
HBA_STATUS_ERROR_NOT_A_TARGET	The identified remote end port does not have SCSI Target functionality.

Item	Description
HBA_STATUS_ERROR_TARGET_BUSY	Unable to send the requested command without causing a SCSI overlapped command condition.
HBA_STATUS_ERROR	Returned to indicate any problem with no required value.

HBA_ScsiReadCapacityV2 Subroutine

Purpose

Sends a SCSI READ CAPACITY command to a remote end port.

Syntax

```
HBA_STATUS HBA_ScsiReadCapacityV2(
        HBA_HANDLE handle,
        HBA_WWN hbaPortWWN,
        HBA_WWN discoveredPortWWN,
        HBA_UINT64 fcLUN,
        void *pRspBuffer,
        HBA_UINT32 *pRspBufferSize,
        HBA_UINT8 *pScsiStatus,
        void *pSenseBuffer,
        HBA_UINT32 *pSenseBufferSize
);
```

Description

The **HBA_ScsiReadCapacityV2** function sends a SCSI READ CAPACITY command to a remote end port.

A SCSI command is never sent to an end port that does not have SCSI target functionality. If sending a SCSI command causes a SCSI overlapped command condition with a correctly operating target, the command will not be sent. Proper use of tagged commands is an acceptable means of avoiding a SCSI overlapped command condition with targets that support tagged commands.

Parameters

Item	Description
handle	A handle to an open HBA through which the SCSI READ CAPACITY command is issued.
hbaPortWWN	The Port Name for a local HBA end port through which the SCSI READ CAPACITY command is issued.
discoveredPortWWN	The Port Name for an end port to which the SCSI READ CAPACITY command is sent.
fcLUN	The SCSI LUN to which the SCSI READ CAPACITY command is sent.
pRspBuffer	Pointer to a buffer to receive the SCSI READ CAPACITY command response.
pRspBufferSize	Pointer to the size in bytes of the buffer to receive the SCSI READ CAPACITY command response.
pScsiStatus	Pointer to a buffer to receive SCSI status.
pSenseBuffer	Pointer to a buffer to receive SCSI sense data.
pSenseBufferSize	Pointer to the size in bytes of the buffer to receive SCSI sense data.

Return Values

The value of the **HBA_ScsiReadCapacityV2** function is a valid status return value that indicates the reason for completion of the requested function. **HBA_STATUS_OK** is returned to indicate that the complete payload of a reply to the SCSI READ CAPACITY command has been returned. A valid status return value that most closely describes the result of the function should be returned to indicate a reason with no required value.

The return values for the following parameters are as follows:

Item	Description
pRspBuffer	Remains unchanged. If the function value is **HBA_STATUS_OK**, the buffer to which it points contains the response to the SCSI READ CAPACITY command.
pRspBufferSize	Remains unchanged. The value of the integer to which it points is the size in bytes of the response returned by the command. This cannot exceed the size passed as an argument at this pointer.
pScsiStatus	Remains unchanged. The value of the byte to which it points is the SCSI status. If the function value is **HBA_STATUS_OK** or **HBA_STATUS_SCSI_CHECK_CONDITION**, the value of the SCSI status can be interpreted based on the SCSI spec. A SCSI status of **HBA_STATUS_OK** indicates that a SCSI response is in the response buffer. A SCSI status of **HBA_STATUS_SCSI_CHECK_CONDITION** indicates that no value is stored in the response, and the sense buffer contains failure information if available.
pSenseBuffer	Remains unchanged. If the function value is **HBA_STATUS_SCSI_CHECK_CONDITION**, the buffer to which it points contains the sense data for the command.
pSenseBufferSize	Remains unchanged. The value of the integer to which it points is the size in bytes of the sense information returned by the command. This cannot exceed the size passed as an argument at this pointer.

Error Codes

Item	Description
HBA_STATUS_ERROR_ILLEGAL_WWN	The HBA referenced by *handle* does not contain an end port with Port Name *hbaPortWWN*.
HBA_STATUS_ERROR_NOT_A_TARGET	The identified remote end port does not have SCSI Target functionality.
HBA_STATUS_ERROR_TARGET_BUSY	Unable to send the requested command without causing a SCSI overlapped command condition.
HBA_STATUS_ERROR	Returned to indicate any problem with no required value.

HBA_ScsiReportLunsV2 Subroutine

Purpose

Sends a SCSI REPORT LUNS command to Logical Unit Number 0 of a remote end port.

Syntax

```
HBA_STATUS HBA_ScsiReportLUNsV2(
        HBA_HANDLE handle,
```

```
        HBA_WWN hbaPortWWN,
        HBA_WWN discoveredPortWWN,
        void *pRspBuffer,
        HBA_UINT32 *pRspBufferSize,
        HBA_UINT8 *pScsiStatus,
        void *pSenseBuffer,
        HBA_UINT32 *pSenseBufferSize
);
```

Description

The **HBA_ScsiReportLunsV2** function shall send a SCSI REPORT LUNS command to Logical Unit Number 0 of a remote end port.

A SCSI command is never sent to an end port that does not have SCSI target functionality. If sending a SCSI command causes a SCSI overlapped command condition with a correctly operating target, the command will not be sent. Proper use of tagged commands is an acceptable means of avoiding a SCSI overlapped command condition with targets that support tagged commands.

Parameters

Item	Description
handle	A handle to an open HBA through which the SCSI REPORT LUNS command is issued.
hbaPortWWN	The Port Name for a local HBA end port through which the SCSI REPORT LUNS command is issued.
discoveredPortWWN	The Port Name for an end port to which the SCSI REPORT LUNS command is sent.
pRspBuffer	Pointer to a buffer to receive the SCSI REPORT LUNS command response.
pRspBufferSize	Pointer to the size in bytes of the buffer to receive the SCSI REPORT LUNS command response.
pScsiStatus	Pointer to a buffer to receive SCSI status.
pSenseBuffer	Pointer to a buffer to receive SCSI sense data.
pSenseBufferSize	Pointer to the size in bytes of the buffer to receive SCSI sense data.

Return Values

The value of the **HBA_ScsiReportLunsV2** function is a valid status return value that indicates the reason for completion of the requested function. **HBA_STATUS_OK** is returned to indicate that the complete payload of a reply to the SCSI REPORT LUNS command has been returned. A valid status return value that most closely describes the result of the function should be returned to indicate a reason with no required value.

The return values for the following parameters are as follows:

Item	Description
pRspBuffer	Remains unchanged. If the function value is **HBA_STATUS_OK**, the buffer to which it points contains the response to the SCSI REPORT LUNS command.
pRspBufferSize	Remains unchanged. The value of the integer to which it points is the size in bytes of the response returned by the command. This cannot exceed the size passed as an argument at this pointer.

Item	Description
pScsiStatus	Remains unchanged. The value of the byte to which it points is the SCSI status. If the function value is **HBA_STATUS_OK** or **HBA_STATUS_SCSI_CHECK_CONDITION**, the value of the SCSI status can be interpreted based on the SCSI spec. A SCSI status of **HBA_STATUS_OK** indicates that a SCSI response is in the response buffer. A SCSI status of **HBA_STATUS_SCSI_CHECK_CONDITION** indicates that no value is stored in the response, and the sense buffer contains failure information if available.
pSenseBuffer	Remains unchanged. If the function value is **HBA_STATUS_SCSI_CHECK_CONDITION**, the buffer to which it points contains the sense data for the command.
pSenseBufferSize	Remains unchanged. The value of the integer to which it points is the size in bytes of the sense information returned by the command. This cannot exceed the size passed as an argument at this pointer.

Error Codes

Item	Description
HBA_STATUS_ERROR_ILLEGAL_WWN	The HBA referenced by *handle* does not contain an end port with Port Name *hbaPortWWN*.
HBA_STATUS_ERROR_NOT_A_TARGET	The identified remote end port does not have SCSI Target functionality.
HBA_STATUS_ERROR_TARGET_BUSY	Unable to send the requested command without causing a SCSI overlapped command condition.
HBA_STATUS_ERROR	Returned to indicate any problem with no required value.

HBA_SendCTPassThru Subroutine

Purpose

Sends a CT pass through frame.

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

HBA_STATUS HBA_SendCTPassThru (handle, pReqBuffer, ReqBufferSize, pRspBuffer, RspBufferSize)
HBA_HANDLE handle;
void *pReqBuffer;
HBA_UINT32 ReqBufferSize;
void *pRspBuffer;
HBA_UINT32 RspBufferSize;
```

Description

The **HBA_SendCTPassThru** subroutine sends a CT pass through frame to a fabric connected to the specified handle. The CT frame is routed in the fabric according to the *GS_TYPE* field in the CT frame.

Parameters

Item	Description
handle	HBA_HANDLE to an open adapter.
pReqBuffer	Pointer to a buffer that contains the CT request.
ReqBufferSize	Size of the request buffer.
pRspBuffer	Pointer to a buffer that receives the response of the command.
RspBufferSize	Size of the response buffer.

Return Values

If successful, HBA_STATUS_OK is returned, and the *pRspBuffer* parameter points to the CT response.

Error Codes

If the adapter specified by the *handle* parameter is connected to an arbitrated loop, the **HBA_SendCTPassThru** subroutine returns HBA_STATUS_ERROR_NOT_SUPPORTED. This subroutine is only valid when connected to a fabric.

HBA_SendCTPassThruV2 Subroutine

Purpose

Sends a CT request payload.

Syntax

```
HBA_STATUS HBA_SendCTPassThruV2(
        HBA_HANDLE handle,
        HBA_WWN hbaPortWWN,
        void *pReqBuffer,
        HBA_UINT32 *ReqBufferSize,
        void *pRspBuffer,
        HBA_UINT32 *pRspBufferSize,
);
```

Description

The **HBA_SendCTPassThruV2** function sends a CT request payload. An HBA should decode this CT_IU request by, routing the CT frame in a fabric according to the **GS_TYPE** field within the CT frame.

Parameters

Item	Description
handle	A handle to an open HBA through which the CT request is issued.
hbaPortWWN	The Port Name for a local HBA **Nx_Port** through which the CT request is issued.
pReqBuffer	Pointer to a buffer containing the full CT payload, including the CT header, to be sent with byte ordering.
ReqBufferSize	The size of the full CT payload, including the CT header, in bytes.
pRSPBuffer	Pointer to a buffer for the CT response.
pRSPBufferSize	Pointer to the size in bytes of the buffer for the CT response payload.

Return Values

The value of the **SendCTPassThruV2** function is a valid status return value that indicates the reason for completion of the requested function. **HBA_STATUS_OK** is returned to indicate that the complete reply to the CT **Passthru** command has been returned. A valid status return value that most closely describes the result of the function should be returned to indicate a reason with no required value.

The return values for the following parameters are as follows:

Item	Description
pRspBuffer	Remains unchanged. The buffer to which it points contains the CT response payload, including the CT header received in response to the frame sent, with byte ordering. If the size of the actual response exceeds the size of the response buffer, trailing data is truncated from the response so that the returned data equals the size of the buffer.
pRspBufferSize	Remains unchanged. The value of the integer to which it points is set to the size (in bytes) of the actual response data.

Error Codes

Item	Description
HBA_STATUS_ERROR_ILLEGAL_WWN	The HBA referenced by *handle* does not contain an **Nx_Port** with Port Name *hbaPortWWN*.
HBA_STATUS_ERROR	Returned to indicate any problem with no required value.

HBA_SendReadCapacity Subroutine

Purpose

Sends a **SCSI READ CAPACITY** command to a Fibre Channel port.

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

HBA_STATUS HBA_SendReadCapacity (handle, portWWN, fcLUN, pRspBuffer, RspBufferSize,
pSenseBuffer,
SenseBufferSize)
HBA_HANDLE handle;
HBA_WWN portWWN;
HBA_UINT64 fcLUN;
void *pRspBuffer;
HBA_UINT32 RspBufferSize;
void *pSenseBuffer;
HBA_UINT32 SenseBufferSize;
```

Description

The **HBA_SendReadCapacity** subroutine sends a **SCSI READ CAPACITY** command to the Fibre Channel port connected to the *handle* parameter and specified by the *portWWN* and *fcLUN* parameters.

Parameters

Item	Description
handle	HBA_HANDLE to an open adapter.
portWWN	Port world-wide name of an adapter.
fcLUN	Fibre Channel LUN to send the **SCSI READ CAPACITY** command to.
pRspBuffer	Pointer to a buffer that receives the response of the command.
RspBufferSize	Size of the response buffer.
pSenseBuffer	Pointer to a buffer that receives sense information.
SenseBufferSize	Size of the sense buffer.

Return Values

If successful, HBA_STATUS_OK is returned and the *pRspBuffer* parameter points to the response to the **READ CAPACITY** command. If an error occurs, HBA_STATUS_ERROR is returned.

Error Codes

If the *portWWN* value is not a valid world-wide name connected to the specified handle, HBA_STATUS_ERROR_ILLEGAL_WWN is returned. On any other types of failures, HBA_STATUS_ERROR is returned.

HBA_SendReportLUNs Subroutine

Purpose

Sends a **SCSI REPORT LUNs** command to a remote port of the end device.

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

HBA_STATUS HBA_SendReportLUNs (handle, PortWWN, pRspBuffer, RspBufferSize, pSenseBuffer, SenseBufferSize)
HBA_HANDLE handle;
HBA_WWN PortWWN;
void *pRspBuffer;
HBA_UINT32 RspBufferSize;
void *pSenseBuffer;
HBA_UINT32 SenseBufferSize;
```

Description

The **HBA_SendReportLUNs** subroutine sends a **SCSI REPORT LUNs** command through a call to **ioctl** with the **SCIOLCMD** operation as its argument. The *arg* parameter for the **SCIOLCMD** operation is the address of a **scsi_iocmd** structure. This structure is defined in the **/usr/include/sys/scsi_buf.h** file. The *scsi_iocmd* parameter block allows the caller to select the SCSI and LUN IDs to be queried. The caller also specifies the SCSI command descriptor block area, command length (SCSI command block length), the time-out value for the command, and a *flags* field.

If successful, the report LUNs data is returned in *pRspBuffer*. The returned report LUNs data must be examined to see if the requested LUN exists.

Parameters

Item	Description
handle	Specifies the open file descriptor obtained from a successful call to the **open** subroutine.
PortWWN	Specifies the world wide name or port name of the target device.
pRspBuffer	Points to a buffer containing the requested instruction for a send/read capacity request to an open adapter.
RspBufferSize	Specifies the size of the buffer to the *pRspBuffer* parameter.
pSenseBuffer	Points to a buffer containing the data returned from a send/read capacity request to an open adapter.
SenseBufferSize	Specifies the size of the buffer to the *pSenseBuffer* parameter.

Return Values

Upon successful completion, the **HBA_SendReportLUNs** subroutine returns a buffer in bytes containing the SCSI report of LUNs, a buffer containing the SCSI sense data, and a value of HBA_STATUS_OK, or a value of 0.

If unsuccessful, an empty buffer for the SCSI report of LUNs, a response buffer containing the failure, and a value of HBA_STATUS_ERROR, or a value of 1 is returned.

Error Codes

The Storage Area Network Host Bus Adapter API subroutines return the following error codes:

Item	Description
HBA_STATUS_OK	A value of 0 on successful completion.
HBA_STATUS_ERROR	A value of 1 if an error occurred.
HBA_STATUS_ERROR_INVALID_HANDLE	A value of 3 if there was an invalid file handle.
HBA_STATUS_ERROR_ILLEGAL_WWN	A value of 5 if the world wide name was not recognized.
HBA_STATUS_SCSI_CHECK_CONDITION	A value of 9 if a SCSI Check Condition was reported.

HBA_SendRLS Subroutine

Purpose

Issues a Read Link Error Status Block (RLS) Extended Link Service through the specified HBA end port.

Syntax

```
HBA_STATUS HBA_SendRLS (
        HBA_HANDLE handle,
        HBA_WWN hbaPortWWN,
        HBA_WWN destWWN,
        void *pRspBuffer,
        HBA_UINT32 *pRspBufferSize,
);
```

Description

The **HBA_SendRLS** function issues a Read Link Error Status Block (RLS) Extended Link Service through the specified HBA end port to request a specified remote FC_Port to return the Link Error Status Block associated with the destination Port Name.

Parameters

Item	Description
handle	A handle to an open HBA through which the ELS is sent.
hbaPortWWN	Port Name of the local HBA end port through which the ELS is sent.
destWWN	Port Name of the remote FC_Port to which the ELS is sent.
pRspBuffer	Pointer to a buffer to receive the ELS response.
pRSPBufferSize	Pointer to the size in bytes of *pRspBuffer*. A size of 28 is sufficient for the largest response.

Return Values

The value of the **HBA_SendRLS** function is a valid status return value that indicates the reason for completion of the requested function. **HBA_STATUS_OK** is returned to indicate that the complete LS_ACC to the RLS ELS has been returned. A valid status return value that most closely describes the result of the function should be returned to indicate a reason with no required value.

The return values for the following parameters are as follows:

Item	Description
pRspBuffer	Remains unchanged. The buffer to which it points contains the payload data from the RLS Reply. Note that if the ELS was rejected, this is the LS_RJT payload. If the size of the reply payload exceeds the size specified in the *pRspBufferSize* parameter at entry to the function, the returned data is truncated to the size specified in the argument.
pRspBufferSize	Remains unchanged. The value of the integer to which it points contains the size in bytes of the complete ELS reply payload. This can exceed the size specified as an argument. This indicates that the data in *pRspBuffer* has been truncated.

Error Codes

Item	Description
HBA_STATUS_ERROR_ELS_REJECT	The RNID ELS was rejected by the destination FC_Port.
HBA_STATUS_ERROR_ILLEGAL_WWN	The HBA referenced by *handle* does not contain an end port with Port Name *hbaPortWWN*.
HBA_STATUS_ERROR	Returned to indicate any problem with no required value.

HBA_SendRNID Subroutine

Purpose

Sends an RNID command through a call to **SCIOLPAYLD** to a remote port of the end device.

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

HBA_STATUS HBA_SendRNID (handle, wwn, wwntype, pRspBuffer, RspBufferSize)
HBA_HANDLE handle;
HBA_WWN wwn;
HBA_WWNTYPE wwntype;
void *pRspBuffer;
HBA_UINT32 RspBufferSize;
```

Description

The **HBA_SendRNID** subroutine sends a **SCSI RNID** command with the Node Identification Data Format set to indicate the default Topology Discovery format. This is done through a call to **ioctl** with the **SCIOLPAYLD** operation as its argument. The *arg* parameter for the **SCIOLPAYLD** operation is the address of an **scsi_trans_payld** structure. This structure is defined in the **/usr/include/sys/scsi_buf.h** file. The *scsi_trans_payld* parameter block allows the caller to select the SCSI and LUN IDs to be queried. In addition, the caller must specify the **fcph_rnid_payld_t** structure to hold the command and the topology format for **SCIOLPAYLD**. The structure for the **fcph_rnid_payld_t** structure is defined in the **/usr/include/sys/fcph.h** file.

If successful, the RNID data is returned in *pRspBuffer*. The returned RNID data must be examined to see if the requested information exists.

Parameters

Item	Description
handle	Specifies the open file descriptor obtained from a successful call to the **open** subroutine.
wwn	Specifies the world wide name or port name of the target device.
wwntype	Specifies the type of the world wide name or port name of the target device.
pRspBuffer	Points to a buffer containing the requested instruction for a send/read capacity request to an open adapter.
RspBufferSize	Specifies the size of the buffer to the *pRspBuffer* parameter.

Return Values

Upon successful completion, the **HBA_SendRNID** subroutine returns a buffer in bytes containing the SCSI RNID data and a value of HBA_STATUS_OK, or a value of 0. If unsuccessful, an empty buffer for the SCSI RNID and a value of HBA_STATUS_ERROR, or a value of 1 is returned.

Error Codes

The Storage Area Network Host Bus Adapter API subroutines return the following error codes:

Item	Description
HBA_STATUS_OK	A value of 0 on successful completion.
HBA_STATUS_ERROR	A value of 1 if an error occurred.
HBA_STATUS_ERROR_NOT_SUPPORTED	A value of 2 if the function is not supported.
HBA_STATUS_ERROR_INVALID_HANDLE	A value of 3 if there was an invalid file handle.
HBA_STATUS_ERROR_ILLEGAL_WWN	A value of 5 if the world wide name was not recognized.

HBA_SendRNIDV2 Subroutine

Purpose

Issues an RNID ELS to another FC_Port requesting a specified Node Identification Data Format.

Syntax

```
HBA_STATUS HBA_SendRNIDV2(
        HBA_HANDLE handle,
        HBA_WWN hbaPortWWN,
        HBA_WWN destWWN,
        HBA_UINT32 destFCID,
        HBA_UINT32 NodeIdDataFormat,
        void *pRspBuffer,
        HBA_UINT32 *pRspBufferSize,
);
```

Description

The **HBA_SendRNIDV2** function issues an RNID ELS to another FC_Port requesting a specified Node Identification Data Format.

The *destFCID* parameter can be set to allow the RNID ELS to be sent to an FC_Port that might not be registered with the name server. If *destFCID* is set to x'00 00 00', the parameter is ignored. If *destFCID* is not 0, the HBA API library verifies that the *destWWN*/*destFCID* pair match in order to limit visibility that can violate scoping mechanisms (such as soft zoning):

- If the *destWWN*/*destFCID* pair matches an entry in the discovered ports table, the RNID is sent.
- If there is no entry in the discovered ports table for the *destWWN* or *destFCID*, the RNID is sent.
- If there is an entry in the discovered ports table for the *destWWN*, but the *destFCID* does not match, then the request is rejected.
- On completion of the **HBA_SendRNIDV2**, if the Common Identification Data Length is nonzero in the RNID response, the API library compares the **N_Port_Name** in the Common Identification Data of the RNID response with *destWWN* and fails the operation without returning the response data if they do not match. If the Common Identification Data Length is 0 in the RNID response, this test is omitted.

Parameters

Item	Description
handle	A handle to an open HBA through which the ELS is sent.
hbaPortWWN	Port Name of the local HBA end port through which the ELS is sent.
destWWN	Port Name of the remote FC_Port to which the ELS is sent.
destFCID	Address identifier of the destination to which the ELS is sent if *destFCID* is nonzero. *destFCID* is ignored if *destFCID* is 0.
NodeIdDataFormat	Valid value for Node Identification Data Format.
pRSPBuffer	Pointer to a buffer to receive the ELS response.
pRSPBufferSize	Pointer to the size in bytes of *pRspBuffer*.

Return Values

The value of the **HBA_SendRNIDV2** function is a valid status return value that indicates the reason for completion of the requested function. **HBA_STATUS_OK** is returned to indicate that the complete LS_ACC

to the RNID ELS has been returned. A valid status return value that most closely describes the result of the function should be returned to indicate a reason with no required value.

The return values for the following parameters are as follows:

Item	Description
pRspBuffer	Remains unchanged. The buffer to which it points contains the payload data from the RNID Reply. Note that if the ELS was rejected, this is the LS_RJT payload. If the size of the reply payload exceeds the size specified in the *pRspBufferSize* parameter at entry to the function, the returned data is truncated to the size specified in the argument.
pRspBufferSize	Remains unchanged. The value of the integer to which it points contains the size in bytes of the complete ELS reply payload. This can exceed the size specified as an argument. This indicates that the data in *pRspBuffer* has been truncated.

Error Codes

Item	Description
HBA_STATUS_ERROR_ELS_REJECT	The RNID ELS was rejected by the destination end port.
HBA_STATUS_ERROR_ILLEGAL_WWN	The HBA referenced by *handle* does not contain an end port with Port Name *hbaPortWWN*.
HBA_STATUS_ERROR_ILLEGAL_FCID	The *destWWN*/*destFCID* pair conflicts with a discovered Port Name/address identifier pair known by the HBA referenced by *handle*.
HBA_STATUS_ERROR_ILLEGAL_FCID	The **N_Port_Name** in the RNID response does not match the *destWWN*.
HBA_STATUS_ERROR	Returned to indicate any problem with no required value.

HBA_SendRPL Subroutine

Purpose

Issues a Read Port List (RPL) Extended Link Service through the specified HBA to a specified end port or domain controller.

Syntax

```
HBA_STATUS HBA_SendRPL (
        HBA_HANDLE handle,
        HBA_WWN hbaPortWWN,
        HBA_WWN agent_wwn,
        HBA_UINT32 agent_domain,
        HBA_UINT32 portIndex,
        void *pRspBuffer,
        HBA_UINT32 *pRspBufferSize,
);
```

Description

The **HBA_SendRPL** function issues a Read Port List (RPL) Extended Link Service through the specified HBA to a specified end port or domain controller.

Parameters

Item	Description
handle	A handle to an open HBA through which the ELS is sent.
hbaPortWWN	Port Name of the local HBA end port through which the ELS is sent.
agent_wwn	Port Name of an FC_Port that is requested to provide its list of FC_Ports if *agent_wwn* is nonzero. If *agent_wwn* is 0, it is ignored.
agent_domain	Domain number and the domain controller for that domain shall be the entity that shall be requested to provide its list of FC_Ports if *agent_wwn* is 0. If *agent_wwn* is nonzero, *agent_domain* is ignored.
portIndex	Index of the first FC_Port requested in the response list. **Note:** If the recipient has proper compliance, the index of the first FC_Port in the complete list maintained by the recipient of the request is 0.
pRSPBuffer	Pointer to a buffer to receive the ELS response.
pRSPBufferSize	Pointer to the size in bytes of *pRspBuffer*. **Note:** If the responding entity has proper compliance, it truncates the list in the response to the number of FC_Ports that fit.

Return Values

The value of the **HBA_SendRPL** function is a valid status return value that indicates the reason for completion of the requested function. **HBA_STATUS_OK** is returned to indicate that the complete LS_ACC to the RPL ELS has been returned. A valid status return value that most closely describes the result of the function should be returned to indicate a reason with no required value.

The return values for the following parameters are as follows:

Item	Description
pRspBuffer	Remains unchanged. The buffer to which it points contains the payload data from the RPL Reply. If the ELS was rejected, this is the LS_RJT payload. If the size of the reply payload exceeds the size specified in the *pRspBufferSize* parameter at entry to the function, the returned data is truncated to the size specified in the argument.
pRspBufferSize	Remains unchanged. The value of the integer to which it points contains the size in bytes of the complete ELS reply payload. This can exceed the size specified as an argument. This indicates that the data in *pRspBuffer* has been truncated. **Note:** Truncation is not necessary if the responding entity is of proper compliance.

Error Codes

Item	Description
HBA_STATUS_ERROR_ELS_REJECT	The RPL ELS was rejected by the destination end port.
HBA_STATUS_ERROR_ILLEGAL_WWN	The HBA referenced by *handle* does not contain an end port with Port Name *hbaPortWWN*.

Item	Description
HBA_STATUS_ERROR	Returned to indicate any problem with no required value.

HBA_SendRPS Subroutine

Purpose

Issues a Read Port Status Block (RPS) Extended Link Service through the specified HBA to a specified FC_Port or domain controller.

Syntax

```
HBA_STATUS HBA_SendRPS (
        HBA_HANDLE handle,
        HBA_WWN hbaPortWWN,
        HBA_WWN agent_wwn,
        HBA_UINT32 agent_domain,
        HBA_WWN object_wwn,
        HBA_UINT32 object_port_number,
        void *pRspBuffer,
        HBA_UINT32 *pRspBufferSize,
);
```

Description

The **HBA_SendRPS** function issues a Read Port Status Block (RPS) Extended Link Service through the specified HBA to a specified FC_Port or domain controller.

Parameters

Item	Description
handle	A handle to an open HBA through which the ELS is sent.
hbaPortWWN	Port Name of the local HBA end port through which the ELS is sent.
agent_wwn	Port Name of an FC_Port that is requested to provide Port Status if *agent_wwn* is nonzero. *agent_wwn* is ignored if its value is 0.
agent_domain	Domain number for the domain controller that is requested to provide Port status if *agent_wwn* is 0. *agent_domain* is ignored if *agent_wwn* is nonzero.
object_wwn	Port Name of an FC_Port for which Port Status is returned if *object_wwn* is nonzero. *object_wwn* is ignored if its value is 0.
object_port_number	Relative port number of the FC_Port for which Port Status is returned if *object_wwn* is 0. The relative port number is defined in a vendor-specific manner within the entity to which the request is sent. *object_port_number* is ignored if *object_wwn* is nonzero.
pRspBuffer	Pointer to a buffer to receive the ELS response.
pRSPBufferSize	Pointer to the size in bytes of *pRspBuffer*. A size of 56 is sufficient for the largest response.

Return Values

The value of the **HBA_SendRPS** function is a valid status return value that indicates the reason for completion of the requested function. **HBA_STATUS_OK** is returned to indicate that the complete LS_ACC

to the RPS ELS has been returned. A valid status return value that most closely describes the result of the function should be returned to indicate a reason with no required value.

The return values for the following parameters are as follows:

Item	Description
pRspBuffer	Remains unchanged. The buffer to which it points contains the payload data from the RPS Reply. If the ELS was rejected, this is the LS_RJT payload. If the size of the reply payload exceeds the size specified in the *pRspBufferSize* parameter at entry to the function, the returned data is truncated to the size specified in the argument.
pRspBufferSize	Remains unchanged. The value of the integer to which it points contains the size in bytes of the complete ELS reply payload. This can exceed the size specified as an argument. This indicates that the data in *pRspBuffer* has been truncated.

Error Codes

Item	Description
HBA_STATUS_ERROR_ELS_REJECT	The RPS ELS was rejected by the destination end port.
HBA_STATUS_ERROR_ILLEGAL_WWN	The HBA referenced by *handle* does not contain an end port with Port Name *hbaPortWWN*.
HBA_STATUS_ERROR	Returned to indicate any problem with no required value.

HBA_SendScsiInquiry Subroutine

Purpose

Sends a SCSI device inquiry command to a remote port of the end device.

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

HBA_STATUS HBA_SendScsiInquiry (handle, PortWWN, fcLUN, EVPD, PageCode, pRspBuffer, RspBufferSize,
pSenseBuffer,
SenseBufferSize)
HBA_HANDLE handle;
HBA_WWN PortWWN;
HBA_UINT64 fcLUN;
HBA_UINT8 EVPD;
HBA_UINT32 PageCode;
void *pRspBuffer;
HBA_UINT32 RspBufferSize;
void *pSenseBuffer;
HBA_UINT32 SenseBufferSize;
```

Description

The **HBA_SendScsiInquiry** subroutine sends a **SCSI INQUIRY** command through a call to **ioctl** with the **SCIOLINQU** operation as its argument. The *arg* parameter for the **SCIOLINQU** operation is the address of an **scsi_inquiry** structure. This structure is defined in the **/usr/include/sys/scsi_buf.h** file. The *scsi_inquiry* parameter block allows the caller to select the SCSI and LUN IDs to be queried. If

successful, the inquiry data is returned in the *pRspBuffer* parameter. Successful completion occurs if a device responds at the requested SCSI ID, but the returned inquiry data must be examined to see if the requested LUN exists.

Parameters

Item	Description
handle	Specifies the open file descriptor obtained from a successful call to the **open** subroutine.
PortWWN	Specifies the world wide name or port name of the target device.
fcLUN	Specifies the fcLUN.
EVPD	Specifies the value for the EVPD bit. If the value is 1, the Vital Product Data page code will be specified by the *PageCode* parameter.
PageCode	Specifies the Vital Product Data that is to be requested if the EVPD parameter is set to 1.
pRspBuffer	Points to a buffer containing the requested instruction for a send/read capacity request to an open adapter. The size of this buffer must not be greater than 255 bytes.
RspBufferSize	Specifies the size of the buffer to the *pRspBuffer* parameter.
pSenseBuffer	Points to a buffer containing the data returned from a send/read capacity request to an open adapter.
SenseBufferSize	Specifies the size of the buffer to the *pSenseBuffer* parameter.

Return Values

Upon successful completion, the **HBA_SendScsiInquiry** subroutine returns a buffer in bytes containing the SCSI inquiry, a buffer containing the SCSI sense data, and a value of HBA_STATUS_OK, or a value of 0.

If unsuccessful, an empty buffer for the SCSI inquiry, a response buffer containing the failure, and a value of HBA_STATUS_ERROR, or a value of 1 is returned.

Error Codes

The Storage Area Network Host Bus Adapter API subroutines return the following error codes:

Item	Description
HBA_STATUS_OK	A value of 0 on successful completion.
HBA_STATUS_ERROR	A value of 1 if an error occurred.
HBA_STATUS_ERROR_INVALID_HANDLE	A value of 3 if there was an invalid file handle.
HBA_STATUS_ERROR_ARG	A value of 4 if there was a bad argument.
HBA_STATUS_ERROR_ILLEGAL_WWN	A value of 5 if the world wide name was not recognized.
HBA_STATUS_SCSI_CHECK_CONDITION	A value of 9 if a SCSI Check Condition was reported.

HBA_SetRNIDMgmtInfo Subroutine

Purpose

Sends a **SCSI SET RNID** command to a remote port of the end device.

Library

Common Host Bus Adapter Library (**libHBAAPI.a**)

Syntax

```
#include <sys/hbaapi.h>

HBA_STATUS HBA_SetRNIDMgmtInfo (handle, info)
HBA_HANDLE handle;
HBA_MGMTINFO info;
```

Description

The **HBA_SetRNIDMgmtInfo** subroutine sends a **SCSI SET RNID** (Request Node Identification Data) command with the **SCIOLCHBA** operation as its argument. This is done through a call to **ioctl**. The *arg* parameter for the **SCIOLCHBA** operation is the address of a **scsi_chba** structure. This structure is defined in the **/usr/include/sys/scsi_buf.h** file. The *scsi_chba* parameter block allows the caller to select the **SET RNID** command to be sent to the adapter. The **info** structure stores the RNID data to be set. The **info** structure is defined in the **/usr/include/sys/hbaapi.h** file. The structure includes:

- wwn
- unittype
- PortId
- NumberOfAttachedNodes
- IPVersion
- UDPort
- IPAddress
- reserved
- TopologyDiscoveryFlags

If successful, the SET RNID data in **info** is sent to the adapter.

Parameters

Item	Description
handle	Specifies the open file descriptor obtained from a successful call to the **open** subroutine.
info	Specifies the structure containing the information to be set or received from the **RNID** command

Return Values

Upon successful completion, the **HBA_SetRNIDMgmtInfo** subroutine returns a value of HBA_STATUS_OK, or a value of 0. If unsuccessful, a value of HBA_STATUS_ERROR, or a 1 is returned.

Error Codes

The Storage Area Network Host Bus Adapter API subroutines return the following error codes:

Item	Description
HBA_STATUS_OK	A value of 0 on successful completion.
HBA_STATUS_ERROR	A value of 1 if an error occurred.
HBA_STATUS_ERROR_INVALID_HANDLE	A value of 3 if there was an invalid file handle.

hpmInit, f_hpminit, hpmStart, f_hpmstart, hpmStop, f_hpmstop, hpmTstart, f_hpmtstart, hpmTstop, f_hpmtstop, hpmGetTimeAndCounters, f_hpmgettimeandcounters, hpmGetCounters, f_hpmgetcounters, hpmTerminate, and f_hpmterminate Subroutine

Purpose

Provides application instrumentation for performance monitoring.

Library

HPM Library (`libhpm.a`)

HPM Library (`libhpm.a`) includes four additional subroutines for threaded applications.

Syntax

```
#include <libhpm.h>

void hpmInit(int  taskID, char  *progName);
void f_hpminit(int  taskID, char  *progName);

void hpmStart(int  instID, char  *label);
void f_hpmstart(int  instID, char  *label);

void hpmStop(int  instID);
void f_hpmstop(int  instID);

(libhpm_r only)
void hpmTstart(int  instID, char  *label);
void f_hpmtstart(int  instID, char  *label);
(libhpm_r only)
void hpmTstop(int  instID);
void f_hpmtstop(int  instID);

void hpmGetTimeAndCounters(int  numCounters, double  *time, long long  *values);
void f_hpmgettimeandcounters(int  numCounters, double  *time, long long  *values);

void hpmGetCounters(long long  *values);
void f_hpmgetcounters(long long  *values);

void hpmTerminate(int  taskID);
void f_hpmterminate(int  taskID);
```

Description

The `hpmInit` and `f_hpminit` subroutines initialize tasks specified by the *taskID* and *progName* parameters.

The `hpmStart` and `f_hpmstart` subroutines debut an instrumented code segment. If more than 100 instrumented sections are required, the `HPM_NUM_INST_PTS` environment variable can be set to indicate the higher value and *instID* should be less than this value.

The `hpmStop` and `f_hpmstop` subroutines indicate the end of the instrumented code segment *instID*. For each call to `hpmStart` and `f_hpmstart`, there should be a corresponding call to `hpmStop` and `f_hpmstop` with the matching *instID*.

The `hpmTstart` and `f_hpmtstart` subroutines perform the same function as `hpmStart` and `f_hpmstart`, but are used in threaded applications.

The hpmTstop and f_hpmtstop subroutines perform the same function as hpmStop and f_hpmstop, but are used in threaded applications.

The hpmGetTimeAndCounters and f_hpmgettimeandcounters subroutines are used to return the time in seconds and the accumulated counts since the call to hpmInit or f_hpminit.

The hpmGetCounters and f_hpmgetcounters subroutines return all the accumulated counts since the call to hpmInit or f_hpminit. To minimize intrusion and overhead, the hpmGetCounters and f_hpmgetcounters subroutines do not perform any check on the size of the *values* array. The number of counters can be obtained from the pm_info2_t.maxpmcs structure element supplied by pm_initialize or by using the pmlist -s command. Alternatively, the application can use the current maximum value of 8.

The hpmTerminate and f_hpmterminate subroutines end the *taskID* and generate the output. Applications that do not call hpmTerminate or f_hpmterminate, do not generate performance information.

A summary report for each task is written by default in the *progName_pid_taskID*.hpm file, where *progName* is the second parameter to the hpmInit subroutine. If *progName* contains a space or tab character, or is otherwise invalid, a diagnostic message is written to stderr and the library exits with an error to avoid further problems.

The output file name can be defined with the HPM_OUTPUT_NAME environment flag. The libhpm still adds the file name suffix *_taskID*.hpm for the performance files. By using this environment variable, you can specify the date and time for the output file name. For example:

```
MYDATE=$(date +"m%d:11/15/18M%S")
export HPM_OUTPUT_NAME=myprogram_$MYDATE
```

where the output file for task 27 will have the following name:

```
myprogram_yyyymmdd:HHMMSS_0027.hpm
```

The GUI and .viz output is deactivated by default. The aligned set of performance files named *progName_pid_taskID*.viz or HPM_OUTPUT_NAME_*taskID*.viz will not be generated (the generation of the .viz file was previously activated by default and avoided with the HPM_VIZ_OUTPUT = FALSE environment variable).

Parameters

Item	Description
instID	Specifies the instrumented section ID as an integer value greater than 0 and less than 100.
label	Specifies a label with a character string.
numCounters	Specifies an integer value that indicates the number of counters to be accessed.
progName	Specifies a program name using a character string label.
taskID	Specifies a node ID with an integer value.
time	Specifies a double precision float.
values	Specifies an array of type long long of size *numCounters*.

Execution Environment

Functionality provided by the libhpm library is dependent upon corresponding functions in the libpmapi and libm libraries. Therefore, the -lpmapi -lm link flags must be specified when compiling applications.

Return Values

No return values are defined.

Error Codes

Upon failure, these `libhpm` subroutines either write error messages explicitly to `stderr` or use the PMAPI `pm_error` function. The `pm_error` function is called following an error return from any of the following subroutines:

- `pm_init_private`
- `pm_set_program_mygroup`
- `pm_stop_mygroup`
- `pm_get_data_mygroup`
- `pm_start_mygroup`
- `pm_stop_mythread`
- `pm_get_data_mythread`
- `pm_start_mythread`
- `pm_get_data_mythread`

Diagnostic messages are explicitly written to `stderr` or `stdout` in the following situations:

- `pm_cycles` or `gettimeofday` returns an error
- The value of the *instID* parameter is invalid
- An event set is out of range
- The `libHPMevents` file or `HPM_flags.env` file has an incorrect format
- There are internal errors.

Error messages that are not fatal are written to `stdout` or `stderr` with the text `WARNING`.

hsearch, hcreate, or hdestroy Subroutine

Purpose

Manages hash tables.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <search.h>

ENTRY *hsearch ( Item,  Action)
ENTRY Item;
Action Action;

int hcreate ( NumberOfElements)
size_t NumberOfElements;
void hdestroy ( )
```

Description

Attention: Do not use the **hsearch**, **hcreate**, or **hdestroy** subroutine in a multithreaded environment.

The **hsearch** subroutine searches a hash table. It returns a pointer into a hash table that indicates the location of the given item. The **hsearch** subroutine uses open addressing with a multiplicative hash function.

The **hcreate** subroutine allocates sufficient space for the table. You must call the **hcreate** subroutine before calling the **hsearch** subroutine. The *NumberOfElements* parameter is an estimate of the maximum number of entries that the table will contain. This number may be adjusted upward by the algorithm in order to obtain certain mathematically favorable circumstances.

The **hdestroy** subroutine deletes the hash table. This action allows you to start a new hash table since only one table can be active at a time. After the call to the **hdestroy** subroutine, the data can no longer be considered accessible.

Parameters

Item	Description
Item	Identifies a structure of the type **ENTRY** as defined in the **search.h** file. It contains two pointers: **Item.key** Points to the comparison key. The key field is of the **char** type. **Item.data** Points to any other data associated with that key. The data field is of the **void** type. Pointers to data types other than the **char** type should be declared to pointer-to-character.
Action	Specifies the value of the *Action* enumeration parameter that indicates what is to be done with an entry if it cannot be found in the table. Values are: **ENTER** Enters the value of the *Item* parameter into the table at the appropriate point. If the table is full, the **hsearch** subroutine returns a null pointer. **FIND** Does not enter the value of the *Item* parameter into the table. If the value of the *Item* parameter cannot be found, the **hsearch** subroutine returns a null pointer. If the value of the *Item* parameter is found, the subroutine returns the address of the item in the hash table.
NumberOfElements	Provides an estimate of the maximum number of entries that the table contains. Under some circumstances, the **hcreate** subroutine may actually make the table larger than specified.

Return Values

The **hcreate** subroutine returns a value of 0 if it cannot allocate sufficient space for the table.

hypot, hypotf, hypotl, hypotd32, hypotd64, and hypotd128 Subroutines

Purpose

Computes the Euclidean distance function and complex absolute value.

Libraries

IEEE Math Library (**libm.a**) System V Math Library (**libmsaa.a**)

Syntax

```
#include <math.h>
```

double hypot (*x*, *y*)
double *x*, *y*;

```
float hypotf (x, y)
float x;
float y;

long double hypotl (x, y)
long double x;
long double y;
_Decimal32 hypotd32 (x, y)
_Decimal32 x, y;

_Decimal64 hypotd64 (x, y)
_Decimal64 x, y;

_Decimal128 hypotd128 (x, y)
_Decimal128 x, y;
```

Description

The **hypot**, **hypotf**, **hypotl**, **hypotd32**, **hypotd64**, and **hypotd128** subroutines compute the value of the square root of $x^2 + y^2$ without undue overflow or underflow.

An application wishing to check for error situations should set the **errno** global variable to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies some double-precision floating-point value.
y	Specifies some double-precision floating-point value.

Return Values

Upon successful completion, the **hypot**, **hypotf**, **hypotl**, **hypotd32**, **hypotd64**, and **hypotd128** subroutines return the length of the hypotenuse of a right-angled triangle with sides of length *x* and *y*.

If the correct value would cause overflow, a range error occurs and the **hypotf**, **hypotl**, **hypotd32**, **hypotd64**, and **hypotd128** subroutines return the value of the macro **HUGE_VALF**, **HUGE_VALL**, **HUGE_VAL_D32**, **HUGE_VAL_D64**, and **HUGE_VAL_D128** respectively.

If *x* or *y* is ±Inf, +Inf is returned (even if one of *x* or *y* is NaN).

If *x* or *y* is NaN, and the other is not ±Inf, a NaN is returned.

If both arguments are subnormal and the correct result is subnormal, a range error may occur and the correct result is returned.

Error Codes

When using the **libm.a** (**-lm**) library, if the correct value overflows, the **hypot** subroutine returns a **HUGE_VAL** value.

Note: (hypot (INF, *value*) and **hypot (***value***,** INF**)** are both equal to **+INF** for all values, even if *value* = NaN.

When using **libmsaa.a** (**-lmsaa**), if the correct value overflows, the **hypot** subroutine returns **HUGE_VAL** and sets the global variable **errno** to **ERANGE**.

These error-handling procedures may be changed with the **matherr** subroutine when using the **libmsaa.a** (**-lmsaa**) library.

i

The following Base Operating System (BOS) runtime services begin with the letter *i*.

iconv Subroutine

Purpose

Converts a string of characters in one character code set to another character code set.

Library

The **iconv** Library (**libiconv.a**)

Syntax

```
#include <iconv.h>
```

```
size_t iconv (CD, InBuf, InBytesLeft, OutBuf, OutBytesLeft)
iconv_t CD;
char **OutBuf, **InBuf;
size_t *OutBytesLeft, *InBytesLeft;
```

Description

The **iconv** subroutine converts the string specified by the *InBuf* parameter into a different code set and returns the results in the *OutBuf* parameter. The required conversion method is identified by the *CD* parameter, which must be valid conversion descriptor returned by a previous, successful call to the **iconv_open** subroutine.

On calling, the *InBytesLeft* parameter indicates the number of bytes in the *InBuf* buffer to be converted, and the *OutBytesLeft* parameter indicates the number of bytes remaining in the *OutBuf* buffer that do not contain converted data. These values are updated upon return so they indicate the new state of their associated buffers.

For state-dependent encodings, calling the **iconv** subroutine with the *InBuf* buffer set to null will reset the conversion descriptor in the *CD* parameter to its initial state. Subsequent calls with the *InBuf* buffer, specifying other than a null pointer, may cause the internal state of the subroutine to be altered a necessary.

Parameters

Item	Description
CD	Specifies the conversion descriptor that points to the correct code set converter.
InBuf	Points to a buffer that contains the number of bytes in the *InBytesLeft* parameter to be converted.
InBytesLeft	Points to an integer that contains the number of bytes in the *InBuf* parameter.
OutBuf	Points to a buffer that contains the number of bytes in the *OutBytesLeft* parameter that has been converted.
OutBytesLeft	Points to an integer that contains the number of bytes in the *OutBuf* parameter.

Return Values

Upon successful conversion of all the characters in the *InBuf* buffer and after placing the converted characters in the *OutBuf* buffer, the **iconv** subroutine returns 0, updates the *InBytesLeft* and *OutBytesLeft* parameters, and increments the *InBuf* and *OutBuf* pointers. Otherwise, it updates the varibles pointed to by the parameters to indicate the extent to the conversion, returns the number of bytes still left to be converted in the input buffer, and sets the **errno** global variable to indicate the error.

Error Codes

If the **iconv** subroutine is unsuccessful, it updates the variables to reflect the extent of the conversion before it stopped and sets the **errno** global variable to one of the following values:

Item	Description
EILSEQ	Indicates an unusable character. If an input character does not belong to the input code set, no conversion is attempted on the unusable on the character. In *InBytesLeft* parameters indicates the bytes left to be converted, including the first byte of the unusable character. *InBuf* parameter points to the first byte of the unusable character sequence. The values of *OutBuf* and *OutBytesLeft* are updated according to the number of bytes available in the output buffer that do not contain converted data.
E2BIG	Indicates an output buffer overflow. If the *OutBuf* buffer is too small to contain all the converted characters, the character that causes the overflow is not converted. The *InBytesLeft* parameter indicates the bytes left to be converted (including the character that caused the overflow). The *InBuf* parameter points to the first byte of the characters left to convert.
EINVAL	Indicates the input buffer was truncated. If the original value of *InBytesLeft* is exhausted in the middle of a character conversion or shift/lock block, the *InBytesLeft* parameter indicates the number of bytes undefined in the character being converted. If an input character of shift sequence is truncated by the *InBuf* buffer, no conversion is attempted on the truncated data, and the *InBytesLeft* parameter indicates the bytes left to be converted. The *InBuf* parameter points to the first bytes if the truncated sequence. The *OutBuf* and *OutBytesLeft* values are updated according to the number of characters that were previously converted. Because some encoding may have ambiguous data, the **EINVAL** return value has a special meaning at the end of stream conversion. As such, if a user detects an EOF character on a stream that is being converted and the last return code from the **iconv** subroutine was **EINVAL**, the **iconv** subroutine should be called again, with the same *InBytesLeft* parameter and the same character string pointed to by the *InBuf* parameter as when the **EINVAL** return occurred. As a result, the converter will either convert the string as is or declare it an unusable sequence (**EILSEQ**).

Files

Item	Description
/usr/lib/nls/loc/iconv/*	Contains code set converter methods.

iconv_close Subroutine

Purpose

Closes a specified code set converter.

Library

iconv Library (**libiconv.a**)

Syntax

```
#include <iconv.h>
```

```
int iconv_close ( CD)
iconv_t CD;
```

Description

The **iconv_close** subroutine closes a specified code set converter and deallocates any resources used by the converter.

Parameters

Item	Description
CD	Specifies the conversion descriptor to be closed.

Return Values

When successful, the **iconv_close** subroutine returns a value of 0. Otherwise, it returns a value of -1 and sets the **errno** global variable to indicate the error.

Error Codes

The following error code is defined for the **iconv_close** subroutine:

Item	Description
EBADF	The conversion descriptor is not valid.

iconv_open Subroutine

Purpose

Opens a character code set converter.

Library

iconv Library (**libiconv.a**)

Syntax

```
#include <iconv.h>
```

```
iconv_t iconv_open ( ToCode,  FromCode)
const char *ToCode, *FromCode;
```

Description

The **iconv_open** subroutine initializes a code set converter. The code set converter is used by the **iconv** subroutine to convert characters from one code set to another. The **iconv_open** subroutine finds the converter that performs the character code set conversion specified by the *FromCode* and *ToCode* parameters, initializes that converter, and returns a conversion descriptor of type **iconv_t** to identify the code set converter.

The **iconv_open** subroutine first searches the **LOCPATH** environment variable for a converter, using the two user-provided code set names, based on the file name convention that follows:

```
FromCode: "IBM-850"
ToCode: "ISO8859-1"
conversion file: "IBM-850_ISO8859-1"
```

The conversion file name is formed by concatenating the *ToCode* code set name onto the *FromCode* code set name, with an **_** (underscore) between them.

The **LOCPATH** environment variable contains a list of colon-separated directory names. The system default for the **LOCPATH** environment variable is:

```
LOCPATH=/usr/lib/nls/loc
```

See Locales in *Globalization Guide and Reference* for more information on the **LOCPATH** environment variable.

The **iconv_open** subroutine first attempts to find the specified converter in an **iconv** subdirectory under any of the directories specified by the **LOCPATH** environment variable, for example, **/usr/lib/nls/loc/iconv**. If the **iconv_open** subroutine cannot find a converter in any of these directories, it looks for a conversion table in an **iconvTable** subdirectory under any of the directories specified by the **LOCPATH** environment variable, for example, **/usr/lib/nls/loc/iconvTable**.

If the **iconv_open** subroutine cannot find the specified converter in either of these locations, it returns (**iconv_t**) -1 to the calling process and sets the **errno** global variable.

The **iconvTable** directories are expected to contain conversion tables that are the output of the **genxlt** command. The conversion tables are limited to single-byte stateless code sets.

If the named converter is found, the **iconv_open** subroutine will perform the **load** subroutine operation and initialize the converter. A converter descriptor (**iconv_t**) is returned.

Note: When a process calls the **exec** subroutine or a **fork** subroutine, all of the opened converters are discarded.

The **iconv_open** subroutine links the converter function using the **load** subroutine, which is similar to the **exec** subroutine and effectively performs a run-time linking of the converter program. Since the **iconv_open** subroutine is called as a library function, it must ensure that security is preserved for certain programs. Thus, when the **iconv_open** subroutine is called from a set root ID program (a program with permission **—-s—s—x**), it will ignore the **LOCPATH** environment variable and search for converters only in the **/usr/lib/nls/loc/iconv** directory.

Parameters

Item	Description
ToCode	Specifies the destination code set.
FromCode	Specifies the originating code set.

Return Values

A conversion descriptor (**iconv_t**) is returned if successful. Otherwise, the subroutine returns -1, and the **errno** global variable is set to indicate the error.

Error Codes

Item	Description
EINVAL	The conversion specified by the *FromCode* and *ToCode* parameters is not supported by the implementation.
EMFILE	The number of file descriptors specified by the **OPEN_MAX** configuration variable is currently open in the calling process.

Item	Description
ENFILE	Too many files are currently open in the system.
ENOMEM	Insufficient storage space is available.

Files

Item	Description
/usr/lib/nls/loc/iconv	Contains loadable method converters.
/usr/lib/nls/loc/iconvTable	Contains conversion tables for single-byte stateless code sets.

idlok Subroutine

Purpose

Allows curses to use the hardware insert/delete line feature.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
idlok( Window,  Flag)
WINDOW *Window;
bool Flag;
```

Description

The **idlok** subroutine enables curses to use the hardware insert/delete line feature for terminals so equipped. If this feature is disabled, curses cannot use it. The insert/delete line feature is always considered. Enable this option only if your application needs the insert/delete line feature; for example, for a screen editor. If the insert/delete line feature cannot be used, curses will redraw the changed portions of all lines that do not match the desired line.

Parameters

Item	Description
Flag	Specifies whether to enable curses to use the hardware insert/delete line feature (True) or not (False).
Window	Specifies the window it will affect.

Examples

1. To enable curses to use the hardware insert/delete line feature in stdscr, enter:

   ```
   idlok(stdscr, TRUE);
   ```

2. To force curses not to use the hardware insert/delete line feature in the user-defined window `my_window` , enter:

```
idlok(my_window, FALSE);
```

ilogbd32, ilogbd64, and ilogbd128 Subroutines

Purpose

Returns an unbiased exponent.

Syntax

```
#include <math.h>

int ilogbd32 (x)
_Decimal32 x;

int ilogbd64 (x)
_Decimal64 x;

int ilogbd128 (x)
_Decimal128 x;
```

Description

The **ilogbd32**, **ilogbd64**, and **ilogbd128** subroutines return the integral part of $\log_r |x|$ as a signed integral value, for nonzero *x*, where *r* is the radix of the machine's floating-point arithmetic (r=10).

An application that wants to check for error situations set the **errno** global variable to zero and call the **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. On return, if the **errno** is of the value of nonzero or the **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is of the value of nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **ilogbd32**, **ilogbd64**, and **ilogbd128** subroutines return the exponent part of *x* as a signed integer value. They are equivalent to calling the corresponding **logb** functions and casting the returned value to type **int**.

If *x* is 0, a domain error occurs, and the value **FP_ILOGB0** is returned.

If *x* is ±Inf, a domain error occurs, and the value **{INT_MAX}** is returned.

If *x* is a NaN, a domain error occurs, and the value **FP_ILOGBNAN** is returned.

If the correct value is greater than **{INT_MAX}**, **{INT_MAX}** is returned and a domain error occurs.

If the correct value is less than **{INT_MIN}**, **{INT_MIN}** is returned and a domain error occurs.

ilogbf, ilogbl, or ilogb Subroutine

Purpose

Returns an unbiased exponent.

Syntax

```
#include <math.h>

int ilogbf (x)
float x;

int ilogbl (x)
long double x;

int ilogb (x)
double x;
```

Description

The **ilogbf**, **ilogbl**, and **ilogb** subroutines return the exponent part of the *x* parameter. The return value is the integral part of $\log_r |x|$ as a signed integral value, for nonzero *x*, where *r* is the radix of the machine's floating-point arithmetic (r=2).

An application wishing to check for error situations should set thre **errno** global variable to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **ilogbf**, **ilogbl**, and **ilogb** subroutines return the exponent part of *x* as a signed integer value. They are equivalent to calling the corresponding **logb** function and casting the returned value to type **int**.

If *x* is 0, a domain error occurs, and the value **FP_ILOGB0** is returned.

If *x* is ±Inf, a domain error occurs, and the value **{INT_MAX}** is returned.

If *x* is a NaN, a domain error occurs, and the value **FP_ILOGBNAN** is returned.

If the correct value is greater than **{INT_MAX}**, **{INT_MAX}** is returned and a domain error occurs.

If the correct value is less than **{INT_MIN}**, **{INT_MIN}** is returned and a domain error occurs.

imaxabs Subroutine

Purpose

Returns absolute value.

Syntax

```
#include <inttypes.h>

intmax_t imaxabs (j)
intmax_t j;
```

Description

The **imaxabs** subroutine computes the absolute value of an integer *j*. If the result cannot be represented, the behavior is undefined.

Parameters

Item	Description
j	Specifies the value to be computed.

Return Values

The **imaxabs** subroutine returns the absolute value.

imaxdiv Subroutine

Purpose

Returns quotient and remainder.

Syntax

```
#include <inttypes.h>

imaxdiv_t imaxdiv (numer, denom)
intmax_t numer;
intmax_t denom;
```

Description

The **imaxdiv** subroutine computes *numer / denom* and *numer % denom* in a single operation.

Parameters

Item	Description
numer	Specifies the numerator value to be computed.
denom	Specifies the denominator value to be computed.

Return Values

The **imaxdiv** subroutine returns a structure of type **imaxdiv_t**, comprising both the quotient and the remainder. The structure contains (in either order) the members *quot* (the quotient) and *rem* (the remainder), each of which has type **intmax_t**.

If either part of the result cannot be represented, the behavior is undefined.

IMAIXMapping Subroutine

Purpose

Translates a pair of *Key* and *State* parameters to a string and returns a pointer to this string.

Library

Input Method Library (**libIM.a**)

Syntax

```
caddr_t IMAIXMapping(IMMap, Key, State, NBytes)
IMMap  IMMap;
```

```
KeySym  Key;
uint  State;
int * NBytes;
```

Description

The **IMAIXMapping** subroutine translates a pair of *Key* and *State* parameters to a string and returns a pointer to this string.

This function handles the diacritic character sequence and Alt-NumPad key sequence.

Parameters

Item	Description
IMMap	Identifies the keymap.
Key	Specifies the key symbol to which the string is mapped.
State	Specifies the state to which the string is mapped.
NBytes	Returns the length of the returning string.

Return Values

If the length set by the *NBytes* parameter has a positive value, the **IMAIXMapping** subroutine returns a pointer to the returning string.

Note: The returning string is not null-terminated.

IMAuxCreate Callback Subroutine

Purpose

Tells the application program to create an auxiliary area.

Syntax

```
int IMAuxCreate( IM,  AuxiliaryID,  UData)
IMObject IM;
caddr_t *AuxiliaryID;
caddr_t UData;
```

Description

The **IMAuxCreate** subroutine is invoked by the input method of the operating system to create an auxiliary area. The auxiliary area can contain several different forms of data and is not restricted by the interface.

Most input methods display one auxiliary area at a time, but callbacks must be capable of handling multiple auxiliary areas.

This subroutine is provided by applications that use input methods.

Parameters

Item	Description
IM	Indicates the input method instance.
AuxiliaryID	Identifies the newly created auxiliary area.

Item	Description
UData	Identifies an argument passed by the **IMCreate** subroutine.

Return Values

On successful return of the **IMAuxCreate** subroutine, a newly created auxiliary area is set to the *AuxiliaryID* value and the **IMError** global variable is returned. Otherwise, the **IMNoError** value is returned.

IMAuxDestroy Callback Subroutine

Purpose

Tells the application to destroy the auxiliary area.

Syntax

```
int IMAuxDestroy( IM,  AuxiliaryID,  UData)
IMObject IM;
caddr_t AuxiliaryID;
caddr_t UData;
```

Description

The **IMAuxDestroy** subroutine is called by the input method of the operating system to tell the application to destroy an auxiliary area.

This subroutine is provided by applications that use input methods.

Parameters

Item	Description
IM	Indicates the input method instance.
AuxiliaryID	Identifies the auxiliary area to be destroyed.
UData	An argument passed by the **IMCreate** subroutine.

Return Values

If an error occurs, the **IMAuxDestroy** subroutine returns the **IMError** global variable. Otherwise, the **IMNoError** value is returned.

IMAuxDraw Callback Subroutine

Purpose

Tells the application program to draw the auxiliary area.

Syntax

```
int IMAuxDraw(IM, AuxiliaryID, AuxiliaryInformation, UData)
IMObject  IM;
caddr_t  AuxiliaryID;
IMAuxInfo * AuxiliaryInformation;
caddr_t  UData;
```

Description

The **IMAuxDraw** subroutine is invoked by the input method to draw an auxiliary area. The auxiliary area should have been previously created.

This subroutine is provided by applications that use input methods.

Parameters

Item	Description
IM	Indicates the input method instance.
AuxiliaryID	Identifies the auxiliary area.
AuxiliaryInformation	Points to the **IMAuxInfo** structure.
UData	An argument passed by the **IMCreate** subroutine.

Return Values

If an error occurs, the **IMAuxDraw** subroutine returns the **IMError** global variable. Otherwise, the **IMNoError** value is returned.

IMAuxHide Callback Subroutine

Purpose

Tells the application program to hide an auxiliary area.

Syntax

int IMAuxHide(*IM*, *AuxiliaryID*, *UData***)**

```
IMObject IM;
caddr_t AuxiliaryID;
caddr_t UData;
```

Description

The **IMAuxHide** subroutine is called by the input method to hide an auxiliary area.

This subroutine is provided by applications that use input methods.

Parameters

Item	Description
IM	Indicates the input method instance.
AuxiliaryID	Identifies the auxiliary area to be hidden.
UData	An argument passed by the **IMCreate** subroutine.

Return Values

If an error occurs, the **IMAuxHide** subroutine returns the **IMError** global variable. Otherwise, the **IMNoError** value is returned.

IMBeep Callback Subroutine

Purpose

Tells the application program to emit a beep sound.

Syntax

```
int IMBeep( IM,  Percent,  UData)
IMObject IM;
int Percent;
caddr_t UData;
```

Description

The **IMBeep** subroutine tells the application program to emit a beep sound.

This subroutine is provided by applications that use input methods.

Parameters

Item	Description
IM	Indicates the input method instance.
Percent	Specifies the beep level. The value range is from -100 to 100, inclusively. A -100 value means no beep.
UData	An argument passed by the **IMCreate** subroutine.

Return Values

If an error occurs, the **IMBeep** subroutine returns the **IMError** global variable. Otherwise, the **IMNoError** value is returned.

IMClose Subroutine

Purpose

Closes the input method.

Library

Input Method Library (**libIM.a**)

Syntax

```
void IMClose( IMfep)
IMFep IMfep;
```

Description

The **IMClose** subroutine closes the input method. Before the **IMClose** subroutine is called, all previously created input method instances must be destroyed with the **IMDestroy** subroutine, or memory will not be cleared.

Parameters

Item	Description
IMfep	Specifies the input method.

IMCreate Subroutine

Purpose

Creates one instance of an **IMObject** object for a particular input method.

Library

Input Method Library (**libIM.a**)

Syntax

```
IMObject IMCreate( IMfep,  IMCallback,  UData)
IMFep IMfep;
IMCallback *IMCallback;
caddr_t UData;
```

Description

The **IMCreate** subroutine creates one instance of a particular input method. Several input method instances can be created under one input method.

Parameters

Item	Description
IMfep	Specifies the input method.
IMCallback	Specifies a pointer to the caller-supplied **IMCallback** structure.
UData	Optionally specifies an application's own information to the callback functions. With this information, the application can avoid external references from the callback functions. The input method does not change this parameter, but merely passes it to the callback functions. The *UData* parameter is usually a pointer to the application data structure, which contains the information about location, font ID, and so forth.

Return Values

The **IMCreate** subroutine returns a pointer to the created input method instance of type **IMObject**. If the subroutine is unsuccessful, a null value is returned and the **imerrno** global variable is set to indicate the error.

IMDestroy Subroutine

Purpose

Destroys an input method instance.

Library

Input Method Library (**libIM.a**)

Syntax

```
void IMDestroy( IM)
IMObject IM;
```

Description

The **IMDestroy** subroutine destroys an input method instance.

Parameters

Item	Description
IM	Specifies the input method instance to be destroyed.

IMFilter Subroutine

Purpose

Determines if a keyboard event is used by the input method for internal processing.

Library

Input Method Library (**libIM.a**)

Syntax

```
int IMFilter(Im, Key, State, String, Length)
IMObect  Im;
Keysym  Key;
uint  State, * Length;
caddr_t  * String;
```

Description

The **IMFilter** subroutine is used to process a keyboard event and determine if the input method for this operating system uses this event. The return value indicates:

- The event is filtered (used by the input method) if the return value is **IMInputUsed**. Otherwise, the input method did not accept the event.
- Independent of the return value, a string may be generated by the keyboard event if pre-editing is complete.

  Note: The buffer returned from the **IMFilter** subroutine is owned by the input method editor and can not continue between calls.

Parameters

Item	Description
Im	Specifies the input method instance.
Key	Specifies the keysym for the event.
State	Defines the state of the keysym. A value of 0 means that the keysym is not redefined.
String	Holds the returned string if one exists. A null value means that no composed string is ready.
Length	Defines the length of the input string. If the string is not null, returns the length.

Return Values

Item	Description
IMInputUsed	The input method for this operating system filtered the event.
IMInputNotUsed	The input method for this operating system did not use the event.

IMFreeKeymap Subroutine

Purpose

Frees resources allocated by the **IMInitializeKeymap** subroutine.

Library

Input Method Library (**libIM.a**)

Syntax

```
void IMFreeKeymap( IMMap)
IMMap IMMap;
```

Description

The **IMFreeKeymap** subroutine frees resources allocated by the **IMInitializeKeymap** subroutine.

Parameters

Item	Description
IMMap	Identifies the keymap.

IMIndicatorDraw Callback Subroutine

Purpose

Tells the application program to draw the indicator.

Syntax

```
int IMIndicatorDraw( IM,  IndicatorInformation,  UData)
IMObject IM;
IMIndicatorInfo *IndicatorInformation;
caddr_t UData;
```

Description

The **IMIndicatorDraw** callback subroutine is called by the input method when the value of the indicator is changed. The application program then draws the indicator.

This subroutine is provided by applications that use input methods.

Parameters

Item	Description
IM	Indicates the input method instance.

Item	Description
IndicatorInformation	Points to the **IMIndicatorInfo** structure that holds the current value of the indicator. The interpretation of this value varies among phonic languages. However, the input method provides a function to interpret this value.
UData	An argument passed by the **IMCreate** subroutine.

Return Values

If an error happens, the **IMIndicatorDraw** subroutine returns the **IMError** global variable. Otherwise, the **IMNoError** value is returned.

IMIndicatorHide Callback Subroutine

Purpose

Tells the application program to hide the indicator.

Syntax

```
int IMIndicatorHide( IM,  UData)
IMObject IM;
caddr_t UData;
```

Description

The **IMIndicatorHide** subroutine is called by the input method to tell the application program to hide the indicator.

This subroutine is provided by applications that use input methods.

Parameters

Item	Description
IM	Indicates the input method instance.
UData	Specifies an argument passed by the **IMCreate** subroutine.

Return Values

If an error occurs, the **IMIndicatorHide** subroutine returns the **IMError** global variable. Otherwise, the **IMNoError** value is returned.

IMInitialize Subroutine

Purpose

Initializes the input method for a particular language.

Library

Input Method Library (**libIM.a**)

Syntax

```
IMFep IMInitialize( Name)
char *Name;
```

Description

The **IMInitialize** subroutine initializes an input method. The **IMCreate**, **IMFilter**, and **IMLookupString** subroutines use the input method to perform input processing of keyboard events in the form of keysym state modifiers. The **IMInitialize** subroutine finds the input method that performs the input processing specified by the *Name* parameter and returns an Input Method Front End Processor (**IMFep**) descriptor.

Before calling any of the key event-handling functions, the application must create an instance of an *IMObject* object using the **IMFep** descriptor. Each input method can produce one or more instances of *IMObject* object with the **IMCreate** subroutine.

When the **IMInitialize** subroutine is called, strings returned from the input method are encoded in the code set of the locale. Each **IMFep** description inherits the code set of the locale when the input method is initialized. The locale setting does not change the code set of the **IMFep** description after it is created.

The **IMInitialize** subroutine calls the **load** subroutine to load a file whose name is in the form *Name*.**im**. The *Name* parameter is passed to the **IMInitialize** subroutine. The loadable input method file is accessed in the directories specified by the **LOCPATH** environment variable. The default location for loadable input-method files is the **/usr/lib/nls/loc** directory. If none of the **LOCPATH** directories contain the input method specified by the *Name* parameter, the default location is searched.

Note: All **setuid** and **setgid** programs will ignore the **LOCPATH** environment variable.

The name of the input method file usually corresponds to the locale name, which is in the form **Language_territory.codesest@***modifier*. In the environment, the modifier is in the form **@im**=*modifier*. The **IMInitialize** subroutine converts the **@im**= substring to **@** when searching for loadable input-method files.

Parameters

Item	Description
Name	Specifies the language to be used. Each input method is dynamically linked to the application program.

Return Values

If **IMInitialize** succeeds, it returns an **IMFep** handle. Otherwise, null is returned and the **imerrno** global variable is set to indicate the error.

Files

Item	Description
/usr/lib/nls/loc	Contains loadable input-method files.

IMInitializeKeymap Subroutine

Purpose

Initializes the keymap associated with a specified language.

Library

Input Method Library (**libIM.a**)

Syntax

```
IMMap IMInitializeKeymap( Name)
char *Name;
```

Description

The **IMInitializeKeymap** subroutine initializes an input method keymap (imkeymap). The **IMAIXMapping** and **IMSimpleMapping** subroutines use the imkeymap to perform mapping of keysym state modifiers to strings. The **IMInitializeKeymap** subroutine finds the imkeymap that performs the keysym mapping and returns an imkeymap descriptor, **IMMap**. The strings returned by the imkeymap mapping functions are treated as unsigned bytes.

The applications that use input methods usually do not need to manage imkeymaps separately. The imkeymaps are managed internally by input methods.

The **IMInitializeKeymap** subroutine searches for an imkeymap file whose name is in the form *Name*.**im**. The *Name* parameter is passed to the **IMInitializeKeymap** subroutine. The imkeymap file is accessed in the directories specified by the **LOCPATH** environment variable. The default location for input method files is the **/usr/lib/nls/loc** directory. If none of the **LOCPATH** directories contain the keymap method specified by the *Name* parameter, the default location is searched.

Note: All **setuid** and **setgid** programs will ignore the **LOCPATH** environment variable.

The name of the imkeymap file usually corresponds to the locale name, which is in the form **Language_territory.codesest@***modifier*. In the AIXwindows environment, the modifier is in the form **@im**=*modifier*. The **IMInitializeKeymap** subroutine converts the **@im**= *substring* to **@** (at sign) when searching for loadable input method files.

Parameters

Item	Description
Name	Specifies the name of the imkeymap.

Return Values

The **IMInitializeKeymap** subroutine returns a descriptor of type **IMMap**. Returning a null value indicates the occurrence of an error. The **IMMap** descriptor is defined in the **im.h** file as the **caddr_t** structure. This descriptor is used for keymap manipulation functions.

Files

Item	Description
/usr/lib/nls/loc	Contains loadable input-method files.

IMIoctl Subroutine

Purpose

Performs a variety of control or query operations on the input method.

Library

Input Method Library (**libIM.a**)

Syntax

```
int IMIoctl( IM,  Operation,  Argument)
IMObject IM;
int Operation;
char *Argument;
```

Description

The **IMIoctl** subroutine performs a variety of control or query operations on the input method specified by the *IM* parameter. In addition, this subroutine can be used to control the unique function of each language input method because it provides input method-specific extensions. Each input method defines its own function.

Parameters

IM
Specifies the input method instance.

Operation
Specifies the operation.

Argument
The use of this parameter depends on which of the following operations is performed.

IM_Refresh
Refreshes the text area, auxiliary areas, and indicator by calling the needed callback functions if these areas are not empty. The *Argument* parameter is not used.

IM_GetString
Gets the current pre-editing string. The *Argument* parameter specifies the address of the **IMSTR** structure supplied by the caller. The callback function is invoked to clear the pre-editing if it exists.

IM_Clear
Clears the text and auxiliary areas if they exist. If the *Argument* parameter is not a null value, this operation invokes the callback functions to clear the screen. The keyboard state remains the same.

IM_Reset
Clears the auxiliary area if it currently exists. If the *Argument* parameter is a null value, this operation clears only the internal buffer of the input method. Otherwise, the **IMAuxHide** subroutine is called, and the input method returns to its initial state.

IM_ChangeLength
Changes the maximum length of the pre-editing string.

IM_ChangeMode
Sets the Processing Mode of the input method to the mode specified by the *Argument* parameter. The valid value for *Argument* is:

IMNormalMode
Specifies the normal mode of pre-editing.

IMSuppressedMode
Suppresses pre-editing.

IM_QueryState
Returns the status of the text area, the auxiliary area, and the indicator. It also returns the beep status and the processing mode. The results are stored into the caller-supplied **IMQueryState** structure pointed to by the *Argument* parameter.

IM_QueryText
Returns detailed information about the text area. The results are stored in the caller-supplied **IMQueryText** structure pointed to by the *Argument* parameter.

IM_QueryAuxiliary
Returns detailed information about the auxiliary area. The results are stored in the caller-supplied **IMQueryAuxiliary** structure pointed to by the *Argument* parameter.

IM_QueryIndicator
Returns detailed information about the indicator. The results are stored in the caller-supplied **IMQueryIndicator** structure pointed to by the *Argument* parameter.

IM_QueryIndicatorString
Returns an indicator string corresponding to the current indicator. Results are stored in the caller-supplied **IMQueryIndicatorString** structure pointed to by the *Argument* parameter. The caller can request either a short or long form with the format member of the **IMQueryIndicatorString** structure.

IM_SupportSelection
Informs the input method whether or not an application supports an auxiliary area selection list. The application must support selections inside the auxiliary area and determine how selections are displayed. If this operation is not performed, the input method assumes the application does not support an auxiliary area selection list.

Return Values

The **IMIoctl** subroutine returns a value to the **IMError** global variable that indicates the type of error encountered. Some error types are provided in the **/usr/include/imerrno.h** file.

IMLookupString Subroutine

Purpose

Maps a *Key/State* (key symbol/state) pair to a string.

Library

Input Method Library (**libIM.a**)

Syntax

```
int IMLookupString(Im, Key, State, String, Length)
IMObject  Im;
KeySym  Key;
uint  State, * Length;
caddr_t * String;
```

Description

The **IMLookupString** subroutine is used to map a *Key/State* pair to a localized string. It uses an internal input method keymap (**imkeymap**) file to map a keysym/modifier to a string. The string returned is encoded in the same code set as the locale of **IMObject** and IM Front End Processor.

Note: The buffer returned from the **IMLookupString** subroutine is owned by the input method editor and can not continue between calls.

Parameters

Item	Description
Im	Specifies the input method instance.
Key	Specifies the key symbol for the event.

Item	Description
State	Defines the state for the event. A value of 0 means that the key is not redefined.
String	Holds the returned string, if one exists. A null value means that no composed string is ready.
Length	Defines the length string on input. If the string is not null, identifies the length returned.

Return Values

Item	Description
IMError	Error encountered.
IMReturnNothing	No string or keysym was returned.
IMReturnString	String returned.

IMProcess Subroutine

Purpose

Processes keyboard events and language-specific input.

Library

Input Method Library **(libIM.a**)

Note: This subroutine will be removed in future releases. Use the **IMFilter** and **IMLookupString** subroutines to process keyboard events.

Syntax

```
int IMProcess (IM, KeySymbol, State, String, Length)
IMObject  IM;
KeySym  KeySymbol;
uint  State;
caddr_t * String;
uint * Length;
```

Description

This subroutine is a main entry point to the input method of the operating system. The **IMProcess** subroutine processes one keyboard event at a time. Processing proceeds as follows:

- Validates the *IM* parameter.
- Performs keyboard translation for all supported modifier states.
- Invokes internal function to do language-dependent processing.
- Performs any necessary callback functions depending on the internal state.
- Returns to application, setting the *String* and *Length* parameters appropriately.

Parameters

Item	Description
IM	Specifies the input method instance.
KeySymbol	Defines the set of keyboard symbols that will be handled.
State	Specifies the state of the keyboard.

Item	Description
String	Holds the returned string. Returning a null value means that the input is used or discarded by the input method. **Note:** The *String* parameter is not a null-terminated string.
Length	Stores the length, in bytes, of the *String* parameter.

Return Values

This subroutine returns the **IMError** global variable if an error occurs. The **IMerrno** global variable is set to indicate the error. Some of the variable values include:

Item	Description
IMError	Error occurred during this subroutine.
IMTextAndAuxiliaryOff	No text string in the Text area, and the Auxiliary area is not shown.
IMTextOn	Text string in the Text area, but no Auxiliary area.
IMAuxiliaryOn	No text string in the Text area, and the Auxiliary area is shown.
IMTextAndAuxiliaryOn	Text string in the Text area, and the Auxiliary is shown.

IMProcessAuxiliary Subroutine

Purpose

Notifies the input method of input for an auxiliary area.

Library

Input Method Library (**libIM.a**)

Syntax

```
int IMProcessAuxiliary(IM, AuxiliaryID, Button, PanelRow
      PanelColumn, ItemRow, ItemColumn, String, Length)

IMObject  IM;
caddr_t  AuxiliaryID;
uint  Button;
uint  PanelRow;
uint  PanelColumn;
uint  ItemRow;
uint  ItemColumn;
caddr_t *String;
uint *Length;
```

Description

The **IMProcessAuxiliary** subroutine notifies the input method instance of input for an auxiliary area.

Parameters

Item	Description
IM	Specifies the input method instance.

Item	Description
AuxiliaryID	Identifies the auxiliary area.
Button	Specifies one of the following types of input: **IM_ABORT** Abort button is pushed. **IM_CANCEL** Cancel button is pushed. **IM_ENTER** Enter button is pushed. **IM_HELP** Help button is pushed. **IM_IGNORE** Ignore button is pushed. **IM_NO** No button is pushed. **IM_OK** OK button is pushed. **IM_RETRY** Retry button is pushed. **IM_SELECTED** Selection has been made. Only in this case do the *PanelRow*, *PanelColumn*, *ItemRow*, and *ItemColumn* parameters have meaningful values. **IM_YES** Yes button is pushed.
PanelRow	Indicates the panel on which the selection event occurred.
PanelColumn	Indicates the panel on which the selection event occurred.
ItemRow	Indicates the selected item.
ItemColumn	Indicates the selected item.
String	Holds the returned string. If a null value is returned, the input is used or discarded by the input method. Note that the *String* parameter is not a null-terminated string.
Length	Stores the length, in bytes, of the *String* parameter.

IMQueryLanguage Subroutine

Purpose

Checks to see if the specified input method is supported.

Library

Input Method Library (**libIM.a**)

Syntax

```
uint IMQueryLanguage( Name)
IMLanguage Name;
```

Description

The **IMQueryLanguage** subroutine checks to see if the input method specified by the *Name* parameter is supported.

Parameters

Item	Description
Name	Specifies the input method.

Return Values

The **IMQueryLanguage** subroutine returns a true value if the specified input method is supported, a false value if not.

IMSimpleMapping Subroutine

Purpose

Translates a pair of *KeySymbol* and *State* parameters to a string and returns a pointer to this string.

Library

Input Method Library (**libIM.a**)

Syntax

```
caddr_t IMSimpleMapping (IMMap, KeySymbol, State, NBytes)
IMMap  IMMap;
KeySym  KeySymbol;
uint  State;
int * NBytes;
```

Description

Like the **IMAIXMapping** subroutine, the **IMSimpleMapping** subroutine translates a pair of *KeySymbol* and *State* parameters to a string and returns a pointer to this string. The parameters have the same meaning as those in the **IMAIXMapping** subroutine.

The **IMSimpleMapping** subroutine differs from the **IMAIXMapping** subroutine in that it does not support the diacritic character sequence or the Alt-NumPad key sequence.

Parameters

Item	Description
IMMap	Identifies the keymap.
KeySymbol	Key symbol to which the string is mapped.
State	Specifies the state to which the string is mapped.
NBytes	Returns the length of the returning string.

IMTextCursor Callback Subroutine

Purpose

Asks the application to move the text cursor.

Syntax

```
int IMTextCursor(IM, Direction, Cursor, UData)
IMObject  IM;
uint  Direction;
int * Cursor;
caddr_t  UData;
```

Description

The **IMTextCursor** subroutine is called by the Input Method when the Cursor Up or Cursor Down key is input to the **IMFilter** and **IMLookupString** subroutines.

This subroutine sets the new display cursor position in the text area to the integer pointed to by the *Cursor* parameter. The cursor position is relative to the top of the text area. A value of -1 indicates the cursor should not be moved.

Because the input method does not know the actual length of the screen it always treats a text string as one-dimensional (a single line). However, in the terminal emulator, the text string sometimes wraps to the next line. The **IMTextCursor** subroutine performs this conversion from single-line to multiline text strings. When you move the cursor up or down, the subroutine interprets the cursor position on the text string relative to the input method.

This subroutine is provided by applications that use input methods.

Parameters

Item	Description
IM	Indicates the Input Method instance.
Direction	Specifies up or down.
Cursor	Specifies the new cursor position or -1.
UData	Specifies an argument passed by the **IMCreate** subroutine.

Return Values

If an error occurs, the **IMTextCursor** subroutine returns the **IMError** global variable. Otherwise, the **IMNoError** value is returned.

IMTextDraw Callback Subroutine

Purpose

Tells the application program to draw the text string.

Syntax

```
int IMTextDraw( IM,  TextInfo,  UData)
IMObject IM;
```

```
IMTextInfo *TextInfo;
caddr_t UData;
```

Description

The **IMTextDraw** subroutine is invoked by the Input Method whenever it needs to update the screen with its internal string. This subroutine tells the application program to draw the text string.

This subroutine is provided by applications that use input methods.

Parameters

Item	Description
IM	Indicates the input method instance.
TextInfo	Points to the **IMTextInfo** structure.
UData	An argument passed by the **IMCreate** subroutine.

Return Values

If an error occurs, the **IMTextDraw** subroutine returns the **IMError** global variable. Otherwise, the **IMNoError** value is returned.

IMTextHide Callback Subroutine

Purpose

Tells the application program to hide the text area.

Syntax

```
int IMTextHide( IM,  UData)
IMObject IM;
caddr_t UData;
```

Description

The **IMTextHide** subroutine is called by the input method when the text area should be cleared. This subroutine tells the application program to hide the text area.

This subroutine is provided by applications that use input methods.

Parameters

Item	Description
IM	Indicates the input method instance.
UData	Specifies an argument passed by the **IMCreate** subroutine.

Return Values

If an error occurs, the **IMTextHide** subroutine returns an **IMError** value. Otherwise, an **IMNoError** value is returned.

IMTextStart Callback Subroutine

Purpose

Notifies the application program of the length of the pre-editing space.

Syntax

```
int IMTextStart( IM,  Space,  UData)
IMObject IM;
int *Space;
caddr_t UData;
```

Description

The **IMTextStart** subroutine is called by the input method when the pre-editing is started, but prior to calling the **IMTextDraw** callback subroutine. This subroutine notifies the input method of the length, in terms of bytes, of pre-editing space. It sets the length of the available space (>=0) on the display to the integer pointed to by the *Space* parameter. A value of -1 indicates that the pre-editing space is dynamic and has no limit.

This subroutine is provided by applications that use input methods.

Parameters

Item	Description
IM	Indicates the input method instance.
Space	Maximum length of pre-editing string.
UData	An argument passed by the **IMCreate** subroutine.

inch, mvinch, mvwinch, or winch Subroutine

Purpose

Inputs a single-byte character and rendition from a window.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
chtype inch(void);
```

```
chtype mvinch(int y,
int x);
```

```
chtype mvwinch(WINDOW  *win,
int y,
int x);
```

```
chtype winch(WINDOW *win);
```

Description

The **inch**, **winch**, **mvinch**, and **mvwinch** subroutines return the character and rendition, of type chtype, at the current or specified position in the current or specified window.

Parameters

Item	Description
**win*	Specifies the window from which to get the character.
x	
y	

Return Values

Upon successful completion, these subroutines return the specified character and rendition. Otherwise, they return (chtype) ERR.

Examples

1. To get the character at the current cursor location in the stdscr, enter:

```
chtype character;

character = inch();
```

2. To get the character at the current cursor location in the user-defined window `my_window`, enter:

```
WINDOW *my_window;
chtype character;

character = winch(my_window);
```

3. To move the cursor to the coordinates y = `0`, x = 5 and then get that character, enter:

```
chtype character;

character = mvinch(0, 5);
```

4. To move the cursor to the coordinates y = `0`, x = 5 in the user-defined window `my_window` and then get that character, enter:

```
WINDOW *my_window;
chtype character;

character = mvwinch(my_window, 0, 5);
```

inet_aton Subroutine

Purpose

Converts an ASCII string into an Internet address.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>
```

int inet_aton (*CharString*, *InternetAddr***)**
char * *CharString*;
struct in_addr * *InternetAddr*;

Description

The **inet_aton** subroutine takes an ASCII string representing the Internet address in dot notation and converts it into an Internet address.

All applications containing the **inet_aton** subroutine must be compiled with **_BSD** set to a specific value. Acceptable values are 43 and 44. In addition, all socket applications must include the BSD **libbsd.a** library.

Parameters

Item	Description
CharString	Contains the ASCII string to be converted to an Internet address.
InternetAddr	Contains the Internet address that was converted from the ASCII string.

Return Values

Upon successful completion, the **inet_aton** subroutine returns 1 if *CharString* is a valid ASCII representation of an Internet address.

The **inet_aton** subroutine returns 0 if *CharString* is not a valid ASCII representation of an Internet address.

Files

Item	Description
/etc/hosts	Contains host names.
/etc/networks	Contains network names.

init_color Subroutine

Purpose

Changes a color definition.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

init_color( Color, R,
G, B)
register short Color,  R,  G,  B;
```

Description

The **init_color** subroutine changes a color definition. A single color is defined by the combination of its red, green, and blue components. The **init_color** subroutine changes all the occurrences of the color on the screen immediately. If the color is changed successfully, this subroutines returns OK. Otherwise, it returns ERR.

Note: The values for the red, green, and blue components must be between 0 (no component) and 1000 (maximum amount of component). The **init_color** subroutine sets values less than 0 to 0 and values greater than 1000 to 1000.

To determine if you can change a terminal's color definitions, see the **can_change_color** subroutine.

Return Values

Item	Description
OK	Indicates the color was changed successfully.
ERR	Indicates the color was not changed.

Parameters

Item	Description
Color	Identifies the color to change. The value of the parameter must be between **0** and **COLORS-1**.
R	Specifies the desired intensity of the red component.
G	Specifies the desired intensity of the green component.
B	Specifies the desired intensity of the blue component.

Examples

To initialize the color definition for color 11 to violet on a terminal that supports at least 12 colors, use:

```
init_color(11,500,0,500);
```

init_pair Subroutine

Purpose

Changes a color-pair definition.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

init_pair( Pair, F, B)
register short Pair,  F,  B;
```

Description

The **init_pair** subroutine changes a color-pair definition. A color pair is a combination of a foreground and a background color. If you specify a color pair that was previously initialized, curses refreshes the screen and changes all occurrences of that color pair to the new definition. You must call the **start_color** subroutine before you call this subroutine.

Return Values

Item	Description
OK	Indicates successful completion.
ERR	Indicates the subroutine failed.

Parameters

Item	Description
Pair	Identifies the color-pair number. The value of the *Pair* parameter must be between **1** and **COLORS_PAIRS-1**.
F	Specifies the foreground color number. This number must be between **0** and **COLORS-1**.
B	Specifies the background color number. This number must be between **0** and **COLORS-1**.

Examples

To initialize the color definition for color-pair 2 to a black foreground (color 0) with a cyan background (color 3), use:

```
init_pair(2,COLOR_BLACK, COLOR_CYAN);
```

initgroups Subroutine

Purpose

Initializes supplementary group ID.

Library

Standard C Library (**libc.a**)

Syntax

```
int initgroups ( User,  BaseGID)
const char *User;
int BaseGID;
```

Description

Attention: The **initgroups** subroutine uses the **getgrent** and **getpwent** family of subroutines. If the program that invokes the **initgroups** subroutine uses any of these subroutines, calling the **initgroups** subroutine overwrites the static storage areas used by these subroutines.

The **initgroups** subroutine reads the defined group membership of the specified *User* parameter and sets the supplementary group ID of the current process to that value. The *BaseGID* parameter is always

included in the supplementary group ID. The supplementary group is normally the principal user's group. If the user is in more than **NGROUPS_MAX** groups, set in the **limits.h** file, only **NGROUPS_MAX** groups are set, including the *BaseGID* group.

Parameters

Item	Description
User	Identifies a user.
BaseGID	Specifies an additional group to include in the group set.

Return Values

Item	Description
0	Indicates that the subroutine was success.
-1	Indicates that the subroutine failed. The **errno** global variable is set to indicate the error.

initialize Subroutine

Purpose

Performs printer initialization.

Library

None (provided by the formatter).

Syntax

```
#include <piostruct.h>

int initialize ()
```

Description

The **initialize** subroutine is invoked by the formatter driver after the **setup**subroutine returns.

If the **-j** flag passed from the **qprt** command has a nonzero value (true), the **initialize** subroutine uses the **piocmdout** subroutine to send a command string to the printer. This action initializes the printer to the proper state for printing the file. Any variables referenced by the command string should be the attribute values from the database, overridden by values from the command line.

If the **-j** flag passed from the **qprt** command has a nonzero value (true), any necessary fonts should be downloaded.

Return Values

Item	Description
0	Indicates a successful operation.

If the **initialize** subroutine detects an error, it uses the **piomsgout** subroutine to invoke an error message. It then invokes the **pioexit** subroutine with a value of **PIOEXITBAD**.

Note: If either the **piocmdout** or **piogetstr** subroutine detects an error, it issues its own error messages and terminates the print job.

initlabeldb and endlabeldb Subroutines

Purpose

Initializes or terminates database.

Library

Trusted AIX Library (**libmls.a**)

Syntax

```
#include <mls/mls.h>
int initlabeldb (dbfile)
const char * dbfile;

int endlabeldb (void)
```

Description

The **initlabeldb** subroutine initializes the label database that the *dbfile* parameter specifies. When the *dbfile* parameter is specified to NULL, the **initlabeldb** subroutine initializes the library data members using the **/etc/security/enc/LabelEncodings** file. The **initlabeldb** subroutine succeeds only if the formation of the label file is correct.

Before any operations on a label, must use the **initlabeldb** subroutine to initialize the database. The database that is initialized will be read only.

The **endlabeldb** subroutine terminates the database by freeing all of the memory that is allocated. There is no write back in this operation.

Parameters

Item	Description
dbfile	Specifies the file name that is to be used for label database initialization.

Security

Access Control: To access the default encodings file **/etc/security/enc/LabelEncodings**, the process must have the **PV_LAB_LEF** privilege.

File Accessed

Mode	File
r	**/etc/security/enc/LabelEncodings**

Return Values

If successful, the **initlabeldb** and **endlabeldb** subroutines return a value of zero. Otherwise, they return a value of -1.

Errors

If the **initlabeldb** subroutine fails, one of the following **errno** values can be set:

Item	Description
EBADF	The parameter that is passed is not NULL and is not a regular file.
EALREADY	The database specified is already initialized with a different encoding file.
EACCESS	The operation is not permitted.
ENOENT	The label encoding file is not found.

If the **endlabeldb** subroutine fails, it returns the following **errno** value:

Item	Description
ENOTREADY	The database is not initialized.

insch, mvinsch, mvwinsch, or winsch Subroutine

Purpose

Inserts a single-byte character and rendition in a window.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
int insch(chtype ch);
```

```
int mvinsch(int y,
chtype h);
```

```
int mvwinsch(WINDOW  *win,
int x,
int y,
chtype h);
```

```
int winsch(WINDOW *win,
chtype h);
```

Description

These subroutines insert the character and rendition into the current or specified window at the current or specified position.

These subroutines do not perform wrapping or advance the cursor position. These functions perform special-character processing, with the exception that if a **newline** is inserted into the last line of a window and scrolling is not enabled, the behavior is unspecified.

Parameters

Item	Description
ch	
y	

Item	Description
x	
**win*	Specifies the window in which to insert the character.

Return Values

Upon successful completion, these subroutines return OK. Otherwise, they return ERR.

Examples

1. To insert the character x in the stdscr, enter:

```
chtype x;
insch(x);
```

2. To insert the character x into the user-defined window `my_window`, enter:

```
WINDOW *my_window
chtype x;
winsch(my_window, x);
```

3. To move the logical cursor to the coordinates Y=10, X=5 prior to inserting the character x in the stdscr, enter:

```
chtype x;
mvinsch(10, 5, x);
```

4. To move the logical cursor to the coordinates y=10, X=5 prior to inserting the character x in the user-defined window `my_window`, enter:

```
WINDOW *my_window;
chtype x;
mvwinsch(my_window, 10, 5, x);
```

insertln or winsertln Subroutine

Purpose

Inserts a blank line above the current line in a window.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
int insertln(void)
```

int winsertln(WINDOW **win*);

Description

The **insertln** and **winsertln** subroutines insert a blank line before the current line in the current or specified window. The bottom line is no longer displayed. The cursor position does not change.

Parameters

Item	Description
**win*	Specifies the window in which to insert the blank line.

Return Values

Upon successful completion, these subroutines return OK. Otherwise, they return ERR.

Examples

1. To insert a blank line above the current line in the stdscr, enter:

```
insertln();
```

2. To insert a blank line above the current line in the user-defined window `my_window`, enter:

```
WINDOW *mywindow;
winsertln(my_window);
```

insque or remque Subroutine

Purpose

Inserts or removes an element in a queue.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <search.h>
```

insque (*Element*, *Pred*)
void ***Element*, ***Pred**;

```
remque (Element)
void *Element;
```

Description

The **insque** and **remque** subroutines manipulate queues built from double-linked lists. Each element in the queue must be in the form of a **qelem** structure. The **next** and **prev** elements of that structure must point to the elements in the queue immediately before and after the element to be inserted or deleted.

The **insque** subroutine inserts the element pointed to by the *Element* parameter into a queue immediately after the element pointed to by the *Pred* parameter.

The **remque** subroutine removes the element defined by the *Element* parameter from a queue.

Parameters

Item	Description
Pred	Points to the element in the queue immediately before the element to be inserted or deleted.

Item	Description
Element	Points to the element in the queue immediately after the element to be inserted or deleted.

install_lwcf_handler Subroutine

Purpose

Registers the signal handler to dump a lightweight core file for signals that normally cause the generation of a core file.

Library

PTools Library (**libptools_ptr.a**)

Syntax

```
void install_lwcf_handler (void);
```

Description

The **install_lwcf_handler** subroutine registers the signal handler to dump a lightweight core file for signals that normally cause a core file to be generated. The format of lightweight core files complies with the Parallel Tools Consortium Lightweight Core File Format.

The **install_lwcf_handler** subroutine uses the **LIGHTWEIGHT_CORE** environment variable to determine the target lightweight core file. If the **LIGHTWEIGHT_CORE** environment variable is defined, a lightweight core file will be generated. Otherwise, a normal core file will be generated.

If the **LIGHTWEIGHT_CORE** environment variable is defined without a value, the lightweight core file is assigned the default file name **lw_core** and is created under the current working directory if it does not already exist.

If the **LIGHTWEIGHT_CORE** environment variable is defined with a value of **STDERR**, the lightweight core file is output to the standard error output device of the process. Keyword STDERR is not case-sensitive.

If the **LIGHTWEIGHT_CORE** environment variable is defined with the value of a character string other than *STDERR*, the string is used as a path name for the lightweight core file generated.

If the target lightweight core file already exists, the traceback information is appended to the file.

The **install_lwcf_handler** subroutine can be called directly from an application to register the signal handler. Alternatively, linker option **-binitfini:install_lwcf_handler** can be used when linking an application, which specifies to execute the **install_lwcf_handler** subroutine when the application is initialized. The advantage of the second method is that the application code does not need to change to invoke the **install_lwcf_handler** subroutine.

Note: The source line information in a `Lightweight_core` file is not displayed by default when the text page size is 64 K. When the text page size is 64K, use the environment variable `AIX_LDSYM=ON` to get the source line information in a `Lightweight_core` file.

intrflush Subroutine

Purpose

Enables or disables flush on interrupt.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

int intrflush(WINDOW * *win*,
bool *bf*);

Description

The **intrflush** subroutine specifies whether pressing an interrupt key (interrupt, suspend, or quit) will flush the input buffer associated with the current screen. If the value of *bf* is TRUE, then flushing of the output buffer associated with the current screen will occur when an interrupt key (interrupt, suspend, or quit) is pressed. If the value of *bf* is FALSE then no flushing of the buffer will occur when an interrupt key is pressed. The default for the option is inherited from the display driver settings. The *win* argument is ignored.

Parameters

Item	Description
bf	
**win*	Specifies the window for which to enable or disable queue flushing.

Return Values

Upon successful completion, the **intrflush** subroutine returns OK. Otherwise, it returns ERR.

Examples

1. To enable queue flushing in the user-defined window `my_window`, enter:

   ```
   intrflush(my_window, TRUE);
   ```

2. To disable queue flushing in the user-defined window `my_window`, enter:

   ```
   intrflush(my_window, FALSE);
   ```

ioctl, ioctlx, ioctl32, or ioctl32x Subroutine

Purpose

Performs control functions associated with open file descriptors.

Library

Standard C Library (**libc.a**)

BSD Library (**libbsd.a**)

Syntax

#include <sys/ioctl.h> #include <sys/types.h> #include <unistd.h> #include <stropts.h>

int ioctl (*FileDescriptor***,** *Command***,** *Argument***) int** *FileDescriptor*, *Command***; void *** *Argument***;**

int ioctlx (*FileDescriptor***,** *Command***,** *Argument***,** *Ext* **) int** *FileDescriptor* **,** *Command* **; void ****Argument***;**
int *Ext***;**

int ioct132 (*FileDescriptor***,** *Command* **,** *Argument***) int** *FileDescriptor***,** *Command***; unsigned int** *Argument***;**

int ioct132x (*FileDescriptor***, *Command* , *Argument*, *Ext*) int** *FileDescriptor*, *Command*; **unsigned int** *Argument*; **unsigned int** *Ext*;

Description

The **ioctl** subroutine performs a variety of control operations on the object associated with the specified open file descriptor. This function is typically used with character or block special files, **sockets**, or generic device support such as the **termio** general terminal interface.

The control operation provided by this function call is specific to the object being addressed, as are the data type and contents of the *Argument* parameter. The **ioctlx** form of this function can be used to pass an additional extension parameter to objects supporting it. The **ioct132** and **ioct132x** forms of this function behave in the same way as **ioctl** and **ioctlx**, but allow 64-bit applications to call the **ioctl** routine for an object that does not normally work with 64-bit applications.

Performing an ioctl function on a file descriptor associated with an ordinary file results in an error being returned.

Parameters

Item	Description
FileDescriptor	Specifies the open file descriptor for which the control operation is to be performed.
Command	Specifies the control function to be performed. The value of this parameter depends on which object is specified by the *FileDescriptor* parameter.
Argument	Specifies additional information required by the function requested in the *Command* parameter. The data type of this parameter (a **void** pointer) is object-specific, and is typically used to point to an object device-specific data structure. However, in some device-specific instances, this parameter is used as an integer.
Ext	Specifies an extension parameter used with the **ioctlx** subroutine. This parameter is passed on to the object associated with the specified open file descriptor. Although normally of type **int**, this parameter can be used as a pointer to a device-specific structure for some devices.

File Input/Output (FIO) ioctl Command Values

A number of file input/output (FIO) ioctl commands are available to enable the **ioctl** subroutine to function similar to the **fcntl** subroutine:

Item	Description

FIOCLEX and FIONCLEX	Manipulate the **close-on-exec** flag to determine if a file descriptor should be closed as part of the normal processing of the **exec** subroutine. If the flag is set, the file descriptor is closed. If the flag is clear, the file descriptor is left open.
	
	The following code sample illustrates the use of the **fcntl** subroutine to set and clear the **close-on-exec** flag:
	
	`/* set the close-on-exec flag for fd1 */`
	`fcntl(fd1,F_SETFD,FD_CLOEXEC);`
	`/* clear the close-on-exec flag for fd2 */`
	`fcntl(fd2,F_SETFD,0);`
	
	Although the **fcntl** subroutine is normally used to set the **close-on-exec** flag, the **ioctl** subroutine may be used if the application program is linked with the Berkeley Compatibility Library (**libbsd.a**) or the Berkeley Thread Safe Library (**libbsd_r.a**). The following ioctl code fragment is equivalent to the preceding **fcntl** fragment:
	
	`/* set the close-on-exec flag for fd1 */`
	`ioctl(fd1,FIOCLEX,0);`
	`/* clear the close-on-exec flag for fd2 */`
	`ioctl(fd2,FIONCLEX,0);`
	
	The third parameter to the **ioctl** subroutine is not used for the **FIOCLEX** and **FIONCLEX** ioctl commands.

FIONBIO	Enables nonblocking I/O. The effect is similar to setting the **O_NONBLOCK** flag with the **fcntl** subroutine. The third parameter to the **ioctl** subroutine for this command is a pointer to an integer that indicates whether nonblocking I/O is being enabled or disabled. A value of 0 disables non-blocking I/O. Any nonzero value enables nonblocking I/O. A sample code fragment follows:
	
	`int flag;`
	`/* enable NBIO for fd1 */`
	`flag = 1;`
	`ioctl(fd1,FIONBIO,&flag);`
	`/* disable NBIO for fd2 */`
	`flag = 0;`
	`ioctl(fd2,FIONBIO,&flag);`

FIONREAD	Determines the number of bytes that are immediately available to be read on a file descriptor. The third parameter to the **ioctl** subroutine for this command is a pointer to an integer variable where the byte count is to be returned. The following sample code illustrates the proper use of the **FIONREAD** ioctl command:
	
	`int nbytes;`
	
	`ioctl(fd,FIONREAD,&nbytes);`

Item	Description

FIOASYNC	Enables a simple form of asynchronous I/O notification. This command causes the kernel to send **SIGIO** signal to a process or a process group when I/O is possible. Only sockets, ttys, and pseudo-ttys implement this functionality.
	
	The third parameter of the **ioctl** subroutine for this command is a pointer to an integer variable that indicates whether the asynchronous I/O notification should be enabled or disabled. A value of 0 disables I/O notification; any nonzero value enables I/O notification. A sample code segment follows:
	
	`int flag;`
	`/* enable ASYNC on fd1 */`
	`flag = 1;`
	`ioctl(fd, FIOASYNC,&flag);`
	`/* disable ASYNC on fd2 */`
	`flag = 0;`
	`ioctl(fd,FIOASYNC,&flag);`

FIOSETOWN	Sets the recipient of the **SIGIO** signals when asynchronous I/O notification (**FIOASYNC**) is enabled. The third parameter to the **ioctl** subroutine for this command is a pointer to an integer that contains the recipient identifier. If the value of the integer pointed to by the third parameter is negative, the value is assumed to be a process group identifier. If the value is positive, it is assumed to be a process identifier.
	
	Sockets support both process groups and individual process recipients, while ttys and psuedo-ttys support only process groups. Attempts to specify an individual process as the recipient will be converted to the process group to which the process belongs. The following code example illustrates how to set the recipient identifier:
	
	`int owner;`
	`owner = -getpgrp();`
	`ioctl(fd,FIOSETOWN,&owner);`
	
	Note: In this example, the asynchronous I/O signals are being enabled on a process group basis. Therefore, the value passed through the owner parameter must be a negative number.
	
	The following code sample illustrates enabling asynchronous I/O signals to an individual process:
	
	`int owner;`
	`owner = getpid();`
	`ioctl(fd,FIOSETOWN,&owner);`

FIOGETOWN	Determines the current recipient of the asynchronous I/O signals of an object that has asynchronous I/O notification (**FIOASYNC**) enabled. The third parameter to the **ioctl** subroutine for this command is a pointer to an integer used to return the owner ID. For example:
	
	`int owner;`
	`ioctl(fd,FIOGETOWN,&owner);`
	
	If the owner of the asynchronous I/O capability is a process group, the value returned in the reference parameter is negative. If the owner is an individual process, the value is positive.

Return Values

If the **ioctl** subroutine fails, a value of -1 is returned. The **errno** global variable is set to indicate the error.

The **ioctl** subroutine fails if one or more of the following are true:

Item	Description
EBADF	The *FileDescriptor* parameter is not a valid open file descriptor.
EFAULT	The *Argument* or *Ext* parameter is used to point to data outside of the process address space.
EINTR	A signal was caught during the **ioctl** or **ioctlx** subroutine and the process had not enabled re-startable subroutines for the signal.
EINTR	A signal was caught during the **ioctl** , **ioctlx** , **ioctl32** , or **ioct132x** subroutine and the process had not enabled re-startable subroutines for the signal.
EINVAL	The *Command* or *Argument* parameter is not valid for the specified object.
ENOTTY	The *FileDescriptor* parameter is not associated with an object that accepts control functions.
ENODEV	The *FileDescriptor* parameter is associated with a valid character or block special file, but the supporting device driver does not support the ioctl function.
ENXIO	The *FileDescriptor* parameter is associated with a valid character or block special file, but the supporting device driver is not in the configured state.

Object-specific error codes are defined in the documentation for associated objects.

is_linetouched, is_wintouched, touchline, touchwin, untouchwin, or wtouchin Subroutine

Purpose

Window refresh control functions.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

bool is_linetouched(WINDOW *win,
int line);
```

```
bool is_wintouched(WINDOW *win);

int touchline(WINDOW *win,
int start,
```

```
int count);

int touchwin(WINDOW *win);

int untouchwin(WINDOW *win);

int wtouchln(WINDOW *win,
int y,
int n,
int changed);
```

Description

The **touchline** subroutine touches the specified window (that is, marks it as having changed more recently than the last refresh operation). The **touchline** subroutine only touches count lines, beginning with line start.

The **untouchwin** subroutine marks all lines in the window as unchanged since the last refresh operation.

Calling the **wtouchln** subroutine, if changed is 1, touches n lines in the specified window, starting at line y. If changed is 0, **wtouchln** marks such lines as unchanged since the last refresh operation.

The **is_wintouchwin** subroutine determines whether the specified window is touched. The **is_linetouched** subroutine determines whether line line of the specified window is touched.

Parameters

Item	Description
line	
start	
count	
changed	
y	
n	
*win	

Return Values

The **is_linetouched** and **is_wintouched** subroutines return TRUE if any of the specified lines, or the specified window, respectively, has been touched since the last refresh operation. Otherwise, they return FALSE.

Upon successful completion, the other subroutines return OK. Otherwise, they return ERR. Exceptions to this are noted in the preceding subroutine.

Examples

For the **touchline** subroutine:

To set 10 lines for refresh starting from line 5 of the user-defined window `my_window`, use:

```
WINDOW *my_window;
touchline(my_window, 5, 10);
wrefresh(my_window);
```

This forces **curses** to disregard any optimization information it may have for lines 0-4 in `my_window`. **curses** assumes all characters in lines 0-4 have changed.

For the **touchwin** subroutine:

To refresh a user-defined parent window, `parent_window`, that has been edited through its subwindows, use:

```
WINDOW *parent_window;
touchwin(parent_window);

wrefresh(parent_window);
```

This forces **curses** to disregard any optimization information it may have for `my_window`. **curses** assumes all lines and columns have changed for `my_window`.

isalpha_l, isupper_l, islower_l, isdigit_l, isxdigit_l, isalnum_l, isspace_l, ispunct_l, isprint_l, isgraph_l, iscntrl_l, or isascii_ l Subroutines

Purpose

Classifies characters in the specified locale.

Library

Standard Character Library (**libc.a**)

Syntax

```
#include <ctype.h>
```

```
int isalpha_l (Character, locale);
int Character;
locale_t locale;
int isupper_l (Character, locale);
int Character;
locale_t locale;
int islower_l (Character, locale);
int Character;
locale_t locale;
int isdigit_l (Character, locale);
int Character;
locale_t locale;
int isxdigit_l (Character, locale);
int Character;
locale_t locale;
int isalnum_l (Character, locale);
int Character;
locale_t locale;
int isspace_l (Character, locale);
int Character;
locale_t locale;
int ispunct_l (Character, locale);
int Character;
locale_t locale;
int isprint_l (Character, locale);
int Character;
locale_t locale;
int isgraph_l (Character, locale);
int Character;
locale_t locale;
```

```
int iscntrl_l (Character, locale);
int Character;
locale_t locale;
```

Description

These routines are the same as the **isalpha**, **isupper**, **islower**, **isdigit**, **isxdigit**, **isalnum**, **isspace**, **ispunct**, **isprint**, **isgraph**, and **iscntrl** subroutines, except that they test the character C in the locale that is represented by locale instead of the current locale.

Return Codes

Refer to the **isupper** subroutine.

isblank, or isblank_l Subroutines

Purpose

Tests for a blank character.

Syntax

```
#include <ctype.h>

int isblank (c)
int c;
```

```
int isblank_l (c, Locale)
int c;
locale_t Locale;
```

Description

The **isblank** and **isblank_l** subroutines test whether the *c* parameter is a character of class **blank** in the program's current locale or in the locale represented by *Locale*.

The *c* parameter is a type **int**, the value of which the application shall ensure is a character representable as an **unsigned char** or equal to the value of the macro EOF. If the parameter has any other value, the behavior is undefined.

Parameters

Item	Description
c	Specifies the character to be tested.
Locale	Specifies the locale, in which the character is tested.

Return Values

The **isblank** and **isblank_l** subroutines return nonzero if *c* is a <blank>; otherwise, it returns 0.

isendwin Subroutine

Purpose

Determines whether the **endwin** subroutine was called without any subsequent refresh calls.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
isendwin()
```

Description

The **isendwin** subroutine determines whether the **endwin** subroutine was called without any subsequent refresh calls. If the **endwin** was called without any subsequent calls to the **wrefresh** or **doupdate** subroutines, the **isendwin** subroutine returns TRUE.

Return Values

Item	Description
TRUE	Indicates the **endwin** subroutine was called without any subsequent calls to the **wrefresh** or **doupdate** subroutines.
FALSE	Indicates subsequest calls to the refresh subroutines.

isfinite Macro

Purpose

Tests for finite value.

Syntax

```
#include <math.h>

int isfinite (x)
real-floating x;
```

Description

The **isfinite** macro determines whether its argument has a finite value (zero, subnormal, or normal, and not infinite or NaN). An argument represented in a format wider than its semantic type is converted to its semantic type. Determination is based on the type of the argument.

Parameters

Item	Description
x	Specifies the value to be tested.

Return Values

The **isfinite** macro returns a nonzero value if its argument has a finite value.

isgreater Macro

Purpose

Tests if *x* is greater than *y*.

Syntax

```
#include <math.h>

int isgreater (x, y)
real-floating x;
real-floating y;
```

Description

The **isgreater** macro determines whether its first argument is greater than its second argument. The value of **isgreater**(*x, y*) is equal to (*x*) > (*y*); however, unlike (*x*) > (*y*), **isgreater**(*x, y*) does not raise the invalid floating-point exception when *x* and *y* are unordered.

Parameters

Item	Description
x	Specifies the first value to be compared.
y	Specifies the first value to be compared.

Return Values

Upon successful completion, the **isgreater** macro returns the value of (*x*) > (*y*).

If *x* or *y* is NaN, 0 is returned.

isgreaterequal Subroutine

Purpose

Tests if *x* is greater than or equal to *y*.

Syntax

```
#include <math.h>

int isgreaterequal (x, y)
real-floating x;
real-floating y;
```

Description

The **isgreaterequal** macro determines whether its first argument is greater than or equal to its second argument. The value of **isgreaterequal** (*x, y*) is equal to (*x*) >= (*y*); however, unlike (*x*) >= (*y*), **isgreaterequal** (*x, y*) does not raise the invalid floating-point exception when *x* and *y* are unordered.

Parameters

Item	Description
x	Specifies the first value to be compared.

Item	Description
y	Specifies the second value to be compared.

Return Values

Upon successful completion, the **isgreaterequal** macro returns the value of (*x*) >= (*y*).

If *x* or *y* is NaN, 0 is returned.

isinf Subroutine

Purpose

Tests for infinity.

Syntax

```
#include <math.h>

int isinf (x)
real-floating x;
```

Description

The **isinf** macro determines whether its argument value is an infinity (positive or negative). An argument represented in a format wider than its semantic type is converted to its semantic type. Determination is based on the type of the argument.

Parameters

Item	Description
x	Specifies the value to be checked.

Return Values

The **isinf** macro returns a nonzero value if its argument has an infinite value.

isless Macro

Purpose

Tests if *x* is less than *y*.

Syntax

```
#include <math.h>
int isless (x, y)
real-floating x;
real-floating y;
```

Description

The **isless** macro determines whether its first argument is less than its second argument. The value of **isless**(*x, y*) is equal to (*x*) < (*y*); however, unlike (*x*) < (*y*), **isless**(*x, y*) does not raise the invalid floating-point exception when *x* and *y* are unordered.

Parameters

Item	Description
x	Specifies the first value to be compared.
y	Specifies the second value to be compared.

Return Values

Upon successful completion, the **isless** macro returns the value of (*x*) < (*y*).

If *x* or *y* is NaN, 0 is returned.

islessequal Macro

Purpose

Tests if *x* is less than or equal to *y*.

Syntax

```
#include <math.h>

int islessequal (x, y)
real-floating x;
real-floating y;
```

Description

The **islessequal** macro determines whether its first argument is less than or equal to its second argument. The value of **islessequal**(*x, y*) is equal to (*x*) <= (*y*); however, unlike (*x*) <= (*y*), **islessequal**(*x, y*) does not raise the invalid floating-point exception when *x* and *y* are unordered.

Parameters

Item	Description
x	Specifies the first value to be compared.
y	Specifies the second value to be compared.

Return Values

Upon successful completion, the **islessequal** macro returns the value of (*x*) <= (*y*).

If *x* or *y* is NaN, 0 is returned.

islessgreater Macro

Purpose

Tests if *x* is less than or greater than *y*.

Syntax

```
#include <math.h>

int islessgreater (x, y)
```

```
real-floating x;
real-floating y;
```

Description

The **islessgreater** macro determines whether its first argument is less than or greater than its second argument. The **islessgreater**(*x, y*) macro is similar to (*x*) < (*y*) || (*x*) > (*y*); however, **islessgreater**(*x, y*) does not raise the invalid floating-point exception when *x* and *y* are unordered (nor does it evaluate *x* and *y* twice).

Parameters

Item	Description
x	Specifies the first value to be compared.
y	Specifies the second value to be compared.

Return Values

Upon successful completion, the **islessgreater** macro returns the value of (*x*) < (*y*) || (*x*) > (*y*).

If *x* or *y* is NaN, 0 is returned.

isnormal Macro

Purpose

Tests for a normal value.

Syntax

```
#include <math.h>

int isnormal (x)
real-floating x;
```

Description

The **isnormal** macro determines whether its argument value is normal (neither zero, subnormal, infinite, nor NaN) or not. An argument represented in a format wider than its semantic type is converted to its semantic type. Determination is based on the type of the argument.

Parameters

Item	Description
x	Specifies the value to be tested.

Return Values

The **isnormal** macro returns a nonzero value if its argument has a normal value.

isunordered Macro

Purpose

Tests if arguments are unordered.

Syntax

```
#include <math.h>
int isunordered (x, y)
real-floating x;
real-floating y;
```

Description

The **isunordered** macro determines whether its arguments are unordered.

Parameters

Item	Description
x	Specifies the first value in the order.
y	Specifies the second value in the order.

Return Values

Upon successful completion, the **isunordered** macro returns 1 if its arguments are unordered, and 0 otherwise.

If *x* or *y* is NaN, 0 is returned.

iswalnum, iswalpha, iswcntrl, iswdigit, iswgraph, iswlower, iswprint, iswpunct, iswspace, iswupper, or iswxdigit Subroutine

Purpose

Tests a wide character for membership in a specific character class.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <wchar.h>
```

```
int iswalnum (WC)
wint_t WC;
```

```
int iswalpha (WC)
wint_t WC;
```

```
int iswcntrl (WC)
wint_t WC;
```

```
int iswdigit (WC)
wint_t WC;
```

```
int iswgraph (WC)
wint_t WC;
```

```
int iswlower (WC)
wint_t WC;
```

```
int iswprint (WC)
wint_t WC;
```

```
int iswpunct (WC)
wint_t WC;
```

```
int iswspace (WC)
wint_t WC;
```

```
int iswupper (WC)
wint_t WC;
```

```
int iswxdigit (WC)
wint_t WC;
```

Description

The **isw** subroutines check the character class status of the wide character code specified by the *WC* parameter. Each subroutine tests to see if a wide character is part of a different character class. If the wide character is part of the character class, the **isw** subroutine returns true; otherwise, it returns false.

Each subroutine is named by adding the **isw** prefix to the name of the character class that the subroutine tests. For example, the **iswalpha** subroutine tests whether the wide character specified by the *WC* parameter is an alphabetic character. The character classes are defined as follows:

Item	Description
alnum	Alphanumeric character.
alpha	Alphabetic character.
cntrl	Control character. No characters in the **alpha** or **print** classes are included.
digit	Numeric digit character.
graph	Graphic character for printing, not including the space character or **cntrl** characters. Includes all characters in the **digit** and **punct** classes.
lower	Lowercase character. No characters in **cntrl**, **digit**, **punct**, or **space** are included.
print	Print character. All characters in the **graph** class are included, but no characters in **cntrl** are included.
punct	Punctuation character. No characters in the **alpha**, **digit**, or **cntrl** classes, or the space character are included.
space	Space characters.
upper	Uppercase character.
xdigit	Hexadecimal character.

Parameters

Item	Description
WC	Specifies a wide character for testing.

Return Values

If the wide character tested is part of the particular character class, the **isw** subroutine returns a nonzero value; otherwise it returns a value of 0.

iswalnum_l, iswalpha_l, iswcntrl_l, iswdigit_l, iswgraph_l, iswlower_l, iswprint_l, iswpunct_l, iswspace_l, iswupper_l, or iswxdigit_l Subroutines

Purpose

Tests a wide character for membership in a specific character class.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <wchar.h>
```

```
int iswalnum_l (WC, locale)
wint_t WC;
locale_t locale;
int iswalpha_l (WC, locale)
wint_t WC;
locale_t locale;
int iswcntrl_l (WC, locale)
wint_t WC;
locale_t locale;
int iswdigit_l (WC, locale)
wint_t WC;
locale_t locale;
int iswgraph_l (WC, locale)
wint_t WC;
locale_t locale;
int iswlower_l (WC, locale)
wint_t WC;
locale_t locale;
int iswprint_l (WC, locale)
wint_t WC;
locale_t locale;
int iswpunct_l (WC, locale)
wint_t WC;
locale_t locale;
int iswspace_l (WC, locale)
wint_t WC;
locale_t locale;
int iswupper_l (WC, locale)
wint_t WC;
locale_t locale;
int iswxdigit_l (WC, locale)
wint_t WC;
locale_t locale;
```

Description

These routines are the same as the **iswalnum**, **iswalpha**, **iswcntrl** , **isdigit**, **iswgraph**, **iswlower**, **iswprint**, **iswpunct**, **iswspace**, **iswupper**, and **iswxdigit** subroutines, except that they test the character WC in the locale that is represented by locale instead of the current locale.

Return Codes

Refer to the **iswupper** subroutine.

iswblank, or iswblank_l Subroutines

Purpose

Tests for a blank wide-character code.

Syntax

```
#include <wctype.h>

int iswblank (wc)
wint_t wc;
```

```
int iswblank_l(wc, Locale)
wint_t wc;
locale_t Locale;
```

Description

The **iswblank** and **iswblank_l** subroutines test whether the *wc* parameter is a wide-character code representing a character of class **blank** in the program's current locale or in the locale represented by *Locale*.

The *wc* parameter is a **wint_t**, the value of which the application ensures is a wide-character code corresponding to a valid character in the current locale, or equal to the value of the macro **WEOF**. If the parameter has any other value, the behavior is undefined.

Parameters

Item	Description
wc	Specifies the value to be tested.
Locale	Specifies the locale, in which the character is tested.

Return Values

The **iswblank** and **iswblank_l** subroutines return a nonzero value if the *wc* parameter is a blank wide-character code; otherwise, it returns a 0.

iswctype, iswctype_l or is_wctype Subroutine

Purpose

Determines properties of a wide character.

Library

Standard C Library (**libc. a**)

Syntax

```
#include  <wchar.h>
```

```
int iswctype  ( WC,  Property)
wint_t WC;
wctype_t Property;
```

```
int iswctype_l  ( WC, Property, Locale)
wint_t WC;
wctype_t Property;
locale_t Locale;
```

```
int is_wctype ( WC,  Property)
wint_t WC;
wctype_t Property;
```

Description

The **iswctype**, and **iswctype_l** subroutines test the wide character specified by the *WC* parameter to determine if it has the property specified by the *Property* parameter. The **iswctype**, and **iswctype_l** subroutines are defined for the wide-character null value and for values in the character range of the current code set, defined in the current locale or in the locale represented by *Locale*. The **is_wctype** subroutine is identical to the **iswctype** subroutine.

The **iswctype** subroutine adheres to X/Open Portability Guide Issue 5.

Parameters

Item	Description
WC	Specifies the wide character to be tested.
Property	Specifies the property for which to test.
Locale	Specifies the locale, in which the character is tested.

Return Values

If the *WC* parameter has the property specified by the *Property* parameter, the **iswctype**, and **iswctype_l** subroutines return a nonzero value. If the value specified by the *WC* parameter does not have the property specified by the *Property* parameter, the **iswctype**, and **iswctype_l** subroutines return a value of zero. If the value specified by the *WC* parameter is not in the subroutine's domain, the result is undefined. If the value specified by the *Property* parameter is not valid (that is, not obtained by a call to the **wctype** subroutine, or the *Property* parameter has been invalidated by a subsequent call to the **setlocale** subroutine that has affected the **LC_CTYPE** category), the result is undefined.

j

The following Base Operating System (BOS) runtime services begin with the letter *j*.

jcode Subroutines

Purpose

Perform string conversion on 8-bit processing codes.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <jcode.h>
```

```
char *jistosj(String1, String2)
char *String1, *String2;
```

```
char *jistouj(String1, String2)
char *String1, *String2;
```

```
char *sjtojis(String1, String2)
char *String1, *String2;
```

```
char *sjtouj(String1, String2)
char *String1, *String2;
```

```
char *ujtojis(String1, String2)
char *String1, *String2;
```

```
char *ujtosj(String1, String2)
char *String1, *String2;
```

```
char *cjistosj(String1, String2)
char *String1, *String2;
```

```
char *cjistouj(String1, String2)
char *String1, *String2;
```

```
char *csjtojis(String1, String2)
char *String1, *String2;
```

```
char *csjtouj(String1, String2)
char *String1, *String2;
```

```
char *cujtojis(String1, String2)
char *String1, *String2;
```

```
char *cujtosj(String1, String2)
char *String1, *String2;
```

Description

The **jistosj**, **jistouj**, **sjtojis**, **sjtouj**, **ujtojis**, and **ujtosj** subroutines perform string conversion on 8-bit processing codes. The *String2* parameter is converted and the converted string is stored in the *String1* parameter. The overflow of the *String1* parameter is not checked. Also, the *String2* parameter must be a valid string. Code validation is not permitted.

The **jistosj** subroutine converts JIS to SJIS. The **jistouj** subroutine converts JIS to UJIS. The **sjtojis** subroutine converts SJIS to JIS. The **sjtouj** subroutine converts SJIS to UJIS. The **ujtojis** subroutine converts UJIS to JIS. The **ujtosj** subroutine converts UJIS to SJIS.

The **cjistosj**, **cjistouj**, **csjtojis**, **csjtouj**, **cujtojis**, and **cujtosj** macros perform code conversion on 8-bit processing JIS Kanji characters. A character is removed from the *String2* parameter, and its code is converted and stored in the *String1* parameter. The *String1* parameter is returned. The validity of the *String2* parameter is not checked.

The **cjistosj** macro converts from JIS to SJIS. The **cjistouj** macro converts from JIS to UJIS. The **csjtojis** macro converts from SJIS to JIS. The **csjtouj** macro converts from SJIS to UJIS. The **cujtojis** macro converts from UJIS to JIS. The **cujtosj** macro converts from UJIS to SJIS.

Parameters

Item	Description
String1	Stores converted string or code.
String2	Stores string or code to be converted.

Japanese conv Subroutines

Purpose

Translates predefined Japanese character classes.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <ctype.h>
int atojis (Character)
int Character;
```

```
int jistoa (Character)
int Character;
```

```
int _atojis (Character)
int Character;
```

```
int _jistoa (Character)
int Character;
```

```
int tojupper (Character)
int Character;
```

```
int tojlower (Character)
int Character;
```

```
int _tojupper (Character)
int Character;
```

```
int _tojlower (Character)
int Character;
```

```
int toujis (Character)
int Character;
```

```
int kutentojis (Character)
int Character;
```

```
int tojhira (Character)
int Character;
```

```
int tojkata (Character)
int Character;
```

Description

When running the operating system with Japanese Language Support on your system, the legal value of the *Character* parameter is in the range from 0 to **NLCOLMAX**.

The **jistoa** subroutine converts an SJIS ASCII equivalent to the corresponding ASCII equivalent. The **atojis** subroutine converts an ASCII character to the corresponding SJIS equivalent. Other values are returned unchanged.

The **_jistoa** and **_atojis** routines are macros that function like the **jistoa** and **atojis** subroutines, but are faster and have no error checking function.

The **tojlower** subroutine converts a SJIS uppercase letter to the corresponding SJIS lowercase letter. The **tojupper** subroutine converts an SJIS lowercase letter to the corresponding SJIS uppercase letter. All other values are returned unchanged.

The **_tojlower** and **_tojupper** routines are macros that function like the **tojlower** and **tojupper** subroutines, but are faster and have no error-checking function.

The **toujis** subroutine sets all parameter bits that are not 16-bit SJIS code to 0.

The **kutentojis** subroutine converts a kuten code to the corresponding SJIS code. The **kutentojis** routine returns 0 if the given kuten code is invalid.

The **tojhira** subroutine converts an SJIS katakana character to its SJIS hiragana equivalent. Any value that is not an SJIS katakana character is returned unchanged.

The **tojkata** subroutine converts an SJIS hiragana character to its SJIS katakana equivalent. Any value that is not an SJIS hiragana character is returned unchanged.

The **_tojhira** and **_tojkata** subroutines attempt the same conversions without checking for valid input.

For all functions except the **toujis** subroutine, the out-of-range parameter values are returned without conversion.

Parameters

Item	Description
Character	Character to be converted.
Pointer	Pointer to the escape sequence.
CharacterPointer	Pointer to a single **NLchar** data type.

Japanese ctype Subroutines

Purpose

Classify characters.

Library

Standard Character Library (**libc.a**)

Syntax

```
#include <ctype.h>
```

```
int isjalpha ( Character)
int Character;
```

```
int isjupper (Character)
int Character;
```

```
int isjlower (Character)
int Character;
```

```
int isjlbytekana (Character)
int Character;
```

```
int isjdigit (Character)
int Character;
```

```
int isjxdigit (Character)
int Character;
```

```
int isjalnum (Character)
int Character;
```

```
int isjspace (Character)
int Character;
```

```
int isjpunct (Character)
int Character;
```

```
int isjparen (Character)
int Character;
```

```
int isparent (Character)
intCharacter;
```

```
int isjprint (Character)
int Character;
```

```
int isjgraph (Character)
int Character;
```

```
int isjis (Character)
int Character;
```

```
int isjhira (wc)
wchar_t wc;
```

```
int isjkanji (wc)
wchar_wc;
```

```
int isjkata (wc)
wchar_t wc;
```

Description

The **Japanese ctype** subroutines classify character-coded integer values specified in a table. Each of these subroutines returns a nonzero value for True and 0 for False.

Parameters

Item	Description
Character	Character to be tested.

Return Values

The **isjprint** and **isjgraph** subroutines return a 0 value for user-defined characters.

k

The following Base Operating System (BOS) runtime services begin with the letter *k*.

keyname, key_name Subroutine

Purpose

Gets the name of keys.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

char *keyname(int c);

char *key_name(wchar_t c);
```

Description

The **keyname** and **key_name** subroutines generate a character string whose value describes the key *c*. The *c* argument of **keyname** can be an 8-bit character or a key code. The *c* argument of **key_name** must be a wide character.

The string has a format according to the first applicable row in the following table:

Item	Description
Input	Format of Returned String
Visible character	The same character
Control character	^X
Meta-character (**keyname** only)	M-X
Key value defined in <curses.h> (**keyname** only)	KEY_name
None of the above	UNKNOWN KEY

The meta-character notation shown above is used only, if meta-characters are enabled.

Parameter

c

Return Values

Upon successful completion, the **keyname** subroutine returns a pointer to a string as described above, Otherwise, it returns a null pointer.

Examples

```
int key;
char *name;
```

```
keypad(stdscr, TRUE);
addstr("Hit a key");
key=getch();
name=keyname(key);
```

Note: If the Page Up key is pressed, keyname will return **KEY_PPAGE**.

keypad Subroutine

Purpose

Enables or disables abbreviation of function keys.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

int keypad(WINDOW **win*,
bool *bf*);

Description

The **keypad** subroutine controls keypad translation. If *bf* is TRUE, keypad translation is turned on. If *bf* is FALSE, keypad translation is turned off. The initial state is FALSE.

This subroutine affects the behavior of any function that provides keyboard input.

If the terminal in use requires a command to enable it to transmit distinctive codes when a function key is pressed, then after keypad translation is first enabled, the implemenation transmits this command to the terminal before an affected input function tries to read any characters from that terminal.

Parameters

Item	Description
bf	
**win*	Specifies the window in which to enable or disable the keypad.

Return Values

Upon successful completion, the **keypad** subroutine returns OK**.** Otherwise, it returns ERR.

Examples

To turn on the keypad in the user-defined window `my_window`, use:

```
WINDOW *my_window;
keypad(my_window, TRUE);
```

killchar or killwchar Subroutine

Purpose

Terminal environment query functions.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
char killchar(void);
```

```
int killwchar(wchar_t *ch);
```

Description

The **killchar** subroutine returns the current line.

The **killchar** subroutine stores the current line kill character in the object pointed to by *ch*. If no line kill character has been defined, the subroutine will fail and the object pointed to by *ch* will not be changed.

Parameters

**ch*

Return Values

The **killchar** subroutine returns the line kill character. The return value is unspecified when this character is a multi-byte character.

Upon successful completion, the **killchar** subroutine returns OK. Otherwise, it returns ERR.

kget_proc_info Kernel Service

Purpose

Allows a kernel extension to get information about a process or process group.

Syntax

```
#include <procinfo.h>
```

kerrno_t kget_proc_info (*cmd*,*id*,*data*,*size***)**
int *cmd***;**
pid_t *id***;**
void * *data***;**
size_t * *size***;**

Parameters

Item	Description
cmd	Command indicating data to be returned.
id	Process group ID (PID) for which the information is retrieved.
data	Data region that contains the data returned
size	Size of the data region

Description

The **kget_proc_info** kernel service retrieves information about a process or process group for a kernel extension. The following **cmd** values are supported, with the specified parameters and return codes:

Parameter	Return Codes
VALIDATE_PID	This command determines if a PID or process group ID is valid. The *data* and *size* parameters are unused. This command will return **0** if the PID is valid, and ESRCH_INVALID_PID if it is not valid.
GET_PROCENTRY64	This command fills in a **procentry64** structure for the given PID. The data should point to a **struct procentry64** and size should be the size of a **struct procentry64**. This command will return 0 on success, EINVAL_NULL_SIZE for a NULL size parameter, EINVAL_NULL_DATA for a NULL data parameter, ESRCH_INVALID_PID if the PID is invalid, ERANGE_INSUFFICIENT_SIZE if size is insufficient to contain the **struct procentry64**, and EPERM_INSUFFICIENT_PRIVS if the current process is not allowed to obtain information about the target process.
GET_PGRP and **GET_PGRP_BY_MEMBER**	These commands fill in an array of PIDs in a process group. The process group is specified either by a process group PID (GET_PGRP) or the PID of a member of the process group (GET_PGRP_BY_MEMBER). If the *data* parameter is NULL, this will update the target *size* parameter with the size needed to hold all the PIDs. On successful return, the *data* parameter is filled with an array of PIDs and the *size* parameter is filled in with the actual size used. A value of 0 is returned for success. This command will return EINVAL_NULL_SIZE for a NULL *size* parameter, ESRCH_INVALID_PID if the PID is invalid, and ERANGE_INSUFFICIENT_SIZE if a *data* parameter is specified and *size* is insufficient to contain the array of PIDs. If the size is insufficient, the *size* parameter is updated with the correct needed size. **Note:** While the data returned is consistent during the call, on return, the process or process group may change. Specifically, the size needed to hold the array of PIDs may be insufficient on a successive call.

Execution Environment

kget_proc_info must be called from the process environment only.

Return Values

Upon successful completion, 0 is returned. If the call is unsuccessful, an error number is returned as detailed in the corresponding command. Additionally, EINVAL_INVALID_COMMAND is returned for an invalid command.

kill or killpg Subroutine

Purpose

Sends a signal to a process or to a group of processes.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/types.h>
#include <signal.h>
```

```
int kill(
 Process,
 Signal)
pid_t Process;
int Signal;
```

```
killpg(
 ProcessGroup, Signal)
int ProcessGroup, Signal;
```

Description

The **kill** subroutine sends the signal specified by the *Signal* parameter to the process or group of processes specified by the *Process* parameter.

To send a signal to another process, either the real or the effective user ID of the sending process must match the real or effective user ID of the receiving process, and the calling process must have root user authority.

The processes that have the process IDs of 0 and 1 are special processes and are sometimes referred to here as *proc0* and *proc1*, respectively.

Processes can send signals to themselves.

Note: Sending a signal does not imply that the operation is successful. All signal operations must pass the access checks prescribed by each enforced access control policy on the system.

The following interface is provided for BSD Compatibility:

```
killpg(ProcessGroup, Signal)
int ProcessGroup; Signal;
```

This interface is equivalent to:

```
if (ProcessGroup < 0)
{
  errno = ESRCH;
  return (-1);
}
return (kill(-ProcessGroup, Signal));
```

Parameters

Item	Description
Process	Specifies the ID of a process or group of processes. If the *Process* parameter is greater than 0, the signal specified by the *Signal* parameter is sent to the process identified by the *Process* parameter. If the *Process* parameter is 0, the signal specified by the *Signal* parameter is sent to all processes, excluding *proc0* and *proc1*, whose process group ID matches the process group ID of the sender. If the value of the *Process* parameter is a negative value other than -1 and if the calling process passes the access checks for the process to be signaled, the signal specified by the *Signal* parameter is sent to all the processes, excluding *proc0* and *proc1*. If the user ID of the calling process has root user authority, all processes, excluding *proc0* and *proc1*, are signaled. If the value of the *Process* parameter is a negative value other than -1, the signal specified by the *Signal* parameter is sent to all processes having a process group ID equal to the absolute value of the *Process* parameter. If the value of the *Process* parameter is -1, the signal specified by the *Signal* parameter is sent to all processes which the process has permission to send that signal.
Signal	Specifies the signal. If the Signal parameter is a null value, error checking is performed but no signal is sent. This parameter is used to check the validity of the *Process* parameter.
ProcessGroup	Specifies the process group.

Return Values

Upon successful completion, the **kill** subroutine returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **kill** subroutine is unsuccessful and no signal is sent if one or more of the following are true:

Item	Description
EINVAL	The *Signal* parameter is not a valid signal number.
EINVAL	The *Signal* parameter specifies the **SIGKILL**, **SIGSTOP**, **SIGTSTP**, or **SIGCONT** signal, and the *Process* parameter is 1 (*proc1*).
ESRCH	No process can be found corresponding to that specified by the *Process* parameter.
EPERM	The real or effective user ID does not match the real or effective user ID of the receiving process, or else the calling process does not have root user authority.

kleenup Subroutine

Purpose

Cleans up the run-time environment of a process.

Library

Syntax

```
int kleenup( FileDescriptor,  SigIgn,  SigKeep)
int FileDescriptor;
int SigIgn[ ];
int SigKeep[ ];
```

Description

The **kleenup** subroutine cleans up the run-time environment for a trusted process by:

- Closing unnecessary file descriptors.
- Resetting the alarm time.
- Resetting signal handlers.
- Clearing the value of the **real directory read** flag described in the **ulimit** subroutine.
- Resetting the **ulimit** value, if it is less than a reasonable value (8192).

Parameters

Item	Description
FileDescriptor	Specifies a file descriptor. The **kleenup** subroutine closes all file descriptors greater than or equal to the *FileDescriptor* parameter.
SigIgn	Points to a list of signal numbers. If these are nonnull values, this list is terminated by 0s. Any signals specified by the *SigIgn* parameter are set to **SIG_IGN**. The handling of all signals not specified by either this list or the *SigKeep* list are set to **SIG_DFL**. Some signals cannot be reset and are left unchanged.
SigKeep	Points to a list of signal numbers. If these are nonnull values, this list is terminated by 0s. The handling of any signals specified by the *SigKeep* parameter is left unchanged. The handling of all signals not specified by either this list or the *SigIgn* list are set to **SIG_DFL**. Some signals cannot be reset and are left unchanged.

Return Values

The **kleenup** subroutine is always successful and returns a value of 0. Errors in closing files are not reported. It is not an error to attempt to modify a signal that the process is not allowed to handle.

knlist Subroutine

Purpose

Translates names to addresses in the running system.

Syntax

```
#include <nlist.h>
```

```
int knlist( NList,  NumberOfElements,  Size)
struct nlist *NList;
int NumberOfElements;
int Size;
```

Description

The **knlist** subroutine allows a program to look up the addresses of symbols exported by the kernel and kernel extensions.

The n_name field in the **nlist** structure specifies the name of a symbol for which the address is requested. If the symbol is found, its address is saved in the **n_value** field, and the remaining fields are not modified. If the symbol is not found, all fields, other than **n_name**, are set to 0.

In a 32-bit program, the **n_value** field is a 32-bit field, which is too small for some kernel addresses. To allow the addresses of all specified symbols to be obtained, 32-bit programs must use the **nlist64** structure, which contains a 64-bit **n_value** field. For example, if NList64 is the address of an array of **nlist64** structures, the **knlist** subroutine can be called as shown in the following example:

```
rc = knlist((struct nlist *)Nlist64,
                  NumberOfElements,
                  sizeof(structure nlist64));
```

The **nlist** and **nlist64** structures include the following fields:

Item	Description
`char *n_name`	Specifies the name of the symbol for which the address is to be retrieved.
`long n_value`	The address of the symbol, filled in by the **knlist** subroutine. This field is included in the **nlist** structure.
`long long n_value`	The address of the symbol, filled in by the **knlist** subroutine. This field is included in the **nlist64** structure.

The **nlist.h** file is automatically included by the **a.out.h** file for compatibility. However, do not include the **a.out.h** file if you only need the information necessary to use the **knlist** subroutine. If you do include the **a.out.h** file, follow the **#include** statement with the following line:

```
#undef n_name
```

Note:

1. If both the **nlist.h** and **netdb.h** files are to be included, the **netdb.h** file should be included before the **nlist.h** file in order to avoid a conflict with the **n_name** structure member. Likewise, if both the **a.out.h** and **netdb.h** files are to be included, the **netdb.h** file should be included before the **a.out.h** file to avoid a conflict with the **n_name** structure.
2. If the **netdb.h** file and either the **nlist.h** or **syms.h** file are included, the n_name field will be defined as _n._n_name. This definition allows you to access the n_name field in the **nlist** or **syment** structure. If you need to access the n_name field in the **netent** structure, undefine the n_name field by entering:

   ```
   #undef n_name
   ```

   before accessing the n_name field in the **netent** structure. If you need to access the n_name field in a **syment** or **nlist** structure after undefining it, redefine the n_name field with:

   ```
   #define n_name _n._n_name
   ```

Parameters

Item	Description
NList	Points to an array of **nlist** or **nlist64** structures.
NumberOfElements	Specifies the number of structures in the array of **nlist** or **nlist64** structures.
Size	Specifies the size of each structure. The only allowed values are `sizeof(struct nlist)` or `sizeof(struct nlist64)`.

Return Values

Upon successful completion, the **knlist** subroutine returns a value of 0. Otherwise, a value of -1 is returned, and the **errno** variable is set to indicate the error.

Error Codes

The **knlist** subroutine fails when one of the following is true:

Item	Description
EINVAL	The *NumberOfElements* parameters is less than 1 or the *Size* parameter is neither `sizeof(struct nlist)` nor `sizeof(struct nlist64)`.
EFAULT	The *NList* parameter is not a valid address. One or more symbols in the array specified by the *Nlist* parameter were not found. The address of one of the symbols does not fit in the **n_value** field. This is only possible if the caller is a 32-bit program and the *Size* parameter is `sizeof(struct nlist))`.

kpidstate Subroutine

Purpose

Returns the status of a process.

Syntax

```
kpidstate (pid)
pid_t pid;
```

Description

The **kpidstate** subroutine returns the state of a process specified by the *pid* parameter. The **kpidstate** subroutine can only be called by a process.

Parameters

Item	Description
pid	Specifies the product ID.

Return Values

If the *pid* parameter is not valid, KP_NOTFOUND is returned. If the pid parameter is valid, the following settings in the process state determine what is returned:

Item	Description
SNONE	Return KP_NOTFOUND.
SIDL	Return KP_INITING.
SZOMB	Return KP_EXITING, also if SEXIT in pv_flag.
SSTOP	Return KP_STOPPED.

Otherwise the pid is alive and KP_ALIVE is returned.

Error Codes

l

The following Base Operating System (BOS) runtime services begin with the letter *l*.

_lazySetErrorHandler Subroutine

Purpose

Installs an error handler into the lazy loading runtime system for the current process.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/ldr.h>
#include <sys/errno.h>
```

```
typedef void (*_handler_t(
char *_module,
char *_symbol,
unsigned int _errVal ))();
```

```
handler_t *_lazySetErrorHandler(err_handler)
handler_t *err_handler;
```

Description

This function allows a process to install a custom error handler to be called when a lazy loading reference fails to find the required module or function. This function should only be used when the main program or one of its dependent modules was linked with the **-blazy** option. To call **_lazySetErrorHandler** from a module that is not linked with the **-blazy** option, you must use the **-lrtl** option. If you use **-blazy**, you do not need to specify **-lrtl**.

This function is not thread safe. The calling program should ensure that **_lazySetErrorHandler** is not called by multiple threads at the same time.

The user-supplied error handler may print its own error message, provide a substitute function to be used in place of the called function, or call the **longjmp** subroutine. To provide a substitute function that will be called instead of the originally referenced function, the error handler should return a pointer to the substitute function. This substitute function will be called by all subsequent calls to the intended function from the same module. If the value returned by the error handler appears to be invalid (for example, a NULL pointer), the default error handler will be used.

Each calling module resolves its lazy references independent of other modules. That is, if module A and B both call **foo** subroutine in module C, but module C does not export **foo** subroutine, the error handler will be called once when **foo** subroutine is called for the first time from A, and once when **foo** subroutine is called for the first time from B.

The default lazy loading error handler will print a message containing: the name of module that the program required; the name of the symbol being accessed; and the error value generated by the failure. Since the default handler considers a lazy load error to be fatal, the process will exit with a status of 1.

During execution of a program that utilizes lazy loading, there are a few conditions that may cause an error to occur. In all cases the current error handler will be called.

1. The referenced module (which is to be loaded upon function invocation) is unavailable or cannot be loaded. The *errVal* parameter will probably indicate the reason for the error if a system call failed.
2. A function is referenced, but the loaded module does not contain a definition for the function. In this case, *errVal* parameter will be **EINVAL**.

Some possibilities as to why either of these errors might occur:

1. The **LIBPATH** environment variable may contain a set of search paths that cause the application to load the wrong version of a module.
2. A module has been changed and no longer provides the same set of symbols that it did when the application was built.
3. The **load** subroutine fails due to a lack of resources available to the process.

Parameters

Item	Description
err_handler	A pointer to the new error handler function. The new function should accept 3 arguments: ***module*** The name of the referenced module. ***symbol*** The name of the function being called at the time the failure occurred. ***errVal*** The value of **errno** at the time the failure occurred, if a system call used to load the module fails. For other failures, errval may be **EINVAL** or **ENOMEM**.

Note that the value of module or symbol may be NULL if the calling module has somehow been corrupted.

If the *err_handler* parameter is NULL, the default error handler is restored.

Return Value

The function returns a pointer to the previous user-supplied error handler, or NULL if the default error handler was in effect.

l3tol or ltol3 Subroutine

Purpose

Converts between 3-byte integers and long integers.

Library

Standard C Library (**libc.a**)

Syntax

```
void l3tol ( LongPointer,  CharacterPointer,  Number)
long *LongPointer;
char *CharacterPointer;
int Number;
```

```
void ltol3 (CharacterPointer, LongPointer, Number)
char *CharacterPointer;
long *LongPointer;
int Number;
```

Description

The **l3tol** subroutine converts a list of the number of 3-byte integers specified by the *Number* parameter packed into a character string pointed to by the *CharacterPointer* parameter into a list of long integers pointed to by the *LongPointer* parameter.

The **ltol3** subroutine performs the reverse conversion, from long integers (the *LongPointer* parameter) to 3-byte integers (the *CharacterPointer* parameter).

These functions are useful for file system maintenance where the block numbers are 3 bytes long.

Parameters

Item	Description
LongPointer	Specifies the address of a list of long integers.
CharacterPointer	Specifies the address of a list of 3-byte integers.
Number	Specifies the number of list elements to convert.

l64a_r Subroutine

Purpose

Converts base-64 long integers to strings.

Library

Thread-Safe C Library (**libc_r.a**)

Syntax

```
#include <stdlib.h>

int l64a_r (Convert, Buffer, Length)
long  Convert;
char * Buffer;
int  Length;
```

Description

The **l64a_r** subroutine converts a given long integer into a base-64 string.

Programs using this subroutine must link to the **libpthreads.a** library.

For base-64 characters, the following ASCII characters are used:

Character	Description
.	Represents 0.
/	Represents 1.
0 -9	Represents the numbers 2-11.
A-Z	Represents the numbers 12-37.
a-z	Represents the numbers 38-63.

The **l64a_r** subroutine places the converted base-64 string in the buffer pointed to by the *Buffer* parameter.

Parameters

Item	Description
Convert	Specifies the long integer that is to be converted into a base-64 ASCII string.
Buffer	Specifies a working buffer to hold the converted long integer.
Length	Specifies the length of the *Buffer* parameter.

Return Values

Item	Description
0	Indicates that the subroutine was successful.
-1	Indicates that the subroutine was not successful. If the **l64a_r** subroutine is not successful, the **errno** global variable is set to indicate the error.

Error Codes

If the **l64a_r** subroutine is not successful, it returns the following error code:

Item	Description
EINVAL	The *Buffer* parameter value is invalid or too small to hold the resulting ASCII string.

labelsession Subroutine

Purpose

Determines user access to system by validating the user security labels against the system labels.

Library

Trusted AIX Library (**libmls.a**)

Syntax

```
#include <mls/mls.h>

int labelsession (Name, Mode, TTY, EffSL, EffTL, Msg [, Flag])
char *Name;
intMode;
char *TTY;
char *EffSL;
char *EffTL;
char **Msg;
int Flag;
```

Description

The **labelsession** subroutine determines whether the user specified by the *Name* parameter is allowed to access the system based on the sensitivity and the integrity clearances of the user. The *Mode* parameter gives the mode of the account usage and the *TTY* parameter defines the terminal that is used for access. The *EffSL* and *EffTL* parameters specify the effective sensitivity label and the effective integrity label for the session respectively. The *Msg* parameter returns an information message that explains the reason that the subroutine fails.

The **labelsession** subroutine fails under the following circumstances:

- The *Mode* parameter is not S_SU and user ID of the user is less than 128. Any user with a user ID (uid) less than 128 is only allowed to login with the **su** command.
- Either the sensitivity labels or the integrity labels, or both labels are not properly dominated.
- The specified effective SL is not within the user's clearance range and the user does not have the **aix.mls.label.outsideaccred** authority.
- The effective SL of the user is not in the TTY's label range.
- The specified effective TL is not in the user's clearance range.
- If the TTY has a TL set, the specified effective TL is not equal to the TTY's TL.
- The *Flag* parameter is not specified for S_SU and the current user's label does not dominate those of the new users.

Restriction: This subroutine is applicable only on a Trusted AIX system.

Parameters

Item	Description
Name	Specifies the user login name.
Mode	Specifies the mode to use. The *Mode* parameter contains one of the following valid values that are defined in the **login.h** file: **S_LOGIN** Local login **S_RLOGIN** Remote login using the **rlogind** and **telnetd** commands **S_SU** Login in using the **su** command **S_FTP** FTP based login
TTY	Specifies the terminal of the originating activity. If this parameter is a null pointer or a null string, no TTY checking is done.
EffSL	Specifies the effective SL that the session requires.
EffTL	Specifies the effective TL that the session requires.
Msg	Returns a message to the user interface that explains the reason why the subroutine fails. The returned value is either a pointer to a valid string within memory allocated storage or a null value.
Flag	When the *Flag* parameter is set to 1, the current user labels do not need to dominate those of the new user to allow access. This parameter is valid only for the S_SU mode. This parameter is ignored for all other session types.

Security

Access Control: The calling process must have access to the account information in the user database and the port information in the port database. The calling process must also have the privileges that are required by the subroutines that this subroutine invokes.

File Accessed

Mode	File
r	**/etc/security/enc/LabelEncodings**
r	**/etc/security/user**

Return Values

If the session labels are valid for the specified usage, the **labelsession** subroutine returns a value of zero. Otherwise, the subroutine returns a value of -1, sets the **errno** global value and the *Msg* parameter returns the error information.

Error Codes

If the subroutine fails, it returns one of the following error codes:

Item	Description
EINVAL	Error in label encodings file or error in the label dominance
EINVAL	The specified effective SL is not valid on the system
ENOATTR	The clearance attributes for the user do not exist
ENOMEM	Memory cannot be allocated to store the returned value
EPERM	No permission to complete the operation

LAPI_Addr_get Subroutine

Purpose

Retrieves a function address that was previously registered using LAPI_Addr_set.

Library

Availability Library (liblapi_r.a)

C Syntax

```
#include <lapi.h>

int LAPI_Addr_get(hndl, addr, addr_hndl)
lapi_handle_t  hndl;
void         **addr;
int            addr_hndl;
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_ADDR_GET(hndl, addr, addr_hndl, ierror)
INTEGER hndl
INTEGER (KIND=LAPI_ADDR_TYPE) :: addr
INTEGER addr_hndl
INTEGER ierror
```

Description

Type of call: local address manipulation

Use this subroutine to get the pointer that was previously registered with LAPI and is associated with the index *addr_hndl*. The value of *addr_hndl* must be in the range 1 <= *addr_hndl* < **LOC_ADDRTBL_SZ**.

Parameters

INPUT

hndl
Specifies the LAPI handle.

addr_hndl
Specifies the index of the function address to retrieve. You should have previously registered the address at this index using `LAPI_Addr_set`. The value of this parameter must be in the range 1 <= *addr_hndl* < **LOC_ADDRTBL_SZ**.

OUTPUT

addr
Returns a function address that the user registered with LAPI.

ierror
Specifies a FORTRAN return code. This is always the last parameter.

C Examples

To retrieve a header handler address that was previously registered using `LAPI_Addr_set`:

```
lapi_handle_t   hndl;      /* the LAPI handle                       */
void          **addr;      /* the address to retrieve               */
int             addr_hndl; /* the index returned from LAPI_Addr_set */

.

addr_hndl = 1;
LAPI_Addr_get(hndl, &addr, addr_hndl);

/* addr now contains the address that was previously registered */
/* using LAPI_Addr_set                                          */
```

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_ADDR_HNDL_RANGE
Indicates that the value of *addr_hndl* is not in the range 1 <= *addr_hndl* < **LOC_ADDRTBL_SZ**.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_RET_PTR_NULL
Indicates that the value of the *addr* pointer is NULL (in C) or that the value of *addr* is `LAPI_ADDR_NULL` (in FORTRAN).

Location

/usr/lib/liblapi_r.a

LAPI_Addr_set Subroutine

Purpose

Registers the address of a function.

Library

Availability Library (`liblapi_r.a`)

C Syntax

```
#include <lapi.h>

int LAPI_Addr_set(hndl, addr, addr_hndl)
lapi_handle_t  hndl;
void          *addr;
int            addr_hndl;
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_ADDR_SET(hndl, addr, addr_hndl, ierror)
INTEGER hndl
INTEGER (KIND=LAPI_ADDR_TYPE) :: addr
INTEGER addr_hndl
INTEGER ierror
```

Description

`Type of call:` local address manipulation

Use this subroutine to register the address of a function (*addr*). LAPI maintains the function address in an internal table. The function address is indexed at location *addr_hndl*. In subsequent LAPI calls, *addr_hndl* can be used in place of *addr*. The value of *addr_hndl* must be in the range 1 <= *addr_hndl* < **LOC_ADDRTBL_SZ**.

For active message communication, you can use *addr_hndl* in place of the corresponding header handler address. LAPI only supports this indexed substitution for remote header handler addresses (but not other remote addresses, such as target counters or base data addresses). For these other types of addresses, the actual address value must be passed to the API call.

Parameters

INPUT

hndl
Specifies the LAPI handle.

addr
Specifies the address of the function handler that the user wants to register with LAPI.

addr_hndl
Specifies a user function address that can be passed to LAPI calls in place of a header handler address. The value of this parameter must be in the range 1 <= *addr_hndl* < **LOC_ADDRTBL_SZ**.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

C Examples

To register a header handler address:

```
lapi_handle_t  hndl;      /* the LAPI handle                   */
void          *addr;      /* the remote header handler address */
int            addr_hndl; /* the index to associate            */

⋮

addr = my_func;
addr_hndl = 1;
LAPI_Addr_set(hndl, addr, addr_hndl);

/* addr_hndl can now be used in place of addr in LAPI_Amsend, */
```

```
/* LAPI_Amsendv, and LAPI_Xfer calls                          */
⋮
```

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_ADDR_HNDL_RANGE
Indicates that the value of *addr_hndl* is not in the range 1 <= *addr_hndl* < **LOC_ADDRTBL_SZ**.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

Location

/usr/lib/liblapi_r.a

LAPI_Address Subroutine

Purpose

Returns an unsigned long value for a specified user address.

Library

Availability Library (`liblapi_r.a`)

C Syntax

```
#include <lapi.h>

int LAPI_Address(my_addr, ret_addr)
void   *my_addr;
ulong  *ret_addr;
```

`Note:` This subroutine is meant to be used by FORTRAN programs. The C version of `LAPI_Address` is provided for compatibility purposes only.

FORTRAN Syntax

```
include 'lapif.h'

LAPI_ADDRESS(my_addr, ret_addr, ierror)
INTEGER (KIND=any_type) :: my_addr
INTEGER (KIND=LAPI_ADDR_TYPE) :: ret_addr
INTEGER ierror
```

where:

any_type
Is any FORTRAN datatype. This type declaration has the same meaning as the type `void *` in C.

Description

`Type of call:` local address manipulation

Use this subroutine in FORTRAN programs when you need to store specified addresses in an array. In FORTRAN, the concept of address (&) does not exist as it does in C. `LAPI_Address` provides FORTRAN programmers with this function.

Parameters

INPUT

my_addr
Specifies the address to convert. The value of this parameter cannot be NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

OUTPUT

ret_addr
Returns the address that is stored in *my_addr* as an unsigned long for use in LAPI calls. The value of this parameter cannot be NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

ierror
Specifies a FORTRAN return code. This is always the last parameter.

FORTRAN Examples

To retrieve the address of a variable:

```
! Contains the address of the target counter
integer (KIND=LAPI_ADDR_TYPE) :: cntr_addr

! Target Counter
type (LAPI_CNTR_T) :: tgt_cntr

! Return code
integer :: ierror

call LAPI_ADDRESS(tgt_cntr, cntr_addr, ierror)

!  cntr_addr now contains the address of tgt_cntr
```

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_ORG_ADDR_NULL
Indicates that the value of *my_addr* is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_TGT_ADDR_NULL
Indicates that the value of *ret_addr* is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

Location

/usr/lib/liblapi_r.a

LAPI_Address_init Subroutine

Purpose

Creates a remote address table.

Library

Availability Library (liblapi_r.a)

C Syntax

```
#include <lapi.h>

int LAPI_Address_init(hndl, my_addr, add_tab)
lapi_handle_t  hndl;
```

```
void          *my_addr;
void          *add_tab[ ];
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_ADDRESS_INIT(hndl, my_addr, add_tab, ierror)
INTEGER hndl
INTEGER (KIND=LAPI_ADDR_TYPE) :: my_addr
INTEGER (KIND=LAPI_ADDR_TYPE) :: add_tab(*)
INTEGER ierror
```

Description

Type of call: collective communication (blocking)

LAPI_Address_init exchanges virtual addresses among tasks of a parallel application. Use this subroutine to create tables of such items as header handlers, target counters, and data buffer addresses.

LAPI_Address_init is a *collective call* over the LAPI handle *hndl*, which fills the table *add_tab* with the virtual address entries that each task supplies. Collective calls must be made in the same order at all participating tasks.

The addresses that are stored in the table *add_tab* are passed in using the *my_addr* parameter. Upon completion of this call, *add_tab[i]* contains the virtual address entry that was provided by task *i*. The array is opaque to the user.

Parameters

INPUT

hndl
Specifies the LAPI handle.

my_addr
Specifies the entry supplied by each task. The value of this parameter can be NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

OUTPUT

add_tab
Specifies the address table containing the addresses that are to be supplied by all tasks. *add_tab* is an array of pointers, the size of which is greater than or equal to **NUM_TASKS**. The value of this parameter cannot be NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

ierror
Specifies a FORTRAN return code. This is always the last parameter.

C Examples

To collectively transfer target counter addresses for use in a communication API call, in which all nodes are either 32-bit or 64-bit:

```
lapi_handle_t  hndl;                /* the LAPI handle                    */
void          *addr_tbl[NUM_TASKS]; /* the table for all tasks' addresses */
lapi_cntr_t    tgt_cntr;            /* the target counter                 */

⋮

LAPI_Address_init(hndl, (void *)&tgt_cntr, addr_tbl);

/* for communication with task t, use addr_tbl[t] */
/* as the address of the target counter           */

⋮
```

For a combination of 32-bit and 64-bit nodes, use LAPI_Address_init64.

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_COLLECTIVE_PSS
Indicates that a collective call was made while in persistent subsystem (PSS) mode.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_RET_PTR_NULL
Indicates that the value of the *add_tab* pointer is NULL (in C) or that the value of *add_tab* is LAPI_ADDR_NULL (in FORTRAN).

Location

/usr/lib/liblapi_r.a

LAPI_Address_init64 Subroutine

Purpose

Creates a 64-bit remote address table.

Library

Availability Library (liblapi_r.a)

C Syntax

```
#include <lapi.h>

int LAPI_Address_init64(hndl, my_addr, add_tab)
lapi_handle_t  hndl;
lapi_long_t    my_addr;
lapi_long_t   *add_tab;
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_ADDRESS_INIT64(hndl, my_addr, add_tab, ierror)
INTEGER hndl
INTEGER (KIND=LAPI_ADDR_TYPE) :: my_addr
INTEGER (KIND=LAPI_LONG_LONG_TYPE) :: add_tab(*)
INTEGER ierror
```

Description

Type of call: collective communication (blocking)

LAPI_Address_init64 exchanges virtual addresses among a mixture of 32-bit and 64-bit tasks of a parallel application. Use this subroutine to create 64-bit tables of such items as header handlers, target counters, and data buffer addresses.

LAPI_Address_init64 is a *collective call* over the LAPI handle *hndl*, which fills the 64-bit table *add_tab* with the virtual address entries that each task supplies. Collective calls must be made in the same order at all participating tasks.

The addresses that are stored in the table *add_tab* are passed in using the *my_addr* parameter. Upon completion of this call, *add_tab[i]* contains the virtual address entry that was provided by task *i*. The array is opaque to the user.

Parameters

INPUT

hndl
Specifies the LAPI handle.

my_addr
Specifies the address entry that is supplied by each task. The value of this parameter can be NULL (in C) or LAPI_ADDR_NULL (in FORTRAN). To ensure 32-bit/64-bit interoperability, it is passed as a `lapi_long_t` type in C.

OUTPUT

add_tab
Specifies the 64-bit address table that contains the 64-bit values supplied by all tasks. *add_tab* is an array of type `lapi_long_t` (in C) or LAPI_LONG_LONG_TYPE (in FORTRAN). The size of *add_tab* is greater than or equal to **NUM_TASKS**. The value of this parameter cannot be NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

ierror
Specifies a FORTRAN return code. This is always the last parameter.

C Examples

To collectively transfer target counter addresses for use in a communication API call with a mixed task environment (any combination of 32-bit and 64-bit):

```
lapi_handle_t hndl;                /* the LAPI handle                     */
lapi_long_t   addr_tbl[NUM_TASKS]; /* the table for all tasks' addresses */
lapi_long_t   tgt_cntr;            /* the target counter                  */

⋮

LAPI_Address_init64(hndl, (lapi_long_t)&tgt_cntr, addr_tbl);

/* For communication with task t, use addr_tbl[t] as the address */
/* of the target counter. For mixed (32-bit and 64-bit) jobs,    */
/* use the LAPI_Xfer subroutine for communication.               */
```

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_COLLECTIVE_PSS
Indicates that a collective call was made while in persistent subsystem (PSS) mode.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_RET_PTR_NULL
Indicates that the value of the *add_tab* pointer is NULL (in C) or that the value of *add_tab* is LAPI_ADDR_NULL (in FORTRAN).

Location

/usr/lib/liblapi_r.a

LAPI_Amsend Subroutine

Purpose

Transfers a user message to a remote task, obtaining the target address on the remote task from a user-specified header handler.

Library

Availability Library (`liblapi_r.a`)

C Syntax

```
#include <lapi.h>

typedef void (compl_hndlr_t) (hndl, user_info);

INTEGER ierror
```

Description

`Type of call:` point-to-point communication (non-blocking)

Use this subroutine to transfer data to a target task, where it is desirable to run a handler on the target task before message delivery begins or after delivery completes. `LAPI_Amsend` allows the user to provide a header handler and optional completion handler. The header handler is used to specify the target buffer address for writing the data, eliminating the need to know the address on the origin task when the subroutine is called.

User data (*uhdr* and *udata*) are sent to the target task. Once these buffers are no longer needed on the origin task, the origin counter is incremented, which indicates the availability of origin buffers for modification. Using the `LAPI_Xfer` call with the `LAPI_AM_XFER` type provides the same type of transfer, with the option of using a send completion handler instead of the origin counter to specify buffer availability.

Upon arrival of the first data packet at the target, the user's header handler is invoked. Note that a header handler must be supplied by the user because it returns the base address of the buffer in which LAPI will write the data sent from the origin task (*udata*). See *RSCT for AIX 5L: LAPI Programming Guide* for an optimization exception to this requirement that a buffer address be supplied to LAPI for single-packet messages.

The header handler also provides additional information to LAPI about the message delivery, such as the completion handler. `LAPI_Amsend` and similar calls (such as `LAPI_Amsendv` and corresponding `LAPI_Xfer` transfers) also allow the user to specify their own message header information, which is available to the header handler. The user may also specify a completion handler parameter from within the header handler. LAPI will pass the information to the completion handler at execution.

Note that the header handler is run inline by the thread running the LAPI dispatcher. For this reason, the header handler must be non-blocking because no other progress on messages will be made until it returns. It is also suggested that execution of the header handler be simple and quick. The completion handler, on the other hand, is normally enqueued for execution by a separate thread. It is possible to request that the completion handler be run inline. See *RSCT for AIX 5L: LAPI Programming Guide* for more information on inline completion handlers.

If a completion handler was not specified (that is, set to `LAPI_ADDR_NULL` in FORTRAN or its pointer set to NULL in C), the arrival of the final packet causes LAPI to increment the target counter on the remote task and send an internal message back to the origin task. The message causes the completion counter (if it is not NULL in C or `LAPI_ADDR_NULL` in FORTRAN) to increment on the origin task.

If a completion handler was specified, the above steps take place after the completion handler returns. To guarantee that the completion handler has executed on the target, you must wait on the completion counter. See *RSCT for AIX 5L: LAPI Programming Guide* for a time-sequence diagram of events in a `LAPI_Amsend` call.

User details

As mentioned above, the user must supply the address of a header handler to be executed on the target upon arrival of the first data packet. The signature of the header handler is as follows:

```
void *hdr_hndlr(lapi_handle_t *hndl, void *uhdr, uint *uhdr_len, ulong *msg_len,
               compl_hndlr_t **cmpl_hndlr, void **user_info);
```

The value returned by the header handler is interpreted by LAPI as an address for writing the user data (*udata*) that was passed to the `LAPI_Amsend` call. The *uhdr* and *uhdr_len* parameters are passed by LAPI into the header handler and contain the information passed by the user to the corresponding parameters of the `LAPI_Amsend` call.

Use of LAPI_Addr_set

Remote addresses are commonly exchanged by issuing a collective LAPI_Address_init call within a few steps of initializing LAPI. LAPI also provides the LAPI_Addr_set mechanism, whereby users can register one or more header handler addresses in a table, associating an index value with each address. This index can then be passed to LAPI_Amsend instead of an actual address. On the target side, LAPI will use the index to get the header handler address. Note that, if all tasks use the same index for their header handler, the initial collective communication can be avoided. Each task simply registers its own header handler address using the well-known index. Then, on any LAPI_Amsend calls, the reserved index can be passed to the header handler address parameter.

Role of the header handler

The user optionally returns the address of a completion handler function through the *cmpl_hndlr* parameter and a completion handler parameter through the *user_info* parameter. The address passed through the *user_info* parameter can refer to memory containing a datatype defined by the user and then cast to the appropriate type from within the completion handler if desired.

The signature for a user completion handler is as follows:

```
typedef void (compl_hndlr_t)(lapi_handle_t *hndl, void *completion_param);
```

The argument returned by reference through the *user_info* member of the user's header handler will be passed to the *completion_param* argument of the user's completion handler. See the **C Examples** for an example of setting the completion handler and parameter in the header handler.

As mentioned above, the value returned by the header handler must be an address for writing the user data sent from the origin task. There is one exception to this rule. In the case of a single-packet message, LAPI passes the address of the packet in the receive FIFO, allowing the entire message to be consumed within the header handler. In this case, the header handler should return NULL (in C) or LAPI_ADDR_NULL (in FORTRAN) so that LAPI does not copy the message to a target buffer. See *RSCT for AIX 5L: LAPI Programming Guide* for more information (including a sample header handler that uses this method for fast retrieval of a single-packet message).

Passing additional information through lapi_return_info_t

LAPI allows additional information to be passed to and returned from the header handler by passing a pointer to lapi_return_info_t through the msg_len argument. On return from a header handler that is invoked by a call to LAPI_Amsend, the *ret_flags* member of lapi_return_info_t can contain one of these values: LAPI_NORMAL (the default), LAPI_SEND_REPLY (to run the completion handler inline), or LAPI_LOCAL_STATE (no reply is sent). The *dgsp_handle* member of lapi_return_info_t should not be used in conjunction with LAPI_Amsend.

For a complete description of the lapi_return_info_t type, see *RSCT for AIX 5L: LAPI Programming Guide*

Inline execution of completion handlers

Under normal operation, LAPI uses a separate thread for executing user completion handlers. After the final packet arrives, completion handler pointers are placed in a queue to be handled by this thread. For performance reasons, the user may request that a given completion handler be run inline instead of being placed on this queue behind other completion handlers. This mechanism gives users a greater degree of control in prioritizing completion handler execution for performance-critical messages.

LAPI places no restrictions on completion handlers that are run "normally" (that is, by the completion handler thread). Inline completion handlers should be short and should not block, because no progress can be made while the main thread is executing the handler. The user must use caution with inline completion handlers so that LAPI's internal queues do not fill up while waiting for the handler to complete. I/O operations must not be performed with an inline completion handler.

Parameters

INPUT

hndl
Specifies the LAPI handle.

tgt
Specifies the task ID of the target task. The value of this parameter must be in the range `0` <= *tgt* < NUM_TASKS.

hdr_hdl
Specifies the pointer to the remote header handler function to be invoked at the target. The value of this parameter can take an address handle that has already been registered using `LAPI_Addr_set`. The value of this parameter cannot be NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

uhdr
Specifies the pointer to the user header data. This data will be passed to the user header handler on the target. If *uhdr_len* is `0`, The value of this parameter can be NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

uhdr_len
Specifies the length of the user's header. The value of this parameter must be a multiple of the processor's word size in the range `0` <= *uhdr_len* <= MAX_UHDR_SZ.

udata
Specifies the pointer to the user data. If *udata_len* is `0`, The value of this parameter can be NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

udata_len
Specifies the length of the user data in bytes. The value of this parameter must be in the range `0` <= *udata_len* <= the value of LAPI constant `LAPI_MAX_MSG_SZ`.

INPUT/OUTPUT

tgt_cntr
Specifies the target counter address. The target counter is incremented after the completion handler (if specified) completes or after the completion of data transfer. If the value of this parameter is NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN), the target counter is not updated.

org_cntr
Specifies the origin counter address (in C) or the origin counter (in FORTRAN). The origin counter is incremented after data is copied out of the origin address (in C) or the origin (in FORTRAN). If the value of this parameter is NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN), the origin counter is not updated.

cmpl_cntr
Specifies the counter at the origin that signifies completion of the completion handler. It is updated once the completion handler completes. If no completion handler is specified, the counter is incremented at the completion of message delivery. If the value of this parameter is NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN), the completion counter is not updated.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_DATA_LEN
Indicates that the value of *udata_len* is greater than the value of LAPI constant `LAPI_MAX_MSG_SZ`.

LAPI_ERR_HDR_HNDLR_NULL
Indicates that the value of the *hdr_hdl* passed in is NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_ORG_ADDR_NULL
Indicates that the value of the *udata* parameter passed in is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), but the value of *udata_len* is greater than 0.

LAPI_ERR_TGT
Indicates that the *tgt* passed in is outside the range of tasks defined in the job.

LAPI_ERR_TGT_PURGED
Indicates that the subroutine returned early because LAPI_Purge_totask() was called.

LAPI_ERR_UHDR_LEN
Indicates that the *uhdr_len* value passed in is greater than MAX_UHDR_SZ or is not a multiple of the processor's doubleword size.

LAPI_ERR_UHDR_NULL
Indicates that the *uhdr* passed in is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), but *uhdr_len* is not 0.

C Examples

To send an active message and then wait on the completion counter:

```
/* header handler routine to execute on target task */
void *hdr_hndlr(lapi_handle_t *hndl, void *uhdr, uint *uhdr_len,
               ulong *msg_len, compl_hndlr_t **cmpl_hndlr,
        void **user_info)
{
/* set completion handler pointer and other information */
/* return base address for LAPI to begin its data copy  */
}

{
    lapi_handle_t hndl;                     /* the LAPI handle                     */
    int           task_id;                  /* the LAPI task ID                    */
    int           num_tasks;                /* the total number of tasks           */
    void         *hdr_hndlr_list[NUM_TASKS]; /* the table of remote header handlers */
    int           buddy;                    /* the communication partner           */
    lapi_cntr_t   cmpl_cntr;                /* the completion counter              */
    int           data_buffer[DATA_LEN];    /* the data to transfer                */

    .
    .
    .
    /* retrieve header handler addresses */
    LAPI_Address_init(hndl, (void *)&hdr_hndlr, hdr_hndlr_list);

    /*
    ** up to this point, all instructions have executed on all
    ** tasks. we now begin differentiating tasks.
    */
    if ( sender ) {                  /* origin task */

        /* initialize data buffer, cmpl_cntr, etc.   */
        .
        .
        .
        /* synchronize before starting data transfer */
        LAPI_Gfence(hndl);

        LAPI_Amsend(hndl, buddy, (void *)hdr_hndlr_list[buddy], NULL,
                    0,&(data_buffer[0]),DATA_LEN*(sizeof(int)),
                    NULL, NULL, cmpl_cntr);

        /* Wait on completion counter before continuing. Completion   */
        /* counter will update when message completes at target.      */

    } else {                                            /* receiver */
        .
        .
        .
        /* to match the origin's synchronization before data transfer */
        LAPI_Gfence(hndl);
    }
```

```
    .
    .
    .
}
```

For a complete program listing, see *RSCT for AIX 5L: LAPI Programming Guide.* Sample code illustrating the LAPI_Amsend call can be found in the LAPI sample files. See *RSCT for AIX 5L: LAPI Programming Guide* for more information about the sample programs that are shipped with LAPI.

Location

/usr/lib/liblapi_r.a

LAPI_Amsendv Subroutine

Purpose

Transfers a user vector to a remote task, obtaining the target address on the remote task from a user-specified header handler.

Library

Availability Library (`liblapi_r.a`)

C Syntax

```
#include <lapi.h>

typedef void (compl_hndlr_t) (hndl, user_info);
lapi_handle_t  *hndl;       /* the LAPI handle passed in from LAPI_Amsendv */
void           *user_info;  /* the buffer (user_info) pointer passed in    */
                            /* from vhdr_hndlr (void *(vhdr_hndlr_t))      */

typedef lapi_vec_t *(vhdr_hndlr_t) (hndl, uhdr, uhdr_len, len_vec, comp_h, uinfo);

lapi_handle_t  *hndl;       /* pointer to the LAPI handle passed in from LAPI_Amsendv */
void           *uhdr;       /* uhdr passed in from LAPI_Amsendv                       */
uint           *uhdr_len;   /* uhdr_len passed in from LAPI_Amsendv                   */
ulong          *len_vec[ ]; /* vector of lengths passed in LAPI_Amsendv               */
compl_hndlr_t **comp_h;     /* function address of completion handler                 */
                            /* (void (compl_hndlr_t)) that needs to be                */
                            /* filled out by this header handler function             */
void          **user_info;  /* pointer to the parameter to be passed                  */
                            /* in to the completion handler                           */

int LAPI_Amsendv(hndl, tgt, hdr_hdl, uhdr, uhdr_len, org_vec,

```

Description

Type of call: point-to-point communication (non-blocking)

LAPI_Amsendv is the vector-based version of the LAPI_Amsend call. You can use it to specify multi-dimensional and non-contiguous descriptions of the data to transfer. Whereas regular LAPI calls allow the specification of a single data buffer address and length, the vector versions allow the specification of a vector of address and length combinations. Additional information is allowed in the data description on the origin task and the target task.

Use this subroutine to transfer a vector of data to a target task, when you want a handler to run on the target task before message delivery begins or after message delivery completes.

To use LAPI_Amsendv, you must provide a header handler, which returns the address of the target vector description that LAPI uses to write the data that is described by the origin vector. The header handler is used to specify the address of the vector description for writing the data, which eliminates the need to know the description on the origin task when the subroutine is called. The header handler is called upon arrival of the first data packet at the target.

Optionally, you can also provide a completion handler. The header handler provides additional information to LAPI about the message delivery, such as the completion handler. You can also specify a completion handler parameter from within the header handler. LAPI passes the information to the completion handler at execution.

With the exception of the address that is returned by the completion handler, the use of counters, header handlers, and completion handlers in LAPI_Amsendv is identical to that of LAPI_Amsend. In both cases, the user header handler returns information that LAPI uses for writing at the target. See LAPI_Amsend for more information. This section presents information that is specific to the vector version of the call (LAPI_Amsendv).

LAPI vectors are structures of type lapi_vec_t, defined as follows:

```
typedef struct  {
    lapi_vectype_t  vec_type;
    uint            num_vecs;
    void            **info;
    ulong           *len;
} lapi_vec_t;
```

vec_type is an enumeration that describes the type of vector transfer, which can be: LAPI_GEN_GENERIC, LAPI_GEN_IOVECTOR, or LAPI_GEN_STRIDED_XFER.

For transfers of type LAPI_GEN_GENERIC and LAPI_GEN_IOVECTOR, the fields are used as follows:

num_vecs
indicates the number of data vectors to transfer. Each data vector is defined by a base address and data length.

info
is the array of addresses.

len
is the array of data lengths.

For example, consider the following vector description:

```
vec_type = LAPI_GEN_IOVECTOR
num_vecs = 3
info     = {addr_0, addr_1, addr_2}
len      = {len_0, len_1, len_2}
```

On the origin side, this example would tell LAPI to read len_0 bytes from addr_0, len_1 bytes from addr_1, and len_2 bytes from addr_2. As a target vector, this example would tell LAPI to write len_0 bytes to addr_0, len_1 bytes to addr_1, and len_2 bytes to addr_2.

Recall that vector transfers require an origin and target vector. For LAPI_Amsendv calls, the origin vector is passed to the API call on the origin task. The address of the target vector is returned by the header handler.

For transfers of type LAPI_GEN_GENERIC, the target vector description must also have type LAPI_GEN_GENERIC. The contents of the *info* and *len* arrays are unrestricted in the generic case; the number of vectors and the length of vectors on the origin and target do not need to match. In this case, LAPI transfers a given number of bytes in noncontiguous buffers specified by the origin vector to a set of noncontiguous buffers specified by the target vector.

If the sum of target vector data lengths (say TGT_LEN) is less than the sum of origin vector data lengths (say ORG_LEN), only the first TGT_LEN bytes from the origin buffers are transferred and the remaining bytes are discarded. If TGT_LEN is greater than ORG_LEN, all ORG_LEN bytes are transferred. Consider the following example:

```
Origin_vector: {
    num_vecs = 3;
    info     = {orgaddr_0, orgaddr_1, orgaddr_2};
    len      = {5, 10, 5}
}

Target_vector: {
    num_vecs = 4;
    info     = {tgtaddr_0, tgtaddr_1, tgtaddr_2, tgtaddr_3};
    len      = {12, 2, 4, 2}
}
```

LAPI copies data as follows:

1. 5 bytes from orgaddr_0 to tgtaddr_0 (leaves 7 bytes of space at a 5-byte offset from tgtaddr_0)
2. 7 bytes from orgaddr_1 to remaining space in tgtaddr_0 (leaves 3 bytes of data to transfer from orgaddr_1)
3. 2 bytes from orgaddr_1 to tgtaddr_1 (leaves 1 byte to transfer from orgaddr_1)
4. 1 byte from orgaddr_1 followed by 3 bytes from orgaddr_2 to tgt_addr_2 (leaves 3 bytes to transfer from orgaddr_2)
5. 2 bytes from orgaddr_2 to tgtaddr_3

LAPI will copy data from the origin until the space described by the target is filled. For example:

```
Origin_vector: {
    num_vecs = 1;
    info     = {orgaddr_0};
    len      = {20}
}

Target_vector: {
    num_vecs = 2;
    info     = {tgtaddr_0, tgtaddr_1};
    len      = {5, 10}
}
```

LAPI will copy 5 bytes from orgaddr_0 to tgtaddr_0 and the next 10 bytes from orgaddr_0 to tgtaddr_1. The remaining 5 bytes from orgaddr_0 will not be copied.

For transfers of type LAPI_GEN_IOVECTOR, the lengths of the vectors must match and the target vector description must match the origin vector description. More specifically, the target vector description must:

- also have type LAPI_GEN_IOVECTOR
- have the same *num_vecs* as the origin vector
- initialize the info array with *num_vecs* addresses in the target address space. For LAPI vectors origin_vector and target_vector described similarly to the example above, data is copied as follows:
  1. transfer origin_vector.len[0] bytes from the address at origin_vector.info[0] to the address at target_vector.info[0]
  2. transfer origin_vector.len[1] bytes from the address at origin_vector.info[1] to the address at target_vector.info[1]
  3. transfer origin_vector.len[*n*] bytes from the address at origin_vector.info[*n*] to the address at target_vector.info[*n*], for *n* = 2 to *n* = [*num_vecs*-3]
  4. transfer origin_vector.len[*num_vecs*-2] bytes from the address at origin_vector.info[*num_vecs*-2] to the address at target_vector.info[*num_vecs*-2]
  5. copy origin_vector.len[*num_vecs*-1] bytes from the address at origin_vector.info[*num_vecs*-1] to the address at target_vector.info[*num_vecs*-1]

Strided vector transfers

For transfers of type LAPI_GEN_STRIDED_XFER, the target vector description must match the origin vector description. Rather than specifying the set of address and length pairs, the *info* array of the origin and target vectors is used to specify a data block "template", consisting of a base address, block size and stride. LAPI thus expects the *info* array to contain three integers. The first integer contains the base address, the second integer contains the block size to copy, and the third integer contains the byte stride. In this case, *num_vecs* indicates the number of blocks of data that LAPI should copy, where the first block begins at the base address. The number of bytes to copy in each block is given by the block size and the starting address for all but the first block is given by previous address + stride. The total amount of data to be copied will be *num_vecs***block_size*. Consider the following example:

```
Origin_vector {
    num_vecs = 3;
    info     = {orgaddr, 5, 8}
}
```

Based on this description, LAPI will transfer 5 bytes from orgaddr, 5 bytes from orgaddr+8 and 5 bytes from orgaddr+16.

Call details

As mentioned above, counter and handler behavior in LAPI_Amsendv is nearly identical to that of LAPI_Amsend. A short summary of that behavior is provided here. See the LAPI_Amsend description for full details.

This is a non-blocking call. The calling task cannot change the *uhdr* (origin header) and *org_vec* data until completion at the origin is signaled by the *org_cntr* being incremented. The calling task cannot assume that the *org_vec* structure can be changed before the origin counter is incremented. The structure (of type lapi_vec_t) that is returned by the header handler cannot be modified before the target counter has been incremented. Also, if a completion handler is specified, it may execute asynchronously, and can only be assumed to have completed after the target counter increments (on the target) or the completion counter increments (at the origin).

The length of the user-specified header (*uhdr_len*) is constrained by the implementation-specified maximum value **MAX_UHDR_SZ**. *uhdr_len* must be a multiple of the processor's doubleword size. To get the best bandwidth, *uhdr_len* should be as small as possible.

If the following requirement is not met, an error condition occurs:

- If a strided vector is being transferred, the size of each block must not be greater than the stride size in bytes.

LAPI does not check for any overlapping regions among vectors either at the origin or the target. If the overlapping regions exist on the target side, the contents of the target buffer are undefined after the operation.

Parameters

hndl
Specifies the LAPI handle.

tgt
Specifies the task ID of the target task. The value of this parameter must be in the range `0` <= *tgt* < **NUM_TASKS**.

hdr_hdl
Points to the remote header handler function to be invoked at the target. The value of this parameter can take an address handle that had been previously registered using the `LAPI_Addr_set/LAPI_Addr_get` mechanism. The value of this parameter cannot be NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

uhdr
Specifies the pointer to the local header (parameter list) that is passed to the handler function. If *uhdr_len* is `0`, The value of this parameter can be NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

uhdr_len
Specifies the length of the user's header. The value of this parameter must be a multiple of the processor's doubleword size in the range `0` <= *uhdr_len* <= **MAX_UHDR_SZ**.

org_vec
Points to the origin vector.

INPUT/OUTPUT

tgt_cntr
Specifies the target counter address. The target counter is incremented after the completion handler (if specified) completes or after the completion of data transfer. If the value of this parameter is NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN), the target counter is not updated.

org_cntr
Specifies the origin counter address (in C) or the origin counter (in FORTRAN). The origin counter is incremented after data is copied out of the origin address (in C) or the origin (in FORTRAN). If the value of this parameter is NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN), the origin counter is not updated.

cmpl_cntr
Specifies the counter at the origin that signifies completion of the completion handler. It is updated once the completion handler completes. If no completion handler is specified, the counter is incremented at the completion of message delivery. If the value of this parameter is NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN), the completion counter is not updated.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

C Examples

1. To send a `LAPI_GEN_IOVECTOR` using active messages:

```
/* header handler routine to execute on target task */
lapi_vec_t *hdr_hndlr(lapi_handle_t *handle, void *uhdr, uint *uhdr_len,
                      ulong *len_vec[ ], compl_hndlr_t **completion_handler,
              void **user_info)
{
     /* set completion handler pointer and other info */
```

```
     /* set up the vector to return to LAPI                                 */
     /* for a LAPI_GEN_IOVECTOR: num_vecs, vec_type, and len must all have */
     /* the same values as the origin vector.  The info array should       */
     /* contain the buffer addresses for LAPI to write the data            */
     vec->num_vecs = NUM_VECS;
     vec->vec_type = LAPI_GEN_IOVECTOR;
     vec->len      = (unsigned long *)malloc(NUM_VECS*sizeof(unsigned long));
     vec->info     = (void **) malloc(NUM_VECS*sizeof(void *));
     for( i=0; i < NUM_VECS; i++ ) {
         vec->info[i] = (void *) &data_buffer[i];
         vec->len[i]  = (unsigned long)(sizeof(int));
     }

     return vec;
}

{

     .
     .
     .

     void        *hdr_hndlr_list[NUM_TASKS]; /* table of remote header handlers */
     lapi_vec_t  *vec;                       /* data for data transfer          */

     vec->num_vecs = NUM_VECS;
     vec->vec_type = LAPI_GEN_IOVECTOR;
     vec->len      = (unsigned long *) malloc(NUM_VECS*sizeof(unsigned long));
     vec->info     = (void **) malloc(NUM_VECS*sizeof(void *));

     /* each vec->info[i] gets a base address                                 */
     /* each vec->len[i] gets the number of bytes to transfer from vec->info[i] */

     LAPI_Amsendv(hndl, tgt, (void *) hdr_hdl_list[buddy], NULL, 0, vec,
                  tgt_cntr, org_cntr, cmpl_cntr);

     /* data will be copied as follows:                    */
     /* len[0] bytes of data starting from address info[0] */
     /* len[1] bytes of data starting from address info[1] */
     .
     .
     .
     /* len[NUM_VECS-1] bytes of data starting from address info[NUM_VECS-1] */

}
```

The above example could also illustrate the LAPI_GEN_GENERIC type, with the following modifications:

- Both vectors would need LAPI_GEN_GENERIC as the vec_type.
- There are no restrictions on symmetry of number of vectors and lengths between the origin and target sides.

2. To send a LAPI_STRIDED_VECTOR using active messages:

```
/* header handler routine to execute on target task */
lapi_vec_t *hdr_hndlr(lapi_handle_t *handle, void *uhdr, uint *uhdr_len,
                      ulong *len_vec[ ], compl_hndlr_t **completion_handler,
              void **user_info)
{

     int block_size;            /* block size */
     int data_size;             /* stride     */
     .
     .
     .
     vec->num_vecs = NUM_VECS;     /* NUM_VECS = number of vectors to transfer */
                                   /* must match that of the origin vector     */
     vec->vec_type = LAPI_GEN_STRIDED_XFER;           /* same as origin vector */

     /* see comments in origin vector setup for a description of how data      */
     /* will be copied based on these settings.                                */
     vec->info[0]  = buffer_address; /* starting address for data copy         */
     vec->info[1]  = block_size;     /* bytes of data to copy                  */
     vec->info[2]  = stride;         /* distance from copy block to copy block */
     .
```

```
     .
     .
     return vec;

}

{
      .
      .
      .
      lapi_vec_t *vec;                                  /* data for data transfer */

      vec->num_vecs = NUM_VECS;        /* NUM_VECS = number of vectors to transfer */
                                       /* must match that of the target vector     */
      vec->vec_type = LAPI_GEN_STRIDED_XFER;          /* same as target vector     */

      vec->info[0]  = buffer_address;    /* starting address for data copy         */
      vec->info[1]  = block_size;        /* bytes of data to copy                  */
      vec->info[2]  = stride;            /* distance from copy block to copy block */
      /* data will be copied as follows:                                           */
      /* block_size bytes will be copied from buffer_address                       */
      /* block_size bytes will be copied from buffer_address+stride                */
      /* block_size bytes will be copied from buffer_address+(2*stride)            */
      /* block_size bytes will be copied from buffer_address+(3*stride)            */
      .
      .
      .
      /* block_size bytes will be copied from buffer_address+((NUM_VECS-1)*stride) */
      .
      .
      .
      /* if uhdr isn't used, uhdr should be NULL and uhdr_len should be 0          */
      /* tgt_cntr, org_cntr and cmpl_cntr can all be NULL                          */
      LAPI_Amsendv(hndl, tgt, (void *) hdr_hdl_list[buddy], uhdr, uhdr_len,
                   vec, tgt_cntr, org_cntr, cmpl_cntr);
     .
     .
     .

}
```

For complete examples, see the sample programs shipped with LAPI.

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_HDR_HNDLR_NULL
Indicates that the *hdr_hdl* passed in is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_ORG_EXTENT
Indicates that the *org_vec*'s extent (stride * *num_vecs*) is greater than the value of LAPI constant LAPI_MAX_MSG_SZ.

LAPI_ERR_ORG_STRIDE
Indicates that the *org_vec* stride is less than block.

LAPI_ERR_ORG_VEC_ADDR
Indicates that the *org_vec->info[i]* is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), but its length (*org_vec->len[i]*) is not 0.

LAPI_ERR_ORG_VEC_LEN
Indicates that the sum of *org_vec->len* is greater than the value of LAPI constant LAPI_MAX_MSG_SZ.

LAPI_ERR_ORG_VEC_NULL
Indicates that *org_vec* is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_ORG_VEC_TYPE
Indicates that the *org_vec->vec_type* is not valid.

LAPI_ERR_STRIDE_ORG_VEC_ADDR_NULL
Indicates that the strided vector address *org_vec*->*info*[0] is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_TGT
Indicates that the *tgt* passed in is outside the range of tasks defined in the job.

LAPI_ERR_TGT_PURGED
Indicates that the subroutine returned early because LAPI_Purge_totask() was called.

LAPI_ERR_UHDR_LEN
Indicates that the *uhdr_len* value passed in is greater than **MAX_UHDR_SZ** or is not a multiple of the processor's doubleword size.

LAPI_ERR_UHDR_NULL
Indicates that the *uhdr* passed in is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), but *uhdr_len* is not 0.

Location

/usr/lib/liblapi_r.a

LAPI_Fence Subroutine

Purpose

Enforces order on LAPI calls.

Library

Availability Library (liblapi_r.a)

C Syntax

```
#include <lapi.h>

int LAPI_Fence(hndl)
lapi_handle_t hndl;
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_FENCE(hndl, ierror)
INTEGER hndl
INTEGER ierror
```

Description

Type of call: Local data synchronization (blocking) (may require progress on the remote task)

Use this subroutine to enforce order on LAPI calls. If a task calls LAPI_Fence, all the LAPI operations that were initiated by that task, before the fence using the LAPI context *hndl*, are guaranteed to complete at the target tasks. This occurs before any of its communication operations using *hndl*, initiated after the LAPI_Fence, start transmission of data. This is a data fence which means that the data movement is complete. This is not an operation fence which would need to include active message completion handlers completing on the target.

LAPI_Fence may require internal protocol processing on the remote side to complete the fence request.

Parameters

INPUT

hndl
Specifies the LAPI handle.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

C Examples

To establish a data barrier in a single task:

```
lapi_handle_t hndl;  /* the LAPI handle */

⋮

/* API communication call 1 */
/* API communication call 2 */

⋮

/* API communication call n */

LAPI_Fence(hndl);

/* all data movement from above communication calls has completed by this point */
/* any completion handlers from active message calls could still be running.    */
```

Location

/usr/lib/liblapi_r.a

LAPI_Get Subroutine

Purpose

Copies data from a remote task to a local task.

Library

Availability Library (`liblapi_r.a`)

C Syntax

```
#include <lapi.h>

int LAPI_Get(hndl, tgt, len, tgt_addr, org_addr, tgt_cntr, org_cntr)
lapi_handle_t hndl;
uint          tgt;
ulong         len;
void         *tgt_addr;
void         *org_addr;
lapi_cntr_t  *tgt_cntr;
lapi_cntr_t  *org_cntr;
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_GET(hndl, tgt, len, tgt_addr, org_addr, tgt_cntr, org_cntr, ierror)
INTEGER hndl
INTEGER tgt
INTEGER (KIND=LAPI_LONG_TYPE) :: len
INTEGER (KIND=LAPI_ADDR_TYPE) :: tgt_addr
INTEGER (KIND=LAPI_ADDR_TYPE) :: org_addr
INTEGER (KIND=LAPI_ADDR_TYPE) :: tgt_cntr
TYPE (LAPI_CNTR_T) :: org_cntr
INTEGER ierror
```

Description

`Type of call:` point-to-point communication (non-blocking)

Use this subroutine to transfer data from a remote (target) task to a local (origin) task. Note that in this case the origin task is actually the *receiver* of the data. This difference in transfer type makes the counter behavior slightly different than in the normal case of origin sending to target.

The origin buffer will still increment on the origin task upon availability of the origin buffer. But in this case, the origin buffer becomes available once the transfer of data is complete. Similarly, the target counter will increment once the target buffer is available. Target buffer availability in this case refers to LAPI no longer needing to access the data in the buffer.

This is a non-blocking call. The caller *cannot* assume that data transfer has completed upon the return of the function. Instead, counters should be used to ensure correct buffer addresses as defined above.

Note that a zero-byte message does not transfer data, but it does have the same semantic with respect to counters as that of any other message.

Parameters

INPUT

hndl
Specifies the LAPI handle.

tgt
Specifies the task ID of the target task that is the source of the data. The value of this parameter must be in the range `0` <= *tgt* < **NUM_TASKS**.

len
Specifies the number of bytes of data to be copied. This parameter must be in the range `0` <= *len* <= the value of LAPI constant `LAPI_MAX_MSG_SZ`.

tgt_addr
Specifies the target buffer address of the data source. If *len* is `0`, The value of this parameter can be NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

INPUT/OUTPUT

tgt_cntr
Specifies the target counter address. The target counter is incremented once the data buffer on the target can be modified. If the value of this parameter is NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN), the target counter is not updated.

org_cntr
Specifies the origin counter address (in C) or the origin counter (in FORTRAN). The origin counter is incremented after data arrives at the origin. If the value of this parameter is NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN), the origin counter is not updated.

OUTPUT

org_addr
Specifies the local buffer address into which the received data is copied. If *len* is 0, The value of this parameter can be NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

ierror
Specifies a FORTRAN return code. This is always the last parameter.

C Examples

```
{
    /* initialize the table buffer for the data addresses */

    /* get remote data buffer addresses                   */
    LAPI_Address_init(hndl,(void *)data_buffer,data_buffer_list);
    .
    .
    .
    LAPI_Get(hndl, tgt, (ulong) data_len, (void *) (data_buffer_list[tgt]),
             (void *) data_buffer, tgt_cntr, org_cntr);

    /* retrieve data_len bytes from address data_buffer_list[tgt] on task tgt. */
    /* write the data starting at address data_buffer. tgt_cntr and org_cntr   */
    /* can be NULL. */
}
```

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_DATA_LEN
Indicates that the value of *udata_len* is greater than the value of LAPI constant LAPI_MAX_MSG_SZ.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_ORG_ADDR_NULL
Indicates that the *org_addr* passed in is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), but *len* is greater than 0.

LAPI_ERR_TGT
Indicates that the *tgt* passed in is outside the range of tasks defined in the job.

LAPI_ERR_TGT_ADDR_NULL
Indicates that the *tgt_addr* passed in is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), but *len* is greater than 0.

LAPI_ERR_TGT_PURGED
Indicates that the subroutine returned early because LAPI_Purge_totask() was called.

Location

/usr/lib/liblapi_r.a

LAPI_Getcntr Subroutine

Purpose

Gets the integer value of a specified LAPI counter.

Library

Availability Library (liblapi_r.a)

C Syntax

```
#include <lapi.h>

int LAPI_Getcntr(hndl, cntr, val)
lapi_handle_t  hndl;
lapi_cntr_t   *cntr;
int           *val;
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_GETCNTR(hndl, cntr, val,  ierror)
INTEGER hndl
TYPE (LAPI_CNTR_T) :: cntr
INTEGER val
INTEGER ierror
```

Description

`Type of call:` Local counter manipulation

This subroutine gets the integer value of *cntr*. It is used to check progress on *hndl*.

Parameters

INPUT

hndl
Specifies the LAPI handle.

cntr
Specifies the address of the counter. The value of this parameter cannot be NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

OUTPUT

val
Returns the integer value of the counter *cntr*. The value of this parameter cannot be NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

ierror
Specifies a FORTRAN return code. This is always the last parameter.

C Examples

```
{
    lapi_cntr_t cntr;
    int         val;

   /* cntr is initialized */

   /* processing/communication takes place */

   LAPI_Getcntr(hndl, &cntr, &val)

   /* val now contains the current value of cntr */
}
```

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_CNTR_NULL
Indicates that the *cntr* pointer is NULL (in C) or that the value of *cntr* is LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_RET_PTR_NULL
Indicates that the value of the *val* pointer is NULL (in C) or that the value of *val* is LAPI_ADDR_NULL (in FORTRAN).

Location

/usr/lib/liblapi_r.a

LAPI_Getv Subroutine

Purpose

Copies vectors of data from a remote task to a local task.

Library

Availability Library (liblapi_r.a)

C Syntax

```
#include <lapi.h>

int LAPI_Getv(hndl, tgt, tgt_vec, org_vec, tgt_cntr, org_cntr)
lapi_handle_t hndl;
uint          tgt;
lapi_vec_t   *tgt_vec;
lapi_vec_t   *org_vec;
lapi_cntr_t  *tgt_cntr;
lapi_cntr_t  *org_cntr;

typedef struct  {
    lapi_vectype_t  vec_type;  /* operation code        */
    uint            num_vecs;  /* number of vectors     */
    void            **info;    /* vector of information */
    ulong           *len;      /* vector of lengths     */
} lapi_vec_t;
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_GETV(hndl, tgt, tgt_vec, org_vec, tgt_cntr, org_cntr, ierror)
INTEGER hndl
INTEGER tgt
INTEGER (KIND=LAPI_ADDR_TYPE) :: tgt_vec
TYPE (LAPI_VEC_T) :: org_vec
INTEGER (KIND=LAPI_ADDR_TYPE) :: tgt_cntr
TYPE (LAPI_CNTR_T) :: org_cntr
INTEGER ierror
```

The 32-bit version of the LAPI_VEC_T type is defined as:

```
TYPE LAPI_VEC_T
   SEQUENCE
   INTEGER(KIND = 4)  :: vec_type
   INTEGER(KIND = 4)  :: num_vecs
   INTEGER(KIND = 4)  :: info
   INTEGER(KIND = 4)  :: len
END TYPE LAPI_VEC_T
```

The 64-bit version of the LAPI_VEC_T type is defined as:

```
TYPE LAPI_VEC_T
   SEQUENCE
   INTEGER(KIND = 4)  :: vec_type
   INTEGER(KIND = 4)  :: num_vecs
   INTEGER(KIND = 8)  :: info
   INTEGER(KIND = 8)  :: len
END TYPE LAPI_VEC_T
```

Description

Type of call: point-to-point communication (non-blocking)

This subroutine is the vector version of the LAPI_Get call. Use LAPI_Getv to transfer vectors of data from the target task to the origin task. Both the origin and target vector descriptions are located in the address space of the origin task. But, the values specified in the *info* array of the target vector must be addresses in the address space of the target task.

The calling program *cannot* assume that the origin buffer can be changed or that the contents of the origin buffers on the origin task are ready for use upon function return. After the origin counter (*org_cntr*) is incremented, the origin buffers can be modified by the origin task. After the target counter (*tgt_cntr*) is incremented, the target buffers can be modified by the target task. If you provide a completion counter (*cmpl_cntr*), it is incremented at the origin after the target counter (*tgt_cntr*) has been incremented at the target. If the values of any of the counters or counter addresses are NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), the data transfer occurs, but the corresponding counter increments do not occur.

If any of the following requirements are not met, an error condition occurs:

- The vector types *org_vec->vec_type* and *tgt_vec->vec_type* must be the same.
- If a strided vector is being transferred, the size of each block must not be greater than the stride size in bytes.
- The length of any vector that is pointed to by *tgt_vec* must be equal to the length of the corresponding vector that is pointed to by *org_vec*.

LAPI does not check for any overlapping regions among vectors either at the origin or the target. If the overlapping regions exist on the origin side, the contents of the origin buffer are undefined after the operation.

See LAPI_Amsendv for details about commuication using different LAPI vector types. (LAPI_Getv does not support the LAPI_GEN_GENERIC type.)

Parameters

INPUT

hndl
Specifies the LAPI handle.

tgt
Specifies the task ID of the target task. The value of this parameter must be in the range 0 <= *tgt* < **NUM_TASKS**.

tgt_vec
Points to the target vector description.

org_vec
Points to the origin vector description.

INPUT/OUTPUT

tgt_cntr
Specifies the target counter address. The target counter is incremented once the data buffer on the target can be modified. If the value of this parameter is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), the target counter is not updated.

org_cntr
Specifies the origin counter address (in C) or the origin counter (in FORTRAN). The origin counter is incremented after data arrives at the origin. If the value of this parameter is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), the origin counter is not updated.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

C Examples

To get a LAPI_GEN_IOVECTOR:

```
{

      /* retrieve a remote data buffer address for data to transfer,  */
      /* such as through LAPI_Address_init                            */

      /* task that calls LAPI_Getv sets up both org_vec and tgt_vec   */
      org_vec->num_vecs = NUM_VECS;
      org_vec->vec_type = LAPI_GEN_IOVECTOR;
      org_vec->len = (unsigned long *)
      malloc(NUM_VECS*sizeof(unsigned long));
      org_vec->info = (void **) malloc(NUM_VECS*sizeof(void *));

      /* each org_vec->info[i] gets a base address on the origin task */
      /* each org_vec->len[i] gets the number of bytes to write to    */
      /* org_vec->info[i]                                             */

      tgt_vec->num_vecs = NUM_VECS;
      tgt_vec->vec_type = LAPI_GEN_IOVECTOR;
      tgt_vec->len = (unsigned long *)
      malloc(NUM_VECS*sizeof(unsigned long));
      tgt_vec->info = (void **) malloc(NUM_VECS*sizeof(void *));

      /* each tgt_vec->info[i] gets a base address on the target task */
      /* each tgt_vec->len[i] gets the number of bytes to transfer    */
      /* from vec->info[i]                                            */
      /* For LAPI_GEN_IOVECTOR, num_vecs, vec_type, and len must be   */
      /* the same                                                     */

      LAPI_Getv(hndl, tgt, tgt_vec, org_vec, tgt_cntr, org_cntr);
      /* tgt_cntr and org_cntr can both be NULL           */

      /* data will be retrieved as follows:               */
      /* org_vec->len[0] bytes will be retrieved from     */
      /* tgt_vec->info[0] and written to org_vec->info[0] */
      /* org_vec->len[1] bytes will be retrieved from     */
      /* tgt_vec->info[1] and written to org_vec->info[1] */
      .
      .
      .
      /* org_vec->len[NUM_VECS-1] bytes will be retrieved */
      /* from tgt_vec->info[NUM_VECS-1] and written to    */
      /* org_vec->info[NUM_VECS-1]                        */

}
```

For examples of other vector types, see LAPI_Amsendv.

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_ORG_EXTENT
Indicates that the *org_vec*'s extent (stride * *num_vecs*) is greater than the value of LAPI constant LAPI_MAX_MSG_SZ.

LAPI_ERR_ORG_STRIDE
Indicates that the *org_vec* stride is less than block size.

LAPI_ERR_ORG_VEC_ADDR
Indicates that some *org_vec*->*info*[*i*] is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN). but the corresponding length (*org_vec*->*len*[*i*]) is not 0.

LAPI_ERR_ORG_VEC_LEN
Indicates that the total sum of all *org_vec*->*len*[*i*] (where [*i*] is in the range 0 <= *i* <= *org_vec*->*num_vecs*) is greater than the value of LAPI constant LAPI_MAX_MSG_SZ.

LAPI_ERR_ORG_VEC_NULL
Indicates that the *org_vec* is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_ORG_VEC_TYPE
Indicates that the *org_vec*->*vec_type* is not valid.

LAPI_ERR_STRIDE_ORG_VEC_ADDR_NULL
Indicates that the strided vector base address *org_vec*->*info*[0] is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_STRIDE_TGT_VEC_ADDR_NULL
Indicates that the strided vector address *tgt_vec*->*info*[0] is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_TGT
Indicates that the *tgt* passed in is outside the range of tasks defined in the job.

LAPI_ERR_TGT_EXTENT
Indicates that *tgt_vec*'s extent (stride * *num_vecs*) is greater than the value of LAPI constant LAPI_MAX_MSG_SZ.

LAPI_ERR_TGT_PURGED
Indicates that the subroutine returned early because LAPI_Purge_totask() was called.

LAPI_ERR_TGT_STRIDE
Indicates that the *tgt_vec*'s stride is less than its block size.

LAPI_ERR_TGT_VEC_ADDR
Indicates that the *tgt_vec*->*info*[i] is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), but its length (*tgt_vec*->*len*[i]) is not 0.

LAPI_ERR_TGT_VEC_LEN
Indicates that the sum of *tgt_vec*->*len* is greater than the value of LAPI constant LAPI_MAX_MSG_SZ.

LAPI_ERR_TGT_VEC_NULL
Indicates that *tgt_vec* is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_TGT_VEC_TYPE
Indicates that the *tgt_vec*->*vec_type* is not valid.

LAPI_ERR_VEC_LEN_DIFF
Indicates that *org_vec* and *tgt_vec* have different lengths (*len*[]).

LAPI_ERR_VEC_NUM_DIFF
Indicates that *org_vec* and *tgt_vec* have different *num_vecs*.

LAPI_ERR_VEC_TYPE_DIFF
Indicates that *org_vec* and *tgt_vec* have different vector types (*vec_type*).

Location

/usr/lib/liblapi_r.a

LAPI_Gfence Subroutine

Purpose

Enforces order on LAPI calls across all tasks and provides barrier synchronization among them.

Library

Availability Library (`liblapi_r.a`)

C Syntax

```
#include <lapi.h>

int LAPI_Gfence(hndl)
lapi_handle_t hndl;
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_GFENCE(hndl, ierror)
INTEGER hndl
INTEGER ierror
```

Description

`Type of call:` collective data synchronization (blocking)

Use this subroutine to enforce global order on LAPI calls. This is a *collective call.* Collective calls must be made in the same order at all participating tasks.

On completion of this call, it is assumed that all LAPI communication associated with *hndl* from all tasks has quiesced. Although *hndl* is local, it represents a set of tasks that were associated with it at `LAPI_Init`, all of which must participate in this operation for it to complete. This is a data fence, which means that the data movement is complete. This is not an operation fence, which would need to include active message completion handlers completing on the target.

Parameters

INPUT

hndl
Specifies the LAPI handle.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

Location

/usr/lib/liblapi_r.a

LAPI_Init Subroutine

Purpose

Initializes a LAPI context.

Library

Availability Library (`liblapi_r.a`)

C Syntax

```
#include <lapi.h>

int LAPI_Init(hndl,lapi_info)
lapi_handle_t *hndl;
lapi_info_t *lapi_info;
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_INIT(hndl,lapi_info,ierror)
INTEGER hndl
TYPE (LAPI_INFO_T) :: lapi_info
INTEGER ierror
```

Description

`Type of call:` Local initialization

Use this subroutine to instantiate and initialize a new LAPI context. A handle to the newly-created LAPI context is returned in *hndl*. All subsequent LAPI calls can use *hndl* to specify the context of the LAPI operation. Except for `LAPI_Address()` and `LAPI_Msg_string()`, the user cannot make any LAPI calls before calling `LAPI_Init()`.

The *lapi_info* structure (`lapi_info_t`) must be "zeroed out" before any fields are filled in. To do this in C, use this statement: `bzero (lapi_info, size of (lapi_info_t))`. In FORTRAN, you need to "zero out" each field manually in the LAPI_INFO_T type. Fields with a description of `Future support` should not be used because the names of those fields might change.

The `lapi_info_t` structure is defined as follows:

```
typedef struct {
    lapi_dev_t     protocol;      /* Protocol device returned                    */
    lapi_lib_t     lib_vers;      /* LAPI library version -- user-supplied       */
    uint           epoch_num;     /* No longer used                              */
    int            num_compl_hndlr_thr; /* Number of completion handler threads  */
    uint           instance_no;   /* Instance of LAPI to initialize [1-16]       */
    int            info6;         /* Future support                              */
    LAPI_err_hndlr *err_hndlr;    /* User-registered error handler               */
    com_thread_info_t *lapi_thread_attr; /* Support thread att and init function */
    void           *adapter_name; /* What adapter to initialize, i.e. css0, ml0  */
    lapi_extend_t  *add_info;     /* Additional structure extension              */
} lapi_info_t;
```

The fields are used as follows:

protocol
LAPI sets this field to the protocol that has been initialized.

lib_vers
Is used to indicate a library version to LAPI for compatibility purposes. Valid values for this field are:

L1_LIB
Provides basic functionality (this is the default).

L2_LIB
Provides the ability to use counters as structures.

LAST_LIB
Provides the most current level of functionality. For new users of LAPI, *lib_vers* should be set to LAST_LIB.

This field must be set to L2_LIB or LAST_LIB to use LAPI_Nopoll_wait and LAPI_Setcntr_wstatus.

epoch_num
This field is no longer used.

num_compl_hndlr_thr
Indicates to LAPI the number of completion handler threads to initialize.

instance_no
Specifies the instance of LAPI to initialize (1 to 16).

info6
This field is for future use.

err_hndlr
Use this field to optionally pass a callback pointer to an error-handler routine.

lapi_thread_attr
Supports thread attributes and initialization function.

adapter_name
Is used in persistent subsystem (PSS) mode to pass an adapter name.

add_info
Is used for additional information in standalone UDP mode.

Parameters

INPUT/OUTPUT

lapi_info
Specifies a structure that provides the parallel job information with which this LAPI context is associated. The value of this parameter cannot be NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

OUTPUT

hndl
Specifies a pointer to the LAPI handle to initialize.

ierror
Specifies a FORTRAN return code. This is always the last parameter.

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_ALL_HNDL_IN_USE
All available LAPI instances are in use.

LAPI_ERR_BOTH_NETSTR_SET
Both the MP_LAPI_NETWORK and MP_LAPI_INET statements are set (only one should be set).

LAPI_ERR_CSS_LOAD_FAILED
LAPI is unable to load the communication utility library.

LAPI_ERR_HNDL_INVALID
The lapi_handle_t * passed to LAPI for initialization is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_INFO_NONZERO_INFO
The future support fields in the `lapi_info_t` structure that was passed to LAPI are not set to zero (and should be).

LAPI_ERR_INFO_NULL
The `lapi_info_t` pointer passed to LAPI is NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

LAPI_ERR_MEMORY_EXHAUSTED
LAPI is unable to obtain memory from the system.

LAPI_ERR_MSG_API
Indicates that the `MP_MSG_API` environment variable is not set correctly.

LAPI_ERR_NO_NETSTR_SET
No network statement is set. Note that if running with POE, this will be returned if `MP_MSG_API` is not set correctly.

LAPI_ERR_NO_UDP_HNDLR
You passed a value of NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN) for both the UDP handler and the UDP list. One of these (the UDP handler or the UDP list) must be initialized for standalone UDP initialization. This error is returned in standalone UDP mode only.

LAPI_ERR_PSS_NON_ROOT
You tried to initialize the persistent subsystem (PSS) protocol as a nonroot user.

LAPI_ERR_SHM_KE_NOT_LOADED
LAPI's shared memory kernel extension is not loaded.

LAPI_ERR_SHM_SETUP
LAPI is unable to set up shared memory. This error will be returned if `LAPI_USE_SHM=only` and tasks are assigned to more than one node.

LAPI_ERR_UDP_PKT_SZ
The UDP packet size you indicated is not valid.

LAPI_ERR_UNKNOWN
An internal error has occurred.

LAPI_ERR_USER_UDP_HNDLR_FAIL
The UDP handler you passed has returned a non-zero error code. This error is returned in standalone UDP mode only.

C Examples

The following environment variable must be set before LAPI is initialized:

```
MP_MSG_API=[ lapi | [ lapi,mpi | mpi,lapi ] | mpi_lapi ]
```

The following environment variables are also commonly used:

```
MP_EUILIB=[ ip | us ] (ip is the default)
MP_PROCS=number_of_tasks_in_job
LAPI_USE_SHM=[ yes | no | only ] (no is the default)
```

To initialize LAPI, follow these steps:

1. Set environment variables (as described in *RSCT for AIX 5L: LAPI Programming Guide*) before the user application is invoked. The remaining steps are done in the user application.
2. Clear `lapi_info_t`, then set any fields.
3. Call `LAPI_Init`.

For systems running PE

Both US and UDP/IP are supported for shared handles as long as they are the same for both handles. Mixed transport protocols such as LAPI IP and shared user space (US) are not supported.

To initialize a LAPI handle:

```
{
    lapi_handle_t hndl;
    lapi_info_t info;

    bzero(&info, sizeof(lapi_info_t));  /* clear lapi_info */

    LAPI_Init(&hndl, &info);
}
```

To initialize a LAPI handle and register an error handler:

```
void my_err_hndlr(lapi_handle_t *hndl, int *error_code, lapi_err_t *err_type,
                  int *task_id, int *src )
{
   /* examine passed parameters and delete desired information */

   if ( user wants to terminate ) {
       LAPI_Term(*hndl);               /* will terminate LAPI */
       exit(some_return_code);
   }

   /* any additional processing */

   return; /* signals to LAPI that error is non-fatal; execution should continue */
}

{
    lapi_handle_t hndl;
    lapi_info_t info;

    bzero(&info, sizeof(lapi_info_t));  /* clear lapi_info */

    /* set error handler pointer */
    info.err_hndlr = (LAPI_err_hndlr) my_err_hndlr;

    LAPI_Init(&hndl, &info);
}
```

For standalone systems (not running PE)

To initialize a LAPI handle for UDP/IP communication using a user handler:

```
int my_udp_hndlr(lapi_handle_t *hndl, lapi_udp_t *local_addr, lapi_udp_t *addr_list,
                lapi_udpinfo_t *info)

{
    /* LAPI will allocate and free addr_list pointer when using */
    /* a user handler                                           */

    /* use the AIX(r) inet_addr call to convert an IP address      */
    /* from a dotted quad to a long                             */
    task_0_ip_as_long = inet_addr(task_0_ip_as_string);
    addr_list[0].ip_addr = task_0_ip_as_long;
    addr_list[0].port_no = task_0_port_as_unsigned;

    task_1_ip_as_long = inet_addr(task_1_ip_as_string);
    addr_list[1].ip_addr = task_1_ip_as_long;
    addr_list[1].port_no = task_1_port_as_unsigned;
    .
    .
    .
    task_num_tasks-1_ip_as_long = inet_addr(task_num_tasks-1_ip_as_string);
    addr_list[num_tasks-1].ip_addr = task_num_tasks-1_ip_as_long;
    addr_list[num_tasks-1].port_no = task_num_tasks-1_port_as_unsigned;

}

{
```

```
    lapi_handle_t hndl;
    lapi_info_t info;
    lapi_extend_t extend_info;

    bzero(&info, sizeof(lapi_info_t));           /* clear lapi_info        */
    bzero(&extend_info, sizeof(lapi_extend_t));  /* clear lapi_extend_info */

    extend_info.udp_hndlr = (udp_init_hndlr *) my_udp_hndlr;
    info.add_info = &extend_info;

    LAPI_Init(&hndl, &info);
}
```

To initialize a LAPI handle for UDP/IP communication using a user list:

```
{
    lapi_handle_t hndl;
    lapi_info_t info;
    lapi_extend_t extend_info;
    lapi_udp_t *addr_list;

    bzero(&info, sizeof(lapi_info_t));           /* clear lapi_info        */
    bzero(&extend_info, sizeof(lapi_extend_t));  /* clear lapi_extend_info */

    /* when using a user list, the user is responsible for allocating          */
    /* and freeing the list pointer                                            */
    addr_list = malloc(num_tasks);

    /* Note, since we need to know the number of tasks before LAPI is          */
    /* initialized, we can't use LAPI_Qenv.  getenv("MP_PROCS") will           */
    /* do the trick.                                                           */

    /* populate addr_list                                                      */
    /* use the AIX(r) inet_addr call to convert an IP address                    */
    /* from a dotted quad to a long                                            */
    task_0_ip_as_long = inet_addr(task_0_ip_as_string);
    addr_list[0].ip_addr = task_0_ip_as_long;
    addr_list[0].port_no = task_0_port_as_unsigned;

    task_1_ip_as_long = inet_addr(task_1_ip_as_string);
    addr_list[1].ip_addr = task_1_ip_as_long;
    addr_list[1].port_no = task_1_port_as_unsigned;
    .
    .
    .
    task_num_tasks-1_ip_as_long = inet_addr(task_num_tasks-1_ip_as_string);
    addr_list[num_tasks-1].ip_addr = task_num_tasks-1_ip_as_long;
    addr_list[num_tasks-1].port_no = task_num_tasks-1_port_as_unsigned;

    /* then assign to extend pointer */
    extend_info.add_udp_addrs = addr_list;

    info.add_info = &extend_info;

    LAPI_Init(&hndl, &info);
    .
    .
    .

    /* user's responsibility only in the case of user list */
    free(addr_list);

}
```

See the LAPI sample programs for complete examples of initialization in standalone mode.

To initialize a LAPI handle for user space (US) communication in standalone mode:

```
export MP_MSG_API=lapi
export MP_EUILIB=us
export MP_PROCS=                  /* number of tasks in job   */
export MP_PARTITION=              /* unique job key           */
export MP_CHILD=                  /* unique task ID           */
```

```
export MP_LAPI_NETWORK=@1:164,sn0   /* LAPI network information */

run LAPI jobs as normal
```

See the README.LAPI.STANDALONE.US file in the standalone/us directory of the LAPI sample files for complete details.

Location

/usr/lib/liblapi_r.a

LAPI_Msg_string Subroutine

Purpose

Retrieves the message that is associated with a subroutine return code.

Library

Availability Library (liblapi_r.a)

C Syntax

```
#include <lapi.h>

LAPI_Msg_string(error_code, buf)
int error_code;
void *buf;
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_MSG_STRING(error_code, buf, ierror)
INTEGER error_code
CHARACTER buf(LAPI_MAX_ERR_STRING)
INTEGER ierror
```

Description

Type of call: local queries

Use this subroutine to retrieve the message string that is associated with a LAPI return code. LAPI tries to find the messages of any return codes that come from the AIX operating system or its communication subsystem.

Parameters

INPUT

error_code
Specifies the return value of a previous LAPI call.

OUTPUT

buf
Specifies the buffer to store the message string.

ierror
Specifies a FORTRAN return code. This is always the last parameter.

C Examples

To get the message string associated with a LAPI return code:

```
{

    char msg_buf[LAPI_MAX_ERR_STRING]; /* constant defined in lapi.h */
    int rc, errc;

    rc = some_LAPI_call();

    errc = LAPI_Msg_string(rc, msg_buf);

    /* msg_buf now contains the message string for the return code   */

}
```

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_CATALOG_FAIL
Indicates that the message catalog cannot be opened. An English-only string is copied into the user's message buffer (*buf*).

LAPI_ERR_CODE_UNKNOWN
Indicates that *error_code* is outside of the range known to LAPI.

LAPI_ERR_RET_PTR_NULL
Indicates that the value of the *buf* pointer is NULL (in C) or that the value of *buf* is LAPI_ADDR_NULL (in FORTRAN).

Location

/usr/lib/liblapi_r.a

LAPI_Msgpoll Subroutine

Purpose

Allows the calling thread to check communication progress.

Library

Availability Library (liblapi_r.a)

C Syntax

```
#include <lapi.h>

int LAPI_Msgpoll(hndl, cnt, info)
lapi_handle_t     hndl;
uint              cnt;
lapi_msg_info_t  *info;

typedef struct {
    lapi_msg_state_t  status;      /* Message status returned from LAPI_Msgpoll */
    ulong             reserve[10]; /* Reserved                                  */
} lapi_msg_info_t;
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_MSGPOLL(hndl, cnt, info, ierror)
INTEGER hndl
INTEGER cnt
TYPE (LAPI_MSG_STATE_T) :: info
INTEGER ierror
```

Description

`Type of call:` local progress monitor (blocking)

The `LAPI_Msgpoll` subroutine allows the calling thread to check communication progress. With this subroutine, LAPI provides a means of running the dispatcher several times until either progress is made or a specified maximum number of dispatcher loops have executed. Here, *progress* is defined as the completion of either a message send operation or a message receive operation.

`LAPI_Msgpoll` is intended to be used when interrupts are turned off. If the user has not explicitly turned interrupts off, LAPI temporarily disables interrupt mode while in this subroutine because the dispatcher is called, which will process any pending receive operations. If the LAPI dispatcher loops for the specified maximum number of times, the call returns. If progress is made before the maximum count, the call will return immediately. In either case, LAPI will report status through a data structure that is passed by reference.

The `lapi_msg_info_t` structure contains a flags field (*status*), which is of type `lapi_msg_state_t`. Flags in the *status* field are set as follows:

LAPI_DISP_CNTR
If the dispatcher has looped *cnt* times without making progress

LAPI_SEND_COMPLETE
If a message send operation has completed

LAPI_RECV_COMPLETE
If a message receive operation has completed

LAPI_BOTH_COMPLETE
If both a message send operation and a message receive operation have completed

LAPI_POLLING_NET
If another thread is already polling the network or shared memory completion

Parameters

INPUT

hndl
Specifies the LAPI handle.

cnt
Specifies the maximum number of times the dispatcher should loop with no progress before returning.

info
Specifies a status structure that contains the result of the `LAPI_Msgpoll()` call.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

C Examples

To loop through the dispatcher no more than 1000 times, then check what progress has been made:

```
{

    lapi_msg_info_t msg_info;
    int cnt = 1000;
    .
    .
    .
    LAPI_Msgpoll(hndl, cnt, &msg_info);

    if ( msg_info.status & LAPI_BOTH_COMPLETE ) {
        /* both a message receive and a message send have been completed */
    } else if ( msg_info.status & LAPI_RECV_COMPLETE ) {
        /* just a message receive has been completed                     */
    } else if ( msg_info.status & LAPI_SEND_COMPLETE ) {
        /* just a message send has been completed                        */
    } else {
        /* cnt loops and no progress                                     */
    }

}
```

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_MSG_INFO_NULL
Indicates that the *info* pointer is NULL (in C) or that the value of *info* is LAPI_ADDR_NULL (in FORTRAN).

Location

/usr/lib/liblapi_r.a

LAPI_Nopoll_wait Subroutine

Purpose

Waits for a counter update without polling.

Library

Availability Library (liblapi_r.a)

C Syntax

```
#include <lapi.h>

void LAPI_Nopoll_wait(hndl, cntr_ptr, val, cur_cntr_val)
lapi_handle_t  hndl;
lapi_cntr_t   *cntr_ptr;
int            val;
int           *cur_cntr_val;
```

FORTRAN Syntax

```
include 'lapif.h'

int LAPI_NOPOLL_WAIT(hndl, cntr, val, cur_cntr_val, ierror)
INTEGER hndl
TYPE (LAPI_CNTR_T) :: cntr
```

```
INTEGER val
INTEGER cur_cntr_val
INTEGER ierror
```

Description

`Type of call:` recovery (blocking)

This subroutine waits for a counter update without polling (that is, without explicitly invoking LAPI's internal communication dispatcher). This call may or may not check for message arrivals over the LAPI context *hndl*. The *cur_cntr_val* variable is set to the current counter value. Although it has higher latency than `LAPI_Waitcntr`, `LAPI_Nopoll_wait` frees up the processor for other uses.

Note: To use this subroutine, the *lib_vers* field in the `lapi_info_t` structure must be set to `L2_LIB` or `LAST_LIB`.

Parameters

INPUT

hndl
Specifies the LAPI handle.

val
Specifies the relative counter value (starting from 1) that the counter needs to reach before returning.

cur_cntr_val
Specifies the integer value of the current counter. The value of The value of this parameter can be NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

INPUT/OUTPUT

cntr_ptr
Points to the `lapi_cntr_t` structure in C.

cntr
Is the `lapi_cntr_t` structure in FORTRAN.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_CNTR_NULL
Indicates that the *cntr_ptr* pointer is NULL (in C) or that the value of *cntr* is `LAPI_ADDR_NULL` (in FORTRAN).

LAPI_ERR_CNTR_VAL
Indicates that the *val* passed in is less than or equal to `0`.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_MULTIPLE_WAITERS
Indicates that more than one thread is waiting for the counter.

LAPI_ERR_TGT_PURGED
Indicates that the subroutine returned early because `LAPI_Purge_totask()` was called.

Restrictions

Use of this subroutine is *not* recommended on a system that is running Parallel Environment (PE).

Location

/usr/lib/liblapi_r.a

LAPI_Probe Subroutine

Purpose

Transfers control to the communication subsystem to check for arriving messages and to make progress in polling mode.

Library

Availability Library (`liblapi_r.a`)

C Syntax

```
#include <lapi.h>

int LAPI_Probe(hndl)
lapi_handle_t hndl;
```

FORTRAN Syntax

```
include 'lapif.h'

int LAPI_PROBE(hndl, ierror)
INTEGER hndl
INTEGER ierror
```

Description

`Type of call:` local progress monitor (non-blocking)

This subroutine transfers control to the communication subsystem in order to make progress on messages associated with the context *hndl*. A `LAPI_Probe` operation lasts for one round of the communication dispatcher.

Note: There is no guarantee about receipt of messages on the return from this function.

Parameters

INPUT

hndl
Specifies the LAPI handle.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

Location

/usr/lib/liblapi_r.a

LAPI_Purge_totask Subroutine

Purpose

Allows a task to cancel messages to a given destination.

Library

Availability Library (`liblapi_r.a`)

C Syntax

```
#include <lapi.h>

int LAPI_Purge_totask(hndl, dest)
lapi_handle_t hndl;
uint          dest;
```

FORTRAN Syntax

```
include 'lapif.h'

int LAPI_PURGE_TOTASK(hndl, dest, ierror)
INTEGER hndl
INTEGER dest
INTEGER ierror
```

Description

`Type of call:` recovery

This subroutine cancels messages and resets the state corresponding to messages in flight or submitted to be sent to a particular target task. This is an entirely local operation. For correct behavior a similar invocation is expected on the destination (if it exists). This function cleans up all the state associated with pending messages to the indicated target task. It is assumed that before the indicated task starts communicating with this task again, it also purges this instance (or that it was terminated and initialized again). It will also wake up all threads that are in `LAPI_Nopoll_wait` depending on how the arguments are passed to the `LAPI_Nopoll_wait` function. The behavior of `LAPI_Purge_totask` is undefined if LAPI collective functions are used.

`Note:` This subroutine should not be used when the parallel application is running in a PE/LoadLeveler environment.

`LAPI_Purge_totask` is normally used after connectivity has been lost between two tasks. If connectivity is restored, the tasks can restored for LAPI communication by calling `LAPI_Resume_totask`.

Parameters

INPUT

hndl
Specifies the LAPI handle.

dest
Specifies the destination instance ID to which pending messages need to be cancelled.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

Restrictions

Use of this subroutine is *not* recommended on a system that is running Parallel Environment (PE).

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_TGT
Indicates that *dest* is outside the range of tasks defined in the job.

Location

/usr/lib/liblapi_r.a

LAPI_Put Subroutine

Purpose

Transfers data from a local task to a remote task.

Library

Availability Library (`liblapi_r.a`)

C Syntax

```
#include <lapi.h>

int LAPI_Put(hndl, tgt, len, tgt_addr, org_addr, tgt_cntr, org_cntr, cmpl_cntr)
lapi_handle_t hndl;
uint          tgt;
ulong         len;
void         *tgt_addr;
void         *org_addr;
lapi_cntr_t  *tgt_cntr;
lapi_cntr_t  *org_cntr;
lapi_cntr_t  *cmpl_cntr;
```

FORTRAN Syntax

```
include 'lapif.h'

int LAPI_PUT(hndl, tgt, len, tgt_addr, org_addr, tgt_cntr, org_cntr, ierror)
INTEGER hndl
INTEGER tgt
INTEGER (KIND=LAPI_LONG_TYPE) :: len
INTEGER (KIND=LAPI_ADDR_TYPE) :: tgt_addr
INTEGER org_addr
INTEGER (KIND=LAPI_ADDR_TYPE) :: tgt_cntr
TYPE (LAPI_CNTR_T) :: org_cntr
TYPE (LAPI_CNTR_T) :: cmpl_cntr
INTEGER ierror
```

Description

`Type of call:` point-to-point communication (non-blocking)

Use this subroutine to transfer data from a local (origin) task to a remote (target) task. The origin counter will increment on the origin task upon origin buffer availability. The target counter will increment on the target and the completion counter will increment at the origin task upon message completion. Because there is no completion handler, message completion and target buffer availability are the same in this case.

This is a non-blocking call. The caller *cannot* assume that the data transfer has completed upon the return of the function. Instead, counters should be used to ensure correct buffer accesses as defined above.

Note that a zero-byte message does not transfer data, but it does have the same semantic with respect to counters as that of any other message.

Parameters

INPUT

hndl
Specifies the LAPI handle.

tgt
Specifies the task ID of the target task. The value of this parameter must be in the range `0` <= *tgt* < **NUM_TASKS**.

len
Specifies the number of bytes to be transferred. This parameter must be in the range `0` <= *len* <= the value of LAPI constant `LAPI_MAX_MSG_SZ`.

tgt_addr
Specifies the address on the target task where data is to be copied into. If *len* is `0`, The value of this parameter can be NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

org_addr
Specifies the address on the origin task from which data is to be copied. If *len* is `0`, The value of this parameter can be NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

INPUT/OUTPUT

tgt_cntr
Specifies the target counter address. The target counter is incremented upon message completion. If this parameter is NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN), the target counter is not updated.

org_cntr
Specifies the origin counter address (in C) or the origin counter (in FORTRAN). The origin counter is incremented at buffer availability. If this parameter is NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN), the origin counter is not updated.

cmpl_cntr
Specifies the completion counter address (in C) or the completion counter (in FORTRAN) that is a reflection of *tgt_cntr*. The completion counter is incremented at the origin after *tgt_cntr* is incremented. If this parameter is NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN), the completion counter is not updated.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

C Examples

```
{
    /* initialize the table buffer for the data addresses          */
    /* get remote data buffer addresses                            */
```

```
    LAPI_Address_init(hndl,(void *)data_buffer,data_buffer_list);
    .
    .
    .
    LAPI_Put(hndl, tgt, (ulong) data_len, (void *)(data_buffer_list[tgt]),
             (void *) data_buffer, tgt_cntr, org_cntr, compl_cntr);

    /* transfer data_len bytes from local address data_buffer.     */
    /* write the data starting at address data_buffer_list[tgt] on */
    /* task tgt. tgt_cntr, org_cntr, and compl_cntr can be NULL.   */

}
```

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_DATA_LEN
Indicates that the value of *len* is greater than the value of LAPI constant LAPI_MAX_MSG_SZ.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_ORG_ADDR_NULL
Indicates that the *org_addr* parameter passed in is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), but *len* is greater than 0.

LAPI_ERR_TGT
Indicates that the *tgt* passed in is outside the range of tasks defined in the job.

LAPI_ERR_TGT_ADDR_NULL
Indicates that the *tgt_addr* parameter passed in is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), but *len* is greater than 0.

LAPI_ERR_TGT_PURGED
Indicates that the subroutine returned early because LAPI_Purge_totask() was called.

Location

/usr/lib/liblapi_r.a

LAPI_Putv Subroutine

Purpose

Transfers vectors of data from a local task to a remote task.

Library

Availability Library (liblapi_r.a)

C Syntax

```
#include <lapi.h>

int LAPI_Putv(hndl, tgt, tgt_vec, org_vec, tgt_cntr, org_cntr, cmpl_cntr)

lapi_handle_t  hndl;
uint           tgt;
lapi_vec_t    *tgt_vec;
lapi_vec_t    *org_vec;
lapi_cntr_t   *tgt_cntr;
lapi_cntr_t   *org_cntr;
lapi_cntr_t   *cmpl_cntr;

typedef struct  {
```

```
    lapi_vectype_t  vec_type;   /* operation code        */
    uint            num_vecs;   /* number of vectors     */
    void            **info;     /* vector of information */
    ulong           *len;       /* vector of lengths     */
} lapi_vec_t;
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_PUTV(hndl, tgt, tgt_vec, org_vec, tgt_cntr, org_cntr , cmpl_cntr, ierror)
INTEGER hndl
INTEGER tgt
INTEGER (KIND=LAPI_ADDR_TYPE) :: tgt_vec
TYPE (LAPI_VEC_T) :: org_vec
INTEGER (KIND=LAPI_ADDR_TYPE) :: tgt_cntr
TYPE (LAPI_CNTR_T) :: org_cntr
TYPE (LAPI_CNTR_T) :: cmpl_cntr
INTEGER ierror
```

The 32-bit version of the LAPI_VEC_T type is defined as:

```
TYPE LAPI_VEC_T
   SEQUENCE
   INTEGER(KIND = 4)  :: vec_type
   INTEGER(KIND = 4)  :: num_vecs
   INTEGER(KIND = 4)  :: info
   INTEGER(KIND = 4)  :: len
END TYPE LAPI_VEC_T
```

The 64-bit version of the LAPI_VEC_T type is defined as:

```
TYPE LAPI_VEC_T
   SEQUENCE
   INTEGER(KIND = 4)  :: vec_type
   INTEGER(KIND = 4)  :: num_vecs
   INTEGER(KIND = 8)  :: info
   INTEGER(KIND = 8)  :: len
END TYPE LAPI_VEC_T
```

Description

Type of call: point-to-point communication (non-blocking)

LAPI_Putv is the vector version of the LAPI_Put call. Use this subroutine to transfer vectors of data from the origin task to the target task. The origin vector descriptions and the target vector descriptions are located in the address space of the *origin* task. However, the values specified in the *info* array of the target vector must be addresses in the address space of the *target* task.

The calling program *cannot* assume that the origin buffer can be changed or that the contents of the target buffers on the target task are ready for use upon function return. After the origin counter (*org_cntr*) is incremented, the origin buffers can be modified by the origin task. After the target counter (*tgt_cntr*) is incremented, the target buffers can be modified by the target task. If you provide a completion counter (*cmpl_cntr*), it is incremented at the origin after the target counter (*tgt_cntr*) has been incremented at the target. If the values of any of the counters or counter addresses are NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), the data transfer occurs, but the corresponding counter increments do not occur.

If a strided vector is being transferred, the size of each block must not be greater than the stride size in bytes.

The length of any vector pointed to by *org_vec* must be equal to the length of the corresponding vector pointed to by *tgt_vec*.

LAPI does not check for any overlapping regions among vectors either at the origin or the target. If the overlapping regions exist on the target side, the contents of the target buffer are undefined after the operation.

See LAPI_Amsendv for more information about using the various vector types. (LAPI_Putv does not support the LAPI_GEN_GENERIC type.)

Parameters

INPUT

hndl
Specifies the LAPI handle.

tgt
Specifies the task ID of the target task. The value of this parameter must be in the range 0 <= *tgt* < **NUM_TASKS**.

tgt_vec
Points to the target vector description.

org_vec
Points to the origin vector description.

INPUT/OUTPUT

tgt_cntr
Specifies the target counter address. The target counter is incremented upon message completion. If this parameter is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), the target counter is not updated.

org_cntr
Specifies the origin counter address (in C) or the origin counter (in FORTRAN). The origin counter is incremented at buffer availability. If this parameter is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), the origin counter is not updated.

cmpl_cntr
Specifies the completion counter address (in C) or the completion counter (in FORTRAN) that is a reflection of *tgt_cntr*. The completion counter is incremented at the origin after *tgt_cntr* is incremented. If this parameter is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), the completion counter is not updated.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

C Examples

To put a LAPI_GEN_IOVECTOR:

```
{

      /* retrieve a remote data buffer address for data to transfer,  */
      /* such as through LAPI_Address_init                            */

      /* task that calls LAPI_Putv sets up both org_vec and tgt_vec   */
      org_vec->num_vecs = NUM_VECS;
      org_vec->vec_type = LAPI_GEN_IOVECTOR;
      org_vec->len      = (unsigned long *)
      malloc(NUM_VECS*sizeof(unsigned long));
      org_vec->info     = (void **) malloc(NUM_VECS*sizeof(void *));

      /* each org_vec->info[i] gets a base address on the origin task */
      /* each org_vec->len[i] gets the number of bytes to transfer    */
      /* from org_vec->info[i]                                        */

      tgt_vec->num_vecs = NUM_VECS;
      tgt_vec->vec_type = LAPI_GEN_IOVECTOR;
      tgt_vec->len      = (unsigned long *)
      malloc(NUM_VECS*sizeof(unsigned long));
      tgt_vec->info     = (void **) malloc(NUM_VECS*sizeof(void *));

      /* each tgt_vec->info[i] gets a base address on the target task           */
      /* each tgt_vec->len[i] gets the number of bytes to write to vec->info[i] */
      /* For LAPI_GEN_IOVECTOR, num_vecs, vec_type, and len must be the same    */
```

```
      LAPI_Putv(hndl, tgt, tgt_vec, org_vec, tgt_cntr, org_cntr, compl_cntr);
      /* tgt_cntr, org_cntr and compl_cntr can all be NULL */

      /* data will be transferred as follows:              */
      /* org_vec->len[0] bytes will be retrieved from      */
      /* org_vec->info[0] and written to tgt_vec->info[0]  */
      /* org_vec->len[1] bytes will be retrieved from      */
      /* org_vec->info[1] and written to tgt_vec->info[1]  */
      .
      .
      .
      /* org_vec->len[NUM_VECS-1] bytes will be retrieved */
      /* from org_vec->info[NUM_VECS-1] and written to    */
      /* tgt_vec->info[NUM_VECS-1]                        */

}
```

See the example in LAPI_Amsendv for information on other vector types.

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_ORG_EXTENT
Indicates that the *org_vec*'s extent (stride * *num_vecs*) is greater than the value of LAPI constant LAPI_MAX_MSG_SZ.

LAPI_ERR_ORG_STRIDE
Indicates that the *org_vec* stride is less than block.

LAPI_ERR_ORG_VEC_ADDR
Indicates that the *org_vec*->*info[i]* is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), but its length (*org_vec*->*len[i]*) is not 0.

LAPI_ERR_ORG_VEC_LEN
Indicates that the sum of *org_vec*->*len* is greater than the value of LAPI constant LAPI_MAX_MSG_SZ.

LAPI_ERR_ORG_VEC_NULL
Indicates that the *org_vec* is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_ORG_VEC_TYPE
Indicates that the *org_vec*->*vec_type* is not valid.

LAPI_ERR_STRIDE_ORG_VEC_ADDR_NULL
Indicates that the strided vector address *org_vec*->*info*[0] is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_STRIDE_TGT_VEC_ADDR_NULL
Indicates that the strided vector address *tgt_vec*->*info*[0] is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_TGT
Indicates that the *tgt* passed in is outside the range of tasks defined in the job.

LAPI_ERR_TGT_EXTENT
Indicates that *tgt_vec*'s extent (stride * *num_vecs*) is greater than the value of LAPI constant LAPI_MAX_MSG_SZ.

LAPI_ERR_TGT_PURGED
Indicates that the subroutine returned early because LAPI_Purge_totask() was called.

LAPI_ERR_TGT_STRIDE
Indicates that the *tgt_vec* stride is less than block.

LAPI_ERR_TGT_VEC_ADDR
Indicates that the *tgt_vec*->*info*[i] is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), but its length (*tgt_vec*->*len*[i]) is not 0.

LAPI_ERR_TGT_VEC_LEN
Indicates that the sum of *tgt_vec->len* is greater than the value of LAPI constant LAPI_MAX_MSG_SZ.

LAPI_ERR_TGT_VEC_NULL
Indicates that *tgt_vec* is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_TGT_VEC_TYPE
Indicates that the *tgt_vec->vec_type* is not valid.

LAPI_ERR_VEC_LEN_DIFF
Indicates that *org_vec* and *tgt_vec* have different lengths (*len[ ]*).

LAPI_ERR_VEC_NUM_DIFF
Indicates that *org_vec* and *tgt_vec* have different *num_vecs*.

LAPI_ERR_VEC_TYPE_DIFF
Indicates that *org_vec* and *tgt_vec* have different vector types (*vec_type*).

Location

LAPI_Qenv Subroutine

Purpose

Used to query LAPI for runtime task information.

Library

Availability Library (liblapi_r.a)

C Syntax

```
#include <lapif.h>

int LAPI_Qenv(hndl, query, ret_val)
lapi_handle_t  hndl;
lapi_query_t   query;
int           *ret_val; /* ret_val's type varies (see Additional query types) */
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_QENV(hndl, query, ret_val, ierror)
INTEGER hndl
INTEGER query
INTEGER ret_val /* ret_val's type varies (see Additional query types) */
INTEGER ierror
```

Description

Type of call: local queries

Use this subroutine to query runtime settings and statistics from LAPI. LAPI defines a set of query types as an enumeration in lapi.h for C and explicitly in the 32-bit and 64-bit versions of lapif.h for FORTRAN.

For example, you can query the size of the table that LAPI uses for the LAPI_Addr_set subroutine using a *query* value of LOC_ADDRTBL_SZ:

```
LAPI_Qenv(hndl, LOC_ADDRTBL_SZ, &ret_val);
```

ret_val will contain the upper bound on the table index. A subsequent call to `LAPI_Addr_set (`*hndl*`, `*addr*`, `*addr_hndl*`);` could then ensure that the value of *addr_hndl* is between `0` and *ret_val*.

When used to show the size of a parameter, a comparison of values, or a range of values, valid values for the *query* parameter of the `LAPI_Qenv` subroutine appear in **SMALL, BOLD** capital letters. For example:

NUM_TASKS

is a shorthand notation for:

`LAPI_Qenv(`*hndl*`, NUM_TASKS, `*ret_val*`)`

In C, `lapi_query_t` defines the valid types of LAPI queries:

```
typedef enum {
        TASK_ID=0,      /* Query the task ID of the current task in the job        */
        NUM_TASKS,      /* Query the number of tasks in the job                    */
        MAX_UHDR_SZ,    /* Query the maximum user header size for active messaging */
        MAX_DATA_SZ,    /* Query the maximum data length that can be sent          */
        ERROR_CHK,      /* Query and set parameter checking on (1) or off (0)      */
        TIMEOUT,        /* Query and set the current communication timeout setting
*/
                        /* in seconds                                              */
        MIN_TIMEOUT, /* Query the minimum communication timeout setting in seconds
*/
        MAX_TIMEOUT, /* Query the maximum communication timeout setting in seconds
*/
        INTERRUPT_SET,  /* Query and set interrupt mode on (1) or off (0)          */
        MAX_PORTS,    /* Query the maximum number of available communication ports */
        MAX_PKT_SZ,     /* This is the payload size of 1 packet                    */
        NUM_REX_BUFS,   /* Number of retransmission buffers                        */
        REX_BUF_SZ,     /* Size of each retransmission buffer in bytes             */
        LOC_ADDRTBL_SZ, /* Size of address store table used by LAPI_Addr_set       */
        EPOCH_NUM,      /* No longer used by LAPI (supports legacy code)           */
        USE_THRESH,     /* No longer used by LAPI (supports legacy code)           */
        RCV_FIFO_SIZE,  /* No longer used by LAPI (supports legacy code)           */
        MAX_ATOM_SIZE,/* Query the maximum atom size for a DGSP accumulate transfer*/
        BUF_CP_SIZE, /* Query the size of the message buffer to save (default 128b)*/
        MAX_PKTS_OUT,   /* Query the maximum number of messages outstanding /
*/
                        /* destination                                             */
        ACK_THRESHOLD,  /* Query and set the threshold of acknowledgments going
*/
                        /* back to the source                                      */
        QUERY_SHM_ENABLED,    /* Query to see if shared memory is enabled          */
        QUERY_SHM_NUM_TASKS,  /* Query to get the number of tasks that use shared
*/
                           /* memory                                               */
        QUERY_SHM_TASKS,  /* Query to get the list of task IDs that make up shared */
                          /* memory; pass in an array of size QUERY_SHM_NUM_TASKS  */
        QUERY_STATISTICS,    /* Query to get packet statistics from LAPI, as       */
                             /* defined by the lapi_statistics_t structure. For    */
                             /* this query, pass in 'lapi_statistics_t *' rather   */
                             /* than 'int *ret_val'; otherwise, the data will      */
                             /* overflow the buffer.                               */
        PRINT_STATISTICS,    /* Query debug print function to print out statistics */
        QUERY_SHM_STATISTICS,/* Similar query as QUERY_STATISTICS for shared       */
                             /* memory path.                                       */
        QUERY_LOCAL_SEND_STATISTICS ,/* Similar query as QUERY_STATISTICS          */
                                     /* for local copy path.                       */
        BULK_XFER, /* Query to see if bulk transfer is enabled (1) or disabled (0) */
        BULK_MIN_MSG_SIZE, /* Query the current bulk transfer minimum message size
*/
        LAST_QUERY
} lapi_query_t;

typedef struct {
```

```
    lapi_long_t Tot_dup_pkt_cnt;     /* Total duplicate packet count  */
    lapi_long_t Tot_retrans_pkt_cnt; /* Total retransmit packet count */
    lapi_long_t Tot_gho_pkt_cnt;     /* Total Ghost packet count      */
    lapi_long_t Tot_pkt_sent_cnt;    /* Total packet sent count       */
    lapi_long_t Tot_pkt_recv_cnt;    /* Total packet receive count    */
    lapi_long_t Tot_data_sent;       /* Total data sent               */
    lapi_long_t Tot_data_recv;       /* Total data receive            */
} lapi_statistics_t;
```

In FORTRAN, the valid types of LAPI queries are defined in `lapif.h` as follows:

```
integer TASK_ID,NUM_TASKS,MAX_UHDR_SZ,MAX_DATA_SZ,ERROR_CHK
integer TIMEOUT,MIN_TIMEOUT,MAX_TIMEOUT
integer INTERRUPT_SET,MAX_PORTS,MAX_PKT_SZ,NUM_REX_BUFS
integer REX_BUF_SZ,LOC_ADDRTBL_SZ,EPOCH_NUM,USE_THRESH
integer RCV_FIFO_SIZE,MAX_ATOM_SIZE,BUF_CP_SIZE
integer MAX_PKTS_OUT,ACK_THRESHOLD,QUERY_SHM_ENABLED
integer QUERY_SHM_NUM_TASKS,QUERY_SHM_TASKS
integer QUERY_STATISTICS,PRINT_STATISTICS
integer QUERY_SHM_STATISTICS,QUERY_LOCAL_SEND_STATISTICS
integer BULK_XFER,BULK_MIN_MSG_SIZE,
integer LAST_QUERY
parameter (TASK_ID=0,NUM_TASKS=1,MAX_UHDR_SZ=2,MAX_DATA_SZ=3)
parameter (ERROR_CHK=4,TIMEOUT=5,MIN_TIMEOUT=6)
parameter (MAX_TIMEOUT=7,INTERRUPT_SET=8,MAX_PORTS=9)
parameter (MAX_PKT_SZ=10,NUM_REX_BUFS=11,REX_BUF_SZ=12)
parameter (LOC_ADDRTBL_SZ=13,EPOCH_NUM=14,USE_THRESH=15)
parameter (RCV_FIFO_SIZE=16,MAX_ATOM_SIZE=17,BUF_CP_SIZE=18)
parameter (MAX_PKTS_OUT=19,ACK_THRESHOLD=20)
parameter (QUERY_SHM_ENABLED=21,QUERY_SHM_NUM_TASKS=22)
parameter (QUERY_SHM_TASKS=23,QUERY_STATISTICS=24)
parameter (PRINT_STATISTICS=25)
parameter (QUERY_SHM_STATISTICS=26,QUERY_LOCAL_SEND_STATISTICS=27)
parameter (BULK_XFER=28,BULK_MIN_MSG_SIZE=29)
parameter (LAST_QUERY=30)
```

Additional query types

LAPI provides additional query types for which the behavior of LAPI_Qenv is slightly different:

PRINT_STATISTICS
When passed this query type, LAPI sends data transfer statistics to standard output. In this case, *ret_val* is unaffected. However, LAPI's error checking requires that the value of *ret_val* is not NULL (in C) or LAPI_ADDR_NULL (in FORTRAN) for all LAPI_Qenv types (including PRINT_STATISTICS).

QUERY_LOCAL_SEND_STATISTICS
When passed this query type, LAPI_Qenv interprets *ret_val* as a pointer to type `lapi_statistics_t`. Upon function return, the fields of the structure contain LAPI's data transfer statistics for data transferred through intra-task local copy. The packet count will be 0.

QUERY_SHM_STATISTICS
When passed this query type, LAPI_Qenv interprets *ret_val* as a pointer to type `lapi_statistics_t`. Upon function return, the fields of the structure contain LAPI's data transfer statistics for data transferred through shared memory.

QUERY_SHM_TASKS
When passed this query type, LAPI_Qenv returns a list of task IDs with which this task can communicate using shared memory. *ret_val* must be an `int *` with enough space to hold NUM_TASKS integers. For each task *i*, if it is possible to use shared memory, *ret_val*[*i*] will contain the shared memory task ID. If it is not possible to use shared memory, *ret_val*[*i*] will contain -1.

QUERY_STATISTICS
When passed this query type, LAPI_Qenv interprets *ret_val* as a pointer to type `lapi_statistics_t`. Upon function return, the fields of the structure contain LAPI's data transfer statistics for data transferred using the user space (US) protocol or UDP/IP.

Parameters

INPUT

hndl
Specifies the LAPI handle.

query
Specifies the type of query you want to request. In C, the values for *query* are defined by the `lapi_query_t` enumeration in `lapi.h`. In FORTRAN, these values are defined explicitly in the 32-bit version and the 64-bit version of `lapif.h`.

OUTPUT

ret_val
Specifies the reference parameter for LAPI to store as the result of the query. The value of this parameter cannot be NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

ierror
Specifies a FORTRAN return code. This is always the last parameter.

Return values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_QUERY_TYPE
Indicates that the query passed in is not valid.

LAPI_ERR_RET_PTR_NULL
Indicates that the value of the *ret_val* pointer is NULL (in C) or that the value of *ret_val* is `LAPI_ADDR_NULL` (in FORTRAN).

C Examples

To query runtime values from LAPI:

```
{
    int               task_id;
    lapi_statistics_t stats;
    .
    .
    .
    LAPI_Qenv(hndl, TASK_ID, &task_id);
    /* task_id now contains the task ID */
    .
    .
    .
    LAPI_Qenv(hndl, QUERY_STATISTICS, (int *)&stats);
    /* the fields of the stats structure are now
       filled in with runtime values */
    .
    .
    .
}
```

Location

/usr/lib/liblapi_r.a

Related Information

Subroutines: `LAPI_Amsend`, `LAPI_Get`, `LAPI_Put`, `LAPI_Senv`, `LAPI_Xfer`

LAPI_Resume_totask Subroutine

Purpose

Re-enables the sending of messages to the task.

Library

Availability Library (`liblapi_r.a`)

C Syntax

```
#include <lapi.h>

int LAPI_Resume_totask(hndl, dest)
lapi_handle_t hndl;
uint    dest;
```

FORTRAN Syntax

```
include 'lapif.h'

int LAPI_RESUME_TOTASK(hndl, dest, ierror)
INTEGER hndl
INTEGER dest
INTEGER ierror
```

Description

`Type of call:` recovery

This subroutine is used in conjunction with `LAPI_Purge_totask`. It enables LAPI communication to be reestablished for a task that had previously been purged. The purged task must either restart LAPI or execute a `LAPI_Purge_totask`/`LAPI_Resume_totask` sequence for this task.

Parameters

INPUT

hndl
Specifies the LAPI handle.

dest
Specifies the destination instance ID with which to resume communication.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

Restrictions

Use of this subroutine is *not* recommmended on a system that is running Parallel Environment (PE).

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_TGT
Indicates that the *tgt* passed in is outside the range of tasks defined in the job.

Location

/usr/lib/liblapi_r.a

LAPI_Rmw Subroutine

Purpose

Provides data synchronization primitives.

Library

Availability Library (`liblapi_r.a`)

C Syntax

INTEGER tgt
INTEGER (KIND=LAPI_ADDR_TYPE) :: tgt_var
INTEGER in_val
INTEGER prev_tgt_val
TYPE (LAPI_CNTR_T) :: org_cntr
INTEGER ierror
```

Description

`Type of call:` point-to-point communication (non-blocking)

Use this subroutine to synchronize two independent pieces of data, such as two tasks sharing a common data structure. The operation is performed at the target task (*tgt*) and is atomic. The operation takes an input value (*in_val*) from the origin and performs one of four operations (*op*) on a variable (*tgt_var*) at the target (*tgt*), and then replaces the target variable (*tgt_var*) with the results of the operation (*op*). The original value (*prev_tgt_val*) of the target variable (*tgt_var*) is returned to the origin.

The operations (*op*) are performed over the context referred to by *hndl*. The outcome of the execution of these calls is as if the following code was executed atomically:

```
*prev_tgt_val = *tgt_var;
*tgt_var      = f(*tgt_var, *in_val);
```

where:

f(a,b) = a + b for **FETCH_AND_ADD**

f(a,b) = a | b for **FETCH_AND_OR** (bitwise or)

f(a,b) = b for SWAP

For **COMPARE_AND_SWAP**, *in_val* is treated as a pointer to an array of two integers, and the *op* is the following atomic operation:

```
 if(*tgt_var == in_val[0]) {
   *prev_tgt_val = TRUE;
   *tgt_var      = in_val[1];
} else {
   *prev_tgt_val = FALSE;
}
```

All LAPI_Rmw calls are non-blocking. To test for completion, use the LAPI_Getcntr and LAPI_Waitcntr subroutines. LAPI_Rmw does not include a target counter (*tgt_cntr*), so LAPI_Rmw calls do not provide any indication of completion on the target task (*tgt*).

Parameters

INPUT

hndl
Specifies the LAPI handle.

op
Specifies the operation to be performed. The valid operations are:

- COMPARE_AND_SWAP
- FETCH_AND_ADD
- FETCH_AND_OR
- SWAP

tgt
Specifies the task ID of the target task where the read-modify-write (Rmw) variable resides. The value of this parameter must be in the range 0 <= *tgt* < **NUM_TASKS**.

tgt_var
Specifies the target read-modify-write (Rmw) variable (in FORTRAN) or its address (in C). The value of this parameter cannot be NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

in_val
Specifies the value that is passed in to the operation (*op*). This value cannot be NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

INPUT/OUTPUT

prev_tgt_val
Specifies the location at the origin in which the previous *tgt_var* on the target task is stored before the operation (*op*) is executed. The value of this parameter can be NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

org_cntr
Specifies the origin counter address (in C) or the origin counter (in FORTRAN). If *prev_tgt_val* is set, the origin counter (*org_cntr*) is incremented when *prev_tgt_val* is returned to the origin side. If *prev_tgt_val* is not set, the origin counter (*org_cntr*) is updated after the operation (*op*) is completed at the target side.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

Restrictions

LAPI statistics are *not* reported for shared memory communication and data transfer, or for messages that a task sends to itself.

C Examples

1. To synchronize a data value between two tasks (with FETCH_AND_ADD):

```
{

       int local_var;
       int *addr_list;

       /* both tasks initialize local_var to a value       */

       /* local_var addresses are exchanged and stored     */
       /* in addr_list (using LAPI_Address_init).          */
       /* addr_list[tgt] now contains the address of       */
       /* local_var on tgt                                 */
       .
       .
       .
       /* add value to local_var on some task               */

       /* use LAPI to add value to local_var on remote task */
       LAPI_Rmw(hndl, FETCH_AND_ADD, tgt, addr_list[tgt],
                value, prev_tgt_val, &org_cntr);

       /* local_var on the remote task has been increased   */
       /* by value.  prev_tgt_val now contains the value    */
       /* of local_var on remote task before the addition   */

}
```

2. To synchronize a data value between two tasks (with SWAP):

```
{

      int local_var;
      int *addr_list;

      /* local_var addresses are exchanged and stored  */
      /* in addr_list (using LAPI_Address_init).       */
      /* addr_list[tgt] now contains the address of    */
      /* local_var on tgt.                             */
      .
      .
      .
      /* local_var is assigned some value              */

      /* assign local_var to local_var on remote task  */
      LAPI_Rmw(hndl, SWAP, tgt, addr_list[tgt],
               local_var, prev_tgt_val, &org_cntr);

      /* local_var on the remote task is now equal to  */
      /* local_var on the local task. prev_tgt_val now */
      /* contains the value of local_var on the remote */
      /* task before the swap.                         */

}
```

3. To conditionally swap a data value (with COMPARE_AND_SWAP):

```
{

      int local_var;
      int *addr_list;
      int in_val[2];

      /* local_var addresses are exchanged and stored        */
      /* in addr_list (using LAPI_Address_init).             */
      /* addr_list[tgt] now contains the address of          */
      /* local_var on tgt.                                   */
      .
      .
      .
      /* if local_var on remote_task is equal to comparator, */
      /* assign value to local_var on remote task            */

      in_val[0] = comparator;
      in_val[1] = value;
```

```
      LAPI_Rmw(hndl, COMPARE_AND_SWAP, tgt, addr_list[tgt],
               in_val, prev_tgt_val, &org_cntr);

      /* local_var on the remote task is now in_val[1] if it */
      /* had previously been equal to in_val[0]. If the swap */
      /* was performed, prev_tgt_val now contains TRUE;      */
      /* otherwise, it contains FALSE.                       */

}
```

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_IN_VAL_NULL
Indicates that the *in_val* pointer is NULL (in C) or that the value of *in_val* is LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_RMW_OP
Indicates that *op* is not valid.

LAPI_ERR_TGT
Indicates that the *tgt* passed in is outside the range of tasks defined in the job.

LAPI_ERR_TGT_PURGED
Indicates that the subroutine returned early because LAPI_Purge_totask() was called.

LAPI_ERR_TGT_VAR_NULL
Indicates that the tgt_var address is NULL (in C) or that the value of tgt_var is LAPI_ADDR_NULL (in FORTRAN).

INTEGER (KIND=LAPI_LONG_LONG_TYPE) :: in_val, prev_tgt_val
TYPE (LAPI_CNTR_T) :: org_cntr
INTEGER ierror
```

Description

`Type of call:` point-to-point communication (non-blocking)

This subroutine is the 64-bit version of `LAPI_Rmw`. It is used to synchronize two independent pieces of 64-bit data, such as two tasks sharing a common data structure. The operation is performed at the target task (*tgt*) and is atomic. The operation takes an input value (*in_val*) from the origin and performs one of four operations (*op*) on a variable (*tgt_var*) at the target (*tgt*), and then replaces the target variable (*tgt_var*) with the results of the operation (*op*). The original value (*prev_tgt_val*) of the target variable (*tgt_var*) is returned to the origin.

The operations (*op*) are performed over the context referred to by *hndl*. The outcome of the execution of these calls is as if the following code was executed atomically:

```
*prev_tgt_val = *tgt_var;
*tgt_var      = f(*tgt_var, *in_val);
```

where:

f(a,b) = a + b for **FETCH_AND_ADD**

f(a,b) = a | b for **FETCH_AND_OR** (bitwise or)

f(a,b) = b for `SWAP`

For `COMPARE_AND_SWAP`, *in_val* is treated as a pointer to an array of two integers, and the *op* is the following atomic operation:

```
if(*tgt_var == in_val[0])  {
   *prev_tgt_val = TRUE;
   *tgt_var      = in_val[1];
} else {
   *prev_tgt_val = FALSE;
}
```

This subroutine can also be used on a 32-bit processor.

All `LAPI_Rmw64` calls are non-blocking. To test for completion, use the `LAPI_Getcntr` and `LAPI_Waitcntr` subroutines. `LAPI_Rmw64` does not include a target counter (*tgt_cntr*), so `LAPI_Rmw64` calls do not provide any indication of completion on the target task (*tgt*).

Parameters

INPUT

hndl
Specifies the LAPI handle.

op
Specifies the operation to be performed. The valid operations are:

- `COMPARE_AND_SWAP`

- FETCH_AND_ADD
- FETCH_AND_OR
- SWAP

tgt
Specifies the task ID of the target task where the read-modify-write (Rmw64) variable resides. The value of this parameter must be in the range 0 <= *tgt* < **NUM_TASKS**.

tgt_var
Specifies the target read-modify-write (Rmw64) variable (in FORTRAN) or its address (in C). The value of this parameter cannot be NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

in_val
Specifies the value that is passed in to the operation (*op*). This value cannot be NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

INPUT/OUTPUT

prev_tgt_val
Specifies the location at the origin in which the previous *tgt_var* on the target task is stored before the operation (*op*) is executed. The value of this parameter can be NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

org_cntr
Specifies the origin counter address (in C) or the origin counter (in FORTRAN). If *prev_tgt_val* is set, the origin counter (*org_cntr*) is incremented when *prev_tgt_val* is returned to the origin side. If *prev_tgt_val* is not set, the origin counter (*org_cntr*) is updated after the operation (*op*) is completed at the target side.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

Restrictions

LAPI statistics are *not* reported for shared memory communication and data transfer, or for messages that a task sends to itself.

C Examples

1. To synchronize a data value between two tasks (with FETCH_AND_ADD):

```
{

      long long local_var;
      long long *addr_list;

      /* both tasks initialize local_var to a value        */

      /* local_var addresses are exchanged and stored      */
      /* in addr_list (using LAPI_Address_init64)          */
      /* addr_list[tgt] now contains address of            */
      /* local_var on tgt                                  */
      .
      .
      .
      /* add value to local_var on some task               */

      /* use LAPI to add value to local_var on remote task */
      LAPI_Rmw64(hndl, FETCH_AND_ADD, tgt, addr_list[tgt],
                 value, prev_tgt_val, &org_cntr);

      /* local_var on remote task has been increased       */
      /* by value.  prev_tgt_val now contains value of     */
      /* local_var on remote task before the addition      */

}
```

2. To synchronize a data value between two tasks (with SWAP):

```
{

      long long local_var;
      long long *addr_list;

      /* local_var addresses are exchanged and stored          */
      /* in addr_list (using LAPI_Address_init64).             */
      /* addr_list[tgt] now contains the address of            */
      /* local_var on tgt.                                     */
      .
      .
      .
      /* local_var is assigned some value                      */

      /* assign local_var to local_var on the remote task      */
      LAPI_Rmw64(hndl, SWAP, tgt, addr_list[tgt],
                 local_var, prev_tgt_val, &org_cntr);

      /* local_var on the remote task is now equal to local_var */
      /* on the local task. prev_tgt_val now contains the value */
      /* of local_var on the remote task before the swap.      */

}
```

3. To conditionally swap a data value (with COMPARE_AND_SWAP):

```
{

      long long local_var;
      long long *addr_list;
      long long in_val[2];

      /* local_var addresses are exchanged and stored        */
      /* in addr_list (using LAPI_Address_init64).           */
      /* addr_list[tgt] now contains the address of          */
      /* local_var on tgt.                                   */
      .
      .
      .
      /* if local_var on remote_task is equal to comparator, */
      /* assign value to local_var on the remote task        */

      in_val[0] = comparator;
      in_val[1] = value;

      LAPI_Rmw64(hndl, COMPARE_AND_SWAP, tgt, addr_list[tgt],
                 in_val, prev_tgt_val, &org_cntr);

      /* local_var on remote task is now in_val[1] if it     */
      /* had previously been equal to in_val[0]. If the      */
      /* swap was performed, prev_tgt_val now contains       */
      /* TRUE; otherwise, it contains FALSE.                 */

}
```

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_IN_VAL_NULL
Indicates that the *in_val* pointer is NULL (in C) or that the value of *in_val* is LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_RMW_OP
Indicates that *op* is not valid.

LAPI_ERR_TGT
Indicates that the *tgt* passed in is outside the range of tasks defined in the job.

LAPI_ERR_TGT_PURGED
Indicates that the subroutine returned early because LAPI_Purge_totask() was called.

LAPI_ERR_TGT_VAR_NULL
Indicates that the tgt_var address is NULL (in C) or that the value of tgt_var is LAPI_ADDR_NULL (in FORTRAN).

Location

/usr/lib/liblapi_r.a

LAPI_Senv Subroutine

Purpose

Used to set a runtime variable.

Library

Availability Library (liblapi_r.a)

C Syntax

```
#include <lapif.h>

int LAPI_Senv(hndl, query, set_val)
lapi_handle_t hndl;
lapi_query_t query;
int set_val;
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_SENV(hndl, query, set_val, ierror)
INTEGER hndl
INTEGER query
INTEGER set_val
INTEGER ierror
```

Description

Type of call: local queries

Use this subroutine to set runtime attributes for a specific LAPI instance. In C, the lapi_query_t enumeration defines the attributes that can be set at runtime. These attributes are defined explicitly in FORTRAN. See LAPI_Qenv for more information.

You can use LAPI_Senv to set these runtime attributes: ACK_THRESHOLD, ERROR_CHK, INTERRUPT_SET, and TIMEOUT.

Parameters

INPUT

hndl
Specifies the LAPI handle.

query
Specifies the type of query that you want to set. In C, the values for *query* are defined by the lapi_query_t enumeration in lapi.h. In FORTRAN, these values are defined explicitly in the 32-bit version and the 64-bit version of lapif.h.

set_val
Specifies the integer value of the query that you want to set.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

Restrictions

LAPI statistics are *not* reported for shared memory communication and data transfer, or for messages that a task sends to itself.

C Examples

The following values can be set using LAPI_Senv:

```
ACK_THRESHOLD:
int value;
LAPI_Senv(hndl, ACK_THRESHOLD, value);
/* LAPI sends packet acknowledgements (acks) in groups, waiting until  */
/* ACK_THRESHOLD packets have arrived before returning a group of acks */
/* The valid range for ACK_THRESHOLD is (1 <= value <= 30)             */
/* The default is 30.                                                  */

ERROR_CHK:
boolean toggle;
LAPI_Senv(hndl, ERROR_CHK, toggle);
/* Indicates whether LAPI should perform error checking.  If set, LAPI */
/* calls will perform bounds-checking on parameters.  Error checking   */
/* is disabled by default.                                             */

INTERRUPT_SET:
boolean toggle;
LAPI_Senv(hndl, INTERRUPT_SET, toggle);
/* Determines whether LAPI will respond to interrupts.  If interrupts  */
/* are disabled, LAPI will poll for message completion.                */
/* toggle==True will enable interrupts, False will disable.            */
/* Interrupts are enabled by default.                                  */

TIMEOUT:
int value;
LAPI_Senv(hndl, TIMEOUT, value);
/* LAPI will time out on a communication if no response is received    */
/* within timeout seconds.  Valid range is (10 <= timeout <= 86400).   */
/* 86400 seconds = 24 hours.  Default value is 900 (15 minutes).       */
```

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_QUERY_TYPE
Indicates the query passed in is not valid.

LAPI_ERR_SET_VAL
Indicates the set_val pointer is not in valid range.

Location

/usr/lib/liblapi_r.a

LAPI_Setcntr Subroutine

Purpose

Used to set a counter to a specified value.

Library

Availability Library (`liblapi_r.a`)

C Syntax

```
#include <lapi.h>

int LAPI_Setcntr(hndl, cntr, val)
lapi_handle_t hndl;
lapi_cntr_t  *cntr;
int           val;
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_SETCNTR(hndl, cntr, val, ierror)
INTEGER hndl
TYPE (LAPI_CNTR_T) :: cntr
INTEGER val
INTEGER ierror
```

Description

`Type of call:` Local counter manipulation

This subroutine sets *cntr* to the value specified by *val*. Because the `LAPI_Getcntr`/`LAPI_Setcntr` sequence cannot be made atomic, you should only use `LAPI_Setcntr` when you know there will not be any competing operations.

Parameters

INPUT

hndl
Specifies the LAPI handle.

val
Specifies the value to which the counter needs to be set.

INPUT/OUTPUT

cntr
Specifies the address of the counter to be set (in C) or the counter structure (in FORTRAN). The value of this parameter cannot be NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

Restrictions

LAPI statistics are *not* reported for shared memory communication and data transfer, or for messages that a task sends to itself.

C Examples

To initialize a counter for use in a communication API call:

```
{
    lapi_cntr_t   my_tgt_cntr, *tgt_cntr_array;
    int           initial_value, expected_value, current_value;
    lapi_handle_t hndl;
    .
    .
    .
    /*
     * Note: the code below is executed on all tasks
     */

    /* initialize, allocate and create structures */
    initial_value  = 0;
    expected_value = 1;

    /* set the cntr to zero */
    LAPI_Setcntr(hndl, &my_tgt_cntr, initial_value);
    /* set other counters   */
    .
    .
    .
    /* exchange counter addresses, LAPI_Address_init synchronizes */
    LAPI_Address_init(hndl, &my_tgt_cntr, tgt_cntr_array);
    /* more address exchanges */
    .
    .
    .
    /* Communication calls using my_tgt_cntr */
    LAPI_Put(....., tgt_cntr_array[tgt], ....);
    .
    .
    .
    /* Wait for counter to reach value */
    for (;;) {
        LAPI_Getcntr(hndl, &my_tgt_cntr, &current_value);
        if (current_value >= expected_value) {
            break; /* out of infinite loop */
        } else {
            LAPI_Probe(hndl);
        }
    }
    .
    .
    .
    /* Quiesce/synchronize to ensure communication using our counter is done */
    LAPI_Gfence(hndl);
    /* Reset the counter */
    LAPI_Setcntr(hndl, &my_tgt_cntr, initial_value);
    /*
     * Synchronize again so that no other communication using the counter can
     * begin from any other task until we're all finished resetting the counter.
     */
    LAPI_Gfence(hndl);

    /* More communication calls */
    .
    .
    .
}
```

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_CNTR_NULL
Indicates that the *cntr* value passed in is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

Location

/usr/lib/liblapi_r.a

LAPI_Setcntr_wstatus Subroutine

Purpose

Used to set a counter to a specified value and to set the associated destination list array and destination status array to the counter.

Library

Availability Library (`liblapi_r.a`)

C Syntax

```
#include <lapi.h>

int LAPI_Setcntr_wstatus(hndl, cntr, num_dest, dest_list, dest_status)

lapi_handle_t  hndl;
lapi_cntr_t   *cntr;
int            num_dest;
uint          *dest_list;
int           *dest_status;
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_SETCNTR_WSTATUS(hndl, cntr, num_dest, dest_list, dest_status, ierror)
INTEGER hndl
TYPE (LAPI_CNTR_T) :: cntr
INTEGER num_dest
INTEGER dest_list(*)
INTEGER dest_status
INTEGER ierror
```

Description

`Type of call:` recovery

This subroutine sets *cntr* to `0`. Use `LAPI_Setcntr_wstatus` to set the associated destination list array (*dest_list*) and destination status array (*dest_status*) to the counter. Use a corresponding `LAPI_Nopoll_wait` call to access these arrays. These arrays record the status of a task from where the thread calling `LAPI_Nopoll_wait()` is waiting for a response.

The return values for *dest_status* are:

LAPI_MSG_INITIAL
The task is purged or is not received.

LAPI_MSG_RECVD
The task is received.

LAPI_MSG_PURGED
The task is purged, but not received.

LAPI_MSG_PURGED_RCVD
The task is received and then purged.

LAPI_MSG_INVALID
Not valid; the task is already purged.

Note: To use this subroutine, the *lib_vers* field in the `lapi_info_t` structure must be set to `L2_LIB` or `LAST_LIB`.

Parameters

INPUT

hndl
Specifies the LAPI handle.

num_dest
Specifies the number of tasks in the destination list.

dest_list
Specifies an array of destinations waiting for this counter update. If the value of this parameter is NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN), no status is returned to the user.

INPUT/OUTPUT

cntr
Specifies the address of the counter to be set (in C) or the counter structure (in FORTRAN). The value of this parameter cannot be NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

OUTPUT

dest_status
Specifies an array of status that corresponds to *dest_list*. The value of this parameter can be NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

ierror
Specifies a FORTRAN return code. This is always the last parameter.

Restrictions

Use of this subroutine is *not* recommmended on a system that is running Parallel Environment (PE).

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_CNTR_NULL
Indicates that the *cntr* value passed in is NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_RET_PTR_NULL
Indicates that the value of *dest_status* is NULL in C (or `LAPI_ADDR_NULL` in FORTRAN), but the value of *dest_list* is not NULL in C (or `LAPI_ADDR_NULL` in FORTRAN).

Location

/usr/lib/liblapi_r.a

LAPI_Term Subroutine

Purpose

Terminates and cleans up a LAPI context.

Library

Availability Library (`liblapi_r.a`)

C Syntax

```
#include <lapi.h>

int LAPI_Term(hndl)
lapi_handle_t hndl;
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_TERM(hndl, ierror)
INTEGER hndl
INTEGER ierror
```

Description

`Type of call:` local termination

Use this subroutine to terminate the LAPI context that is specified by *hndl*. Any LAPI notification threads that are associated with this context are terminated. An error occurs when any LAPI calls are made using *hndl* after `LAPI_Term` is called.

A DGSP that is registered under that LAPI handle remains valid even after `LAPI_Term` is called on *hndl*.

Parameters

INPUT

hndl
Specifies the LAPI handle.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

Restrictions

LAPI statistics are *not* reported for shared memory communication and data transfer, or for messages that a task sends to itself.

C Examples

To terminate a LAPI context (represented by *hndl*):

```
LAPI_Term(hndl);
```

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

Location

/usr/lib/liblapi_r.a

LAPI_Util Subroutine

Purpose

Serves as a wrapper function for such data gather/scatter operations as registration and reservation, for updating UDP port information, and for obtaining pointers to locking and signaling functions that are associated with a shared LAPI lock.

Library

Availability Library (`liblapi_r.a`)

C Syntax

```
#include <lapi.h>

int LAPI_Util(hndl, util_cmd)
lapi_handle_t hndl;
lapi_util_t *util_cmd;
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_UTIL(hndl, util_cmd, ierror)
INTEGER hndl
TYPE (LAPI_UTIL_T) :: util_cmd
INTEGER ierror
```

Description

`Type of call:` Data gather/scatter program (DGSP), UDP port information, and lock sharing utilities

This subroutine is used for several different operations, which are indicated by the command type value in the beginning of the command structure. The `lapi_util_t` structure is defined as:

```
typedef union {
    lapi_util_type_t    Util_type;
    lapi_reg_dgsp_t     RegDgsp;
    lapi_dref_dgsp_t    DrefDgsp;
    lapi_resv_dgsp_t    ResvDgsp;
    lapi_reg_ddm_t      DdmFunc;
    lapi_add_udp_port_t Udp;
    lapi_pack_dgsp_t    PackDgsp;
    lapi_unpack_dgsp_t  UnpackDgsp;
    lapi_thread_func_t  ThreadFunc;
} lapi_util_t;
```

The enumerated type `lapi_util_type_t` has these values:

Table 2. lapi_util_type_t types

Value of *Util_type*	**Union member as interpreted by LAPI_Util**
LAPI_REGISTER_DGSP	lapi_reg_dgsp_t
LAPI_UNRESERVE_DGSP	lapi_dref_dgsp_t
LAPI_RESERVE_DGSP	lapi_resv_dgsp_t
LAPI_REG_DDM_FUNC	lapi_reg_ddm_t
LAPI_ADD_UDP_DEST_PORT	lapi_add_udp_port_t
LAPI_DGSP_PACK	lapi_pack_dgsp_t

Table 2. lapi_util_type_t types (continued)	
Value of *Util_type*	**Union member as interpreted by LAPI_Util**
LAPI_DGSP_UNPACK	lapi_unpack_dgsp_t
LAPI_GET_THREAD_FUNC	lapi_thread_func_t

hndl is not checked for command type LAPI_REGISTER_DGSP, LAPI_RESERVE_DGSP, or LAPI_UNRESERVE_DGSP.

LAPI_REGISTER_DGSP

You can use this operation to register a LAPI DGSP that you have created. To register a LAPI DGSP, lapi_dgsp_descr_t *idgsp* must be passed in. LAPI returns a handle (lapi_dg_handle_t *dgsp_handle*) to use for all future LAPI calls. The *dgsp_handle* that is returned by a register operation is identified as a lapi_dg_handle_t type, which is the appropriate type for LAPI_Xfer and LAPI_Util calls that take a DGSP. This returned *dgsp_handle* is also defined to be castable to a pointer to a lapi_dgsp_descr_t for those situations where the LAPI user requires read-only access to information that is contained in the cached DGSP. The register operation delivers a DGSP to LAPI for use in future message send, receive, pack, and unpack operations. LAPI creates its own copy of the DGSP and protects it by reference count. All internal LAPI operations that depend on a DGSP cached in LAPI ensure the preservation of the DGSP by incrementing the reference count when they begin a dependency on the DGSP and decrementing the count when that dependency ends. A DGSP, once registered, can be used from any LAPI instance. LAPI_Term does not discard any DGSPs.

You can register a DGSP, start one or more LAPI operations using the DGSP, and then unreserve it with no concern about when the LAPI operations that depend on the DGSP will be done using it. See LAPI_RESERVE_DGSP and LAPI_UNRESERVE_DGSP for more information.

In general, the DGSP you create and pass in to the LAPI_REGISTER_DGSP call using the *dgsp* parameter is discarded after LAPI makes and caches its own copy. Because DGSP creation is complex, user errors may occur, but extensive error checking at data transfer time would hurt performance. When developing code that creates DGSPs, you can invoke extra validation at the point of registration by setting the LAPI_VERIFY_DGSP environment variable. LAPI_Util will return any detected errors. Any errors that exist and are not detected at registration time will cause problems during data transfer. Any errors detected during data transfer will be reported by an asynchronous error handler. A segmentation fault is one common symptom of a faulty DGSP. If multiple DGSPs are in use, the asynchronous error handler will not be able to identify which DGSP caused the error. For more information about asynchronous error handling, see LAPI_Init.

LAPI_REGISTER_DGSP uses the lapi_reg_dgsp_t command structure.

Table 3. The lapi_reg_dgsp_t fields		
lapi_reg_dgsp_t field	**lapi_reg_dgsp_t field type**	**lapi_reg_dgsp_t usage**
Util_type	lapi_util_type_t	LAPI_REGISTER_DGSP
idgsp	lapi_dgsp_descr_t	IN - pointer to DGSP program
dgsp_handle	lapi_dg_handle_t	OUT - handle for a registered DGSP program
in_usr_func	lapi_usr_fcall_t	For debugging only
status	lapi_status_t	OUT - future support

LAPI_RESERVE_DGSP

You can use this operation to reserve a DGSP. This operation is provided because a LAPI client might cache a LAPI DGSP handle for later use. The client needs to ensure the DGSP will not be discarded before the cached handle is used. A DGSP handle, which is defined to be a pointer to a DGSP description that is already cached inside LAPI, is passed to this operation. The DGSP handle is also defined to be a

structure pointer, so that client programs can get direct access to information in the DGSP. Unless the client can be certain that the DGSP will not be "unreserved" by another thread while it is being accessed, the client should bracket the access window with its own reserve/unreserve operation. The client is not to modify the cached DGSP, but LAPI has no way to enforce this. The reserve operation increments the user reference count, thus protecting the DGSP until an unreserve operation occurs. This is needed because the thread that placed the reservation will expect to be able to use or examine the cached DGSP until it makes an unreserve call (which decrements the user reference count), even if the unreserve operation that matches the original register operation occurs within this window on some other thread.

LAPI_RESERVE_DGSP uses the `lapi_resv_dgsp_t` command structure.

Table 4. The lapi_resv_dgsp_t fields

lapi_resv_dgsp_t field	lapi_resv_dgsp_t field type	lapi_resv_dgsp_t usage
Util_type	`lapi_util_type_t`	LAPI_RESERVE_DGSP
dgsp_handle	`lapi_dg_handle_t`	OUT - handle for a registered DGSP program
in_usr_func	`lapi_usr_fcall_t`	For debugging only
status	`lapi_status_t`	OUT - future support

LAPI_UNRESERVE_DGSP

You can use this operation to unregister or unreserve a DGSP. This operation decrements the user reference count. If external and internal reference counts are zero, this operation lets LAPI free the DGSP. All operations that decrement a reference count cause LAPI to check to see if the counts have both become `0` and if they have, dispose of the DGSP. Several internal LAPI activities increment and decrement a second reference count. The cached DGSP is disposable only when all activities (internal and external) that depend on it and use reference counting to preserve it have discharged their reference. The DGSP handle is passed to LAPI as a value parameter and LAPI does not nullify the caller's handle. It is your responsibility to not use this handle again because in doing an unreserve operation, you have indicated that you no longer count on the handle remaining valid.

LAPI_UNRESERVE_DGSP uses the `lapi_dref_dgsp_t` command structure.

Table 5. The lapi_dref_dgsp_t fields

lapi_dref_dgsp_t field	lapi_dref_dgsp_t field type	lapi_dref_dgsp_t usage
Util_type	`lapi_util_type_t`	LAPI_UNRESERVE_DGSP
dgsp_handle	`lapi_dg_handle_t`	OUT - handle for a registered DGSP program
in_usr_func	`lapi_usr_fcall_t`	For debugging only
status	`lapi_status_t`	OUT - future support

LAPI_REG_DDM_FUNC

You can use this operation to register data distribution manager (DDM) functions. It works in conjunction with the DGSM CONTROL instruction. Primarily, it is used for `MPI_Accumulate`, but LAPI clients can provide any DDM function. It is also used to establish a callback function for processing data that is being scattered into a user buffer on the destination side.

The native LAPI user can install a callback without affecting the one MPI has registered for `MPI_Accumulate`. The function prototype for the callback function is:

```
typedef long ddm_func_t (        /* return number of bytes processed */
        void      *in,           /* pointer to inbound data          */
        void      *inout,        /* pointer to destination space     */
        long      bytes,         /* number of bytes inbound          */
        int       operand,       /* CONTROL operand value            */
```

```
        int       operation      /* CONTROL operation value          */
);
```

A DDM function acts between the arrival of message data and the target buffer. The most common usage is to combine inbound data with data already in the target buffer. For example, if the target buffer is an array of integers and the incoming message consists of integers, the DDM function can be written to add each incoming integer to the value that is already in the buffer. The *operand* and *operation* fields of the DDM function allow one DDM function to support a range of operations with the CONTROL instruction by providing the appropriate values for these fields.

See *RSCT for AIX 5L: LAPI Programming Guide* for more information about DGSP programming.

LAPI_REG_DDM_FUNC uses the `lapi_reg_ddm_t` command structure. Each call replaces the previous function pointer, if there was one.

Table 6. The lapi_reg_ddm_t fields

lapi_reg_ddm_t field	lapi_reg_ddm_t field type	lapi_reg_ddm_t usage
Util_type	`lapi_util_type_t`	LAPI_REG_DDM_FUNC
ddm_func	`ddm_func_t *`	IN - DDM function pointer
in_usr_func	`lapi_usr_fcall_t`	For debugging only
status	`lapi_status_t`	OUT - future support

LAPI_DGSP_PACK

You can use this operation to gather data to a pack buffer from a user buffer under control of a DGSP. A single buffer may be packed by a series of calls. The caller provides a *position* value that is initialized to the starting offset within the buffer. Each pack operation adjusts *position*, so the next pack operation can begin where the previous pack operation ended. In general, a series of pack operations begins with *position* initialized to `0`, but any offset is valid. There is no state carried from one pack operation to the next. Each pack operation starts at the beginning of the DGSP it is passed.

LAPI_DGSP_PACK uses the `lapi_pack_dgsp_t` command structure.

Table 7. The lapi_pack_dgsp_t fields

lapi_pack_dgsp_t field	lapi_pack_dgsp_t field type	lapi_pack_dgsp_t usage
Util_type	`lapi_util_type_t`	LAPI_DGSP_PACK
dgsp_handle	`lapi_dg_handle_t`	OUT - handle for a registered DGSP program
in_buf	`void *`	IN - source buffer to pack
bytes	`ulong`	IN - number of bytes to pack
out_buf	`void *`	OUT - output buffer for pack
out_size	`ulong`	IN - output buffer size in bytes
position	`ulong`	IN/OUT - current buffer offset
in_usr_func	`lapi_usr_fcall_t`	For debugging only
status	`lapi_status_t`	OUT - future support

LAPI_DGSP_UNPACK

You can use this operation to scatter data from a packed buffer to a user buffer under control of a DGSP. A single buffer may be unpacked by a series of calls. The caller provides a *position* value that is initialized to the starting offset within the packed buffer. Each unpack operation adjusts *position*, so the

next unpack operation can begin where the previous unpack operation ended. In general, a series of unpack operations begins with *position* initialized to 0, but any offset is valid. There is no state carried from one unpack operation to the next. Each unpack operation starts at the beginning of the DGSP it is passed.

LAPI_DGSP_UNPACK uses the lapi_unpack_dgsp_t command structure.

Table 8. The lapi_unpack_dgsp_t fields

lapi_unpack_dgsp_t field	lapi_unpack_dgsp_t field type	lapi_unpack_dgsp_t usage
Util_type	lapi_util_type_t	LAPI_DGSP_UNPACK
dgsp_handle	lapi_dg_handle_t	OUT - handle for a registered DGSP program
buf	void *	IN - source buffer for unpack
in_size	ulong	IN - source buffer size in bytes
out_buf	void *	OUT - output buffer for unpack
bytes	ulong	IN - number of bytes to unpack
out_size	ulong	IN - output buffer size in bytes
position	ulong	IN/OUT - current buffer offset
in_usr_func	lapi_usr_fcall_t	For debugging only
status	lapi_status_t	OUT - future support

LAPI_ADD_UDP_DEST_PORT

You can use this operation to update UDP port information about the destination task. This operation can be used when you have written your own UDP handler (*udp_hndlr*) and you need to support recovery of failed tasks. You cannot use this operation under the POE runtime environment.

LAPI_ADD_UDP_DEST_PORT uses the lapi_add_udp_port_t command structure.

Table 9. The lapi_add_udp_port_t fields

lapi_add_udp_port_t field	lapi_add_udp_port_t field type	lapi_add_udp_port_t usage
Util_type	lapi_util_type_t	LAPI_ADD_UDP_DEST_PORT
tgt	uint	IN - destination task ID
udp_port	lapi_udp_t *	IN - UDP port information for the target
instance_no	uint	IN - Instance number of UDP
in_usr_func	lapi_usr_fcall_t	For debugging only
status	lapi_status_t	OUT - future support

LAPI_GET_THREAD_FUNC

You can use this operation to retrieve various shared locking and signaling functions. Retrieval of these functions is valid only after LAPI is initialized and before LAPI is terminated. You should not call any of these functions after LAPI is terminated.

LAPI_GET_THREAD_FUNC uses the lapi_thread_func_t command structure.

Table 10. The lapi_thread_func_t fields		
lapi_thread_func_t field	**lapi_thread_func_t field type**	**lapi_thread_func_t usage**
Util_type	`lapi_util_type_t`	`LAPI_GET_THREAD_FUNC`
mutex_lock	`lapi_mutex_lock_t`	OUT - mutex lock function pointer
mutex_unlock	`lapi_mutex_unlock_t`	OUT - mutex unlock function pointer
mutex_trylock	`lapi_mutex_trylock_t`	OUT - mutex try lock function pointer
mutex_getowner	`lapi_mutex_getowner_t`	OUT - mutex get owner function pointer
cond_wait	`lapi_cond_wait_t`	OUT - condition wait function pointer
cond_timedwait	`lapi_cond_timedwait_t`	OUT - condition timed wait function pointer
cond_signal	`lapi_cond_signal_t`	OUT - condition signal function pointer
cond_init	`lapi_cond_init_t`	OUT - initialize condition function pointer
cond_destroy	`lapi_cond_destroy_t`	OUT - destroy condition function pointer

LAPI uses the pthread library for thread ID management. You can therefore use `pthread_self()` to get the running thread ID and `lapi_mutex_getowner_t` to get the thread ID that owns the shared lock. Then, you can use `pthread_equal()` to see if the two are the same.

Mutex thread functions

`LAPI_GET_THREAD_FUNC` includes the following mutex thread functions: mutex lock, mutex unlock, mutex try lock, and mutex get owner.

`Mutex lock function pointer`

```
int (*lapi_mutex_lock_t)(lapi_handle_t hndl);
```

This function acquires the lock that is associated with the specified LAPI handle. The call blocks if the lock is already held by another thread. Deadlock can occur if the calling thread is already holding the lock. You are responsible for preventing and detecting deadlocks.

`Parameters`

INPUT

hndl
Specifies the LAPI handle.

`Return values`

0
Indicates that the lock was acquired successfully.

EINVAL
Is returned if the lock is not valid because of an incorrect *hndl* value.

`Mutex unlock function pointer`

```
int (*lapi_mutex_unlock_t)(lapi_handle_t hndl);
```

This function releases the lock that is associated with the specified LAPI handle. A thread should only unlock its own locks.

`Parameters`

INPUT

hndl
Specifies the LAPI handle.

Return values

0
Indicates that the lock was released successfully.

EINVAL
Is returned if the lock is not valid because of an incorrect *hndl* value.

Mutex try lock function pointer

```
int (*lapi_mutex_trylock_t)(lapi_handle_t hndl);
```

This function tries to acquire the lock that is associated with the specified LAPI handle, but returns immediately if the lock is already held.

Parameters

INPUT

hndl
Specifies the LAPI handle.

Return values

0
Indicates that the lock was acquired successfully.

EBUSY
Indicates that the lock is being held.

EINVAL
Is returned if the lock is not valid because of an incorrect *hndl* value.

Mutex get owner function pointer

```
int (*lapi_mutex_getowner_t)(lapi_handle_t hndl, pthread_t *tid);
```

This function gets the pthread ID of the thread that is currently holding the lock associated with the specified LAPI handle. LAPI_NULL_THREAD_ID indicates that the lock is not held at the time the function is called.

Parameters

INPUT

hndl
Specifies the LAPI handle.

OUTPUT

tid
Is a pointer to hold the pthread ID to be retrieved.

Return values

0
Indicates that the lock owner was retrieved successfully.

EINVAL
Is returned if the lock is not valid because of an incorrect *hndl* value.

Condition functions

LAPI_GET_THREAD_FUNC includes the following condition functions: condition wait, condition timed wait, condition signal, initialize condition, and destroy condition.

Condition wait function pointer

```
int (*lapi_cond_wait_t)(lapi_handle_t hndl, lapi_cond_t *cond);
```

This function waits on a condition variable (*cond*). The user must hold the lock associated with the LAPI handle (*hndl*) before making the call. Upon the return of the call, LAPI guarantees that the lock is still

being held. The same LAPI handle must be supplied to concurrent `lapi_cond_wait_t` operations on the same condition variable.

`Parameters`

INPUT

hndl
Specifies the LAPI handle.

cond
Is a pointer to the condition variable to be waited on.

`Return values`

0
Indicates that the condition variable has been signaled.

EINVAL
Indicates that the value specified by *hndl* or *cond* is not valid.

`Condition timed wait function pointer`

```
int (*lapi_cond_timedwait_t)(lapi_handle_t hndl,
                             lapi_cond_t *cond,
                             struct timespec *timeout);
```

This function waits on a condition variable (*cond*). The user must hold the lock associated with the LAPI handle (*hndl*) before making the call. Upon the return of the call, LAPI guarantees that the lock is still being held. The same LAPI handle must be supplied to concurrent `lapi_cond_timedwait_t` operations on the same condition variable.

`Parameters`

INPUT

hndl
Specifies the LAPI handle.

cond
Is a pointer to the condition variable to be waited on.

timeout
Is a pointer to the absolute time structure specifying the timeout.

`Return values`

0
Indicates that the condition variable has been signaled.

ETIMEDOUT
Indicates that time specified by *timeout* has passed.

EINVAL
Indicates that the value specified by *hndl*, *cond*, or *timeout* is not valid.

`Condition signal function pointer`

```
int (*lapi_cond_wait_t)(lapi_handle_t hndl, lapi_cond_t *cond);
typedef int (*lapi_cond_signal_t)(lapi_handle_t hndl, lapi_cond_t *cond);
```

This function signals a condition variable (*cond*) to wake up a thread that is blocked on the condition. If there are multiple threads waiting on the condition variable, which thread to wake up is decided randomly.

`Parameters`

INPUT

hndl
Specifies the LAPI handle.

cond
Is a pointer to the condition variable to be signaled.

Return values

0
Indicates that the condition variable has been signaled.

EINVAL
Indicates that the value specified by *hndl* or *cond* is not valid.

Initialize condition function pointer

```
int (*lapi_cond_init_t)(lapi_handle_t hndl, lapi_cond_t *cond);
```

This function initializes a condition variable.

Parameters

INPUT

hndl
Specifies the LAPI handle.

cond
Is a pointer to the condition variable to be initialized.

Return values

0
Indicates that the condition variable was initialized successfully.

EAGAIN
Indicates that the system lacked the necessary resources (other than memory) to initialize another condition variable.

ENOMEM
Indicates that there is not enough memory to initialize the condition variable.

EINVAL
Is returned if the *hndl* value is not valid.

Destroy condition function pointer

```
int (*lapi_cond_destroy_t)(lapi_handle_t hndl, lapi_cond_t *cond);
```

This function destroys a condition variable.

Parameters

INPUT

hndl
Specifies the LAPI handle.

cond
Is a pointer to the condition variable to be destroyed.

Return values

0
Indicates that the condition variable was destroyed successfully.

EBUSY
Indicates that the implementation has detected an attempt to destroy the object referenced by *cond* while it is referenced (while being used in a `lapi_cond_wait_t` or `lapi_cond_timedwait_t` by another thread, for example).

EINVAL
Indicates that the value specified by *hndl* or *cond* is not valid.

Parameters

INPUT

hndl
Specifies the LAPI handle.

INPUT/OUTPUT

util_cmd
Specifies the command type of the utility function.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_DGSP
Indicates that the DGSP that was passed in is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN) or is not a registered DGSP.

LAPI_ERR_DGSP_ATOM
Indicates that the DGSP has an *atom_size* that is less than 0 or greater than MAX_ATOM_SIZE.

LAPI_ERR_DGSP_BRANCH
Indicates that the DGSP attempted a branch that fell outside of the code array. This is returned only in validation mode.

LAPI_ERR_DGSP_COPY_SZ
Is returned with DGSP validation turned on when MCOPY block < 0 or COPY instruction with bytes < 0. This is returned only in validation mode.

LAPI_ERR_DGSP_FREE
Indicates that LAPI tried to free a DGSP that is not valid or is no longer registered. There should be one LAPI_UNRESERVE_DGSP operation to close the LAPI_REGISTER_DGSP operation and one LAPI_UNRESERVE_DGSP operation for each LAPI_RESERVE_DGSP operation.

LAPI_ERR_DGSP_OPC
Indicates that the DGSP *opcode* is not valid. This is returned only in validation mode.

LAPI_ERR_DGSP_STACK
Indicates that the DGSP has a greater GOSUB depth than the allocated stack supports. Stack allocation is specified by the dgsp->depth member. This is returned only in validation mode.

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_MEMORY_EXHAUSTED
Indicates that LAPI is unable to obtain memory from the system.

LAPI_ERR_UDP_PORT_INFO
Indicates that the *udp_port* information pointer is NULL (in C) or that the value of *udp_port* is LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_UTIL_CMD
Indicates that the command type is not valid.

C Examples

1. To create and register a DGSP:

```
{
      /*
      ** DGSP code array.  DGSP instructions are stored
      ** as ints (with constants defined in lapi.h for
      ** the number of integers needed to store each
      ** instruction).  We will have one COPY and one ITERATE
      ** instruction in our DGSP.  We use LAPI's constants
      ** to allocate the appropriate storage.
```

```
*/
int code[LAPI_DGSM_COPY_SIZE+LAPI_DGSM_ITERATE_SIZE];

/* DGSP description */
lapi_dgsp_descr_t dgsp_d;

/*
** Data structure for the xfer call.
*/
lapi_xfer_t   xfer_struct;

/* DGSP data structures */
lapi_dgsm_copy_t     *copy_p;   /* copy instruction    */
lapi_dgsm_iterate_t  *iter_p;   /* iterate instruction */
int                  *code_ptr; /* code pointer        */

/* constant for holding code array info */
int                   code_less_iterate_size;

/* used for DGSP registration */
lapi_reg_dgsp_t     reg_util;

/*
** Set up dgsp description
*/

/* set pointer to code array */
dgsp_d.code = &code[0];

/* set size of code array */
dgsp_d.code_size = LAPI_DGSM_COPY_SIZE + LAPI_DGSM_ITERATE_SIZE;

/* not using DGSP gosub instruction */
dgsp_d.depth = 1;

/*
** set density to show internal gaps in the
** DGSP data layout
*/
dgsp_d.density = LAPI_DGSM_SPARSE;

/* transfer 4 bytes at a time */
dgsp_d.size = 4;

/* advance the template by 8 for each iteration */
dgsp_d.extent = 8;

/*
** ext specifies the memory 'footprint' of
** data to be transferred. The lext specifies
** the offset from the base address to begin
** viewing the data.  The rext specifies the
** length from the base address to use.
*/
dgsp_d.lext = 0;
dgsp_d.rext = 4;
/* atom size of 0 lets LAPI choose the packet size */
dgsp_d.atom_size = 0;

/*
** set up the copy instruction
*/
copy_p = (lapi_dgsm_copy_t *)(dgsp_d.code);
copy_p->opcode = LAPI_DGSM_COPY;

/* copy 4 bytes at a time */
copy_p->bytes = (long) 4;

/* start at offset 0 */
copy_p->offset = (long) 0;

/* set code pointer to address of iterate instruction */
code_less_iterate_size =  dgsp_d.code_size - LAPI_DGSM_ITERATE_SIZE;
code_ptr = ((int *)(code))+code_less_iterate_size;

/*
** Set up iterate instruction
*/
iter_p = (lapi_dgsm_iterate_t *) code_ptr;
iter_p->opcode = LAPI_DGSM_ITERATE;
```

```
        iter_p->iter_loc = (-code_less_iterate_size);

        /* Set up and do DGSP registration */
        reg_util.Util_type = LAPI_REGISTER_DGSP;
        reg_util.idgsp = &dgsp_d;
        LAPI_Util(hndl, (lapi_util_t *)&reg_util);

        /*
        ** LAPI returns a usable DGSP handle in
        ** reg_util.dgsp_handle
        ** Use this handle for subsequent reserve/unreserve
        ** and Xfer calls.  On the receive side, this
        ** handle can be returned by the header handler using the
        ** return_info_t mechanism.  The DGSP will then be used for
        ** scattering data.
        */

}
```

2. To reserve a DGSP handle:

```
{

        reg_util.dgsp_handle = dgsp_handle;

        /*
        ** dgsp_handle has already been created and
        ** registered as in the above example
        */

        reg_util.Util_type = LAPI_RESERVE_DGSP;
        LAPI_Util(hndl, (lapi_util_t *)&reg_util);

        /*
        ** LAPI's internal reference count to dgsp_handle
        ** will be incremented.  DGSP will
        ** remain available until an unreserve is
        ** done for each reserve, plus one more for
        ** the original registration.
        */

}
```

3. To unreserve a DGSP handle:

```
{

        reg_util.dgsp_handle = dgsp_handle;

        /*
        ** dgsp_handle has already created and
        ** registered as in the above example, and
        ** this thread no longer needs it.
        */

        reg_util.Util_type = LAPI_UNRESERVE_DGSP;
        LAPI_Util(hndl, (lapi_util_t *)&reg_util);

        /*
        ** An unreserve is required for each reserve,
        ** plus one more for the original registration.
        */

}
```

Location

/usr/lib/liblapi_r.a

Related Information

Subroutines: LAPI_Init, LAPI_Xfer

LAPI_Waitcntr Subroutine

Purpose

Waits until a specified counter reaches the value specified.

Library

Availability Library (`liblapi_r.a`)

C Syntax

```
#include <lapi.h>

int LAPI_Waitcntr(hndl, cntr, val, cur_cntr_val)
lapi_handle_t  hndl;
lapi_cntr_t   *cntr;
int            val;
int           *cur_cntr_val;
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_WAITCNTR(hndl, cntr, val, cur_cntr_val, ierror)
INTEGER hndl
TYPE (LAPI_CNTR_T) :: cntr
INTEGER val
INTEGER cur_cntr_val
INTEGER ierror
```

Description

`Type of call:` local progress monitor (blocking)

This subroutine waits until *cntr* reaches or exceeds the specified *val*. Once *cntr* reaches *val*, *cntr* is decremented by the value of *val*. In this case, "decremented" is used (as opposed to "set to zero") because *cntr* could have contained a value that was greater than the specified *val* when the call was made. This call may or may not check for message arrivals over the LAPI context *hndl*. The *cur_cntr_val* variable is set to the current counter value.

Parameters

INPUT

hndl
Specifies the LAPI handle.

val
Specifies the value the counter needs to reach.

INPUT/OUTPUT

cntr
Specifies the counter structure (in FORTRAN) to be waited on or its address (in C). The value of this parameter cannot be NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

OUTPUT

cur_cntr_val
Specifies the integer value of the current counter. This value can be NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

ierror
Specifies a FORTRAN return code. This is always the last parameter.

Restrictions

LAPI statistics are *not* reported for shared memory communication and data transfer, or for messages that a task sends to itself.

C Examples

To wait on a counter to reach a specified value:

```
{

      int          val;
      int          cur_cntr_val;
      lapi_cntr_t  some_cntr;
      .
      .
      .
      LAPI_Waitcntr(hndl, &some_cntr, val, &cur_cntr_val);
      /* Upon return, some_cntr has reached val */

}
```

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_CNTR_NULL
Indicates that the *cntr* pointer is NULL (in C) or that the value of *cntr* is LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

Location

/usr/lib/liblapi_r.a

LAPI_Xfer Subroutine

Purpose

Serves as a wrapper function for LAPI data transfer functions.

Library

Availability Library (liblapi_r.a)

C Syntax

```
#include <lapi.h>

int LAPI_Xfer(hndl, xfer_cmd)
lapi_handle_t hndl;
lapi_xfer_t *xfer_cmd;

    uint            src;          /* Target task ID    */
    uint            reason;       /* LAPI return codes */
    ulong           reserve[6];   /* Reserved          */
} lapi_sh_info_t;

typedef void (scompl_hndlr_t)(lapi_handle_t *hndl, void *completion_param,
```

```
                                lapi_sh_info_t *info);
```

FORTRAN Syntax

```
include 'lapif.h'

LAPI_XFER(hndl, xfer_cmd, ierror)
INTEGER hndl
TYPE (fortran_xfer_type) :: xfer_cmd
INTEGER ierror
```

Description

`Type of call:` point-to-point communication (non-blocking)

The `LAPI_Xfer` subroutine provides a superset of the functionality of these subroutines: `LAPI_Amsend`, `LAPI_Amsendv`, `LAPI_Put`, `LAPI_Putv`, `LAPI_Get`, `LAPI_Getv`, and `LAPI_Rmw`. In addition, `LAPI_Xfer` provides data gather/scatter program (DGSP) messages transfer.

In C, the `LAPI_Xfer` command is passed a pointer to a union. It examines the first member of the union, `Xfer_type`, to determine the transfer type, and to determine which union member was passed. `LAPI_Xfer` expects every field of the identified union member to be set. It does not examine or modify any memory outside of the identified union member. `LAPI_Xfer` treats all union members (except `status`) as read-only data.

This subroutine provides the following functions:

- The remote address fields are expanded to be of type `lapi_long_t`, which is long enough for a 64-bit address. This allows a 32-bit task to send data to 64-bit addresses, which may be important in client/server programs.
- `LAPI_Xfer` allows the origin counter to be replaced with a send completion callback.
- `LAPI_Xfer` is used to transfer data using LAPI's data gather/scatter program (DGSP) interface.

The `lapi_xfer_t` structure is defined as:

```
typedef union {
        lapi_xfer_type_t   Xfer_type;
        lapi_get_t         Get;
        lapi_am_t          Am;
        lapi_rmw_t         Rmw;
        lapi_put_t         Put;
        lapi_getv_t        Getv;
        lapi_putv_t        Putv;
        lapi_amv_t         Amv;
        lapi_amdgsp_t      Dgsp;
} lapi_xfer_t;
```

Though the `lapi_xfer_t` structure applies only to the C version of `LAPI_Xfer`, the following tables include the FORTRAN equivalents of the C datatypes.

Table 11 on page 803 list the values of the `lapi_xfer_type_t` structure for C and the explicit *Xfer_type* values for FORTRAN.

Table 11. LAPI_Xfer structure types

Value of *Xfer_type* (C or FORTRAN)	**Union member as interpreted by LAPI_Xfer (C)**	**Value of *fortran_xfer_type* (FORTRAN)**
LAPI_AM_XFER	lapi_am_t	LAPI_AM_T
LAPI_AMV_XFER	lapi_amv_t	LAPI_AMV_T
LAPI_DGSP_XFER	lapi_amdgsp_t	LAPI_AMDGSP_T
LAPI_GET_XFER	lapi_get_t	LAPI_GET_T

Table 11. LAPI_Xfer structure types (continued)		
Value of *Xfer_type* (C or FORTRAN)	**Union member as interpreted by LAPI_Xfer (C)**	**Value of *fortran_xfer_type* (FORTRAN)**
LAPI_GETV_XFER	lapi_getv_t	LAPI_GETV_T
LAPI_PUT_XFER	lapi_put_t	LAPI_PUT_T
LAPI_PUTV_XFER	lapi_putv_t	LAPI_PUTV_T
LAPI_RMW_XFER	lapi_rmw_t	LAPI_RMW_T

lapi_am_t details

Table 12 on page 804 shows the correspondence among the parameters of the LAPI_Amsend subroutine, the fields of the C lapi_am_t structure and their datatypes, and the equivalent FORTRAN datatypes. The lapi_am_t fields are listed in Table 12 on page 804 in the order that they occur in the lapi_xfer_t structure.

Table 12. LAPI_Amsend and lapi_am_t equivalents			
lapi_am_t field name (C)	**lapi_am_t field type (C)**	**Equivalent FORTRAN datatype**	**Equivalent LAPI_Amsend parameter**
Xfer_type	lapi_xfer_type_t	INTEGER(KIND = 4)	implicit in C LAPI_Xfer value in FORTRAN: LAPI_AM_XFER
flags	int	INTEGER(KIND = 4)	none LAPI_Xfer parameter in FORTRAN: *flags*
tgt	uint	INTEGER(KIND = 4)	*tgt*
none	none	INTEGER(KIND = 4)	LAPI_Xfer parameter in FORTRAN: *pad*
hdr_hdl	lapi_long_t	INTEGER(KIND = 8)	*hdr_hdl*
uhdr_len	uint	INTEGER(KIND = 4)	*uhdr_len*
none	none	INTEGER(KIND = 4)	LAPI_Xfer parameter in FORTRAN (64-bit): *pad2*
uhdr	void *	INTEGER(KIND = 4) (32-bit) INTEGER(KIND = 8) (64-bit)	*uhdr*
udata	void *	INTEGER(KIND = 4) (32-bit) INTEGER(KIND = 8) (64-bit)	*udata*
udata_len	ulong	INTEGER(KIND = 4) (32-bit) INTEGER(KIND = 8) (64-bit)	*udata_len*
shdlr	scompl_hndlr_t *	INTEGER(KIND = 4) (32-bit) INTEGER(KIND = 8) (64-bit)	none LAPI_Xfer parameter in FORTRAN: *shdlr*

Table 12. LAPI_Amsend and lapi_am_t equivalents (continued)			
lapi_am_t field name (C)	**lapi_am_t field type (C)**	**Equivalent FORTRAN datatype**	**Equivalent LAPI_Amsend parameter**
sinfo	`void *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	none `LAPI_Xfer` parameter in FORTRAN: *sinfo*
tgt_cntr	`lapi_long_t`	`INTEGER(KIND = 8)`	*tgt_cntr*
org_cntr	`lapi_cntr_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*org_cntr*
cmpl_cntr	`lapi_cntr_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*cmpl_cntr*

When the origin data buffer is free to be used, the pointer to the send completion handler (*shdlr*) is called with the send completion data (*sinfo*) if *shdlr* is not a NULL pointer (in C) or `LAPI_ADDR_NULL` (in FORTRAN). Otherwise, the behavior is identical to that of `LAPI_Amsend`.

lapi_amv_t details

Table 13 on page 805 shows the correspondence among the parameters of the `LAPI_Amsendv` subroutine, the fields of the C `lapi_amv_t` structure and their datatypes, and the equivalent FORTRAN datatypes. The `lapi_amv_t` fields are listed in Table 13 on page 805 in the order that they occur in the `lapi_xfer_t` structure.

Table 13. LAPI_Amsendv and lapi_amv_t equivalents			
lapi_amv_t field name (C)	**lapi_amv_t field type (C)**	**Equivalent FORTRAN datatype**	**Equivalent LAPI_Amsendv parameter**
Xfer_type	`lapi_xfer_type_t`	`INTEGER(KIND = 4)`	implicit in C `LAPI_Xfer` value in FORTRAN: `LAPI_AMV_XFER`
flags	`int`	`INTEGER(KIND = 4)`	none `LAPI_Xfer` parameter in FORTRAN: *flags*
tgt	`uint`	`INTEGER(KIND = 4)`	*tgt*
none	none	`INTEGER(KIND = 4)`	`LAPI_Xfer` parameter in FORTRAN: *pad*

cmpl_cntr	`lapi_cntr_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*cmpl_cntr*

lapi_amdgsp_t details

Table 14 on page 806 shows the correspondence among the fields of the C `lapi_amdgsp_t` structure and their datatypes, how they are used in `LAPI_Xfer`, and the equivalent FORTRAN datatypes. The `lapi_amdgsp_t` fields are listed in Table 14 on page 806 in the order that they occur in the `lapi_xfer_t` structure.

Table 14. The lapi_amdgsp_t fields			
lapi_amdgsp_t field name (C)	**lapi_amdgsp_t field type (C)**	**Equivalent FORTRAN datatype**	**LAPI_Xfer usage**
Xfer_type	`lapi_xfer_type_t`	`INTEGER(KIND = 4)`	`LAPI_DGSP_XFER`
flags	`int`	`INTEGER(KIND = 4)`	This field allows users to specify directives or hints to LAPI. If you do not want to use any directives or hints, you must set this field to `0`. See The lapi_amdgsp_t flags field for more information.
tgt	`uint`	`INTEGER(KIND = 4)`	target task
none	none	`INTEGER(KIND = 4)`	*pad* (padding alignment for FORTRAN only)
hdr_hdl	`lapi_long_t`	`INTEGER(KIND = 8)`	header handler to invoke at target
uhdr_len	`uint`	`INTEGER(KIND = 4)`	user header length (multiple of processor's doubleword size)
none	none	`INTEGER(KIND = 4)`	*pad2* (padding alignment for 64-bit FORTRAN only)

Table 14. The lapi_amdgsp_t fields (continued)			
lapi_amdgsp_t field name (C)	**lapi_amdgsp_t field type (C)**	**Equivalent FORTRAN datatype**	**LAPI_Xfer usage**
uhdr	`void *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	pointer to user header
udata	`void *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	pointer to user data
udata_len	`ulong`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	user data length
shdlr	`scompl_hndlr_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	send completion handler (optional)
sinfo	`void *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	data pointer to pass to send completion handler (optional)
tgt_cntr	`lapi_long_t`	`INTEGER(KIND = 8)`	target counter (optional)
org_cntr	`lapi_cntr_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	origin counter (optional)
cmpl_cntr	`lapi_cntr_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	completion counter (optional)
dgsp	`lapi_dg_handle_t`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	Handle of a registered DGSP
status	`lapi_status_t`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	Status to return (future use)
none	none	`INTEGER(KIND = 4)`	*pad3* (padding alignment for 64-bit FORTRAN only)

When the origin data buffer is free to be modified, the send completion handler (*shdlr*) is called with the send completion data (*sinfo*), if *shdlr* is not a NULL pointer (in C) or `LAPI_ADDR_NULL` (in FORTRAN).

See Using lapi_am_dgsp_t for scatter-side DGSP processing for more information.

The lapi_amdgsp_t flags field

One or more flags can be set using the | (bitwise or) operator. User directives are always followed and could result in incorrect results if used improperly. Appropriate hints might improve performance, but they may be ignored by LAPI. Inappropriate hints might degrade performance, but they will not cause incorrect results.

The following directive flags are defined:

USE_TGT_VEC_TYPE
Instructs LAPI to use the vector type of the target vector (*tgt_vec*). In other words, *tgt_vec* is to be interpreted as type `lapi_vec_t`; otherwise, it is interpreted as type `lapi_lvec_t`. The `lapi_lvec_t` type uses `lapi_long_t`. The `lapi_vec_t` type uses `void *` or `long`. Incorrect results will occur if one type is used in place of the other.

BUFFER_BOTH_CONTIGUOUS
Instructs LAPI to treat all data to be transferred as contiguous, which can improve performance. If this flag is set when non-contiguous data is sent, data will likely be corrupted.

The following hint flags are defined:

LAPI_NOT_USE_BULK_XFER
Instructs LAPI not to use bulk transfer, independent of the current setting for the task.

LAPI_USE_BULK_XFER
Instructs LAPI to use bulk transfer, independent of the current setting for the task.

If neither of these hint flags is set, LAPI will use the behavior defined for the task. If both of these hint flags are set, LAPI_NOT_USE_BULK_XFER will take precedence.

These hints may or may not be honored by the communication library.

Using lapi_am_dgsp_t for scatter-side DGSP processing

LAPI allows additional information to be returned from the header handler through the use of the `lapi_return_info_t` datatype. See *RSCT for AIX 5L: LAPI Programming Guide* for more information about `lapi_return_info_t`. In the case of transfer type `lapi_am_dgsp_t`, this mechanism can be used to instruct LAPI to run a user DGSP to scatter data on the receive side.

To use this mechanism, pass a `lapi_return_info_t *` pointer back to LAPI through the *msg_len* member of the user header handler. The *dgsp_handle* member of the passed structure must point to a DGSP description that has been registered on the receive side. See `LAPI_Util` and *RSCT for AIX 5L: LAPI Programming Guide* for details on building and registering DGSPs.

lapi_get_t details

Table 15 on page 808 shows the correspondence among the parameters of the `LAPI_Get` subroutine, the fields of the C `lapi_get_t` structure and their datatypes, and the equivalent FORTRAN datatypes. The `lapi_get_t` fields are listed in Table 15 on page 808 in the order that they occur in the `lapi_xfer_t` structure.

Table 15. LAPI_Get and lapi_get_t equivalents

lapi_get_t field name (C)	lapi_get_t field type (C)	Equivalent FORTRAN datatype	Equivalent LAPI_Get parameter
Xfer_type	`lapi_xfer_type_t`	`INTEGER(KIND = 4)`	implicit in C `LAPI_Xfer` value in FORTRAN: `LAPI_GET_XFER`
flags	`int`	`INTEGER(KIND = 4)`	none `LAPI_Xfer` parameter in FORTRAN: *flags*
tgt	`uint`	`INTEGER(KIND = 4)`	*tgt*
none	none	`INTEGER(KIND = 4)`	`LAPI_Xfer` parameter in FORTRAN: *pad*
tgt_addr	`lapi_long_t`	`INTEGER(KIND = 8)`	*tgt_addr*
org_addr	`void *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*org_addr*
len	`ulong`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*len*
tgt_cntr	`lapi_long_t`	`INTEGER(KIND = 8)`	*tgt_cntr*

Table 15. LAPI_Get and lapi_get_t equivalents (continued)			
lapi_get_t field name (C)	**lapi_get_t field type (C)**	**Equivalent FORTRAN datatype**	**Equivalent LAPI_Get parameter**
org_cntr	`lapi_cntr_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*org_cntr*
chndlr	`compl_hndlr_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	none `LAPI_Xfer` parameter in FORTRAN: *chndlr*
cinfo	`void *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	none `LAPI_Xfer` parameter in FORTRAN: *cinfo*

When the origin data buffer has completely arrived, the pointer to the completion handler (*chndlr*) is called with the completion data (*cinfo*), if *chndlr* is not a NULL pointer (in C) or `LAPI_ADDR_NULL` (in FORTRAN). Otherwise, the behavior is identical to that of `LAPI_Get`.

lapi_getv_t details

Table 16 on page 809 shows the correspondence among the parameters of the `LAPI_Getv` subroutine, the fields of the C `lapi_getv_t` structure and their datatypes, and the equivalent FORTRAN datatypes. The `lapi_getv_t` fields are listed in Table 15 on page 808 in the order that they occur in the `lapi_xfer_t` structure.

Table 16. LAPI_Getv and lapi_getv_t equivalents			
lapi_getv_t field name (C)	**lapi_getv_t field type (C)**	**Equivalent FORTRAN datatype**	**Equivalent LAPI_Getv parameter**
Xfer_type	`lapi_xfer_type_t`	`INTEGER(KIND = 4)`	implicit in C `LAPI_Xfer` value in FORTRAN: `LAPI_GETV_XFER`
flags	`int`	`INTEGER(KIND = 4)`	none `LAPI_Xfer` parameter in FORTRAN: *flags*

none	none	`INTEGER(KIND = 4)`	`LAPI_Xfer` parameter in FORTRAN (64-bit): *pad*
org_vec	`lapi_vec_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*org_vec*
tgt_vec	`void *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*tgt_vec*
none	none	`INTEGER(KIND = 4)`	`LAPI_Xfer` parameter in FORTRAN (32-bit): *pad*
tgt_cntr	`lapi_long_t`	`INTEGER(KIND = 8)`	*tgt_cntr*
org_cntr	`lapi_cntr_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*org_cntr*

Table 16. LAPI_Getv and lapi_getv_t equivalents (continued)			
lapi_getv_t field name (C)	**lapi_getv_t field type (C)**	**Equivalent FORTRAN datatype**	**Equivalent LAPI_Getv parameter**
chndlr	`compl_hndlr_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	none `LAPI_Xfer` parameter in FORTRAN: *chndlr*
cinfo	`void *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	none `LAPI_Xfer` parameter in FORTRAN: *cinfo*
none	none	`INTEGER(KIND = 4)`	`LAPI_Xfer` parameter in FORTRAN (32-bit): *pad2*

The `flags` field accepts `USE_TGT_VEC_TYPE` (see lapi_amdgsp_t flags field) to indicate that `tgt_vec` is to be interpreted as type `lapi_vec_t`; otherwise, it is interpreted as type `lapi_lvec_t`. Note the corresponding field is `lapi_vec_t` in the `LAPI_Getv` call.

When the origin data buffer has completely arrived, the pointer to the completion handler (`chndlr`) is called with the completion data (`cinfo`) if `chndlr` is not a NULL pointer (in C) or `LAPI_ADDR_NULL` (in FORTRAN). Otherwise, the behavior is identical to that of `LAPI_Getv`.

lapi_put_t details

Table 17 on page 810 shows the correspondence among the parameters of the `LAPI_Put` subroutine, the fields of the C `lapi_put_t` structure and their datatypes, and the equivalent FORTRAN datatypes. The `lapi_put_t` fields are listed in Table 17 on page 810 in the order that they occur in the `lapi_xfer_t` structure.

Table 17. LAPI_Put and lapi_put_t equivalents			
lapi_put_t field name (C)	**lapi_put_t field type (C)**	**Equivalent FORTRAN datatype**	**Equivalent LAPI_Put parameter**
Xfer_type	`lapi_xfer_type_t`	`INTEGER(KIND = 4)`	implicit in C `LAPI_Xfer` value in FORTRAN: `LAPI_PUT_XFER`
flags	`int`	`INTEGER(KIND = 4)`	none `LAPI_Xfer` parameter in FORTRAN: *flags*
tgt	`uint`	`INTEGER(KIND = 4)`	*tgt*
none	none	`INTEGER(KIND = 4)`	`LAPI_Xfer` parameter in FORTRAN: *pad*
tgt_addr	`lapi_long_t`	`INTEGER(KIND = 8)`	*tgt_addr*
org_addr	`void *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*org_addr*
len	`ulong`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*len*

Table 17. LAPI_Put and lapi_put_t equivalents (continued)			
lapi_put_t field name (C)	**lapi_put_t field type (C)**	**Equivalent FORTRAN datatype**	**Equivalent LAPI_Put parameter**
shdlr	`scompl_hndlr_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	none `LAPI_Xfer` parameter in FORTRAN: *shdlr*
sinfo	`void *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	none `LAPI_Xfer` parameter in FORTRAN: *sinfo*
tgt_cntr	`lapi_long_t`	`INTEGER(KIND = 8)`	*tgt_cntr*
org_cntr	`lapi_cntr_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*org_cntr*
cmpl_cntr	`lapi_cntr_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*cmpl_cntr*

When the origin data buffer is free to be used, the pointer to the send completion handler (*shdlr*) is called with the send completion data (*sinfo*), if *shdlr* is not a NULL pointer (in C) or `LAPI_ADDR_NULL` (in FORTRAN). Otherwise, the behavior is identical to that of `LAPI_Put`.

lapi_putv_t details

Table 18 on page 811 shows the correspondence among the parameters of the `LAPI_Putv` subroutine, the fields of the C `lapi_putv_t` structure and their datatypes, and the equivalent FORTRAN datatypes. The `lapi_putv_t` fields are listed in Table 17 on page 810 in the order that they occur in the `lapi_xfer_t` structure.

Table 18. LAPI_Putv and lapi_putv_t equivalents			
lapi_putv_t field name (C)	**lapi_putv_t field type (C)**	**Equivalent FORTRAN datatype**	**Equivalent LAPI_Putv parameter**
Xfer_type	`lapi_xfer_type_t`	`INTEGER(KIND = 4)`	implicit in C `LAPI_Xfer` value in FORTRAN: `LAPI_PUT_XFER`
flags	`int`	`INTEGER(KIND = 4)`	none `LAPI_Xfer` parameter in FORTRAN: *flags*
tgt	`uint`	`INTEGER(KIND = 4)`	*tgt*
none	none	`INTEGER(KIND = 4)`	`LAPI_Xfer` parameter in FORTRAN (64-bit): *pad*
shdlr	`scompl_hndlr_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	none `LAPI_Xfer` parameter in FORTRAN: *shdlr*
sinfo	`void *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	none `LAPI_Xfer` parameter in FORTRAN: *sinfo*

Table 18. LAPI_Putv and lapi_putv_t equivalents (continued)			
lapi_putv_t field name (C)	**lapi_putv_t field type (C)**	**Equivalent FORTRAN datatype**	**Equivalent LAPI_Putv parameter**
org_vec	`lapi_vec_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*org_vec*
tgt_vec	`void *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*tgt_vec*
none	none	`INTEGER(KIND = 4)`	`LAPI_Xfer` parameter in FORTRAN (32-bit): *pad*
tgt_cntr	`lapi_long_t`	`INTEGER(KIND = 8)`	*tgt_cntr*
org_cntr	`lapi_cntr_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*org_cntr*
cmpl_cntr	`lapi_cntr_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*cmpl_cntr*

The `flags` field accepts `USE_TGT_VEC_TYPE` (see lapi_amdgsp_t flags field) to indicate that `tgt_vec` is to be interpreted as `lapi_vec_t`; otherwise, it is interpreted as a `lapi_lvec_t`. Note that the corresponding field is `lapi_vec_t` in the `LAPI_Putv` call.

When the origin data buffer is free to be modified, the pointer to the send completion handler (`shdlr`) is called with the send completion data (`sinfo`), if `shdlr` is not a NULL pointer (in C) or `LAPI_ADDR_NULL` (in FORTRAN). Otherwise, the behavior is identical to that of `LAPI_Putv`.

lapi_rmw_t details

Table 19 on page 812 shows the correspondence among the parameters of the `LAPI_Rmw` subroutine, the fields of the C `lapi_rmw_t` structure and their datatypes, and the equivalent FORTRAN datatypes. The `lapi_rmw_t` fields are listed in Table 17 on page 810 in the order that they occur in the `lapi_xfer_t` structure.

Table 19. LAPI_Rmw and lapi_rmw_t equivalents			
lapi_rmw_t field name (C)	**lapi_rmw_t field type (C)**	**Equivalent FORTRAN datatype**	**Equivalent LAPI_Rmw parameter**
Xfer_type	`lapi_xfer_type_t`	`INTEGER(KIND = 4)`	implicit in C `LAPI_Xfer` value in FORTRAN: `LAPI_RMW_XFER`
op	`Rmw_ops_t`	`INTEGER(KIND = 4)`	*op*
tgt	`uint`	`INTEGER(KIND = 4)`	*tgt*
size	`uint`	`INTEGER(KIND = 4)`	implicit in C `LAPI_Xfer` parameter in FORTRAN: *size* (must be 32 or 64)
tgt_var	lapi_long_t	`INTEGER(KIND = 8)`	*tgt_var*
in_val	`void *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*in_val*

Table 19. LAPI_Rmw and lapi_rmw_t equivalents (continued)			
lapi_rmw_t field name (C)	**lapi_rmw_t field type (C)**	**Equivalent FORTRAN datatype**	**Equivalent LAPI_Rmw parameter**
prev_tgt_val	`void *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*prev_tgt_val*
org_cntr	`lapi_cntr t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	*org_cntr*
shdlr	`scompl_hndlr_t *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	none `LAPI_Xfer` parameter in FORTRAN: *shdlr*
sinfo	`void *`	`INTEGER(KIND = 4)` (32-bit) `INTEGER(KIND = 8)` (64-bit)	none `LAPI_Xfer` parameter in FORTRAN: *shdlr*
none	none	`INTEGER(KIND = 4)`	`LAPI_Xfer` parameter in FORTRAN (32-bit): *pad*

When the origin data buffer is free to be used, the pointer to the send completion handler (*shdlr*) is called with the send completion data (*sinfo*), if *shdlr* is not a NULL pointer (in C) or `LAPI_ADDR_NULL` (in FORTRAN). The *size* value must be either 32 or 64, indicating whether you want the *in_val* and *prev_tgt_val* fields to point to a 32-bit or 64-bit quantity, respectively. Otherwise, the behavior is identical to that of `LAPI_Rmw`.

Parameters

INPUT

hndl
Specifies the LAPI handle.

xfer_cmd
Specifies the name and parameters of the data transfer function.

OUTPUT

ierror
Specifies a FORTRAN return code. This is always the last parameter.

Return Values

LAPI_SUCCESS
Indicates that the function call completed successfully.

LAPI_ERR_DATA_LEN
Indicates that the value of *udata_len* or *len* is greater than the value of LAPI constant `LAPI_MAX_MSG_SZ`.

LAPI_ERR_DGSP
Indicates that the DGSP that was passed in is NULL (in C) or `LAPI_ADDR_NULL` (in FORTRAN) or is not a registered DGSP.

LAPI_ERR_DGSP_ATOM
Indicates that the DGSP has an *atom_size* that is less than `0` or greater than MAX_ATOM_SIZE.

LAPI_ERR_DGSP_BRANCH
Indicates that the DGSP attempted a branch that fell outside the code array.

LAPI_ERR_DGSP_CTL
Indicates that a DGSP control instruction was encountered in a non-valid context (such as a gather-side control or scatter-side control with an atom size of 0 at gather, for example).

LAPI_ERR_DGSP_OPC
Indicates that the DGSP op-code is not valid.

LAPI_ERR_DGSP_STACK
Indicates that the DGSP has greater GOSUB depth than the allocated stack supports. Stack allocation is specified by the dgsp->depth member.

LAPI_ERR_HDR_HNDLR_NULL
Indicates that the *hdr_hdl* passed in is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_HNDL_INVALID
Indicates that the *hndl* passed in is not valid (not initialized or in terminated state).

LAPI_ERR_IN_VAL_NULL
Indicates that the *in_val* pointer is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_MEMORY_EXHAUSTED
LAPI is unable to obtain memory from the system.

LAPI_ERR_OP_SZ
Indicates that the lapi_rmw_t *size* field is not set to 32 or 64.

LAPI_ERR_ORG_ADDR_NULL
Indicates either that the *udata* parameter passed in is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN) and *udata_len* is greater than 0, or that the *org_addr* passed in is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN) and *len* is greater than 0.

Note: if *Xfer_type* = LAPI_DGSP_XFER, the case in which *udata* is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN) and *udata_len* is greater than 0 is valid, so an error is not returned.

LAPI_ERR_ORG_EXTENT
Indicates that the *org_vec*'s extent (stride * *num_vecs*) is greater than the value of LAPI constant LAPI_MAX_MSG_SZ.

LAPI_ERR_ORG_STRIDE
Indicates that the *org_vec* stride is less than block.

LAPI_ERR_ORG_VEC_ADDR
Indicates that the *org_vec->info[i]* is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), but its length (*org_vec->len[i]*) is not 0.

LAPI_ERR_ORG_VEC_LEN
Indicates that the sum of *org_vec*->len is greater than the value of LAPI constant LAPI_MAX_MSG_SZ.

LAPI_ERR_ORG_VEC_NULL
Indicates that the *org_vec* value is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_ORG_VEC_TYPE
Indicates that the *org_vec->vec_type* is not valid.

LAPI_ERR_RMW_OP
Indicates the op is not valid.

LAPI_ERR_STRIDE_ORG_VEC_ADDR_NULL
Indicates that the strided vector address *org_vec->info*[0] is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_STRIDE_TGT_VEC_ADDR_NULL
Indicates that the strided vector address *tgt_vec->info*[0] is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_TGT
Indicates that the *tgt* passed in is outside the range of tasks defined in the job.

LAPI_ERR_TGT_ADDR_NULL
Indicates that *ret_addr* is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_TGT_EXTENT
Indicates that *tgt_vec*'s extent (stride * *num_vecs*) is greater than the value of LAPI constant LAPI_MAX_MSG_SZ.

LAPI_ERR_TGT_PURGED
Indicates that the subroutine returned early because LAPI_Purge_totask() was called.

LAPI_ERR_TGT_STRIDE
Indicates that the *tgt_vec* stride is less than block.

LAPI_ERR_TGT_VAR_NULL
Indicates that the *tgt_var* address is NULL (in C) or that the value of *tgt_var* is LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_TGT_VEC_ADDR
Indicates that the *tgt_vec*->*info*[i] is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), but its length (*tgt_vec*->*len*[i]) is not 0.

LAPI_ERR_TGT_VEC_LEN
Indicates that the sum of *tgt_vec*->*len* is greater than the value of LAPI constant LAPI_MAX_MSG_SZ.

LAPI_ERR_TGT_VEC_NULL
Indicates that *tgt_vec* is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN).

LAPI_ERR_TGT_VEC_TYPE
Indicates that the *tgt_vec*->*vec_type* is not valid.

LAPI_ERR_UHDR_LEN
Indicates that the *uhdr_len* value passed in is greater than MAX_UHDR_SZ or is not a multiple of the processor's doubleword size.

LAPI_ERR_UHDR_NULL
Indicates that the *uhdr* passed in is NULL (in C) or LAPI_ADDR_NULL (in FORTRAN), but *uhdr_len* is not 0.

LAPI_ERR_VEC_LEN_DIFF
Indicates that *org_vec* and *tgt_vec* have different lengths (*len[ ]*).

LAPI_ERR_VEC_NUM_DIFF
Indicates that *org_vec* and *tgt_vec* have different *num_vecs*.

LAPI_ERR_VEC_TYPE_DIFF
Indicates that *org_vec* and *tgt_vec* have different vector types (*vec_type*).

LAPI_ERR_XFER_CMD
Indicates that the *Xfer_cmd* is not valid.

C Examples

1. To run the sample code shown in LAPI_Get using the LAPI_Xfer interface:

```
{

      lapi_xfer_t xfer_struct;

      /* initialize the table buffer for the data addresses */

      /* get remote data buffer addresses */
      LAPI_Address_init(hndl,(void *)data_buffer,data_buffer_list);
      .
      .
      .
      /* retrieve data_len bytes from address data_buffer_list[tgt] on */
      /* task tgt. write the data starting at address data_buffer.     */
      /* tgt_cntr and org_cntr can be NULL.                            */

      xfer_struct.Get.Xfer_type = LAPI_GET_XFER;
      xfer_struct.Get.flags = 0;
      xfer_struct.Get.tgt = tgt;
      xfer_struct.Get.tgt_addr = data_buffer_list[tgt];
      xfer_struct.Get.org_addr = data_buffer;
      xfer_struct.Get.len = data_len;
```

```
      xfer_struct.Get.tgt_cntr = tgt_cntr;
      xfer_struct.Get.org_cntr = org_cntr;

      LAPI_Xfer(hndl, &xfer_struct);

}
```

2. To implement the LAPI_STRIDED_VECTOR example from LAPI_Amsendv using the LAPI_Xfer interface:

```
{
    lapi_xfer_t   xfer_struct;                        /* info for LAPI_Xfer call
*/
    lapi_vec_t    vec;                                /* data for data transfer
*/
    .
    .
    .
    vec->num_vecs = NUM_VECS;        /* NUM_VECS = number of vectors to transfer
*/
                                     /* must match that of the target vector
*/
    vec->vec_type = LAPI_GEN_STRIDED_XFER;              /* same as target vector
*/

    vec->info[0]  = buffer_address;    /* starting address for data copy
*/
    vec->info[1]  = block_size;        /* bytes of data to copy
*/
    vec->info[2]  = stride;            /* distance from copy block to copy block
*/
    /* data will be copied as follows:
*/
    /* block_size bytes will be copied from buffer_address
*/
    /* block_size bytes will be copied from buffer_address+stride
*/
    /* block_size bytes will be copied from buffer_address+(2*stride)
*/
    /* block_size bytes will be copied from buffer_address+(3*stride)
*/
    .
    .
    .
    /* block_size bytes will be copied from buffer_address+((NUM_VECS-1)*stride)
*/
    .
    .
    .
    xfer_struct.Amv.Xfer_type = LAPI_AMV_XFER;
    xfer_struct.Amv.flags     = 0;
    xfer_struct.Amv.tgt       = tgt;
    xfer_struct.Amv.hdr_hdl   = hdr_hdl_list[tgt];
    xfer_struct.Amv.uhdr_len  = uhdr_len;  /* user header length */
    xfer_struct.Amv.uhdr      = uhdr;

    /* LAPI_AMV_XFER allows the use of a send completion handler */
    /* If non-null, the shdlr function is invoked at the point   */
    /* the origin counter would increment.  Note that both the   */
    /* org_cntr and shdlr can be used.                           */
    /* The user's shdlr must be of type scompl_hndlr_t *.        */
    /* scompl_hndlr_t is defined in /usr/include/lapi.h          */
    xfer_struct.shdlr = shdlr;

    /* Use sinfo to pass user-defined data into the send         */
    /* completion handler, if desired.                           */
    xfer_struct.sinfo     = sinfo;       /* send completion data */

    xfer_struct.org_vec   = vec;
```

```
    xfer_struct.tgt_cntr  = tgt_cntr;
    xfer_struct.org_cntr  = org_cntr;
    xfer_struct.cmpl_cntr = cmpl_cntr;

    LAPI_Xfer(hndl, &xfer_struct);
    .
    .
    .
}
```

See the LAPI_Amsendv subroutine for more information about the header handler definition.

Location

/usr/lib/liblapi_r.a

layout_object_create Subroutine

Purpose

Initializes a layout context.

Library

Layout Library (**libi18n.a**)

Syntax

```
#include <sys/lc_layout.h>
```

```
int layout_object_create (locale_name, layout_object)
const char * locale_name;
LayoutObject * layout_object;
```

Description

The **layout_object_create** subroutine creates the **LayoutObject** structure associated with the locale specified by the *locale_name* parameter. The **LayoutObject** structure is a symbolic link containing all the data and methods necessary to perform the layout operations on context dependent and bidirectional characters of the locale specified.

When the **layout_object_create** subroutine completes without errors, the *layout_object* parameter points to a valid **LayoutObject** structure that can be used by other BIDI subroutines. The returned **LayoutObject** structure is initialized to an initial state that defines the behavior of the BIDI subroutines. This initial state is locale dependent and is described by the layout values returned by the **layout_object_getvalue** subroutine. You can change the layout values of the **LayoutObject** structure using the **layout_object_setvalue** subroutine. Any state maintained by the **LayoutObject** structure is independent of the current global locale set with the **setlocale** subroutine.

Note: If you are developing internationalized applications that may support multibyte locales, please see **Use of the libcur Package** in *General Programming Concepts: Writing and Debugging Programs*

Parameters

Item	Description
locale_name	Specifies a locale. It is recommended that you use the **LC_CTYPE** category by calling the **setlocale** (**LC_CTYPE**,NULL) subroutine.

Item	Description
layout_object	Points to a valid **LayoutObject** structure that can be used by other layout subroutines. This parameter is used only when the **layout_object_create** subroutine completes without errors. The *layout_object* parameter is not set and a non-zero value is returned if a valid **LayoutObject** structure cannot be created.

Return Values

Upon successful completion, the **layout_object_create** subroutine returns a value of 0. The *layout_object* parameter points to a valid handle.

Error Codes

If the **layout_object_create** subroutine fails, it returns the following error codes:

Item	Description
LAYOUT_EINVAL	The locale specified by the *locale_name* parameter is not available.
LAYOUT_EMFILE	The OPEN_MAX value of files descriptors are currently open in the calling process.
LAYOUT_ENOMEM	Insufficient storage space is available.

layout_object_editshape or wcslayout_object_editshape Subroutine

Purpose

Edits the shape of the context text.

Library

Layout library (**libi18n.a**)

Syntax

```
#include <sys/lc_layout.h>
```

```
int layout_editshape ( layout_object, EditType, index, InpBuf, Inpsize,
OutBuf, OutSize)
LayoutObject layout_object;
BooleanValue EditType;
size_t *index;
const char *InpBuf;
size_t *Inpsize;
void *OutBuf;
size_t *OutSize;
```

```
int wcslayout_object_editshape(layout_object, EditType, index, InpBuf, Inpsize, OutBuf, OutSize)
LayoutObject layout_object;
BooleanValue EditType;
size_t *index;
const wchar_t *InpBuf;
size_t *InpSize;
```

```
void *OutBuf;
size_t *OutSize;
```

Description

The **layout_object_editshape** and **wcslayout_object_editshape** subroutines provide the shapes of the context text. The shapes are defined by the code element specified by the *index* parameter and any surrounding code elements specified by the ShapeContextSize layout value of the **LayoutObject** structure. The *layout_object* parameter specifies this **LayoutObject** structure.

Use the **layout_object_editshape** subroutine when editing code elements of one byte. Use the **wcslayout_object_editshape** subroutine when editing single code elements of multibytes. These subroutines do not affect any state maintained by the **layout_object_transform** or **wcslayout_object_transform** subroutine.

Note: If you are developing internationalized applications that may support multibyte locales, please see Use of the libcur Package in *General Programming Concepts: Writing and Debugging Programs*

Parameters

Item	Description
layout_object	Specifies the **LayoutObject** structure created by the **layout_object_create** subroutine.
EditType	Specifies the type of edit shaping. When the *EditType* parameter stipulates the `EditInput` field, the subroutine reads the current code element defined by the *index* parameter and any preceding code elements defined by ShapeContextSize layout value of the **LayoutObject** structure. When the *EditType* parameter stipulates the `EditReplace` field, the subroutine reads the current code element defined by the *index* parameter and any surrounding code elements defined by ShapeContextSize layout value of the **LayoutObject** structure. **Note:** The editing direction defined by the Orientation and TEXT_VISUAL of the TypeOfText layout values of the **LayoutObject** structure determines which code elements are preceding and succeeding. When the ActiveShapeEditing layout value of the **LayoutObject** structure is set to True, the **LayoutObject** structure maintains the state of the `EditInput` field that may affect subsequent calls to these subroutines with the `EditInput` field defined by the *EditType* parameter. The state of the `EditInput` field of **LayoutObject** structure is not affected when the *EditType* parameter is set to the `EditReplace` field. To reset the state of the `EditInput` field to its initial state, call these subroutines with the *InpBuf* parameter set to NULL. The state of the `EditInput` field is not affected if errors occur within the subroutines.
index	Specifies an offset (in bytes) to the start of a code element in the *InpBuf* parameter on input. The *InpBuf* parameter provides the base text to be edited. In addition, the context of the surrounding code elements is considered where the minimum set of code elements needed for the specific context dependent script(s) is identified by the ShapeContextSize layout value. If the set of surrounding code elements defined by the *index*, *InpBuf*, and *InpSize* parameters is less than the size of front and back of the ShapeContextSize layout value, these subroutines assume there is no additional context available. The caller must provide the minimum context if it is available. The *index* parameter is in units associated with the type of the *InpBuf* parameter. On return, the *index* parameter is modified to indicate the offset to the first code element of the *InpBuf* parameter that required shaping. The number of code elements that required shaping is indicated on return by the *InpSize* parameter.

Item	Description
InpBuf	Specifies the source to be processed. A Null value with the `EditInput` field in the *EditType* parameter indicates a request to reset the state of the `EditInput` field to its initial state. Any portion of the *InpBuf* parameter indicates the necessity for redrawing or shaping.
InpSize	Specifies the number of code elements to be processed in units on input. These units are associated with the types for these subroutines. A value of -1 indicates that the input is delimited by a Null code element. On return, the value is modified to the actual number of code elements needed by the *InpBuf* parameter. A value of 0 when the value of the *EditType* parameter is the `EditInput` field indicates that the state of the `EditInput` field is reset to its initial state. If the *OutBuf* parameter is not NULL, the respective shaped code elements are written into the *OutBuf* parameter.
OutBuf	Contains the shaped output text. You can specify this parameter as a Null pointer to indicate that no transformed text is required. If Null, the subroutines return the *index* and *InpSize* parameters, which specify the amount of text required, to be redrawn. The encoding of the *OutBuf* parameter depends on the ShapeCharset layout value defined in *layout_object* parameter. If the ActiveShapeEditing layout value is set to False, the encoding of the *OutBuf* parameter is to be the same as the code set of the locale associated with the specified **LayoutObject** structure.
OutSize	Specifies the size of the output buffer on input in number of bytes. Only the code elements required to be shaped are written into the *OutBuf* parameter. The output buffer should be large enough to contain the shaped result; otherwise, only partial shaping is performed. If the ActiveShapeEditing layout value is set to True, the *OutBuf* parameter should be allocated to contain at least the number of code elements in the *InpBuf* parameter multiplied by the value of the ShapeCharsetSize layout value. On return, the *OutSize* parameter is modified to the actual number of bytes placed in the output buffer. When the *OutSize* parameter is specified as 0, the subroutines calculate the size of an output buffer large enough to contain the transformed text from the input buffer. The result will be returned in this field. The content of the buffers specifies by the *InpBuf* and *OutBuf* parameters, and the value of the *InpSize* parameter, remain unchanged.

Return Values

Upon successful completion, these subroutines return a value of 0. The *index* and *InpSize* parameters return the minimum set of code elements required to be redrawn.

Error Codes

If these subroutines fail, they return the following error codes:

Item	Description
LAYOUT_EILSEQ	Shaping stopped due to an input code element that cannot be shaped. The *index* parameter indicates the code element that caused the error. This code element is either a valid code element that cannot be shaped according to the ShapeCharset layout value or an invalid code element not defined by the code set defined in the **LayoutObject** structure. Use the **mbtowc** or **wctomb** subroutine in the same locale as the **LayoutObject** structure to determine if the code element is valid.
LAYOUT_E2BIG	The output buffer is too small and the source text was not processed. The *index* and *InpSize* parameters are not guaranteed on return.
LAYOUT_EINVAL	Shaping stopped due to an incomplete code element or shift sequence at the end of input buffer. The *InpSize* parameter indicates the number of code elements successfully transformed. **Note:** You can use this error code to determine the code element causing the error.
LAYOUT_ERANGE	Either the *index* parameter is outside the range as defined by the *InpSize* parameter, more than 15 embedding levels are in the source text, or the *InpBuf* parameter contains unbalanced Directional Format (Push/Pop).

layout_object_getvalue Subroutine

Purpose

Queries the current layout values of a **LayoutObject** structure.

Library

Layout Library (**libi18n.a**)

Syntax

```
#include <sys/lc_layout.h>

int layout_object_getvalue( layout_object,  values,  index)
LayoutObject layout_object;
LayoutValues values;
int *index;
```

Description

The **layout_object_getvalue** subroutine queries the current setting of layout values within the **LayoutObject** structure. The *layout_object* parameter specifies the **LayoutObject** structure created by the **layout_object_create** subroutine.

The name field of the LayoutValues structure contains the name of the layout value to be queried. The value field is a pointer to where the layout value is stored. The values are queried from the **LayoutObject** structure and represent its current state.

For example, if the layout value to be queried is of type T, the *value* parameter must be of type T*. If T itself is a pointer, the **layout_object_getvalue** subroutine allocates space to store the actual data. The caller must free this data by calling the **free(**T**)** subroutine with the returned pointer.

When setting the value field, an extra level of indirection is present that is not present using the **layout_object_setvalue** parameter. When you set a layout value of type T, the value field contains T. However, when querying the same layout value, the value field contains &T.

Note: If you are developing internationalized applications that may support multibyte locales, please see Use of the libcur Package in*General Programming Concepts: Writing and Debugging Programs*

Parameters

Item	Description
layout_object	Specifies the **LayoutObject** structure created by the **layout_object_create** subroutine.
values	Specifies an array of layout values of type LayoutValueRec that are to be queried in the **LayoutObject** structure. The end of the array is indicated by `name=0`.
index	Specifies a layout value to be queried. If the value cannot be queried, the *index* parameter causing the error is returned and the subroutine returns a non-zero value.

Return Values

Upon successful completion, the **layout_object_getvalue** subroutine returns a value of 0. All layout values were successfully queried.

Error Codes

If the **layout_object_getvalue** subroutine fails, it returns the following values:

Item	Description
LAYOUT_EINVAL	The layout value specified by the *index* parameter is unknown or the *layout_object* parameter is invalid.
LAYOUT_EMOMEM	Insufficient storage space is available.

Examples

The following example queries whether the locale is bidirectional and gets the values of the `in` and `out` orienations.

```
#include <sys/lc_layout.h>
#include <locale.h>
main()
{
LayoutObject plh;
int RC=0;
LayoutValues layout;
LayoutTextDescriptor Descr;
int index;

RC=layout_object_create(setlocale(LC_CTYPE,""),&plh); /* create object */
if (RC) {printf("Create error !!\n"); exit(0);}

layout=malloc(3*sizeof(LayoutValueRec));
                                        /* allocate layout array */
layout[0].name=ActiveBidirection;       /* set name */
layout[1].name=Orientation;             /* set name */
layout[1].value=(caddr_t)&Descr;
            /* send address of memory to be allocated by function */

layout[2].name=0;                     /* indicate end of array */
RC=layout_object_getvalue(plh,layout,&index);
if (RC) {printf("Getvalue error at %d !!\n",index); exit(0);}
printf("ActiveBidirection = %d \n",*(layout[0].value));
                                                  /*print output*/
printf("Orientation in = %x  out = %x \n", Descr->>in, Descr->>out);
```

```
free(layout);                          /* free layout array */
free (Descr);              /* free memory allocated by function */
RC=layout_object_free(plh);          /* free layout object */
if (RC) printf("Free error !!\n");
}
```

layout_object_setvalue Subroutine

Purpose

Sets the layout values of a **LayoutObject** structure.

Library

Layout Library (**libi18n.a**)

Syntax

```
#include <sys/lc_layout.h>
```

```
int layout_object_setvalue( layout_object,  values,  index)
LayoutObject layout_object;
LayoutValues values;
int *index;
```

Description

The **layout_object_setvalue** subroutine changes the current layout values of the **LayoutObject** structure. The *layout_object* parameter specifies the **LayoutObject** structure created by the **layout_object_create** subroutine. The values are written into the **LayoutObject** structure and may affect the behavior of subsequent layout functions.

Note: Some layout values do alter internal states maintained by a **LayoutObject** structure.

The name field of the LayoutValueRec structure contains the name of the layout value to be set. The value field contains the actual value to be set. The value field is large enough to support all types of layout values. For more information on layout value types, see **Layout Values for the Layout Library** in *General Programming Concepts: Writing and Debugging Programs* .

Note: If you are developing internationalized applications that may support multibyte locales, please see **Use of the libcur Package** in *General Programming Concepts: Writing and Debugging Programs*

Parameters

Item	Description
layout_object	Specifies the **LayoutObject** structure returned by the **layout_object_create** subroutine.
values	Specifies an array of layout values of the type LayoutValueRec that this subroutine sets. The end of the array is indicated by `name=0`.
index	Specifies a layout value to be queried. If the value cannot be queried, the index parameter causing the error is returned and the subroutine returns a non-zero value. If an error is generated, a subset of the values may have been previously set.

Return Values

Upon successful completion, the **layout_object_setvalue** subroutine returns a value of 0. All layout values were successfully set.

Error Codes

If the **layout_object_setvalue** subroutine fails, it returns the following values:

Item	Description
LAYOUT_EINVAL	The layout value specified by the *index* parameter is unknown, its value is invalid, or the *layout_object* parameter is invalid.
LAYOUT_EMFILE	The **(OPEN_MAX)** file descriptors are currently open in the calling process.
LAYOUT_ENOMEM	Insufficient storage space is available.

Examples

The following example sets the TypeofText value to Implicit and the out value to Visual.

```
#include <sys/lc_layout.h>
#include <locale.h>

main()
{
LayoutObject plh;
int RC=0;
LayoutValues layout;
LayoutTextDescriptor Descr;
int index;

RC=layout_object_create(setlocale(LC_CTYPE,""),&plh); /* create object */
if (RC) {printf("Create error !!\n"); exit(0);}

layout=malloc(2*sizeof(LayoutValueRec)); /*allocate layout array*/
Descr=malloc(sizeof(LayoutTextDescriptorRec)); /* allocate text descriptor */
layout[0].name=TypeOfText;            /* set name */
layout[0].value=(caddr_t)Descr;       /* set value */
layout[1].name=0;                     /* indicate end of array */

Descr->in=TEXT_IMPLICIT;
Descr->out=TEXT_VISUAL;  RC=layout_object_setvalue(plh,layout,&index);
if (RC) printf("SetValue error at %d!!\n",index); /* check return code */
free(layout);                        /* free allocated memory */
free (Descr);
RC=layout_object_free(plh);          /* free layout object */
if (RC) printf("Free error !!\n");
}
```

layout_object_shapeboxchars Subroutine

Purpose

Shapes box characters.

Library

Layout Library (**libi18n.a**)

Syntax

```
#include <sys/lc_layout.h>int layout_object_shapeboxchars
(layout_object,InpBuf,InpSize,OutBuf)
LayoutObject layout_object;
const char *InpBuf;
const size_t InpSize;
char *OutBuf;
```

Description

The **layout_object_shapeboxchars** subroutine shapes box characters into the VT100 box character set.

Note: If you are developing internationalized applications that may support multibyte locales, please see Use of the libcur Package in *General Programming Concepts: Writing and Debugging Programs*

Parameters

Item	Description
layout_object	Specifies the **LayoutObject** structure created by the **layout_object_create** subroutine.
InpBuf	Specifies the source text to be processed.
InpSize	Specifies the number of code elements to be processed.
OutBuf	Contains the shaped output text.

Return Values

Upon successful completion, this subroutine returns a value of 0.

Error Codes

If this subroutine fails, it returns the following values:

Item	Description
LAYOUT_EILSEQ	Shaping stopped due to an input code element that cannot be mapped into the VT100 box character set.
LAYOUT_EINVAL	Shaping stopped due to an incomplete code element or shift sequence at the end of the input buffer.

layout_object_transform or wcslayout_object_transform Subroutine

Purpose

Transforms text according to the current layout values of a **LayoutObject** structure.

Library

Layout Library (**libi18n.a**)

Syntax

```
#include <sys/lc_layout.h>
int layout_object_transform
( layout_object,  InpBuf,  InpSize,  OutBuf,  OutSize,  InpToOut,  OutToInp,
BidiLvl)
LayoutObject layout_object;
const char *InpBuf;
size_t *InpSize;
void * OutBuf;
size_t *OutSize;
size_t  *InpToOut;
size_t *OutToInp;
unsigned char *BidiLvl;
```

```
int wcslayout_object_transform
(layout_object, InpBuf, InpSize, OutBuf, OutSize, InpToOut, OutToInp, BidiLvl)
LayoutObject layout_object;
const char *InpBuf;
size_t *InpSize;
void *OutBuf;
Size_t *OutSize;
size_t *InpToOut;
size_t *OutToInp;
unsigned char *BidiLvl;
```

Description

The **layout_object_transform** and **wcslayout_object_transform** subroutines transform the text specified by the *InpBuf* parameter according to the current layout values in the **LayoutObject** structure. Any layout value whose type is LayoutTextDescriptor describes the attributes within the *InpBuf* and *OutBuf* parameters. If the attributes are the same as the *InpBuf* and *OutBuf* parameters themselves, a null transformation is done with respect to that specific layout value.

The output of these subroutines may be one or more of the following results depending on the setting of the respective parameters:

Item	Description
OutBuf, *OutSize*	Any transformed data is stored in the *OutBuf* parameter.
InpToOut	A cross reference from each code element of the *InpBuf* parameter to the transformed data.
OutToInp	A cross reference to each code element of the *InpBuf* parameter from the transformed data.
BidiLvl	A weighted value that represents the directional level of each code element of the *InpBuf* parameter. The level is dependent on the internal directional algorithm of the **LayoutObject** structure.

You can specify each of these output parameters as Null to indicate that no output is needed for the specific parameter. However, you should set at least one of these parameters to a nonNULL value to perform any significant work.

To perform shaping of a text string without reordering of code elements, set the TypeOfText layout value to **TEXT_VISUAL** and the in and out values of the Orientation layout value alike. These layout values are in the **LayoutObject** structure.

Note: If you are developing internationalized applications that may support multibyte locales, please see Use of the libcur Package in *General Programming Concepts: Writing and Debugging Programs*

Parameters

Item	Description
layout_object	Specifies the **LayoutObject** structure created by the **layout_object_create** subroutine.
InpBuf	Specifies the source text to be processed. This parameter cannot be null.
InpSize	Specifies the units of code elements processed associated with the bytes for the **layout_object_transform** and **wcslayout_object_transform** subroutines. A value of -1 indicates that the input is delimited by a null code element. On return, the value is modified to the actual number of code elements processed in the *InBuf* parameter. However, if the value in the *OutSize* parameter is zero, the value of the *InpSize* parameter is not changed.

Item	Description
OutBuf	Contains the transformed data. You can specify this parameter as a null pointer to indicate that no transformed data is required. The encoding of the *OutBuf* parameter depends on the ShapeCharset layout value defined in the **LayoutObject** structure. If the ActiveShapeEditing layout value is set to True, the encoding of the *OutBuf* parameter is the same as the code set of the locale associated with the **LayoutObject** structure.
OutSize	Specifies the size of the output buffer in number of bytes. The output buffer should be large enough to contain the transformed result; otherwise, only a partial transformation is performed. If the ActiveShapeEditing layout value is set to True, the *OutBuf* parameter should be allocated to contain at least the number of code elements multiplied by the ShapeCharsetSize layout value. On return, the *OutSize* parameter is modified to the actual number of bytes placed in this parameter. When you specify the *OutSize* parameter as 0, the subroutine calculates the size of an output buffer to be large enough to contain the transformed text. The result is returned in this field. The content of the buffers specified by the *InpBuf* and *OutBuf* parameters, and a value of the *InpSize* parameter remains unchanged.
InpToOut	Represents an array of values with the same number of code elements as the *InpBuf* parameter if *InpToOut* parameter is not a null pointer. On output, the *n*th value in *InpToOut* parameter corresponds to the *n*th code element in *InpBuf* parameter. This value is the index in *OutBuf* parameter which identifies the transformed ShapeCharset element of the *n*th code element in *InpBuf* parameter. You can specify the *InpToOut* parameter as null if no index array from the *InpBuf* to *OutBuf* parameters is desired.
OutTolnp	Represents an array of values with the same number of code elements as contained in the *OutBuf* parameter if the *OutToInp* parameter is not a null pointer. On output, the *n*th value in the *OutTolnp* parameter corresponds to the *n*th ShapeCharset element in the *OutBuf* parameter. This value is the index in the *InpBuf* parameter which identifies the original code element of the *n*th ShapeCharset element in the *OutBuf* parameter. You can specify the *OutTolnp* parameter as NULL if no index array from the *OutBuf* to *InpBuf* parameters is desired.
BidiLvl	Represents an array of values with the same number of elements as the source text if the *BidiLvl* parameter is not a null pointer. The *n*th value in the *BidiLvl* parameter corresponds to the *n*th code element in the *InpBuf* parameter. This value is the level of this code element as determined by the bidirectional algorithm. You can specify the *BidiLvl* parameter as null if a levels array is not desired.

Return Values

Upon successful completion, these subroutines return a value of 0.

Error Codes

If these subroutines fail, they return the following values:

Item	Description
LAYOUT_EILSEQ	Transformation stopped due to an input code element that cannot be shaped or is invalid. The *InpSize* parameter indicates the number of the code element successfully transformed. **Note:** You can use this error code to determine the code element causing the error. This code element is either a valid code element but cannot be shaped into the ShapeCharset layout value or is an invalid code element not defined by the code set of the locale of the **LayoutObject** structure. You can use the **mbtowc** and **wctomb** subroutines to determine if the code element is valid when used in the same locale as the **LayoutObject** structure.
LAYOUT_E2BIG	The output buffer is full and the source text is not entirely processed.
LAYOUT_EINVAL	Transformation stopped due to an incomplete code element or shift sequence at the end of the input buffer. The *InpSize* parameter indicates the number of the code elements successfully transformed. **Note:** You can use this error code to determine the code element causing the error.
LAYOUT_ERANGE	More than 15 embedding levels are in the source text or the *InpBuf* parameter contains unbalanced Directional Format (Push/Pop). When the size of *OutBuf* parameter is not large enough to contain the entire transformed text, the input text state at the end of the **LAYOUT_E2BIG** error code is returned. To resume the transformation on the remaining text, the application calls the **layout_object_transform** subroutine with the same **LayoutObject** structure, the same *InpBuf* parameter, and *InpSize* parameter set to 0.

Examples

The following is an example of transformation of both directional re-ordering and shaping.

Note:

1. Uppercase represent left-to-right characters; lowercase represent right-to-left characters.
2. xyz represent the shapes of cde.

```
Position:           0123456789
InpBuf:             AB cde 12Z

Position:           0123456789
OutBuf:             AB 12 zyxZ

Position:           0123456789
ToTarget:           0128765349

Position:           0123456789
ToSource:           0127865439

Position:           0123456789
BidiLevel:          0001111220
```

layout_object_free Subroutine

Purpose

Frees a **LayoutObject** structure.

Library

Layout library (**libi18n.a**)

Syntax

```
#include <sys/lc_layout.h>
```

int layout_object_free(*layout_object***)**
LayoutObject *layout_object*;

Description

The **layout_object_free** subroutine releases all the resources of the **LayoutObject** structure created by the **layout_object_create** subroutine. The *layout_object* parameter specifies this **LayoutObject** structure.

Note: If you are developing internationalized applications that may support multibyte locales, please see Use of the libcur Package in *General Programming Concepts: Writing and Debugging Programs*

Parameters

Item	Description
layout_object	Specifies a **LayoutObject** structure returned by the **layout_object_create** subroutine.

Return Values

Upon successful completion, the **layout_object_free** subroutine returns a value of 0. All resources associated with the *layout_object* parameter are successfully deallocated.

Error Codes

If the **layout_object_free** subroutine fails, it returns the following error code:

Item	Description
LAYOUT_EFAULT	Errors occurred while processing the request.

lckpwdf Subroutine

Purpose

Locks the password database file.

Library

Security Library (`libc.a`)

Syntax

```
#include <pwd.h>

int lckpwdf()
```

Description

The `lckpwdf` subroutine opens the temporary file and locks it to prevent the concurrent modification of the `/etc/passwd` and `/etc/security/passwd` database files.

The **ulckpwdf** subroutine can be called to release this lock. Both the **lckpwdf** and **ulckpwdf** subroutines use the `/etc/security/.pwdlck` database file as a lock file.

Note:

There is no protection against direct access of password database files or the programs that do not use the **lckpwdf** and **ulckpwdf** subroutines.

Return Values

Upon successful completion of attaining a lock, the **lckpwdf** subroutine returns a value of 0. Otherwise, a value of -1 is returned when the lock is acquired by other process.

ldahread Subroutine

Purpose

Reads the archive header of a member of an archive file.

Library

Object File Access Routine Library (**libld.a**)

Syntax

```
#include <stdio.h>
#include <ar.h>
#include <ldfcn.h>

int ldahread(ldPointer,ArchiveHeader)
LDFILE *ldPointer;
ARCHDR *ArchiveHeader;
```

Description

If the **TYPE(***ldPointer***)** macro from the **ldfcn.h** file is the archive file magic number, the **ldahread** subroutine reads the archive header of the extended common object file currently associated with the *ldPointer* parameter into the area of memory beginning at the *ArchiveHeader* parameter.

Parameters

Item	Description
ldPointer	Points to the **LDFILE** structure that was returned as the result of a successful call to **ldopen** or **ldaopen**.
ArchiveHeader	Points to a **ARCHDR** structure.

Return Values

The **ldahread** subroutine returns a SUCCESS or FAILURE value.

Error Codes

The **ldahread** routine fails if the **TYPE(***ldPointer***)** macro does not represent an archive file, or if it cannot read the archive header.

ldclose or ldaclose Subroutine

Purpose

Closes a common object file.

Library

Object File Access Routine Library (**libld.a**)

Syntax

```
#include <stdio.h>
#include <ldfcn.h>

int ldclose( ldPointer)
LDFILE *ldPointer;

int ldaclose(ldPointer)
LDFILE *ldPointer;
```

Description

The **ldopen** and **ldclose** subroutines provide uniform access to both simple object files and object files that are members of archive files. Thus, an archive of common object files can be processed as if it were a series of simple common object files.

If the **ldfcn.h** file **TYPE(***ldPointer***)** macro is the magic number of an archive file, and if there are any more files in the archive, the **ldclose** subroutine reinitializes the **ldfcn.h** file **OFFSET(***ldPointer***)** macro to the file address of the next archive member and returns a failure value. The **ldfile** structure is prepared for a subsequent **ldopen**.

If the **TYPE(***ldPointer***)** macro does not represent an archive file, the **ldclose** subroutine closes the file and frees the memory allocated to the **ldfile** structure associated with *ldPointer.*

The **ldaclose** subroutine closes the file and frees the memory allocated to the **ldfile** structure associated with the *ldPointer* parameter regardless of the value of the **TYPE**(*ldPointer***)** macro.

Parameters

Item	Description
ldPointer	Pointer to the **LDFILE** structure that was returned as the result of a successful call to **ldopen** or **ldaopen**.

Return Values

The **ldclose** subroutine returns a SUCCESS or FAILURE value.

The **ldaclose** subroutine always returns a SUCCESS value and is often used in conjunction with the **ldaopen** subroutine.

Error Codes

The **ldclose** subroutine returns a failure value if there are more files to archive.

ldexpd32, ldexpd64, and ldexpd128 Subroutines

Purpose

Loads the exponent of a decimal floating-point number.

Syntax

```
#include <math.h>

_Decimal32 ldexpd32 (x, exp)
_Decimal32 x;
int exp;

_Decimal64 ldexpd64 (x, exp)
_Decimal64 x;
int exp;

_Decimal128 ldexpd128 (x, exp)
_Decimal128 x;
int exp;
```

Description

The **ldexpd32**, **ldexpd64**, and **ldexpd128** subroutines compute the quantity *x* * 10^{exp}.

An application that wants to check for error situations must set the **errno** global variable to the value of zero and call the **feclearexcept**(**FE_ALL_EXCEPT**) before calling these functions. On return, if the **errno** is of the value of nonzero or the **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is of the value of nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.
exp	Specifies the exponent of 10.

Return Values

Upon successful completion, the **ldexpd32**, **ldexpd64**, and **ldexpd128** subroutines return *x* multiplied by 10 to the power of *exp*.

If the **ldexpd32**, **ldexpd64**, or **ldexpd128** subroutines would cause overflow, a range error occurs and the **ldexpd32**, **ldexpd64**, and **ldexpd128** subroutines return ±**HUGE_VAL_D32**, ±**HUGE_VAL_D64**, and ±**HUGE_VAL_D128** (according to the sign of *x*), respectively.

If the correct value will cause underflow, and is not representable, a range error might occur, and 0.0 is returned.

If *x* is NaN, a NaN is returned.

If *x* is ±0 or Inf, *x* is returned.

If *exp* is 0, *x* is returned.

If the correct value will cause underflow, and is representable, a range error might occur and the correct value is returned.

ldexp, ldexpf, or ldexpl Subroutine

Purpose

Loads exponent of a floating-point number.

Syntax

```
#include <math.h>
float ldexpf (x, exp)
float x;
```

```
int exp;

long double ldexpl (x, exp)
long double x;
int exp;

double ldexp (x, exp)
double  x;
int exp;
```

Description

The **ldexpf**, **ldexpl**, and **ldexp** subroutines compute the quantity *x* * 2^{exp}.

An application wishing to check for error situations should set the **errno** global variable to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these functions. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.
exp	Specifies the exponent of 2.

Return Values

Upon successful completion, the **ldexpf**, **ldexpl**, and **ldexp** subroutines return *x* multiplied by 2, raised to the power *exp*.

If the **ldexpf**, **ldexpl**, or **ldexp** subroutines would cause overflow, a range error occurs and the **ldexpf**, **ldexpl**, and **ldexp** subroutines return ±**HUGE_VALF**, ±**HUGE_VALL**, and ±**HUGE_VAL** (according to the sign of *x*), respectively.

If the correct value would cause underflow, and is not representable, a range error may occur, and 0.0 is returned.

If *x* is NaN, a NaN is returned.

If *x* is ±0 or Inf, *x* is returned.

If *exp* is 0, *x* is returned.

If the correct value would cause underflow, and is representable, a range error may occur and the correct value is returned.

Error Codes

If the result of the **ldexp** or **ldexpl** subroutine overflows, then +/- **HUGE_VAL** is returned, and the global variable **errno** is set to **ERANGE**.

If the result of the **ldexp** or **ldexpl** subroutine underflows, 0 is returned, and the **errno** global variable is set to a **ERANGE** value.

ldfhread Subroutine

Purpose

Reads the file header of an XCOFF file.

Library

Object File Access Routine Library (**libld.a**)

Syntax

```
#include <stdio.h>
#include <ldfcn.h>

int ldfhread ( ldPointer,  FileHeader)
LDFILE *ldPointer;
void *FileHeader;
```

Description

The **ldfhread** subroutine reads the file header of the object file currently associated with the *ldPointer* parameter into the area of memory beginning at the *FileHeader* parameter. It is the responsibility of the calling routine to provide a pointer to a buffer large enough to contain the file header of the associated object file. Since the **ldopen** subroutine provides magic number information (via the **HEADER**(*ldPointer*)**.f_magic** macro), the calling application can always determine whether the *FileHeader* pointer should refer to a 32-bit FILHDR or 64-bit FILHDR_64 structure.

Parameters

Item	Description
ldPointer	Points to the **LDFILE** structure that was returned as the result of a successful call to **ldopen** or **ldaopen** subroutine.
FileHeader	Points to a buffer large enough to accommodate a **FILHDR** structure, according to the object mode of the file being read.

Return Values

The **ldfhread** subroutine returns Success or Failure.

Error Codes

The **ldfhread** subroutine fails if it cannot read the file header.

Note: In most cases, the use of **ldfhread** can be avoided by using the **HEADER** (*ldPointer*) macro defined in the **ldfcn.h** file. The information in any field or fieldname of the header file may be accessed using the **header** *(ldPointer*) **fieldname** macro.

Examples

The following is an example of code that opens an object file, determines its mode, and uses the **ldfhread** subroutine to acquire the file header. This code would be compiled with both **_XCOFF32_** and **_XCOFF64_** defined:

```
#define __XCOFF32__
#define __XCOFF64__

#include <ldfcn.h>

/* for each FileName to be processed */

if ( (ldPointer = ldopen(fileName, ldPointer)) != NULL)
{
    FILHDR    FileHead32;
    FILHDR_64 FileHead64;
    void      *FileHeader;
```

```
    if ( HEADER(ldPointer).f_magic == U802TOCMAGIC )
        FileHeader = &FileHead32;
    else if ( HEADER(ldPointer).f_magic == U803XTOCMAGIC )
        FileHeader = &FileHead64;
    else
        FileHeader = NULL;

    if ( FileHeader && (ldfhread( ldPointer, FileHeader ) == SUCCESS) )
    {
        /* ...successfully read header... */
        /* ...process according to magic number... */
    }
}
```

ldgetname Subroutine

Purpose

Retrieves symbol name for common object file symbol table entry.

Library

Object File Access Routine Library (**libld.a)**

Syntax

```
#include <stdio.h>
#include <ldfcn.h>

char *ldgetname ( ldPointer,  Symbol)
LDFILE *ldPointer;
void *Symbol;
```

Description

The **ldgetname** subroutine returns a pointer to the name associated with *Symbol* as a string. The string is in a static buffer local to the **ldgetname** subroutine that is overwritten by each call to the **ldgetname** subroutine and must therefore be copied by the caller if the name is to be saved.

The common object file format handles arbitrary length symbol names with the addition of a string table. The **ldgetname** subroutine returns the symbol name associated with a symbol table entry for an XCOFF-format object file.

The calling routine to provide a pointer to a buffer large enough to contain a symbol table entry for the associated object file. Since the **ldopen** subroutine provides magic number information (via the **HEADER(***ldPointer***).f_magic** macro), the calling application can always determine whether the Symbol pointer should refer to a 32-bit SYMENT or 64-bit SYMENT_64 structure.

The maximum length of a symbol name is **BUFSIZ**, defined in the **stdio.h** file.

Parameters

Item	Description
ldPointer	Points to an **LDFILE** structure that was returned as the result of a successful call to the **ldopen** or **ldaopen** subroutine.
Symbol	Points to an initialized 32-bit or 64-bit **SYMENT** structure.

Error Codes

The **ldgetname** subroutine returns a null value (defined in the **stdio.h** file) for a COFF-format object file if the name cannot be retrieved. This situation can occur if one of the following is true:

- The string table cannot be found.
- The string table appears invalid (for example, if an auxiliary entry is handed to the **ldgetname** subroutine wherein the name offset lies outside the boundaries of the string table).
- The name's offset into the string table is past the end of the string table.

Typically, the **ldgetname** subroutine is called immediately after a successful call to the **ldtbread** subroutine to retrieve the name associated with the symbol table entry filled by the **ldtbread** subroutine.

Examples

The following is an example of code that determines the object file type before making a call to the **ldtbread** and **ldgetname** subroutines.

```
#define __XCOFF32__
#define __XCOFF64__

#include <ldfcn.h>

SYMENT    Symbol32;
SYMENT_64 Symbol64;
void      *Symbol;

if ( HEADER(ldPointer).f_magic == U802TOCMAGIC )
    Symbol = &Symbol32;
else if ( HEADER(ldPointer).f_magic == U64_TOCMAGIC )
    Symbol = &Symbol64;
else
    Symbol = NULL;

if ( Symbol )
    /* for each symbol in the symbol table */
    for ( symnum = 0 ; symnum < HEADER(ldPointer).f_nsyms ; symnum++ )
    {
        if ( ldtbread(ldPointer,symnum,Symbol) == SUCCESS )
        {
            char *name = ldgetname(ldPointer,Symbol)

            if ( name )
            {
                /* Got the name... */
                .
                .
            }

            /* Increment symnum by the number of auxiliary entries */
            if ( HEADER(ldPointer).f_magic == U802TOCMAGIC )
                symnum += Symbol32.n_numaux;
            else if ( HEADER(ldPointer).f_magic == U64_TOCMAGIC )
                symnum += Symbol64.n_numaux;
        }
        else
        {
            /* Should have been a symbol...indicate the error */
                .
                .
        }
    }
```

ldlread, ldlinit, or ldlitem Subroutine

Purpose

Manipulates line number entries of a common object file function.

Library

Object File Access Routine Library (**libld.a**)

Syntax

```
#include <stdio.h>
#include <ldfcn.h>

int ldlread ( ldPointer,  FunctionIndex,  LineNumber,  LineEntry)
LDFILE *ldPointer;
int FunctionIndex;
unsigned short LineNumber;
void *LineEntry;

int ldlinit (ldPointer, FunctionIndex)
LDFILE *ldPointer;
int FunctionIndex;

int ldlitem (ldPointer, LineNumber, LineEntry)
LDFILE *ldPointer;
unsigned short LineNumber;
void *LineEntry;
```

Description

The **ldlread** subroutine searches the line number entries of the XCOFF file currently associated with the *ldPointer* parameter. The **ldlread** subroutine begins its search with the line number entry for the beginning of a function and confines its search to the line numbers associated with a single function. The function is identified by the *FunctionIndex* parameter, the index of its entry in the object file symbol table. The **ldlread** subroutine reads the entry with the smallest line number equal to or greater than the *LineNumber* parameter into the memory beginning at the *LineEntry* parameter. It is the responsibility of the calling routine to provide a pointer to a buffer large enough to contain the line number entry for the associated object file type. Since the **ldopen** subroutine provides magic number information (via the **HEADER**(*ldPointer*)**.f_magic** macro), the calling application can always determine whether the *LineEntry* pointer should refer to a 32-bit LINENO or 64-bit LINENO_64 structure.

The **ldlinit** and **ldlitem** subroutines together perform the same function as the **ldlread** subroutine. After an initial call to the **ldlread** or **ldlinit** subroutine, the **ldlitem** subroutine may be used to retrieve successive line number entries associated with a single function. The **ldlinit** subroutine simply locates the line number entries for the function identified by the *FunctionIndex* parameter. The **ldlitem** subroutine finds and reads the entry with the smallest line number equal to or greater than the *LineNumber* parameter into the memory beginning at the *LineEntry* parameter.

Parameters

Item	Description
ldPointer	Points to the **LDFILE** structure that was returned as the result of a successful call to the **ldopen** , **lddopen**,or **ldaopen** subroutine.
LineNumber	Specifies the index of the first *LineNumber* parameter entry to be read.
LineEntry	Points to a buffer that will be filled in with a **LINENO** structure from the object file.
FunctionIndex	Points to the symbol table index of a function.

Return Values

The **ldlread**, **ldlinit**, and **ldlitem** subroutines return a SUCCESS or FAILURE value.

Error Codes

The **ldlread** subroutine fails if there are no line number entries in the object file, if the *FunctionIndex* parameter does not index a function entry in the symbol table, or if it finds no line number equal to or greater than the *LineNumber* parameter. The **ldlinit** subroutine fails if there are no line number entries in the object file or if the *FunctionIndex* parameter does not index a function entry in the symbol table. The **ldlitem** subroutine fails if it finds no line number equal to or greater than the *LineNumber* parameter.

ldlseek or ldnlseek Subroutine

Purpose

Seeks to line number entries of a section of a common object file.

Library

Object File Access Routine Library (**libld.a**)

Syntax

```
#include <stdio.h>
#include <ldfcn.h>

int ldlseek ( ldPointer,  SectionIndex)
LDFILE *ldPointer;
unsigned short SectionIndex;

int ldnlseek (ldPointer,  SectionName)
LDFILE *ldPointer;
char *SectionName;
```

Description

The **ldlseek** subroutine seeks to the line number entries of the section specified by the *SectionIndex* parameter of the common object file currently associated with the *ldPointer* parameter. The first section has an index of 1.

The **ldnlseek** subroutine seeks to the line number entries of the section specified by the *SectionName* parameter.

Both subroutines determine the object mode of the associated file before seeking to the relocation entries of the indicated section.

Parameters

Item	Description
ldPointer	Points to the **LDFILE** structure that was returned as the result of a successful call to the **ldopen** or **ldaopen** subroutine.
SectionIndex	Specifies the index of the section whose line number entries are to be seeked to.
SectionName	Specifies the name of the section whose line number entries are to be seeked to.

Return Values

The **ldlseek** and **ldnlseek** subroutines return a SUCCESS or FAILURE value.

Error Codes

The **ldlseek** subroutine fails if the *SectionIndex* parameter is greater than the number of sections in the object file. The **ldnlseek** subroutine fails if there is no section name corresponding with the *SectionName* parameter. Either function fails if the specified section has no line number entries or if it cannot seek to the specified line number entries.

ldohseek Subroutine

Purpose

Seeks to the optional file header of a common object file.

Library

Object File Access Routine Library (**libld.a**)

Syntax

```
#include <stdio.h>
#include <ldfcn.h>

int ldohseek ( ldPointer)
LDFILE *ldPointer;
```

Description

The **ldohseek** subroutine seeks to the optional auxiliary header of the common object file currently associated with the *ldPointer* parameter. The subroutine determines the object mode of the associated file before seeking to the end of its file header.

Parameters

Item	Description
ldPointer	Points to the **LDFILE** structure that was returned as the result of a successful call to **ldopen** or **ldaopen** subroutine.

Return Values

The **ldohseek** subroutine returns a SUCCESS or FAILURE value.

Error Codes

The **ldohseek** subroutine fails if the object file has no optional header, if the file is not a 32-bit or 64-bit object file, or if it cannot seek to the optional header.

ldopen or ldaopen Subroutine

Purpose

Opens an object or archive file for reading.

Library

Object File Access Routine Library (**libld.a**)

Syntax

```
#include <stdio.h>
#include <ldfcn.h>

LDFILE *ldopen( FileName,  ldPointer)
char *FileName;
LDFILE *ldPointer;

LDFILE *ldaopen(FileName, ldPointer)
char *FileName;
LDFILE *ldPointer;

LDFILE *lddopen(FileDescriptor, type, ldPointer)
int FileDescriptor;
char *type;
LDFILE *ldPointer;
```

Description

The **ldopen** and **ldclose** subroutines provide uniform access to both simple object files and object files that are members of archive files. Thus, an archive of object files can be processed as if it were a series of ordinary object files.

If the *ldPointer* is null, the **ldopen** subroutine opens the file named by the *FileName* parameter and allocates and initializes an **LDFILE** structure, and returns a pointer to the structure.

If the *ldPointer* parameter is not null and refers to an **LDFILE** for an archive, the structure is updated for reading the next archive member. In this case, and if the value of the **TYPE(***ldPointer***)** macro is the archive magic number **ARTYPE**.

The **ldopen** and **ldclose** subroutines are designed to work in concert. The **ldclose** subroutine returns failure only when the *ldPointer* refers to an archive containing additional members. Only then should the **ldopen** subroutine be called with a num-null *ldPointer* argument. In all other cases, in particular whenever a new *FileName* parameter is opened, the **ldopen** subroutine should be called with a null *ldPointer* argument.

If the value of the *ldPointer* parameter is not null, the **ldaopen** subroutine opens the *FileName* parameter again and allocates and initializes a new **LDFILE** structure, copying the **TYP**E, **OFFSET**, and **HEADER** fields from the *ldPointer* parameter. The **ldaopen** subroutine returns a pointer to the new **ldfile** structure. This new pointer is independent of the old pointer, *ldPointer*. The two pointers may be used concurrently to read separate parts of the object file. For example, one pointer may be used to step sequentially through the relocation information, while the other is used to read indexed symbol table entries.

The **lddopen** function accesses the previously opened file referenced by the *FileDescriptor* parameter. In all other respects, it functions the same as the **ldopen** subroutine.

The functions transparently open both 32-bit and 64-bit object files, as well as both small format and large format archive files. Once a file or archive is successfully opened, the calling application can examine the **HEADER(***ldPointer***).f_magic** field to check the magic number of the file or archive member associated with *ldPointer*. (This is necessary due to an archive potentially containing members that are not object files.) The magic numbers U802TOCMAGIC and U803XTOCMAGIC are defined in the **ldfcn.h** file. If the value of **TYPE(**l*dPointer***)** is the archive magic number**ARTYPE**, the flags field can be checked for the archive type. Large format archives will have the flag bit **AR_TYPE_BIG** set in **LDFLAGS(***ldPointer***)**.

Parameters

Item	Description
FileName	Specifies the file name of an object file or archive.
ldPointer	Points to an **LDFILE** structure.
FileDescriptor	Specifies a valid open file descriptor.
type	Points to a character string specifying the mode for the open file. The **fdopen** function is used to open the file.

Error Codes

Both the **ldopen** and **ldaopen** subroutines open the file named by the *FileName* parameter for reading. Both functions return a null value if the *FileName* parameter cannot be opened, or if memory for the **LDFILE** structure cannot be allocated.

A successful open does not ensure that the given file is a common object file or an archived object file.

Examples

The following is an example of code that uses the **ldopen** and **ldclose** subroutines:

```
/* for each FileName to be processed */

 ldPointer = NULL;
 do

 if((ldPointer = ldopen(FileName, ldPointer)) != NULL)

                      /* check magic number */
                      /* process the file */
                 "
                 "
   while(ldclose(ldPointer) == FAILURE );
```

ldrseek or ldnrseek Subroutine

Purpose

Seeks to the relocation entries of a section of an XCOFF file.

Library

Object File Access Routine Library (**libld.a**)

Syntax

```
#include <stdio.h>
#include <ldfcn.h>

int ldrseek ( ldPointer,  SectionIndex)
ldfile *ldPointer;
unsigned short SectionIndex;

int ldnrseek (ldPointer,  SectionName)
ldfile *ldPointer;
char *SectionName;
```

Description

The **ldrseek** subroutine seeks to the relocation entries of the section specified by the *SectionIndex* parameter of the common object file currently associated with the *ldPointer* parameter.

The **ldnrseek** subroutine seeks to the relocation entries of the section specified by the *SectionName* parameter.

The **ldrseek** subroutine and the **ldnrseek** subroutine determine the object mode of the associated file before seeking to the relocation entries of the indicated section.

Parameters

Item	Description
ldPointer	Points to an **LDFILE** structure that was returned as the result of a successful call to the **ldopen**, **lddopen**, or **ldaopen** subroutines.
SectionIndex	Specifies an index for the section whose relocation entries are to be sought.
SectionName	Specifies the name of the section whose relocation entries are to be sought.

Return Values

The **ldrseek** and **ldnrseek** subroutines return a SUCCESS or FAILURE value.

Error Codes

The **ldrseek** subroutine fails if the contents of the *SectionIndex* parameter are greater than the number of sections in the object file. The **ldnrseek** subroutine fails if there is no section name corresponding with the *SectionName* parameter. Either function fails if the specified section has no relocation entries or if it cannot seek to the specified relocation entries.

Note: The first section has an index of 1.

ldshread or ldnshread Subroutine

Purpose

Reads a section header of an XCOFF file.

Library

Object File Access Routine Library (**libld.a**)

Syntax

```
#include <stdio.h>
#include <ldfcn.h>

int ldshread (ldPointer,SectionIndex,SectionHead)
LDFILE *ldPointer;
unsigned short SectionIndex;
void *SectionHead;

int ldnshread (ldPointer,SectionName, SectionHead)
LDFILE *ldPointer;
char *SectionName;
void *SectionHead;
```

Description

The **ldshread** subroutine reads the section header specified by the *SectionIndex* parameter of the common object file currently associated with the *ldPointer* parameter into the area of memory beginning at the location specified by the *SectionHead* parameter.

The **ldnshread** subroutine reads the section header named by the *SectionName* argument into the area of memory beginning at the location specified by the *SectionHead* parameter. It is the responsibility of the calling routine to provide a pointer to a buffer large enough to contain the section header of the associated object file. Since the **ldopen** subroutine provides magic number information (via the **HEADER(***ldPointer* **).f_magic** macro), the calling application can always determine whether the *SectionHead* pointer should refer to a 32-bit **SCNHDR** or 64-bit **SCNHDR_64** structure.

Only the first section header named by the *SectionName* argument is returned by the **ldshread** subroutine.

Parameters

Item	Description
ldPointer	Points to an **LDFILE** structure that was returned as the result of a successful call to the **ldopen**, **lldopen**, or **ldaopen** subroutine.
SectionIndex	Specifies the index of the section header to be read. **Note:** The first section has an index of 1.
SectionHead	Points to a buffer large enough to accept either a 32-bit or a 64-bit **SCNHDR** structure, according to the object mode of the file being read.
SectionName	Specifies the name of the section header to be read.

Return Values

The **ldshread** and **ldnshread** subroutines return a SUCCESS or FAILURE value.

Error Codes

The **ldshread** subroutine fails if the *SectionIndex* parameter is greater than the number of sections in the object file. The **ldnshread** subroutine fails if there is no section with the name specified by the *SectionName* parameter. Either function fails if it cannot read the specified section header.

Examples

The following is an example of code that opens an object file, determines its mode, and uses the **ldnshread** subroutine to acquire the .text section header. This code would be compiled with both **__XCOFF32__** and **__XCOFF64__** defined:

```
#define __XCOFF32__
#define __XCOFF64__

#include <ldfcn.h>

/* for each FileName to be processed */

if ( (ldPointer = ldopen(FileName, ldPointer)) != NULL )
{
    SCNHDR    SectionHead32;
    SCNHDR_64 SectionHead64;
    void      *SectionHeader;

    if ( HEADER(ldPointer).f_magic == U802TOCMAGIC )
```

```
        SectionHeader = &SectionHead32;
    else if ( HEADER(ldPointer).f_magic == U803XTOCMAGIC )
        SectionHeader = &SectionHead64;
    else
        SectionHeader = NULL;

    if ( SectionHeader && (ldnshread( ldPointer, ".text", SectionHeader ) ==
SUCCESS) )
    {
        /* ...successfully read header... */
        /* ...process according to magic number... */
    }
}
```

ldsseek or ldnsseek Subroutine

Purpose

Seeks to an indexed or named section of a common object file.

Library

Object File Access Routine Library (**libld.a**)

Syntax

```
#include <stdio.h>
#include <ldfcn.h>

int ldsseek ( ldPointer,  SectionIndex)
LDFILE *ldPointer;
unsigned short SectionIndex;

int ldnsseek (ldPointer,  SectionName)
LDFILE *ldPointer;
char *SectionName;
```

Description

The **ldsseek** subroutine seeks to the section specified by the *SectionIndex* parameter of the common object file currently associated with the *ldPointer* parameter. The subroutine determines the object mode of the associated file before seeking to the indicated section.

The **ldnsseek** subroutine seeks to the section specified by the *SectionName* parameter.

Parameters

Item	Description
ldPointer	Points to the **LDFILE** structure that was returned as the result of a successful call to the **ldopen** or **ldaopen** subroutine.
SectionIndex	Specifies the index of the section whose line number entries are to be seeked to.
SectionName	Specifies the name of the section whose line number entries are to be seeked to.

Return Values

The **ldsseek** and **ldnsseek** subroutines return a SUCCESS or FAILURE value.

Error Codes

The **ldsseek** subroutine fails if the *SectionIndex* parameter is greater than the number of sections in the object file. The **ldnsseek** subroutine fails if there is no section name corresponding with the *SectionName* parameter. Either function fails if there is no section data for the specified section or if it cannot seek to the specified section.

Note: The first section has an index of 1.

ldtbindex Subroutine

Purpose

Computes the index of a symbol table entry of a common object file.

Library

Object File Access Routine Library (**libld.a**)

Syntax

```
#include <stdio.h>
#include <ldfcn.h>

long ldtbindex ( ldPointer)
LDFILE *ldPointer;
```

Description

The **ldtbindex** subroutine returns the index of the symbol table entry at the current position of the common object file associated with the *ldPointer* parameter.

The index returned by the **ldtbindex** subroutine may be used in subsequent calls to the **ldtbread** subroutine. However, since the **ldtbindex** subroutine returns the index of the symbol table entry that begins at the current position of the object file, if the **ldtbindex** subroutine is called immediately after a particular symbol table entry has been read, it returns the index of the next entry.

Parameters

Item	Description
ldPointer	Points to the **LDFILE** structure that was returned as a result of a successful call to the **ldopen** or **ldaopen** subroutine.

Return Values

The **ldtbindex** subroutine returns the value BADINDEX upon failure. Otherwise a value greater than or equal to zero is returned.

Error Codes

The **ldtbindex** subroutine fails if there are no symbols in the object file or if the object file is not positioned at the beginning of a symbol table entry.

Note: The first symbol in the symbol table has an index of 0.

ldtbread Subroutine

Purpose

Reads an indexed symbol table entry of a common object file.

Library

Object File Access Routine Library (**libld.a**)

Syntax

```
#include <stdio.h>
#include <ldfcn.h>

int ldtbread ( ldPointer,  SymbolIndex,  Symbol)
LDFILE *ldPointer;
long SymbolIndex;
void *Symbol;
```

Description

The **ldtbread** subroutine reads the symbol table entry specified by the *SymbolIndex* parameter of the common object file currently associated with the *ldPointer* parameter into the area of memory beginning at the *Symbol* parameter. It is the responsibility of the calling routine to provide a pointer to a buffer large enough to contain the symbol table entry of the associated object file. Since the ldopen subroutine provides magic number information (via the **HEADER(***ldPointer***).f_magic** macro), the calling application can always determine whether the *Symbol* pointer should refer to a 32-bit **SYMENT** or 64-bit **SYMENT_64** structure.

Parameters

Item	Description
ldPointer	Points to the **LDFILE** structure that was returned as the result of a successful call to the **ldopen** or **ldaopen** subroutine.
SymbolIndex	Specifies the index of the symbol table entry to be read.
Symbol	Points to a either a 32-bit or a 64-bit **SYMENT** structure.

Return Values

The **ldtbread** subroutine returns a SUCCESS or FAILURE value.

Error Codes

The **ldtbread** subroutine fails if the *SymbolIndex* parameter is greater than or equal to the number of symbols in the object file, or if it cannot read the specified symbol table entry.

Note: The first symbol in the symbol table has an index of 0.

ldtbseek Subroutine

Purpose

Seeks to the symbol table of a common object file.

Library

Object File Access Routine Library (**libld.a**)

Syntax

```
#include <stdio.h>
#include <ldfcn.h>

int ldtbseek ( ldPointer)
LDFILE *ldPointer;
```

Description

The **ldtbseek** subroutine seeks to the symbol table of the common object file currently associated with the *ldPointer* parameter.

Parameters

Item	Description
ldPointer	Points to the **LDFILE** structure that was returned as the result of a successful call to the **ldopen** or **ldaopen** subroutine.

Return Values

The **ldtbseek** subroutine returns a SUCCESS or FAILURE value.

Error Codes

The **ldtbseek** subroutine fails if the symbol table has been stripped from the object file or if the subroutine cannot seek to the symbol table.

leaveok Subroutine

Purpose

Controls physical cursor placement after a call to the **refresh** subroutine.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

leaveok( Window,  Flag)
WINDOW *Window;
bool Flag;
```

Description

The **leaveok** subroutine controls cursor placement after a call to the **refresh** (“refresh or wrefresh Subroutine” on page 1728) subroutine. If the *Flag* parameter is set to FALSE, curses leaves the physical cursor in the same location as logical cursor when the window is refreshed.

If the *Flag* parameter is set to TRUE, curses leaves the cursor as is and does not move the physical cursor when the window is refreshed. This option is useful for applications that do not use the cursor, because it reduces physical cursor motions.

By default **leaveok** is FALSE, and the physical cursor is moved to the same position as the logical cursor after a refresh.

Parameters

Item	Description
Flag	Specifies whether to leave the physical cursor alone after a refresh (TRUE) or to move the physical cursor to the logical cursor after a refresh (FALSE).
Window	Identifies the window to set the *Flag* parameter for.

Return Values

Item	Description
OK	Indicates the subroutine completed. The **leaveok** subroutine always returns this value.

Examples

1. To move the physical cursor to the same location as the logical cursor after refreshing the user-defined window `my_window`, enter:

```
WINDOW *my_window;
leaveok(my_window, FALSE);
```

2. To leave the physical cursor alone after refreshing the user-defined window `my_window`, enter:

```
WINDOW *my_window;
leaveok(my_window, TRUE);
```

lgamma, lgammaf, lgammal, lgammad32, lgammad64, and lgammad128 Subroutine

Purpose

Computes the log gamma.

Syntax

```
#include <math.h>

extern int signgam;

double lgamma (x)
double x;

float lgammaf (x)
float x;

long double lgammal (x)
long double x;
_Decimal32 lgammad32 (x)
_Decimal32 x;

_Decimal64 lgammad64 (x)
_Decimal64 x;
```

```
_Decimal128 lgammad128 (x)
_Decimal128 x;
```

Description

The sign of Gamma (*x*) is returned in the external integer **signgam** for the **lgamma**, **lgammaf**, and **lgammal** subroutines.

The **lgamma**, **lgammaf**, and **lgammal** subroutines are not reentrant. A function that is not required to be reentrant is not required to be thread-safe.

An application wishing to check for error situations should set the **errno** global variable to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **lgamma**, **lgammaf**, **lgammal**, **lgammad32**, **lgammad64**, and **lgammad128** subroutines return the logarithmic gamma of *x*.

If *x* is a non-positive integer, a pole error shall occur and the **lgamma**, **lgammaf**, **lgammal**, **lgammad32**, **lgammad64**, and **lgammad128** subroutines will return +**HUGE_VAL**, +**HUGE_VALF**, +**HUGE_VALL**, +**HUGE_VAL_D32**, +**HUGE_VAL_D64**, and +**HUGE_VAL_D128** respectively.

If the correct value would cause overflow, a range error shall occur and the **lgamma**, **lgammaf**, **lgammal**, **lgammad32**, **lgammad64**, and **lgammad128** subroutines will return ±**HUGE_VAL**, ±**HUGE_VALF**, ±**HUGE_VALL**, +**HUGE_VAL_D32**, +**HUGE_VAL_D64**, and +**HUGE_VAL_D128** respectively.

If *x* is NaN, a NaN is returned.

If *x* is 1 or 2, +0 is returned.

If *x* is ±Inf, +Inf is returned.

lineout Subroutine

Purpose

Formats a print line.

Library

None (provided by the print formatter)

Syntax

```
#include <piostruct.h>

int lineout ( fileptr)
FILE *fileptr;
```

Description

The **lineout** subroutine is invoked by the formatter driver only if the **setup** subroutine returns a non-null pointer. This subroutine is invoked for each line of the document being formatted. The **lineout** subroutine reads the input data stream from the *fileptr* parameter. It then formats and outputs the print line until it recognizes a situation that causes vertical movement on the page.

The **lineout** subroutine should process all characters to be printed and all printer commands related to horizontal movement on the page.

The **lineout** subroutine should not output any printer commands that cause vertical movement on the page. Instead, it should update the **vpos** (new vertical position) variable pointed to by the **shars_vars** structure that it shares with the formatter driver to indicate the new vertical position on the page. It should also refresh the **shar_vars** variables for vertical increment and vertical decrement (reverse line-feed) commands.

When the **lineout** subroutine returns, the formatter driver sends the necessary commands to the printer to advance to the new vertical position on the page. This position is specified by the **vpos** variable. The formatter driver automatically handles top and bottom margins, new pages, initial pages to be skipped, and progress reports to the **qdaemon** daemon.

The following conditions can cause vertical movements:

- Line-feed control character or variable line-feed control sequence
- Vertical-tab control character
- Form-feed control character
- Reverse line-feed control character
- A line too long for the printer that wraps to the next line

Other conditions unique to a specific printer also cause vertical movement.

Parameters

Item	Description
fileptr	Specifies a file structure for the input data stream.

Return Values

Upon successful completion, the **lineout** subroutine returns the number of bytes processed from the input data stream. It excludes the end-of-file character and any control characters or escape sequences that result only in vertical movement on the page (for example, line feed or vertical tab).

If a value of 0 is returned and the value in the **vpos** variable pointed to by the **shars_vars** structure has not changed, or there are no more data bytes in the input data stream, the formatter driver assumes that printing is complete.

If the **lineout** subroutine detects an error, it uses the **piomsgout** subroutine to issue an error message. It then invokes the **pioexit** subroutine with a value of PIOEXITBAD.

Note: If either the **piocmdout** or **piogetstr** subroutine detects an error, it automatically issues its own error messages and terminates the print job.

link and linkat Subroutine

Purpose

Creates an additional directory entry for an existing file.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <unistd.h>
```

```
int link ( Path1,  Path2)
const char *Path1, *Path2;

int linkat ( DirFileDescriptor1,Path1,DirFileDescriptor2,Path2,Flag)
int DirFileDescriptor1, DirFileDescriptor2;
const char *Path1, *Path2;
int Flag;
```

Description

The **link** and **linkat** subroutines create an additional hard link (directory entry) for an existing file. Both the old and the new links share equal access rights to the underlying object.

The **linkat** subroutine is equivalent to the link subroutine if the *Flag* parameter has the **AT_SYMLINK_FOLLOW** bit set and if both the *DirFileDescriptor1* and *DirFileDescriptor2* parameters are **AT_FDCWD** or both the *Path1* and *Path2* parameters are absolute path names. If *DirFileDescriptor1* is a valid file descriptor of an open directory and *Path1* is a relative path name, *Path1* is considered to be relative to the directory that is associated with the *DirFileDescriptor1* parameter instead of the current working directory. The same applies to the *DirFileDescriptor2* and *Path2* parameters.

If either directory in the **linkat** subroutine was opened without the **O_SEARCH** open flag, the subroutine checks to determine whether directory searches are permitted for that directory by using the current permissions of the directory. If either directory was opened with the **O_SEARCH** open flag, the subroutine does not perform the check for that directory.

If the Flag parameter of the **linkat** subroutine does not have the **AT_SYMLINK_FOLLOW** bit set and the *Path1* parameter specifies a symbolic link, the subroutine creates a link to the symbolic link, not its target.

Parameters

Item	Description
Path1	Points to the path name of an existing file. If *DirFileDescriptor1* is specified and *Path1* is a relative path name, then *Path1* is considered relative to the directory specified by *DirFileDescriptor1*.
Path2	Points to the path name of the directory entry to be created. If *DirFileDescriptor2* is specified and *Path2* is a relative path name, then *Path2* is considered relative to the directory specified by *DirFileDescriptor2*.
DirFileDescriptor1	Specifies the file descriptor of an open directory.
DirFileDescriptor2	Specifies the file descriptor of an open directory.
Flag	Specifies a bit field. If it contains the **AT_SYMLINK_FOLLOW** bit and *Path1* points to a symbolic link, then the link is created to the file the symbolic link points at, else the link is created to the symbolic link.

Note:

1. If Network File System (NFS) is installed on your system, these paths can cross into another node.
2. With hard links, both the *Path1* and *Path2* parameters must reside on the same file system. Creating links to directories requires root user authority.

Return Values

Upon successful completion, the **link** and **linkat** subroutines return a value of 0. Otherwise, a value of -1 is returned, and the **errno** global variable is set to indicate the error.

Error Codes

The **link** and **linkat** subroutines are unsuccessful if one of the following is true:

Item	Description
EACCES	Indicates the requested link requires writing in a directory that denies write permission.
EDQUOT	Indicates the directory in which the entry for the new link is being placed cannot be extended, or disk blocks could not be allocated for the link because the user or group quota of disk blocks or i-nodes on the file system containing the directory has been exhausted.
EEXIST	Indicates the link named by the *Path2* parameter already exists.
EMLINK	Indicates the file already has the maximum number of links.
ENOENT	Indicates the file named by the *Path1* parameter does not exist.
ENOSPC	Indicates the directory in which the entry for the new link is being placed cannot be extended because there is no space left on the file system containing the directory.
EPERM	Indicates the file named by the *Path1* parameter is a directory, and the calling process does not have root user authority.
EROFS	Indicates the requested link requires writing in a directory on a read-only file system.
EXDEV	Indicates the link named by the *Path2* parameter and the file named by the *Path1* parameter are on different file systems, or the file named by *Path1* refers to a named STREAM.

The **linkat** subroutine is unsuccessful if one or more of the following is true:

Item	Description
EBADF	The *Path1* or *Path2* parameter does not specify an absolute path and the corresponding *DirFileDescriptor1* or *DirFileDescriptor2* parameter is neither **AT_FDCWD** nor a valid file descriptor.
ENOTDIR	The *Path1* or *Path2* parameter does not specify an absolute path and the corresponding *DirFileDescriptor1* or *DirFileDescriptor2* parameter is neither **AT_FDCWD** nor a file descriptor associated with a directory.
EINVAL	The value of the *Flag* parameter is not valid.

The **link** and **linkat** subroutines can be unsuccessful for other reasons.

If NFS is installed on the system, the **link** and **linkat** subroutines are unsuccessful if the following is true:

Item	Description
ETIMEDOUT	Indicates the connection timed out.

lio_listio or lio_listio64 Subroutine

The **lio_listio** or **lio_listio64** subroutine includes information for the POSIX AIO **lio_listio** subroutine (as defined in the IEEE std 1003.1-2001), and the Legacy AIO **lio_listio** subroutine.

POSIX AIO lio_listio Subroutine

Purpose

Initiates a list of asynchronous I/O requests with a single call.

Syntax

```
#include <aio.h>
int lio_listio(mode, list, nent, sig)
int mode;
struct aiocb *restrict const list[restrict];
int nent;
struct sigevent *restrict sig;
```

Description

The *lio_listio* subroutine initiates a list of I/O requests with a single function call.

The *mode* parameter takes one of the values (LIO_WAIT, LIO_NOWAIT or LIO_NOWAIT_AIOWAIT) declared in **<aio.h>** and determines whether the subroutine returns when the I/O operations have been completed, or as soon as the operations have been queued. If the *mode* parameter is set to LIO_WAIT, the subroutine waits until all I/O is complete and the *sig* parameter is ignored.

If the *mode* parameter is set to LIO_NOWAIT or LIO_NOWAIT_AIOWAIT, the subroutine returns immediately. If LIO_NOWAIT is set, asynchronous notification occurs, according to the *sig* parameter, when all I/O operations complete. If *sig* is NULL, no asynchronous notification occurs. If *sig* is not NULL, asynchronous notification occurs when all the requests in *list* have completed. If LIO_NOWAIT_AIOWAIT is set, the **aio_nwait** subroutine must be called for the aio control blocks to be updated.

The I/O requests enumerated by *list* are submitted in an unspecified order.

The *list* parameter is an array of pointers to **aiocb** structures. The array contains *nent* elements. The array may contain NULL elements, which are ignored.

The *aio_lio_opcode* field of each **aiocb** structure specifies the operation to be performed. The supported operations are LIO_READ, LIO_WRITE, and LIO_NOP; these symbols are defined in **<aio.h>**. The LIO_NOP operation causes the list entry to be ignored. If the *aio_lio_opcode* element is equal to LIO_READ, an I/O operation is submitted as if by a call to **aio_read** with the *aiocbp* equal to the address of the **aiocb** structure. If the *aio_lio_opcode* element is equal to LIO_WRITE, an I/O operation is submitted as if by a call to **aio_write** with the *aiocbp* argument equal to the address of the **aiocb** structure.

The *aio_fildes* member specifies the file descriptor on which the operation is to be performed.

The *aio_buf* member specifies the address of the buffer to or from which the data is transferred.

The *aio_nbytes* member specifies the number of bytes of data to be transferred.

The members of the **aiocb** structure further describe the I/O operation to be performed, in a manner identical to that of the corresponding **aiocb** structure when used by the **aio_read** and **aio_write** subroutines.

The *nent* parameter specifies how many elements are members of the list.

The behavior of the **lio_listio** subroutine is altered according to the definitions of synchronized I/O data integrity completion and synchronized I/O file integrity completion if synchronized I/O is enabled on the file associated with *aio_fildes* .

For regular files, no data transfer occurs past the offset maximum established in the open file description.

Parameters

mode
Determines whether the subroutine returns when the I/O operations are completed, or as soon as the operations are queued.

list
An array of pointers to aio control structures defined in the **aio.h** file.

nent
Specifies the length of the array.

sig
Determines when asynchronous notification occurs.

Execution Environment

The **lio_listio** and **lio_listio64** subroutines can be called from the **process environment** only.

Return Values

When the **lio_listio** subroutine is successful, it returns a value of 0. Otherwise, it returns a value of -1 and sets the **errno** global variable to identify the error. The returned value indicates the success or failure of the **lio_listio** subroutine itself and not of the asynchronous I/O requests (except when the command is **LIO_WAIT**). The **aio_error** subroutine returns the status of each I/O request. The possible **errno** values are as follows:

EAGAIN
The resources necessary to queue all the I/O requests were not available. The application may check the error status of each **aiocb** to determine the individual request(s) that failed.

The number of entries indicated by *nent* would cause the system-wide limit (AIO_MAX) to be exceeded.

EINVAL
The *mode* parameter is not a proper value, or the value of *nent* was greater than AIO_LISTIO_MAX.

EINTR
A signal was delivered while waiting for all I/O requests to complete during an LIO_WAIT operation. Since each I/O operation invoked by the **lio_listio** subroutine may provoke a signal when it completes, this error return may be caused by the completion of one (or more) of the very I/O operations being awaited. Outstanding I/O requests are not canceled, and the application examines each list element to determine whether the request was initiated, canceled, or completed.

EIO
One or more of the individual I/O operations failed. The application may check the error status for each **aiocb** structure to determine the individual request(s) that failed.

If the **lio_listio** subroutine succeeds or fails with errors of **EAGAIN**, **EINTR**, or **EIO**, some of the I/O specified by the list may have been initiated. If the **lio_listio** subroutine fails with an error code other than **EAGAIN**, **EINTR**, or **EIO**, no operations from the list were initiated. The I/O operation indicated by each list element can encounter errors specific to the individual read or write function being performed. In this event, the error status for each *aiocb* control block contains the associated error code. The error codes that can be set are the same as would be set by the **read** or **write** subroutines, with the following additional error codes possible:

EAGAIN
The requested I/O operation was not queued due to resource limitations.

ECANCELED
The requested I/O was canceled before the I/O completed due to an **aio_cancel** request.

EFBIG
The *aio_lio_opcode* argument is LIO_WRITE, the file is a regular file, *aio_nbytes* is greater than 0, and *aio_offset* is greater than or equal to the offset maximum in the open file description associated with *aio_fildes*.

EINPROGRESS
The requested I/O is in progress.

EOVERFLOW
The *aio_lio_opcode* argument is set to LIO_READ, the file is a regular file, *aio_nbytes* is greater than 0, and the *aio_offset* argument is before the end-of-file and is greater than or equal to the offset maximum in the open file description associated with *aio_fildes*.

Legacy AIO lio_listio Subroutine

Purpose

Initiates a list of asynchronous I/O requests with a single call.

Syntax

```
#include <aio.h>
```

```
int lio_listio (cmd,
list, nent, eventp)
int  cmd,  nent;
struct liocb * list[ ];
struct event * eventp;
```

```
int lio_listio64
(cmd, list,nent, eventp)
int cmd, nent; struct liocb64 *list;
struct event *eventp;
```

Description

The **lio_listio** subroutine allows the calling process to initiate the *nent* parameter asynchronous I/O requests. These requests are specified in the **liocb** structures pointed to by the elements of the *list* array. The call may block or return immediately depending on the *cmd* parameter. If the *cmd* parameter requests that I/O completion be asynchronously notified, a **SIGIO** signal is delivered when all I/O operations are completed.

The **lio_listio64** subroutine is similar to the **lio_listio** subroutine except that it takes an array of pointers to **liocb64** structures. This allows the **lio_listio64** subroutine to specify offsets in excess of OFF_MAX (2 gigbytes minus 1).

In the large file enabled programming environment, **lio_listio** is redefined to be **lio_listio64**.

Note: The pointer to the **event** structure *eventp* parameter is currently not in use, but is included for future compatibility.

Parameters

cmd

The *cmd* parameter takes one of the following values:

LIO_WAIT
Queues the requests and waits until they are complete before returning.

LIO_NOWAIT
Queues the requests and returns immediately, without waiting for them to complete. The *event* parameter is ignored.

LIO_NOWAIT_AIOWAIT
Queues the requests and returns immediately, without waiting for them to complete. The **aio_nwait** subroutine must be called for the aio control blocks to be updated. Use of the **aio_suspend** subroutine and the **aio_cancel** subroutine on these requests are not supported, nor is any form of asynchronous notification for individual requests.

LIO_ASYNC
Queues the requests and returns immediately, without waiting for them to complete. An enhanced signal is delivered when all the operations are completed. Currently this command is not implemented.

LIO_ASIG
Queues the requests and returns immediately, without waiting for them to complete. A **SIGIO** signal is generated when all the I/O operations are completed.

LIO_NOWAIT_GMCS
Queues the requests and returns immediately, without waiting for them to complete. The **GetMultipleCompletionStatus** subroutine must be called to retrieve the completion status for

the requests. The aio control blocks are not updated. Use of the **aio_suspend** subroutine and the **aio_cancel** subroutine on these requests are not supported, nor is any form of asynchronous notification.

list
Points to an array of pointers to **liocb** structures. The structure array contains *nent* elements:

lio_aiocb
The asynchronous I/O control block associated with this I/O request. This is an actual **aiocb** structure, not a pointer to one.

lio_fildes
Identifies the file object on which the I/O is to be performed.

lio_opcode
This field may have one of the following values defined in the **/usr/include/sys/aio.h** file:

LIO_READ
Indicates that the read I/O operation is requested.

LIO_WRITE
Indicates that the write I/O operation is requested.

LIO_NOP
Specifies that no I/O is requested (that is, this element will be ignored).

nent
Specifies the length of the array.

eventp
Points to an **event** structure to be used when the *cmd* parameter is set to the **LIO_ASYNC** value. This parameter is currently ignored.

Execution Environment

The **lio_listio** and **lio_listio64** subroutines can be called from the **process environment** only.

Return Values

When the **lio_listio** subroutine is successful, it returns a value of 0. Otherwise, it returns a value of -1 and sets the **errno** global variable to identify the error. The returned value indicates the success or failure of the **lio_listio** subroutine itself and not of the asynchronous I/O requests (except when the command is **LIO_WAIT**). The **aio_error** subroutine returns the status of each I/O request.

If the `lio_listio` subroutine succeeds or fails with errors of `EAGAIN`, `EINTR`, or `EIO`, some of the I/O specified by the list might have been initiated. If the `lio_listio` subroutine fails with an error code other than `EAGAIN`, `EINTR`, or `EIO`, no operations from the list were initiated. The I/O operation indicated by each list element can encounter errors specific to the individual read or write function being performed. In this event, the error status for each `aiocb` control block contains the associated error code. The error codes that can be set are the same as would be set by the read or write subroutines, with the following additional error codes possible:

EAGAIN
Indicates that the system resources required to queue the request are not available. Specifically, the transmit queue may be full, or the maximum number of opens may have been reached.

EINTR
Indicates that a signal or event interrupted the **lio_listio** subroutine call.

EINVAL
Indicates that the `aio_whence` field does not have a valid value or that the resulting pointer is not valid.

EIO
One or more of the individual I/O operations failed. The application can check the error status for each `aiocb` structure to determine the individual request that failed.

listea Subroutine

Purpose

Lists the extended attributes associated with a file.

Syntax

```
#include <sys/ea.h>

ssize_t listea(const char *path, char *list, size_t size);
ssize_t flistea (int filedes, char *list, size_t size);
ssize_t llistea (const char *path, char *list, size_t size);
```

Description

Extended attributes are name:value pairs associated with the file system objects (such as files, directories, and symlinks). They are extensions to the normal attributes that are associated with all objects in the file system (that is, the **stat(2)** data).

Do not define an extended attribute name with eight characters prefix "(0xF8)SYSTEM(0xF8)". Prefix "(0xF8)SYSTEM(0xF8)" is reserved for system use only.

Note: The 0xF8 prefix represents a non-printable character.

The **listea** subroutine retrieves the list of extended attribute names associated with the given *path* in the file system. The *list* is the set of (NULL-terminated) names, one after the other. Names of extended attributes to which the calling process does not have access might be omitted from the list. The length of the attribute name list is returned. The **flistea** subroutine is identical to **listea**, except that it takes a file descriptor instead of a path. The **llistea** subroutine is identical to **listea**, except, in the case of a symbolic link, the link itself is interrogated, not the file that it refers to.

An empty buffer of size 0 can be passed into these calls to return the current size of the list of extended attribute names, which can be used to estimate whether the size of a buffer is sufficiently large to hold the list of names.

Parameters

Item	Description
path	The path name of the file.
list	A pointer to a buffer in which the list of attributes will be stored.
size	The size of the buffer.
filedes	A file descriptor for the file.

Return Values

If the **listea** subroutine succeeds, a nonnegative number is returned that indicates the length in bytes of the attribute name list. Upon failure, -1 is returned and **errno** is set appropriately.

Error Codes

Item	Description
EACCES	Caller lacks read permission on the base file, or lacks the appropriate ACL privileges for named attribute **read**.
EFAULT	A bad address was passed for *path* or *list*.

Item	Description
EFORMAT	File system is capable of supporting EAs, but EAs are disabled.
ENOTSUP	Extended attributes are not supported by the file system.
ERANGE	The size of the list buffer is too small to hold the result.

llrint, llrintf, llrintl, llrintd32, llrintd64, and llrintd128 Subroutines

Purpose

Round to the nearest integer value using current rounding direction.

Syntax

```
#include <math.h>

long long llrint (x)
double x;

long long llrintf (x)
float x;

long long llrintl (x)
long double x;

long long llrintd32(x)
_Decimal32 x;

long long llrintd64(x)
_Decimal64 x;

long long llrintd128(x)
_Decimal128 x;
```

Description

The **llrint**, **llrintf**, **llrintl**, **llrintd32**, **llrintd64**, and **llrintd128** subroutines round the *x* parameter to the nearest integer value, according to the current rounding direction.

An application wishing to check for error situations should set the **errno** global variable to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be rounded.

Return Values

Upon successful completion, the **llrint**, **llrintf**, **llrintl**, **llrintd32**, **llrintd64**, and **llrintd128** subroutines return the rounded integer value.

If *x* is NaN, a domain error occurs, and an unspecified value is returned.

If *x* is +Inf, a domain error occurs and an unspecified value is returned.

If *x* is -Inf, a domain error occurs and an unspecified value is returned.

If the correct value is positive and too large to represent as a **long long**, a domain error occur and an unspecified value is returned.

If the correct value is negative and too large to represent as a **long long**, a domain error occurs and an unspecified value is returned.

llround, llroundf, llroundl, llroundd32, llroundd64, and llroundd128 Subroutines

Purpose

Round to the nearest integer value.

Syntax

```
#include <math.h>

long long llround (x)
double x;

long long llroundf (x)
float x;

long long llroundl (x)
long double x;

long long llroundd32(x)
_Decimal32 x;

long long llroundd64(x)
_Decimal64 x;

long long llroundd128(x)
_Decimal128 x;
```

Description

The **llround**, **llroundf**, **llroundl**, **llroundd32**, **llroundd64**, and **llroundd128** subroutines round the *x* parameter to the nearest integer value, rounding halfway cases away from zero, regardless of the current rounding direction.

An application wishing to check for error situations should set the **errno** global variable to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be rounded.

Return Values

Upon successful completion, the **llround**, **llroundf**, **llroundl**, **llroundd32**, **llroundd64**, and **llroundd128** subroutines return the rounded integer value.

If *x* is NaN, a domain error occurs, and an unspecified value is returned.

If *x* is +Inf, a domain error occurs and an unspecified value is returned.

If *x* is –Inf, a domain error occurs and an unspecified value is returned.

If the correct value is positive and too large to represent as a **long long**, a domain error occurs and an unspecified value is returned.

If the correct value is negative and too large to represent as a **long long**, a domain error occurs and an unspecified value is returned.

load and loadAndInit Subroutines

Purpose

Loads a module into the current process.

Syntax

```
int *load ( ModuleName, Flags, LibraryPath)
char *ModuleName;
uint Flags;
char *LibraryPath;
```

```
int *loadAndInit ( ModuleName, Flags, LibraryPath)
char *ModuleName;
uint Flags;
char *LibraryPath;
```

Description

The **load** and `loadAndInit` subroutines load the specified module into the calling process's address space. A module can be a regular file or a member of an archive. When adding a new module to the address space of a 32-bit process, the load operation may cause the break value to change.

The **load** subroutine is not a preferred method to load C++ modules. Use **loadAndInit** subroutine instead. The **loadAndInit** subroutine uses the same interface as **load** but performs C++ initialization.

The **exec** subroutine is similar to the **load** subroutine, except that:

- The **load** subroutine does not replace the current program with a new one.
- The **exec** subroutine does not have an explicit library path parameter; it has only the **LIBPATH** and `LD_LIBRARY_PATH` environment variables. Also, these library path environment variables are ignored when the program using the **exec** subroutine has more privilege than the caller (for example, in the case of a **set-UID** program).

A large application can be split up into one or more modules in one of two ways that allow execution within the same process. The first way is to create each of the application's modules separately and use **load** to explicitly load a module when it is needed. The other way is to specify the relationship between the modules when they are created by defining imported and exported symbols.

Modules can import symbols from other modules. Whenever symbols are imported from one or more other modules, these modules are automatically loaded to resolve the symbol references if the required modules are not already loaded, and if the imported symbols are not specified as deferred imports. These modules can be archive members in libraries or individual files and can have either shared or private file characteristics that control how and where they are loaded.

Shared modules (typically members of a shared library archive) are loaded into the shared library region, when their access permissions allow sharing, that is, when they have read-other permission. Private modules, and shared modules without the required permissions for sharing, are loaded into the process private region.

When the loader resolves a symbol, it uses the file name recorded with that symbol to find the module that exports the symbol. If the file name contains any **/** (slash) characters, it is used directly and must name an appropriate file or archive member. However, if the file name is a base name (contains no **/** characters), the loader searches the directories specified in the default library path for a file (i.e. a module or an archive) with that base name.

The *LibraryPath* is a string containing one or more directory path names separated by colons. See the section “Searching for Dependent Modules” on page 861 for information on library path searching.

When a process is executing under **ptrace** control, portions of the process's address space are recopied after the **load** processing completes. For a 32-bit process, the main program text (loaded in segment 1) and shared library modules (loaded in segment 13) are recopied. Any breakpoints or other modifications to these segments must be reinserted after the **load** call. For a 64-bit process, shared library modules are recopied after a **load** call. The debugger will be notified by setting the **W_SLWTED** flag in the status returned by **wait**, so that it can reinsert breakpoints.

When a process executing under **ptrace** control calls **load**, the debugger is notified by setting the **W_SLWTED** flag in the status returned by **wait**. Any modules newly loaded into the shared library segments will be copied to the process's private copy of these segments, so that they can be examined or modified by the debugger.

The **load** subroutine will call initialization routines (**init** routines) for the new module and any of its dependents if they were not already loaded.

Modules loaded by this subroutine are automatically unloaded when the process terminates or when the **exec** subroutine is executed. They are explicitly unloaded by calling the **unload** subroutine.

Searching for Dependent Modules

The load operation and the exec operation differ slightly in their dependent module search mechanism. When a module is added to the address space of a running process (the load operation), the rules outlined in the next section are used to find the named module. Note that dependency relationships may be loosely defined as a tree but recursive relationships between modules may also exist. The following components may used to create a complete library search path:

1. If the **L_LIBPATH_EXEC** flag is set, the library search path used at exec-time.
2. The value of the *LibraryPath* parameter if it is non-null. Note that a null string is a valid search path which refers to the current working directory. If the *LibraryPath* parameter is NULL, the value of the **LIBPATH** environment variable, or alternatively the LD_LIBRARY_PATH environment variable (if LIBPATH is not set), is used instead.
3. The library search path contained in the loader section of the module being loaded (the *ModuleName* parameter).
4. The library search path contained in the loader section of the module whose immediate dependents are being loaded. Note that this per-module information changes when searching for each module's immediate dependents.

To find the *ModuleName* module, components 1 and 2 are used. To find dependents, components 1, 2, 3 and 4 are used in order. Note that if any modules that are already part of the running process satisfy the dependency requirements of the newly loaded module(s), pre-existing modules are not loaded again.

For each colon-separated portion of the aggregate search specification, if the base name is not found the search continues. Additionally, if the needed file is not an archive member, the search will continue past a file having the wrong object mode. If an archive member is needed, searching stops when the first match of the file name is found. If the file is not of the proper form, or in the case of an archive that does not contain the required archive member, or does not export a definition of a required symbol, an error occurs. The library path search is not performed when either a relative or an absolute path name is specified for a dependent module.

The library search path stored within the module is specified at link-edit time.

The **load** subroutine may cause the calling process to fail if the module specified has a very long chain of dependencies, (for example, lib1.a, which depends on lib2.a, which depends on lib3.a, etc). This is because the loader processes such relationships recursively on a fixed-size stack. This limitation is exposed only when processing a dependency chain that has over one thousand elements.

Parameters

Item	Description
ModuleName	Points to the name of the module to be loaded. The module name consists of a path name, and, an optional member name. If the path name contains at least on / character, the name is used directly, and no directory searches are performed to locate the file. If the path name contains no / characters, it is treated as a base name, and should be in one of the directories listed in the library path. The library path is either the value of the *LibraryPath* parameter if not a null value, or the value of the **LIBPATH** environment variable (if set; otherwise, LD_LIBRARY_PATH environment variable, if set) or the library path used at process exec time (if the **L_LIBPATH_EXEC** is set). If no library path is provided, the module should be in the current directory. The *ModuleName* parameter may explicitly name an archive member. The syntax is *pathname*(*member*) where *pathname* follows the rules specified in the previous paragraph, and *member* is the name of a specific archive member. The parentheses are a required portion of the specification and no intervening spaces are allowed. If an archive member is named, the **L_LOADMEMBER** flag must be added to the *Flags* parameter. Otherwise, the entire *ModuleName* parameter is treated as an explicit filename.
Flags	Modifies the behavior of the **load** and the loadAndInit services as follows (see the **ldr.h** file). If no special behavior is required, set the value of the flags parameter to 0 (zero). For compatibility, a value of 1 (one) may also be specified. **L_LIBPATH_EXEC** Specifies that the library path used at process exec time should be prepended to any library path specified in the **load** call (either as an argument or environment variable). It is recommended that this flag be specified in all calls to the **load** subroutine. **L_LOADMEMBER** Indicates that the *ModuleName* parameter may specify an archive member. The *ModuleName* argument is searched for parentheses, and if found the parameter is treated as a filename/member name pair. If this flag is present and the *ModuleName* parameter does not contain parenthesis the entire *ModuleName* parameter is treated as a filename specification. Under either condition the filename is expected to be found within the library path or the current directory. **L_NOAUTODEFER** Specifies that any deferred imports in the module being loaded must be explicitly resolved by use of the **loadbind** subroutine. This allows unresolved imports to be explicitly resolved at a later time with a specified module. If this flag is not specified, deferred imports (marked for deferred resolution) are resolved at the earliest opportunity when any subsequently loaded module exports symbols matching unresolved imports.
LibraryPath	Points to a character string that specifies the default library search path. If the *LibraryPath* parameter is NULL, the **LIBPATH** environment variable is used, if set; otherwise, the LD_LIBRARY_PATH environment variable is used. The library path is used to locate dependent modules that are specified as basenames (that is, their pathname components do not contain a / (slash) character. Note the difference between setting the *LibraryPath* parameter to null, and having the *LibraryPath* parameter point to a null string (" "). A null string is a valid library path which consists of a single directory: the current directory.

Return Values

Upon successful completion, the **load** and `loadAndInit` subroutines return the pointer to function for the entry point of the module. If the module has no entry point, the address of the data section of the module is returned.

Error Codes

If the **load** and `loadAndInit` subroutines fail, a null pointer is returned, the module is not loaded, and **errno** global variable is set to indicate the error. The **load** and `loadAndInit` subroutines fail if one or more of the following are true of a module to be explicitly or automatically loaded:

Item	Description
EACCES	Indicates the file is not an ordinary file, or the mode of the program file denies execution permission, or search permission is denied on a component of the path prefix.
EINVAL	Indicates the file or archive member has a valid magic number in its header, but the header is damaged or is incorrect for the machine on which the file is to be run.
ELOOP	Indicates too many symbolic links were encountered in translating the path name.
ENOEXEC	Indicates an error occurred when loading or resolving symbols for the specified module. This can be due to an attempt to load a module with an invalid **XCOFF** header, a failure to resolve symbols that were not defined as deferred imports or several other load time related problems. The **loadquery** subroutine can be used to return more information about the load failure. If runtime linking is used, the **load** and the **loadAndInit** subroutines will fail if the runtime linker could not resolve some symbols. In this case, **errno** will be set to **ENOEXEC**, but the **loadquery** subroutine will not return any additional information.
ENOMEM	Indicates the program requires more memory than is allowed by the system-imposed maximum.
ETXTBSY	Indicates the file is currently open for writing by some process.
ENAMETOOLONG	Indicates a component of a path name exceeded 255 characters, or an entire path name exceeded 1023 characters.
ENOENT	Indicates a component of the path prefix does not exist, or the path name is a null value. For the **dlopen** subroutine, RTLD_MEMBER is not used when trying to open a member within the archive file.
ENOTDIR	Indicates a component of the path prefix is not a directory.
ESTALE	Indicates the process root or current directory is located in a virtual file system that has been unmounted.

loadbind Subroutine

Purpose

Provides specific run-time resolution of a module's deferred symbols.

Syntax

```
int loadbind( Flag,  ExportPointer,  ImportPointer)
int Flag;
void *ExportPointer, *ImportPointer;
```

Description

The **loadbind** subroutine controls the run-time resolution of a previously loaded object module's unresolved imported symbols.

The **loadbind** subroutine is used when two modules are loaded. Module A, an object module loaded at run time with the **load** subroutine, has designated that some of its imported symbols be resolved at a later time. Module B contains exported symbols to resolve module A's unresolved imports.

To keep module A's imported symbols from being resolved until the **loadbind** service is called, you can specify the **load** subroutine flag, **L_NOAUTODEFER**, when loading module A.

When a 32-bit process is executing under **ptrace** control, portions of the process's address space are recopied after the **loadbind** processing completes. The main program text (loaded in segment 1) and shared library modules (loaded in segment 13) are recopied. Any breakpoints or other modifications to these segments must be reinserted after the **loadbind** call.

When a 32-bit process executing under **ptrace** control calls **loadbind**, the debugger is notified by setting the **W_SLWTED** flag in the status returned by **wait**.

When a 64-bit process under **ptrace** control calls **loadbind**, the debugger is not notified and execution of the process being debugged continues normally.

Parameters

Item	Description
Flag	Currently not used.
ExportPointer	Specifies the function pointer returned by the **load** subroutine when module B was loaded.
ImportPointer	Specifies the function pointer returned by the **load** subroutine when module A was loaded.

Note: The *ImportPointer* or *ExportPointer* parameter may also be set to any exported static data area symbol or function pointer contained in the associated module. This would typically be the function pointer returned from the **load** of the specified module.

Return Values

A 0 is returned if the **loadbind** subroutine is successful.

Error Codes

A -1 is returned if an error is detected, with the **errno** global variable set to an associated error code:

Item	Description
EINVAL	Indicates that either the *ImportPointer* or *ExportPointer* parameter is not valid (the pointer to the *ExportPointer* or *ImportPointer* parameter does not correspond to a loaded program module or library).
ENOMEM	Indicates that the program requires more memory than allowed by the system-imposed maximum.

After an error is returned by the **loadbind** subroutine, you may also use the **loadquery** subroutine to obtain additional information about the **loadbind** error.

loadquery Subroutine

Purpose

Returns error information from the **load** or **exec** subroutine; also provides a list of object files loaded for the current process.

Syntax

```
int loadquery( Flags,  Buffer,  BufferLength)
int Flags;
void *Buffer;
unsigned int BufferLength;
```

Description

The **loadquery** subroutine obtains detailed information about an error reported on the last **load** or **exec** subroutine executed by a calling process. The **loadquery** subroutine may also be used to obtain a list of object file names for all object files that have been loaded for the current process, or the library path that was used at process exec time.

Parameters

Item	Description
Buffer	Points to a *Buffer* in which to store the information.
BufferLength	Specifies the number of bytes available in the *Buffer* parameter.

Item	Description

Flags	Specifies the action of the **loadquery** subroutine as follows:
	L_GETINFO
	Returns a list of all object files loaded for the current process, and stores the list in the *Buffer* parameter. The object file information is contained in a sequence of **LD_INFO** structures as defined in the **sys/ldr.h** file. Each structure contains the module location in virtual memory and the path name that was used to load it into memory. The file descriptor field in the **LD_INFO** structure is not filled in by this function.
	L_GETMESSAGE
	Returns detailed error information describing the failure of a previously invoked **load** or **exec** function, and stores the error message information in *Buffer.* Upon successful return from this function the beginning of the *Buffer* contains an array of character pointers. Each character pointer points to a string in the buffer containing a loader error message. The character array ends with a null character pointer. Each error message string consists of an ASCII message number followed by zero or more characters of error-specific message data. Valid message numbers are listed in the **sys/ldr.h** file.
	You can format the error messages returned by the **L_GETMESSAGE** function and write them to standard error using the standard system command **/usr/sbin/execerror** as follows:
	`char *buffer[1024];`
	`buffer[0] = "execerror";`
	`buffer[1] = "name of program that failed to load";`
	`loadquery(L_GETMESSAGES, &buffer[2],\`
	`  sizeof buffer-2*sizeof(char*));`
	`execvp("/usr/sbin/execerror",buffer);`
	This sample code causes the application to terminate after the messages are written to standard error.
	L_GETLIBPATH
	Returns the library path that was used at process exec time. The library path is a null terminated character string.
	L_GETXINFO
	Returns a list of all object files loaded for the current process and stores the list in the *Buffer* parameter. The object file information is contained in a sequence of **LD_XINFO** structures as defined in the **sys/ldr.h** file. Each structure contains the module location in virtual memory and the path name that was used to load it into memory. The file descriptor field in the **LD_XINFO** structure is not filled in by this function.

Return Values

Upon successful completion, **loadquery** returns the requested information in the caller's buffer specified by the *Buffer* and *BufferLength* parameters.

Error Codes

The **loadquery** subroutine returns with a return code of -1 and the **errno** global variable is set to one of the following when an error condition is detected:

Item	Description
ENOMEM	Indicates that the caller's buffer specified by the *Buffer* and *BufferLength* parameters is too small to return the information requested. When this occurs, the information in the buffer is undefined.

Item	Description
EINVAL	Indicates the function specified in the *Flags* parameter is not valid.
EFAULT	Indicates the address specified in the *Buffer* parameter is not valid.

localeconv Subroutine

Purpose

Sets the locale-dependent conventions of an object.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <locale.h>
```

```
struct lconv *localeconv ( )
```

Description

The **localeconv** subroutine sets the components of an object using the **lconv** structure. The **lconv** structure contains values appropriate for the formatting of numeric quantities (monetary and otherwise) according to the rules of the current locale.

The fields of the structure with the type **char *** are strings, any of which (except `decimal_point`) can point to a null string, which indicates that the value is not available in the current locale or is of zero length. The fields with type **char** are nonnegative numbers, any of which can be the **CHAR_MAX** value which indicates that the value is not available in the current locale. The fields of the **Iconv** structure include the following:

Item	Description
`char *decimal_point`	The decimal-point character used to format non-monetary quantities.
`char *thousands_sep`	The character used to separate groups of digits to the left of the decimal point in formatted non-monetary quantities.
`char *grouping`	A string whose elements indicate the size of each group of digits in formatted non-monetary quantities. The value of the `grouping` field is interpreted according to the following: **CHAR_MAX** No further grouping is to be performed. **0** The previous element is to be repeatedly used for the remainder of the digits. **other** The value is the number of digits that comprise the current group. The next element is examined to determine the size of the next group of digits to the left of the current group.

Item	Description
`char *int_curr_symbol`	The international currency symbol applicable to the current locale, left-justified within a four-character space-padded field. The character sequences are in accordance with those specified in ISO 4217, "Codes for the Representation of Currency and Funds."
`char *currency_symbol`	The local currency symbol applicable to the current locale.
`char *mon_decimal_point`	The decimal point used to format monetary quantities.
`char *mon_thousands_sep`	The separator for groups of digits to the left of the decimal point in formatted monetary quantities.
`char *mon_grouping`	A string whose elements indicate the size of each group of digits in formatted monetary quantities. The value of the `mon_grouping` field is interpreted according to the following: **CHAR_MAX** No further grouping is to be performed. **0** The previous element is to be repeatedly used for the remainder of the digits. **other** The value is the number of digits that comprise the current group. The next element is examined to determine the size of the next group of digits to the left of the current group.
`char *positive_sign`	The string used to indicate a nonnegative formatted monetary quantity.
`char *negative_sign`	The string used to indicate a negative formatted monetary quantity.
`char int_frac_digits`	The number of fractional digits (those to the right of the decimal point) to be displayed in a formatted monetary quantity.
`char p_cs_precedes`	Set to 1 if the specified currency symbol (the `currency_symbol` or `int_curr_symbol` field) precedes the value for a nonnegative formatted monetary quantity and set to 0 if the specified currency symbol follows the value for a nonnegative formatted monetary quantity.
`char p_sep_by_space`	Set to 1 if the `currency_symbol` or `int_curr_symbol` field is separated by a space from the value for a nonnegative formatted monetary quantity and set to 0 if the `currency_symbol` or `int_curr_symbol` field is not separated by a space from the value for a nonnegative formatted monetary quantity.
`char n_cs_precedes`	Set to 1 if the `currency_symbol` or `int_curr_symbol` field precedes the value for a negative formatted monetary quantity and set to 0 if the `currency_symbol` or `int_curr_symbol` field follows the value for a negative formatted monetary quantity.

Item	Description
`char n_sep_by_space`	Set to 1 if the `currency_symbol` or `int_curr_symbol` field is separated by a space from the value for a negative formatted monetary quantity and set to 0 if the `currency_symbol` or `int_curr_symbol` field is not separated by a space from the value for a negative formatted monetary quantity. Set to 2 if the symbol and the sign string are adjacent and separated by a blank character.
`char p_sign_posn`	Set to a value indicating the positioning of the positive sign (the `positive_sign` fields) for nonnegative formatted monetary quantity.
`char n_sign_posn`	Set to a value indicating the positioning of the negative sign (the `negative_sign` fields) for a negative formatted monetary quantity. The values of the `p_sign_posn` and `n_sign_posn` fields are interpreted according to the following definitions: **0** Parentheses surround the quantity and the specified currency symbol or international currency symbol. **1** The sign string precedes the quantity and the currency symbol or international currency symbol. **2** The sign string follows the quantity and currency symbol or international currency symbol. **3** The sign string immediately precedes the currency symbol or international currency symbol. **4** The sign string immediately follows the currency symbol or international currency symbol.

The following table illustrates the rules that can be used by three countries to format monetary quantities:

Country	Formats
Italy	**Positive Format:** L.1234 **Negative Format:** -L.1234 **International Format:** ITL.1234
Norway	**Positive Format:** krl.234.56 **Negative Format:** krl.234.56- **International Format:** NOK 1.234.56

Country	Formats
Switzerland	**Positive Format:** SFrs.1.234.56 **Negative Format:** SFrs.1.234.56C **International Format:** CHF 1.234.56

The following table shows the values of the monetary members of the structure returned by the **localeconv** subroutine for these countries:

struct localeconv	Countries
char *in_curr_symbol	**Italy:** "ITL." **Norway:** "NOK" **Switzerland:** "CHF"
char *currency_symbol	**Italy:** "L." **Norway:** "kr" **Switzerland:** "SFrs."
char *mon_decimal_point	**Italy:** " " **Norway:** "." **Switzerland:** "."
char *mon_thousands_sep	**Italy:** "." **Norway:** "." **Switzerland:** "."
char *mon_grouping	**Italy:** "\3" **Norway:** "\3" **Switzerland:** "\3"

struct localeconv	Countries
char *positive_sign	**Italy:** " " **Norway:** " " **Switzerland:** " "
char *negative_sign	**Italy:** "-" **Norway:** "-" **Switzerland:** "C"
char int_frac_digits	**Italy:** 0 **Norway:** 2 **Switzerland:** 2
char frac_digits	**Italy:** 0 **Norway:** 2 **Switzerland:** 2
char p_cs_precedes	**Italy:** 1 **Norway:** 1 **Switzerland:** 1
char p_sep_by_space	**Italy:** 0 **Norway:** 0 **Switzerland:** 0
char n_cs_precedes	**Italy:** 1 **Norway:** 1 **Switzerland:** 1

struct localeconv	Countries
char n_sep_by_space	**Italy:** 0 **Norway:** 0 **Switzerland:** 0
char p_sign_posn	**Italy:** 1 **Norway:** 1 **Switzerland:** 1
char n_sign_posn	**Italy:** 1 **Norway:** 2 **Switzerland:** 2

Return Values

A pointer to the filled-in object is returned. In addition, calls to the **setlocale** subroutine with the **LC_ALL**, **LC_MONETARY** or **LC_NUMERIC** categories may cause subsequent calls to the **localeconv** subroutine to return different values based on the selection of the locale.

Note: The structure pointed to by the return value is not modified by the program but may be overwritten by a subsequent call to the **localeconv** subroutine.

lockfx, lockf, flock, or lockf64 Subroutine

Purpose

Locks and unlocks sections of open files.

Libraries

lockfx, **lockf**: Standard C Library (**libc.a**)

Item	Description
flock:	Berkeley Compatibility Library (**libbsd.a**)

Syntax

```
#include <fcntl.h>
```

```
int lockfx (FileDescriptor,
Command, Argument)
int  FileDescriptor;
```

```
int  Command;
struct flock * Argument;
```

```
#include <sys/lockf.h>
#include <unistd.h>
```

```
int lockf
(FileDescriptor, Request, Size)
int FileDescriptor;
int  Request;
off_t  Size;
```

```
int lockf64 (FileDescriptor,
Request, Size)
int FileDescriptor;
int  Request;
off64_t  Size;
```

```
#include <sys/file.h>
```

```
int flock (FileDescriptor,  Operation)
int FileDescriptor;
int Operation;
```

Description

Attention: Buffered I/O does not work properly when used with file locking. Do not use the standard I/O package routines on files that are going to be locked.

The **lockfx** subroutine locks and unlocks sections of an open file. The **lockfx** subroutine provides a subset of the locking function provided by the **fcntl** subroutine.

The **lockf** subroutine also locks and unlocks sections of an open file. However, its interface is limited to setting only write (exclusive) locks.

Although the **lockfx**, **lockf**, **flock**, and **fcntl** interfaces are all different, their implementations are fully integrated. Therefore, locks obtained from one subroutine are honored and enforced by any of the lock subroutines.

The *Operation* parameter to the **lockfx** subroutine, which creates the lock, determines whether it is a read lock or a write lock.

The file descriptor on which a write lock is being placed must have been opened with write access.

lockf64 is equivalent to **lockf** except that a 64-bit lock request size can be given. For **lockf**, the largest value which can be used is **OFF_MAX**, for **lockf64**, the largest value is **LONGLONG_MAX**.

In the large file enabled programming environment, **lockf** is redefined to be **lock64**.

The **flock** subroutine locks and unlocks entire files. This is a limited interface maintained for BSD compatibility, although its behavior differs from BSD in a few subtle ways. To apply a shared lock, the file must be opened for reading. To apply an exclusive lock, the file must be opened for writing.

Locks are not inherited. Therefore, a child process cannot unlock a file locked by the parent process.

Parameters

Item	Description
Argument	A pointer to a structure of type **flock**, defined in the **flock.h** file**.**

Item	Description
Command	Specifies one of the following constants for the **lockfx** subroutine: **F_SETLK** Sets or clears a file lock. The `l_type` field of the **flock** structure indicates whether to establish or remove a read or write lock. If a read or write lock cannot be set, the **lockfx** subroutine returns immediately with an error value of -1. **F_SETLKW** Performs the same function as **F_SETLK** unless a read or write lock is blocked by existing locks. In that case, the process sleeps until the section of the file is free to be locked. **F_GETLK** Gets the first lock that blocks the lock described in the **flock** structure. If a lock is found, the retrieved information overwrites the information in the **flock** structure. If no lock is found that would prevent this lock from being created, the structure is passed back unchanged except that the `l_type` field is set to **F_UNLCK**.
FileDescriptor	A file descriptor returned by a successful **open** or **fcntl** subroutine, identifying the file to which the lock is to be applied or removed.
Operation	Specifies one of the following constants for the **flock** subroutine: **LOCK_SH** Apply a shared (read) lock. **LOCK_EX** Apply an exclusive (write) lock. **LOCK_NB** Do not block when locking. This value can be logically ORed with either **LOCK_SH** or **LOCK_EX**. **LOCK_UN** Remove a lock.
Request	Specifies one of the following constants for the **lockf** subroutine: **F_ULOCK** Unlocks a previously locked region in the file. **F_LOCK** Locks the region for exclusive (write) use. This request causes the calling process to sleep if the requested region overlaps a locked region, and to resume when granted the lock. **F_TEST** Tests to see if another process has already locked a region. The **lockf** subroutine returns 0 if the region is unlocked. If the region is locked, then -1 is returned and the **errno** global variable is set to **EACCES**. **F_TLOCK** Locks the region for exclusive use if another process has not already locked the region. If the region has already been locked by another process, the **lockf** subroutine returns a -1 and the **errno** global variable is set to **EACCES**.

Item	Description
Size	The number of bytes to be locked or unlocked for the **lockf** subroutine. The region starts at the current location in the open file, and extends forward if the *Size* value is positive and backward if the *Size* value is negative. If the *Size* value is 0, the region starts at the current location and extends forward to the maximum possible file size, including the unallocated space after the end of the file.

Return Values

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **lockfx**, **lockf**, and **flock** subroutines fail if one of the following is true:

Item	Description
EBADF	The *FileDescriptor* parameter is not a valid open file descriptor.
EINVAL	The function argument is not one of **F_LOCK**, **F_TLOCK**, **F_TEST** or **F_ULOCK**; or *size* plus the current file offset is less than 0.
EINVAL	An attempt was made to lock a fifo or pipe.
EDEADLK	The lock is blocked by a lock from another process. Putting the calling process to sleep while waiting for the other lock to become free would cause a deadlock.
ENOLCK	The lock table is full. Too many regions are already locked.
EINTR	The command parameter was **F_SETLKW** and the process received a signal while waiting to acquire the lock.
EOVERFLOW	The offset of the first, or if *size* is not 0 then the last, byte in the requested section cannot be represented correctly in an object of type *off_t*.

The **lockfx** and **lockf** subroutines fail if one of the following is true:

Item	Description
EACCES	The *Command* parameter is **F_SETLK**, the `l_type` field is **F_RDLCK**, and the segment of the file to be locked is already write-locked by another process.
EACCES	The *Command* parameter is **F_SETLK**, the `l_type` field is **F_WRLCK**, and the segment of a file to be locked is already read-locked or write-locked by another process.

The **flock** subroutine fails if the following is true:

Item	Description
EWOULDBLOCK	The file is locked and the **LOCK_NB** option was specified.

log10, log10f, log10l, log10d32, log10d64, and log10d128 Subroutine

Purpose

Computes the Base 10 logarithm.

Syntax

```
#include <math.h>

float log10f (x)
float x;

long double log10l (x)
long double x;

double log10 (x)
double x;
_Decimal32 log10d32 (x)
_Decimal32 x;

_Decimal64 log10d64 (x)
_Decimal64 x;

_Decimal128 log10d128 (x)
_Decimal128 x;
```

Description

The **log10f**, **log10l**, **log10**, **log10d32**, **log10d64**, and **log10d128** subroutines compute the base 10 logarithm of the *x* parameter, $\log_{10}(x)$.

An application wishing to check for error situations should set **errno** to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **log10**, **log10f**, **log10l**, **log10d32**, **log10d64**, and **log10d128** subroutines return the base 10 logarithm of *x*.

If *x* is ±0, a pole error occurs and **log10**, **log10f**, **log10l**, **log10d32**, **log10d64**, and **log10d128** subroutines return -**HUGE_VAL**, -**HUGE_VALF**, -**HUGE_VALL**, **HUGE_VAL_D32**, **HUGE_VAL_D64**, and **HUGE_VAL_D128** respectively.

For finite values of *x* that are less than 0, or if *x* is -Inf, a domain error occurs, and a NaN is returned.

If *x* is NaN, a NaN is returned.

If *x* is 1, +0 is returned.

If *x* is +Inf, +Inf is returned.

Error Codes

When using the **libm.a** library:

Item	Description
log10	If the *x* parameter is less than 0, the **log10** subroutine returns a **NaNQ** value and sets **errno** to **EDOM**. If x= 0, the **log10** subroutine returns a -**HUGE_VAL** value and sets **errno** to **ERANGE**.

When using **libmsaa.a**(**-lmsaa**):

Item	Description
log10	If the *x* parameter is not positive, the **log10** subroutine returns a **-HUGE_VAL** value and sets **errno** to **EDOM**. A message indicating DOMAIN error (or SING error when *x* = 0) is output to standard error.
log10	If *x* < 0, **log10l** returns the value **NaNQ** and sets **errno** to **EDOM**. If *x* equals 0, **log10l** returns the value **-HUGE_VAL** but does not modify **errno**.

log1p, log1pf, log1pl, log1pd32, log1pd64, and log1pd128 Subroutines

Purpose

Computes a natural logarithm.

Syntax

```
#include <math.h>

float log1pf (x)
float x;

long double log1pl (x)
long double x;

double log1p (x)
double x;
_Decimal32 log1pd32 (x)
_Decimal32 x;

_Decimal64 log1pd64 (x)
_Decimal64 x;

_Decimal128 log1pd128 (x)
_Decimal128 x;
```

Description

The **log1pf**, **log1pl**, **log1p**, **log1pd32**, **log1pd64**, and **log1pd128** subroutines compute $\log_e (1.0 + x)$.

An application wishing to check for error situations should set the **errno** global variable to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **log1pf**, **log1pl**, **log1p**, **log1pd32**, **log1pd64**, and **log1pd128** subroutines return the natural logarithm of 1.0 + *x*.

If *x* is -1, a pole error occurs and the **log1pf**, **log1pl**, **log1p**, **log1pd32**, **log1pd64**, and **log1pd128** subroutines return **-HUGE_VALF**, **-HUGE_VALL**, **-HUGE_VAL**, **-HUGE_VAL_D32**, **-HUGE_VAL_D64**, and **-HUGE_VAL_D128** respectively.

For finite values of *x* that are less than -1, or if *x* is -Inf, a domain error occurs, and a NaN is returned.

If *x* is NaN, a NaN is returned.

If *x* is ±0, or +Inf, *x* is returned.

If *x* is subnormal, a range error may occur and *x* should be returned.

log2, log2f, log2l, log2d32, log2d64, and log2d128 Subroutine

Purpose

Computes base 2 logarithm.

Syntax

```
#include <math.h>

double log2 (x)
double x;

float log2f (x)
float x;

long double log2l (x)
long double x;
_Decimal32 log2d32 (x)
_Decimal32 x;

_Decimal64 log2d64 (x)
_Decimal64 x;

_Decimal128 log2d128 (x)
_Decimal128 x;
```

Description

The **log2**, **log2f**, **log2l**, **log2d32**, **log2d64**, and **log2d128** subroutines compute the base 2 logarithm of the *x* parameter, $\log_2 (x)$.

An application wishing to check for error situations should set **errno** to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **log2**, **log2f**, **log2l**, **log2d32**, **log2d64**, and **log2d128** subroutines return the base 2 logarithm of *x*.

If *x* is ±0, a pole error occurs and the **log2**, **log2f**, **log2l**, **log2d32**, **log2d64**, and **log2d128** subroutines return -**HUGE_VAL**, -**HUGE_VALF**, -**HUGE_VALL**, -**HUGE_VAL_D32**, -**HUGE_VAL_D64**, and -**HUGE_VAL_D128** respectively.

For finite values of *x* that are less than 0, or if *x* is -Inf, a domain error occurs, and a NaN is returned.

If *x* is NaN, a NaN is returned.

If *x* is 1, +0 is returned.

If *x* is +Inf, *x* is returned.

logbd32, logbd64, and logbd128 Subroutines

Purpose

Computes the radix-independent exponent.

Syntax

```
#include <math.h>

_Decimal32 logbd32 (x)
_Decimal32 x;

_Decimal64 logbd64 (x)
_Decimal64 x;

_Decimal128 logbd128 (x)
_Decimal128 x;
```

Description

The **logbd32**, **logbd64**, and **logbd128** subroutines compute the exponent of *x*, which is an integral part of $\log_r |x|$, as a signed floating-point value, for nonzero *x*. In the $\log_r |x|$, the *r* is the radix of the machine's decimal floating-point arithmetic. For AIX, FLT_RADIX r=10.

An application that wants to check for error situations must set the **errno** to zero and call the **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. On return, if the **errno** is of the value of nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is of the value of nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **logbd32**, **logbd64**, and **logbd128** subroutines return the exponent of *x*.

If *x* is ±0, a pole error occurs and the **logbd32**, **logbd64**, and **logbd128** subroutines return -**HUGE_VAL_D32**, -**HUGE_VAL_D64**, and -**HUGE_VAL_D128**, respectively.

If *x* is NaN, a NaN is returned.

If *x* is ±Inf, +Inf is returned.

logbf, logbl, or logb Subroutine

Purpose

Computes the radix-independent exponent.

Syntax

```
#include <math.h>

float logbf (x)
float x;

long double logbl (x)
long double x;
```

```
double logb(x)
double x;
```

Description

The **logbf** and **logbl** subroutines compute the exponent of *x*, which is the integral part of $\log_r |x|$, as a signed floating-point value, for nonzero *x*, where *r* is the radix of the machine's floating-point arithmetic. For AIX, FLT_RADIX r=2.

If *x* is subnormal, it is treated as though it were normalized; thus for finite positive *x*:

```
1 <= x * FLT_RADIX^-logb(x) < FLT_RADIX
```

An application wishing to check for error situations should set **errno** to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Note: When the *x* parameter is finite and not zero, the **logb** *(x)* subroutine satisfies the following equation:

```
1 < = scalb (|x|, -(int) logb (x)) < 2
```

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **logbf** and **logbl** subroutines return the exponent of *x*.

If *x* is ±0, a pole error occurs and the **logbf** and **logbl** subroutines return -**HUGE_VALF** and -**HUGE_VALL**, respectively.

If *x* is NaN, a NaN is returned.

If *x* is ±Inf, +Inf is returned.

Error Codes

The **logb** function returns **-HUGE_VAL** when the x parameter is set to a value of 0 and sets **errno** to **EDOM**.

log, logf, logl, logd32, logd64, and logd128 Subroutines

Purpose

Computes the natural logarithm.

Syntax

```
#include <math.h>

float logf (x)
float x;

long double logl (x)
long double x;

double log (x)
double x;
```

```
_Decimal32 logd32 (x)
_Decimal32 x;

_Decimal64 logd64 (x)
_Decimal64 x;

_Decimal128 logd128 (x)
_Decimal128 x;
```

Description

The **logf**, **logl**, **log**, **logd32**, **logd64**, and **logd128** subroutines compute the natural logarithm of the *x* parameter, $\log_e(x)$.

An application wishing to check for error situations should set the **errno** global variable to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be computed.

Return Values

Upon successful completion, the **logf**, **logl**, **log**, **logd32**, **logd64**, and **logd128** subroutines return the natural logarithm of *x*.

If *x* is ±0, a pole error occurs and the **logf**, **logl**, and **log** subroutines return -**HUGE_VALF** and -**HUGE_VALL**, -**HUGE_VAL**, **HUGE_VAL_D32**, **HUGE_VAL_D64**, and **HUGE_VAL_D128** respectively.

For finite values of *x* that are less than 0, or if *x* is -Inf, a domain error occurs, and a NaN is returned.

If *x* is NaN, a NaN is returned.

If *x* is 1, +0 is returned.

If *x* is +Inf, *x* is returned.

Error Codes

When using the **libm.a** library:

Item	Description
log	If the *x* parameter is less than 0, the **log** subroutine returns a **NaNQ** value and sets **errno** to **EDOM**. If x= 0, the **log** subroutine returns a -**HUGE_VAL** value but does not modify **errno**.

When using **libmsaa.a**(**-lmsaa**):

Item	Description
log	If the *x* parameter is not positive, the **log** subroutine returns a -**HUGE_VAL** value, and sets **errno** to a **EDOM** value. A message indicating DOMAIN error (or SING error when *x* = 0) is output to standard error.
log	If *x*<0, the **logl** subroutine returns a **NaNQ** value

loginfailed Subroutine

Purpose

Records an unsuccessful login attempt.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
int loginfailed ( User,  Host,  Tty, Reason)
char *User;
char *Host;
char *Tty;
int Reason;
```

Note: This subroutine is not thread-safe.

Description

The **loginfailed** subroutine performs the processing necessary when an unsuccessful login attempt occurs. If the specified user name is not valid, the **UNKNOWN_USER** value is substituted for the user name. This substitution prevents passwords entered as the user name from appearing on screen.

The following attributes in **/etc/security/lastlog** file are updated for the specified user, if the user name is valid:

Item	Description
time_last_unsuccessful_login	Contains the current time.
tty_last_unsuccessful_login	Contains the value specified by the *Tty* parameter.
host_last_unsuccessful_login	Contains the value specified by the *Host* parameter, or the local hostname if the *Host* parameter is a null value.
unsuccessful_login_count	Indicates the number of unsuccessful login attempts. The **loginfailed** subroutine increments this attribute by one for each failed attempt.

A login failure audit record is cut to indicate that an unsuccessful login attempt occurred. A **utmp** entry is appended to **/etc/security/failedlogin** file, which tracks all failed login attempts.

If the current unsuccessful login and the previously recorded unsuccessful logins constitute too many unsuccessful login attempts within too short of a time period (as specified by the **logindisable** and **logininterval** port attributes), the port is locked. When a port is locked, a PORT_Locked audit record is written to inform the system administrator that the port has been locked.

If the login retry delay is enabled (as specified by the **logindelay** port attribute), a sleep occurs before this subroutine returns. The length of the sleep (in seconds) is determined by the **logindelay** value multiplied by the number of unsuccessful login attempts that occurred in this process.

Parameters

Item	Description
User	Specifies the user's login name who has unsuccessfully attempted to login.

Item	Description
Host	Specifies the name of the host from which the user attempted to login. If the *Host* parameter is Null, the name of the local host is used.
Tty	Specifies the name of the terminal on which the user attempted to login.
Reason	Specifies a reason code for the login failure. Valid values are AUDIT_FAIL and AUDIT_FAIL_AUTH defined in the **sys/audit.h** file.

Security

Access Control: The calling process must have access to the account information in the user database and the port information in the port database.

File Accessed:

Mode	File
r	/etc/security/user
rw	/etc/security/lastlog
r	/etc/security/login.cfg
rw	/etc/security/portlog
w	/etc/security/failedlogin

Auditing Events:

Event	Information
USER_Login	username
PORT_Locked	portname

Return Values

Upon successful completion, the **loginfailed** subroutine returns a value of 0. If an error occurs, a value of -1 is returned and errno is set to indicate the error.

Error Codes

The **loginfailed** subroutine fails if one or more of the following values is true:

Item	Description
EACCES	The current process does not have access to the user or port database.
EPERM	The current process does not have permission to write an audit record.

loginrestrictions Subroutine

Purpose

Determines if a user is allowed to access the system.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
#include <login.h>
```

```
int loginrestrictions (Name, Mode, Tty, Msg)
char * Name;
int  Mode;
char * Tty;
char ** Msg;
```

Note: This subroutine is not thread-safe.

Description

The **loginrestrictions** subroutine determines if the user specified by the *Name* parameter is allowed to access the system. The *Mode* parameter gives the mode of account usage and the *Tty* parameter defines the terminal used for access. The *Msg* parameter returns an informational message explaining why the **loginrestrictions** subroutine failed.

This subroutine is unsuccessful if any of the following conditions exists:

- The user's account has expired as defined by the **expires** user attribute.
- The user's account has been locked as defined by the **account_locked** user attribute.
- The user attempted too many unsuccessful logins as defined by the **loginretries** user attribute.
- The user is not allowed to access the given terminal as defined by the **ttys** user attribute.
- The user is not allowed to access the system at the present time as defined by the **logintimes** user attribute.
- The *Mode* parameter is set to the **S_LOGIN** value or the **S_RLOGIN** value, and too many users are logged in as defined by the **maxlogins** system attribute.
- The *Mode* parameter is set to the **S_LOGIN** value and the user is not allowed to log in as defined by the **login** user attribute.
- The *Mode* parameter is set to the **S_RLOGIN** value and the user is not allowed to log in from the network as defined by the **rlogin** user attribute.
- The *Mode* parameter is set to the **S_SU** value and other users are not allowed to use the **su** command as defined by the **su** user attribute, or the group ID of the current process cannot use the **su** command to switch to this user as defined by the **sugroups** user attribute.
- The *Mode* parameter is set to the **S_DAEMON** value and the user is not allowed to run processes from the **cron** or **src** subsystem as defined by the **daemon** user attribute.
- The terminal is locked as defined by the **locktime** port attribute.
- The user cannot use the terminal to access the system at the present time as defined by the **logintimes** port attribute.
- The user is not the root user and the **/etc/nologin** file exists.

Note: The **loginrestrictions** subroutine is not safe in a multi-threaded environment. To use **loginrestrictions** in a threaded application, the application must keep the integrity of each thread.

Parameters

Item	Description
Name	Specifies the user's login name whose account is to be validated.

Item	Description
Mode	Specifies the mode of usage. Valid values as defined in the **login.h** file are listed below. The *Mode* parameter has a value of 0 or one of the following values: **S_LOGIN** Verifies that local logins are permitted for this account. **S_SU** Verifies that the **su** command is permitted and the current process has a group ID that can invoke the **su** command to switch to the account. **S_DAEMON** Verifies the account can invoke daemon or batch programs through the **src** or **cron** subsystems. **S_RLOGIN** Verifies the account can be used for remote logins through the **rlogind** or **telnetd** programs.
Tty	Specifies the terminal of the originating activity. If this parameter is a null pointer or a null string, no tty origin checking is done.
Msg	Returns an informative message indicating why the **loginrestrictions** subroutine failed. Upon return, the value is either a pointer to a valid string within memory allocated storage or a null value. If a message is displayed, it is provided based on the user interface.

Security

Access Control:The calling process must have access to the account information in the user database and the port information in the port database.

File Accessed:

Mode	Files
r	/etc/security/user
r	/etc/security/login.cfg
r	/etc/security/portlog
r	/etc/passwd

Return Values

If the account is valid for the specified usage, the **loginrestrictions** subroutine returns a value of 0. Otherwise, a value of -1 is returned, the **errno** global value is set to the appropriate error code, and the *Msg* parameter returns an informative message explaining why the specified account usage is invalid.

Error Codes

The **loginrestrictions** subroutine fails if one or more of the following values is true:

Item	Description
ENOENT	The user specified does not have an account.
ESTALE	The user's account is expired.
EPERM	The user's account is locked, the specified terminal is locked, the user has had too many unsuccessful login attempts, or the user cannot log in because the **/etc/nologin** file exists.

Item	Description
EACCES	One of the following conditions exists: • The specified terminal does not have access to the specified account. • The *Mode* parameter is the **S_SU** value and the current process is not permitted to use the **su** command to access the specified user. • Access to the account is not permitted in the specified mode. • Access to the account is not permitted at the current time. • Access to the system with the specified terminal is not permitted at the current time.
EAGAIN	The *Mode* parameter is either the **S_LOGIN** value or the **S_RLOGIN** value, and all the user licenses are in use.
EINVAL	The *Mode* parameter has a value other than **S_LOGIN**, **S_SU**, **S_DAEMON**, **S_RLOGIN**, or **0**.

loginrestrictionsx Subroutine

Purpose

Determines, in multiple methods, if a user is allowed to access the system.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
#include <login.h>

int loginrestrictionsx (Name, Mode, Tty, Message, State)
char * Name;
int  Mode;
char *Tty;
char **Message;
void **State;
```

Description

The **loginrestrictionsx** subroutine determines if the user specified by the *Name* parameter is allowed to access the system. The *Mode* parameter gives the mode of account usage, and the *Tty* parameter defines the terminal used for access. The *Msg* parameter returns an informational message explaining why the **loginrestrictionsx** subroutine failed. The user's **SYSTEM** attribute determines the administrative domains to examine for permission.

The *State* parameter contains information about the login restrictions for the user. A call to the **authenticatex** subroutine will not use an administrative domain for authentication if an earlier call to **loginrestrictionsx** indicated that the user was unable to log in using that administrative domain's authentication data. The result is that administrative domains that are used for authentication must permit the user to log in. The *State* parameter returned by **loginrestrictionsx** can be used as input to a subsequent call to the **authenticatex** subroutine.

This subroutine is unsuccessful if any of the following conditions exists:

- The user's account has been locked as defined by the **account_locked** user attribute.
- The user's account has expired as defined by the **expires** user attribute.

- The *Mode* parameter is set to the **S_LOGIN** value or the **S_RLOGIN** value, and too many users are logged in as defined by the **maxlogins** system attribute.
- The *Mode* parameter is not set to the **S_SU** or **S_DAEMON** value, and the user is not allowed to log in to the current host as defined by the user's **hostallowedlogin** and **hostdeniedlogin** attributes.
- The user is not allowed to access the system at the present time as defined by the **logintimes** user attribute.
- The user attempted too many unsuccessful logins as defined by the **loginretries** user attribute.
- The user is not allowed to access the given terminal or network protocol as defined by the **ttys** user attribute. This test is not performed when the *Mode* parameter is set to the **S_DAEMON** value.
- The *Mode* parameter is set to the **S_LOGIN** value, and the user is not allowed to log in as defined by the **login** user attribute.
- The *Mode* parameter is set to the **S_RLOGIN** value and the user is not allowed to log in from the network as defined by the **rlogin** user attribute.
- The Mode parameter is set to the **S_SU** value, and other users are not allowed to use the **su** command as defined by the **su** user attribute; or, the group ID of the current process cannot use the **su** command to switch to this user as defined by the **sugroups** user attribute.
- The *Mode* parameter is set to the **S_DAEMON** value, and the user is not allowed to run processes from the **cron** or **src** subsystem as defined by the **daemon** user attribute.
- The terminal is locked as defined by the **locktime** port attribute.
- The user cannot use the terminal to access the system at the present time as defined by the **logintimes** port attribute.
- The user is not the root user, and the **/etc/nologin** file exists.

Additional restrictions can be enforced by loadable authentication modules for any administrative domain used in the user's **SYSTEM** attribute.

Parameters

Item	Description
Name	Specifies the user's login name whose account is to be validated.
Mode	Specifies the mode of usage. The valid values in the following list are defined in the **login.h** file. The *Mode* parameter has a value of 0 or one of the following values: **S_LOGIN** Verifies that local logins are permitted for this account. **S_SU** Verifies that the **su** command is permitted and the current process has a group ID that can invoke the **su** command to switch to the account. **S_DAEMON** Verifies that the account can invoke daemon or batch programs through the **src** or **cron** subsystems. **S_RLOGIN** Verifies that the account can be used for remote logins through the **rlogind** or **telnetd** programs.
Tty	Specifies the terminal of the originating activity. If this parameter is a null pointer or a null string, no **tty** origin checking is done. The *Tty* parameter can also have the value **RSH** or **REXEC** to indicate that the caller is the **rsh** or **rexec** command.
Message	Returns an informative message indicating why the **loginrestrictionsx** subroutine failed. Upon return, the value is either a pointer to a valid string within memory-allocated storage or a null value. If a message is displayed, it is provided based on the user interface.

Item	Description
State	Points to a pointer that the **loginrestrictionsx** subroutine allocates memory for and fills in. The *State* parameter can also be the result of an earlier call to the **authenticatex** subroutine. The *State* parameter contains information about the results of the **loginrestrictionsx** subroutine for each term in the user's **SYSTEM** attribute. The calling application is responsible for freeing this memory when it is no longer needed for a subsequent call to the **authenticatex**, **passwdexpiredx**, or **chpassx** subroutines.

Security

Access Control: The calling process must have access to the account information in the user database and the port information in the port database.

Files accessed:

Item	Description
Mode	**File**
r	**/etc/security/user**
r	**/etc/security/login.cfg**
r	**/etc/security/portlog**
r	**/etc/passwd**

Return Values

If the account is valid for the specified usage, the **loginrestrictionsx** subroutine returns a value of 0. Otherwise, a value of -1 is returned, the **errno** global value is set to the appropriate error code, and the *Message* parameter returns an informative message explaining why the specified account usage is invalid.

Error Codes

If the **loginrestrictionsx** subroutine fails if one of the following values is true:

Item	Description
EACCES	One of the following conditions exists: • The specified terminal does not have access to the specified account. • The *Mode* parameter is the **S_SU** value, and the current process is not permitted to use the **su** command to access the specified user. • Access to the account is not permitted in the specified mode. • Access to the account is not permitted at the current time. • Access to the system with the specified terminal is not permitted at the current time.
EAGAIN	The *Mode* parameter is either the **S_LOGIN** value or the **S_RLOGIN** value, and all the user licenses are in use.
EINVAL	The *Mode* parameter has a value other than **S_LOGIN**, **S_SU**, **S_DAEMON**, **S_RLOGIN**, or 0.
ENOENT	The user specified does not have an account.
EPERM	The user's account is locked, the specified terminal is locked, the user has had too many unsuccessful login attempts, or the user cannot log in because the **/etc/nologin** file exists.

Item	Description
ESTALE	The user's account is expired.

loginsuccess Subroutine

Purpose

Records a successful log in.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
int loginsuccess (User, Host, Tty, Msg)
char * User;
char * Host;
char * Tty;
char ** Msg;
```

Note: This subroutine is not thread-safe.

Description

The **loginsuccess** subroutine performs the processing necessary when a user successfully logs into the system. This subroutine updates the following attributes in the **/etc/security/lastlog** file for the specified user:

Item	Description
time_last_login	Contains the current time.
tty_last_login	Contains the value specified by the *Tty* parameter.
host_last_login	Contains the value specified by the *Host* parameter or the local host name if the *Host* parameter is a null value.
unsuccessful_login_count	Indicates the number of unsuccessful login attempts. The **loginsuccess** subroutine resets this attribute to a value of 0.

Additionally, a login success audit record is cut to indicate in the audit trail that this user has successfully logged in.

A message is returned in the *Msg* parameter that indicates the time, host, and port of the last successful and unsuccessful login. The number of unsuccessful login attempts since the last successful login is also provided to the user.

Parameters

Item	Description
User	Specifies the login name of the user who has successfully logged in.
Host	Specifies the name of the host from which the user logged in. If the *Host* parameter is a null value, the name of the local host is used.
Tty	Specifies the name of the terminal which the user used to log in.

Item	Description
Msg	Returns a message indicating the delete time, host, and port of the last successful and unsuccessful logins. The number of unsuccessful login attempts since the last successful login is also provided. Upon return, the value is either a pointer to a valid string within memory allocated storage or a null pointer. It is the responsibility of the calling program to **free( )** the returned storage.

Security

Access Control: The calling process must have access to the account information in the user database.

File Accessed:

Mode	File
rw	/etc/security/lastlog

Auditing Events:

Event	Information
USER_Login	username

Return Values

Upon successful completion, the **loginsuccess** subroutine returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global value is set to indicate the error.

Note: If the load module does not have interface support that is defined in the security library, the **loginsuccess** subroutine might return a value of 0 (success), and display ENOSYS as the **errno** value.

Error Codes

The **loginsuccess** subroutine fails if one or more of the following values is true:

Item	Description
ENOENT	The specified user does not exist.
EACCES	The current process does not have write access to the user database.
EPERM	The current process does not have permission to write an audit record.
ENOSYS	The load module does not have the required interface support defined in the security library.

lpar_get_info Subroutine

Purpose

Retrieves the characteristics of the calling partition.

Syntax

```
#include <sys/dr.h>

int lpar_get_info (command, lparinfo, bufsize)
int command;
void *lparinfo;
size_t bufsize;
```

Description

The **lpar_get_info** subroutine retrieves processor module information, and both LPAR and Micro-Partitioning® attributes of low-frequency use and high-frequency use. Because the low-frequency attributes, as defined in the **lpar_info_format1_t** structure, are static in nature, a reboot is required to effect any change. The high-frequency attributes, as defined in the **lpar_info_format2_t** structure, can be changed dynamically at any time either by the platform or through dynamic logical partitioning (DLPAR) procedures. The latter provides a mechanism for notifying applications of changes. The signature of this system call, its parameter types, and the order of the member fields in both the **lpar_info_format1_t** and **lpar_info_format2_t** structures are specific to the AIX platform. If the **WPAR_INFO_FORMAT** command is specified, the WPAR attributes are returned in a **wpar_info_format_t** structure. To request processor module information, specify the **PROC_MODULE_INFO** command. The information is provided as an array of **proc_module_info_t** structures. To obtain this information, you must provide a buffer of exact length to accommodate one **proc_module_info_t** structure for each module type. The module count can be obtained by using the **NUM_PROC_MODULE_TYPES** command, and it is in the form of a **uint64_t** type. Processor module information is reported for the entire system. This information is available on POWER6® and later systems.

To see the complete structures of **lpar_info_format1_t**, **lpar_info_format2_t**, **wpar_info_format_t**, and **proc_module_info_t**, see the **dr.h** header file.

The **lpar_get_info** system call provides information about the operating system environment, including the following:

- Type of partition: dedicated processor partition or micro-partition
- Type of micro-partition: capped or uncapped
- Variable capacity weight of micro-partition
- Partition name and number
- SMT-capable partition
- SMT-enabled partition
- Minimum, desired, online, and maximum number of virtual processors
- Minimum, online, and maximum number of logical processors
- Minimum, desired, online, and maximum entitled processor capacity
- Minimum, desired, online (megabytes), and maximum number of logical memory blocks (LMBs)
- Maximum number of potential installed physical processors in the server, including unlicensed and potentially hot-pluggable
- Number of active licensed installed physical processors in the server
- Number of processors in the shared processor pool
- Workload partition static identifier
- Workload partition dynamic identifier
- Workload partition processor limits
- Socket, chip, and core topology of the system that the processor module information provides
- Logical pages coalesced in active memory sharing enabled partitions.
- Physical pages coalesced in memory pools in active memory sharing enabled partitions.
- PURR and SPURR consumed for page coalescing in active memory sharing enabled partitions.

This subroutine is used by the DRM to determine whether a client partition is migration capable and MSP capable. The kernel presents these capabilities based on the presence of the **hcall-vasi** function set and the type of partition that is evident. If the partition is a VIOS partition, the MSP capability will be noted. Otherwise, the OS partition migration capability will be noted.

Parameters

Item	Description
command	Specifies whether the user wants **format1**, **format2**, workload partition, or processor module details.
lparinfo	Pointer to the user-allocated buffer that is passed in.
bufsize	Size of the buffer that is passed in.

Return Values

Upon success, the **lpar_get_info** subroutine returns a value of 0. Upon failure, a value of -1 is returned, and **errno** is set to indicate the appropriate error.

Error Codes

Item	Description
EFAULT	Buffer size is smaller than expected.
EINVAL	Invalid input parameter.
ENOSYS	The hardware or the current firmware level does not support this operation.
ENOTSUP	The platform does not support this operation.

Example

The following example demonstrates how to retrieve processor module information using the **lpar_get_info** subroutine:

```
uint64_t             module_count;
proc_module_info_t   *buffer = NULL;
int                  rc = 0;

/* Retrieve the total count of modules on the system */
rc = lpar_get_info(NUM_PROC_MODULE_TYPES,
                   &module_count, sizeof(uint64_t));

if (rc)
    return(1);  /* Error */

/* Allocate buffer of exact size to accomodate module information */
buffer = malloc(module_count * sizeof(proc_module_info_t));

if (buffer == NULL)
    return(2);

rc = lpar_get_info(PROC_MODULE_INFO, buffer, (module_count * sizeof(proc_module_info_t)));

if (rc)
    return(3);  /* Error */

/*  If rc is 0, then buffer contains an array of proc_module_info_t
 *  structures with module_count elements.  For an element of
 *  index i:
 *
 *      buffer[i].nsockets is the total number of sockets
 *      buffer[i].nchips   is the number of chips per socket
 *      buffer[i].ncores   is the number of cores per chip
 */
```

lpar_set_resources Subroutine

Purpose

Modifies the calling partition's characteristics.

Library

Standard C Library (`lib.c`)

Syntax

```
#include  <sys/dr.h>
```

```
int lpar_set_resources ( lpar_resource_id,lpar_resource )
int lpar_resource_id;
void *lpar_resource;
```

Description

The `lpar_set_resources` subroutine modifies the configuration attributes (dynamic resources) on a current partition indicated by the *lpar_resource_id*. The pointer to a value of the dynamic resource indicated by *lpar_resource_id* is passed to this call in *lpar_resource*. This subroutine modifies one partition dynamic resource at a time. To reconfigure multiple resources, multiple calls must be made. The following resources for the calling partition can be modified:

- Processor Entitled Capacity
- Processor Variable Capacity Weight
- Number of online virtual processors
- Number of available memory in megabytes
- I/O Entitled Memory Capacity in bytes
- Variable Memory Capacity Weight

These resource IDs are defined in the <**sys/dr.h**> header file. To modify the Processor Entitled Capacity and Processor Variable Capacity Weight attributes, ensure that the current partition is an SPLPAR partition. Otherwise, an error is returned.

Note: The **lpar_set_resources** subroutine can only be called in a process owned by a root user or a user with the CAP_EWLM_AGENT capability. Otherwise, an error is returned.

Parameters

Item	Description
lpar_resource_id	Identifies the dynamic resource whose value is being changed.
lpar_resource	Pointer to a new value of the dynamic resource identified by the *lpar_resource_id*.

Security

The `lpar_set_resources` subroutine can only be called in a process owned by a root user (super user) or a user with the `CAP_EWLM_AGENT` capability.

Return Values

Upon success, the `lpar_set_resources` subroutine returns a value of `0`. Upon failure, a negative value is returned, and `errno` is set to the appropriate error.

Error Codes

Item	Description
EINVAL	Invalid configuration parameters.
EPERM	Insufficient authority.
EEXIST	Resource already exists.
EBUSY	Resource is busy.
EAGAIN	Resource is temporarily unavailable.
ENOMEM	Resource allocation failed.
ENOTREADY	Resource is not ready.
ENOTSUP	Operation is not supported.
EFAULT/EIO	Operation failed because of an I/O error.
EINPROGRESS	Operation in progress.
ENXIO	Resource is not available.
ERANGE	Parameter value is out of range.
All others	Internal error.

lrint, lrintf, lrintl, lrintd32, lrintd64, and lrintd128 Subroutines

Purpose

Round to nearest integer value using the current rounding direction.

Syntax

```
#include <math.h>

long lrint (x)
double x;

long lrintf (x)
float x;

long lrintl (x)
long double x;

long lrintd32 (x)
_Decimal32 x;

long lrintd64 (x)
_Decimal64 x;

long lrintd128 (x)
_Decimal128 x;
```

Description

The **lrint**, **lrintf**, **lrintl**, **lrintd32**, **lrintd64**, and **lrintd128** subroutines round the *x* parameter to the nearest integer value, rounding according to the current rounding direction.

An application wishing to check for error situations should set the **errno** global variable to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be rounded.

Return Values

Upon successful completion, the **lrint**, **lrintf**, **lrintl**, **lrintd32**, **lrintd64**, and **lrintd128** subroutines return the rounded integer value.

If *x* is NaN, a domain error occurs and an unspecified value is returned.

If *x* is +Inf, a domain error occurs and an unspecified value is returned.

If *x* is -Inf, a domain error occurs and an unspecified value is returned.

If the correct value is positive and too large to represent as a long, a domain error occurs and an unspecified value is returned.

If the correct value is negative and too large to represent as a long, a domain error occurs and an unspecified value is returned.

lround, lroundf, lroundl, lroundd32, lroundd64, and lroundd128 Subroutines

Purpose

Rounds to the nearest integer value.

Syntax

```
#include <math.h>

long lround (x)
double x;

long lroundf (x)
float x;

long lroundl (x)
long double x;

long lroundd32(x)
_Decimal32 x;

long lroundd64(x)
_Decimal64 x;

long lroundd128(x)
_Decimal128 x;
```

Description

The **lround**, **lroundf**, **lroundl**, **lroundd32**, **lroundd64**, and **lroundd128** subroutines round the *x* parameter to the nearest integer value, rounding halfway cases away from zero, regardless of the current rounding direction.

An application wishing to check for error situations should set the **errno** global variable to zero and call **feclearexcept**(**FE_ALL_EXCEPT**) before calling these subroutines. Upon return, if **errno** is nonzero or **fetestexcept**(**FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW**) is nonzero, an error has occurred.

Parameters

Item	Description
x	Specifies the value to be rounded.

Return Values

Upon successful completion, the **lround**, **lroundf**, **lroundl**, **lroundd32**, **lroundd64**, and **lroundd128** subroutines return the rounded integer value.

If *x* is NaN, a domain error occurs and an unspecified value is returned.

If *x* is +Inf, a domain error occurs and an unspecified value is returned.

If *x* is -Inf, a domain error occurs and an unspecified value is returned.

If the correct value is positive and too large to represent as a **long**, a domain error occurs and an unspecified value is returned.

If the correct value is negative and too large to represent as a **long**, a domain error occurs and an unspecified value is returned.

lsearch or lfind Subroutine

Purpose

Performs a linear search and update.

Library

Standard C Library (**libc.a**)

Syntax

```
void *lsearch (Key, Base, NumberOfElementsPointer, Width, ComparisonPointer)
const void *Key;
void *Base;
size_t Width, *NumberOfElementsPointer;
int (*ComparisonPointer) (cont void*, const void*);
```

```
void *lfind (Key, Base, NumberOfElementsPointer, Width, ComparisonPointer)
const void *Key, Base;
size_t Width, *NumberOfElementsPointer;
int (*ComparisonPointer) (cont void*, const void*);
```

Description

Warning: Undefined results can occur if there is not enough room in the table for the **lsearch** subroutine to add a new item.

The **lsearch** subroutine performs a linear search.

The algorithm returns a pointer to a table where data can be found. If the data is not in the table, the program adds it at the end of the table.

The **lfind** subroutine is identical to the **lsearch** subroutine, except that if the data is not found, it is not added to the table. In this case, a NULL pointer is returned.

The pointers to the *Key* parameter and the element at the base of the table should be of type pointer-to-element and cast to type pointer-to-character. The value returned should be cast into type pointer-to-element.

The comparison function need not compare every byte; therefore, the elements can contain arbitrary data in addition to the values being compared.

Parameters

Item	Description
Base	Points to the first element in the table.
ComparisonPointer	Specifies the name (that you supply) of the comparison function (**strcmp**, for example). It is called with two parameters that point to the elements being compared.
Key	Specifies the data to be sought in the table.
NumberOfElementsPointer	Points to an integer containing the current number of elements in the table. This integer is incremented if the data is added to the table.
Width	Specifies the size of an element in bytes.

The comparison function compares its parameters and returns a value as follows:

- If the first parameter equals the second parameter, the *ComparisonPointer* parameter returns a value of 0.
- If the first parameter does not equal the second parameter, the *ComparisonPointer* parameter returns a value of 1.

Return Values

If the sought entry is found, both the **lsearch** and **lfind** subroutines return a pointer to it. Otherwise, the **lfind** subroutine returns a null pointer and the **lsearch** subroutine returns a pointer to the newly added element.

lseek, llseek or lseek64 Subroutine

Purpose

Moves the read-write file pointer.

Library

Standard C Library (**libc.a**)

Syntax

```
off_t lseek ( FileDescriptor,  Offset,  Whence)
int FileDescriptor, Whence;
off_t Offset;
```

```
offset_t llseek (FileDescriptor, Offset, Whence)
int FileDescriptor, Whence;
offset_t Offset;
```

```
off64_t lseek64 (FileDescriptor, Offset, Whence)
int FileDescriptor, Whence;
off64_t Offset;
```

Description

The **lseek**, **llseek**, and **lseek64** subroutines set the read-write file pointer for the open file specified by the *FileDescriptor* parameter. The **lseek** subroutine limits the *Offset* to **OFF_MAX**.

In the large file enabled programming environment, **lseek** subroutine is redefined to **lseek64**.

If the *FileDescriptor* parameter refers to a shared memory object, the **lseek** subroutine fails with **EINVAL**.

Parameters

Item	Description
FileDescriptor	Specifies a file descriptor obtained from a successful **open** or **fcntl** subroutine.
Offset	Specifies a value, in bytes, that is used in conjunction with the *Whence* parameter to set the file pointer. A negative value causes seeking in the reverse direction.
Whence	Specifies how to interpret the *Offset* parameter by setting the file pointer associated with the *FileDescriptor* parameter to one of the following variables: **SEEK_SET** Sets the file pointer to the value of the *Offset* parameter. **SEEK_CUR** Sets the file pointer to its current location plus the value of the *Offset* parameter. **SEEK_END** Sets the file pointer to the size of the file plus the value of the *Offset* parameter.

Return Values

Upon successful completion, the resulting pointer location, measured in bytes from the beginning of the file, is returned. If either the **lseek** or **llseek** subroutines are unsuccessful, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **lseek** or **llseek** subroutines are unsuccessful and the file pointer remains unchanged if any of the following are true:

Item	Description
EBADF	The *FileDescriptor* parameter is not an open file descriptor.
EINVAL	The resulting offset would be greater than the maximum offset allowed for the file or device associated with *FileDescriptor*. The **lseek** subroutine was used with a file descriptor obtained from a call to the **shm_open** subroutine.
EINVAL	Whence is not one of the supported values.
EOVERFLOW	The resulting offset is larger than can be returned properly.
ESPIPE	The *FileDescriptor* parameter is associated with a pipe (FIFO) or a socket.

Files

Item	Description
/usr/include/unistd.h	Defines standard macros, data types and subroutines.

lvm_querylv Subroutine

Purpose

Queries a logical volume and returns all pertinent information.

Library

Logical Volume Manager Library (**liblvm.a**)

Syntax

```
#include <lvm.h>
```

```
int lvm_querylv ( LV_ID,  QueryLV,  PVName)
struct lv_id *LV_ID;
struct querylv **QueryLV;
char *PVName;
```

Description

Note: The **lvm_querylv** subroutine uses the **sysconfig** system call, which requires root user authority, to query and update kernel data structures describing a volume group. You must have root user authority to use the **lvm_querylv** subroutine.

The **lvm_querylv** subroutine returns information for the logical volume specified by the *LV_ID* parameter.

The **querylv** structure, found in the **lvm.h** file, is defined as follows:

```
struct querylv {
      char lvname[LVM_NAMESIZ];
      struct unique_id vg_id;
      long maxsize;
      long mirror_policy;
      long lv_state;
      long currentsize;
      long ppsize;
      long permissions;
      long bb_relocation;
      long write_verify;
      long mirwrt_consist;
      long open_close;
      struct pp *mirrors[LVM_NUMCOPIES];
      unsigned int     stripe_exp;
      unsigned int     striping_width;
}
struct pp {
      struct unique_id pv_id;
      long lp_num;
      long pp_num;
      long ppstate;
 }
```

Field	Description
lvname	Specifies the special file name of the logical volume and can be either the full path name or a single file name that must reside in the **/dev** directory (for example, **rhd1**). All name fields must be null-terminated strings of from 1 to **LVM_NAMESIZ** bytes, including the null byte. If a raw or character device is not specified for the **lvname** field, the Logical Volume Manager (LVM) will add an **r** to the file name to have a raw device name. If there is no raw device entry for this name, the LVM will return the **LVM_NOTCHARDEV** error code.
vg_id	Specifies the unique ID of the volume group that contains the logical volume.

Field	Description
maxsize	Indicates the maximum size in logical partitions for the logical volume and must be in the range of 1 to **LVM_MAXLPS**.
mirror_policy	Specifies how the physical copies are written. The **mirror_policy** field should be either **LVM_SEQUENTIAL** or **LVM_PARALLEL** to indicate how the physical copies of a logical partition are to be written when there is more than one copy.
lv_state	Specifies the current state of the logical volume and can have any of the following bit-specific values ORed together: **LVM_LVDEFINED** The logical volume is defined. **LVM_LVSTALE** The logical volume contains stale partitions.
currentsize	Indicates the current size in logical partitions of the logical volume. The size, in bytes, of every physical partition is 2 to the power of the **ppsize** field.
ppsize	Specifies the size of the physical partitions of all physical volumes in the volume group.
permissions	Specifies the permission assigned to the logical volume and can be one of the following values: **LVM_RDONLY** Access to this logical volume is read only. **LVM_RDWR** Access to this logical volume is read/write.
bb_relocation	Specifies if bad block relocation is desired and is one of the following values: **LVM_NORELOC** Bad blocks will not be relocated. **LVM_RELOC** Bad blocks will be relocated.
write_verify	Specifies if write verification for the logical volume is desired and returns one of the following values: **LVM_NOVERIFY** Write verification is not performed for this logical volume. **LVM_VERIFY** Write verification is performed on all writes to the logical volume.

Field	Description
mirwrt_consist	Indicates whether mirror-write consistency recovery will be performed for this logical volume. The LVM always ensures data consistency among mirrored copies of a logical volume during normal I/O processing. For every write to a logical volume, the LVM generates a write request for every mirror copy. A problem arises if the system crashes in the middle of processing a mirrored write (before all copies are written). If mirror write consistency recovery is requested for a logical volume, the LVM keeps additional information to allow recovery of these inconsistent mirrors. Mirror write consistency recovery should be performed for most mirrored logical volumes. Logical volumes, such as page space, that do not use the existing data when the volume group is re-varied on do not need this protection. Values for the **mirwrt_consist** field are: **LVM_CONSIST** Mirror-write consistency recovery will be done for this logical volume. **LVM_NOCONSIST** Mirror-write consistency recovery will not be done for this logical volume.
open_close	Specifies if the logical volume is opened or closed. Values for this field are: **LVM_QLV_NOTOPEN** The logical volume is closed. **LVM_QLVOPEN** The logical volume is opened by one or more processes.
mirrors	Specifies an array of pointers to partition map lists (physical volume id, logical partition number, physical partition number, and physical partition state for each copy of the logical partitions for the logical volume). The **ppstate** field can be **LVM_PPFREE**, **LVM_PPALLOC**, or **LVM_PPSTALE**. If a logical partition does not contain any copies, its **pv_id**, **lp_num**, and **pp_num** fields will contain zeros.
stripe_exp	Specifies the log base 2 of the logical volume strip size (the strip size multiplied by the number of disks in an array equals the stripe size). For example, 2^20 is 1048576 (that is, 1 MB). Therefore, if the strip size is 1 MB, the **stripe_exp** field is 20. If the logical volume is not striped, the **stripe_exp** field is 0.
stripe_width	Specifies the number of disks that form the striped logical volume. If the logical volume is not striped, the **striping_width** field is 0.

The *PVName* parameter enables the user to query from a volume group descriptor area on a specific physical volume instead of from the Logical Volume Manager's (LVM) most recent, in-memory copy of the descriptor area. This method should only be used if the volume group is varied off.

Note: The data returned is not guaranteed to be the most recent or correct, and it can reflect a back-level descriptor area.

The *PVName* parameter should specify either the full path name of the physical volume that contains the descriptor area to query, or a single file name that must reside in the **/dev** directory (for example, **rhdisk1**). This parameter must be a null-terminated string between 1 and **LVM_NAMESIZ** bytes, including the null byte, and must represent a raw device entry. If a raw or character device is not specified for the *PVName* parameter, the LVM adds an **r** to the file name to have a raw device name. If there is no raw device entry for this name, the LVM returns the **LVM_NOTCHARDEV** error code.

If a *PVName* parameter is specified, only the **minor_num** field of the *LV_ID* parameter need be supplied. The LVM fills in the **vg_id** field and returns it to the user. If the user wishes to query from the LVM's in-memory copy, the *PVName* parameter should be set to null. When using this method of query, the volume group must be varied on, or an error is returned.

Note: As long as the *PVName* parameter is not null, the LVM will attempt a query from a physical volume and *not* from its in-memory copy of data.

In addition to the *PVName* parameter, the caller passes the ID of the logical volume to be queried (*LV_ID* parameter) and the address of a pointer to the **querylv** structure, specified by the *QueryLV* parameter. The LVM separately allocates the space needed for the **querylv** structure and the struct **pp** arrays, and returns the **querylv** structure's address in the pointer variable passed in by the user. The user is responsible for freeing the space by first freeing the struct **pp** pointers in the **mirrors** array and then freeing the **querylv** structure.

Attention: To prevent corruption when there are many pp arrays, the caller of `lvm_querylv` must set *`QueryLV`*`->mirrors k != NULL`.

Parameters

Item	Description
LV_ID	Points to an **lv_id** structure that specifies the logical volume to query.
QueryLV	Contains the address of a pointer to the **querylv** structure.
PVName	Names the physical volume from which to use the volume group descriptor for the query. This parameter can also be null.

Return Values

If the **lvm_querylv** subroutine is successful, it returns a value of 0.

Error Codes

If the **lvm_querylv** subroutine does not complete successfully, it returns one of the following values:

Item	Description
LVM_ALLOCERR	The subroutine could not allocate enough space for the complete buffer.
LVM_INVALID_MIN_NUM	The minor number of the logical volume is not valid.
LVM_INVALID_PARAM	A parameter passed into the routine is not valid.
LVM_INV_DEVENT	The device entry for the physical volume specified by the *Pvname* parameter is not valid and cannot be checked to determine if it is raw.
LVM_NOTCHARDEV	The physical volume name given does not represent a raw or character device.
LVM_OFFLINE	The volume group containing the logical volume to query was offline. If the query originates from the varied-on volume group's current volume group descriptor area, one of the following error codes is returned:
LVM_DALVOPN	The volume group reserved logical volume could not be opened.
LVM_MAPFBSY	The volume group is currently locked because system management on the volume group is being done by another process.
LVM_MAPFOPN	The mapped file, which contains a copy of the volume group descriptor area used for making changes to the volume group, could not be opened.
LVM_MAPFRDWR	The mapped file could not be read or written.

If a physical volume name has been passed, requesting that the query originate from a specific physical volume, one of the following error codes is returned:

Item	Description
LVM_BADBBDIR	The bad-block directory could not be read or written.
LVM_LVMRECERR	The LVM record, which contains information about the volume group descriptor area, could not be read.
LVM_NOPVVGDA	There are no volume group descriptor areas on the physical volume specified.
LVM_NOTVGMEM	The physical volume specified is not a member of a volume group.
LVM_PVDAREAD	An error occurred while trying to read the volume group descriptor area from the specified physical volume.
LVM_PVOPNERR	The physical volume device could not be opened.
LVM_VGDA_BB	A bad block was found in the volume group descriptor area located on the physical volume that was specified for the query. Therefore, a query cannot be done from the specified physical volume.

lvm_querypv Subroutine

Purpose

Queries a physical volume and returns all pertinent information.

Library

Logical Volume Manager Library (**liblvm.a**)

Syntax

```
#include <lvm.h>
```

```
int lvm_querypv (VG_ID, PV_ID, QueryPV, PVName)
struct unique_id * VG_ID;
struct unique_id * PV_ID;
struct querypv ** QueryPV;
char * PVName;
```

Description

Note: The **lvm_querypv** subroutine uses the **sysconfig** system call, which requires root user authority, to query and update kernel data structures describing a volume group. You must have root user authority to use the **lvm_querypv** subroutine.

The **lvm_querypv** subroutine returns information on the physical volume specified by the *PV_ID* parameter.

The **querypv** structure, defined in the **lvm.h** file, contains the following fields:

```
struct querypv {
      long ppsize;
      long pv_state;
      long pp_count;
      long alloc_ppcount;
      long pvnum_vgdas;
      struct pp_map *pp_map;
      char hotspare;
      struct unique_id  pv_id;
```

```
     long freespace;
}
struct pp_map {
     long pp_state;
     struct lv_id lv_id;
     long lp_num;
     long copy;
     struct unique_id fst_alt_vol;
     long fst_alt_part;
     struct unique_id snd_alt_vol;
     long snd_alt_part;
 }
```

Field	Description
ppsize	Specifies the size of the physical partitions, which is the same for all partitions within a volume group. The size in bytes of a physical partition is 2 to the power of ppsize.
pv_state	Contains the current state of the physical volume.
pp_count	Contains the total number of physical partitions on the physical volume.
alloc_ppcount	Contains the number of allocated physical partitions on the physical volume.

Field	Description
pp_map	Points to an array that has entries for each physical partition of the physical volume. Each entry in this array will contain the pp_state that specifies the state of the physical partition (**LVM_PPFREE**, **LVM_PPALLOC**, or **LVM_PPSTALE**) and the lv_id, field, the ID of the logical volume that it is a member of. The pp_map array also contains the physical volume IDs (fst_alt_vol and snd_alt_vol) and the physical partition numbers (fst_alt_part and snd_alt_part) for the first and second alternate copies of the physical partition, and the logical partition number (lp_num) that the physical partition corresponds to. If the physical partition is free (that is, not allocated), *all* of its **pp_map** fields will be zero. **fst_alt_vol** Contains zeros if the logical partition has only one physical copy. **fst_alt_part** Contains zeros if the logical partition has only one physical copy. **snd_alt_vol** Contains zeros if the logical partition has only one or two physical copies. **snd_alt_part** Contains zeros if the logical partition has only one or two physical copies. **copy** Specifies which copy of a logical partition this physical partition is allocated to. This field will contain one of the following values: **LVM_PRIMARY** Primary and only copy of a logical partition **LVM_PRIMOF2** Primary copy of a logical partition with two physical copies **LVM_PRIMOF3** Primary copy of a logical partition with three physical copies **LVM_SCNDOF2** Secondary copy of a logical partition with two physical copies **LVM_SCNDOF3** Secondary copy of a logical partition with three physical copies **LVM_TERTOF3** Tertiary copy of a logical partition with three physical copies.
pvnum_vgdas	Contains the number of volume group descriptor areas (0, 1, or 2) that are on the specified physical volume.
hotspare	Specifies that the physical volume is a hotspare.
pv_id	Specifies the physical volume identifier.
freespace	Specifies the number of physical partitions in the volume group.

The *PVName* parameter enables the user to query from a volume group descriptor area on a specific physical volume instead of from the Logical Volume Manager's (LVM) most recent, in-memory copy of the descriptor area. This method should only be used if the volume group is varied off. The data returned is not guaranteed to be most recent or correct, and it can reflect a back level descriptor area.

The *PVname* parameter should specify either the full path name of the physical volume that contains the descriptor area to query or a single file name that must reside in the **/dev** directory (for example, **rhdisk1**). This field must be a null-terminated string of from 1 to **LVM_NAMESIZ** bytes, including the

null byte, and represent a raw or character device. If a raw or character device is not specified for the *PVName* parameter, the LVM will add an **r** to the file name in order to have a raw device name. If there is no raw device entry for this name, the LVM will return the **LVM_NOTCHARDEV** error code. If a *PVName* is specified, the volume group identifier, `VG_ID`, will be returned by the LVM through the *VG_ID* parameter passed in by the user. If the user wishes to query from the LVM in-memory copy, the *PVName* parameter should be set to null. When using this method of query, the volume group must be varied on, or an error will be returned.

Note: As long as the *PVName* is not null, the LVM will attempt a query from a physical volume and *not* from its in-memory copy of data.

In addition to the *PVName* parameter, the caller passes the *VG_ID* parameter, indicating the volume group that contains the physical volume to be queried, the unique ID of the physical volume to be queried, the *PV_ID* parameter, and the address of a pointer of the type *QueryPV*. The LVM will separately allocate enough space for the **querypv** structure and the struct `pp_map` array and return the address of the **querypv** structure in the *QueryPV* pointer passed in. The user is responsible for freeing the space by freeing the struct *pp_map* pointer and then freeing the *QueryPV* pointer.

Parameters

Item	Description
VG_ID	Points to a **unique_id** structure that specifies the volume group of which the physical volume to query is a member.
PV_ID	Points to a **unique_id** structure that specifies the physical volume to query.
QueryPV	Specifies the address of a pointer to a **querypv** structure.
PVName	Names a physical volume from which to use the volume group descriptor area for the query. This parameter can be null.

Return Values

The **lvm_querypv** subroutine returns a value of 0 upon successful completion.

Error Codes

If the **lvm_querypv** subroutine fails it returns one of the following error codes:

Item	Description
LVM_ALLOCERR	The routine cannot allocate enough space for a complete buffer.
LVM_INVALID_PARAM	An invalid parameter was passed into the routine.
LVM_INV_DEVENT	The device entry for the physical volume is invalid and cannot be checked to determine if it is raw.
LVM_OFFLINE	The volume group specified is offline and should be online.

If the query originates from the varied-on volume group's current volume group descriptor area, one of the following error codes may be returned:

Item	Description
LVM_DALVOPN	The volume group reserved logical volume could not be opened.
LVM_MAPFBSY	The volume group is currently locked because system management on the volume group is being done by another process.
LVM_MAPFOPN	The mapped file, which contains a copy of the volume group descriptor area used for making changes to the volume group, could not be opened.

Item	Description
LVM_MAPFRDWR	Either the mapped file could not be read, or it could not be written.

If a physical volume name has been passed, requesting that the query originate from a specific physical volume, then one of the following error codes may be returned:

Item	Description
LVM_BADBBDIR	The bad-block directory could not be read or written.
LVM_LVMRECERR	The LVM record, which contains information about the volume group descriptor area, could not be read.
LVM_NOPVVGDA	There are no volume group descriptor areas on this physical volume.
LVM_NOTCHARDEV	A device is not a raw or character device.
LVM_NOTVGMEM	The physical volume is not a member of a volume group.
LVM_PVDAREAD	An error occurred while trying to read the volume group descriptor area from the specified physical volume.
LVM_PVOPNERR	The physical volume device could not be opened.
LVM_VGDA_BB	A bad block was found in the volume group descriptor area located on the physical volume that was specified for the query. Therefore, a query cannot be done from the specified physical volume.

lvm_queryvg Subroutine

Purpose

Queries a volume group and returns pertinent information.

Library

Logical Volume Manager Library (**liblvm.a**)

Syntax

```
#include <lvm.h>
```

```
int lvm_queryvg ( VG_ID,  QueryVG,  PVName)
struct unique_id *VG_ID;
struct queryvg **QueryVG;
char *PVName;
```

Description

Note: The **lvm_queryvg** subroutine uses the **sysconfig** system call, which requires root user authority, to query and update kernel data structures describing a volume group. You must have root user authority to use the **lvm_queryvg** subroutine.

The **lvm_queryvg** subroutine returns information on the volume group specified by the *VG_ID* parameter.

The **queryvg** structure, found in the **lvm.h** file, contains the following fields:

```
struct queryvg {
      long maxlvs;
      long ppsize;
      long freespace;
      long num_lvs;
      long num_pvs;
```

```
      long total_vgdas;
      struct lv_array *lvs;
      struct pv_array *pvs;
      short conc_capable;
      short default_mode;
      short conc_status;
      unsigned int maxpvs;
      unsigned int maxpvpps;
      unsigned int maxvgpps;
      int total_pps;
      char vgtype;
      daddr32_t beg_psn;
}
struct pv_array {
    struct unique_id pv_id;
    char   state;
    char   res[3];
    long pvnum_vgdas;
}
struct lv_array {
     struct lv_id   lv_id;
     char  lvname[LVM_NAMESIZ];
     char   state;
     char   res[3];
}
```

Field	Description
conc_capable	Indicates that the volume group was created concurrent mode capable if the value is equal to one.
conc_status	Indicates that the volume group is varied on in concurrent mode.
beg_psn	Specifies the physical sector number of the first physical partition.
default_mode	The behavior of this value is undefined.
freespace	Contains the number of free physical partitions in this volume group.
lvs	Points to an array of unique IDs, names, and states of the logical volumes in the volume group.
maxlvs	Specifies the maximum number of logical volumes allowed in the volume group.
maxpvs	Specifies the maximum number of physical volumes allowed in the volume group.
maxpvpps	Specifies the maximum number of physical partitions allowed for a physical volume in the volume group.
maxvgpps	Specifies the maximum number of physical partitions allowed for the entire volume group.
num_lvs	Indicates the number of logical volumes.
num_pvs	Indicates the number of physical volumes.
ppsize	Specifies the size of all physical partitions in the volume group. The size in bytes of each physical partitions is 2 to the power of the ppsize field.
pvs	Points to an array of unique IDs, states, and the number of volume group descriptor areas for each of the physical volumes in the volume group.
total_pps	Specifies the total number of physical partitions contained in the volume group.
total_vgdas	Specifies the total number of volume group descriptor areas for the entire volume group.

Field	Description
vgtype	Indicates the type of the volume group. If the value of the vgtype field is zero, the volume group is an original volume group. If the value is one, the volume group is a big volume group. If the value is two, the volume group is a scalable volume group.

The *PVName* parameter enables the user to query from a descriptor area on a specific physical volume instead of from the Logical Volume Manager's (LVM) most recent, in-memory copy of the descriptor area. This method should only be used if the volume group is varied off. The data returned is *not guaranteed* to be most recent or correct, and it can reflect a back level descriptor area. The *Pvname* parameter should specify either the full path name of the physical volume that contains the descriptor area to query or a single file name that must reside in the **/dev** directory (for example, **rhdisk1**). The name must represent a raw device. If a raw or character device is not specified for the *PVName* parameter, the Logical Volume Manager will add an r to the file name in order to have a raw device name. If there is no raw device entry for this name, the LVM returns the **LVM_NOTCHARDEV** error code. This field must be a null-terminated string of from 1 to **LVM_NAMESIZ** bytes, including the null byte. If a *PVName* is specified, the LVM will return the *VG_ID* to the user through the *VG_ID* pointer passed in. If the user wishes to query from the LVM in-memory copy, the *PVName* parameter should be set to null. When using this method of query, the volume group must be varied on, or an error will be returned.

Note: As long as the *PVName* parameter is not null, the LVM will attempt a query from a physical volume and *not* its in-memory copy of data.

In addition to the *PVName* parameter, the caller passes the unique ID of the volume group to be queried (*VG_ID*) and the address of a pointer to a **queryvg** structure. The LVM will separately allocate enough space for the **queryvg** structure, as well as the **lv_array** and **pv_array** structures, and return the address of the completed structure in the *QueryVG* parameter passed in by the user. The user is responsible for freeing the space by freeing the lv and pv pointers and then freeing the *QueryVG* pointer.

Parameters

Item	Description
VG_ID	Points to a **unique_id** structure that specifies the volume group to be queried.
QueryVG	Specifies the address of a pointer to the **queryvg** structure.
PVName	Specifies the name of the physical volume that contains the descriptor area to query and must be the name of a raw device.

Return Values

The **lvm_queryvg** subroutine returns a value of zero upon successful completion.

Error Codes

If the **lvm_queryvg** subroutine fails it returns one of the following error codes:

Item	Description
LVM_ALLOCERR	The subroutine cannot allocate enough space for a complete buffer.
LVM_FORCEOFF	The volume group has been forcefully varied off due to a loss of quorum.
LVM_INVALID_PARAM	An invalid parameter was passed into the routine.
LVM_OFFLINE	The volume group is offline and should be online.

If the query originates from the varied-on volume group's current volume group descriptor area, one of the following error codes may be returned:

Item	Description
LVM_DALVOPN	The volume group reserved logical volume could not be opened.
LVM_INV_DEVENT	The device entry for the physical volume specified by the *PVName* parameter is invalid and cannot be checked to determine if it is raw.
LVM_MAPFBSY	The volume group is currently locked because system management on the volume group is being done by another process.
LVM_MAPFOPN	The mapped file, which contains a copy of the volume group descriptor area used for making changes to the volume group, could not be opened.
LVM_MAPFRDWR	Either the mapped file could not be read, or it could not be written.
LVM_NOTCHARDEV	A device is not a raw or character device.

If a physical volume name has been passed, requesting that the query originate from a specific physical volume, one of the following error codes may be returned:

Item	Description
LVM_BADBBDIR	The bad-block directory could not be read or written.
LVM_LVMRECERR	The LVM record, which contains information about the volume group descriptor area, could not be read.
LVM_NOPVVGDA	There are no volume group descriptor areas on this physical volume.
LVM_NOTVGMEM	The physical volume is not a member of a volume group.
LVM_PVDAREAD	An error occurred while trying to read the volume group descriptor area from the specified physical volume.
LVM_PVOPNERR	The physical volume device could not be opened.
LVM_VGDA_BB	A bad block was found in the volume group descriptor area located on the physical volume that was specified for the query. Therefore, a query cannot be done from this physical volume.

lvm_queryvgs Subroutine

Purpose

Queries volume groups and returns information to online volume groups.

Library

Logical Volume Manager Library (**liblvm.a**)

Syntax

```
#include <lvm.h>

int lvm_queryvgs ( QueryVGS,  Kmid)
struct queryvgs **QueryVGS;
mid_t Kmid;
```

Description

Note: The **lvm_queryvgs** subroutine uses the **sysconfig** system call, which requires root user authority, to query and update kernel data structures describing a volume group. You must have root user authority to use the **lvm_queryvgs** subroutine.

The **lvm_queryvgs** subroutine returns the volume group IDs and major numbers for all volume groups in the system that are online.

The caller passes the address of a pointer to a **queryvgs** structure, and the Logical Volume Manager (LVM) allocates enough space for the structure and returns the address of the structure in the pointer passed in by the user. The caller also passes in a *Kmid* parameter, which identifies the entry point of the logical device driver module:

```
struct queryvgs {
       long num_vgs;
       struct {
       long major_num
       struct unique_id vg_id;
       } vgs  [LVM_MAXVGS];
 }
```

Field	Description
num_vgs	Contains the number of online volume groups on the system. The vgs is an array of the volume group IDs and major numbers of all online volume groups in the system.

Parameters

Item	Description
QueryVGS	Points to the **queryvgs** structure.
Kmid	Identifies the address of the entry point of the logical volume device driver module.

Return Values

The **lvm_queryvgs** subroutine returns a value of 0 upon successful completion.

Error Codes

If the **lvm_queryvgs** subroutine fails, it returns one of the following error codes:

Item	Description
LVM_ALLOCERR	The routine cannot allocate enough space for the complete buffer.
LVM_INVALID_PARAM	An invalid parameter was passed into the routine.
LVM_INVCONFIG	An error occurred while attempting to configure this volume group into the kernel. This error will normally result if the module ID is invalid, if the major number given is already in use, or if the volume group device could not be opened.

longname Subroutine

Purpose

Returns the verbose name of a terminal.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
char *longname(void);
```

Description

The **longname** subroutine generates a verbose description for the current terminal. The maximum length of a verbose description is 128 bytes. It is defined only after the call to the **initscr** or **newterm** subroutines.

The area is overwritten by each call to the **newterm** subroutine, so the value should be saved if you plan on using the **longname** subroutine with multiple terminals.

Return Values

Upon successful completion, the **longname** subroutine returns a pointer to the description specified above. Otherwise, it returns a null pointer on error.

m

The following Base Operating System (BOS) runtime services begin with the letter *m*.

malloc, free, realloc, calloc, mallopt, mallinfo, mallinfo_heap, alloca, valloc, or posix_memalign Subroutine

Purpose

Provides a complete set of memory allocation, reallocation, deallocation, and heap management tools.

Libraries

Berkeley Compatibility Library (**libbsd.a**)

Standard C Library (**libc.a**)

Malloc Subsystem APIs

- malloc
- free
- realloc
- calloc
- mallopt
- mallinfo
- mallinfo_heap
- alloca
- valloc
- posix_memalign

malloc

Syntax (malloc)

```
#include <stdlib.h>
```

```
void *malloc (Size)
size_t Size;
```

Description (malloc)

The **malloc** subroutine returns a pointer to a block of memory of at least the number of bytes specified by the *Size* parameter. The block is aligned so that it can be used for any type of data. Undefined results occur if the space assigned by the **malloc** subroutine is overrun.

Parameters (malloc)

Item	Description
Size	Specifies the size, in bytes, of memory to allocate.

Return Values (malloc)

Upon successful completion, the **malloc** subroutine returns a pointer to space suitably aligned for the storage of any type of object. If the size requested is 0, **malloc** returns NULL in normal circumstances. However, if the program was compiled with the defined **_LINUX_SOURCE_COMPAT** macro, **malloc** returns a valid pointer to a space of size 0.

If the request cannot be satisfied for any reason, the **malloc** subroutine returns NULL.

Error Codes (malloc)

Item	Description
ENOMEM	Insufficient storage space is available to service the request.

free

Syntax (free)

```
#include <stdlib.h>
```

void free (*Pointer*)
void * *Pointer*;

Description (free)

The **free** subroutine deallocates a block of memory previously allocated by the **malloc** subsystem. Undefined results occur if the *Pointer* parameter is not an address that has previously been allocated by the **malloc** subsystem, or if the *Pointer* parameter has already been deallocated. If the *Pointer* parameter is NULL, no action occurs.

Parameters (free)

Item	Description
Pointer	Specifies a pointer to space previously allocated by the **malloc** subsystem.

Return Values (free)

The **free** subroutine does not return a value. Upon successful completion with nonzero arguments, the **realloc** subroutine returns a pointer to the (possibly moved) allocated space. If the *Size* parameter is 0 and the *Pointer* parameter is not null, no action occurs.

Error Codes (free)

The **free** subroutine does not set **errno**.

realloc (free)

Syntax (realloc)

```
#include <stdlib.h>
```

void *realloc (*Pointer*, *Size*)
**void ***Pointer;
size_t *Size*;

Description (realloc)

The **realloc** subroutine changes the size of the memory object pointed to by the *Pointer* parameter to the number of bytes specified by the *Size* parameter. The *Pointer* must point to an address returned by a **malloc** subsystem allocation routine, and must not have been previously deallocated. Undefined results occur if *Pointer* does not meet these criteria.

The contents of the memory object remain unchanged up to the lesser of the old and new sizes. If the current memory object cannot be enlarged to satisfy the request, the **realloc** subroutine acquires a new memory object and copies the existing data to the new space. The old memory object is then freed. If no memory object can be acquired to accommodate the request, the object remains unchanged.

If the *Pointer* parameter is null, the **realloc** subroutine is equivalent to a **malloc** subroutine of the same size.

If the *Size* parameter is 0 and the *Pointer* parameter is not null, the **realloc** subroutine is equivalent to a **free** subroutine of the same size.

Parameters (realloc)

Item	Description
Pointer	Specifies a *Pointer* to space previously allocated by the **malloc** subsystem.
Size	Specifies the new size, in bytes, of the memory object.

Return Values (realloc)

Upon successful completion with nonzero arguments, the **realloc** subroutine returns a pointer to the (possibly moved) allocated space. If the *Size* parameter is 0 and the *Pointer* parameter is not null, return behavior is equivalent to that of the **free** subroutine. If the *Pointer* parameter is null and the *Size* parameter is not zero, return behavior is equivalent to that of the **malloc** subroutine.

Error Codes (realloc)

Item	Description
ENOMEM	Insufficient storage space is available to service the request.

calloc

Syntax (calloc)

```
#include <stdlib.h>

void *calloc (NumberOfElements, ElementSize)
size_t NumberOfElements;
size_t ElementSize;
```

Description (calloc)

The **calloc** subroutine allocates space for an array containing the *NumberOfElements* objects. The *ElementSize* parameter specifies the size of each element in bytes. After the array is allocated, all bits are initialized to 0.

The order and contiguity of storage allocated by successive calls to the **calloc** subroutine is unspecified. The pointer returned points to the first (lowest) byte address of the allocated space. The allocated space is aligned so that it can be used for any type of data. Undefined results occur if the space assigned by the **calloc** subroutine is overrun.

Parameters (calloc)

Item	Description
NumberOfElements	Specifies the number of elements in the array.
ElementSize	Specifies the size, in bytes, of each element in the array.

Return Values (calloc)

Upon successful completion, the **calloc** subroutine returns a pointer to the allocated, zero-initialized array. If the size requested is 0, the **calloc** subroutine returns NULL in normal circumstances. However, if the program was compiled with the macro **_LINUX_SOURCE_COMPAT** defined, the **calloc** subroutine returns a valid pointer to a space of size 0.

If the request cannot be satisfied for any reason, the **calloc** subroutine returns NULL.

Error Codes (calloc)

Item	Description
ENOMEM	Insufficient storage space is available to service the request.

mallopt

Syntax (mallopt)

```
#include <malloc.h>
#include <stdlib.h>
```

```
int mallopt (Command, Value)
int Command;
int Value;
```

Description (mallopt)

The **mallopt** subroutine is provided for source-level compatibility with the System V **malloc** subroutine. The **mallopt** subroutine supports the following commands:

Table 20. Commands and effects

Command	Value	Effect
M_MXFAST	0	If called before any other **malloc** subsystem subroutine, this enables the Default allocation policy for the process.
M_MXFAST	1	If called before any other **malloc** subsystem subroutine, this enables the 3.1 allocation policy for the process.
M_DISCLAIM	0	If called while the Default Allocator is enabled, all free memory in the process heap is disclaimed.

Table 20. Commands and effects (continued)		
Command	**Value**	**Effect**
M_MALIGN	N	If called at runtime, sets the default `malloc` allocation alignment to the value *N*. The *N* value must be a power of 2 (greater than or equal to the size of a pointer).

Parameters (mallopt)

Item	Description
Command	Specifies the **mallopt** command to be executed.
Value	Specifies the size of each element in the array.

Return Values (mallopt)

Upon successful completion, the **mallopt** subroutine returns 0. Otherwise, 1 is returned. If an invalid alignment is requested (one that is not a power of 2), `mallopt` fails with a return value of 1, although subsequent calls to `malloc` are unaffected and continue to provide the alignment value from before the failed `mallopt` call.

Error Codes (mallopt)

The **mallopt** subroutine does not set **errno**.

mallinfo

Syntax (mallinfo)

```
#include <malloc.h>
#include <stdlib.h>

struct mallinfo mallinfo();
```

Description (mallinfo)

The **mallinfo** subroutine can be used to obtain information about the heap managed by the **malloc** subsystem.

Return Values (mallinfo)

The **mallinfo** subroutine returns a structure of type **struct mallinfo**, filled in with relevant information and statistics about the heap. The contents of this structure can be interpreted using the definition of **struct mallinfo** in the **/usr/include/malloc.h** file.

Error Codes (mallinfo)

The **mallinfo** subroutine does not set **errno**.

mallinfo_heap

Syntax (mallinfo_heap)

```
#include <malloc.h>
#include <stdlib.h>
```

struct mallinfo_heap mallinfo_heap (*Heap*)
int *Heap*;

Description (mallinfo_heap)

In a multiheap context, the **mallinfo_heap** subroutine can be used to obtain information about a specific heap managed by the **malloc** subsystem.

Parameters (mallinfo_heap)

Item	Description
Heap	Specifies which heap to query.

Return Values (mallinfo_heap)

mallinfo_heap returns a structure of type **struct mallinfo_heap**, filled in with relevant information and statistics about the heap. The contents of this structure can be interpreted using the definition of **struct mallinfo_heap** in the **/usr/include/malloc.h** file.

Error Codes (mallinfo_heap)

The **mallinfo_heap** subroutine does not set **errno**.

alloca

Syntax (alloca)

```
#include <stdlib.h>
```

char *alloca (*Size*)
int *Size*;

Description (alloca)

The **alloca** subroutine returns a pointer to a block of memory of at least the number of bytes specified by the *Size* parameter. The space is allocated from the stack frame of the caller and is automatically freed when the calling subroutine returns.

If the **alloca** subroutine is used in code compiled with the IBM XL C for AIX compiler, `#pragma alloca` must be added to the source code before referencing the **alloca** subroutine. Alternatively, you can add the **-ma** compiler flag or the **<alloca.h>** header file.

Parameters (alloca)

Item	Description
Size	Specifies the size, in bytes, of memory to allocate.

Return Values (alloca)

The **alloca** subroutine returns a pointer to space of the requested size.

Error Codes (alloca)

The **alloca** subroutine does not set **errno**.

valloc

Syntax (valloc)

```
#include <stdlib.h>
```

void *valloc (*Size*)
size_t *Size*;

Description (valloc)

The **valloc** subroutine is supported as a compatibility interface in the Berkeley Compatibility Library (**libbsd.a**), as well as in **libc.a**. The **valloc** subroutine has the same effect as **malloc**, except that the allocated memory is aligned to a multiple of the value returned by **sysconf** (**_ SC_PAGESIZE**).

Parameters (valloc)

Item	Description
Size	Specifies the size, in bytes, of memory to allocate.

Return Values (valloc)

Upon successful completion, the **valloc** subroutine returns a pointer to a memory object that is *Size* bytes in length, aligned to a page-boundary. Undefined results occur if the space assigned by the **valloc** subroutine is overrun.

If the request cannot be satisfied for any reason, **valloc** returns NULL.

Error Codes (valloc)

Item	Description
ENOMEM	Insufficient storage space is available to service the request.

posix_memalign

Syntax (posix_memalign)

```
#include <stdlib.h>
```

int posix_memalign(void **Pointer2Pointer, *Align*, *Size*)
**void ** *Pointer2Pointer*;
size_t *Align*;
size_t *Size*;

Description (posix_memalign)

The **posix_memalign** subroutine allocates *Size* bytes of memory aligned on a boundary specified by *Align*. The address of this memory is stored in *Pointer2Pointer*.

Parameters (posix_memalign)

Item	Description
Pointer2Pointer	Specifies the location in which the address should be copied.
Align	Specifies the alignment of the allocated memory, in bytes. The *Align* parameter must be a power-of-two multiple of the size of a pointer.
Size	Specifies the size, in bytes, of memory to allocate.

Return Values (posix_memalign)

Upon successful completion, **posix_memalign** returns 0. Otherwise, an error number is returned to indicate the error.

Error Codes (posix_memalign)

Item	Description
EINVAL	The value of *Align* is not a power-of-two multiple of the size of a pointer.
ENOMEM	Insufficient storage space is available to service the request.

madd, msub, mult, mdiv, pow, gcd, invert, rpow, msqrt, mcmp, move, min, omin, fmin, m_in, mout, omout, fmout, m_out, sdiv, or itom Subroutine

Purpose

Multiple-precision integer arithmetic.

Library

Berkeley Compatibility Library (**libbsd.a**)

Syntax

```
#include <mp.h>
#include <stdio.h>
```

typedef struct mint {int *Length*; **short *** *Value*} **MINT;**

madd(*a*, *b*, *c*)
msub(*a*,*b*,*c*)
mult(*a*,*b*,*c*)
mdiv(*a*,*b*, *q*, *r*)
pow(*a*,*b*, *m*,*c*)
gcd(*a*,*b*,*c*)
invert(*a*,*b*,*c*)
rpow(*a*,*n*,*c*)
msqrt(*a*,*b*,*r*)
mcmp(*a*,*b*)
move(*a*,*b*)
min(*a*)
omin(*a*)
fmin(*a*,*f*)
m_in(*a*, *n*,*f*)

```
mout(a)
omout(a)
fmout(a,f)
m_out(a,n,f)
MINT *a, *b, *c, *m, *q, *r;
FILE * f;
int n;
```

```
sdiv(a,n,q,r)
MINT *a, *q;
short n;
short *r;
```

```
MINT *itom(n)
```

Description

These subroutines perform arithmetic on integers of arbitrary *Length*. The integers are stored using the defined type **MINT**. Pointers to a **MINT** can be initialized using the **itom** subroutine, which sets the initial *Value* to *n*. After that, space is managed automatically by the subroutines.

The **madd** subroutine, **msub** subroutine, and **mult** subroutine assign to *c* the sum, difference, and product, respectively, of *a* and *b*.

The **mdiv** subroutine assigns to *q* and *r* the quotient and remainder obtained from dividing *a* by *b*.

The **sdiv** subroutine is like the **mdiv** subroutine except that the divisor is a short integer *n* and the remainder is placed in a short whose address is given as *r*.

The **msqrt** subroutine produces the integer square root of *a* in *b* and places the remainder in *r*.

The **rpow** subroutine calculates in c the value of *a* raised to the (regular integral) power *n*, while the **pow** subroutine calculates this with a full multiple precision exponent *b* and the result is reduced modulo *m*.

Note: The **pow** subroutine is also present in the IEEE Math Library, **libm.a**, and the System V Math Library, **libmsaa.a**. The **pow** subroutine in **libm.a** or **libmsaa.a** may be loaded in error unless the **libbsd.a** library is listed before the **libm.a** or **libmsaa.a** library on the command line.

The **gcd** subroutine returns the greatest common denominator of *a* and *b* in *c*, and the **invert** subroutine computes *c* such that *a***c* mod *b*=1, for *a* and *b* relatively prime.

The **mcmp** subroutine returns a negative, 0, or positive integer value when *a* is less than, equal to, or greater than *b*, respectively.

The **move** subroutine copies *a* to *b*. The **min** subroutine and **mout** subroutine do decimal input and output while the **omin** subroutine and **omout** subroutine do octal input and output. More generally, the **fmin** subroutine and **fmout** subroutine do decimal input and output using file *f*, and the **m_in** subroutine and **m_out** subroutine do inputs and outputs with arbitrary radix *n*. On input, records should have the form of strings of digits terminated by a new line; output records have a similar form.

Programs that use the multiple-precision arithmetic functions must link with the **libbsd.a** library.

Bases for input and output should be less than or equal to 10.

pow is also the name of a standard math library routine.

Parameters

Item	Description
Length	Specifies the length of an integer.
Value	Specifies the initial value to be used in the routine.
a	Specifies the first operand of the multiple-precision routines.

Item	Description
b	Specifies the second operand of the multiple-precision routines.
c	Contains the integer result.
f	A pointer of the type **FILE** that points to input and output files used with input/output routines.
m	Indicates modulo.
n	Provides a value used to specify radix with **m_in** and **m_out**, power with **rpow**, and divisor with **sdiv**.
q	Contains the quotient obtained from **mdiv**.
r	Contains the remainder obtained from **mdiv, sdiv,** and **msqrt**.

Error Codes

Error messages and core images are displayed as a result of illegal operations and running out of memory.

Files

Item	Description
/usr/lib/libbsd.a	Object code library.

madvise Subroutine

Purpose

Advises the system of expected paging behavior.

Library

Standard C Library **(libc.a)**.

Syntax

```
#include <sys/types.h>
#include <sys/mman.h>

int madvise( addr,  len,  behav)
caddr_t addr;
size_t len;
int behav;
```

Description

The **madvise** subroutine permits a process to advise the system about its expected future behavior in referencing a mapped file region or anonymous memory region.

The **madvise** subroutine has no functionality and is supported for compatibility only.

Parameters

Item	Description
addr	Specifies the starting address of the memory region. Must be a multiple of the page size returned by the **sysconf** subroutine using the **_SC_PAGE_SIZE** value for the *Name* parameter.

Item	Description
len	Specifies the length, in bytes, of the memory region. If the *len* value is not a multiple of page size as returned by the **sysconf** subroutine using the **_SC_PAGE_SIZE** value for the *Name* parameter, the length of the region will be rounded up to the next multiple of the page size.
behav	Specifies the future behavior of the memory region. The following values for the *behav* parameter are defined in the **/usr/include/sys/mman.h** file: **Value** **Paging Behavior Message** **MADV_NORMAL** The system provides no further special treatment for the memory region. **MADV_RANDOM** The system expects random page references to that memory region. **MADV_SEQUENTIAL** The system expects sequential page references to that memory region. **MADV_WILLNEED** The system expects the process will need these pages. **MADV_DONTNEED** The system expects the process does not need these pages. **MADV_SPACEAVAIL** The system will ensure that memory resources are reserved.

Return Values

When successful, the **madvise** subroutine returns 0. Otherwise, it returns -1 and sets the **errno** global variable to indicate the error.

Error Codes

If the **madvise** subroutine is unsuccessful, the **errno** global variable can be set to one of the following values:

Item	Description
EINVAL	The *behav* parameter is invalid.
ENOSPC	C:\A Workspace\71S\src\idd\en_US\basetrf1The *behav* parameter specifies **MADV_SPACEAVAIL** and resources cannot be reserved.

makecontext or swapcontext Subroutine

Purpose

Modifies the context specified by *ucp*.

Library

(**libc.a**)

Syntax

#include <ucontext.h>

void makecontext (ucontext_t ****ucp*, **(void ****func*) **(), **int** *argc*, ...**); int swapcontext (uncontext_t ****oucp*, **const uncontext_t ****ucp*);

Description

The **makecontext** subroutine modifies the context specified by *ucp*, which has been initialized using **getcontext** subroutine. When this context is resumed using **swapcontext** subroutine or **setcontext** subroutine, program execution continues by calling *func* parameter, passing it the arguments that follow *argc* in the **makecontext** subroutine.

Before a call is made to **makecontext** subroutine, the context being modified should have a stack allocated for it. The value of *argc* must match the number of integer argument passed to *func* parameter, otherwise the behavior is undefined.

The **uc_link** member is used to determine the context that will be resumed when the context being modified by **makecontext** subroutine returns. The **uc_link** member should be initialized prior to the call to **makecontext** subroutine.

The **swapcontext** subroutine function saves the current context in the context structure pointed to by *oucp* parameter and sets the context to the context structure pointed to by *ucp*.

Parameters

Item	Description
ucp	A pointer to a user structure.
oucp	A pointer to a user structure.
func	A pointer to a function to be called when *ucp* is restored.
argc	The number of arguments being passed to *func* parameter.

Return Values

On successful completion, **swapcontext** subroutine returns 0. Otherwise, a value of -1 is returned and **errno** is set to indicate the error.

Item	Description
-1	Not successful and the **errno** global variable is set to one of the following error codes.

Error Codes

Item	Description
ENOMEM	The *ucp* argument does not have enough stack left to complete the operation.

makenew Subroutine

Purpose

Creates a new window buffer and returns a pointer.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
WINDOW *makenew( )
```

Description

The **makenew** subroutine creates a new window buffer and returns a pointer to it. The **makenew** subroutine is called by the **newwin** subroutine to create the window structure. The **makenew** subroutine should not be called directly by a program.

matherr Subroutine

Purpose

Math error handling function.

Library

System V Math Library (**libmsaa.a**)

Syntax

```
#include <math.h>
```

```
int matherr (x)
struct exception *x;
```

Description

The **matherr** subroutine is called by math library routines when errors are detected.

You can use **matherr** or define your own procedure for handling errors by creating a function named `matherr` in your program. Such a user-designed function must follow the same syntax as **matherr.** When an error occurs, a pointer to the exception structure will be passed to the user-supplied `matherr` function. This structure, which is defined in the **math.h** file, includes:

```
int type;
char *name;
double arg1, arg2, retval;
```

Parameters

Item	Description
type	Specifies an integer describing the type of error that has occurred from the following list defined by the **math.h** file: **DOMAIN** Argument domain error **SING** Argument singularity **OVERFLOW** Overflow range error **UNDERFLOW** Underflow range error **TLOSS** Total loss of significance **PLOSS** Partial loss of significance.
name	Points to a string containing the name of the routine that caused the error.
arg1	Points to the first argument with which the routine was invoked.
arg2	Points to the second argument with which the routine was invoked.
retval	Specifies the default value that is returned by the routine unless the user's **matherr** function sets it to a different value.

Return Values

If the user's **matherr** function returns a non-zero value, no error message is printed, and the **errno** global variable will not be set.

Error Codes

If the function **matherr** is not supplied by the user, the default error-handling procedures, described with the math library routines involved, will be invoked upon error. In every case, the **errno** global variable is set to **EDOM** or **ERANGE** and the program continues.

MatchAllAuths, MatchAnyAuths, MatchAllAuthsList, or MatchAnyAuthsList Subroutine

Purpose

Compare authorizations.

Library

Security Library (**libc.a**)

Syntax

```
#include <usersec.h>
```

```
int MatchAllAuths(CommaListOfAuths)
char *CommaListOfAuths;
```

```
int MatchAllAuthsList(CommaListOfAuths, NSListOfAuths)
char *CommaListOfAuths;
char *NSListOfAuths;
```

```
int MatchAnyAuths(CommaListOfAuths)
char *CommaListOfAuths;
```

```
int MatchAnyAuthsList(CommaListOfAuths, NSListOfAuths)
char *CommaListOfAuths;
char *NSListOfAuths;
```

Description

The **MatchAllAuthsList** subroutine compares the *CommaListOfAuths* against the *NSListOfAuths*. It returns a non-zero value if all the authorizations in *CommaListOfAuths* are contained in *NSListOfAuths*. The **MatchAllAuths** subroutine calls the **MatchAllAuthsList** subroutine passing in the results of the **GetUserAuths** subroutine in place of *NSListOfAuths*. If *NSListOfAuths* contains the OFF keyword, **MatchAllAuthsList** will return a zero value. If *NSListOfAuths* contains the ALL keyword and not the OFF keyword, **MatchAllAuthsList** will return a non-zero value.

The **MatchAnyAuthsList** subroutine compares the *CommaListOfAuths* against the *NSListOfAuths*. It returns a non-zero value if one or more of the authorizations in *CommaListOfAuths* are contained in *NSListOfAuths*. The **MatchAnyAuths** subroutine calls the **MatchAnyAuthsList** subroutine passing in the results of the **GetUserAuths** subroutine in place of *NSListOfAuths*. If *NSListOfAuths* contains the OFF keyword, **MatchAnyAuthsList** will return a zero value. If *NSListOfAuths* contains the ALL keyword and not the OFF keyword, **MatchAnyAuthsList** will return a non-zero value.

Parameters

Item	Description
CommaListOfAuths	Specifies one or more authorizations, each separated by a comma.
NSListOfAuths	Specifies zero or more authorizations. Each authorization is null terminated. The last entry in the list must be a null string.

Return Values

The subroutines return a non-zero value if a proper match was found. Otherwise, they will return zero. If an error occurs, the subroutines will return zero and set **errno** to indicate the error. If the subroutine returns zero and no error occurred, **errno** is set to zero.

maxlen_sl, maxlen_cl, and maxlen_tl Subroutines

Purpose

Determine the maximum size of the sensitivity label (SL), the clearance label (CL), and the integrity label (TL).

Library

Trusted AIX Library (**libmls.a**)

Syntax

```
#include <mls/mls.h>

int maxlen_sl (void)

int maxlen_cl (void)
```

```
int maxlen_tl (void)
```

Description

The **maxlen_sl** subroutine retrieves the maximum possible length of a sensitivity label (SL) that is defined in the current label encodings file.

The **maxlen_cl** subroutine retrieves the maximum possible length of a clearance label (CL) that is defined in the current label encodings file.

The **maxlen_tl** subroutine retrieves the maximum possible length of a integrity label (TL) that is defined in the current label encodings file.

For a label encoding file, the maximum length of a SL, a CL, or a TL is calculated and is constant, unless the labels configuration is modified.

Requirement: Must initialize the database before running these subroutines.

Files Access

Mode	File
r	**/etc/security/enc/LabelEncodings**

Return Values

If successful, these subroutines return the maximum length of NULL terminated label. Otherwise, they return a value of -1.

Error Codes

If these subroutines fail, they set one of the following error codes:

Item	Description
ENOTREADY	The database is not initialized.

mblen Subroutine

Purpose

Determines the length in bytes of a multibyte character.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdlib.h>

int mblen( MbString,  Number)
const char *MbString;
size_t Number;
```

Description

The **mblen** subroutine determines the length, in bytes, of a multibyte character.

Parameters

Item	Description
Mbstring	Points to a multibyte character string.
Number	Specifies the maximum number of bytes to consider.

Return Values

The **mblen** subroutine returns 0 if the *MbString* parameter points to a null character. It returns -1 if a character cannot be formed from the number of bytes specified by the *Number* parameter. If *MbString* is a null pointer, 0 is returned.

mbrlen Subroutine

Purpose

Get number of bytes in a character (restartable).

Library

Standard Library (**libc.a**)

Syntax

```
#include <wchar.h>
```

```
size_t mbrlen (const char *s, size_t n, mbstate_t *ps )
```

Description

If *s* is not a null pointer, **mbrlen** determines the number of bytes constituting the character pointed to by *s*. It is equivalent to:

```
mbstate_t internal;
mbrtowc(NULL, s, n, ps != NULL ? ps : &internal);
```

If *ps* is a null pointer, the **mbrlen** function uses its own internal **mbstate_t** object, which is initialized at program startup to the initial conversion state. Otherwise, the mbstate_t object pointed to by *ps* is used to completely describe the current conversion state of the associated character sequence. The implementation will behave as if no function defined in this specification calls **mbrlen**.

The behavior of this function is affected by the LC_CTYPE category of the current locale.

Return Values

The **mbrlen** function returns the first of the following that applies:

Item	Description
0	If the next **n** or fewer bytes complete the character that corresponds to the null wide-character
positive	If the next **n** or fewer bytes complete a valid character; the value returned is the number of bytes that complete the character.

Item	Description
(size_t)-2	If the next **n** bytes contribute to an incomplete but potentially valid character, and all n bytes have been processed. When n has at least the value of the MB_CUR_MAX macro, this case can only occur if s points at a sequence of redundant shift sequences (for implementations with state-dependent encodings).
(size_t)-1	If an encoding error occurs, in which case the next n or fewer bytes do not contribute to a complete and valid character. In this case, EILSEQ is stored in **errno** and the conversion state is undefined.

Error Codes

The **mbrlen** function may fail if:

Item	Description
EINVAL	**ps** points to an object that contains an invalid conversion state.
EILSEQ	Invalid character sequence is detected.

mbrtoc16, mbrtoc32 Subroutine

Purpose

The **mbrtoc16** and **mbrtoc32** subroutine converts a 16-bit wide character (UTF-16) and a 32-bit wide character (UTF-32) to the corresponding multibyte character of the current locale.

Library

Standard C library (**libc.a**)

Syntax

```
#include <uchar.h>
size_t mbrtoc16 (char16_t * restrict pc16,  const char * restrict s, size_t n, mbstate_t *
restrict ps);

size_t mbrtoc32 (char32_t * restrict pc32,  const char * restrict s, size_t n, mbstate_t *
restrict ps);
```

Description

If the value of the **s** parameter is a null pointer, the **mbrtoc16** subroutine is equivalent to the following call:

```
mbrtoc16(NULL, "", 1, ps).
```

In this case, the values of the **pc16** and **n** parameters are ignored.

If the value of the **s** parameter is not a null pointer, the **mbrtoc16** subroutine inspects the value of **n** bytes beginning with the byte specified by the **s** parameter to determine the number of bytes that is needed to complete the next multibyte character, including any shift sequences.

If the subroutine determines that the next multibyte character is complete and valid, the subroutine determines the values of the corresponding wide characters. If the value of the **pc16** subroutine is not a null pointer, the subroutine stores the value of the first character in the object specified by the **pc16** parameter.

If the value of the **s** parameter is a null pointer, the **mbrtoc32** subroutine is equivalent to the following call:

```
mbrtoc32(NULL, "", 1, ps).
```

In this case, the values of the **pc32** and **n** parameters are ignored.

If the value of the **s** parameter is not a null pointer, the **mbrtoc32** subroutine inspects the greater value of **n** bytes beginning with the byte specified by the **s** parameter to determine the number of bytes that is needed to complete the next multibyte character, including any shift sequences.

If the subroutine determines that the next multibyte character is complete and valid, the subroutine determines the values of the corresponding wide characters. If the value of the **pc32** subroutine is not a null pointer, the subroutine stores the value of the first character in the object specified by the **pc32** parameter.

Subsequent calls will store the successive wide characters without using any additional input until all the characters are stored. If the corresponding wide character is a null wide character, the resulting state that is described is the initial conversion state.

Note: The **mbrtoc16** and **mbrtoc32** subroutines includes the **ps** parameter which is of the type pointer to **mbstate_t** that points to an object which describes the current conversion state of the associated multibyte character sequence, which the subroutines alter as necessary. If **ps** is a null pointer, each subroutine uses its own internal **mbstate_t** object. The **mbrtoc16** and **mbrtoc32** subroutines do not avoid data races with other calls to the same subroutine.

Parameters

Item	Description
n	Specifies the number of bytes to be examined to determine the next multibyte character.
pc16, pc32	Specifies the location of the first wide character to be stored.
ps	Specifies the state of the conversion.
s	Specifies the beginning of the bytes that are examined.

Example

- The **mbstate_t** pointer can be used as follows:

```
 mbstate_t ss = 0;
```

```
int x = mbrtoc16(&c16, mbs, MB_CUR_MAX, &ss);
```

Return Values

The **mbrtoc16** and **mbrtoc32** subroutine returns any one of the following values that applies to the current conversion state.

Item	Description
0	If the next **n** or fewer bytes complete the multibyte character that corresponds to the null wide-character (which is the value that is stored) from 1 to **n** and if the next **n** or fewer bytes complete a valid multibyte character (which is the value that is stored), the value that is returned is the number of bytes that complete the multibyte character.
(size_t)(-3)	If the next character resulting from a previous call has been stored, no bytes from the input is used by this call.

Item	Description
(size_t)(-2)	If the next **n** bytes contribute to an incomplete but a valid multibyte character, and all **n** bytes are processed, and no value is stored.
(size_t)(-1)	If an encoding error occurs, that is the next **n** or fewer bytes do not contribute to a complete and valid multibyte character (no value is stored), the value of the **EILSEQ** macro is stored in the **errno** variable. The conversion state is unspecified.

Error codes

The **mbrtoc16** and **mbrtoc32** subroutine are unsuccessful if the following error code is set.

Item	Description
EILSEQ	Indicates an invalid multibyte character sequence.

Files

The **uchar.h** file defines standard macros, data types, and subroutines.

mbrtowc Subroutine

Purpose

Convert a character to a wide-character code (restartable).

Library

Standard Library (**libc.a**)

Syntax

```
#include <wchar.h>
```

```
size_t mbrtowc (wchar_t * pwc, const char * s, size_t n, mbstate_t * ps) ;
```

Description

If *s* is a null pointer, the **mbrtowc** function is equivalent to the call:

```
mbrtowc(NULL, '''', 1, ps)
```

In this case, the values of the arguments **pwc** and **n** are ignored.

If *s* is not a null pointer, the **mbrtowc** function inspects at most *n* bytes beginning at the byte pointed to by *s* to determine the number of bytes needed to complete the next character (including any shift sequences). If the function determines that the next character is completed, it determines the value of the corresponding wide-character and then, if *pwc* is not a null pointer, stores that value in the object pointed to by *pwc.* If the corresponding wide-character is the null wide-character, the resulting state described is the initial conversion state.

If *ps* is a null pointer, the **mbrtowc** function uses its own internal **mbstate_t** object, which is initialized at program startup to the initial conversion state. Otherwise, the **mbstate_t** object pointed to by ps is used to completely describe the current conversion state of the associated character sequence. The implementation will behave as if no function defined in this specification calls **mbrtowc**.

The behavior of this function is affected by the LC_CTYPE category of the current locale.

Return Values

The **mbrtowc** function returns the first of the following that applies:

Item	Description
0	If the next n or fewer bytes complete the character that corresponds to the null wide-character (which is the value stored).
positive	If the next n or fewer bytes complete a valid character (which is the value stored); the value returned is the number of bytes that complete the character.
(size_t)-2	If the next n bytes contribute to an incomplete but potentially valid character, and all n bytes have been processed (no value is stored). When n has at least the value of the MB_CUR_MAX macro, this case can only occur if s points at a sequence of redundant shift sequences (for implementations with state-dependent encodings).
(size_t)-1	If an encoding error occurs, in which case the next n or fewer bytes do not contribute to a complete and valid character (no value is stored). In this case, EILSEQ is stored in errno and the conversion state is undefined.

Error Codes

The **mbrtowc** function may fail if:

Item	Description
EINVAL	ps points to an object that contains an invalid conversion state.
EILSEQ	Invalid character sequence is detected.

mbsadvance Subroutine

Purpose

Advances to the next multibyte character.

Note: The **mbsadvance** subroutine is specific to the manufacturer. It is not defined in the POSIX, ANSI, or X/Open standards. Use of this subroutine may affect portability.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <mbstr.h>
```

```
char *mbsadvance ( S)
const char *S;
```

Description

The **mbsadvance** subroutine locates the next character in a multibyte character string. The **LC_CTYPE** category affects the behavior of the **mbsadvance** subroutine.

Parameters

Item	Description
S	Contains a multibyte character string.

Return Values

If the *S* parameter is not a null pointer, the **mbsadvance** subroutine returns a pointer to the next multibyte character in the string pointed to by the *S* parameter. The character at the head of the string pointed to by the *S* parameter is skipped. If the *S* parameter is a null pointer or points to a null string, a null pointer is returned.

Examples

To find the next character in a multibyte string, use the following:

```
#include <mbstr.h>
#include <locale.h>
#include <stdlib.h>
```

```
main()
{
   char *mbs, *pmbs;
   (void) setlocale(LC_ALL, "");
   /*
   ** Let mbs point to the beginning of a multi-byte string.
   */
   pmbs = mbs;
   while(pmbs){
      pmbs = mbsadvance(mbs);
      /* pmbs points to the next multi-byte character
      ** in mbs */
}
```

mbscat, mbscmp, or mbscpy Subroutine

Purpose

Performs operations on multibyte character strings.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <mbstr.h>
```

```
char *mbscat(MbString1, MbString2)
char *MbString1, *MbString2;
```

```
int mbscmp(MbString1, MbString2)
char *MbString1, *MbString2;
```

```
char *mbscpy(MbString1, MbString2)
char *MbString1, *MbString2;
```

Description

The **mbscat**, **mbscmp**, and **mbscpy** subroutines operate on null-terminated multibyte character strings.

The **mbscat** subroutine appends multibyte characters from the *MbString2* parameter to the end of the *MbString1* parameter, appends a null character to the result, and returns *MbString1*.

The **mbscmp** subroutine compares multibyte characters based on their collation weights as specified in the **LC_COLLATE** category. The **mbscmp** subroutine compares the *MbString1* parameter to the *MbString2* parameter, and returns an integer greater than 0 if *MbString1* is greater than *MbString2*. It returns 0 if the strings are equivalent and returns an integer less than 0 if *MbString1* is less than *MbString2*.

The **mbscpy** subroutine copies multibyte characters from the *MbString2* parameter to the *MbString1* parameter and returns *MbString1*. The copy operation terminates with the copying of a null character.

mbschr Subroutine

Purpose

Locates a character in a multibyte character string.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <mbstr.h>

char *mbschr( MbString,  MbCharacter)
char *MbString;
mbchar_t MbCharacter;
```

Description

The **mbschr** subroutine locates the first occurrence of the value specified by the *MbCharacter* parameter in the string pointed to by the *MbString* parameter. The *MbCharacter* parameter specifies a multibyte character represented as an integer. The terminating null character is considered to be part of the string.

The **LC_CTYPE** category affects the behavior of the **mbschr** subroutine.

Parameters

Item	Description
MbString	Points to a multibyte character string.
MbCharacter	Specifies a multibyte character represented as an integer.

Return Values

The **mbschr** subroutine returns a pointer to the value specified by the *MbCharacter* parameter within the multibyte character string, or a null pointer if that value does not occur in the string.

mbsinit Subroutine

Purpose

Determine conversion object status.

Library

Standard Library (**libc.a**)

Syntax

```
#include <wchar.h>
```

```
int mbsinit (const mbstate_t * ps) ;
```

Description

If *ps* is not a null pointer, the **mbsinit** function determines whether the object pointed to by ps describes an initial conversion state.

The **mbstate_t** object is used to describe the current conversion state from a particular character sequence to a wide-character sequence (or vice versa) under the rules of a particular setting of the LC_CTYPE category of the current locale.

The initial conversion state corresponds, for a conversion in either direction, to the beginning of a new character sequence in the initial shift state. A zero valued **mbstate_t** object is at least one way to describe an initial conversion state. A zero valued **mbstate_t** object can be used to initiate conversion involving any character sequence, in any LC_CTYPE category setting.

Return Values

The **mbsinit** function returns non-zero if **ps** is a null pointer, or if the pointed-to object describes an initial conversion state; otherwise, it returns zero.

If an **mbstate_t** object is altered by any of the functions described as `restartable`, and is then used with a different character sequence, or in the other conversion direction, or with a different LC_CTYPE category setting than on earlier function calls, the behavior is undefined.

mbsinvalid Subroutine

Purpose

Validates characters of multibyte character strings.

Note: The **mbsinvalid** subroutine is specific to the manufacturer. It is not defined in the POSIX, ANSI, or X/Open standards. Use of this subroutine may affect portability.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <mbstr.h>
```

```
char *mbsinvalid ( S)
const char *S;
```

Description

The **mbsinvalid** subroutine examines the string pointed to by the *S* parameter to determine the validity of characters. The **LC_CTYPE** category affects the behavior of the **mbsinvalid** subroutine.

Parameters

Item	Description
S	Contains a multibyte character string.

Return Values

The **mbsinvalid** subroutine returns a pointer to the byte following the last valid multibyte character in the *S* parameter. If all characters in the *S* parameter are valid multibyte characters, a null pointer is returned. If the *S* parameter is a null pointer, the behavior of the **mbsinvalid** subroutine is unspecified.

mbslen Subroutine

Purpose

Determines the number of characters (code points) in a multibyte character string.

Note: The **mbslen** subroutine is specific to the manufacturer. It is not defined in the POSIX, ANSI, or X/Open standards. Use of this subroutine may affect portability.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdlib.h>

size_t mbslen( MbString)
char *mbs;
```

Description

The **mbslen** subroutine determines the number of characters (code points) in a multibyte character string. The **LC_CTYPE** category affects the behavior of the **mbslen** subroutine.

Parameters

Item	Description
MbString	Points to a multibyte character string.

Return Values

The **mbslen** subroutine returns the number of multibyte characters in a multibyte character string. It returns 0 if the *MbString* parameter points to a null character or if a character cannot be formed from the string pointed to by this parameter.

mbsncat, mbsncmp, or mbsncpy Subroutine

Purpose

Performs operations on a specified number of null-terminated multibyte characters.

Note: These subroutines are specific to the manufacturer. They are not defined in the POSIX, ANSI, or X/Open standards. Use of these subroutines may affect portability.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <mbstr.h>
```

```
char *mbsncat(MbString1, MbString2, Number)
char * MbString1, * MbString2;
size_t  Number;
```

```
int mbsncmp(MbString1, MbString2, Number)
char *MbString1, *MbString2;
size_t Number;
```

```
char *mbsncpy(MbString1, MbString2, Number)
char *MbString1, *MbString2;
size_t Number;
```

Description

The **mbsncat**, **mbsncmp**, and **mbsncpy** subroutines operate on null-terminated multibyte character strings.

The **mbsncat** subroutine appends up to the specified maximum number of multibyte characters from the *MbString2* parameter to the end of the *MbString1* parameter, appends a null character to the result, and then returns the *MbString1* parameter.

The **mbsncmp** subroutine compares the collation weights of multibyte characters. The **LC_COLLATE** category specifies the collation weights for all characters in a locale. The **mbsncmp** subroutine compares up to the specified maximum number of multibyte characters from the *MbString1* parameter to the *MbString2* parameter. It then returns an integer greater than 0 if *MbString1* is greater than *MbString2*. It returns 0 if the strings are equivalent. It returns an integer less than 0 if *MbString1* is less than *MbString2*.

The **mbsncpy** subroutine copies up to the value of the *Number* parameter of multibyte characters from the *MbString2* parameter to the *MbString1* parameter and returns *MbString1*. If *MbString2* is shorter than *Number* multi-byte characters, *MbString1* is padded out to *Number* characters with null characters.

Parameters

Item	Description
MbString1	Contains a multibyte character string.
MbString2	Contains a multibyte character string.
Number	Specifies a maximum number of characters.

mbspbrk Subroutine

Purpose

Locates the first occurrence of multibyte characters or code points in a string.

Note: The **mbspbrk** subroutine is specific to the manufacturer. It is not defined in the POSIX, ANSI, or X/Open standards. Use of this subroutine may affect portability.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <mbstr.h>
```

char *mbspbrk(*MbString1*, *MbString2***)**
**char ***MbString1*, ***MbString2*;

Description

The **mbspbrk** subroutine locates the first occurrence in the string pointed to by the *MbString1* parameter, of any character of the string pointed to by the *MbString2* parameter.

Parameters

Item	Description
MbString1	Points to the string being searched.
MbString2	Pointer to a set of characters in a string.

Return Values

The **mbspbrk** subroutine returns a pointer to the character. Otherwise, it returns a null character if no character from the string pointed to by the *MbString2* parameter occurs in the string pointed to by the *MbString1* parameter.

mbsrchr Subroutine

Purpose

Locates a character or code point in a multibyte character string.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <mbstr.h>
```

char *mbsrchr(*MbString*, *MbCharacter***)**
**char ***MbString*;
int *MbCharacter*;

Description

The **mbschr** subroutine locates the last occurrence of the *MbCharacter* parameter in the string pointed to by the *MbString* parameter. The *MbCharacter* parameter is a multibyte character represented as an integer. The terminating null character is considered to be part of the string.

Parameters

Item	Description
MbString	Points to a multibyte character string.
MbCharacter	Specifies a multibyte character represented as an integer.

Return Values

The **mbsrchr** subroutine returns a pointer to the *MbCharacter* parameter within the multibyte character string. It returns a null pointer if *MbCharacter* does not occur in the string.

mbsrtowcs Subroutine

Purpose

Convert a character string to a wide-character string (restartable).

Library

Standard Library (**libc.a**)

Syntax

```
#include <wchar.h>
```

```
size_t mbsrtowcs ((wchar_t * dst, const char ** src, size_t len, mbstate_t * ps) ;
```

Description

The **mbsrtowcs** function converts a sequence of characters, beginning in the conversion state described by the object pointed to by *ps*, from the array indirectly pointed to by **src** into a sequence of corresponding wide-characters. If *dst* is not a null pointer, the converted characters are stored into the array pointed to by *dst*. Conversion continues up to and including a terminating null character, which is also stored. Conversion stops early in either of the following cases:

- When a sequence of bytes is encountered that does not form a valid character.
- When *len* codes have been stored into the array pointed to by **dst** (and *dst* is not a null pointer).

Each conversion takes place as if by a call to the **mbrtowc** function.

If *dst* is not a null pointer, the pointer object pointed to by src is assigned either a null pointer (if conversion stopped due to reaching a terminating null character) or the address just past the last character converted (if any). If conversion stopped due to reaching a terminating null character, and if *dst* is not a null pointer, the resulting state described is the initial conversion state.

If *ps* is a null pointer, the **mbsrtowcs** function uses its own internal **mbstate_t** object, which is initialised at program startup to the initial conversion state. Otherwise, the **mbstate_t** object pointed to by ps is used to completely describe the current conversion state of the associated character sequence. The implementation will behave as if no function defined in this specification calls **mbsrtowcs**.

The behavior of this function is affected by the LC_CTYPE category of the current locale.

Return Values

If the input conversion encounters a sequence of bytes that do not form a valid character, an encoding error occurs. In this case, the **mbsrtowcs** function stores the value of the macro EILSEQ in errno and

returns (**size_t)-1**); the conversion state is undefined. Otherwise, it returns the number of characters successfully converted, not including the terminating null (if any).

Error Codes

The **mbsrtowcs** function may fail if:

Item	Description
EINVAL	ps points to an object that contains an invalid conversion state.
EILSEQ	Invalid character sequence is detected.

mbstomb Subroutine

Purpose

Extracts a multibyte character from a multibyte character string.

Note: The **mbstomb** subroutine is specific to the manufacturer. It is not defined in the POSIX, ANSI, or X/Open standards. Use of this subroutine may affect portability.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <mbstr.h>

mbchar_t mbstomb ( MbString)
const char *MbString;
```

Description

The **mbstomb** subroutine extracts the multibyte character pointed to by the *MbString* parameter from the multibyte character string. The **LC_CTYPE** category affects the behavior of the **mbstomb** subroutine.

Parameters

Item	Description
MbString	Contains a multibyte character string.

Return Values

The **mbstomb** subroutine returns the code point of the multibyte character as a **mbchar_t** data type. If an unusable multibyte character is encountered, a value of 0 is returned.

mbstowcs Subroutine

Purpose

Converts a multibyte character string to a wide character string.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdlib.h>
```

size_t mbstowcs(*WcString*, *String*, *Number***)**
wchar_t ***_WcString_;**
const char ***_String_;**
size_t *Number***;**

Description

The **mbstowcs** subroutine converts the sequence of multibyte characters pointed to by the *String* parameter to wide characters and places the results in the buffer pointed to by the *WcString* parameter. The multibyte characters are converted until a null character is reached or until the number of wide characters specified by the *Number* parameter have been processed.

Parameters

Item	Description
WcString	Points to the area where the result of the conversion is stored.
String	Points to a multibyte character string.
Number	Specifies the maximum number of wide characters to be converted.

Return Values

The **mbstowcs** subroutine returns the number of wide characters converted, not including a null terminator, if any. If an invalid multibyte character is encountered, a value of -1 is returned. The *WcString* parameter does not include a null terminator if the value *Number* is returned.

If *WcString* is a null wide character pointer, the **mbstowcs** subroutine returns the number of elements required to store the wide character codes in an array.

Error Codes

The **mbstowcs** subroutine fails if the following occurs:

Item	Description
EILSEQ	Invalid byte sequence is detected.

mbswidth Subroutine

Purpose

Determines the number of multibyte character string display columns.

Note: The **mbswidth** subroutine is specific to this manufacturer. It is not defined in the POSIX, ANSI, or X/Open standards. Use of this subroutine may affect portability.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <mbstr.h>
```

```
int mbswidth ( MbString,  Number)
const char *MbString;
size_t Number;
```

Description

The **mbswidth** subroutine determines the number of display columns required for a multibyte character string.

Parameters

Item	Description
MbString	Contains a multibyte character string.
Number	Specifies the number of bytes to read from the *s* parameter.

Return Values

The **mbswidth** subroutine returns the number of display columns that will be occupied by the *MbString* parameter if the number of bytes (specified by the *Number* parameter) read from the *MbString* parameter form valid multibyte characters. If the *MbString* parameter points to a null character, a value of 0 is returned. If the *MbString* parameter does not point to valid multibyte characters, -1 is returned. If the *MbString* parameter is a null pointer, the behavior of the **mbswidth** subroutine is unspecified.

mbtowc Subroutine

Purpose

Converts a multibyte character to a wide character.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <stdlib.h>

int mbtowc ( WideCharacter,  String,  Number)
wchar_t *WideCharacter;
const char *String;
size_t Number;
```

Description

The **mbtowc** subroutine converts a multibyte character to a wide character and returns the number of bytes of the multibyte character.

The **mbtowc** subroutine determines the number of bytes that comprise the multibyte character pointed to by the *String* parameter. It then converts the multibyte character to a corresponding wide character and, if the *WideCharacter* parameter is not a null pointer, places it in the location pointed to by the *WideCharacter* parameter. If the *WideCharacter* parameter is a null pointer, the **mbtowc** subroutine returns the number of converted bytes but does not change the *WideCharacter* parameter value. If the *WideCharacter* parameter returns a null value, the multibyte character is not converted.

Parameters

Item	Description
WideCharacter	Specifies the location where a wide character is to be placed.
String	Specifies a multibyte character.
Number	Specifies the maximum number of bytes of a multibyte character.

Return Values

The **mbtowc** subroutine returns a value of 0 if the *String* parameter is a null pointer. The subroutine returns a value of -1 if the bytes pointed to by the *String* parameter do not form a valid multibyte character before the number of bytes specified by the *Number* parameter (or fewer) have been processed. It then sets the **errno** global variable to indicate the error. Otherwise, the number of bytes comprising the multibyte character is returned.

Error Codes

The **mbtowc** subroutine fails if the following occurs:

Item	Description
EILSEQ	Invalid byte sequence is detected.

memccpy, memchr, memcmp, memcpy, memset, memset_s, or memmove Subroutine

Purpose

Performs memory operations and handles runtime constraint violations.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <memory.h>
#include <string.h>
#define STDC_WANT_LIB_EXT1 1
```

```
void *memccpy (Target, Source, C, N)
void *Target;
const void *Source;
int C;
size_t N;
```

```
void *memchr ( S, C, N)
const void *S;
int C;
size_t N;
```

```
int memcmp (Target, Source, N)
const void *Target, *Source;
size_t N;
```

```
void *memcpy (Target, Source, N)
void *Target;
```

```
const void *Source;
size_t N;
```

```
void *memset (S, C, N)
void *S;
int C;
size_t N;
```

```
void *memmove (Target, Source,N)
void *Source;
const void *Target;
size_t N;
```

```
errno_t memset_s (s,smax,c,n)
void * s;
rsize_t smax;
int c;
rsize_t n;
```

Description

The **memory** subroutines operate on memory areas. A memory area is an array of characters bounded by a count. The **memory** subroutines do not check for the overflow of any receiving memory area. All of the **memory** subroutines are declared in the **memory.h** file.

The **memccpy** subroutine copies characters from the memory area specified by the *Source* parameter into the memory area specified by the *Target* parameter. The **memccpy** subroutine stops after the first character specified by the *C* parameter (converted to the **unsigned char** data type) is copied, or after *N* characters are copied, whichever comes first. If copying takes place between objects that overlap, the behavior is undefined.

The **memcmp** subroutine compares the first *N* characters as the **unsigned char**data type in the memory area specified by the *Target* parameter to the first *N* characters as the **unsigned char** data type in the memory area specified by the *Source* parameter.

The **memcpy** subroutine copies *N* characters from the memory area specified by the *Source* parameter to the area specified by the *Target* parameter and then returns the value of the *Target* parameter.

The **memset** subroutine sets the first *N* characters in the memory area specified by the *S* parameter to the value of character *C* and then returns the value of the *S* parameter.

Like the **memcpy** subroutine, the **memmove** subroutine copies *N* characters from the memory area specified by the *Source* parameter to the area specified by the *Target* parameter. However, if the areas of the *Source* and *Target* parameters overlap, the move is performed non-destructively, proceeding from right to left.

The **memccpy** subroutine is not in the ANSI C library.

The **memset_s** subroutine copies the value of **c** (converted to an unsigned character) into each of the first **n** characters of the object pointed by **s**. Unlike **memset**, any call to the **memset_s** function is evaluated according to the rules of the abstract machine and considers that the memory indicated by **s** and **n** might be accessible in the future and contains the values indicated by **c**.

Runtime Constraints

1. For the **memset_s** subroutine, the parameter **s** must not be a null pointer. Either **smax** or **n** can be greater than **RSIZE_MAX**, but **n** cannot be greater than **smax**.
2. If there is a runtime constraint violation and **s** is not a null pointer and **smax** is not greater than **RSIZE_MAX**, the **memset_s** subroutine stores the value of **c** (converted to an unsigned character) into each of the first **smax** characters of the object pointed by **s**.

Parameters

Item	Description
Target	Points to the start of a memory area.
Source	Points to the start of a memory area.
C	Specifies a character to search.
N	Specifies the number of characters to search.
S	Points to the start of a memory area.
s	Specifies the destination buffer for the copy.
c	Specifies the value to be copied.
smax	Specifies the maximum number of characters that can be copied.
n	Specifies the number of characters to be copied.

Return Values

The **memccpy** subroutine returns a pointer to character *C* after it is copied into the area specified by the *Target* parameter, or a null pointer if the *C* character is not found in the first *N* characters of the area specified by the *Source* parameter.

The **memchr** subroutine returns a pointer to the first occurrence of the *C* character in the first *N* characters of the memory area specified by the *S* parameter, or a null pointer if the *C* character is not found.

The **memcmp** subroutine returns the following values:

Item	Description
Less than 0	If the value of the *Target* parameter is less than the values of the *Source* parameter.
Equal to 0	If the value of the *Target* parameter equals the value of the *Source* parameter.
Greater than 0	If the value of the *Target* parameter is greater than the value of the *Source* parameter.

The **memset_s** subroutine returns zero if there is no runtime constraint violation. Otherwise, a nonzero value is returned.

meta Subroutine

Purpose

Enables/disables meta-keys.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>

int meta(WINDOW *win,
bool bf);
```

Description

Initially, whether the terminal returns 7 or 8 significant bits on input depends on the control mode of the display driver. To force 8 bits to be returned, invoke the **meta** subroutine (win, TRUE). To force 7 bits to be returned, invoke the **meta** subroutine (win, FALSE). The *win* argument is always ignored.

If the terminfo capabilities **smm** (meta_on) and **rmm** (meta_off) are defined for the terminal, **smm** is sent to the terminal when **meta** (win, TRUE) is called and **rmm** is sent when **meta** (win, FALSE) is called.

Parameters

Item	Description
bf	
**win*	

Return Values

Upon successful completion, the **meta** subroutine returns OK. Otherwise, it returns ERR.

Examples

1. To request an 8-bit character return when using a **getch** routine, enter:

```
WINDOW *some_window;
meta(some_window, TRUE);
```

2. To strip the highest bit off the character returns in the user-defined window `my_window`, enter:

```
WINDOW *some_window;
meta(some_window, FALSE);
```

mincore Subroutine

Purpose

Determines residency of memory pages.

Library

Standard C Library (**libc.a**).

Syntax

```
int mincore ( addr,  len, * vec)
caddr_t addr;
size_t len;
char *vec;
```

Description

The **mincore** subroutine returns the primary-memory residency status for regions created from calls made to the **mmap** subroutine. The status is returned as a character for each memory page in the range specified by the *addr* and *len* parameters. The least significant bit of each character returned is set to 1 if the referenced page is in primary memory. Otherwise, the bit is set to 0. The settings of the other bits in each character are undefined.

Parameters

Item	Description
addr	Specifies the starting address of the memory pages whose residency is to be determined. Must be a multiple of the page size returned by the **sysconf** subroutine using the **_SC_PAGE_SIZE** value for the *Name* parameter.
len	Specifies the length, in bytes, of the memory region whose residency is to be determined. If the *len* value is not a multiple of the page size as returned by the **sysconf** subroutine using the **_SC_PAGE_SIZE** value for the *Name* parameter, the length of the region is rounded up to the next multiple of the page size.
vec	Specifies the character array where the residency status is returned. The system assumes that the character array specified by the *vec* parameter is large enough to encompass a returned character for each page specified.

Return Values

When successful, the **mincore** subroutine returns 0. Otherwise, it returns -1 and sets the **errno** global variable to indicate the error.

Error Codes

If the **mincore** subroutine is unsuccessful, the **errno** global variable is set to one of the following values:

Item	Description
EFAULT	A part of the buffer pointed to by the *vec* parameter is out of range or otherwise inaccessible.
EINVAL	The *addr* parameter is not a multiple of the page size as returned by the **sysconf** subroutine using the **_SC_PAGE_SIZE** value for the *Name* parameter.
ENOMEM	Addresses in the (*addr*, *addr* + *len*) range are invalid for the address space of the process, or specify one or more pages that are not mapped.

MIO_aio_read64 Subroutine

Purpose

Read asynchronously from a file through MIO library.

Library

Modular I/O Library (**libmio.a**)

Syntax

```
#include <libmio.h>

int MIO_aio_read64( FileDescriptor, aiocbp )
```

```
int FileDescriptor;
struct aiocb64 *aiocbp;
```

Description

This subroutine is an entry point of the MIO library for the **Legacy AIO aio_read64** subroutine. Use this subroutine to instrument your application with the MIO library. You can replace the **Legacy AIO aio_read64 kernel I/O** subroutine with this equivalent MIO subroutine. See **Modular I/O** in *Performance management* for MIO library implementation.

Use this subroutine to read asynchronously from an open file specified by the *FileDescriptor* parameter. The *FileDescriptor* parameter results from an **MIO_open64** subroutine.

Parameters

The parameters are those of the corresponding standard POSIX system call aio_read64.

Return Values

The return values are those of the corresponding standard POSIX system call aio_read64.

Error Codes

The error codes are those of the corresponding standard POSIX system call aio_read64.

Location

/usr/lib/libmio.a

MIO_aio_suspend64 Subroutine

Purpose

Suspend the calling process until one or more asynchronous I/O requests are completed.

Library

Modular I/O Library (**libmio.a**)

Syntax

```
#include <libmio.h>

int MIO_aio_suspend64( Count, aiocbplist )
int Count;
struct aiocb64 **aiocbplist;
```

Description

This subroutine is an entry point of the MIO library for the **Legacy AIO aio_suspend64** subroutine. Use this subroutine to instrument your application with the MIO library. You can replace the **Legacy AIO aio_suspend64 kernel I/O** subroutine with this equivalent MIO subroutine. See **Modular I/O** in *Performance management* for the MIO library implementation.

The **aio_suspend64** subroutine suspends the calling process until one or more of the *Count* parameter asynchronous I/O requests are completed or a signal interrupts the subroutine. Specifically, the **aio_suspend64** subroutine handles requests associated with the aio control block (aiocb) structures pointed to by the *aiocbplist* parameter.

Parameters

The parameters are those of the corresponding standard POSIX system call aio_suspend64.

Return Values

The return values are those of the corresponding standard POSIX system call aio_suspend64.

Error Codes

The error codes are those of the corresponding standard POSIX system call aio_suspend64.

Location

/usr/lib/libmio.a

MIO_aio_write64 Subroutine

Purpose

Write asynchronously to a file through the MIO library.

Library

Modular I/O library (**libmio.a**)

Syntax

```
#include <libmio.h>

int MIO_aio_write64( FileDescriptor, aiocbp )
int FileDescriptor;struct aiocb64 *aiocbp;
struct aiocb64 *aiocbp;
```

Description

This subroutine is an entry point of the MIO library for the **Legacy AIO aio_write64** subroutine. Use this subroutine to instrument your application with the MIO library. You can replace the **Legacy AIO aio_write64 kernel I/O** subroutine with this equivalent MIO subroutine. See **Modular I/O** in *Performance management* for the MIO library implementation.

Use this subroutine to write asynchronously to an open file specified by the *FileDescriptor* parameter. The *FileDescriptor* parameter results from an **MIO_open64** subroutine.

Parameters

The parameters are those of the corresponding standard POSIX system call aio_write64.

Return Values

The return values are those of the corresponding standard POSIX system call aio_write64.

Error Codes

The error codes are those of the corresponding standard POSIX system call aio_write64.

Location

/usr/lib/libmio.a

MIO_close Subroutine

Purpose

Close a file descriptor through the MIO library.

Library

Modular I/O library (**libmio.a**)

Syntax

```
#include <libmio.h>

int MIO_close (FileDescriptor)

int FileDescriptor;
```

Description

This subroutine is an entry point of the MIO library. Use this subroutine to instrument your application with the MIO library. You can replace the **close kernel I/O** subroutine with this equivalent MIO subroutine. See the **Modular I/O** in *Performance management* for the MIO library implementation.

Use this subroutine to close a file with the *FileDescriptor* parameter through the Modular I/O (MIO) library. The *FileDescriptor* parameter results from the **MIO_open64** subroutine.

Parameters

The parameters are those of the corresponding standard POSIX system call close.

Return Values

The return values are those of the corresponding standard POSIX system call close.

Error Codes

The error codes are those of the corresponding standard POSIX system call close.

Standard Output

MIO library outputs are flushed on the **MIO_close** subroutine call in the **stats** file.

The following is the information found in the diagnostic output file. It contains debug information:

- If you set the stats option of the trace module (trace/stats), it runs diagnostics from the trace module.
- If you set the stats option of the pf module (pf/stats), it runs diagnostics from the pf module.
- If you set the stats option of the recov module (recov/stats), it runs diagnostics from the recovery trace.
- If you set the nostats option of the trace or the pf module, these diagnostics are suppressed.

The diagnostic file name is defined in the MIO_STATS environment variable if the stats option is set to the default value of *mioout*.

To separate the trace, pf or recov module diagnostics from other outputs, set the stats options to the following other file names:

- trace/stats=<*tracefile*>
- pf/stats=<*pffile*>
- recov/stats=<*recovfile*>

The *tracefile*, *pffile* and *recovfile* are templates for the file names of module diagnostics output. You can give file names for the output of the trace, pf or recov module diagnostics.

Standard output includes the following information:

Header, which contains the following information:

- Date
- Hostname
- Enabled or disabled AIO
- Program name
- MIO library version
- Environment variables

Debug, which contains the following information:

- The list of all the debug options
- The table of all of the modules' definitions if the DEF debug option is set
- Open request made to the `MIO_open64` subroutine if the OPEN debug option is set
- The modules invoked if the MODULES debug option is set

Trace module diagnostic, which contains the following information:

- Time if the TIMESTAMP debug option is set
- Trace on close or on intermediate interrupt
- Trace module position in module_list
- Processed file name
- Rate, which is the amount of data divided by the total time. The total time here means the cumulative amount of time spent beneath the trace module
- Demand rate, which is the amount of data divided by the length of time when the file is opened (including the time of opening and closing the file)
- The current (when tracing) file size and the maximum size of the file during this file processing
- File system information: file type and sector size
- Open mode and flags of the file
- For each subroutine, the following information is displayed:

  name of the subroutine
  count of calling of this subroutine
  time of processing for this subroutine
- For read or write subroutines, the following information is displayed:

  requested (requested size to read or write) total (real size read or write: returned by AIX(r) system call) min (minimum size to read or write) max (maximum size to read or write)
- For the seek subroutine, the following information is displayed:

  the average seek delta (total seek delta/seek count)
- For the **aread** or **awrite** subroutine:

  count, time and rate of transfer time including suspend, and read or write time
- For the **fcntl** subroutine, the number of pages is returned.

The following is an example of a `trace` diagnostic:

date

```
Trace onclose or intermediate:
previous module or calling program<->next module:file name:
```

```
(total transferred bytes/total time)=rate
  demand rate=rate/s=total transferred bytes/(close time-open time)
  current size=actual size of the file
max_size=max size of the file
mode=file open mode
FileSystemType=file system type given by fststat(stat_b.f_vfstype)
sector size=Minimum direct i/o transfer size
oflags=file open flags
open     open count     open time
fcntl    fcntl count    fcntl time
read     read count     read time  requested size    total size   minimum    maximum
aread    aread count    aread time requested size    total size   minimum    maximum
suspend count time rate
write    write count    write time  requested size   total size   minimum    maximum
seek     seek count     seek time   average seek delta
size
page     fcntl page_info count
```

The following is a sample of a `trace` diagnostic:

```
MIO statistics file : Tue May 10 14:14:08 2005

```

The following is a template of the `pf` module diagnostic:

pf close for<*name of the file in the cache*>
pf close for global or private cache <*global cache number*>
<*nb_pg_compute*>**page of**<*page-size*> <*sector_size*> **bytes per sector**
<*nb_real_pg_not_pf*>/<*nb_pg_not_pf*> **pages not preread for write**
<*nb_unused_pf*>**unused prefetches out of**<*nb_start_pf*>
prefetch=<*nb_pg_to_pf*>
<*number*> **of write behind**
<*number*> **of page syncs forced by ill formed writes**
<*number*> **of pages retained over close**
<*unit*> **transferred / Number of requests**
program --> <*bytes written into the cache by parent*>**/**
<*number of write from parent*>--> **pf** -->
<*written out of the cache from the child*>**/**<*number of partial page written*>
program --> <*bytes read out of the cache by parent*>**/**
<*number of read from parent*><- **pf** <-
<*bytes read in from child of the cache*>**/**<*number of page read from child*>

The following is explanation of the terms in the `pf` module template:

- *nb_pg_compute*= number of page compute by cache_size/ page size
- *nb_real_pg_not_pf*= real number page not prefetch because of *pffw* option (suppress number of page prefetch because sector not *valid*)
- *nb_pg_not_pf*= page of unused prefetch
- *nb_unused_pf*= number of started prefetch
- *nb_pg_to_pf*= number of page to prefetch

The following is a sample of the `pf` module diagnostic:

```
pf close for /home/user1/pthread/258/SM20182_0.SCR300
50 pages of 2097152 bytes 131072 bytes per sector
133/133 pages not preread for write
23 unused prefetches out of 242 : prefetch=2
95 write behinds
mbytes transferred / Number of requests
program --> 257/257 --> pf --> 257/131 --> aix
program <-- 269/269 <-- pf <-- 265/133 <-- aix
```

The following is the **recov** module output:

If open or write routine failed, the `recov` module, if set, is called. The `recov` module adds the following comments in the output file:

- The value of the *open_command* option
- The value of the *command* option
- The `errno`
- The index of retry

The following is a sample of the `recov` module:

```
15:30:00
   recov : command=ls -l file=file.dat errno=28 try=0
   recov : failure : new_ret=-1
```

Location

/usr/lib/libmio.a

MIO_fcntl Subroutine

Purpose

Control open file descriptors through the MIO library.

Library

Modular I/O library (**libmio.a**)

Syntax

```
#include <libmio.h>

int MIO_fcntl ( FileDescriptor, Command, Argument )

int  FileDescriptor, Command, Argument;
```

Description

This subroutine is an entry point of the MIO library, offering the same features as the **fcntl** subroutine. Use this subroutine to instrument your application with the MIO library. You can replace the **fcntl kernel I/O** subroutine with this equivalent MIO subroutine. See **Modular I/O** in *Performance management* for the MIO library implementation.

Use this subroutine to perform controlling operations on the open file specified by the *FileDescriptor* parameter. The *FileDescriptor* parameter results from the **MIO_open64** subroutine.

Parameters

The parameters are those of the corresponding standard POSIX system call fcntl.

Return Values

The return values are those of the corresponding standard POSIX system call fcntl.

Error Codes

The error codes are those of the corresponding standard POSIX system call fcntl.

Location

/usr/lib/libmio.a

MIO_ffinfo Subroutine

Purpose

Return file information through the MIO library.

Library

Modular I/O library (**libmio.a**)

Syntax

```
#include <libmio.h>
int MIO_ffinfo (FileDescriptor, Command, Buffer, Length)
int FileDescriptor;
int Command;
struct diocapbuf  *Buffer;
int Length;
```

Description

This subroutine is an entry point of the MIO library. Use this subroutine to instrument your application with the MIO library. You can replace the **ffinfo kernel I/O** subroutine with this equivalent MIO subroutine. See the **Modular I/O** in *Performance management* for MIO library implementation.

Use this subroutine to obtain specific file information for the open file referenced by the *FileDescriptor* parameter. The *FileDescriptor* parameter results from the **MIO_open64** subroutine.

Parameters

The parameters are those of the corresponding standard POSIX system call ffinfo.

Return Values

The return values are those of the corresponding standard POSIX system call ffinfo.

Error Codes

The error codes are those of the corresponding standard POSIX system call ffinfo.

Location

/usr/lib/libmio.a

MIO_fstat64 Subroutine

Purpose

Provide information about a file through the MIO library.

Library

Modular I/O library (**libmio.a**)

Syntax

```
#include <libmio.h>

int MIO_fstat64 (Filedescriptor, Buffer)
int FileDescriptor;
struct stat64 *Buffer;
```

Description

This subroutine is an entry point of the MIO library. Use this subroutine to instrument your application with the MIO library. You can replace the **fstat64 kernel I/O** subroutine with this equivalent MIO subroutine. See the **Modular I/O** in *Performance management* for the MIO library implementation.

Use this subroutine to obtain information about the open file referenced by *FileDescriptor* parameter. The *FileDescriptor* parameter results from the **MIO_open64** subroutine.

Parameters

The parameters are those of the corresponding standard POSIX system call fstat64.

Return Values

The return values are those of the corresponding standard POSIX system call fstat64.

Error Codes

The error codes are those of the corresponding standard POSIX system call fstat64.

Location

/usr/lib/libmio.a

MIO_fsync Subroutine

Purpose

Save changes in a file to permanent storage through the MIO library.

Library

Modular I/O library (**libmio.a**)

Syntax

```
#include <libmio.h>

int MIO_fsync (FileDescriptor)

int FileDescriptor;
```

Description

This subroutine is an entry point of the MIO library. Use this subroutine to instrument your application with the MIO library. You can replace the fsync kernel I/O subroutine with this equivalent MIO subroutine. See the **Modular I/O** in *Performance management* for the MIO library implementation.

Use this subroutine to save to permanent storage all modified data in the specified range of the open file specified by the *FileDescriptor* parameter. The *FileDescriptor* parameter results from the **MIO_open64** subroutine.

Parameters

The parameters are those of the corresponding standard POSIX system call fsync.

Return Values

The return values are those of the corresponding standard POSIX system call fsync.

Error Codes

The error codes are those of the corresponding standard POSIX system call fsync.

Location

/usr/lib/libmio.a

MIO_ftruncate64 Subroutine

Purpose

Change the length of regular files through the MIO library.

Library

Modular I/O library (**libmio.a**)

Syntax

```
#include <libmio.h>

int MIO_ftruncate64 (FileDescriptor, Length)

int FileDescriptor;

int64 Length;
```

Description

This subroutine is an entry point of the MIO library. Use this subroutine to instrument your application with the MIO library. You can replace the **ftruncate64 kernel I/O** subroutine with this equivalent MIO subroutine. See the **Modular I/O** in *Performance management* for the MIO library implementation.

Use this subroutine to change the length of the open file specified by the *FileDescriptor* parameter through Modular I/O (MIO) library. The *FileDescriptor* parameter results from the **MIO_open64** subroutine.

Parameters

The parameters are those of the corresponding standard POSIX system call ftruncate64.

Return Values

The return values are those of the corresponding standard POSIX system call ftruncate64.

Error Codes

The error codes are those of the corresponding standard POSIX system call ftruncate64.

Location

/usr/lib/libmio.a

MIO_lio_listio64 Subroutine

Purpose

Initiate a list of asynchronous I/O requests with a single call.

Library

Modular I/O library (**libmio.a**)

Syntax

```
#include <libmio.h>

int MIO_lio_listio64 (Command, List, Nent, Eventp)
int Command;
struct liocb64 *List;
int Nent;
struct event *Eventp;
```

Description

This subroutine is an entry point of the MIO library for the **Legacy AIO lio_listio64** Subroutine. Use this subroutine to instrument your application with MIO library. You can replace the **Legacy AIO lio_listio64**

kernel I/O subroutine with this equivalent MIO subroutine. See the **Modular I/O** in *Performance management* for the MIO library implementation.

The **lio_listio64** subroutine allows the calling process to initiate the *Nent* parameter asynchronous I/O requests. These requests are specified in the liocb structures pointed to by the elements of the *List* array. The call may block or return immediately depending on the *Command* parameter. If the *Command* parameter requests that I/O completion be asynchronously notified, a SIGIO signal is delivered when all of the I/O operations are completed.

Parameters

The parameters are those of the corresponding standard POSIX system call lio_listio64.

Return Values

The return values are those of the corresponding standard POSIX system call lio_listio64.

Error Codes

The error codes are those of the corresponding standard POSIX system call lio_listio64.

Location

/usr/lib/libmio.a

MIO_lseek64 Subroutine

Purpose

Move the read-write file pointer through the MIO library.

Library

Modular I/O library (**libmio.a**)

Syntax

```
#include <libmio.h>

int64 MIO_lseek64 (FileDescriptor, Offset, Whence)
int FileDescriptor;
int64 Offset;
int Whence;
```

Description

This subroutine is an entry point of the MIO library. Use this subroutine to instrument your application with the MIO library. You can replace the **fseek64 kernel I/O** subroutine with this equivalent MIO subroutine. See the **Modular I/O** in *Performance management* for the MIO library implementation.

Use this subroutine to set the read-write file pointer for the open file specified by the *FileDescriptor* parameter through the Modular I/O (MIO) library. The FileDescriptor parameter results from the **MIO_open64** subroutine.

Parameters

The parameters are those of the corresponding standard POSIX system call lseek64.

Return Values

The return values are those of the corresponding standard POSIX system call lseek64.

Error Codes

The error codes are those of the corresponding standard POSIX system call lseek64.

Location

/usr/lib/libmio.a

MIO_open64 Subroutine

Purpose

Opens a file for reading or writing through the MIO library.

Library

Modular I/O library (**libmio.a**)

Syntax

```
#include <libmio.h>

int MIO_open64 (Path, OFlag, Mode, Extra)
char *Path;
int OFlag;int Mode;
struct mio_extra *Extra;
```

Description

This subroutine is an entry point of the MIO library. Use this subroutine to instrument your application with the MIO library. You can replace the **open64 kernel I/O** subroutine with this equivalent MIO subroutine. See the **Modular I/O** in *Performance management* for the MIO library implementation.

Use this subroutine to open a file through the Modular I/O (MIO) library. This library creates the context for this open file, according to the configuration set in MIO environment variables, or in the *Extra* parameter.

To analyze your application I/O and tune the I/O, use the MIO subroutines in the place of the standard I/O subroutines.

The MIO subroutines are:

- MIO_close
- MIO_lseek64
- MIO_read
- MIO_write
- MIO_ftruncate64
- MIO_fstat64
- MIO_fcntl
- MIO_ffinfo
- MIO_fsync

The standard I/O subroutines are:

- close

- lseek64
- read
- write
- ftruncate64
- fstat64
- fcntl
- finfo
- fsync

Parameters

Item	Description

Extra	Specifies some extra arguments for the MIO library. The simplest implementation is for any application to pass a zero pointer as the fourth argument. The fourth argument is a pointer to the mio_extra structure, you can usually pass a zero pointer, but you can also pass an mio_extra pointer (use this technique only if you are very familiar with how to code this argument).
	The mio_extra structure is defined in the following way:
	`struct mio_extra {`
	`int cookie ;`
	`/* Default value: MIO_EXTRA_COOKIE/`
	`int taskid ;`
	`/* for later */`
	`int64 bufsiz ;`
	`/* if > 1 : force the prefetch for write pffw */`
	`char *modules ;`
	`/* explicit module name,`
	`if any modules returns from MIO_FILES environment variable match */`
	`char *logical_name ;`
	`/* logical file name to open`
	`if file name don't match with MIO_FILES regexp`
	`*/`
	`int flags ;`
	`/* if MIO_EXTRA_SKIP_MIO_FILES_FLAG :`
	`don't use MIO_FILES env variable, but use extra->modules */`
	`} ;`

Mode	Specifies the modes. For more information, see the *Mode* flag in the **open64** subroutine.
Oflag	Specifies the type of access, the special open processing, the type of update, and the initial state of the open file. For more information, see the **open64** subroutine.
Path	Specifies the file to be opened.

Note: For applications that would not use the environment variable interface to apply the MIO modules to a file, the mio_extra hook provides an easy way to do that.

Environment variables

MIO is controlled by the following environment variables, which define the MIO features and are processed by the MIO_open64 subroutine:

The *MIO_STATS* variable is used to indicate a file that will be used as a repository for diagnostic messages and for output requested from the MIO modules. It is interpreted as a file name with two special cases. If the file is either the*stderr* or *stdout* output, the output will be directed towards the appropriate file stream. If the first character of the *MIO_STATS* variable is a plus sign (+), the file name to be used is the string following the plus sign (+), and the file is opened for appending. Without the preceding plus sign (+), the file is overwritten.

The *MIO_FILES* variable is the key to determine which modules are to be invoked for a given file when the MIO_open64 subroutine is called. The format for the *MIO_FILES* variable is the following:

```
first_file_name_list [ module list ] second_file_name_list [ module list] ...
```

When the MIO_open64 subroutine is called, MIO checks for the existence of the *MIO_FILES* variable and parses it as follows:

The *MIO_FILES* variable is parsed left to right. All characters up to the next occurrence of the bracket ([) are taken as a file name list. A file name list is a colon-separated list of file name templates. A file name template is used to match the name of the file opened by MIO and can use the following wildcard characters:

*****
Matches zero or more characters of a directory or file name.

?
Matches one character of a directory or file name.

******
Matches all remaining characters of a full path name.

If the file name templates does not contain a forward slash (/) , then all of the path directory information in the file name passed to the MIO_open64 subroutine is ignored and matching is applied only to the file name of the file being opened.

If the name of the file being opened is matched by one of the file name templates in the file name list then the module list to be invoked is taken as the string between brackets ([ ]). If the name of the file match two or more file name templates, the first match is taken into account. If the name of the file being opened does not match any of the file name templates in any of the file name lists then the file is opened with a default invocation of the AIX module.

If a match has occurred, the modules to be invoked are taken from the associated module list in the *MIO_FILES* variable. The modules are invoked left to right, with the left-most being closest to the user program and the right-most being closest to the operating system. If the module list does not start with the MIO module, a default invocation of the MIO module is added as a prefix. If the AIX module is not specified, a default invocation of the AIX module is appended.

The following is an example of the *MIO_FILES* variable:

```
setenv MIO_FILES " *.dat [ trace/stats ]"
```

Assume the *MIO_FILES* variable is set as follows:

```
MIO_FILES= *.dat:*.scr [ trace ] *.f01:*.f02:*.f03 [ trace | pf | trace ]
```

If the **test.dat** file is opened by the MIO_open64 subroutine, the **test.dat** file name matches ***.dat** and the following modules are invoked:

```
mio | trace | aix
```

If the **test.f02** file is opened by the MIO_open64 subroutine, the **test.f02** file name matches the second file name templates in the second file name list and the following modules are invoked:

```
mio | trace | pf | trace | aix
```

Each module has its own hardcoded default options for a default invocation. You can override the default options by specifying them in the associated *MIO_FILES* module list. The following example turns on the **stats** option for the trace module and requests that the output be directed to the **my.stats** file:

```
MIO_FILES= *.dat : *.scr [ trace/stats=my.stats ]
```

The options for a module are delimited with a forward slash (/). Some options require an associated string value and others might require an integer value. For those requiring a string value, if the string includes a forward slash (/), enclose the string in braces ({ }).

For those options requiring an integer value, append the integer value with a k, m, g, or t to represent kilo, mega, giga, or tera. You might also input integer values in base 10, 8, or 16. If you add a `0x` prefix to the integer value, the integer is interpreted as base 16. If you add a `0` prefix to the integer value, the integer is interpreted as base 8. If you add neither a `0x` prefix nor a `0` prefix to the integer value, the integer is interpreted as base 10.

The *MIO_DEFAULTS* variable is intended as a way to keep the *MIO_FILES* variable more readable. If the user is specifying several modules for multiple file name list and module list pairs, then the *MIO_FILES* variable might become quite long. To repeatedly override the hardcoded defaults in the same manner, you can specify new defaults for a module by specifying such defaults in the *MIO_DEFAULTS* variable. The *MIO_DEFAULTS* variable is a comma separated list of modules with their new defaults.

The following is an example of the *MIO_DEFAULTS* variable:

```
setenv MIO_DEFAULTS " trace/kbytes "
```

Assume that *MIO_DEFAULTS* variable is set as follows:

```
MIO_DEFAULTS = trace/events=prob.events , aix/debug
```

Any default invocation of the trace module will have binary event tracing enabled and directed towards the **prob.events** file and any default invocation of the AIX module will have debug enabled.

The *MIO_DEBUG* variable is intended as an aid in debugging the use of MIO. MIO searches the *MIO_DEFAULTS* variable for keywords and provides debugging output for the option. The available keywords are the following:

ALL
Turns on all of the *MIO_DEBUG* variable keywords.

ENV
Outputs environment variable matching requests.

OPEN
Outputs open requests made to the `MIO_open64` subroutine.

MODULES
Outputs modules invoked for each call to the `MIO_open64` subroutine.

TIMESTAMP
Places a timestamp preceding each entry into a **stats** file.

DEF
Outputs the definition table of each module. When the file opens, the outputs of all of the MIO library's definitions are processed for all the MIO library modules.

Return Values

The return values are those of the corresponding standard POSIX system call **open64**.

Error Codes

The error codes are those of the corresponding standard POSIX system call **open64**.

Standard Output

There is no MIO library output for the **MIO_open64** subroutine.

Note: MIO library output statistics are written in the **MIO_close** subroutine. This output filename is configurable with the *MIO_STATS* environment variable.

In the **example.stats** MIO output file, the module trace is set and reported, and the open requests are output. All of the values are in kilobytes.

Examples

The following **example.c** file issues 100 writes of 16 KB, seeks to the beginning of the file, issues 100 reads of 16 KB, and then seeks backward through the file reading 16 KB records. At the end the file is truncated to 0 bytes in length.

The *filename* argument to the following example is the file to be created, written to and read forwards and backwards:

```
------------------------------------------------------------------------------
#define _LARGE_FILES
#include <fcntl.h>
#include <stdio.h>
#include <errno.h>

#include "libmio.h"

/* Define open64, lseek64 and ftruncate64,  not
 * open, lseek, and ftruncate that are used in the code.  This is
 * because libmio.h defines _LARGE_FILES which forces <fcntl.h> to
 * redefine open, lseek, and ftruncate as open64, lseek64, and
 * ftruncate64
 */

#define open64(a,b,c) MIO_open64(a,b,c,0)
#define close         MIO_close
#define lseek64       MIO_lseek64
#define write         MIO_write
#define read          MIO_read
#define ftruncate64   MIO_ftruncate64

#define RECSIZE 16384
#define NREC    100

main(int argc, char **argv)
{
int i, fd, status ;
char *name ;
char *buffer ;
int64 ret64 ;

      if( argc < 2 ){
      fprintf(stderr,"Usage : example file_name\n");
      exit(-1);
   }
   name = argv[1] ;

   buffer = (char *)malloc(RECSIZE);
   memset( buffer, 0, RECSIZE ) ;

   fd = open(name, O_RDWR|O_TRUNC|O_CREAT, 0640 ) ;
   if( fd < 0 ){
      fprintf(stderr,"Unable to open file %s errno=%d\n",name,errno);
      exit(-1);
   }

/* write the file */
   for(i=0;i<NREC;i++){
      status = write( fd, buffer, RECSIZE ) ;
   }

/* read the file forwards */
   ret64 = lseek(fd, 0, SEEK_SET ) ;
   for(i=0;i<NREC;i++){
      status = read( fd, buffer, RECSIZE ) ;
   }
/* read the file backwards */
   for(i=0;i<NREC;i++){
      ret64 = lseek(fd, (NREC-i-1)*RECSIZE, SEEK_SET ) ;
      status = read( fd, buffer, RECSIZE ) ;
   }

/* truncate the file back to 0 bytes*/
   status = ftruncate( fd, 0 ) ;
```

```
   free(buffer);

/* close the file */
   status = close(fd);
}

-------------------------------------------------------------------------------
```

Both a script that sets the environment variables, compiles and calls the application and the **example.c** example are delivered and installed with the `libmio` file, as follows:

```
cc -o example example.c  -lmio

./example file.dat
```

The following environment variables are set to configure MIO:

setenv MIO_STATS example.stats
setenv MIO_FILES " *.dat [trace/stats] "
setenv MIO_DEFAULTS " trace/kbytes "
setenv MIO_DEBUG OPEN

See the **/usr/samples/libmio/README** file and sample files for details.

Location

/usr/lib/libmio.a

MIO_open Subroutine

Purpose

Opens a file for reading or writing through the MIO library.

Library

Modular I/O library (**libmio.a**)

Syntax

```
#include <libmio.h>

int MIO_open (Path, OFlag, Mode, Extra)
char *Path;
int OFlag;
int Mode;
struct mio_extra *Extra;
```

Description

The **MIO_open** subroutine is a redirection to the `MIO_open64` subroutine and is an entry point of the MIO library. To use the MIO library, the files have to be opened with the **O_LARGEFILE** flag. For more details on the **O_LARGEFILE** flag, see the `fcntl.h` File.

Use the **MIO_open** subroutine to instrument your application with the MIO library. You can replace the **open kernel I/O** subroutine with this equivalent MIO subroutine. See the **Modular I/O** in *Performance management* for the MIO library implementation.

Use this subroutine to open a file through the Modular I/O (MIO) library. This library creates the context for this open file, according to the configuration set in the MIO environment variables, or in the *Extra* parameter.

To analyze your application I/O and tune the I/O, use the MIO subroutines in the place of the standard I/O subroutines.

The MIO subroutines are:

- MIO_close
- MIO_lseek64
- MIO_read
- MIO_write
- MIO_ftruncate64
- MIO_fstat64
- MIO_fcntl
- MIO_ffinfo
- MIO_fsync

The standard I/O subroutines are:

- close
- lseek64
- read
- write
- ftruncate64
- fstat64
- fcntl
- finfo
- fsync

Parameters

Item	Description

Extra	Specifies additional arguments for the MIO library. The simplest implementation is to pass a zero pointer as the fourth argument. The fourth argument is a pointer to the mio_extra structure, you can usually pass a zero pointer, but you can also pass an mio_extra pointer (use this technique only if you are very familiar with how to code this argument).
	The mio_extra structure is defined as follows:
	`struct mio_extra {`
	`int cookie ;`
	`/* Default value: MIO_EXTRA_COOKIE/`
	`int taskid ;`
	`/* for later */`
	`int64 bufsiz ;`
	`/* if > 1 : force the prefetch for write pffw */`
	`char *modules ;`
	`/* explicit module name,`
	`if any modules returns from MIO_FILES environment variable match */`
	`char *logical_name ;`
	`/* logical file name to open`
	`if file name don't match with MIO_FILES regexp`
	`*/`
	`int flags ;`
	`/* if MIO_EXTRA_SKIP_MIO_FILES_FLAG :`
	`don't use MIO_FILES env variable, but use extra->modules */`
	`} ;`

Mode	Specifies the modes. For more information, see the *Mode* flag in the **open64** subroutine.

Item	Description
Oflag	Specifies the type of access, the special open processing, the type of update, and the initial state of the open file. For more information, see the **open64** subroutine.
Path	Specifies the file to be opened.

Note: For applications that would not use the environment variable interface to apply MIO modules to a file, the mio_extra hook provides an easy way to do that.

Environment variables

MIO is controlled through the following four environment variables. These environment variables, which define the MIO features, are processed by the MIO_open64 subroutine.

The *MIO_STATS* variable is used to indicate a file that will be used as a repository for diagnostic messages and for output requested from the MIO modules. It is interpreted as a file name with two special cases. If the file is either the*stderr* or *stdout* output, the output will be directed towards the appropriate file stream. If the first character of the *MIO_STATS* variable is a plus sign (+), the file name to be used is the string following the plus sign (+), and the file is opened for appending. Without the preceding plus sign (+), the file is overwritten.

The *MIO_FILES* variable is the key to determine which modules are to be invoked for a given file when the MIO_open64 subroutine is called. The format for the *MIO_FILES* variable is the following:

```
first_file_name_list [ module list ] second_file_name_list [ module list]
```

When the MIO_open64 subroutine is called, MIO checks for the existence of the *MIO_FILES* variable and parses it as follows:

The *MIO_FILES* variable is parsed left to right. All characters up to the next occurrence of the bracket ([) are taken as a file name list. A file name list is a colon-separated list of file name templates. A file name template is used to match the name of the file opened by MIO and can use the following wildcard characters:

*****
Matches zero or more characters of a directory or file name.

?
Matches one character of a directory or file name.

******
Matches all remaining characters of a full path name.

If the file name template does not contain a forward slash (/) , then all of the path directory information in the file name passed to the MIO_open64 subroutine is ignored and matching is applied only to the file name of the file being opened.

If the name of the file being opened is matched by one of the file name templates in the file name list then the module list to be invoked is taken as the string between brackets ([ ]). If the name of the file match two or more file name templates, the first match is taken into account. If the name of the file being opened does not match any of the file name templates in any of the file name lists then the file is opened with a default invocation of the AIX module.

If a match has occurred, the modules to be invoked are taken from the associated module list in the *MIO_FILES* variable. The modules are invoked left to right, with the left-most being closest to the user program and the right-most being closest to the operating system. If the module list does not start with the MIO module, a default invocation of the MIO module is added as a prefix. If theAIX module is not specified, a default invocation of theAIX module is appended.

The following is an example of the *MIO_FILES* variable:

```
setenv MIO_FILES " *.dat [ trace/stats ]"
```

Assume the *MIO_FILES* variable is set as follows:

```
MIO_FILES= *.dat:*.scr [ trace ] *.f01:*.f02:*.f03 [ trace | pf | trace ]
```

If the **test.dat** file is opened by the MIO_open64 subroutine, the **test.dat** file name matches ***.dat** and the following modules are invoked:

```
mio | trace | aix
```

If the **test.f02** file is opened by the MIO_open64 subroutine, the **test.f02** file name matches the second file name templates in the second file name list and the following modules are invoked:

```
mio | trace | pf | trace | aix
```

Each module has its own hardcoded default options for a default invocation. You can override the default options by specifying them in the associated *MIO_FILES* module list. The following example turns on the **stats** option for the trace module and requests that the output be directed to the **my.stats** file:

```
MIO_FILES= *.dat : *.scr [ trace/stats=my.stats ]
```

The options for a module are delimited with a forward slash (/). Some options require an associated string value and others might require an integer value. For those requiring a string value, if the string includes a forward slash (/), enclose the string in braces ({ }).

For those options requiring an integer value, append the integer value with a k, m, g, or t to represent kilo, mega, giga, or tera. You might also input integer values in base 10, 8, or 16. If you add a 0x prefix to the integer value, the integer is interpreted as base 16. If you add a 0 prefix to the integer value, the integer is interpreted as base 8. If you add neither a 0x prefix nor a 0 prefix to the integer value, the integer is interpreted as base 10.

The *MIO_DEFAULTS* variable is intended as a way to keep the *MIO_FILES* variable more readable. If the user is specifying several modules for multiple file name list and module list pairs, then the *MIO_FILES* variable might become quite long. To repeatedly override the hardcoded defaults in the same manner, you can specify new defaults for a module by specifying such defaults in the *MIO_DEFAULTS* variable. The *MIO_DEFAULTS* variable is a comma separated list of modules with their new defaults.

The following is an example of the *MIO_DEFAULTS* variable:

```
setenv MIO_DEFAULTS " trace/kbytes "
```

Assume that *MIO_DEFAULTS* variable is set as follows:

```
MIO_DEFAULTS = trace/events=prob.events , aix/debug
```

Any default invocation of the trace module will have binary event tracing enabled and directed towards the **prob.events** file and any default invocation of the AIX module will have debug enabled.

The *MIO_DEBUG* variable is intended as an aid in debugging the use of MIO. MIO searches the *MIO_DEFAULTS* variable for keywords and provides debugging output for the option. The available keywords are the following:

ALL
Turns on all of the *MIO_DEBUG* variable keywords.

ENV
Outputs environment variable matching requests.

OPEN
Outputs open requests made to the MIO_open64 subroutine.

MODULES
Outputs modules invoked for each call to the MIO_open64 subroutine.

TIMESTAMP
Places a timestamp preceding each entry into a **stats** file.

DEF
Outputs the definition table of each module. When the file opens, the outputs of all of the MIO library's definitions are processed for all the MIO library modules.

Return values

The return values are those of the corresponding standard POSIX system call **open64**.

Error codes

The error codes are those of the corresponding standard POSIX system call **open64**.

Standard output

There is no MIO library output for the **MIO_open64** subroutine.

MIO library output statistics are written in the **MIO_close** subroutine. This output filename is configurable with the *MIO_STATS* environment variable.

In the **example.stats**. MIO output file, the module trace is set and reported, and the open requests are output. All the values are in kilobytes.

Examples

The following **example.c** file issues 100 writes of 16 KB, seeks to the beginning of the file, issues 100 reads of 16 KB, and then seeks backward through the file reading 16 KB records. At the end the file is truncated to 0 bytes in length.

The *filename* argument to the following example is the file to be created, written to and read forwards and backwards:

```
------------------------------------------------------------------------------
#define _LARGE_FILES
#include <fcntl.h>
#include <stdio.h>
#include <errno.h>

#include "libmio.h"

/* Define open64, lseek64 and ftruncate64,  not
 * open, lseek, and ftruncate that are used in the code.  This is
 * because libmio.h defines _LARGE_FILES which forces <fcntl.h> to
 * redefine open, lseek, and ftruncate as open64, lseek64, and
 * ftruncate64
 */

#define open64(a,b,c) MIO_open64(a,b,c,0)
#define close         MIO_close
#define lseek64       MIO_lseek64
#define write         MIO_write
#define read          MIO_read
#define ftruncate64   MIO_ftruncate64

#define RECSIZE 16384
#define NREC    100

main(int argc, char **argv)
{
int i, fd, status ;
char *name ;
char *buffer ;
int64 ret64 ;

      if( argc < 2 ){
      fprintf(stderr,"Usage : example file_name\n");
      exit(-1);
   }
   name = argv[1] ;

   buffer = (char *)malloc(RECSIZE);
   memset( buffer, 0, RECSIZE ) ;
```

```
   fd = open(name, O_RDWR|O_TRUNC|O_CREAT, 0640 ) ;
   if( fd < 0 ){
      fprintf(stderr,"Unable to open file %s errno=%d\n",name,errno);
      exit(-1);
   }

/* write the file */
   for(i=0;i<NREC;i++){
      status = write( fd, buffer, RECSIZE ) ;
   }

/* read the file forwards */
   ret64 = lseek(fd, 0, SEEK_SET ) ;
   for(i=0;i<NREC;i++){
      status = read( fd, buffer, RECSIZE ) ;
   }
/* read the file backwards */
   for(i=0;i<NREC;i++){
      ret64 = lseek(fd, (NREC-i-1)*RECSIZE, SEEK_SET ) ;
      status = read( fd, buffer, RECSIZE ) ;
   }

/* truncate the file back to 0 bytes*/
   status = ftruncate( fd, 0 ) ;

   free(buffer);

/* close the file */
   status = close(fd);
}

--------------------------------------------------------------------------------
```

Both a script that sets the environment variables, compiles and calls the application and the **example.c** example are delivered and installed with the `libmio`, as follows:

```
cc -o example example.c  -lmio

./example file.dat
```

The following environment variables are set to configure MIO:

setenv MIO_STATS example.stats
setenv MIO_FILES " *.dat [trace/stats] "
setenv MIO_DEFAULTS " trace/kbytes "
setenv MIO_DEBUG OPEN

See the **/usr/samples/libmio/README** and sample files for details.

Location

/usr/lib/libmio.a

MIO_read Subroutine

Purpose

Read from a file through the MIO library.

Library

Modular I/O library (**libmio.a**)

Syntax

```
#include <libmio.h>

int MIO_read(FileDescriptor,
```

```
Buffer, NBytes)
int  FileDescriptor;
void * Buffer;
int NBytes;
```

Description

This subroutine is an entry point of the MIO library. Use this subroutine to instrument your application with the MIO library. You can replace the **read kernel I/O** subroutine with this equivalent MIO subroutine. See the **Modular I/O** in *Performance management* for the MIO library implementation.

Use this subroutine to read to the number of bytes of data specified by the *NBytes* parameter from the file associated with the *FileDescriptor* parameter into the buffer, through the Modular I/O (MIO) library. The *Buffer* parameter points to the buffer. The *FileDescriptor* parameter results from the **MIO_open64** subroutine.

Parameters

The parameters are those of the corresponding standard POSIX system call read.

Return Values

The return values are those of the corresponding standard POSIX system call read.

Error Codes

The error codes are those of the corresponding standard POSIX system call read.

Location

/usr/lib/libmio.a

MIO_write Subroutine

Purpose

Write to a file through the MIO library.

Library

Modular I/O library (**libmio.a**)

Syntax

```
#include <libmio.h>

int MIO_write(FileDescriptor,
Buffer, NBytes)
int  FileDescriptor;
void * Buffer;
int  NBytes;
```

Description

This subroutine is an entry point of the MIO library. Use this subroutine to instrument your application with the MIO library. You can replace the **write kernel I/O** subroutine with this equivalent MIO subroutine. See the **Modular I/O** in *Performance management* for the MIO library implementation.

Use this subroutine to write the number of bytes of data specified by the *NBytes* parameter from the buffer to the file associated with the *FileDescriptor* parameter through the Modular I/O (MIO) library. The *Buffer* parameter points to the buffer. The *FileDescriptor* parameter results from the **MIO_open64** subroutine.

Parameters

The parameters are those of the corresponding standard POSIX system call write.

Return Values

The return values are those of the corresponding standard POSIX system call write.

Error Codes

The error codes are those of the corresponding standard POSIX system call write.

Location

/usr/lib/libmio.a

mkdir or mkdirat Subroutine

Purpose

Creates a directory.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/stat.h>

int mkdir (Path,  Mode)
const char *Path;
mode_t Mode;

int mkdirat (DirFileDescriptor, Path, Mode)
int DirFileDescriptor;
const char * Path;
mode_t Mode;
```

Description

The **mkdir** and **mkdirat** subroutines create a new directory.

The new directory has the following:

- The owner ID is set to the process-effective user ID.
- If the parent directory has the *SetFileGroupID* (**S_ISGID**) attribute set, the new directory inherits the group ID of the parent directory. Otherwise, the group ID of the new directory is set to the effective group ID of the calling process.
- Permission and attribute bits are set according to the value of the *Mode* parameter, with the following modifications:
  - All bits set in the process-file mode-creation mask are cleared.

  - The *SetFileUserID* and *Sticky* (**S_ISVTX**) attributes are cleared.
- If the *Path* variable names a symbolic link, the link is followed. The new directory is created where the variable pointed.

The **mkdirat** subroutine is equivalent to the **mkdir** subroutine if the *DirFileDescriptor* parameter is set to **AT_FDCWD** or the *Path* parameter is an absolute path name. If the *DirFileDescriptor* parameter is a valid file descriptor of an open directory and the *Path* parameter is a relative path name, the *Path* parameter is considered as the relative path to the directory that is associated with the *DirFileDescriptor* parameter instead of the current working directory.

If the *DirFileDescriptor* parameter is opened without the **O_SEARCH** open flag, the subroutine checks to determine whether directory searches are permitted for that directory by using the current permissions of the directory. If the directory is opened with the **O_SEARCH** open flag, the subroutine does not perform the check for that directory.

Parameters

Item	Description
Path	Specifies the name of the new directory. If Network File System (NFS) is installed on your system, this path can cross into another node. In this case, the new directory is created at that node. To execute the **mkdir** or **mkdirat** subroutine successfully, a process must have write permission to the parent directory of the *Path* parameter.
Mode	Specifies the mask for the read, write, and execute flags for owner, group, and others. The *Mode* parameter specifies directory permissions and attributes. This parameter is constructed by logically ORing values described in the **<sys/mode.h>** file.
DirFileDescriptor	Specifies the file descriptor of an open directory.

Return Values

Upon successful completion, the **mkdir** and **mkdirat** subroutines return a value of 0. Otherwise, a value of -1 is returned, and the **errno** global variable is set to indicate the error.

Error Codes

The **mkdir** and **mkdirat** subroutines are unsuccessful and the directory is not created if one or more of the following are true:

Item	Description
EACCES	Creating the requested directory requires writing in a directory with a mode that denies write permission.
EEXIST	The named file already exists.
EROFS	The named file resides on a read-only file system.
ENOSPC	The file system does not contain enough space to hold the contents of the new directory or to extend the parent directory of the new directory.
EMLINK	The link count of the parent directory exceeds the maximum **(LINK_MAX)** number. **(LINK_MAX)** is defined in **limits.h** file.
ENAMETOOLONG	The *Path* parameter or a path component is too long and cannot be truncated.

Item	Description
ENOENT	A component of the path prefix does not exist or the *Path* parameter points to an empty string.
ENOTDIR	A component of the path prefix is not a directory.
EDQUOT	The directory in which the entry for the new directory is being placed cannot be extended, or an i-node or disk blocks could not be allocated for the new directory because the user's or group's quota of disk blocks or i-nodes on the file system containing the directory is exhausted.

The **mkdirat** subroutine is unsuccessful if one or more of the following settings are true:

Item	Description
EBADF	The *Path* parameter does not specify an absolute path and the *DirFileDescriptor* parameter is neither **AT_FDCWD** nor a valid file descriptor.
ENOTDIR	The *Path* parameter does not specify an absolute path and the *DirFileDescriptor* parameter is neither **AT_FDCWD** nor a file descriptor associated with a directory.

The **mkdir** and **mkdirat** subroutines can be unsuccessful for other reasons. See "Appendix A. Base Operating System Error Codes for Services That Require Path-Name Resolution" for a list of additional errors.

If NFS is installed on the system, the **mkdir** and **mkdirat** subroutines are also unsuccessful if the following is true:

Item	Description
ETIMEDOUT	The connection timed out.

mknod, mknodat, mkfifo or mkfifoat, Subroutine

Purpose

Creates an ordinary file, first-in-first-out (FIFO), or special file.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/stat.h>
```

```
int mknod (const char * Path, mode_t  Mode, dev_tDevice)
char *Path;
int Mode;
dev_t Device;
```

```
int mknodat (int DirFileDescriptor, const char * Path, mode_tMode, dev_tDevice)
int DirFileDescriptor;
char *Path;
int Mode;
dev_t Device;
```

```
int mkfifo (const char *Path, mode_t Mode)
const char *Path;
int Mode;
```

```
int mkfifoat (int DirFileDescriptor, const char *Path, mode_tMode)
int DirFileDescriptor;
const char *Path;
int Mode;
```

Description

The **mknod** and **mknodat** subroutines create a new regular file, special file, or FIFO file. Using the **mknod** or **mknodat** subroutine to create file types (other than FIFO or special files) requires root user authority.

For the **mknod** or **mknodat** subroutine to complete successfully, a process must have both search and write permission in the parent directory of the *Path* parameter.

The **mkfifo** and **mkfifoat** subroutines are interfaces to the **mknod** subroutine, where the new file to be created is a FIFO or special file. No special system privileges are required.

The new file has the following characteristics:

- File type is specified by the *Mode* parameter.
- Owner ID is set to the effective user ID of the process.
- Group ID of the file is set to the group ID of the parent directory if the *SetGroupID* attribute (**S_ISGID**) of the parent directory is set. Otherwise, the group ID of the file is set to the effective group ID of the calling process.
- Permission and attribute bits are set according to the value of the *Mode* parameter. All bits set in the file-mode creation mask of the process are cleared.

Upon successful completion, the **mkfifo** subroutine marks for update the `st_atime`, `st_ctime`, and `st_mtime` fields of the file. It also marks for update the `st_ctime` and `st_mtime` fields of the directory that contains the new entry.

If the new file is a character special file having the **S_IMPX** attribute (multiplexed character special file), when the file is used, additional path-name components can appear after the path name as if it were a directory. The additional part of the path name is available to the device driver of the file for interpretation. This feature provides a multiplexed interface to the device driver.

The **mknodat** subroutine is equivalent to the **mknod** subroutine, and the **mkfifoat** subroutine is equivalent to the **mkfifo** subroutine if the *DirFileDescriptor* parameter is **AT_FDCWD** or *Path* is an absolute path name. If *DirFileDescriptor* is a valid file descriptor of an open directory and *Path* is a relative path name, *Path* is considered to be relative to the directory that is associated with the *DirFileDescriptor* parameter instead of the current working directory.

If *DirFileDescriptor* was opened without the **O_SEARCH** open flag, the subroutine checks to determine whether directory searches are permitted for that directory by using the current permissions of the directory. If the directory was opened with the **O_SEARCH** open flag, the subroutine does not perform the check for that directory.

Parameters

Item	Description
DirFileDescriptor	Specifies the file descriptor of an open directory.
Path	Names the new file. If Network File System (NFS) is installed on your system, this path can cross into another node. If *DirFileDescriptor* is specified and *Path* is a relative path name, then *Path* is considered relative to the directory specified by *DirFileDescriptor*.

Item	Description
Mode	Specifies the file type, attributes, and access permissions. This parameter is constructed by logically ORing values described in the **<sys/mode.h>** file.
Device	Specifies the ID of the device, which corresponds to the `st_rdev` member of the structure returned by the **statx** subroutine. This parameter is configuration-dependent and used only if the *Mode* parameter specifies a block or character special file. If the file you specify is a remote file, the value of the *Device* parameter must be meaningful on the node where the file resides.

Return Values

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and the **errno** global variable is set to indicate the error.

Error Codes

The **mknod** and **mknodat** subroutines fail and the new file is not created if one or more of the following are true:

Item	Description
EEXIST	The named file exists.
EDQUOT	The directory in which the entry for the new file is being placed cannot be extended, or an i-node could not be allocated for the file because the user's or group's quota of disk blocks or i-nodes on the file system is exhausted.
EISDIR	The *Mode* parameter specifies a directory. Use the **mkdir** subroutine instead.
ENOSPC	The directory that would contain the new file cannot be extended, or the file system is out of file-allocation resources.
EPERM	The *Mode* parameter specifies a file type other than **S_IFIFO**, and the calling process does not have root user authority.
EROFS	The directory in which the file is to be created is located on a read-only file system.

The **mknodat** and **mkfifoat** subroutines fail and the new file is not created if one or more of the following are true:

Item	Description
EBADF	The *Path* parameter does not specify an absolute path and the *DirFileDescriptor* parameter is neither **AT_FDCWD** nor a valid file descriptor.
ENOTDIR	The *Path* parameter does not specify an absolute path and the *DirFileDescriptor* parameter is neither **AT_FDCWD** nor a file descriptor associated with a directory.

The **mknod**, **mknodat**, **mkfifo**, and **mkfifoat** subroutines can be unsuccessful for other reasons. See "Appendix. A Base Operating System Error Codes for Services That Require Path-Name Resolution" for a list of additional errors.

If NFS is installed on the system, the subroutines can also fail if the following is true:

Item	Description
ETIMEDOUT	The connection timed out.

mktemp or mkstemp Subroutine

Purpose

Constructs a unique file name.

Libraries

Standard C Library (**libc.a**)

Berkeley Compatibility Library (**libbsd.a**)

Syntax

```
#include <stdlib.h>

char *mktemp ( Template)
char *Template;

int mkstemp ( Template)
char *Template;
```

Description

The **mktemp** subroutine replaces the contents of the string pointed to by the *Template* parameter with a unique file name.

Note: The **mktemp** subroutine creates a filename and checks to see if the file exist. It that file does not exist, the name is returned. If the user calls **mktemp** twice without creating a file using the name returned by the first call to **mktemp**, then the second **mktemp** call may return the same name as the first **mktemp** call since the name does not exist.

To avoid this, either create the file after calling **mktemp** or use the **mkstemp** subroutine. The **mkstemp** subroutine creates the file for you.

To get the BSD version of this subroutine, compile with Berkeley Compatibility Library (**libbsd.a**).

The **mkstemp** subroutine performs the same substitution to the template name and also opens the file for reading and writing.

In BSD systems, the **mkstemp** subroutine was intended to avoid a race condition between generating a temporary name and creating the file. Because the name generation in the operating system is more random, this race condition is less likely. BSD returns a file name of / (slash).

Former implementations created a unique name by replacing X's with the process ID and a unique letter.

Parameters

Item	Description
Template	Points to a string to be replaced with a unique file name. The string in the *Template* parameter is a file name with up to six trailing X's. Since the system randomly generates a six-character string to replace the X's, it is recommended that six trailing X's be used.

Return Values

Upon successful completion, the **mktemp** subroutine returns the address of the string pointed to by the *Template* parameter.

If the string pointed to by the *Template* parameter contains no X's, and if it is an existing file name, the *Template* parameter is set to a null character, and a null pointer is returned; if the string does not match any existing file name, the exact string is returned.

Upon successful completion, the **mkstemp** subroutine returns an open file descriptor. If the **mkstemp** subroutine fails, it returns a value of -1.

mlock and munlock Subroutine

Purpose

Locks or unlocks a range of process address space.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/mman.h>

int mlock (addr, len)
const void *addr;
size_t len;

int munlock (addr, len)
const void *addr;
size_t len;
```

Description

The **mlock** subroutine causes those whole pages containing any part of the address space of the process starting at address *addr* and continuing for *len* bytes to be memory-resident until unlocked or until the process exits or executes another process image. If the starting address *addr* is not a multiple of PAGESIZE, it is rounded down to the lowest page boundary. The *len* is rounded up to a multiple of PAGESIZE.

The **munlock** subroutine unlocks those whole pages containing any part of the address space of the process starting at address *addr* and continuing for *len* bytes, regardless of how many times **mlock** has been called by the process for any of the pages in the specified range.

If any of the pages in the range specified in a call to the **munlock** subroutine are also mapped into the address spaces of other processes, any locks established on those pages by another process are unaffected by the call of this process to the **munlock** subroutine. If any of the pages in the range specified by a call to the **munlock** subroutine are also mapped into other portions of the address space of the calling process outside the range specified, any locks established on those pages through other mappings are also unaffected by this call.

Upon successful return from **mlock**, pages in the specified range are locked and memory-resident. Upon successful return from **munlock**, pages in the specified range are unlocked with respect to the address space of the process.

The calling process must have the root user authority to use this subroutine.

Parameters

Item	Description
addr	Specifies the address space of the process to be locked or unlocked.
len	Specifies the length in bytes of the address space.

Return Values

Upon successful completion, the **mlock** and **munlock** subroutines return zero. Otherwise, no change is made to any locks in the address space of the process, the surbroutines return -1 and set **errno** to indicate the error.

Error Codes

The **mlock** and **munlock** subroutines fail if:

Item	Description
ENOMEM	Some or all of the address range specified by the *addr* and *len* parameters does not correspond to valid mapped pages in the address space of the process.
EINVAL	The process has already some plocked memory or the *len* parameter is negative.
EPERM	The calling process does not have the appropriate privilege to perform the requested operation.

The **mlock** subroutine might fail if:

Item	Description
ENOMEM	Locking the pages mapped by the specified range would exceed the limit on the amount of memory the process may lock.

mlockall and munlockall Subroutine

Purpose

Locks or unlocks the address space of a process.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/mman.h>

int mlockall (flags)
int flags;

int munlockall (void);
```

Description

The **mlockall** subroutine causes all of the pages mapped by the address space of a process to be memory-resident until unlocked or until the process exits or executes another process image. The *flags* parameter determines whether the pages to be locked are those currently mapped by the address space of the process, those that are mapped in the future, or both. The *flags* parameter is constructed from the bitwise-inclusive OR of one or more of the following symbolic constants, defined in the **sys/mman.h** header file:

MCL_CURRENT
Lock all of the pages currently mapped into the address space of the process.

MCL_FUTURE
Lock all of the pages that become mapped into the address space of the process in the future, when those mappings are established.

When **MCL_FUTURE** is specified, the future mapping functions might fail if the system is not able to lock this amount of memory because of lack of resources, for example.

The **munlockall** subroutine unlocks all currently mapped pages of the address space of the process. Any pages that become mapped into the address space of the process after a call to the **munlockall** subroutine are not locked, unless there is an intervening call to the **mlockall** subroutine specifying **MCL_FUTURE** or a subsequent call to the **mlockall** subroutine specifying **MCL_CURRENT**. If pages mapped into the address space of the process are also mapped into the address spaces of other processes and are locked by those processes, the locks established by the other processes are unaffected by a call to the **munlockall** subroutine.

Regarding libraries that are pinned, a distinction has been made internally between a user referencing memory to perform a task related to the application and the system referencing memory on behalf of the application. The former is pinned, and the latter is not. The user-addressable loader data that remains unlocked includes:

- loader entries
- user loader entries
- page-descriptor segment
- usla heap segment
- usla text segment
- all the global segments related to the 64-bit shared library loadlist (shlib heap segment, shlib le segment, shlib text and data heap segments).

This limit affects implementation only, and it does not cause the API to fail.

Upon successful return from a **mlockall** subroutine that specifies **MCL_CURRENT**, all currently mapped pages of the process' address space are memory-resident and locked. Upon return from the **munlockall** subroutine, all currently mapped pages of the process' address space are unlocked with respect to the process' address space.

The calling process must have the root user authority to use this subroutine.

Parameters

Item	Description
flags	Determines whether the pages to be locked are those currently mapped by the address space of the process, those that are mapped in the future, or both.

Return Values

Upon successful completion, the **mlockall** subroutine returns 0. Otherwise, no additional memory is locked, and the subroutine returns -1 and sets **errno** to indicate the error.

Upon successful completion, the **munlockall** subroutine returns 0. Otherwise, no additional memory is unlocked, and the subroutine returns -1 and sets **errno** to indicate the error.

Error Codes

The **mlockall** subroutine fails if:

Item	Description
EINVAL	The *flags* parameter is 0, or includes unimplemented flags or the process has already some plocked memory.

Item	Description
ENOMEM	Locking all of the pages currently mapped into the address space of the process would exceed the limit on the amount of memory that the process may lock.
EPERM	The calling process does not have the appropriate authority to perform the requested operation.

The **munlockall** subroutine fails if:

Item	Description
EINVAL	The process has already some plocked memory
EPERM	The calling process does not have the appropriate privilege to perform the requested operation

mmap or mmap64 Subroutine

Purpose

Maps a file-system object into virtual memory.

Library

Standard C library (**libc.a**)

Syntax

```
#include <sys/types.h>
#include <sys/mman.h>
```

```
void *mmap (addr, len, prot, flags, fildes, off)
void * addr;
size_t  len;
int  prot,  flags,  fildes;
off_t  off;
```

```
void *mmap64 (addr, len, prot, flags, fildes, off)
void * addr;
size_t  len;
int  prot,  flags,  fildes;
off64_t  off;
```

Description

Attention: A file-system object should not be simultaneously mapped using both the **mmap** and **shmat** subroutines. Unexpected results may occur when references are made beyond the end of the object.

The **mmap** subroutine creates a new mapped file or anonymous memory region by establishing a mapping between a process-address space and a file-system object. Care needs to be taken when using the **mmap** subroutine if the program attempts to map itself. If the page containing executing instructions is currently referenced as data through an mmap mapping, the program will hang. Use the -H4096 binder option, and that will put the executable text on page boundaries. Then reset the file that contains the executable material, and view via an **mmap** mapping.

A region created by the mmap subroutine cannot be used as the buffer for read or write operations that involve a device. Similarly, an mmap region cannot be used as the buffer for operations that require either a **pin** or **xmattach** operation on the buffer.

Modifications to a file-system object are seen consistently, whether accessed from a mapped file region or from the **read** or **write** subroutine.

Child processes inherit all mapped regions from the parent process when the **fork** subroutine is called. The child process also inherits the same sharing and protection attributes for these mapped regions. A successful call to any **exec** subroutine will unmap all mapped regions created with the **mmap** subroutine.

The **mmap64** subroutine is identical to the **mmap** subroutine except that the starting offset for the file mapping is specified as a 64-bit value. This permits file mappings which start beyond **OFF_MAX**.

In the large file enabled programming environment, **mmap** is redefined to be **mmap64**.

If the application has requested SPEC1170 compliant behavior then the **st_atime** field of the mapped file is marked for update upon successful completion of the **mmap** call.

If the application has requested SPEC1170 compliant behavior then the **st_ctime** and **st_mtime** fields of a file that is mapped with **MAP_SHARED** and **PROT_WRITE** are marked for update at the next call to **msync** subroutine or **munmap** subroutine if the file has been modified.

Parameters

Item	Description
addr	Specifies the starting address of the memory region to be mapped. When the **MAP_FIXED** flag is specified, this address must be a multiple of the page size returned by the **sysconf** subroutine using the **_SC_PAGE_SIZE** value for the *Name* parameter. A region is never placed at address zero, or at an address where it would overlap an existing region.
len	Specifies the length, in bytes, of the memory region to be mapped. The system performs mapping operations over whole pages only. If the *len* parameter is not a multiple of the page size, the system will include in any mapping operation the address range between the end of the region and the end of the page containing the end of the region.

Item	Description
prot	Specifies the access permissions for the mapped region. The **sys/mman.h** file defines the following access options: **PROT_READ** Region can be read. **PROT_WRITE** Region can be written. **PROT_EXEC** Region can be executed. **PROT_NONE** Region cannot be accessed. The *prot* parameter can be the **PROT_NONE** flag, or any combination of the **PROT_READ** flag, **PROT_WRITE** flag, and **PROT_EXEC** flag logically ORed together. If the **PROT_NONE** flag is not specified, access permissions may be granted to the region in addition to those explicitly requested. However, write access will not be granted unless the **PROT_WRITE** flag is specified. **Note:** The operating system generates a **SIGSEGV** signal if a program attempts an access that exceeds the access permission given to a memory region. For example, if the **PROT_WRITE** flag is not specified and a program attempts a write access, a **SIGSEGV** signal results. If the region is a mapped file that was mapped with the **MAP_SHARED** flag, the **mmap** subroutine grants read or execute access permission only if the file descriptor used to map the file was opened for reading. It grants write access permission only if the file descriptor was opened for writing. If the region is a mapped file that was mapped with the **MAP_PRIVATE** flag, the **mmap** subroutine grants read, write, or execute access permission only if the file descriptor used to map the file was opened for reading. If the region is an anonymous memory region, the **mmap** subroutine grants all requested access permissions.

Item	Description
flags	Specifies attributes of the mapped region. Values for the *flags* parameter are constructed by a bitwise-inclusive ORing of values from the following list of symbolic names defined in the **sys/mman.h** file: **MAP_FILE** Specifies the creation of a new mapped file region by mapping the file associated with the *fildes* file descriptor. The mapped region can extend beyond the end of the file, both at the time when the **mmap** subroutine is called and while the mapping persists. This situation could occur if a file with no contents was created just before the call to the **mmap** subroutine, or if a file was later truncated. However, references to whole pages following the end of the file result in the delivery of a **SIGBUS** signal. Only one of the **MAP_FILE** and **MAP_ANONYMOUS** flags must be specified with the **mmap** subroutine. **MAP_ANONYMOUS** Specifies the creation of a new, anonymous memory region that is initialized to all zeros. This memory region can be shared only with the descendants of the current process. When using this flag, the *fildes* parameter must be -1. Only one of the **MAP_FILE** and **MAP_ANONYMOUS** flags must be specified with the **mmap** subroutine. **MAP_ VARIABLE** Specifies that the system select an address for the new memory region if the new memory region cannot be mapped at the address specified by the *addr* parameter, or if the *addr* parameter is null. Only one of the **MAP_VARIABLE** and **MAP_FIXED** flags must be specified with the **mmap** subroutine. **MAP_FIXED** Specifies that the mapped region be placed exactly at the address specified by the *addr* parameter. If the application has requested SPEC1170 complaint behavior and the **mmap** request is successful, the mapping replaces any previous mappings for the process' pages in the specified range. If the application has not requested SPEC1170 compliant behavior and a previous mapping exists in the range then the request fails. Only one of the **MAP_VARIABLE** and **MAP_FIXED** flags must be specified with the **mmap** subroutine. **MAP_SHARED** When the **MAP_SHARED** flag is set, modifications to the mapped memory region will be visible to other processes that have mapped the same region using this flag. If the region is a mapped file region, modifications to the region will be written to the file. You can specify only one of the **MAP_SHARED** or **MAP_PRIVATE** flags with the **mmap** subroutine. **MAP_PRIVATE** is the default setting when neither flag is specified unless you request SPEC1170 compliant behavior. In this case, you must choose either **MAP_SHARED** or **MAP_PRIVATE**. **MAP_PRIVATE** When the **MAP_PRIVATE** flag is specified, modifications to the mapped region by the calling process are not visible to other processes that have mapped the same region. If the region is a mapped file region, modifications to the region are not written to the file. If this flag is specified, the initial write reference to an object page creates a private copy of that page and redirects the mapping to the copy. Until then, modifications to the page by processes that have mapped the same region with the **MAP_SHARED** flag are visible. You can specify only one of the **MAP_SHARED** or **MAP_PRIVATE** flags with the **mmap** subroutine. **MAP_PRIVATE** is the default setting when neither flag is specified unless you request SPEC1170 compliant behavior. In this case, you must choose either **MAP_SHARED** or **MAP_PRIVATE**.

Item	Description
fildes	Specifies the file descriptor of the file-system object or of the shared memory object to be mapped. If the **MAP_ANONYMOUS** flag is set, the *fildes* parameter must be -1. After the successful completion of the **mmap** subroutine, the file or the shared memory object specified by the *fildes* parameter can be closed without affecting the mapped region or the contents of the mapped file. Each mapped region creates a file reference, similar to an open file descriptor, which prevents the file data from being deallocated. **Note:** The **mmap** subroutine supports the mapping of shared memory object and regular files only. An **mmap** call that specifies a file descriptor for a special file fails, returning the **ENODEV** error code. An example of a file descriptor for a special file is one that might be used for mapping either I/O or device memory.
off	Specifies the file byte offset at which the mapping starts. This offset must be a multiple of the page size returned by the **sysconf** subroutine using the **_SC_PAGE_SIZE** value for the *Name* parameter.

Return Values

If successful, the **mmap** subroutine returns the address at which the mapping was placed. Otherwise, it returns -1 and sets the **errno** global variable to indicate the error.

Error Codes

Under the following conditions, the **mmap** subroutine fails and sets the **errno** global variable to:

Item	Description
EACCES	The file referred to by the *fildes* parameter is not open for read access, or the file is not open for write access and the **PROT_WRITE** flag was specified for a **MAP_SHARED** mapping operation. Or, the file to be mapped has enforced locking enabled and the file is currently locked.
EAGAIN	The *fildes* parameter refers to a device that has already been mapped.
EBADF	The *fildes* parameter is not a valid file descriptor, or the **MAP_ANONYMOUS** flag was set and the *fildes* parameter is not -1.
EFBIG	The mapping requested extends beyond the maximum file size associated with *fildes*.
EINVAL	The *flags* or *prot* parameter is invalid, or the *addr* parameter or *off* parameter is not a multiple of the page size returned by the **sysconf** subroutine using the **_SC_PAGE_SIZE** value for the *Name* parameter.
EINVAL	The application has requested SPEC1170 compliant behavior and the value of flags is invalid (neither **MAP_PRIVATE** nor **MAP_SHARED** is set).
EMFILE	The application has requested SPEC1170 compliant behavior and the number of mapped regions would excedd and implementation-dependent limit (per process or per system).
ENODEV	The *fildes* parameter refers to an object that cannot be mapped, such as a terminal.
ENOMEM	There is not enough address space to map *len* bytes, or the application has not requested Single UNIX Specification, Version 2 compliant behavior and the **MAP_FIXED** flag was set and part of the address-space range (*addr*, *addr+len*) is already allocated.
ENXIO	The addresses specified by the range (*off*, *off+len*) are invalid for the *fildes* parameter.

Item	Description
EOVERFLOW	The mapping requested extends beyond the offset maximum for the file description associated with *fildes*.

mmcr_read Subroutine

Purpose

Reads the monitor mode control registers **MMCR0**, **MMCR2**, and **MMCRA** in problem state.

Library

Performance Monitor APIs Library (**libpmapi.a**)

Syntax

```
#include <pmapi.h>
int mmcr_read (void * buffer)
```

Description

The **mmcr_read** subroutine reads the registers **MMCR0**, **MMCR2**, and **MMCRA** in the same order into the address of the buffer that is passed as a parameter to the function.

The three 64-bit **MMCR** registers **MMCR0**, **MMCR2**, and **MMCRA** are read into the buffer.

Return Values

If unsuccessful, a value of other than zero is returned and positive error code is set. If successful, a value of zero is returned and no errors are detected.

Files

The **pmapi.h** file defines standard macros, data types, and subroutines.

mmcr_write Subroutine

Purpose

Writes the specified monitor mode control register in problem state.

Library

Performance Monitor APIs Library (**libpmapi.a**)

Syntax

```
#include <pmapi.h>
int mmcr_write (int reg_num, void *buffer)
```

Description

The **mmcr_write** subroutine writes a specified monitor mode control register (MMCR) in problem state.

The function takes two parameters namely the Special Purpose Register (SPR) number of the MMCR into which the value is written, and the address from where the value is written to the MMCR. The **mmcr_write**

subroutine writes the value of the address specified in the second argument into the register specified in the first argument.

Return Values

If unsuccessful, a value other than zero is returned and positive error code is set. If successful, a value of zero is returned and no errors are detected.

Files

The **pmapi.h** file defines standard macros, data types, and subroutines.

mntctl Subroutine

Purpose

Returns the mount status of file systems, or alters the status of mounted file systems.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/types.h>
#include <sys/mntctl.h>
#include <sys/vmount.h>

int mntctl ( Command,  Size,  Buffer)
int Command;
int Size;
char *Buffer;
```

Description

The **mntctl** subroutine is used to query the status of virtual file systems (also known as *mounted* file systems). It can also be used to alter the state of mounted file systems.

Each virtual file system (VFS) is described by a **vmount** structure. This structure is supplied when the VFS is created by the **vmount** subroutine. The **vmount** structure is defined in the **sys/vmount.h** file.

Parameters

Item	Description
Command	Specifies the operation to be performed. Valid commands are defined in the **sys/vmount.h** file. At present, the only command is: **MCTL_QUERY** Query mount information. **MCTL_REMNT** Re-mount a mounted file system with the options specified in the **vmount** structure passed in. The **MCTL_REMNT** command is only passed to file systems that support the capability to re-mount. For more information, see the **gfsadd** Kernel Service.

Item	Description
Buffer	For the **MCTL_QUERY** command, the *Buffer* parameter points to a data area that will contain an array of the **vmount** structures. Because the **vmount** structure is variable-length, it is necessary to reference the **vmt_length** field of each structure to determine where in the *Buffer* area the next structure begins. For the **MCTL_REMNT** command, the *Buffer* parameter points to a data area that contains the **vmount** structure that is passed in.
Size	Specifies the length, in bytes, of the buffer pointed to by the *Buffer* parameter.

Return Values

For the **MCTL_QUERY** command, if the **mntctl** subroutine is successful, the number of **vmount** structures that are copied into the *Buffer* parameter is returned. If the *Size* parameter indicates that the supplied buffer is too small to hold the **vmount** structures for all of the current VFSs, the **mntctl** subroutine sets the first word of the *Buffer* parameter to the required size (in bytes) and returns the value of 0. If the **mntctl** subroutine otherwise fails, a value of -1 is returned, and the **errno** global variable is set to indicate the error.

For the **MCTL_REMNT** command, if the **mntctl** subroutine fails, a value of -1 is returned, and the **errno** global variable is set to indicate the error.

Error Codes

The **mntctl** subroutine fails and the requested operation is not performed if one or both of the following are true:

Item	Description
EINVAL	The *Command* parameter is not recognized, or the *Size* parameter is not a positive value.
EFAULT	The *Buffer* parameter points to a location outside of the allocated address space of the process.

modf, modff, modfl, modfd32, modfd64, and modfd128 Subroutines

Purpose

Decomposes a floating-point number.

Syntax

```
#include <math.h>

float modff (x, iptr)
float x;
float *iptr;

double modf (x, iptr)
double x, *iptr;

long double modfl (x, iptr)
long double x, *iptr;

_Decimal32 modfd32 (x, iptr)
_Decimal32 x, *iptr;

_Decimal64 modfd64 (x, iptr)
_Decimal64 x, *iptr;
```

```
_Decimal128 modf128 (x, iptr)
_Decimal128 x, *iptr;
```

Description

The **modff**, **modf**, **modfl**, **modfd32**, **modfd64**, and **modfd128** subroutines divide the *x* parameter into integral and fractional parts, each of which has the same sign as the arguments. These subroutines store the integral part as a floating-point value in the object pointed to by the *iptr* parameter.

Parameters

Item	Description
x	Specifies the value to be computed.
iptr	Points to the object where the integral part is stored.

Return Values

Upon successful completion, the **modff**, **modf**, **modfl**, **modfd32**, **modfd64**, and **modfd128** subroutines return the signed fractional part of *x*.

If *x* is NaN, a NaN is returned, and **iptr* is set to a NaN.

If *x* is ±Inf, ±0 is returned, and **iptr* is set to ±Inf.

moncontrol Subroutine

Purpose

Starts and stops execution profiling after initialization by the **monitor** subroutine.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <mon.h>
```

```
int moncontrol ( Mode)
int Mode;
```

Description

The **moncontrol** subroutine starts and stops profiling after profiling has been initialized by the **monitor** subroutine. It may be used with either **-p** or **-pg** profiling. When **moncontrol** stops profiling, no output data file is produced. When profiling has been started by the **monitor** subroutine and the **exit** subroutine is called, or when the **monitor** subroutine is called with a value of 0, then profiling is stopped, and an output file is produced, regardless of the state of profiling as set by the **moncontrol** subroutine.

The **moncontrol** subroutine examines global and parameter data in the following order:

1. When the **_mondata.prof_type** global variable is neither -1 (**-p** profiling defined) nor +1 (**-pg** profiling defined), no action is performed, 0 is returned, and the function is considered complete.

   The global variable is set to -1 in the **mcrt0.o** file and to +1 in the **gcrt0.o** file and defaults to 0 when the **crt0.o** file is used.
2. When the *Mode* parameter is 0, profiling is stopped. For any other value, profiling is started.

The following global variables are used in a call to the **profil** subroutine:

Item	Description
_mondata.*ProfBuf*	Buffer address
_mondata.*ProfBufSiz*	Buffer size/multirange flag
_mondata.*ProfLoPC*	PC offset for hist buffer - I/O limit
_mondata.*ProfScale*	PC scale/compute scale flag.

These variables are initialized by the **monitor** subroutine each time it is called to start profiling.

Parameters

Item	Description
Mode	Specifies whether to start (resume) or stop profiling.

Return Values

The **moncontrol** subroutine returns the previous state of profiling. When the previous state was STOPPED, a 0 is returned. When the previous state was STARTED, a 1 is returned.

Error Codes

When the **moncontrol** subroutine detects an error from the call to the **profil** subroutine, a -1 is returned.

monitor Subroutine

Purpose

Starts and stops execution profiling using data areas defined in the function parameters.

Library

Standard C Library (**libc.a**)

Syntax

#include <mon.h>int monitor (*LowProgramCounter***,***HighProgramCounter***,***Buffer***,***BufferSize***,***NFunction***)**OR **int monitor (***NotZeroA***,***DoNotCareA***, *Buffer*,**-1**, *NFunction***)**OR **int monitor((caddr_t)**0**)caddr_t** *LowProgramCounter***, *HighProgramCounter*;HISTCOUNTER *****Buffer*;**int** *BufferSize***, *NFunction*;caddr_t** *NotZeroA***, *DoNotCareA*;**

Description

The **monitor** subroutine initializes the buffer area and starts profiling, or else stops profiling and writes out the accumulated profiling data. Profiling, when started, causes periodic sampling and recording of the program location within the program address ranges specified. Profiling also accumulates function call count data compiled with the **-p** or **-pg** option.

Executable programs created with the **cc -p** or **cc -pg** command automatically include calls to the **monitor** subroutine (through the **monstartup** and **exit** subroutines) to profile the complete user program, including system libraries. In this case, you do not need to call the **monitor** subroutine.

The **monitor** subroutine is called by the **monstartup** subroutine to begin profiling and by the **exit** subroutine to end profiling. The **monitor** subroutine requires a global data variable to define which kind of profiling, **-p** or **-pg**, is in effect. The **monitor** subroutine initializes four global variables that are used as parameters to the **profil** subroutine by the **moncontrol** subroutine:

- The **monitor** subroutine calls the **moncontrol** subroutine to start the profiling data gathering.
- The **moncontrol** subroutine calls the **profil** subroutine to start the system timer-driven program address sampling.
- The **prof** command processes the data file produced by **-p** profiling.
- The **gprof** command processes the data file produced by **-pg** profiling.

The **monitor** subroutine examines the global data and parameter data in this order:

1. When the **_mondata.prof_type** global variable is neither -1 (**-p** profiling defined) nor +1 (**-pg** profiling defined), an error is returned, and the function is considered complete.

   The global variable is set to -1 in the **mcrt0.o** file and to +1 in the **gcrt0.o** file, and defaults to 0 when the **crt0.o** file is used.
2. When the first parameter to the **monitor** subroutine is 0, profiling is stopped and the data file is written out.

   If **-p** profiling was in effect, then the file is named **mon.out**. If **-pg** profiling was in effect, the file is named **gmon.out**. The function is complete.
3. When the first parameter to the **monitor** subroutine is not , the **monitor** parameters and the profiling global variable, **_mondata.prof_type,** are examined to determine how to start profiling.
4. When the *BufferSize* parameter is not -1, a single program address range is defined for profiling, and the first **monitor** definition in the syntax is used to define the single program range.
5. When the *BufferSize* parameter is -1, multiple program address ranges are defined for profiling, and the second **monitor** definition in the syntax is used to define the multiple ranges. In this case, the *ProfileBuffer* value is the address of an array of **prof** structures. The size of the **prof** array is denoted by a zero value for the*HighProgramCounter* (`p_high`) field of the last element of the array. Each element in the array, except the last, defines a single programming address range to be profiled. Programming ranges must be in ascending order of the program addresses with ascending order of the **prof** array index. Program ranges may not overlap.

   The buffer space defined by the `p_buff` and `p_bufsize` fields of all of the **prof** entries must define a single contiguous buffer area. Space for the function-count data is included in the first range buffer. Its size is defined by the *NFunction* parameter. The `p_scale` entry in the **prof** structure is ignored. The **prof** structure is defined in the**mon.h** file. It contains the following fields:

```
caddr_t p_low;        /* low sampling address */
caddr_t p_high;       /* high sampling address */
HISTCOUNTER *p_buff;  /* address of sampling buffer */
int p_bufsize;        /* buffer size- monitor/HISTCOUNTERs,\
                         profil/bytes */
uint p_scale;         /* scale factor */
```

Parameters

Item	Description
LowProgramCounter (**prof** name: `p_low`)	Defines the lowest execution-time program address in the range to be profiled. The value of the *LowProgramCounter* parameter cannot be 0 when using the**monitor** subroutine to begin profiling.

Item	Description
HighProgramCounter (**prof** name: p_high)	Defines the next address after the highest-execution time program address in the range to be profiled. The program address parameters may be defined by function names or address expressions. If defined by a function name, then a function name expression must be used to dereference the function pointer to get the address of the first instruction in the function. This is required because the function reference in this context produces the address of the function descriptor. The first field of the descriptor is the address of the function code. See the examples for typical expressions to use.
Buffer (**prof** name: p_buff)	Defines the beginning address of an array of *BufferSize* HISTCOUNTERs to be used for data collection. This buffer includes the space for the program address-sampling counters and the function-count data areas. In the case of a multiple range specification, the space for the function-count data area is included at the beginning of the first range in the *BufferSize* specification.
BufferSize (**prof** name: p_bufsize)	Defines the size of the buffer in number of HISTCOUNTERs. Each counter is of type HISTCOUNTER (defined as short in the **mon.h** file). When the buffer includes space for the function-count data area (single range specification and first range of a multi-range specification) the *NFunction* parameter defines the space to be used for the function count data, and the remainder is used for program-address sampling counters for the range defined. The scale for the **profil** call is calculated from the number of counters available for program address-sample counting and the address range defined by the *LowProgramCounter* and *HighProgramCounter* parameters. See the**mon.h** file.

Item	Description

NFunction	Defines the size of the space to be used for the function-count data area. The space is included as part of the first (or only) range buffer.
	
	When **-p** profiling is defined, the *NFunction* parameter defines the maximum number of functions to be counted. The space required for each function is defined to be:
	
	`sizeof(struct poutcnt)`
	
	The **poutcnt** structure is defined in the **mon.h** file. The total function-count space required is:
	
	`NFunction * sizeof(struct poutcnt)`
	
	When **-pg** profiling is defined, the *NFunction* parameter defines the size of the space (in bytes) available for the function-count data structures, as follows:
	
	`range = HighProgramCounter - LowProgramCounter; tonum = TO_NUM_ELEMENTS( range ); if ( tonum < MINARCS ) tonum = MINARCS; if ( tonum > TO_MAX-1 ) tonum = TO_MAX-1; tosize = tonum * sizeof( struct tostruct ); fromsize = FROM_STG_SIZE( range ); rangesize = tosize + fromsize + sizeof(struct gfctl);`
	
	This is computed and summed for all defined ranges. In this expression, the functions and variables in capital letters as well as the structures are defined in the **mon.h** file.

NotZeroA	Specifies a value of parameter 1, which is any value except 0. Ignored when it is not zero.
DoNotCareA	Specifies a value of parameter 2, of any value, which is ignored.

Return Values

The **monitor** subroutine returns 0 upon successful completion.

Error Codes

If an error is found, the **monitor** subroutine sends an error message to **stderr** and returns -1.

Examples

1. This example shows how to profile the main load module of a program with **-p** profiling:

```
#include <sys/types.h>
#include <mon.h>
main()
{
extern caddr_t etext;  /*system end of main module text symbol*/
extern int start();    /*first function in main program*/
extern struct monglobal _mondata; /*profiling global variables*/
struct desc {         /*function descriptor fields*/
    caddr_t begin;    /*initial code address*/
```

```
    caddr_t toc;      /*table of contents address*/
    caddr_t env;      /*environment pointer*/
} ;                  /*function descriptor structure*/
struct desc *fd;       /*pointer to function descriptor*/
int rc;               /*monitor return code*/
int range;             /*program address range for profiling*/
int numfunc;           /*number of functions*/
HISTCOUNTER *buffer;    /*buffer address*/
int numtics;        /*number of program address sample counters*/
int BufferSize;  /*total buffer size in numbers of HISTCOUNTERs*/
fd = (struct desc*)start; /*init descriptor pointer to start\
 function*/
numfunc = 300;          /*arbitrary number for example*/
range = etext - fd->begin; /*compute program address range*/
numtics =NUM_HIST_COUNTERS(range); /*one counter for each 4 byte\
 inst*/
BufferSize = numtics + ( numfunc*sizeof (struct poutcnt) \
 HIST_COUNTER_SIZE );     /*allocate buffer space*/
buffer = (HISTCOUNTER *) malloc (BufferSize * HIST_COUNTER_SIZE);
if ( buffer == NULL )  /*didn't get space, do error recovery\
 here*/
   return(-1);
_mondata.prof_type = _PROF_TYPE_IS_P; /*define -p profiling*/
rc = monitor( fd->begin, (caddr_t)etext, buffer, BufferSize, \
 numfunc);
/*start*/
if ( rc != 0 ) /*profiling did not start, do error recovery\
 here*/
   return(-1);
/*other code for analysis*/
rc = monitor( (caddr_t)0);  /*stop profiling and write data file\
 mon.out*/
if ( rc != 0 ) /*did not stop correctly, do error recovery here*/
   return (-1);
}
```

2. This example profiles the main program and the **libc.a** shared library with **-p** profiling. The range of addresses for the shared **libc.a** is assumed to be:

```
low = d0300000
high = d0312244
```

These two values can be determined from the **loadquery** subroutine at execution time, or by using a debugger to view the loaded programs' execution addresses and the loader map.

```
#include <sys/types.h>
#include <mon.h>
main()
{
extern caddr_t etext;   /*system end of text symbol*/
extern int start();    /*first function in main program*/
extern struct monglobal _mondata; /*profiling global variables*/
struct prof pb[3];     /*prof array of 3 to define 2 ranges*/
int rc;               /*monitor return code*/
int range;            /*program address range for profiling*/
int numfunc;          /*number of functions to count (max)*/
int numtics;          /*number of sample counters*/
int num4fcnt;   /*number of HISTCOUNTERs used for fun cnt space*/
int BufferSize1;      /*first range BufferSize*/
int BufferSize2;      /*second range BufferSize*/
caddr_t liblo=0xd0300000;  /*lib low address (example only)*/
caddr_t libhi=0xd0312244;  /*lib high address (example only)*/
numfunc = 400;          /*arbitrary number for example*/
/*compute first range buffer size*/
range = etext - *(uint *) start;   /*init range*/
numtics = NUM_HIST_COUNTERS( range );
/*one counter for each 4 byte inst*/
num4fcnt = numfunc*sizeof( struct poutcnt )/HIST_COUNTER_SIZE;
BufferSize1 = numtics + num4fcnt;
/*compute second range buffer size*/
range = libhi-liblo;
BufferSize2 = range / 12; /*counter for every 12 inst bytes for\
 a change*/
/*allocate buffer space - note: must be single contiguous\
 buffer*/
pb[0].p_buff = (HISTCOUNTER *)malloc( (BufferSize1 +BufferSize2)\
 *HIST_COUNTER_SIZE);
if ( pb[0].p_buff == NULL )   /*didn't get space - do error\
```

```
 recovery here* ;/
    return(-1);
/*set up the first range values*/
pb[0].p_low = *(uint*)start;       /*start of main module*/
pb[0].p_high = (caddr_t)etext;     /*end of main module*/
pb[0].p_BufferSize = BufferSize1;  /*prog addr cnt space + \
func cnt space*/
/*set up last element marker*/
pb[2].p_high = (caddr_t)0;
_mondata.prof_type = _PROF_TYPE_IS_P;   /*define -p\
profiling*/
rc = monitor( (caddr_t)1, (caddr_t)1, pb, -1, numfunc); \
 /*start*/
if ( rc != 0 )   /*profiling did not start - do error recovery\
 here*/
   return (-1);
/*other code for analysis ...*/
rc = monitor( (caddr_t)0);   /*stop profiling and write data \
file mon.out*/
if ( rc != 0 )   /*did not stop correctly - do error recovery\
 here*/
    return (-1);
```

3. This example shows how to profile contiguously loaded functions beginning at `zit` up to but not including `zot` with **-pg** profiling:

```
#include <sys/types.h>
#include <mon.h>
main()
{
extern zit();           /*first function to profile*/
extern zot();           /*upper bound function*/
extern struct monglobal _mondata; /*profiling global variables*/
int rc;                /*monstartup return code*/
_mondata.prof_type = _PROF_TYPE_IS_PG; /*define -pg profiling*/
/*Note cast used to obtain function code addresses*/
rc = monstartup(*(uint *)zit,*(uint *)zot); /*start*/
if ( rc != 0 ) /*profiling did not start, do error recovery\
 here*/
   return(-1);
/*other code for analysis ...*/
exit(0);    /*stop profiling and write data file gmon.out*/
}
```

Files

Item	Description
mon.out	Data file for **-p** profiling.
gmon.out	Data file for **-pg** profiling.
/usr/include/mon.h	Defines the **_mondata.prof_type** global variable in the **monglobal** data structure, the **prof** structure, and the functions referred to in the previous examples.

monstartup Subroutine

Purpose

Starts and stops execution profiling using default-sized data areas.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <mon.h>
```

int monstartup (*LowProgramCounter*, *HighProgramCounter*)

OR

int monstartup((caddr_t)-1), (caddr_t) *FragBuffer*)

OR

int monstartup((caddr_t)-1, (caddr_t)0)

```
caddr_t LowProgramCounter;
caddr_t HighProgramCounter;
```

Description

The **monstartup** subroutine allocates data areas of default size and starts profiling. Profiling causes periodic sampling and recording of the program location within the program address ranges specified, and accumulation of function-call count data for functions that have been compiled with the **-p** or **-pg** option.

Executable programs created with the **cc -p** or **cc -pg** command automatically include a call to the **monstartup** subroutine to profile the complete user program, including system libraries. In this case, you do not need to call the **monstartup** subroutine.

The **monstartup** subroutine is called by the **mcrt0.o** (**-p**) file or the **gcrt0.o** (**-pg**) file to begin profiling. The **monstartup** subroutine requires a global data variable to define whether **-p** or **-pg** profiling is to be in effect. The **monstartup** subroutine calls the **monitor** subroutine to initialize the data areas and start profiling.

The **prof** command is used to process the data file produced by **-p** profiling. The **gprof** command is used to process the data file produced by **-pg** profiling.

The **monstartup** subroutine examines the global and parameter data in the following order:

1. When the **_mondata.prof_type** global variable is neither -1 (**-p** profiling defined) nor +1 (**-pg** profiling defined), an error is returned and the function is considered complete.

   The global variable is set to -1 in the **mcrt0.o** file and to +1 in the **gcrt0.o** file, and defaults to 0 when **crt0.o** is used.
2. When the *LowProgramCounter* value is not -1:

   - A single program address range is defined for profiling

   AND

   - The first **monstartup** definition in the syntax is used to define the program range.
3. When the *LowProgramCounter* value is -1 and the *HighProgramCounter* value is not 0:

   - Multiple program address ranges are defined for profiling

   AND

   - The second **monstartup** definition in the syntax is used to define multiple ranges. The *HighProgramCounter* parameter, in this case, is the address of a **frag** structure array. The **frag** array size is denoted by a zero value for the *HighProgramCounter* (p_high) field of the last element of the array. Each array element except the last defines one programming address range to be profiled. Programming ranges must be in ascending order of the program addresses with ascending order of the **prof** array index. Program ranges may not overlap.
4. When the *LowProgramCounter* value is -1 and the *HighProgramCounter* value is 0:

- The whole program is defined for profiling

AND

- The third **monstartup** definition in the syntax is used. The program ranges are determined by **monstartup** and may be single range or multirange.

Parameters

Item	Description
LowProgramCounter (**frag** name: p_low)	Defines the lowest execution-time program address in the range to be profiled.
HighProgramCounter(**frag** name: p_high)	Defines the next address after the highest execution-time program address in the range to be profiled. The program address parameters may be defined by function names or address expressions. If defined by a function name, then a function name expression must be used to dereference the function pointer to get the address of the first instruction in the function. This is required because the function reference in this context produces the address of the function descriptor. The first field of the descriptor is the address of the function code. See the examples for typical expressions to use.
FragBuffer	Specifies the address of a frag structure array.

Examples

1. This example shows how to profile the main load module of a program with **-p** profiling:

```
#include <sys/types.h>
#include <mon.h>
main()
{
extern caddr_t etext;      /*system end of text
symbol*/
extern int start();      /*first function in main\
            program*/
extern struct monglobal _mondata; /*profiling global variables*/
struct desc {         /*function
descriptor fields*/
   caddr_t begin;      /*initial code
address*/
   caddr_t toc;      /*table of contents
address*/
   caddr_t env;      /*environment
pointer*/
 }
;            /*function
descriptor structure*/
struct desc *fd;      /*pointer to function\
            descriptor*/
int  rc;         /*monstartup
return code*/
fd = (struct desc *)start;   /*init descriptor pointer to\
            start
function*/
_mondata.prof_type = _PROF_TYPE_IS_P;   /*define -p profiling*/
rc = monstartup( fd->begin, (caddr_t) &etext);   /*start*/
if ( rc != 0 )         /*profiling did
not start - do\
           error
recovery here*/   return(-1);
           /*other code
for analysis ...*/
```

```
return(0);         /*stop profiling and
write data\
             file
mon.out*/
}
```

2. This example shows how to profile the complete program with **-p** profiling:

```
#include <sys/types.h>
#include <mon.h>
main()
{
extern struct monglobal _mondata;   /*profiling global\
                variables*/
int  rc;         /*monstartup
return code*/
_mondata.prof_type = _PROF_TYPE_IS_P;   /*define -p profiling*/
rc = monstartup( (caddr_t)-1, (caddr_t)0);   /*start*/
if ( rc != 0 )         /*profiling did
not start -\

  do error recovery here*/
   return (-1);
            /*other code
for analysis ...*/
return(0);         /*stop profiling and
write data\
             file
mon.out*/
}
```

3. This example shows how to profile contiguously loaded functions beginning at `zit` up to but not including `zot` with **-pg** profiling:

```
#include <sys/types.h>
#include <mon.h>
main()
{
extern zit();         /*first function
to profile*/
extern zot();         /*upper bound
function*/
extern struct monglobal _mondata; /*profiling global variables*/
int  rc;         /*monstartup
return code*/
_mondata.prof_type = _PROF_TYPE_IS_PG;   /*define -pg profiling*/
/*Note cast used to obtain function code addresses*/
rc = monstartup(*(uint *)zit,*(uint *)zot);   /*start*/
if ( rc != 0 )         /*profiling did
not start - do\
             error
recovery here*/
   return(-1);
            /*other code
for analysis ...*/
exit(0);   /*stop profiling and write data file gmon.out*/
}
```

Return Values

The **monstartup** subroutine returns 0 upon successful completion.

Error Codes

If an error is found, the **monstartup** subroutine outputs an error message to **stderr** and returns -1.

Files

Item	Description
mon.out	Data file for **-p** profiling.
gmon.out	Data file for **-pg** profiling.

Item	Description
mon.h	Defines the **_mondata.prof_type** variable in the **monglobal** data structure, the **prof** structure, and the functions referred to in the examples.

move or wmove Subroutine

Purpose

Window location cursor functions.

Library

Curses Library (**libcurses.a**)

Syntax

```
#include <curses.h>
```

```
int move (int y, int x);
int wmove (WINDOW *win, int y, int x);
```

Description

The **move** and **wmove** subroutines move the logical cursor associated with the current or specified window to (y, x) relative to the window's origin. This subroutine does not move the cursor of the terminal until the next **refresh** (“refresh or wrefresh Subroutine” on page 1728) operation.

Parameters

Item	Description
y	Holds the line or row coordinate of the logical cursor.
x	Holds the column coordinate of the logical cursor.
**win*	Identifies the window in which the cursor is being moved.

Return Values

Upon successful completion, these subroutines return OK. Otherwise, they return ERR.

Examples

1. To move the logical cursor in the stdscr to the coordinates y = 5, x = 10, use:

   ```
   move(5, 10);
   ```

2. To move the logical cursor in the user-defined window `my_window` to the coordinates y = 5, x = 10, use:

   ```
   WINDOW *my_window;
   wmove(my_window, 5, 10);
   ```

mprotect Subroutine

Purpose

Modifies access protections for memory mapping or shared memory.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/types.h>
#include <sys/mman.h>
```

```
int mprotect ( addr,  len,  prot)
void *addr;
size_t len;
int prot;
```

Description

The **mprotect** subroutine modifies the access protection of a mapped file or shared memory region or anonymous memory region created by the **mmap** subroutine. Processes running in an environment where the MPROTECT_SHM=ON environmental variable is defined can also use the **mprotect** subroutine to modify the access protection of a shared memory region created by the **shmget**, **ra_shmget**, or **ra_shmgetv** subroutine and attached by the **shmat** subroutine.

Processes running in an environment where the MPROTECT_TXT=ON environmental variable is defined can use the **mprotect** subroutine to modify access protections on main text, shared library, and loaded code. There is no requirement for these areas to be mapped using the **mmap** subroutine prior to their modification by the **mprotect** subroutine. A private copy of any modification to the application text is made using the copy-on-write semantics. Modifications to the content of application text are not persistent. Modifications to the application text will be propagated to the child processes across fork calls. Subsequent modifications by forker and sibling remain private to each other.

The user who protects shared memory with the **mprotect** subroutine must be also be either the user who created the shared memory descriptor, the user who owns the shared memory descriptor, or the root user.

The **mprotect** subroutine can only be used on shared memory regions backed with 4 KB or 64 KB pages; shared memory regions backed by 16 MB and 16 GB pages are not supported by the **mprotect** subroutine. The page size used to back a shared memory region can be obtained using the **vmgetinfo** subroutine and specifying VM_PAGE_INFO for the *command* parameter.

The **mprotect** subroutine cannot be used for shared memory that has been pre-translated. This includes shared memory regions created with the SHM_PIN flag specified to the **shmget** subroutine as well as shared memory regions that have been pinned using the **shmctl** subroutine with the SHM_LOCK flag specified.

Parameters

addr
Specifies the address of the region to be modified. Must be a multiple of the page size backing the memory region.

len
Specifies the length, in bytes, of the region to be modified. For shared memory regions backed with 4 KB pages, the *len* parameter will be rounded off to the next multiple of the page size. Otherwise, the *len* parameter must be a multiple of the page size backing the memory region.

prot
Specifies the new access permissions for the mapped region. Legitimate values for the *prot* parameter are the same as those permitted for the **mmap** subroutine, as follows:

PROT_READ
Region can be read.

PROT_WRITE
Region can be written.

PROT_EXEC
Region can be executed.

PROT_NONE
Region cannot be accessed. PROT_NONE is not a valid *prot* parameter for shared memory attached with the **shmat** subroutine.

Return Values

When successful, the **mprotect** subroutine returns 0. Otherwise, it returns -1 and sets the **errno** global variable to indicate the error.

Note: The return value for the **mprotect** subroutine is 0 if it fails because the region given was not created by **mmap** unless XPG 1170 behavior is requested by setting the **XPG_SUS_ENV** environment variable to **ON**.

Error Codes

If the **mprotect** subroutine is unsuccessful, the **errno** global variable might be set to one of the following values:

Attention: If the **mprotect** subroutine is unsuccessful because of a condition other than that specified by the **EINVAL** error code, the access protection for some pages in the (*addr*, *addr* + *len*) range might have been changed.

Item	Description
EACCES	The *prot* parameter specifies a protection that conflicts with the access permission set for the underlying file.
EPERM	The user is not the creator or owner of the shared memory region and is not the root user.
ENOTSUP	The *prot* parameter specified is not valid for the region specified.
EINVAL	The *addr* or *len* parameter is not a multiple of the page size backing the memory region.
ENOMEM	The application has requested Single UNIX Specification, Version 2 compliant behavior, but addresses in the range are not valid for the address space of the process, or the addresses specify one or more pages that are not attached to the user's address space by a previous **mmap** or **shmat** subroutine call.
ENOTSUP	The shared memory region specified is backed by 64 KB pages, but the *addr* or *len* parameter is not 64 KB aligned, or PROT_NONE protection was specified for a shared memory region, or a pre-translated shared memory region was specified, or a shared memory region backed by 16 MB or 16 GB pages was specified.

mq_close Subroutine

Purpose

Closes a message queue.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <mqueue.h>

int mq_close (mqdes)
mqd_t mqdes;
```

Description

The **mq_close** subroutine removes the association between the message queue descriptor, *mqdes*, and its message queue. The results of using this message queue descriptor after successful return from the **mq_close** subroutine, and until the return of this message queue descriptor from a subsequent **mq_open** call, are undefined.

If the process has successfully attached a notification request to the message queue through the *mqdes* parameter, this attachment is removed, and the message queue is available for another process to attach for notification.

Parameters

Item	Description
mqdes	Specifies the message queue descriptor.

Return Values

Upon successful completion, the **mq_close** subroutine returns a zero. Otherwise, the subroutine returns a -1 and sets **errno** to indicate the error.

Error Codes

The **mq_close** subroutine fails if:

Item	Description
EBADF	The *mqdes* parameter is not a valid message queue descriptor.
ENOMEM	Insufficient memory for the required operation.
ENOTSUP	This function is not supported with processes that have been checkpoint-restart'ed.

mq_getattr Subroutine

Purpose

Gets message queue attributes.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <mqueue.h>
```

```
int mq_getattr (mqdes, mqstat)
mqd_t mqdes;
struct mq_attr *mqstat;
```

Description

The **mq_getattr** subroutine obtains status information and attributes of the message queue and the open message queue description associated with the message queue descriptor.

The results are returned in the **mq_attr** structure referenced by the *mqstat* parameter.

Upon return, the following members have the values associated with the open message queue description as set when the message queue was opened and as modified by subsequent calls to the **mq_setattr** subroutine:

- *mq_flags*

The following attributes of the message queue are returned as set at message queue creation:

- *mq_maxmsg*
- *mq_msgsize*

Upon return, the following member within the **mq_attr** structure referenced by the *mqstat* parameter is set to the current state of the message queue:

Item	Description
mq_curmsgs	The number of messages currently on the queue.

Parameters

Item	Description
mqdes	Specifies a message queue descriptor.
mqstat	Points to the **mq_attr** structure.

Return Values

Upon successful completion, the **mq_getattr** subroutine returns zero. Otherwise, the subroutine returns -1 and sets **errno** to indicate the error.

Error Codes

The **mq_getattr** subroutine fails if:

Item	Description
EBADF	The *mqdes* parameter is not a valid message queue descriptor.
EFAULT	Invalid user address.
EINVAL	The *mqstat* parameter value is not valid.
ENOMEM	Insufficient memory for the required operation.
ENOTSUP	This function is not supported with processes that have been checkpoint-restart'ed.

mq_notify Subroutine

Purpose

Notifies a process that a message is available.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <mqueue.h>

int mq_notify (mqdes, notification)
mqd_t mqdes;
const struct sigevent *notification;
```

Description

If the *notification* parameter is not NULL, the **mq_notify** subroutine registers the calling process to be notified of message arrival at an empty message queue associated with the specified message queue descriptor, *mqdes*. The notification specified by the *notification* parameter is sent to the process when the message queue transitions from empty to non-empty. At any time only one process may be registered for notification by a message queue. If the calling process or any other process has already registered for notification of message arrival at the specified message queue, subsequent attempts to register for that message queue fails.

If notification is NULL and the process is currently registered for notification by the specified message queue, the existing registration is removed.

When the notification is sent to the registered process, its registration is removed. The message queue is then available for registration.

If a process has registered for notification of message arrival at a message queue and a thread is blocked in the **mq_receive** or **mq_timedreceive** subroutines waiting to receive a message, the arriving message satisfies the appropriate **mq_receive** or **mq_timedreceive** subroutine respectively. The resulting behavior is as if the message queue remains empty, and no notification is sent.

Parameters

Item	Description
mqdes	Specifies a message queue descriptor.
notification	Points to the **sigevent** structure.

Return Values

Upon successful completion, the **mq_notify** subroutine returns a zero. Otherwise, it returns a value of -1 and sets **errno** to indicate the error.

Error Codes

The **mq_notify** subroutine fails if:

Item	Description
EBADF	The *mqdes* parameter is not a valid message queue descriptor.
EBUSY	A process is already registered for notification by the message queue.
EFAULT	Invalid used address.
ENOMEM	Insufficient memory for the required operation.
ENOTSUP	This function is not supported with processes that have been checkpoint-restart'ed.
EINVAL	The current process is not registered for notification for the specified message queue and registration removal was requested.

mq_open Subroutine

Purpose

Opens a message queue.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <mqueue.h>

mqd_t mq_open (name, oflag [mode, attr])
const char *name;
int oflag;
mode_t mode;
mq_attr *attr;
```

Description

The **mq_open** subroutine establishes a connection between a process and a message queue with a message queue descriptor. It creates an open message queue description that refers to the message queue, and a message queue descriptor that refers to that open message queue description. The message queue descriptor is used by other subroutines to refer to that message queue.

The *name* parameter points to a string naming a message queue, and has no representation in the file system. The *name* parameter conforms to the construction rules for a pathname. It may or may not begin with a slash character, but contains at least one character. Processes calling the **mq_open** subroutine with the same value of *name* refer to the same message queue object, as long as that name has not been removed. If the *name* parameter is not the name of an existing message queue and creation is not requested, the **mq_open** subroutine will fail and return an error.

The *oflag* parameter requests the desired receive and send access to the message queue. The requested access permission to receive messages or send messages is granted if the calling process would be granted read or write access, respectively, to an equivalently protected file.

The value of the *oflag* parameter is the bitwise-inclusive OR of values from the following list. Applications specify exactly one of the first three values (access modes) below in the value of the *oflag* parameter:

O_RDONLY
Open the message queue for receiving messages. The process can use the returned message queue descriptor with the **mq_receive** subroutine, but not the **mq_send** subroutine. A message queue may be open multiple times in the same or different processes for receiving messages.

O_WRONLY
Open the queue for sending messages. The process can use the returned message queue descriptor with the **mq_send** subroutine but not the **mq_receive** subroutine. A message queue may be open multiple times in the same or different processes for sending messages.

O_RDWR
Open the queue for both receiving and sending messages. The process can use any of the functions allowed for the **O_RDONLY** and **O_WRONLY** flags. A message queue may be open multiple times in the same or different processes for sending messages.

Any combination of the remaining flags may be specified in the value of the *oflag* parameter:

O_CREAT
Create a message queue. It requires two additional arguments: *mode*, which is of **mode_t** type, and *attr*, which is a pointer to an **mq_attr** structure. If the pathname *name* has already been used to create a message queue that still exists, this flag has no effect, except as noted under the **O_EXCL** flag. Otherwise, a message queue is created without any messages in it. The user ID of the message

queue is set to the effective user ID of the process, and the group ID of the message queue is set to the effective group ID of the process. The file permission bits are set to the value of *mode*. When bits in the *mode* parameter other than file permission bits are set, they have no effect. If *attr* is NULL, the message queue is created with default message queue attributes. Default values are 128 for *mq_maxmsg* and 1024 for *mq_msgsize*. If *attr* is non-NULL, the message queue *mq_maxmsg* and *mq_msgsize* attributes are set to the values of the corresponding members in the **mq_attr** structure referred to by *attr*.

O_EXCL
If the **O_EXCL** and **O_CREAT** flags are set, the **mq_open** subroutine fails if the message queue name exists. The check for the existence of the message queue and the creation of the message queue if it does not exist is atomic with respect to other threads executing **mq_open** naming the same name with the **O_EXCL** and **O_CREAT** flags set. If the **O_EXCL** flag is set and the **O_CREAT** flag is not set, the **O_EXCL** flag is ignored.

O_NONBLOCK
Determines whether the **mq_send** or **mq_receive** subroutine waits for resources or messages that are not currently available, or fails with **errno** set to **EAGAIN**; see **mq_send** and **mq_receive** for details.
