-m	Creates map files that specify the mapping of the logical-to-physical partitions for each logical volume in the volume group. This mapping can be used to allocate the same logical-to-physical mapping when the image is restored. The map file locations are stored in the MAPFILE field in the **/image.data** file for each logical volume. Sufficient space would exist in the **/tmp** file system for map creation because the installation routines place the maps in the **/tmp** file system before issuing the **mklv** command. For example, for the **hd7** logical volume, the location of the map file is **/tmp/vgdata/rootvg/hd7.map**. The MAPFILE field in the **/image.data** file for the **hd7** logical volume is under the entry `MAPFILE=/tmp/vgdata/rootvg/hd7.map`. The map files in the backup image are copied after the **image.data** or *vgname***.data** files.
-X	Expands **/tmp** if needed.
vgname	Name of volume group to backup.
-x *file*	Excludes the file systems that are listed in the file from the output file. File system mount points must be listed one per line.

Note: Use care when excluding file systems because a resulting backup can be unusable for system restoration.

Files

Item	Description
/image.data	Created when the volume group is **rootvg**.
/tmp/vgdata/*vgname***/***vgname***.data**	Created when the volume group is not **rootvg** and where *vgname* is the name of the volume group.

mkvirprt Command

Purpose

Makes a virtual printer.

Syntax

mkvirprt [**-A** *AttachmentType*] **-d** *QueueDevice* **-n** *Device* **-q** *PrintQueue* **-s** *DataStream* **-t** *PrinterType* **-T**

mkvirprt -A *AttachmentType*

Description

The **mkvirprt** command creates a virtual printer definition and assigns it to the specified print queue and queue device. A virtual printer definition is a set of attribute values that describe a particular data stream for a particular printer. Before a print job can be queued with the **enq** command, **qprt** command, **lp** command, or **lpr** command, a virtual printer definition must be created for the printer's print queue and queue device.

Printers that support only one printer data stream, such as the 4201-3 Proprinter III, need only one virtual printer defined. Printers that support multiple printer data streams, such as the IBM 4216-31 Page Printer II, need a virtual printer defined for each data stream.

To create a virtual printer definition for a printer attached to an ASCII terminal, use the **-T** flag with the **mkvirprt** command.

After a virtual printer definition is created, its attribute values can be displayed with the **lsvirprt** command and changed with the **chvirprt** command.

The **mkvirprt** command becomes interactive if only the -A flag is specified with the command. Prompts are issued requesting the necessary parameter values. Prerequisite spooler queues and spooler queue devices are generated automatically, and all virtual printer definitions needed for the printer are defined with a single invocation of the **mkvirprt** command for the specified attachment type.

When the first prompt asks for a device name, if the device name entered is not that of a printer, or if an * (asterisk) precedes the device name, a list of printers is displayed. Otherwise, the printer type is assumed to be the same as that of the device.

Also, when a prompt asks for a print queue name, the queue name entered may optionally be followed by a colon and a queue device name. If no queue device name is provided, the queue device name is assumed to be the same as the device name.

> **Note:** Queue and device names must begin with an alphabetic character.

You can use the System Management Interface Tool (SMIT) **smit mkvirprt** fast path to run this command.

Flags

Item	Description
-A *AttachmentType*	Specifies the type of printer attachment. The most common values for the *AttachmentType* variable value are: **Attachment Type** Represents **local** Locally connected printers **remote** Remote print queues **ascii** Printers attached to an ASCII terminal **file** Print output redirected to a regular file. This flag is optional, and if the **-A** flag is not specified the default attachment type is **file**. If the **-A** flag is the only flag specified on the command line, the **mkvirprt** command goes into interactive mode and executes steps specified in the corresponding **.config** file.
-d *QueueDeviceName*	Specifies the name of an existing queue device to which the virtual printer is assigned.
-n *DeviceName*	Specifies the name of the printer device. Device names include **lp0** for printer 0, **lp1** for printer 1, and so on.
-q *PrintQueueName*	Specifies the special file name of an existing print queue to which the virtual printer is to be assigned. Note that you do not have to specify the path name to the file, such as the **/dev/lp0** file, you just need to specify **lp0**.
-s *DataStreamType*	Specifies the printer data stream type. Data stream types include: **Type** Description **asc** Extended ASCII **ps** PostScript **pcl** Hewlett-Packard PCL **630** Diablo 630 **855** Texas Instruments 855 **gl** Hewlett-Packard GL **kji** Kanji
-t *PrinterType*	Specifies the printer type. Printer types include 4201-3**,** ti2115**,** and so on.
-T	Specifies that the printer is attached to an ASCII terminal.

Examples

1. To make a virtual printer for the `asc` printer data stream for the 4029 printer attached locally, enter:

```
mkvirprt -A local -d mypro -n lp0 -q proq -s asc -t 4019
```

2. To make a virtual printer for a printer connected to an ENA 4033 network adapter, and to be prompted for the parameter values, enter:

```
mkvirprt -A ena
```

Files

Item	Description
/usr/sbin/mkvirprt	Contains the **mkvirprt** command.
/etc/qconfig	Contains configuration files.
/usr/lib/lpd/pio/predef/*	Contains predefined printer attribute files.
/var/spool/lpd/pio/@local/custom/*	Contains customized virtual printer attribute files.
/usr/lib/lpd/pio/etc/*.attach	Contains attachment type files.
/usr/lib/lpd/pio/etc/*.config	Contains the configuration file for the printer.
/var/spool/lpd/pio/@local/ddi*	Contains digested virtual printer attribute files.

mkwpar Command

Purpose

Creates a system workload partition (WPAR), or a WPAR specification file.

Syntax

/usr/sbin/mkwpar [**-a**] [**-A**] [**-b** *devexportsfile*] [**-c**] [**-C**] [**-E** *directory*] [**-d** *directory*] [**-B** *wparbackupdevice*] [**-D** *attribute=value* ...] ... [**-F**] [**-g** *vg*] [**-h** *hostname*] [**-H** *architecture*] [**-i**] [**-I** *attribute=value* ...] [**-k**]... [**-l**] [**-L** *attribute=value*...] [**-M** *attribute=value* ...] ... [**-N** *attribute=value* ...] ... [**-P**] [**-r**] [**-R** *attribute=value* ...] [**-S** *attribute*[+|-]=*value* ...] [**-t**] [**-T** attribute=value ...] [**-s**] [**-u** *userscript*] [**-X** *attribute=value* ...] [**-U** [*uuid*]] { **-n** *wparname* [**-p** [*name*]] [**-e** *existingwparname* **-W** | **-f** *infile*] [**-o** *outfile* [**-w**]] | **-p** [*name*] [**-n** *wparname*] [**-e** *existingwparname* **-W** | **-f** *infile*] [**-o** *outfile* [**-w**]] | **-f** *infile* [**-n** *wparname*] [**-p** [*name*]] [**-o** *outfile* [**-w**]] | **-w** **-o** *outfile* [**-n** *wparname*] [**-p** [*name*]] [**-e** *existingwparname* **-W** | **-f** *infile*] }

Restriction:

- White space must be included between a flag and its argument for *attribute=value* type flags. The **mkwpar** command is not supported on the TCB systems. Regardless of locale, only ASCII characters are allowed as arguments to **mkwpar**, **chwpar**, or **wparexec**.
- You must not run the **mkwpar** command during the AIX Live Update operation.

In addition to the previous command restrictions, more restrictions follow for the WPAR name:

- Must not be more than 25 bytes.
- Must not contain white space or any of the following symbols:

```
= : / ! ; ` ' " < > ~ & ( ) * + [ ] , . ^ 0 { } | \
```

- Must not start with hyphen (-) or 0.

Description

The **mkwpar** command builds the infrastructure to prepare a system workload partition for use. This command includes the following tasks:

- Creating the configuration data of the workload partition in the workload partition database
- Creating and populating file systems of the workload partition
- Creating an SRC subsystem for the init process of the workload partition
- Defining the resource control profile of the workload partition through Workload Manager

The following options are also available:

- Writing a specification file to simplify creation of other, similar workload partitions
- Starting the workload partitions
- Specifying whether the workload partitions must be automatically started on system start or when **/etc/rc.wpars** is started
- Specifying WPAR specific routing, by using the **-i** and **-I** flags

The **mkwpar** command supports advanced logical volume and file system options by specifying the **image.data** file as an argument to the **mkwpar -L** flag.

The **mkwpar** command supports creating a rootvg WPAR, in which the root file systems are located solely in WPAR storage devices.

Flags

Item	Description
-a	Automatically resolves conflicting static settings if required. Resolvable settings are base directory, host name, and network configuration.
-A	Specifies that the workload partition must be started each time **/etc/rc.wpars** is run, which is added to the global **/etc/inittab** to run each time that the system starts. The default is not to start the workload partition automatically. **Tip:** The workload partition is started immediately upon completion of the **mkwpar** command. To start the workload partition immediately, use the **-s** flag.
-b *devexportsfile*	Specifies an alternative file to use as the master device exports file. This file must match the format of a Device Exports File. If you do not specify a file name, **/etc/wpars/devexports** is used.
-B *wparbackupdevice*	Specifies a device that contains a workload partition backup image. This image is used to populate the workload partition file systems. The *wparBackupDevice* parameter is a workload partition image that is created with the **savewpar**, **mkcd**, or **mkdvd** command. The **-B** flag is used by the **restwpar** command as part of the process of creating a workload partition from a backup image. **Note:** The **-B** flag is mutually exclusive with the **-p** flag.
-c	Configures the workload partition to be checkpointable. This option is valid only when more checkpoints or restart software are installed and configured. When you specify this flag, any file systems that are associated with only this flag (for example, through the **-M** flag) must be remote (for example, **vfs=nfs**).
-C	Creates a versioned workload partition. This option is valid only when more versioned workload partition software is installed.
-d *directory*	Specifies a base directory for the workload partition. If you do not specify a directory name, **/wpars/<wparname>** is used.

Item	Description
-D [**devname**=*device name* | **devid**=*device identifier*] [**rootvg**=*yes* | *no*] [**devtype**=[*clone* | *pseudo* | *disk* | *adapter* | *cdrom* | *tape*]]	Configures exporting or virtualization of a global device into the workload partition every time the system starts. You can specify more than one **-D** flag to allocate multiple devices. Separate the attribute=value by blank spaces. You can specify the following attributes for the **-D** flag: **devname=device name** Specifies the device name to allocate to the workload partition. For pseudo and clone type devices, this command is the full path to the device (that is, /dev/pty10). For storage type devices, it is the logical device short name. **devid=device identifier** Specifies the unique device identifier of a disk type device to allocate to the workload partition. This attribute applies only to disk, cdrom, or tape type devices. **devtype=[clone | pseudo | disk | adapter | cdrom | tape]** Specifies the device type of the device to allocate to the workload partition. **rootvg= [yes | no]** Used to indicate whether the specified disk device is to be used as a rootvg workload partition device. If the **rootvg** attribute is not specified, the command takes the default of number.
-e *existingwparname*	Uses an existing workload partition as the source for specification data. This flag is mutually exclusive with the **-f** flag. Any values that you specify using other **mkwpar** flags override those from the existing workload partition.
-E	Specifies a directory which contains additional filesets to install when a versioned workload partition is created. If you do not specify a directory name, `/usr/sys/inst.images` is used. This option is used only during creation of a versioned WPAR.
-f *infile*	Indicates a specification file from which default values are read. This flag is mutually exclusive with the **-e** flag. Any values that you specify by using other **mkwpar** flags, override those flags from the loaded specification file.
-F	Forces the command to continue rather than fail for most error conditions.
-g *vg*	Indicates the default volume group. If you do not specify a value, rootvg is used. This volume group is used for each localfs file system whose volume group is not specified by using the *vg* parameter of the **-M** flag. The volume group for file systems that you specified in the **image.data** file, supersedes the volume group that is specified with the **-g** flag.
-h *hostname*	Specifies a host name for the workload partition. you do not specify a value, the **mkwpar** command uses the workload partition name for the host name.
-H *architecture*	Creates an architecture compatible workload partition. The valid architecture values are *{pwr4, ppc970, pwr5, pwr6, pwr7, and pwr8}*. The architecture value must be lower than, or equal to, the system hardware level. The applications in the workload partition are presented with the lowest common denominator of the specified architecture. If the workload partition is checkpointable, the workload partition must be able to migrate between systems with hardware levels greater than, or equal to, the workload partition architecture. **Note:** Values *pwr5* and *ppc970* are not compatible with each other. You cannot create a *ppc970* compatible WPAR on a POWER5 processor-based system even though the *ppc970* processor preceded the POWER 5 processor.
-i	Enables WPAR specific routing for the workload partition. A default route is not created automatically. The **-I** flag is used to specify routes, including the default route. By default, outgoing network traffic from a workload partition is routed as if it is being sent from the global environment: • Traffic between addresses that are hosted on the same global system is sent through the loopback interface. • Routing table entries that are configured in the global system, including the default route, are used to transmit workload partition traffic. If you enable WPAR specific routing by specifying the **-i** flag, the workload partition creates and uses its own routing table for outgoing traffic. Routing entries are created automatically for each of the network addresses of the workload partition to accommodate broadcast, loopback, and subnet routes. For more information about the network attributes, see the **-N** flag. You can create explicit additions to the routing table of the workload partition using the **-I** flag.
-I *attribute=value ...*	Adds routing table entries to those tables that are automatically created when WPAR specific routing is in effect. You can specify more than one **-I** flag to configure multiple routes. Using the **-I** flag automatically enables WPAR specific routing as described under the **-i** flag. You can specify the following attributes with the **-I** flag:

Item	Description	
	rtdest=*destination*	(Required) Identifies the host or network to which you are directing the route. You can specify the value by using either symbolic name or numeric address. You can use the keyword **default** to specify a default route. For more information about the route **rtdest** attribute, see the *Destination* parameter of the **route** command.
	rtgateway=*gateway*	(Required) Identifies the gateway to which packets are addressed. You can specify the value by using either symbolic name or numeric address.
	rtnetmask=*A.B.C.D*	Specifies the network mask to the destination address.
	rtprefixlen=*n*	Specifies the length of a destination prefix, which is the number of bits in the netmask. The value must be a positive integer.
	rttype={*net*|*host*}	Forces the **rtdest** attribute to be interpreted as the specified type.
	rtinterface=*if*	Specifies the interface, for example, `en0`, to associate with the route so that packets are sent by using the interface when the route is chosen.
	rtfamily =*{inet|inet6}*	Specifies the address family.
-k	Specifies the path to a user provided post installation customization script. The script is run in the global environment after the WPAR is created while WPAR file systems are mounted. The post customization script is called with the WPAR name as the first argument, and the WPAR base directory as the second argument. If the script exits with a nonzero return code, a warning is printed, but the **mkwpar** command has not failed.	
-l	Creates private and writable versions of the **/usr** and **/opt** file systems.	
-L [**image_data**= *imagedatafile*] [**shrink**= {**yes**|**no**}] [**ignore_maps**= {**yes**|**no**}]	**image_data** Specifies the path to the **image.data** file to be used for logical volume and file system options. The format of the **image.data** file is described in *Files Reference* and the **/usr/lpp/bosinst/image.template** file. File system specifications in the **image.data** file supersede file system specifications in the **Specifications** File. The **-c** flag and **-L image_data=** flags are mutually exclusive. **shrink** Specifies that the **LV_MIN_LPS** attribute, rather than the **LPs** attribute, must be used to determine the number of logical partitions for the logical volume. The **LV_MIN_LPS** attribute is from the **lv_data** stanzas from the file that the **image_data** attribute specifies. This attribute can minimize the amount of disk space that is required for a workload partition file system. This attribute has no effect if the **image_data** attribute is not specified. **ignore_maps** Specifies that the **MAPFILES** attribute must not be used to provide a disk mapping for the logical volumes that are associated with a workload partition. The **MAPFILES** attribute is from the **lv_data** stanzas from the file that the **image_data** attribute specifies. This attribute has no effect if the **image_data** attribute is not specified. **ignore_lvs** Specifies that the information from the **lv_data** stanzas is not used when the **image.data** file is being processed. The logical volumes are created with the default characteristics when the file systems are created. This attribute has no effect if the **image.dita** attribute is not specified. If this attribute is specified, the **ignore_maps** attribute is ignored.	

Item	Description
-M directory=*dir* [**vfs**=*type*] [**size**=*sizespec*] [**vg**=*volumegroup*] [**logname**=*loglv*] [**dev**=*devicepath*] [**host**=*remotehost*] [=] [**mountopts**=*mountopts*]	Specifies mount configuration attributes. Attributes must be separated by a blank space. You can specify more than one **-M** flag. By default, the **/usr** and **/opt** file systems of the workload partition are mounted over the global **/usr** and **/opt** file systems in read-only mode. The **/proc** file system of the workload partition is mounted over the global **/proc** file system in read/write mode. New logical volumes that are created in **rootvg** for **/, /var, /tmp,** and **/home**. The default settings for a specified file system can be overridden by using the **-M** flag with the **directory** attribute set to the file system name. You can specify more file systems with additional **-M** flags. The **directory** attribute denotes the directory within the workload partition where the device must be mounted. File system specifications in the **-M** flag supersede file system specifications in the **image.data** file. There are 4 basic workload partition mount forms: **localfs** Disk-based file system (**vfs**=jfs or **vfs**=jfs2) to be created at the location that is specified by the value of the **directory** within the directory structure of the workload partition. If you specify a **dev** attribute, it denotes an existing logical volume in the global environment, which is to be used to host the file system. For localfs file systems, you must specify the **size** attribute. Other optional attributes, which are of the form *attr=value*, include those attributes in the following list: **logname** Specifies the log device to use for this file system. This attribute must be specified only if the default log device that the file system uses is insufficient. • For vfs=jfs2, the default is to use an inline log. • For vfs=jfs, the default is that the file system uses an existing log device if available. Otherwise, it creates one. When the **logname** attribute is being specified, make sure that the named log device exists. **mode** Specifies the octal permission mode to assign to the base directory of this file system. The default is 755. **size** Specifies the size of the file system that is created in a format acceptable to the **crfs** command. **vg** Specifies the volume group in which the file system (if no existing logical volume device is specified by using the **dev** attribute) is created. If you do not specify a value, the volume group that is specified in the **-g** flag is used. If you do not specify the **-g** flag, **rootvg** is assumed. Specifies other options to pass to the **crfs** command when the file system is being created. Options are passed directly to the **crfs** command so the value must be in the form that is required by the **crfs** command.

Item	Description
-M directory=*dir* [**vfs**=*type*] [**size**=*sizespec*] [**vg**=*volumegroup*] [**logname**=*loglv*] [**dev**=*devicepath*] [**host**=*RemoteHost*] [=] [**mountopts**=*mountopts*] (continued)	**Restriction:** Do not specify any options to the **crfs** command that correspond to the flags in the **mkwpar** command. The **mkwpar** command must not be specified by using the attribute because incorrect results might occur: • **-a logname**=*lvname* (logname) • **-a size**=*value* (size) • **-d** *device* (dev) • **-g** *volumegroup* (vg) • **-m** *mountpoint* (directory) • **-v** *vfstype* (vfs) For more information, see **crfs** documentation for further information about the **crfs** command. **mountopts** Specifies the mount options (corresponding to the "options" attribute in an /etc/filesystems stanza). If you do not specify a mount option, by default, no mount flags are used. Option values that you can specify correspond to the **-o** options of the **mount** command. **namefs** Specifies that the global directory that is specified by the **dev** attribute is mounted over the directory that is specified by the directory attribute in the file system structure of the workload partition. The only other attribute that is applicable to a **namefs** mount is **mountopts**. For the **namefs** type, you cannot map the /, `/var`, `/opt`, `/usr`, `/tmp`, or `/proc` file system of a workload partition with write privileges to a real /, `/var`, `/opt`, `/usr`, `/tmp`, or `/proc` file system. The **namefs** mount can also be used with rootvg workload partitions. In this case, the content of the namefs mount is not saved by using the **savewpar** command. **nfs** Specifies that the directory that is specified by the **dev** attribute on the system that is exported by the **host** attribute is mounted over the workload partition **directory**. The only other attribute that is applicable to a nfs mount is **mountopts**. **Requirement:** The global system and the workload partition must both have root permissions to the NFS device. You can give the global and the WPAR root permission to the NFS device, when you export the NFS mount, by specifying the root access for the host names of both the global system and the workload partition. When an NFS device is mounted, you cannot map the **/, /var, /opt**, or **/usr** file system of a workload partition with write privileges to a real **/, /var, /opt**, or **/usr** file system. **directory** Specifies that the directory that is specified by the **directory** attribute is added to the file system structure of the workload partition. No file system is created. Use this attribute to reduce the number of file systems to manage in a workload partition, such as by eliminating the separate file systems for **/tmp** and **/var**. Ensure that the size of the containing file system is adjusted accordingly. **Note:** A directory mount cannot be used for **/usr** or **/opt**.
-n *wparname*	Specifies the name for the workload partition to be created. You must specify a name, either by using the **-n** flag, or in a specification file by using the **-f** flag, unless the **-p** name or both **-w** and **-o** flags are used.

Item	Description
-N *attribute=value*	Specifies network configuration attributes. Separate the *attribute=value* pairs by blank spaces. You can specify more than one **-N** flag to configure multiple IP addresses. You must always specify the **address** or the **address6** attribute when you use the **-N** flag. Any other values that are not specified are taken from the settings of the global system. If you do not specify the **-N** flag, the **mkwpar** command attempts to discover an appropriate IP address for the workload partition. To do that, the **mkwpar** command performs the **gethostbyname** subroutine on the workload partition host name (specified with the **-h** flag). If no **-N** flag is specified and no host name is specified, the **mkwpar** command attempts to discover the IP address by performing the **gethostbyname** subroutine on the workload partition name (specified with the **-n** flag). If you can find an address on the same subnet as any global interface, use that interface settings with the resolved IP address to create the default network entry. You can specify the following attributes for the **-N** flag: • **interface**= *if* or **interface**=*namemappedif* • **address**=*A.B.C.D* • **netmask**=*A.B.C.D* • **broadcast**=*A.B.C.D* • **address6**=*S*:*T*:*U*:*V*:*W*:*X*:*Y*:*Z* • **prefixlen**=*n* The name-mapped interface is defined in the **/etc/wpars/devmap** file. You can specify the mapping between the name-mapped interface and the system interface as follows: `# The comments start with '#'` `# Each line contains a pair of name-mapped interface` `# and real interface separated by tab or blank spaces.` `foo en0` `goo en1` `soo en2` To define an IPv6 network configuration, specify the **-N** flag with the **address6**, **prefixlen**, and **interface** attributes. The **address6** attribute is a 128-bit address. The address is represented by eight 16-bit integers that are separated by colons. Each integer is represented by 4 hex digits. Leading zeros can be skipped, and consecutive null 16-bit integers can be replaced by two colons (one time per address). The **prefixlen** attribute is the number of high-order bits that are used to mask the IPv6 address and to comprise the prefix. The value of the **prefixlen** attribute ranges from 0 through 128. Each **-N** flag can accept either IPv4 attributes, or IPv6 attributes, but not both.
-o *outfile*	Indicates an output path and file name to which to write specification data. This specification file can then be used to create a workload partition later, by using the **-f** flag.
-O	This flag is used to force an existing volume group to be overwritten on a particular set of devices, specified with the **-D rootvg=yes** flag directive. If not specified, the overwrite value defaults to FALSE. This flag must be specified only once, as its setting is applied to all devices specified with the **-D rootvg=yes** flag directive.
-p [*name*]	Indicates that the workload partition's file systems exist and must be preserved, which means the root part must not be populated. You must specify the existing file systems to the **mkwpar** command in one of the following two ways: • Use the *name* parameter to specify an existing mount group in **/etc/filesystems**. Such a mount group usually exists because a previous workload partition was removed by using **rmwpar -p**. If you specify the *name* parameter, it cannot match the name of an existing workload partition on the system. If you specify the **-d** flag, the mount points of the file systems are adjusted accordingly. If you do not specify the **-d** flag, the base directory of the workload partition is determined based on the mount points that are associated with the discovered file systems. • If the file systems are not defined in **/etc/filesystems**, use the **-p** flag with the **-M** flag or mount stanzas in the specification file to define the attributes of the file systems. If you specify the **-p** flag with the *name* parameter, and no workload partition name is provided by using other means (for example, the **-n** flag or **general.name** in the specification file), you can also use the *name* parameter as the workload partition name. **Note:** The **-p** flag is mutually exclusive with the **-B** flag. The **-p** flag can be used to re-create a versioned workload partition. The workload partition's file systems must be preserved. To re-create such a versioned workload partition, the **-f infile** flag is included to provide a specification file that is saved from the original workload partition. The specification file is required to preserve the **ostype** value of the workload partition.
-P	Sets the root password for the workload partition. The **mkwpar** command prompts you for the password interactively.

Item	Description
-r	Duplicates the network name resolution configuration from the global system. The following files, if they exist, are copied into the workload partition: • **/etc/resolv.conf** • **/etc/hosts** • **/etc/netsvc.conf** • **/etc/irs.conf** • **/etc/networks** If the NSORDER environment variable is defined in the calling environment, it is added to the workload partition's `/etc/environment` file.
-R *attribute=value*	Allows specification of resource control attributes. You specify only one **-R** flag. Most resource controls are similar to those resource control attributes that are supported by Workload Manager. You can use the following attributes: **active={yes|no}** • **Active=no** means that the resource attributes are defined but the resource controls are not activated when the WPAR is started. • **Active=yes** means that the resource control attributes are activated when the WPAR starts. **Tip:** If this field is set to 'no', performance metrics such as processor and memory usage are not available by using such commands as **topas** and **wlmstat**, either inside and outside of the workload partition. **rset**=*rset* Configures the workload partition to use a resource set that was created by the **mkrset** command. **shares_CPU**=*n* Specifies the number of processor shares that are available to the workload partition. **CPU**=*m*%-*SM*%,*HM*% Specifies the percentage processor limits for the processes of the workload partition. **shares_memory**=*n* Specifies the number of memory shares that are available to the workload partition. **memory**=*m*%-*SM*%,*HM*% Specifies the percentage memory limits for the processes of the workload partition. **procVirtMem**=*n*[M|MB|G|GB|T|TB] Specifies the maximum amount of virtual memory that a single process can consume. Processes that exceed the specified limit are terminated. The valid units are megabytes (M or MB), gigabytes (G or GB), and terabytes (T or TB). The minimum limit that is allowed is 1 MB. The maximum limit that can be specified is 8796093022207M, 8589934591G, or 8388607T. If you set the value to -1 (no units), the limit is disabled. See Workload Manager limits File. **totalVirtMem**=*n*[M|MB|G|GB|T|TB] The maximum amount of virtual memory that can be consumed by the WPAR as a whole. Processes that cause the specified limit to be exceeded are terminated. The valid range and units are the same as **procVirtMem**. If you set the value to -1 (no units), the limit is disabled. See Workload Manager limits File. **totalProcesses**=*n* Specifies the total number of processes that are allowed in the workload partition. See Workload Manager limits File. **totalPTYs**=*n* Specifies the total number of pseudo terminals that are allowed in the workload partition. See pty Special File. **totalLargePages**=*n* Specifies the number of large pages that can be allowed for the workload partition. See Large Pages. **pct_msgIDs**=*n*% Specifies the percentage of the maximum number of message queue IDs of the system that are allowed in the workload partition. See Message Queue Kernel Services. **pct_semIDs**=*n*%

Item	Description
	Specifies the percentage of the maximum number of semaphore IDs of the system that are allowed in the workload partition. **pct_shmIDs**=*n*% Specifies the percentage of the maximum number of shared memory IDs of the system that are allowed in the workload partition. See Shared Memory. **pct_pinMem**=*n*% Specifies the percentage of the maximum pinned memory of the system that can be allocated to the workload partition. See Support for pinned memory. **totalThreads**=*n* Specifies the total number of threads that are allowed in the workload partition. See Workload Manager limits File.
rootvg=*yes*|*no*	Used to indicate whether the specified disk device is to be used as a rootvg WPAR device. If the **rootvg** option is not specified, the command takes the default of *no*.
-s	Starts the workload partition after it is created.
-S secfile = */path/to/secattrs* **privs[+|-]** = *list*	Configures the set of privileges that can be assigned to processes that are running in a system workload partition. You can provide privileges in a specification file (see the **-f** flag), in a separate security attributes file through **-S secfile=***/path/to/secattrs*, or on the command line by using the **-S privs=***list* flag. If you do not provide security attributes through one of these mechanisms, the **/etc/wpars/secattrs** file is used by default. When you use a separate security attributes file (either the default file or the file that is supplied through **-S secfile**), this file is read once when the workload partition is created to determine the privileges that are associated with the workload partition. Subsequent changes to the file have no effect on existing workload partitions. The default security attributes file */etc/wpars/secattrs* must not be modified directly as it might be overwritten in the future. If you use a base list of privileges from a specification file or security attributes file (including the default), individual privileges can be added to or removed from the list by specifying **-S privs+=***list*, **-S privs-=***list*, or both. Separate attributes must be separated by a blank space and must be unique, which means **secfile=, privs=, privs+=**, and **privs-=** cannot be specified more than once. Privileges must be comma-separated (without spaces) and must be unique. Attributes are processed in the following order regardless of the order that is specified in either the command line or the specification file: 1. The first attribute to be processed is the **privs** attribute without the **+** or **-** modifier. For example, **privs=PV_AZ_READ,PV_AZ_ADMIN**. If this attribute is found, no other attributes can be used. 2. The next attribute to be processed is the **secfile** attribute. See the security stanza of the Specification File Format for details on the format of this file. 3. If none of the attributes that are listed previously are specified, the **/etc/wpars/secattrs** file is used to populate the list of privileges. 4. The next attribute to be processed is an attribute with the **+** modifier. For example, **privs+=PV_DAC_UID,PV_AZ_ROOT**. This command adds the specified privileges to the list of privileges that are specified in the security file. 5. The final attribute to be processed is an attribute with the **-** modifier. For example, **privs-=PV_AZ_ROOT**. This command removes the specified privileges from the list of privileges that are specified in the security file. **Tip:** If you specify the **-S** flag on the command line, any security attributes in the specification file are ignored.

Item	Description
-u *userscript*	Specifies the path to a user script to be run by workload partition commands at various administration points. The parameter of the **-u** flag can be a string that is enclosed in quotation marks, including more arguments to be passed to the script. The first component of the parameter of the **-u** flag must be an absolute path to an existing executable file. The script is started in the following manner: `/path/to/userScript <action> <wparName>` The first argument indicates the administrative action that is being performed, as follows: **WPAR_LOAD** A script runs in the global environment after the kernel is configured, and before the tracked process is created. If the script returns a value other than zero, the workload partition cannot be started. **WPAR_START** A script runs in the global environment as soon as the workload partition becomes active. For system workload partitions, the script runs after the device configuration is complete. For application workload partitions, the script runs as soon as the tracked process is started. In the latter case, this code path can be run asynchronously by a dissociated process with its standard I/O streams closed or redirected. Internal messaging must be handled accordingly, and the script must account for the fact that short-lived workload partitions might be stopped or stopping at any point during the execution of the script. If the script returns a value other than zero, a warning is logged, but no other behavior changes. **WPAR_STOP** A script runs in the global environment after all workload partition processes finish before the kernel is unconfigured. **Note:** This code path can be started by a dissociated process with its standard I/O streams closed or redirected to SRC logs. If the script returns a value other than zero, a warning is logged, but no other behavior changes The second argument is the name of the workload partition. The script can use the **lswpar** command to obtain any other necessary configuration data.
-U [*Workload Partition UUID*]	Specifies the Workload Partition UUID. If you do not specify the value, the UUID is automatically generated for the corresponding Workload Partition.
-w	Writes the specification file only. Used with the **-o** flag, the **-w** flag causes the **mkwpar** command to quit after the new specification file is written, without actually creating the workload partition.
-W	Filters the bootset related information from the WPAR specification file. When the **-W** flag is used with the **-e** flag to generate a specification file from an existing WPAR, the resulting specification file does not include the bootset related attributes, such as bootset and bootlist.
-X [**exportfile**=*/path/to/file* |[**kext**=[*/path/to/extension*|*ALL*]] [**local**=*yes* | *no*] [**major**=*yes* | *no*]	Configures exporting kernel extensions that will be allowed to load inside a workload partition. You can specify more than one **-X** flag to allocate multiple kernel extensions. Separate the **attribute**=*value* by blank spaces. This flag is not valid for application workload partitions. You can specify the following attributes for the **-X** flag: **exportfile=*/path/to/file*** Specify a file containing valid extension stanzae that will be exported. An extension stanza should contain at least the **kext** attribute. The **local** and **major** attribute can also be specified in the stanza which are described below. The **exportfile** attribute is mutually exclusive with the **kext** attribute. It is also mutually exclusive with the local and major attribute because these can be specified for each extension stanza in the **exportfile**. This is a file that can be created by a user to use with **exportfile**=*/path/to/file* for **mkwpar** and **chwpar**. It can contain multiple extension stanzas. The **kext** attribute is required for each extension stanza. The local and major are optional as they both have default value **no**. The **exportfile** will look similar to the following. extension: `major = "yes"` `local = "no"` `kext = "/usr/lib/drivers/ldterm"` **kext=*/path/to/extension*** Specify a kernel extension that will be exported. This is a kernel extension located in the global system's filesystem. The keyword **ALL** can also be specified. This will allow a workload partition to load any extension. When **ALL** is specified, the **local** and **major** attributes are restricted to **local**=*yes* and **major**=*no*. Additional **-X** flags can be specified to overide the restricted local and major values. The **kext** attribute is mutually exclusive with the **-X exportfile** attribute. **local=*yes*/*no*** Specifying **local**=*yes* will make an instance of the kernel extension accessible to only the workload partition that is loading it. Specifying **local**=*no* will share the instance of the kernel extension loaded in the global system. By default, **local**=*no*. **major=*yes*/*no*** This attribute should only be used for kernel extensions that have an associated device major. By default, **major**=*no*.

Item	Description
-t	Copies the file systems from the rootvg volume groups from a system backup image specified by the **-B** flag or the global system.
-T [**preserve_private** ={**yes**|**no**}] [**preserve_wpars** ={**yes**|**no**}]	Controls behavior when copying the file systems from a rootvg volume group or system backup.
preserve_private ={**yes**|**no**}	Controls whether filesets that are designated as not visible within WPARs remain in a WPAR that is created by copying a rootvg volume group from a system backup or global system. The default value is no.
preserve_wpars ={**yes**|**no**}	Indicates whether the file systems associated with WPARs are available in the source system in a WPAR, which is created by copying a rootvg volume group from a global system. The default value is no.

Security

Access Control: Only the root user can run this command.

Examples

1. To create a workload partition called `roy`, enter the following command:

   ```
   mkwpar -n roy -N address=192.168.0.51
   ```

   All values that are not specified are generated or discovered from the global system settings.
2. To create a workload partition based on an existing specification file, enter the following command:

   ```
   mkwpar -f /tmp/wpar1.spec
   ```
3. To create a modified copy of a specification file with a new IP address, host name, and workload partition name (without creating a workload partition), enter the following command:

   ```
   mkwpar -f /tmp/wpar1.spec -N address=219.168.45.132 -h www.flowers.com -n wpar2
   -o /tmp/wpar2.spec -w
   ```
4. To create a specification file, which is based on an existing workload partition, enter the following command:

   ```
   mkwpar -e wpar1 -o /tmp/wpar2.spec -w
   ```
5. To recreate a workload partition that was previously removed with the **rmwpar -p** command, enter the following command:

   ```
   mkwpar -p wparname
   ```
6. To create a rootvg workload partition, enter the following command:

   ```
   mkwpar -n test -D devname=hdisk1 rootvg=yes -O
   ```
7. To create a rootvg workload partition called wpar1 with the storage device on an adapter, enter the following command (assuming that hdisk3 is attached to the adapter, fcs2):

   ```
   mkwpar -n wpar1 -D devname=fcs2 -D devname=hdisk3 rootvg=yes
   ```
8. To create a specification file from an existing workload partition, without including bootset related information, enter the following command:

   ```
   mkwpar -e <existing wparname> -W -w -o <path to spec file>
   ```
9. To create a WPAR with a default route, enter the following command:

   ```
   mkwpar -n wparB -N address=192.162.1.2 interface=en0 netmask=255.255.255.0 -i
   -I rtdest=0.0.0.0 rtgateway=192.162.1.1
   ```

10. To create a WPAR with its own routing table but no default route, enter the following command:

```
mkwpar -n wparA -N address=192.152.1.2 interface=en0 netmask=255.255.255.0 -i
```

Files

Item	Description
/etc/wpars/devexports	Default device export control file for workload partitions.
/etc/wpars/secattrs	Default security file for workload partitions.
/usr/samples/wpars/sample.spec	An annotated workload partition specification file.

mkwpardata Command

Purpose

Creates a file containing information about a workload partition for use by the **savewpar** and **restwpar** commands.

Syntax

mkwpardata [**-X**] [**-m**] *WparName*

Description

The **mkwpardata** command creates a file containing information about a workload partition (WPAR) for use by the **savewpar** and **restwpar** commands. The information includes the list of logical volumes, file systems and their sizes, the list of volume groups, and the WPAR name. The following files are created:You can edit the information in the file before issuing the **savewpar** command.

Flags

Item	Description
-m	Creates map files that specify the mapping of the logical-to-physical partitions for each logical volume in the WPAR. This mapping can be used to allocate the same logical-to-physical mapping when the image is restored. The map file locations are stored in the MAPFILE field in the **image.data** file for each logical volume. For example, for the **hd7** logical volume, the location of the map file is **/tmp/wpardata/***WparName***/hd7.map**. The MAPFILE field in the **image.data** file for the **hd7** logical volume is under the entry **MAPFILE=/tmp/wpardata/***WparName***/hd7.map**. The map files in the backup image are copied after the **image.data** file.
-X	Expands the **/tmp** file system if needed.

Parameters

Item	Description
WparName	Specifies the name of workload partition to back up.

Files

Item	Description
/tmp/wpardata/*WparName***/image.data**	Created for general and storage information about a WPAR. The *WparName* variable reflects the name of the WPAR. The **savewpar** command uses this file to create a backup image that can be used by the **restwpar** command to reinstall the WPAR. The **mkwpardata** command overwrites this file if it already exists. The **image.data** file is located in the **/tmp/wpardata/***WparName* directory, where *WparName* is the workload partition name.

mm Command

Purpose

Prints documents formatted with memorandum macros.

Syntax

mm [**-M** *Media*] [**-c**] [**-e**] [**-E**] [**-t**] [**-12**] [**-T***Name*] { *File* ... | **-** }

Description

The **mm** command formats documents that use the **nroff** command and the **mm** macro package. The **mm** command has flags that specify preprocessing by the **tbl** and **neqn** commands and postprocessing by various terminal-oriented output filters. The proper pipelines and the required flags for the **nroff** command are generated depending on the flags that are selected.

Notes:

1. Use the **-o***List* flag of the **nroff** command to specify ranges of output pages. Remember that if the **mm** command is called with the **-e**, **-t**, or **-** (minus sign) flags together with the **-o***List* flag, and if the last page of the document is not specified by the *List* variable, you may receive a `broken pipe` message. This message is not an indication of any problem and can be ignored.
2. The **mm** command calls the **nroff** command with the **-h** flag. With this flag, the **nroff** command assumes that the workstation has tabs set every 8 character positions.
3. If you use the **-s** flag of the **nroff** command (to stop between pages of output), use a linefeed (rather than the Enter key or a newline character) to restart the output. The **-s** flag of the **nroff** command does not work with the **-c** flag of the **mm** command or if the **mm** command automatically calls the **col** command**.**
4. Providing inaccurate information to the **mm** command about the kind of workstation its output is to be printed on will produce unsatisfactory results. However, if you are redirecting output to a file, use the **-T37** flag. Then, use the appropriate workstation filter when you print the file.

To obtain a list of **mm** command flags, enter the command name with no parameters. The flags can occur in any order, but they must come before the *File* parameter. Any other flags (for instance, **-r***ANumber*) are passed to the **nroff** command.

Flags

Item	Description
-M *Media*	Specifies a paper size in order to determine the amount of imageable area on the paper. Valid values for the *Media* variable are: **A4** Specifies a paper size of 8.27 X 11.69 inches (210 X 297 mm). **B5** Specifies a paper size of 6.93 X 9.84 inches (176 X 250 mm). **EXEC** Specifies a paper size of 7.25 X 10.5 inches (184.2 X 266.7 mm). **LEGAL** Specifies a paper size of 8.5 X 14 inches (215.9 X 355.6 mm). **LETTER** Specifies a paper size of 8.5 X 11 inches (215.9 X 279.4 mm). This is the default value. **Note:** The *Media* variable is not case sensitive.
-c	Calls the **col** command. Note that the **col** command is called automatically by the **mm** command for the following terminal names. The following devices can be specified by the **-T***Name* flag, the **$TERM** shell variable, or by using the default: • **ppds** • **lp** • **2631** • **8510**
-e	Calls the **neqn** command; also causes the **neqn** command to read the **/usr/share/lib/pub/eqnchar** file. See the **eqnchar** file format.
-E	Calls the **-e** flag of the **nroff** command.
-t	Calls the **tbl** command.
-12	Uses 12-pitch font. Use this when the **$TERM** shell variable is set to 300, 300s, 450, or 1620. (The pitch switch on the DASI 300 and 300s workstations must be manually set to 12 if this flag is used.)
-T*Name*	Uses the workstation type specified by the *Name* variable. By default, the **mm** command uses the value of the **$TERM** shell variable from the environment as the value of the *Name* variable. If the **$TERM** shell variable is not set, the **mm** command uses **lp** (the generic name for printers that can underline and tab). If several workstation types are specified, the last one listed applies.
-	Forces input to be read from standard input.

Parameters

Item	Description
File	Specifies the file that the **mm** command formats.

Examples

1. When the **$TERM** shell variable is set in the environment to the **hplj** command, the following two command lines are equivalent:

```
mm -t -rC3 File
tbl File | nroff -mm -Thplj -h -rC3
```

2. The **mm** command reads the standard input when you specify a **-** (minus sign) flag instead of a value for the *File* variable. This option allows you to use the **mm** command as a filter, as follows:

```
cat File | mm -
```

Note: Using other files together with a **-** (minus sign) flag leads to undesired results.

Environment Variables

Item	Description
$TERM	Specifies the terminal names.

Files

Item	Description
/usr/share/lib/pub/eqnchar	Contains special character definitions for the **eqn** command and the **neqn** command.

mmt Command

Purpose

Typesets documents.

Syntax

mmt [**-M** *Media*] [**-a**] [**-c**] [**-e**] [**-g**] [**-p**] [**-t**] [**-z**] [**-T***Name* | **-D***Destination*] [*File* | **-**]

Description

Similar to the **mm** command, the **mmt** command typesets its input using the **troff** command, rather than formatting it with the **nroff** command. The **mmt** command uses the **mm** macro package. There are flags to specify preprocessing by the **tbl**, **pic**, **eqn**, and **grap** commands. The proper pipelines, required parameters, and flags for the **troff** command and the **mm** macro package are generated, depending on the flags selected.

There are several flags that are specific to the **mmt** command. Any other parameters or flags (for instance, **-r***ANumber* or **-a**) that you give the **mmt** command are passed to the **troff** command. You can put flags in any order, but they must be listed before any input files. *File* specifies the file that the **mmt** command formats. If you do not give *File* parameters or other flag variables, the **mmt** command prints a list of its flags.

The **mmt** command, unlike the **troff** command, automatically pipes its output to a postprocessor, unless specifically requested not to do so. The user should not specify a postprocessor when using the **mmt** command. The precedence is as follows:

1. The **-z** flag; no postprocessor is used.
2. The **-T***Name* flag.
3. The **TYPESETTER** environment variable is read.
4. The default is set to **ibm3816**.

The **mmt** command reads standard input when you specify a **-** (minus sign) instead of any *File* parameters.

Use the **-o***List* flag of the **troff** command to specify ranges of pages to be output.

> **Note:** If you call the **mmt** command with one or more of the **-e**, **-c**, **-t**, **-p**, **-g**, and - (minus sign) flags together with the **-o***List* flag of the **troff** command, you may receive a `broken pipe` message if the last page of the document is not specified by the *List* variable. This broken pipe message is not an indication of any problem and can be ignored.

Flags

Item	Description
-M *Media*	Specifies a paper size in order to determine the amount of imageable area on the paper. Valid values for the *Media* variable are: **A4** Specifies a paper size of 8.27 X 11.69 inches (210 X 297 mm). **A5** Specifies a paper size of 5.83 X8.27 inches (148 X 210 mm). **B5** Specifies a paper size of 6.93 X 9.84 inches (176 X 250 mm). **EXEC** Specifies a paper size of 7.25 X 10.5 inches (184.2 X 266.7 mm). **LEGAL** Specifies a paper size of 8.5 X 14 inches (215.9 X 355.6 mm). **LETTER** Specifies a paper size of 8.5 X 11 inches (215.9 X 279.4 mm). This is the default value. **Note:** The *Media* variable is not case sensitive.
-a	Displays readable **troff** output to the terminal.
-c	Preprocesses the input files with the **cw** command.
-e	Calls the **eqn** command; also causes the **eqn** command to read the **/usr/share/lib/pub/eqnchar** file (see the **eqnchar** file format).
-g	Calls the **grap** command, which in turn calls the **pic** command.
-p	Calls the **pic** command.
-t	Calls the **tbl** command.
-z	Starts no output filter to process or redirect the output of the **troff** command.
-D*Destination*	Directs the output to a device specified by the *Destination* variable. Supported destination devices for English-language output is 4014, which is the Tektronix 4014 terminal by way of the **tc** command.

Item	Description
-T*Name*	Creates output for a **troff** device as specified by the *Name* variable. The output is sent through the appropriate postprocessor.. The default value is **ibm3816**. Possible Name variables are: **ibm3812** 3812 Pageprinter II. **ibm3816** 3816 Pageprinter. **hplj** Hewlett-Packard LaserJet II. **ibm5587G** 5587-G01 Kanji Printer multi-byte language support. **psc** PostScript printer. **X100** AIXwindows display.
-	Forces input to be read from standard input.

mmtu Command

Purpose

Displaying, adding, and deleting maximum transfer unit (MTU) values used for path MTU discovery.

Syntax

mmtu { **-a** *Value* | **-d** *Value* | **-s** }

Description

Use the **mmtu** command to display, add, and delete maximum transfer unit (MTU) values to the list of potential path MTU values. Path MTU discovery uses the list of potential path MTU values to detect the path MTU. The list of potential path MTU values is only used when there are routers in the path that do not comply with RFC 1191. The user must have administrative authority to add or delete MTU values.

Note: The **-a** and **-d** flags used to modify the list of potential path MTU values are disallowed when executed within workload partitions.

Flags

Item	Description
-a *Value*	Adds the new MTU to the list of potential path MTU values.
-d *Value*	Deletes the value from the list of potential path MTU values.
-s	Displays the current list of potential path MTU values.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges,

see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To add a value to the list of potential path MTU values, enter:

```
mmtu -a mtu-value
```

2. To delete a value from the list of potential path MTU values, enter:

```
mmtu -d mtu-value
```

3. To display the contents of the list of potential path MTU values, enter:

```
mmtu -s
```

Files

Item	Description
/usr/sbin/mmtu	Contains the **mmtu** command.

mobip6ctrl Command

Purpose

Configures and manages the mobile IPv6 home agent and correspondent node functionality.

Syntax

mobip6ctrl [**-c**] [**-R**] [**-b**] [**-S** { **0** | **1** }] [**-n** { **0** | **1** }] [**-l** *LifeTime*] [**-a** | **-d** *HomeAddress CareOfAddress MyAddress*]

Description

The **mobip6ctrl** command is used to configure and manage the mobile IPv6 home agent and correspondent node. It can enable and disable NDP proxy and IP security checking, and it can be used to display or modify the mobile IPv6 binding cache.

NDP proxy must be enabled if the system is configured as a home agent. This allows the home agent to intercept packets addressed to mobile nodes that are not currently on their home network.

IP security checking enables checking to ensure that IP security is used for the Binding Update and Binding Acknowledgement messages sent for mobile IPv6. Because these two types of messages have the ability to affect the routing of packets addressed to a mobile node, they would represent a significant security vulnerability if not protected by IP security. If checking is enabled, the mobile IPv6 home agent or correspondent node will discard any Binding Update or Binding Acknowledgement packets that are not protected by IP security.

The mobile IPv6 binding cache on a home agent or correspondent node maps home addresses to the current care-of addresses for each mobile node. This allows the home agent to tunnel traffic to the mobile node at its current location, and allows a correspondent node to send packets directly to a mobile node at its current location. The **mobip6ctrl** command can be used to view the binding cache or manually edit it for debugging purposes.

Normally, this command is used from the **/etc/rc.mobip6** script when mobile IPv6 has been configured using system management.

Flags

Item	Description
-a *HomeAddress CareOfAddress MyAddress*	Adds this entry to the binding cache.
-b	Displays all binding cache entries.
-c	Compatibility option which enables the support of the mobiles implementing the draft #13 of the *Mobility support in IPv6* specification. Using this option, the home agent or correspondent node will accept the binding update messages sent using a Destination Option and using an Authentication Header (AH) to protect these packets with IPsec.
-d*HomeAddress CareOfAddress MyAddress*	Delete this entry from the binding cache.
-l *LifeTime*	Specifies the default life time value for binding cache entries in seconds.
-n 0 | **1**	Activates or deactivates NDP proxy capabilities. A value of 1 activates the NDP proxy capabilities, and a value of 0 disables NDP proxy capabilities. The default value is 0.
-R	Resets all the binding cache entries.
-S 0 | **1**	Enables or disables checking to ensure that IP security is used for all Binding Update and Binding Acknowledgement packets. A value of 1 enables checking, and a value of 0 disables checking. The default value is 0.

Exit Status

0
The command completed successfully.

>0
An error occurred.

Security

You must be the root user or a member of the system group to execute this command.

Examples

1. The following example enables NDP proxy and IP security checking for mobile IPv6:

```
mobipctrl -S 1 -n 1
```

2. The following example displays all entries in the binding cache:

```
mobip6ctrl -b
```

The output from this command looks similar to the following:

```
                BINDING CACHE LIST (1 elem)

Home Address.........: 3ffe:300:20:1102::217
Care-Of Address......: 3ffe:300:20:1101::217
My Address...........: 3ffe:300:20:1102::223
Life time............: 518
Time since last usage: 50
Rate limit time......: 0
```

```
Retransmit count.....: 0
Sequence number......: 14
Registered by me.....: 1
Prefix length........: 64
```

mobip6reqd Daemon

Purpose

Provides the Mobile IPv6 home agent daemon.

Syntax

To run the daemon using the System Resource Controller:

startsrc -s mobip6reqd

To run the daemon without using the System Resource Controller:

mobip6reqd

Description

The **mobip6reqd** daemon must be running in order for the system to function as a mobile IPv6 home agent. This daemon enables the home agent to perform NDP proxying for mobile nodes. The daemon is normally started automatically by the **/etc/rc.mobip6** script if the mobile IPv6 home agent has been enabled using system management.

Exit Status

0
The command completed successfully.

>0
An error occurred.

Security

You must be the root user or a member of the system group to execute this command.

Examples

1. The following example starts the **mobip6reqd** daemon:

```
startsrc -s mobip6reqd
```

2. The following example stops the **mobip6reqd** daemon:

```
stopsrc -s mobip6reqd
```

monacct Command

Purpose

Performs monthly or periodic accounting.

Syntax

/usr/sbin/acct/monacct [**-X**] [*Number*]

Description

The **monacct** command performs monthly or periodic accounting. The intervals are set in the **crontab** file. You can set the **cron** daemon to run the **monacct** command once each month or at some other specified time period. The **monacct** example shows how to set up this command for use with the **cron** daemon. See the **crontab** command for more information about setting up **cron** files.

The *Number* parameter indicates which month or other accounting period to process. The default value of the *Number* parameter is the current month. The **monacct** command creates summary files in the **/var/adm/acct/fiscal** file and restarts summary files in the **/var/adm/acct/sum** file, the cumulative summary to which daily reports are appended.

> **Note:** You should not share accounting files among nodes in a distributed environment. Each node should have its own copy of the various accounting files.

Flags

Item	Description
-X	Processes all available characters for each user name instead of truncating to the first 8 characters. The **-X** flag will also cause the **monacct** command to use the **/var/adm/acct/sumx** and **/var/adm/acct/fiscalx** directories instead of the **/var/adm/acct/sum** and **/var/adm/acct/fiscal** directories.

Security

Access Control: This command should grant execute (x) access only to members of the administrative group.

Example

To produce automatically a monthly accounting report, add the following to the **/var/spool/cron/crontabs/root** file:

```
15 5 1 * * /usr/sbin/acct/monacct
```

This example shows the instructions that the **cron** daemon will read and act upon. The **monacct** command will run at 5:15 (15 5) the first day of each month (1). This command is only one of the accounting instructions normally given to the **cron** daemon.

Files

Item	Description
/usr/sbin/acct	Contains the accounting commands.
/var/adm/acct/fiscal	Contains accounting data files.
/var/adm/acct/sum	Cumulative daily accounting records.
/var/spool/cron/crontabs	Contains the commands to be run by the **cron** daemon at regularly scheduled intervals.

mon-cxma Command

Purpose

Monitor status of 128-port asynchronous subsystem and attached devices.

Syntax

To Display All 128-Port Adapters:

mon-cxma

To Display Syntax or Slots and Bus Information:

mon-cxma { **-h** | **-x** }

To Display Specific Slots and Bus Information:

mon-cxma { [**-l** [*LogFile*] [**-f** [*DeviceFile*]] [**-s** [*SlotNumber*]] [**-b** [*BusNumber*]] }

Description

The **mon-cxma** command is a software tool which provides a means to monitor the status of serial devices and remote async nodes (RAN) attached to the IBM 128-port asynchronous adapter. It is used for subsystem problem determination and can be accessed locally and remotely via modem. The only restriction on modem access is that the modem can not be physically attached to the 128-port adapter being monitored.

When the user enters the **mon-cxma** command at the command line, it automatically detects and displays all available 128-port adapters in the system. The bus and slot location within the system is displayed for each adapter and the user can select adapter to monitor.

You can use the System Management Interface Tool (SMIT) **smit 128psync** fast path to advance directly to the "128-Port Asynchronous Adapter" menu. When run from SMIT, the **mon-cxma** command automatically displays all available 128-port adapters in the system.

Flags

Item	Description
-b [*BusNumber*]	Specifies the bus number of the device. Valid values for *BusNumber* are 0 to (n-1), where n is the number of buses the system has.
-f [*DeviceFile*]	Specifies the device special file. Use this file to look at a specific device driver without having to make a selection. The default device special file is **/dev/cxma0**.
-h	Shows syntax information.
-l [*LogFile*]	(Lowercase L) Specifies the file to be used as the log. Use this file to store information from the screen when the IMAGE key is pressed. The default log file is **/tmp/mon-cxma.log**.
-s [*SlotNumber*]	Specifies the slot number of the device. Valid values for *SlotNumber* are 0 to (n-1), where n is the number of slots the system has.
-x	Shows the POS (Programmable Select Option) register values for all the slots and buses.

Note: -x and **-h** ignore other options.

Security

Access Control: Root authority required to run this command.

Auditing Events: N/A

Examples

1. To run the mon-cxma command using the SMITfastpath, enter:

```
smit 128psync
```

2. To display all 128-port adapters, enter:

```
/usr/lbin/tty/mon-cxma
```

Files

Item	Description
/usr/lbin/tty/mon-cxma	Contains the **mon-cxma** command.
/tmp/mon-cxma.log	Contains the log file.

monitord Daemon

Purpose

Communicates with the License Use Management server and requests a concurrent-use license for each countable login.

Syntax

monitord [**-t** *Minutes*] [**-v** *Version*.*Release*]

Description

The operating system has multiple ways to access the system, and each of them has a different behavior upon exit. The **monitord** daemon provides a common interface to the License Use Management **netlsd**. **monitord** communicates with the License Use Management server and requests a concurrent-use license for each countable login.

> **Note:** The License Use Management licensing mechanism is used only if the system has the *floating license mode* enabled.

After user logout, **monitord** requests **netlsd** to release the specific license the user was using, in order to make it available for further logins.

monitord is started when the **chlicense -f on** command is used to enable the *floating license mode*. When the *floating license mode* is enabled, **monitord** is started upon system startup via an entry in **/etc/inittab**. The default (invoked without **-t** option) is an interval of fifteen minutes.

The entry in **/etc/inittab** looks like the following:

```
monitord:2:once:/usr/sbin/monitord >/dev/console 2>&1
```

Flags

Item	Description
-t *Minutes*	Sets the value in minutes of the heartbeat interval. A value of 0 sets an infinite interval. The default is fifteen minutes.
-v *Version*.*Release*	Enables the *floating license mode* for a license of the specified *Version* and *Release*.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

moo Command

Purpose

Starts the number-guessing game.

Syntax

moo

Description

The **moo** command picks a combination of four random, non-repeating numbers. You guess four numbers at the `your guess?` prompt. Each correct number in an incorrect position in the four number combination scores "cow." Each correct number in the correct position in the four number combination scores a "bull." For example:

```
your guess?
1470
bulls = 0  cows = 1
your guess?
```

In this example, one of the four numbers (1, 4, 7, and 0) is correct but in the incorrect position. None of the numbers are correct and in the correct position.

To quit the game, press the Interrupt (Ctrl-C) or End Of File (Ctrl-D) key sequence.

File

Item	Description
/usr/games	Contains the system's games.

more Command

Purpose

Displays file contents one screen at a time.

Syntax

more [**-c**] [**-d**] [**-e**] [**-H**] [**-i**] [**-l**] [**-N**] [**-s**] [**-u**] [**-v**] [**-z**] [**-n** *Number*] [**-p** *Subcommand*] [**-t** *Tagstring*] [**-W** *Option*] [**-x** *Tabs*] [*File* ...]

Description

The **more** command reads files and displays the text one screen at a time. The command pauses after each screen and prints the word `More` at the bottom of the screen. If you then press a carriage return,

the **more** command displays an additional line. If you press the space bar, the **more** command displays another full screen of text.

Note: On some terminal models, the **more** command clears the screen, instead of scrolling.

Instead of naming files to read, you can either redirect or pipe standard output, such as a long directory listing, to the **more** command. The command adds a % (percent sign) to its prompt when reading from a file rather than a pipe. This provides the percentage of the file (in characters, not lines) that the **more** command has read.

The **more** command sets the terminal to NOECHO mode so the output can be continuous. With the exception of the / and ! subcommands, commands that are typed do not normally show up on the terminal. If the standard output is not a terminal, the **more** command will act just like the **cat** command, except that a header will be printed before each file in a series.

Environment Variables

Environment variables affect the way the **more** command works. You can set some environment characteristics in the **/etc/environment** file and system profile files, such as the **.ksh**, **.csh**, and **.profile** files.

The **more** command uses the **TERM** variable to determine terminal characteristics. If this variable is NULL or not set, the command uses the default terminal type. The **/usr/share/lib/terminfo** directory contains definitions for terminal characteristics.

By default, the **more** command window size is 2 lines less than what the system terminal is capable of. The command sets the default window size based on the **LINES** variable. Also, you can easily adjust the window size for each run of the command by adding the **-n** flag.

Use the **MORE** variable to customize the **more** command with your preferred configuration each time the system starts. This variable accepts **more** command flags.

Flags

Flags Description

Item	Description
-c	Prevents the screen from scrolling, which makes text easier to read as the **more** command writes to the screen. The system ignores the **-c** flag if the terminal cannot clear to the end of a line.
-d	Prints a message, appended to the `More` prompt at the bottom of the screen, about which keys continue, quit, and provide help for the **more** command. Displays error messages rather than ringing the terminal bell if an unrecognized command is used. This is helpful for inexperienced users.
-e	Exits automatically after displaying the last line of the last file.
-H	Disables the search pattern highlighting feature by default.
-i	Searches for patterns without considering uppercase and lowercase.
-l	Pauses after detecting a page break in the input. If the `-l` flag is not used, the **more** command pauses to accept commands after any line containing a ^L (CTRL-L) character. Also, if a file begins with a FORMFEED, the screen is cleared before the file is printed.
-N	Suppresses line numbering. The default display, with line numbers, can slow the **more** command's performance on very large input files. The line numbering feature displays the line number in the **=** subcommand and passes the line number to the editor (if it is the **vi** editor).

Flags Description *(continued)*

Item	Description
-n *Number*	Configures the **more** command to display the specified number of lines in the window. Without the **-n** flag, the **more** command defaults to two lines less than what the terminal is capable of. For example, on a 24-line terminal, the default is 22 lines. The `-n` option overrides any values obtained from the environment.
-p *Subcommand*	Starts the **more** command and specified subcommand for each *File* operand. For example, **more -p 50j text1 text2** displays the **text1** file at the fiftieth line; then does the same for the **text2** file when you finish the first. See "Subcommands" for descriptions of **more** subcommands. If the command is a positioning command, such as a line number or a regular expression search, set the current position to represent the final results of the command, without writing any intermediate lines of the file. For example, the two commands: `more -p 1000j` *`filename`* `more -p 1000G` *`filename`* are functionally the same and will start the display with the current position at line 1000, passing the lines that j would write and would scroll off the screen if it had been issued during the file examination. If the positioning command is unsuccessful, the first line in the file will be the current position.
-s	Reduces multiple blank lines in the output to only one blank line. The **-s** flag is particularly helpful in viewing output from the **nroff** command.
-t *Tagstring*	Displays the portion of the file that contains the specified tag. This flag works only on files containing tags created with the **ctags** command.
-u	Prevents the **more** command from treating a backspace character as a printable control character (displayed as a ^H (CTRL-H)), suppressing backspacing, underlining, or creating reverse video text for underlined information in a source file. The **-u** flag also forces the **more** command to recognize a carriage-return character, if it exists, at the end of a line.
-v	Suppresses the graphical translation of nonprinting characters. Without the **-v** flag, the **more** command graphically interprets all non-ASCII and most control characters, except Tab, Backspace, and Return. For example, if you do not use the **-v** flag, the **more** command displays the non-ASCII characters Ctrl-x as ^X and x as `M-x`.

Flags Description *(continued)*

Item	Description
-W *Option*	Provides the specified *Option* to the **more** command as an extension: **notite** Prevents the **more** command from sending the terminal initialization string (either the **ti termcap** or the **smcup terminfo** capability) before displaying the file. This option also prevents the **more** command from sending the terminal de-initialization string (either the **te termcap** or the **rmcup terminfo** capability) before exiting. **tite** Causes the **more** command to send the initialization and de-initialization strings. This is the default. These options control whether the **more** command sends the initialization strings described, which, for certain terminals (such as some xterms), cause the **more** command to switch to an alternative screen. The effect of switching screens is to erase the display of the file you were viewing.
-x *Tabs*	Sets tab stops at the specified *Tabs* position. The default tab setting is 8 columns.
-z	Graphically displays the Tab, Backspace, and Return control characters. With the **-z** flag, the **more** command translates the Backspace character as ^H, Return as ^M, and Tab as ^I.

Subcommands

The **more** command accepts subcommands when the command pauses and as parameters for the **-p** flag. Many subcommands take an optional integer, symbolized here by *K*, which you must enter before the subcommand, with no space between. The **more** command, in the paused state, processes subcommands immediately and does not require you to press the Enter key.

The **more** command uses the following subcommands:

more command

Item	Description
h	Displays a help screen that describes the **more** subcommands.
v	Starts the **vi** editor, editing the current file in the current line.
r or **^L**	Refreshes the display.
R	Refreshes the display and removes buffered input.
[*K*](Spacebar)	Moves forward *K* lines when you press the spacebar. If you do not give a value for *K*, pressing the spacebar displays the next full screen by default. This spacebar subcommand is the same as [*K*]**f** or [*K*]**^F** or [*K*]**z**.
[*K*]**f** or [*K*]**^F** or [*K*]**z**	Moves forward *K* lines, or one full screen if you do not give a value for *K*.
[*K*]**b** or [*K*]**^B**	Moves backward *K* lines, or one full screen if you do not give a value for *K*.
[*K*]**d** or [*K*]**^D**	Moves forward *K* lines, or half a screen if you do not give a value for *K*. If you give a value for *K*, the **more** command sets the **d** and **u** scroll size to *K* lines for the session.

Item	Description
[*K*]**u** or [*K*]**^U**	Moves backward *K* lines, or half a screen if you do not give a value for *K*. If you give a value for *K*, the **more** command sets the **d** and **u** scroll size to *K* lines for the session.
[*K*]**j** or [*K*](Enter) or [*K*]**^E**	Moves forward *K* lines, or one line if you do not give a value for *K*.
[*K*]**k** or [*K*]**^Y**	Moves backward *K* lines, or one line if you do not give a value for *K*.
[*K*]**g**	Moves to the beginning of the file, unless you give a line number for *K*. The default for *K* is line number 1.
[*K*]**G**	Moves to the last line in the file, unless you give a line number for *K*. The default for *K* is the last line in the file.
[*K*]**p** or [*K*]**%**	Moves to the point in the file that is *K* percent of the total file. The default for *K* is one percent, or the first line in the file.
m*a-z*	Marks the current position in the file with the specified letter.
'*a-z*	(Single quote) Moves to the position marked with the specified letter.
''	(Two single quotes) Returns to the position from which the last large movement (moving more than a page) command was run. If no such movements have been made, returns to the beginning of the file.
[*K*]**/***pattern*	(Slash) Searches forward, from the current position, for the specified occurrence of the specified pattern of characters. The default value for *K* is the first occurrence.
[*K*]**/!***pattern*	(Slash, exclamation mark) Searches forward, from the current position, for the specified occurrence of a line that does not contain the specified pattern of characters. The default value for *K* is the first occurrence.
[*K*]**?***pattern*	(Question mark) Searches backward, from the current position, for the specified occurrence of the specified pattern of characters. The default value for *K* is the first occurrence.
[*K*]**?!***pattern*	(Question mark, exclamation mark) Searches backward, from the current position, for the specified occurrence of a line that does not contain the specified pattern of characters. The default value for *K* is the first occurrence.
[*K*]**n**	Repeats the last search, specifying an occurrence of the pattern (or an occurrence *not* containing the pattern if the search subcommand included **!**). The default value for *K* is the first occurrence.
:a	Lists the file or files you named in the **more** command line.

more command *(continued)*

Item	Description
:f or **^G** or **=**	Displays information about the current file: • file name • order of the file in the list of files • current line number • current position in the file, given as a percentage • current byte number and total bytes to display.
:e[*File*] or **E**[*File*]	Examines the specified file, provided you named it in the **more** command line.
[*K*]**:n** or [*K*]**N**	Examines either the next file (if you do not give a value for *K*) or the file *K* number of positions forward in the list of files you named in the **more** command line.
[*K*]**:p** or [*K*]**P**	Examines either the previous file (if you do not give a value for *K*) or the file *K* number of positions backward in the list of files you named in the **more** command line.
:t *Tagstring*	Displays the portion of the file that contains the specified tag. This subcommand works only on files containing tags created with the **ctags** command. The **:t** subcommand is the interactive version of the **-t** flag.
:q or **q** or **Q**	Exits the **more** command.
:!*command* or **!***command*	Starts the specified command in a new shell.
H	Toggles the search pattern highlighting feature on or off.

Exit Status

This command returns the following exit values:

Exit Status

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To view a file named `myfile`, enter:

```
more myfile
```

2. To view output from the **nroff** command, enter:

```
ls -l | more
```

3. To view each file starting at its last screen, enter:

```
more -p G file1 file2
```

4. To view each file with the 100th line at the current position, enter:

```
more -p 100 file1 file2
```

Typically, the current position in a **more** command display is the third line on the screen. In this example, the first line on the screen is the 98th line in the file.

5. To view each file starting with the first line that contains the `foo` string, enter:

```
more -p /foo file1 file2
```

The **more** command displays the line in the current position, the third line on the screen.

Files

Files

Item	Description
/usr/share/lib/terminfo	Indicates the terminal information database.

mosy Command

Purpose

Converts the ASN.1 definitions of Structure and Identification of Management Information (SMI) and Management Information Base (MIB) modules into objects definition files for the **snmpinfo** command.

Syntax

mosy -o *output_defs_file* [**-s**] *inputfile* ...

mosy -x *output_desc_file* [**-o** *output_defs_file*] [**-s**] *inputfile* ...

mosy -c *output_c_file* [**-x** *output_desc_file*] [**-o** *output_defs_file*] [**-s**] *inputfile* ...

Description

The **mosy** command reads in the ASN.1 definitions of SMI and MIB modules and produces objects definition files in specific formats. The resulting objects definition files are used by the **snmpinfo** command.

The *inputfile* parameter files are required to be in the **smi.my** or **mibII.my** format. Sample files are the **/usr/samples/snmpd/smi.my** and **/usr/samples/snmpd/mibII.my** files. See the **smi.my** and the **mibII.my** files for information on the required format of the file specified by the *inputfile* parameter.

The **mosy -o** command is used to create the objects definition file specified by the *output_defs_file* parameter for the **snmpinfo** command. This file is normally the **/etc/mib.defs** file.

The objects definition file can be created with one pass of the **mosy** compiler if the **smi.my** and **mibII.my** files are both specified as *inputfile* parameters. The **smi.my** file must precede the **mibII.my** file on the command line.

The **mosy -o** command can also be used to create subfiles. If subfiles are created separately from the SMI and MIB modules, you must concatenate the various subfiles before the **snmpinfo** command can successfully use the resultant **mib.defs** file. The SMI subfile must be at the top of the final objects definition file.

You can add objects definitions for experimental MIB modules or private-enterprise-specific MIB modules to the **/etc/mib.defs** file, but you must first obtain the private MIB module from the vendor that supports those MIB variables.

To update the **/etc/mib.defs** file to incorporate a vendor's private or experimental MIB objects definitions, create a subfile and then concatenate that subfile to the existing MIB II **/etc/mib.defs** file. See example 3.

Flags

Item	Description
-c *output_c_file*	Creates a C code file.
-o *output_defs_file*	Defines the path and file name of the MIB objects definition file for the **snmpinfo** command. There is no default path and file name for this flag. If this flag is not specified, the objects definition file is not created.
-s	Suppresses the conversion verification messages. If this flag is not specified, the conversion verification messages are printed to standard output.
-x *output_desc_file*	Creates a description file in **mib.desc** file format.

Parameters

Item	Description
inputfile	Defines the ASN.1 object definitions module for input to the **mosy** compiler. This file can be formatted according to either the **smi.my** or **mibll.my** file format.

Examples

1. To create an objects definition file for use by the **snmpinfo** command with one pass of the **mosy** command, enter:

   ```
   mosy -o /etc/mib.defs /usr/samples/snmpd/smi.my
   /usr/samples/snmpd/mibII.my
   ```

   In this example, **/usr/samples/snmpd/smi.my** and **/usr/samples/snmpd/mibII.my** are both specified as input files and the resultant objects definition file is the **/etc/mib.defs** file.

2. To create objects definition subfiles, enter:

   ```
   mosy -o /tmp/smi.obj /usr/samples/snmpd/smi.my
   mosy -o /tmp/mibII.obj /usr/samples/snmpd/mibII.my
   cat /tmp/smi.obj /tmp/mibII.obj > /etc/mib.defs
   ```

   In this example, the first command creates an SMI objects file, `/tmp/smi.obj`, from the **/usr/samples/snmpd/smi.my** file. The second command creates the MIB objects definition file, `/tmp/mibII.obj`, from the **/usr/samples/snmpd/mibII.my** file. The final command concatenates the subfiles, placing the SMI objects definition file first in the resultant **/etc/mib.defs** file.

3. To add private enterprise specific MIB objects definitions to an existing **/etc/mib.defs** file for use by the **snmpinfo** command, enter:

   ```
   mosy -o /tmp/private.obj /tmp/private.my
   cat /etc/mib.defs /tmp/private.obj > /tmp/mib.defs
   mv /tmp/mib.defs /etc/mib.defs
   ```

   In this example, the first command creates the `/tmp/private.obj` objects definition file. The second command concatenates the **/etc/mib.defs** MIB objects definition file with the `/tmp/private.obj` private MIB file and places the concatenated contents into the `/tmp/mib.defs` temporary MIB objects definition file. The final command moves the temporary file to the **/etc/mib.defs** file for use by the **snmpinfo** command.

4. To create a description file in **/tmp/smi.desc**, a C code file named **/tmp/smi.c**, and a Management Information Base (MIB) definition file named **/tmp/smi.defs**, enter:

```
mosy  -x /tmp/smi.desc -c /tmp/smi.c -o /tmp/smi.defs -s smi.my mibII.my
```

Files

Item	Description
/etc/mib.defs	Defines the Management Information Base (MIB) variables the SNMP agent should recognize and handle. The format of the **/etc/mib.defs** file is required by the **snmpinfo** command.
/usr/samples/snmpd/smi.my	Defines the ASN.1 definitions by which the SMI is defined as in RFC 1155.
/usr/samples/snmpd/mibII.my	Defines the ASN.1 definitions for the MIB II variables as defined in RFC 1213.

mount Command

Purpose

Makes a file system available for use.

Syntax

mount [**-f**] [**-n** *node*] [**-o** *options*] [**-p**] [**-r**] [**-v** *vfsname*] [**-F** *AltFSfile*] [**-t** *type* | [*device* | *node***:***directory*] *directory* | **all** | **-a**] [**-V** [*generic_options*] *special_mount_points*]

Description

The **mount** command instructs the operating system to make a file system available for use at a specified location (the mount point). In addition, you can use the **mount** command to build other file trees made up of directory and file mounts. The **mount** command mounts a file system expressed as a device using the *device* or *node***:***directory* parameter on the directory specified by the *directory* parameter. After the **mount** command has finished, the directory specified becomes the root directory of the newly mounted file system.

Only users with root authority or are members of the system group and have write access to the mount point can issue file or directory mounts. The file or directory may be a symbolic link. The **mount** command uses the real user ID, not the effective user ID, to determine if the user has appropriate access. System group members can issue device mounts, provided they have write access to the mount point and those mounts specified in the **/etc/file systems** file. Users with root user authority can issue any **mount** command.

Users can mount a device provided they belong to the system group and have appropriate access. When mounting a device, the **mount** command uses the *device* parameter as the name of the block device and the *directory* parameter as the directory on which to mount the file system.

If you enter the **mount** command without flags, the command displays the following information for the mounted file systems:

- the node (if the mount is remote)
- the object mounted
- the mount point
- the virtual-file-system type
- the time mounted

- any mount options

If you specify only the *directory* or *node*:*directory* parameter, the **mount** command takes it to be the name of the directory or file on which a file system, directory, or file is usually mounted (as defined in the **/etc/file systems** file). The **mount** command looks up the associated device, directory, or file and mounts it. This is the most convenient way of using the **mount** command, because it does not require you to remember what is normally mounted on a directory or file. You can also specify only the device. In this case, the command obtains the mount point from the **/etc/file systems** file.

The **/etc/file systems** file should include a stanza for each mountable file system, directory, or file. This stanza should specify at least the name of the file system and either the device on which it resides or the directory name. If the stanza includes a mount attribute, the **mount** command uses the associated values. It recognizes five values for the mount attributes: **automatic**, **true**, **false**, **removable**, and **readonly**.

The **mount all** command causes all file systems with the **mount=true** attribute to be mounted in their normal places. This command is typically used during system initialization, and the corresponding mount operations are referred to as automatic mount operations.

By default, the **mount** command runs the **wlmcntrl** command to refresh the current assignment rules in the kernel after mounting the file system. In some situations (such as when many file systems are mounted at once, or when a rule for an inaccessible remote mount is present in the workload manager configuration), calling **wlmcntrl** automatically after mount might be undesirable.

If you wish to override this behavior, set the environment variable *MOUNT_WLMCNTRL_SELFMANAGE* to any value. This will avoid calling the **wlmcntrl** command during the mount operation. You must manually run `wlmcntrl -u -d ""` to refresh the current assignment rules in the kernel. For more information, see **wlmcntrl** command.

Note:

1. If the **cdromd** CD and DVD **automount** daemon is enabled, those devices will be automatically mounted as specified in the **/etc/cdromd.conf** file. Use the **cdumount** or **cdeject** command to unmount an automatically mounted CD or DVD. Use **stopsrc -s cdromd** to disable the CD/DVD **automount** daemon.
2. For CacheFS, the remote file system that is to be cached locally must be exported such that the root ID of the local system is not remapped on the remote host to nobody (or the ID that the remote host uses as the anonymous user). For example, if host A were to export a file system **/F**, which would be mounted with CacheFS on host B, then the **/etc/exports** on host A would need to have an entry similar to:

   ```
   /F -rw,root=B
   or
   /F -ro,root=B
   ```

   depending on the mount options used for the local CacheFS mount.
3. Mounting a JFS file system on a read-only logical volume is not supported.
4. Mounting a JFS2 file system with EAv1 on Trusted AIX system converts the file system to EAv2.

Using mount on a JFS2 File System

The **mount** command can also be used to access a snapshot of a JFS2 file system as a directory tree. The snapshot on *device* is mounted read-only at *directory*. A snapshot can only be mounted once. When mounting a JFS2 file system with snapshots, the snapshots are activated.

You can use the System Management Interface Tool (SMIT) **smit mount** fast path to run this command.

Note: If the **mount** command encounters a Journaled File System (JFS) or Enhanced Journaled File System (JFS2) which was not unmounted before reboot, a replay of any JFS or JFS2 log records is attempted. In order to move a compatible JFS file system to a system running an earlier release of the operating system, the file system must always be unmounted cleanly prior to its movement. Failure to unmount first may result in an incompatible JFS log device. If the movement results in an unknown log device, the file system should be returned to the system running the latter operating system release, and **fsck** should be run on the file system.

Flags

Item	Description
-a	Mounts all file systems in the **/etc/file systems** file with stanzas that contain the **true** mount attribute.
all	Same as the **-a** flag.
-f	Requests a forced mount during system initialization to enable mounting over the root file system.
-F *AltFSfile*	Mounts on a file of an alternate file system, other than the **/etc/file systems** file.
-n *node*	Specifies the remote node that holds the directory to be mounted. The node can be specified as a colon-separated IPv6 address. If this is done with the `node:directory` format, the colon-separated IPv6 address must be enclosed in square brackets.
-p	Mounts a file system as a removable file system. While open files are on it, a removable mounted file system behaves the same as a normally mounted file system. However, when no files are open (and no process has a current directory on the file system), all of the file system disk buffers in the file system are written to the medium, and the operating system forgets the structure of the file system.
-r	Mounts a file system as a read-only file system, regardless of its previous specification in the **/etc/file systems** file or any previous command-line options.
-t *type*	Mounts all stanzas in the **/etc/file systems** file that contain the **type=***type* attribute and are not mounted. The *type* parameter specifies the name of the group.
-v *vfsname*	Specifies that the file system is defined by the *vfsname* parameter in the **/etc/vfs** file.

File System Specific Options

Item	Description
-o *options*	Specifies options. Options entered on the command line should be separated only by a comma. The following file system-specific options do not apply to all virtual file system types: **atime** Turns on access-time updates. If neither **atime** nor **noatime** is specified, **atime** is the default value. **bsy** Prevents the mount operation if the directory to be mounted over is the current working directory of a process. **cio** Specifies the file system to be mounted for concurrent readers and writers. I/O on files in this file system will behave as if they had been opened with **O_CIO** specified in the **open()** system call. Using this option will prevent access in any manner other than CIO. It is impossible to use cached I/O on a file system mounted with the cio option. This means that mapping commands such as `mmap()` and `shmat()` will fail with EINVAL when used on any file in a file system mounted with the `cio` option. One side-effect of this is that it is impossible to run binaries out of a `cio` mounted file system, since the loader may use `mmap()`. **Note:** When you mount the file system by using the `cio` option, all applications must manage the serialization of files. Quotas are not supported by the `cio` option because quotas have their own serialization code.

Item	Description
	dev Specifies that you can open devices from this mount. If neither **dev** nor **nodev** is specified, **dev** is the default value.
	dio Specifies that I/O on the file system will behave as if all the files had been opened with **O_DIRECT** specified in the **open()** system call. **Note:** Using the **-odio** or **-ocio** flags can help performance on certain workloads, but users should be aware that using these flags will prevent file caching for these file systems. Because readahead is disabled for these file systems, this may decrease performance for large sequential reads.
	fmode=*octal* Specifies the mode for a file and directory. The default is 755.
	gid=gid Specifies the GID that is assigned to files in the mount. The default is **bin**.
	log=*lvname* Specifies the full path name of the file system logging logical volume name where the following file-system operations are logged.
	log=*NULL* Turns off logging for JFS2 file systems. JFS2 depends on the log for metadata consistency, so if the system abnormally stops during JFS2 metadata operations, the file system cannot be recovered to a consistent state upon reboot. In these cases, the file system must be recreated.  **Attention:** Because of the risk of data loss, use this flag with caution.
	maxpout=*value* Specifies the pageout level for files on this file system at which threads should be slept. If **maxpout** is specified, **minpout** must also be specified. Value must be non-negative and greater than **minpout**. The default is the kernel **maxpout** level.
	minpout=*value* Specifies the pageout level for files on this file system at which threads should be readied. If **minpout** is specified, **maxpout** must also be specified. Value must be non-negative. The default is the kernel **minpout** level.
	noatime Turns off access-time updates. Using this option can improve performance on file systems where a large number of files are read frequently and seldom updated. If you use the option, the last access time for a file cannot be determined. If neither **atime** nor **noatime** is specified, **atime** is the default value.
	nocase Turns-off case mapping. This is useful for CDROMs using the ISO 9660:1998/HSG standard.
	nodev Specifies that you cannot open devices from this mount. This option returns a value of **ENXIO** if a failure occurs. If neither **dev** nor **nodev** is specified, **dev** is the default value.

Item	Description
	noguard Mount the filesystem regardless of the current mountguard setting which would otherwise guard the filesystem against unsupported concurrent mounts in a PowerHA or other clustering environment. If mountguard is enabled by the **chfs** or **crfs** command, the filesystem cannot be mounted if it appears to be mounted on another node or system. Specifying the noguard option temporarily overrides the mountguard setting.
	norbr Mounts the file system without the release-behind-when-reading capability. If none of the release-behind options are specified, **norbrw** is the default value.
	norbrw Mounts the file system without both the release-behind-when-reading and release-behind-when-writing capabilities. If none of the release-behind options are specified, **norbrw** is the default value.
	norbw Mounts the file system without the release-behind-when-writing capability. If none of the release-behind options are specified, **norbrw** is the default value.
	nosuid Specifies that execution of **setuid** and **setgid** programs by way of this mount is not allowed. This option returns a value of **EPERM** if a failure occurs. If neither **suid** nor **nosuid** is specified, **suid** is the default value.
	rbr Mount file system with the release-behind-when-reading capability. When sequential reading of a file in this file system is detected, the real memory pages used by the file will be released once the pages are copied to internal buffers. If none of the release-behind options are specified, **norbrw** is the default. **Note:** When **rbr** is specified, the **D_RB_READ** flag is ultimately set in the **_devflags** field in the **pdtentry** structure.
	rbw Mount file system with the release-behind-when-writing capability. When sequential writing of a file in this file system is detected, the real memory pages used by the file will be released once the pages written to disk. If none of the release-behind options are specified, **norbrw** is the default. **Note:** When **rbw** is specified, the **D_RB_WRITE** flag is set.
	rbrw Mount file system with both release-behind-when-reading and release-behind-when-writing capabilities. If none of the release-behind options are specified, **norbrw** is the default. **Note:** If **rbrw** is specified, both the **D_RB_READ** and the **D_RB_WRITE** flags are set.

Item	Description

remount

Changes the mount options of a mounted file system. For JFS2 file systems, you can specify the following mount options with the remount option to change the settings of a mounted file system. For any mount options not specified, no change is made to the current corresponding settings of the file system.

atime, **noatime**; **dev**, **nodev**; **maxpout**, **minpout**; **rbr**, **norbr**; **rbw**, **norbw**; **rbrw**, **norbrw**, **rw**, **ro**, **rox**; **suid**, **nosuid**.

Note:

1. External-snapshot mounted file systems cannot be remounted to read-write file systems.
2. You cannot use the **rw** and **ro** remount options on a file system that is managed by data management application programming interface (DMAPI).

For NFS, there are three types of mount requests.

duplicate mount

If the node, object, mount point, and the options that are specified in the **mount** command are the same as those for an existing mount, the **mount** command returns information about a successful mount, but a new mount is not created.

new mount

If the remount option is not specified, the **mount** command creates a new mount. If the node, object, mount point, or the constant options that are specified in the **mount** command are different than those for the existing mounts, the **mount** command fails if the remount option is specified.

remount

If the node, object, and mount point are the same as those for a top-most mount, but the remount options are different, the remount operation modifies the mount options of an existing mount. In this case, NFS performs the remount operation.

A top-most mount does not have another mount on top of it. For remount requests, the following options can be modified: **acdirmax**, **acdirmin**, **acregmax**, **acregmin**, **actimeo**, **fastattr**, **grpid**, **hard**, **intr**, **noac**, **nocto**, **nodev**, **nointr**, **nosuid**, **posix**, **retrans**, **ro**, **rsize**, **rw**, **secure**, **sec**, **soft**, **timeo**, **wsize**, **biods**, **extraattr**, **nodircache**, **prefer**, **otwattr**, **maxgroups**, and **proto**. Other options are classified as constant options.

ro

Specifies that the mounted file is read-only, regardless of its previous option specification in the **/etc/file systems** file or any previous command-line options. The default value is **rw**.

rw

Specifies that the mounted file is read/write accessible, regardless of its previous option specification in the **/etc/file systems** file or any previous command-line options. The default value is **rw**.

snapshot

Specifies the *device* to be mounted is a snapshot. The snapped file system for the specified snapshot must already be mounted or an error message will display.

Item	Description
	snapto=*snapshot* Specifies the location to start a snapshot with the value of *snapshot* when mounting the specified JFS2 file system. The *snapshot* parameter specifies the name of an internal snapshot if the *snapshot* parameter does not included a forward slash (/), that is, no path information.
	suid Specifies that execution of **setuid** and **setgid** programs by way of this mount is allowed. If neither **suid** nor **nosuid** is specified, **suid** is the default value.
	upcase Changes case mapping from default lowercase to uppercase. This is useful for CDROMs using the ISO 9660:1998/HSG standard.
	uid=uid Specifies the UID that is assigned to files in the mount, the default is bin.
	wrkgrp=workgroup Specifies the workgroup that the SMB server belongs.

NFS Specific Options

Item	Description
-o *options*	Specifies options. Options you enter on the command line should be separated only by a comma, not a comma and a space. The following NFS-specific options do not apply to all virtual file system types:
	acdirmax=*n* Holds cached attributes for no more than *n* seconds after directory update. The default is 60 seconds.
	acdirmin=*n* Holds cached attributes for at least *n* seconds after directory update. The default is 30 seconds.
	acl Requests using the Access Control List RPC program for this NFS mount. If the **acl** option is used, the ACL RPC program is used only if the NFS server provides it. The default is **noacl**.
	acregmax=*n* Holds cached attributes for no longer that *n* seconds after file modification. The default is 60 seconds.
	acregmin=*n* Holds cached attributes for at least *n* seconds after file modification. The default is 30 seconds.
	actimeo=*n* Sets minimum and maximum times for regular files and directories to *n* seconds. If this option is set, it overrides any settings for the **acregmin**, **acregmax**, **acdirmin**, and **acdirmax** options.
	bg Attempts mount in background if first attempt is unsuccessful. The default value is **fg**.

Item	Description

biods=*n*

Sets the maximum number of `biod` threads that perform asynchronous I/O RPC requests for an NFS mount. The maximum value that can be set is 128. Values greater than 128 are limited to 128 within the NFS client. The NFS client dynamically manages the number of running `biod` threads up to the maximum based on activity. The default maximums for the different NFS protocols are 7 for NFS version 2 and 32 for NFS version 3 and NFS version 4. These defaults are subject to change in future releases.

cio

Specifies the file system to be mounted for concurrent readers and writers. I/O on files in this file system will behave as if they had been opened with **O_CIO** specified in the **open()** system call. Using this option will prevent access in any manner other than CIO. It is impossible to use cached I/O on a file system mounted with the cio option. This means that mapping commands such as `mmap()` and `shmat()` will fail with EINVAL when used on any file in a file system mounted with the `cio` option. One side-effect of this is that it is impossible to run binaries out of a `cio` mounted file system, since the loader may use `mmap()`.

Note: When you mount the file system by using the `cio` option, all applications must manage the serialization of files. Quotas are not supported by the `cio` option because quotas have their own serialization code.

cior

Specifies to allow read-only files to open in the file system. I/O on files in this file system will behave as if they had been opened with **O_CIO | O_CIOR** specified in the **open()** system call. Using this option will prevent access in any manner other than **O_CIO | O_CIOR** and read-only. An attempt to open with **O_CIO** only will also fail. This option can only be used in conjunction with `cio`.

dio

Specifies that I/O on the file system will behave as if all the files had been opened with **O_DIRECT** specified in the **open()** system call.

Note: Using the **-odio** or **-ocio** flags can help performance on certain workloads, but users should be aware that using these flags will prevent file caching for these file systems. Because readahead is disabled for these file systems, this may decrease performance for large sequential reads.

fastattr

Bypasses the requirement that files currently being written will be sent to the server before the attributes of the file is read. This option is to be used with caution, since it will cause the client to assume that the file data that has not yet reached the server will be written without problem. In case of write errors, the client and server will have different opinions on what the size of the file really is. Likewise, a client will not be aware of attribute changes to the file being made by another client, so this option must not be used in environments where two clients are writing to the same files.

fg

Attempts mount in foreground if first attempt is unsuccessful. **fg** is the default value.

grpid

Directs any file or directory created on the file system to inherit the group ID of the parent directory.

Item	Description

hard
Retries a request until server responds. The option is the default value.

intr
Allows keyboard interrupts on hard mounts.

llock
Requests that files lock locally at the NFS client. NFS network file locking requests are not sent to the NFS server if the **llock** option is used.

maxgroups=*n*
Indicates that NFS RPC calls using **AUTH_UNIX** may include up to *n* member groups of information. Using this option to increase the number of member groups beyond the RPC protocol standard of 16 will only work against servers that support more than 16 member groups. Otherwise, the client will experience errors.

Values below 16 or greater than 64 will be ignored. By default, the protocol standard maximum of 16 is adhered to. AIX NFS servers will accept and process **AUTH_UNIX** credentials with up to 64 groups starting with AIX 5L Version 5.2 with the 5200-01 Recommended Maintenance package. The actual number of member groups sent by the NFS client is dependent on the number of groups the involved user is a member of, and may be limited by the length of the NFS client's hostname (which is included in the **AUTH_UNIX** information).

noac
Specifies that the **mount** command performs no attribute or directory caching. If you do not specify this option, the attributes (including permissions, size, and timestamps) for files and directories are cached to reduce the need to perform over-the-wire **NFSPROC_GETATTR** Remote Procedure Calls (RPCs). The **NFSPROC_GETATTR** RPC enables a client to prompt the server for file and directory attributes. The **acregmin**, **acregmax**, **acdirmin**, and **acdirmax** options control the length of time for which the cached values are retained.

noacl
Specifies not to use the Access Control List RPC program for this NFS mount request. The default is **noacl**.

nointr
Specifies no keyboard interrupts allowed on hard mounts.

port=*n*
Sets server Internet Protocol (IP) port number to n. The default value is the 2049.

posix
Requests that pathconf information be exchanged and made available on an NFS Version 2 mount. Requires a mount Version 2 **rpc.mountd** at the NFS server.

proto=[udp|tcp]
Specifies the transport protocol. The default is **tcp**. Use the **proto=[udp|tcp]** option to override the default.

proto=udp cannot be specified if **vers=4**.

Item	Description

retrans=*n*
Sets the number of NFS transmissions to *n*. The default value is 5. The `retrans` setting determines how many times the NFS client retransmits a given UDP RPC request to an NFS server for file system operations. The `retrans` setting is not used during communication with the NFS server `rpc.mountd` service when processing NFS version 2 and 3 mounts. Retries to `rpc.mountd` are controlled with the `retry mount` option.

retry=*n*
Sets the number of times the mount is attempted to *n*; the default value is 1000. When the retry value is 0, the system makes 10,000 attempts.

rsize=*n*
Sets the read buffer size to *n* bytes. Beginning with AIX Version 6.1, the default value is 64 KB and the maximum value is 512 KB when using Version 3 and Version 4 of the NFS protocol.

secure
Specifies that the **mount** command uses Data Encryption Standard (DES) for NFS transactions. Data Encryption Standard (DES) is not supported in NFS Version 4, use *krb5* instead.

sec=*flavor*[:*flavor*...]
Specifies a list of security methods that may be used to access files under the mount point. Allowable flavor values are:

sys
UNIX authentication. This is the default method.

dh
DES authentication. Data Encryption Standard (DES) is not supported in NFS Version 4, use *krb5* instead.

krb5
Kerberos. Authentication only.

krb5i
Kerberos. Authentication and integrity.

krb5p
Kerberos. Authentication, integrity, and privacy.

The **secure** option may be specified, but not in conjunction with a **sec** option. The **secure** option is deprecated and may be eliminated in a future release. Use **sec=dh** instead.

sec=[*flavor1:...:flavorn*]
The `sec` option specifies the security flavor list for the NFS mount. The available flavors are `des`, `unix`, `sys`, `krb5`, `krb5i`, and `krb5p`. This option only applies to AIX 5.3 or later.

shortdev
Specifies that you are mounting a file system from a host that does not support 32-bit device special files.

soft
Returns an error if the server does not respond. The default value is **hard**.

Item	Description
	timeo=*n* Sets the Network File System (NFS) time out period to *n* tenths of a second. For TCP mounts, the default timeout is 100, which equals 10 seconds. For UDP mounts, the default timeout is 11, which equals 1.1 seconds, but varies depending on the NFS operation taking place. For UDP mounts, the timeout will increase for each failed transmission, with a maximum value of 20 seconds. Each transmission will be attempted twice, after which the timeout value is updated. The `timeo` option does not apply to communication from the NFS client to the `rpc.mountd` service on NFS servers. A timeout of 30 seconds is used when making calls to `rpc.mountd`.
	vers=[2|3|4] Specifies NFS version. The default is the version of NFS protocol used between the client and server and is the highest one available on both systems. If the NFS server does not support NFS Version 3, the NFS mount will use NFS Version 2. Use the `vers=[2|3|4]` option to select the NFS version. By default, the NFS mount will never use NFS Version 4 unless specified. The `vers=4` only applies to AIX 5.3 or later.
	wsize=*n* Sets the write buffer size to *n* bytes. Beginning with AIX Version 6.1, the default value is 64 KB and the maximum value is 512 KB when using Version 3 and Version 4 of the NFS protocol.

CacheFS Specific Options

The CacheFS-specific version of the **mount** command mounts a cached file system; if necessary, it NFS-mounts its back file system. It also provides a number of CacheFS-specific options for controlling the caching process.

To mount a CacheFS file system, use the **mount** command with the **-V** flag followed by the argument. The following **mount** flags are available.

The following arguments to the **-o** flag are specifically for CacheFS mounts. Options you enter on the command line should be separated only by a comma, not a comma and a space.

Note: The **backfstype** argument must be specified.

Item	Description
-o	Specifies options.
	acdirmax=*n* Specifies that cached attributes are held for no more than *n* seconds after directory update. Before *n* seconds, CacheFS checks to see if the directory modification time on the back file system has changed. If it has, all information about the directory is purged from the cache and new data is retrieved from the back file system. The default value is 60 seconds.
	acdirmin=*n* Specifies that cached attributes are held for at least *n* seconds after directory update. After *n* seconds, CacheFS checks to see if the directory modification time on the back file system has changed. If it has, all information about the directory is purged from the cache and new data is retrieved from the back file system. The default value is 30 seconds.

Item	Description
	acregmax=*n*
	Specifies that cached attributes are held for no more than n seconds after file modification. After *n* seconds, all file information is purged from the cache. The default value is 30 seconds.
	acregmin=*n*
	Specifies that cached attributes are held for at least *n* seconds after file modification. After *n* seconds, CacheFS checks to see if the file modification time on the back file system has changed. If it has, all information about the file is purged from the cache and new data is retrieved from the back file system. The default value is 30 seconds.
	actimeo=*n*
	Sets **acregmin**, **acregmax**, **acdirmin**, and **acdirmax** to *n*.
	backfstype=*file_system_type*
	The file system type of the back file system (for example, nfs).
	backpath=*path*
	Specifies where the back file system is already mounted. If this argument is not supplied, CacheFS determines a mount point for the back file system.
	cachedir=*directory*
	The name of the cache directory.
	cacheid=*ID*
	ID is a string specifying a particular instance of a cache. If you do not specify a cache ID, CacheFS will construct one.
	demandconst
	Enables maximum cache consistency checking. By default, periodic consistency checking is enabled. When you enable **demandconst**, it checks on every read and write. **Note:** If this option is used the first time a specific CacheFS is mounted, then the option must also be specified for subsequent mounts. There is state information stored in the cache control files that enforces consistent use of this option.
	local_access
	Causes the front file system to interpret the mode bits used for access checking instead or having the back file system verify access permissions. Do not use this argument with secure NFS.
	noconst
	Disables cache consistency checking. By default, periodic consistency checking is enabled. Specify **noconst** only when you know that the back file system will not be modified. Trying to perform cache consistency check using **cfsadmin-s** will result in error. **demandconst** and **noconst** are mutually exclusive. **Note:** If this option is used the first time a specific CacheFS is mounted, then the option must also be specified for subsequent mounts. There is state information stored in the cache control files that enforces consistent use of this option.

Item	Description
	purge Purges any cached information for the specified file system. **Note:** If this option is used the first time a specific CacheFS is mounted, then the option must also be specified for subsequent mounts. There is state information stored in the cache control files that enforces consistent use of this option. **rw | ro** Read-write (default) or read-only. **suid | nosuid** Allows (default) or disallows set-uid execution **write-around | non-shared** Writes modes for CacheFS. The write-around mode (the default) handles writes the same as NFS does; that is, writes are made to the back file system, and the affected file is purged from the cache. You can use the non-shared mode when you are sure that no one else will be writing to the cached file system. **Note:** If this option is used the first time a specific CacheFS is mounted, then the option must also be specified for subsequent mounts. There is state information stored in the cache control files that enforces consistent use of this option. **mfsid** Turns on global view. In NFS v4 system, you can traverse through the exported namespace on the server side. You need to specify this option to go over the file system. **Restriction: mfsid** is an option if the backend file system for CacheFS is NFS v4.
-V	Mounts a CacheFS file system.

Server Message Block (SMB) client file system specific options

Item	Description
-o *options*	Specifies options for mounting the SMB client file system. Options that you enter on the command line must be separated only by a comma. Do not insert a space before or after a comma. The following options are available for the SMB client file system: **fmode** Sets a file or directory to octal mode for access permissions. The default value is 755. **uid** Assigns a user ID to files during the mount operation. The default value is `root`. **gid** Assigns a group ID to files during the mount operation. The default value is `system`. **wrkgrp** Specifies the workgroup to which the SMB server belongs. This parameter is mandatory to mount the SMB client file system. **port** Specifies the port number. The valid values are 445 and 139. The default value is 445. Port 139 is supported only when the specified server address is in IPv4 format. **Note:** `encryption` option is not supported when the port specified is 139. **pver** Specifies version of the SMB protocol that is used to communicate with the SMB server. The valid values are `2.1,3.0.2` and `auto`. For the value `auto`, the SMB protocol version `2.1` or version `3.0.2` is used based on the specified SMB server. **signing** Specifies whether the file system in the SMB client needs digital signature for communication with the SMB server filesystem. The valid values are `enabled` and `required`. When this parameter is set to `enabled`, the file system in the SMB client does not digitally sign the data packets unless the file system in the SMB server needs digital signatures for communication with the file system in the SMB server. When this is set to `required`, the file system in the SMB client must digitally sign the data packets for communication with the file system in the SMB server. If you do not specify the value for the `signing` parameter by using the **mount** command, a default value is used from the tunable parameter values of the kernel that are set by using the **smbctune** command. **secure_negotiate** Specifies whether the file system in the SMB client needs secure dialect negotiation capability. SMB Dialect 3.0.2 implements secure dialect negotiation to protect against security-downgrade attacks. The valid values are `desired`, `required`, and `disabled`. If you do not specify the value by using the **mount** command, a default value is used from tunable parameter values of the kernel that are set by using the **smbctune** command. **encryption** Specifies whether the file system in the SMB client requires data encryption. The valid values are `desired`, `required`, and `disabled`. If you do not specify the value by using the **mount** command, a default value is used from the tunable parameter values of the kernel that are set by using the **smbctune** command. **Note:** `encryption` option is not supported when the port specified is 139.

If the options that are used with the **mount** command (`pver, signing, secure_negotiate, or encryption`) are unspecified by using the **-o** flag, the default values for the **mount** command options are initialized by using the new values of the kernel tunable parameters (`smbc_protocol_version,`

`smbc_signing, smbc_secure_negotiate, smbc_encryption`). The kernel tunable parameters are initialized from tunable parameters defined in the `smbctune.conf` file. These parameters can also be modified by using the **smbctune** command.

The following table shows the kernel tunable parameters of the **mount** command and the corresponding kernel tunable parameters that can be set in the `smbctune.conf` file:

Options of the -o flag (mount command)	Corresponding kernel tunable parameter of the smbctune.con file	Valid values
pver	smbc_protocol_version	2.1, 3.0.2, auto
signing	smbc_signing	enabled, required
secure_negotiate	smbc_secure_negotiate	desired, required, disabled
encryption	smbc_encryption	desired, required, disabled

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To list the mounted file systems, enter the following command:

   ```
   mount
   ```

   This command produces output similar to the following:

   ```
   node   mounted          mounted over  vfs    date              options
   ----   -------          ------------ ---  ------------   -------------------
          /dev/hd0         /            jfs   Dec 17 08:04   rw, log  =/dev/hd8
          /dev/hd3         /tmp         jfs   Dec 17 08:04   rw, log  =/dev/hd8
          /dev/hd1         /home        jfs   Dec 17 08:06   rw, log  =/dev/hd8
          /dev/hd2         /usr         jfs   Dec 17 08:06   rw, log  =/dev/hd8
   sue    /home/local/src  /usr/code    nfs   Dec 17 08:06   ro, log  =/dev/hd8
   ```

   For each file system, the **mount** command lists the node name, the device name, the name under which it is mounted, the virtual-file-system type, the date and time it was mounted, and its options.

2. To mount all default file systems, enter the following command:

   ```
   mount all
   ```

   This command sequence mounts all standard file systems in the **/etc/file systems** file marked by the **mount=true** attribute.

3. To mount a remote directory, enter the following command:

   ```
   mount -n nodeA /home/tom.remote /home/tom.local
   ```

   This command sequence mounts the `/home/tom.remote` directory located on nodeA onto the local `/home/tom.local` directory. It assumes the default *VfsName* parameter=**remote**, which must be defined in the **/etc/vfs** file.

4. To mount a file or directory from the **/etc/file systems** file with a specific type, enter the following command:

   ```
   mount -t remote
   ```

This command sequence mounts all files or directories in the **/etc/file systems** file that have a stanza that contains the **type=remote** attribute.

5. To CacheFS-mount the file system which is already NFS-mounted on **/usr/abc**, enter the following command:

```
mount -V cachefs -o backfstype=nfs,backpath=/usr/abc,
cachedir=/cache1 server1:/user2 /xyz
```

The lines similar to the following appear in the **/etc/mnttab** file after the mount command is executed:

```
server1:/user2 /usr/abc nfs
/usr/abc /cache1/xyz cachefs backfstype=nfs
```

6. To mount a snapshot, enter the following command:

```
mount -o snapshot /dev/snapsb /home/janet/snapsb
```

This command mounts the snapshot contained on the **/dev/snapsb** device onto the **/home/janet/snapsb** directory.

7. To mount a file system and create a snapshot, enter the following command:

```
mount -o snapto=/dev/snapsb /dev/sb /home/janet/sb
```

This command mounts the file system contained on the **/dev/sb**device onto the **/home/janet/sb** directory and creates a snapshot for the file system on the **/dev/snapsb**device.

8. To access files on an SMB server as a local file system, enter the following command:

```
mount -v cifs -n pezman/user1/pass1 -o uid=201,fmode=750 /home /mnt
```

9. To mount an SMB client file system as a local mount point, enter the following command:

```
mount -v smbc -n llm140.xyz.com/cec102usr1/Passw0rd     \
-o wrkgrp=SMB_21.FVT,port=445,signing=required /some_share /mnt
```

Where, `llm140.xyz.com` is the Windows server, `cec102usr1` is the Kerberos user name, `Passw0rd` is the password of the Kerberos user, `SMB_21.FVT` is the workgroup, `some_share` is the share point on the Windows system, and `/mnt` is the local mount point.

10. To remount the mounted read-only JFS2 file system to a read-write file system, enter the following command:

```
mount –o remount,rw fsname
```

11. To mount all on a file **/tmp/fs1** of an alternate file system, enter the following command:

```
mount -F /tmp/fs1 all
```

Files

Item	Description
/etc/file systems	Lists the known file systems and defines their characteristics.
/etc/vfs	Contains descriptions of virtual-file-system types.

mountd Daemon

Purpose

Answers requests from clients for file system mounts.

Syntax

/usr/sbin/rpc.mountd [**-n**] [**-N**] [**-x**][**-r**]

Description

The **mountd** daemon is a Remote Procedure Call (RPC) that answers a client request to mount a file system. The **mountd** daemon finds out which file systems are available by reading the **/etc/xtab** file.

In addition, the **mountd** daemon provides a list of currently mounted file systems and the clients on which they are mounted. You can display this list by using the **showmount** command.

The **mountd** daemon listens for requests on the port specified in the **/etc/services** file for the service **mountd**. If the **/etc/services** file does not specify a port, one will be chosen when the daemon starts. For example, adding the lines:

```
mountd   6666/tcp
mountd   6666/udp
```

will cause **mountd** to listen for requests on port 6666.

Examples

The **mountd** daemon is started from the **/etc/rc.nfs** file. The **mountd** daemon can be started and stopped by the following System Resource Controller (SRC) commands:

```
startsrc -s rpc.mountd
stopsrc -s rpc.mountd
```

To change the parameters passed to the **mountd** daemon, use the **chssys** command. For example:

```
chssys -s rpc.mountd -a Argument
```

The change will not take effect until the daemon is restarted.

Flags

Item	Description
-n	Allows clients that use older versions of NFS to mount file systems. This option makes the system less secure. It is the default.
-N	Deny mount requests originating from non-privileged ports. This is the opposite of using the **-n** flag, and is not enabled by default.
-x	Allows mount request without reverse lookup check.
-r	Turn off the **/etc/rmtab** file updates.

Files

Item	Description
/etc/exports	Lists the directories that the server can export.
/etc/inetd.conf	Defines how the **inetd** daemon handles Internet service requests.
/etc/xtab	Lists currently exported directories.
/etc/services	Defines the sockets and protocols used for Internet services. Contains information about the known services used in the DARPA Internet network.

mpcstat Command

Purpose

Displays operational information about a Multi-Protocol Over ATM (MPOA) Client.

Syntax

mpcstat [**-a** **-c** **-e** **-i** **-m** **-r** **-s** **-t** **-v**] [Device_Name]

Description

This command displays Multi-Protocol Over ATM (MPOA) Client operational information gathered by a specified MPOA Client device. If a MPOA Client (MPC) device name is not entered, information for the available MPC appear. You can use the flags to narrow down your search to specify specific categories of information such as Configuration, Egress Cache Entries, Ingress Cache Entries, MPOA Servers, Shortcut Virtual Connections, and Statistics, or you can elect to have all of the information categories display.

You can also toggle debug tracing on or off and reset statistics counters.

Parameters

Item	Description
Device_Name	The name of the MPOA Client device name, for example, *mpc0*.

Flags

Item	Description
-a	Requests that all of the MPOA Client information appear. Note that this flag does not reset statistics counters or toggle trace. If a flag is not entered, the **-a** flag is the default flag.
-c	Requests the configuration
-e	Requests the egress (incoming) cache
-i	Requests the ingress (outgoing) cache.
-m	Requests the list of MPOA Servers in use.
-r	Resets the statistics counters after reading.
-s	Requests the statistics counters.
-t	Toggles full debug trace on or off.
-v	Requests the list of Shortcut Virtual Connections.

The following information appears for all valid calls and contains the following fields:

Device Name
Displays the device name of the MPOA Client.

MPC State
Displays the current state of the MPOA Client.

Example States:

```
Idle              Registering with the ELAN.
Initializing      Registering with the switch.
Operational       Fully operational.
Network Down      Network is currently unavailable.
```

MPC Address
Displays the MPOA Client's 20-byte ATM address for a specific ATM adapter port device name. The adapter port device name is also displayed.

Elapsed Time
Displays the real time period which has elapsed since statistics were last reset.

MPC Configuration
Selected with the **-a** or **-c** flags. Displays the network administrator's pre-configured attributes for the MPOA Client, or the values provided by a Lan Emulation Configuration Server (LECS).

MPC Egress Cache
Selected with the **-a** or **-e** flags. Displays the current egress cache entries. Included are the state of the entry, its Level-3 address, and ATM shortcut address, as well as additional descriptive values associated with each entry.

Example States

```
Active          Has active shortcut connection.
Purging         Purging the egress MPOA Server entry.
DP Purge        Purging the remote MPOA Client data plane.
Inactive        No current activity on shortcut connection.
```

MPC Ingress Cache:
Selected with the **-a** or **-i** flags. Displays the current ingress cache entries. Included are the state of the entry, its Level-3 address, and ATM shortcut address, as well as additional descriptive values associated with each entry.

Example States

```
Flow Detect     Waiting for packet threshold to enable shortcut.
Resolution      Packet threshold reached, resolving shortcut.
Hold Down       Shortcut resolution failed, waiting for retry.
Resolved        Shortcut resolution sequence complete.
```

MPOA Server List
Selected with the **-a** or **-m** flags. Displays a list of MPOA Servers currently known by this MPC. Included in each entry are the name of the LE Client that identified the MPS, the MPS ATM address, and the MPS LAN MAC address.

MPC Statistics
Selected with the **-a** or **-s** flags. Displays the current Transmit, Receive, and General statistics for this MPOA Client.

Shortcut Virtual Connection
Selected with the **-a** or **-v** flags. Displays the current list of shortcut virtual circuits in use by the MPOA client. Included are virtual path and channel values, VC state, ATM device name, as well as additional descriptive values associated with each entry.

Example States:

```
Idle            Call idle.
Signalling      Call placed but not established.
Operational     Call connected; data path valid.
Released        Call released.
Retry           Temporary call failure; will be retried.
Hold Down       Call failure; will be suspended for hold down period.
```

Exit Status

If an invalid *Device_Name* is specified, this command produces error messages stating that it could not connect to the device. Note that MPOA is a protocol extension to the ATM LAN Emulation protocol, and must have a corresponding and available LE Client to be operational. Examples of an invalid device error message are:

```
MPCSTAT: Device is not an MPOA device.
MPCSTAT: No LEC device with MPOA enabled.
MPCSTAT: Device is not available.
```

mpio_get_config Command

Purpose

Displays information about the DS3000 or the DS4000® subsystem that is based on multiple path I/O (MPIO) and the hdisks that are associated with the subsystem.

Syntax

mpio_get_config [**-v**] [**-a**] **-A** | **-l** *<hdisk#>* | **-?** | **-h**

Description

The **mpio_get_config** command displays information about the MPIO-based DS3000 or DS4000 subsystem and the hdisks that are associated with the subsystem.

Specifically, the command displays the information about the subsystem, including the assigned name of the subsystem, the worldwide name of the subsystem, and a list of hdisks in the **Available** state that are associated with the subsystem.

The following information about the hdisk# is displayed:

- hdisk name
- LUN number
- Current ownership
- Preferred path
- Adapter information
- User-assigned label for the volume

Flags

Item	Description
-A	Lists information for all attached subsystems.
-l	Lists information for the subsystem that includes the hdisk that is specified by the *hdisk#* parameter.
-v	Lists additional information about the controller and partition.
-a	Lists the adapter information.

Parameters

Item	Description
hdisk#	Specifies the hdisk name.

Examples

1. To display information about the subsystem that **hdisk11** is a member of, enter the following command:

```
mpio_get_config -l hdisk11
```

The system displays a message similar to the following message:

```
Storage Subsystem Name = 'Twister'

hdisk#           LUN #   Ownership          User Label
hdisk11              0   A (preferred)      1_disk_0
hdisk12              1   A (preferred)      1_disk_1
hdisk13              2   A (preferred)      1_disk_2
hdisk14              3   A (preferred)      1_disk_3
```

2. To display the information about the subsystem that **hdisk11** is a member of, along with the adapter information, enter the following command:

```
mpio_get_config -a -l hdisk11
```

The system displays a message similar to the following message:

```
Storage Subsystem Name = 'Twister'
hdisk#           LUN #   Ownership           Adapter  User Label
hdisk11              0   A (preferred)        fscsi0  1_disk_0
hdisk12              1   A (preferred)      Inactive  1_disk_1
hdisk13              2   A (preferred)      Inactive  1_disk_2
hdisk14              3   A (preferred)      Inactive  1_disk_3
```

3. To display information about all the attached subsystems, enter the following command:

```
mpio_get_config -A
```

The system displays a message similar to the following message:

```
Storage Subsystem worldwide name: 60ab80026982e000045f255d7
Storage Subsystem Name = 'Twister'

hdisk#           LUN #   Ownership          User Label
hdisk11              0   A (preferred)      1_disk_0
hdisk12              1   A (preferred)      1_disk_1
hdisk13              2   A (preferred)      1_disk_2
hdisk14              3   A (preferred)      1_disk_3
```

4. To display additional information about all the attached subsystems, enter the following command:

```
mpio_get_config -A -v
```

The system displays a message similar to the following message:

```
Frame id 0:
Storage Subsystem worldwide name: 60ab80026982e000045f255d7
Controller count: 2
Partition count: 1
Partition 0:
Storage Subsystem Name = 'Twister'
hdisk#           LUN #   Ownership          User Label
hdisk11              0   A (preferred)      1_disk_0
hdisk12              1   A (preferred)      1_disk_1
hdisk13              2   A (preferred)      1_disk_2
hdisk14              3   A (preferred)      1_disk_3
```

mpstat Command

Purpose

Collects and displays performance statistics for all logical processors in the system.

Syntax

`mpstat` [{ `-d` | `-i` | `-s` | `-a` | `-h` | `-v` | `-E` }] [`-w`][**`-O`** *Options*] [`-@` *wparname*] [*interval* [*count*]]

mpstat [**-X** [-o *filename*]] [interval[count]]

Restriction: The *wparname* parameter is restricted to use inside workload partitions.

Description

The `mpstat` command collects and displays performance statistics for all logical processors in the system. Users can define both, the number of times the statistics are displayed, and the interval at which the data is updated.

The *interval* parameter specifies the amount of time in seconds between each report. If you do not specify the *interval* parameter, the **mpstat** command generates a single report that contains statistics for the time since system startup and then exits. You can specify the *count* parameter only with the *interval* parameter. If you specify the *count* parameter, its value determines the number of reports that are generated and the number of seconds apart. If you specify the *interval* parameter without the *count* parameter, reports are continuously generated. Do not specify a value of zero to the *count* parameter.

The **mpstat** command with no options generates a single report that contains the performance statistics for all logical processors since boot time.

When the `mpstat` command is invoked, it displays two sections of statistics. The first section displays the System Configuration, which is displayed when the command starts and whenever there is a change in the system configuration. The second section displays the Utilization Statistics which are displayed in intervals and at any time the values of these metrics are deltas from previous interval.

The following information is displayed in the system configuration section:

lcpu
Indicates the number of online logical processors.

ent
Indicates the entitled processing capacity in processor units. This information is displayed only when the partition type is shared.

mode
Indicates whether the partition processor capacity is capped or uncapped allowing it to consume idle cycles from the shared pool. Dedicated LPAR is capped or donating.

rset
Indicates the resource-set type (regular or exclusive) that is associated with the WPAR. This information is displayed only when there is a resource set that is associated with the WPAR.

The performance statistics displayed by `mpstat` are listed below:

CPU
(All flags) Logical processor ID.

Note: The logical processor ID that is associated with the resource set of a WPAR is prefixed by an asterisk (*) when you run the **mpstat** command inside a WPAR with the **-s** or **-@** flag.

min
(Default, `-a` flag) Minor page faults (page faults with no IO).

maj
(Default, `-a` flag) Major page faults (page faults with disk IO).

mpcs
(`-a`, `-i` flag) Number of `mpc` send interrupts.

mpcr
(`-a`, `-i` flag) Number of `mpc` receive interrupts.

mpc
(Only default) Total number of inter-processor calls .

dev
(`-a`, `-i` flag) Number of device interrupts.

soft
(`-a`, `-i` flag) Number of software interrupts.

dec
(-a, -i flag) Number of decrementer interrupts.

ph
(-a, -i flag) Number of phantom interrupts.

int
(Only default) Total number of interrupts.

cs
(Default, -a flag) Total number of context switches.

ics
(Default, -a flag) Total number of involuntary context switches.

bound
(-a, -d flag) Total number of threads that are bound.

rq
(Default, -a, -d flag) Run queue size.

push
(-a, -d flag) Number of migrations due to starvation load balancing .

S3pull
(-a, -d flag) Number of migrations outside the scheduling affinity domain 3 due to idle stealing.

S3grd
(-a, -d flag) Number of dispatches from global runqueue, outside the scheduling affinity domain 3.

mig
(Only default) Total number of thread migrations (to another logical processor).

S0rd
(**-a**, **-d** flag) The percentage of thread redispatches within the same logical processor with scheduling affinity domain 0.

S1rd
(**-a**, **-d** flag) The percentage of thread redispatches within the same physical processor or core with scheduling affinity domain 1.

S2rd
(-a, -d flag) The percentage of thread redispatches within the same chip set, but not within the same processor core with scheduling affinity domain 2.

S3rd
(-a, -d flag) The percentage of thread redispatches within the same MCM (multiple chip module) , but not within the same chip set with scheduling affinity domain 3.

S4rd
(-a, -d flag) The percentage of thread redispatches on different MCMs within the same CEC or Plane with scheduling affinity domain 4.

S5rd
(-a, -d flag) The percentage of thread redispatches on a different CEC or Plane with scheduling affinity domain 5.

S3hrd
(-a, -d flag) The percentage of local thread dispatches on this logical processor.

S4hrd
(-a, -d flag) The percentage of near thread dispatches on this logical processor.

S5hrd
(-a, -d flag) The percentage of far thread dispatches on this logical processor.

lpa
(Only default) Logical processor affinity. The percentage of logical processor re-dispatches within the scheduling affinity domain 3.

sysc
(Default, -a flag) Number of system calls.

us
(Default, -a flag, -v flag) The percentage of physical processor utilization that occurred while executing at the user level (application).

If the -v flag is used, then utilization is based on the virtual processor.

sy
(Default, -a flag, -v flag) The percentage of physical processor utilization that occurred while executing at the system level (kernel).

If the -v flag is used, then utilization is based on the virtual processor.

wa
(Default, -a flag, -v flag) The percentage of time that the logical processor was idle during which it had an outstanding disk I/O request.

If the -v flag is used, then utilization is based on the virtual processor.

id
(Default, -a flag, -v flag) The percentage of time that the logical processor was idle and it did not have an outstanding disk I/O request.

If the -v flag is used, then utilization is based on the virtual processor.

pc
(Default, -a flag, -h flag, -v flag) The number or fraction of physical processor consumed. It is displayed in both a shared partition and a dedicated partition. For the default flag in the dedicated partition, it is not displayed when both donation and simultaneous multithreading are disabled.

The pc of the cpuid U row represents the number of unused physical processors.

%ec
(Default, -a flag) The percentage of entitled capacity consumed by the logical processor. The %ec of the ALL CPU row represents the percentage of entitled capacity consumed. Because the time base over which this data is computed can vary, the entitled capacity percentage can sometimes exceed 100%. This excess is noticeable only with small sampling intervals. The attribute is displayed only in a shared partition.

ilcs
(-a, -d, -h flag) Number of involuntary logical processor context switches, displayed only in shared partition. For the -h and -a flags, it is also displayed in dedicated partition.

vlcs
(-a, -d, -h flag) Number of voluntary logical processor context switches. Displayed only in shared partition. For the -h and -a flags, it is also displayed in dedicated partition.

lcs
(Default) Total number of logical processor context switches. Displayed only in shared partition or when a dedicated partition is donating.

%idon
(-a, -h flag) Shows the percentage of physical processor utilization that occurs while explicitly donating idle cycles. Displayed only in dedicated partition that is donating.

%bdon
(-a, -h flag) Shows the percentage of physical processor utilization that occurs while donating busy cycles. Displayed only in dedicated partition that is donating.

%istol
(-a, -h flag) Shows the percentage of physical processor utilization that occurs while the Hypervisor is stealing idle cycles. Displayed only in dedicated partition.

%bstol
(-a, -h flag) Shows the percentage of physical processor utilization that occurs while the Hypervisor is stealing busy cycles. Displayed only in dedicated partition.

%nsp
(-a, -d flag) Shows the current average processor speed as a percentage of nominal speed. Displayed only if the hardware uses Scaled Processor Utilization Resource Register (SPURR).

vcpu
(-v flag) Shows the virtual processor id.

lcpu
(-v flag) Shows the logical processor id.

pbusy
(-v, -E flag) Shows the percentage of physical time during which the physical processor is busy.

VTB
(-v flag) Shows the time taken for a virtual processor in milliseconds.

physc
(-E flag) Shows the number of physical processors that are used by the logical processor.

freq
(-E flag) Shows the operating frequency in GHz.

scaled physc
(-E flag) Shows the number of physical processors that are used by the logical processor based on SPURR.

The `mpstat` command displays all the above statistics for every logical processor in the partition. When running a shared partition, a special processor row with the `cpuid U` can be displayed when the entitled processing capacity has not entirely been consumed.

The `mpstat` command also displays a special processor row with the `cpuid ALL` which shows the partition-wide utilization. On that row, except for uncapped partitions with current physical processor consumption above their entitled capacity, the percentages are relative to the entitled processing capacity. For dedicated partitions, the entitled processing capacity is the number of physical processors. And for a WPAR , the processors present in the associated resource set, if any, are indicated by asterisks (*) only when the **-s** or **-@** flag is used.

When the `-s` flag is specified, the `mpstat` command reports simultaneous multithreading utilization, if it is enabled. This report displays the virtual processor engines utilization and utilization of each thread (logical processor) associated with the virtual processor engine.

If `mpstat` is running in a dedicated partition and simultaneous multithreading is enabled, then only the thread (logical processor) utilization is displayed.

If `mpstat` is running on an interval based mode, then it would be average value calculated per second.

Flags

Item	Description
`-a`	Displays all the statistics.
`-d`	Displays detailed affinity and migration statistics for AIX threads and dispatching statistics for logical processors.
`-i`	Displays detailed interrupts statistics.
`-s`	Displays simultaneous multithreading threads utilization, this flag is available only when `mpstat` runs in a simultaneous multithreading enabled partition.
`-h`	Displays pc and processor switches, with stolen and donation statistics for dedicated partitions.
`-w`	Displays wide column output, switches to wide output mode. Default is 80 column output mode.

Item	Description
@ *wparname*	Displays the statistics for the specified WPAR.
-O *Options*	Specifies the command option. **-O options=value...** Following are the supported options: • **sortcolumn** = Name of the metrics in the **mpstat** command output • **sortorder** = [asc|desc] • **topcount** = Number of CPUs to be displayed in the **mpstat** command sorted output
-X	Generates the XML output. The default file name is **mpstat_DDMMYYHHMM.xml** unless you specify a different file name by using with the **–o** option.
-o	Specifies the file name for the XML output.
`-v`	Displays utilization statistics at the virtual processor level. **Note:** The **-v** flag is available only for POWER8 processors, and later.
`-E`	Displays SPURR-based utilization metrics on a SPURR-capable processor.

Note:

1. The `-a`, `-d`, and `-i` flags implicitly turn on wide-column output.
2. Inside a WPAR, the **-@** flag reports statistics of all processors.
3. Processor statistics that are displayed inside a WPAR is always system wide.
4. Only **-o** option is allowed with **-X** option.

Parameters

Item	Description
interval	Specifies the interval between the iterations. If *interval* is not specified, just one snapshot of metrics is displayed which actually reports the values from the time system is up. If *interval* is specified, the tool waits for that duration before printing the first set of data. Each set of data is followed by a separation line, a line with average values for each columns (except the processor, which is replaced by ALL), followed by an empty line.
count	Specifies number of iterations. If *interval* is specified and *count* is not specified then `mpstat` runs infinitely. *count* can not be specified without specifying *interval*.

Examples

1. To see the default set of utilization metrics, enter the following command:

   ```
   mpstat 1 1
   ```

2. To see the default set of utilization metrics in wide display mode, enter the following command:

   ```
   mpstat –w 1 1
   ```

3. To see the detailed dispatch & affinity metrics, enter the following command:

   ```
    mpstat –d 1 1
   ```

4. To see the detailed interrupts report, enter the following command:

```
mpstat –i 1 1
```

5. To see all the statistics, enter the following command:

```
mpstat –a 1 1
```

6. To see simultaneous multithreading utilization, enter the following command:

```
mpstat –s 1 1
```

7. To see all the processor metrics of a WPAR, enter the following command:

```
mpstat -@ wparname
```

Note: To see all the processor metrics of a WPAR inside the WPAR, enter the following command:

```
mpstat -@
```

8. To see the sorted output for the column **cs**, enter the following command:

```
mpstat -d -O sortcolumn=cs
```

9. To see the list of the top 10 CPUs, enter the following command:

```
mpstat -a -O sortcolumn=min,sortorder=desc,topcount=10
```

10. To see metrics based on the virtual processor, enter the following command:

```
mpstat –v
```

Files

Item	Description
`/usr/bin/mpstat`	Contains the `mpstat` command.

mrouted Daemon

Purpose

Forwards a multicast datagram.

Syntax

/usr/sbin/mrouted [**-p**] [**-c** *Config_File*] [**-d** [*Debug_Level*]]

Description

The **mrouted** daemon is an implementation of the Distance Vector Multicast Routing Protocol (DVMRP), an earlier version of which is specified in RFC 1075. It maintains topological knowledge using a distance vector routing protocol (like RIP, described in RFC 1058), on which it implements a multicast datagram forwarding algorithm called Reverse Path Multicasting.

The **mrouted** daemon forwards a multicast datagram along a shortest (reverse) path tree rooted at the subnet on which the datagram originates. The multicast delivery tree may be thought of as a broadcast delivery tree that has been pruned back so that it does not extend beyond those subnetworks that have members of the destination group. Hence, datagrams are not forwarded along those branches that have no listeners of the multicast group. The IP time-to-live of a multicast datagram can be used to limit the range of multicast datagrams.

To support multicasting among subnets that are separated by (unicast) routers that do not support IP multicasting, the **mrouted** daemon includes support for tunnels, which are virtual point-to-point links between pairs of the **mrouted** daemons located anywhere in an Internet. IP multicast packets are encapsulated for transmission through tunnels, so that they look like typical unicast datagrams to intervening routers and subnets. The encapsulation is added on entry to a tunnel, and stripped off on exit from a tunnel. By default, the packets are encapsulated using the IP-in-IP protocol (IP protocol number 4). Older versions of the **mrouted** tunnel use IP source routing, which puts a heavy load on some types of routers. This version does not support IP source-route tunneling.

The tunneling mechanism allows the **mrouted** daemon to establish a virtual Internet, for the purpose of multicasting only, which is independent of the physical Internet and which may span multiple Autonomous Systems. This capability is intended for experimental support of Internet multicasting only, pending widespread support for multicast routing by the regular (unicast) routers. The **mrouted** daemon suffers from the well-known scaling problems of any distance-vector routing protocol and does not support hierarchical multicast routing.

The **mrouted** daemon automatically configures itself to forward on all multicast-capable interfaces (that is, interfaces that have the IFF_MULTICAST flag set, excluding the loopback interface), and it finds other **mrouted** daemons directly reachable using those interfaces.

The **mrouted** daemon does not initiate execution if it has fewer than two enabled virtual interfaces, where a virtual interface (Vif) is either a physical multicast-capable interface or a tunnel. It logs a warning if all of its virtual interfaces are tunnels; such an **mrouted** daemon's configuration would be better replaced by more direct tunnels.

The **mrouted** daemon handles multicast routing only; there might be unicast-routing software running on the same machine as the **mrouted** daemon. With the use of tunnels, it is unnecessary for the **mrouted** daemon to have access to more than one physical subnet to perform multicast forwarding.

Flags

Item	Description
-c *Config_File*	Starts the **mrouted** command using an alternate configuration file specified by the *Config_File* variable. There are five types of configuration entries: **phyint** local-addr **[disable]** [metric m] **[threshold** t] **[rate_limit** b] **[boundary (**boundary-name**|**scoped-addr**/**mask-len**)] [altnet** network**/**mask-len**]** **tunnel** *local-addr remote-addr* [**metric** *m*] [**threshold** *t*] [**rate_limit** *b*] [**boundary** (*boundary-name* | *scoped-addr* / *mask-len*)] **cache_lifetime** *ct* **pruning** *off* | *on* **name** *boundary-name scoped-addr* / *mask-len*
-d	Sets the debug level. If no **-d** option is given, or if the debug level is specified as 0, the **mrouted** daemon detaches from the invoking terminal. Otherwise, it remains attached to the invoking terminal and responsive to signals from that terminal. If **-d** is given with no argument, the debug level defaults to 2. Regardless of the debug level, the **mrouted** daemon always writes warning and error messages to the system log demon. Non-zero debug levels have the following effects: **level 1** All syslog'ed messages are also printed to **stderr**. **level 2** All level 1 messages plus notifications of significant events are printed to **stderr**. **level 3** All level 2 messages plus notifications of all packet arrivals and departures are printed to **stderr**. Upon startup, the **mrouted** daemon writes its pid to the file **/etc/mrouted.pid**.
-p	Turns off pruning. Default is pruning enabled.

Signals

The following signals can be sent to the **mrouted** daemon:

Item	Description
HUP	Restarts the **mrouted** daemon. The configuration file is reread every time this signal is evoked.
INT	Terminates execution gracefully (that is, by sending good-bye messages to all neighboring routers).
TERM	Same as **INT**.
USR1	Dumps the internal routing tables to **/usr/tmp/mrouted.dump**.
USR2	Dumps the internal cache tables to **/usr/tmp/mrouted.cache**.
QUIT	Dumps the internal routing tables to **stderr** (if the **mrouted** daemon was invoked with a nonzero debug level).

For convenience in sending signals, the **mrouted** daemon writes its pid to **/etc/mrouted.pid** on startup.

Examples

1. To display routing table information, type:

```
kill -USR1 *cat /etc/mrouted.pid*
```

This produces the following output:

```
Virtual Interface Table
 Vif Local-Address                    Metric   Thresh   Flags
  0  36.2.0.8     subnet: 36.2           1        1     querier
                  groups: 224.0.2.1
                          224.0.0.4
                pkts in: 3456
               pkts out: 2322323

  1  36.11.0.1    subnet: 36.11          1        1     querier
                  groups: 224.0.2.1
                          224.0.1.0
                          224.0.0.4
                pkts in: 345
               pkts out: 3456

  2  36.2.0.8      tunnel: 36.8.0.77       3        1
                  peers: 36.8.0.77 (2.2)
             boundaries: 239.0.1
                       : 239.1.2
                pkts in: 34545433
               pkts out: 234342

  3  36.2.0.8     tunnel: 36.6.8.23       3        16

Multicast Routing Table (1136 entries)
 Origin-Subnet    From-Gateway         Metric Tmr In-Vif Out-Vifs
 36.2                                 1    45  0     1* 2 3*
 36.8             36.8.0.77            4    15  2     0* 1* 3*
 36.11                                1    20  1     0* 2 3*
 .
 .
 .
```

In this example, there are four virtual interfaces connecting to two subnets and two tunnels. The Vif 3 tunnel is not in use (no peer address). The Vif 0 and Vif 1 subnets have some groups present; tunnels never have any groups. This instance of the **mrouted** daemon is the one responsible for sending periodic group membership queries on the Vif 0 and Vif 1 subnets, as indicated by the **querier** flags. The list of boundaries indicate the scoped addresses on that interface. A count of the no. of incoming and outgoing packets is also shown at each interface.

Associated with each subnet from which a multicast datagram can originate is the address of the previous hop router (unless the subnet is directly connected), the metric of the path back to the origin,

the amount of time since an update for this subnet was last received, the incoming virtual interface for multicasts from that origin, and a list of outgoing virtual interfaces. The * (asterisk) means that the outgoing virtual interface is connected to a leaf of the broadcast tree rooted at the origin, and a multicast datagram from that origin will be forwarded on that outgoing virtual interface only if there are members of the destination group on that leaf.

The **mrouted** daemon also maintains a copy of the kernel forwarding cache table. Entries are created and deleted by the **mrouted** daemon.

2. To display cache table information, type:

```
kill -USR2 *cat /etc/mrouted.pid*
```

This produces the following output:

```
Multicast Routing Cache Table (147 entries)
 Origin          Mcast-group      CTmr   Age  Ptmr  IVif  Forwvifs
 13.2.116/22     224.2.127.255      3m    2m    -    0     1
 >13.2.116.19
 >13.2.116.196
 138.96.48/21    224.2.127.255      5m    2m    -    0     1
 >138.96.48.108
 128.9.160/20    224.2.127.255      3m    2m    -    0     1
 >128.9.160.45
 198.106.194/24 224.2.135.190       9m    28s   9m    0P
 >198.106.194.22
```

Each entry is characterized by the origin subnet number and mask and the destination multicast group. The **CTmr** field indicates the lifetime of the entry. The entry is deleted from the cache table when the timer decrements to zero. The Age field is the time since this cache entry was originally created. Because cache entries get refreshed if traffic is flowing, routing entries can grow very old. The **Ptmr** field is a hyphen if no prune was sent upstream or the amount of time until the upstream prune will time out. The **Ivif** field indicates the incoming virtual interface for multicast packets from that origin. Each router also maintains a record of the number of prunes received from neighboring routers for a particular source and group. If there are no members of a multicast group on any downward link of the multicast tree for a subnet, a prune message is sent to the upstream router. They are indicated by a P after the virtual interface number. The **Forwvifs** field shows the interfaces along which datagrams belonging to the source group are forwarded. A p indicates that no datagrams are being forwarded along that interface. An unlisted interface is a leaf subnet with are no members of the particular group on that subnet. A b on an interface indicates that it is a boundary interface, that is, traffic will not be forwarded on the scoped address on that interface. An additional line with a > (greater-than sign) as the first character is printed for each source on the subnet. There can be many sources in one subnet.

Files

Item	Description
/etc/mrouted.conf	Contains the configuration information for the **mrouted** daemon.
/usr/tmp/mrouted.dump	Contains the internal routing tables for the **mrouted** daemon.
/etc/mrouted.pid	Contains the process ID for the **mrouted** daemon.
/usr/tmp/mrouted.cache	Contains the internal cache tables for the **mrouted** daemon.

msgchk Command

Purpose

Checks for messages.

Syntax

msgchk [*User* ...]

Description

The **msgchk** command checks mail drops for messages. The **msgchk** command reports whether the mail drop for the specified user contains messages and indicates if the user has already seen these messages. By default, the **msgchk** command checks the mail drop for the current user.

Flags

Item	Description
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For the Message Handler (MH), the name of this flag must be fully spelled out.

Examples

1. To check to see if you have any new messages, enter:

   ```
   msgchk
   ```

   If you have new messages, the system responds with a message similar to the following:

   ```
   You have new Internet mail waiting
   ```

   If you have no messages, the system responds with a message similar to the following:

   ```
   You don't have any mail waiting
   ```

2. To check to see if user `karen` on your local system has any new messages, enter:

   ```
   msgchk karen
   ```

   In this example, if user `karen` on your local system has new messages, the system responds with a message similar to the following:

   ```
   karen has new Internet mail waiting
   ```

   If user `karen` on your local system has no messages, the system responds with a message similar to the following:

   ```
   karen doesn't have any mail waiting
   ```

Files

Item	Description
$HOME/.mh_profile	Contains the user's MH profile.
/etc/mh/mtstailor	Contains the MH tailor file.
/var/spool/Mail/$USER	Defines the location of the mail drop.
/usr/bin/msgchk	Contains the **msgchk** command.

msh Command

Purpose

Creates a Message Handler (MH) shell.

Syntax

msh [*File*] [**-prompt** *String*] [**-notopcur** | **-topcur**]

Description

The **msh** command creates an MH shell for use with messages that are packed in a file. By default, this command looks for the **msgbox** file in the current directory. Within the MH shell, you can use the following MH commands:

```
ali             burst           comp        dist
folder          forw            inc         mark
mhmail          msgchk          next        packf
pick            prev            refile      repl
rmm             scan            send        show
sortm           whatnow         whom
```

These commands operate with limited functionality in the MH shell. To see how a command operates in the MH shell, enter the command name followed by the **-help** flag. Entering `help` or a `?` (question mark) displays a list of the MH commands you can use.

To leave the **msh** shell, press the Ctrl-D key sequence or enter `quit`.

Flags

Item	Description
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For MH, the name of this flag must be fully spelled out.
-notopcur	Makes the current message track the center line of the **vmh** scan window when the **msh** command is started using the **vmh** command. This flag is the default.
-prompt *String*	Prompts for the **msh** commands with the specified string.
-topcur	Makes the current message track the top line of the **vmh** scan window when the **msh** command is started using the **vmh** command.

Profile Entries

The following entries are found in the *UserMhDirectory***/.mh_profile** file:

Item	Description
`fileproc:`	Specifies the program used to refile messages.
`Msg-Protect:`	Sets the protection level for your new message files.
`Path:`	Specifies the user's MH directory.
`showproc:`	Specifies the program used to show messages.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To start an **msh** shell, enter:

   ```
   msh
   ```

   If the **msgbox** file exists in the current directory, the system responds with a message similar to the following:

   ```
   Reading ./msgbox, currently at message 1 of 10
   ```

   Then, the system prompt appears as follows:

   ```
   (msh)
   ```

   In this example, the current message is message 1 in the `msgbox` file. You can now enter a modified subset of MH commands.
2. To start an **msh** shell to manipulate the messages stored in the `meetings` file, enter:

   ```
   msh meetings
   ```

Files

Item	Description
$HOME/.mh_profile	Specifies the user's MH profile.
/etc/mh/mtstailor	Contains the MH tailor file.
/usr/bin/msh	Contains the **msh** command.

mt Command (BSD)

Purpose

Gives subcommands to streaming tape device.

Syntax

mt [**-f** *TapeName*] *Subcommand* [*Count*]

Description

The **mt** command gives subcommands to a streaming tape device. If you do not specify the **-f** flag with the *TapeName* parameter, the **TAPE** environment variable is used. If the environment variable does not exist, the **mt** command uses the **/dev/rmt0.1** device. The *TapeName* parameter must be a raw (not block) tape device. You can specify more than one operation with the *Count* parameter.

Subcommands

Item	Description
eof, weof	Writes the number of end-of-file markers specified by the *Count* parameter at the current position on the tape.
fsf	Moves the tape forward the number of files specified by the *Count* parameter and positions it to the beginning of the next file.

Item	Description
bsf	Moves the tape backwards the number of files specified by the *Count* parameter and positions it to the beginning of the last file skipped. If using the bsf subcommand would cause the tape head to move back past the beginning of the tape, then the tape will be rewound, and the **mt** command will return **EIO**.
fsr	Moves the tape forward the number of records specified by the *Count* parameter.
bsr	Moves the tape backwards the number of records specified by the *Count* parameter.
rewoff1, rewind	Rewinds the tape. The *Count* parameter is ignored.
status	Prints status information about the specified tape device. The output of the status command may change in future implementations.

Flag

Item	Description
-f *TapeName*	Specifies the *TapeName* parameter.

Examples

1. To rewind the `rmt1` tape device, enter:

```
mt -f /dev/rmt1 rewind
```

2. To move forward two files on the default tape device, enter:

```
mt fsf 2
```

3. To write two end-of-file markers on the tape in the `/dev/rmt0.6` file, enter:

```
mt -f /dev/rmt0.6 weof 2
```

Exit Status

Item	Description
0	Indicates a successful completion.
>0	Indicates an error occurred.

Files

Item	Description
/dev/rmt/*n***.***n*	Specifies the raw streaming tape interface.
/usr/bin/mt	Contains the **mt** command file.

mtrace Command

Purpose

Prints a multicast path from a source to a receiver.

Syntax

mtrace [**-l**] [**-M**] [**-n**] [**-p**] [**-s**] [**-U**] [**-g** *gateway*] [**-i** *if_addr*] [**-m** *max_hops*] [**-q** *nqueries*] [**-r** *resp_dest*] [**-S** *statint*] [**-t** *ttl*] [**-w** *wait*] *source* [*receiver*] [*group*]

Description

A trace query is passed hop-by-hop along the path from the receiver to the source, collecting hop addresses, packet counts, and routing error conditions along the path, and then the response is returned to the requestor. The default receiver is the host running the **mtrace** command, and the default group is 0.0.0.0.

Note: The **mtrace** command is intended for use in network testing, measurement, and management. Because the **mtrace** command heavily loads on the network, avoid using the **mtrace** command during typical operations or from automated scripts. It should be used primarily or with manual fault isolation. If the **-g** flag is specified, the source defaults to the host running **mtrace** and the receiver defaults to the router being addressed.

By default, the **mtrace** command first attempts to trace the full reverse path, unless the number of hops to trace is explicitly set with the **-m** flag. If there is no response within a 3-second timeout interval (changed with the **-w** flag), an * (asterisk) is printed and the probing switches to hop-by-hop mode. Trace queries are issued starting with a maximum hop count of one and increasing by one until the full path is traced or no response is received. At each hop, multiple probes are sent (default is three, changed with **-q** flag). The first half of the attempts (default is two) are made with the reply address set to standard multicast address, mtrace.mcast.net (224.0.1.32) with the *ttl* set to 32 more than what is needed to pass the thresholds seen so far along the path to the receiver. For each additional attempt, the *ttl* is increased by another 32 each time up to a maximum of 192. Because the desired router may not be able to send a multicast reply, the remainder of the attempts request that the response be sent via unicast to the host running the **mtrace** command.

Alternatively, the multicast *ttl* can be set explicitly with the **-t** flag, the initial multicast attempts can be forced to use unicast instead with the **-U** flag, the final unicast attempts can be forced to use multicast instead with the **-M** flag, or if you specify **-UM**, the **mtrace** command will first attempt using unicast and then multicast. For each attempt, if no response is received within the timeout, an * (asterisk) is printed. After the specified number of attempts have failed, the **mtrace** command will try to query the next hop router with a **DVMRP_ASK_NEIGHBORS2** request to see what kind of router it is. The **mtrace** command will try to query three (changed with the **-e** flag) hops past a non-responding router. Even though the **mtrace** command is incapable of sending a response, it might be capable of forwarding the request.

Flags

Item	Description
-g *gateway*	Sends the trace query via unicast directly to the multicast router *gateway* rather than multicasting the query. This must be the last-hop router on the path from the intended source to the receiver.
-i *if_addr*	Uses *if_addr* as the local interface address (on a multi-homed host) for sending the trace query and as the default for the receiver and the response destination.
-l	Loops indefinitely printing packet rate and loss statistics for the multicast path every 10 seconds (see -S *stat_int*).
-m *max_hops*	Sets *max_hops* to the maximum number of hops that will be traced from the receiver to the source. The default is 32 hops and infinity for the DVMRP routing protocol).

Item	Description
-M	Always requests the response using multicast rather than attempting unicast for the last half of the tries.
-n	Prints hop addresses numerically rather than symbolically and numerically (saves a name server address-to-name lookup for each router found on the path).
-p	Listens passively for multicast responses from traces initiated by others. This works best when run on a multicast router.
-q *nqueries*	Sets the maximum number of query attempts for any hop to *nqueries*. The default is 3.
-r *resp_dest*	Sends the trace response to dhost rather than to the host on which the **mtrace** command is being run, or to a multicast address other than the one registered for this purpose (224.0.1.32).
-s	Prints a short form output including only the multicast path and not the packet rate and loss statistics.
-S *statint*	Changes the interval between statistics gathering traces to *statint* seconds (default 10 seconds).
-t *ttl*	Sets the *ttl* (time-to-live, or number of hops) for multicast trace queries and responses. The default is 127, except for local queries to the `all routers` multicast group that use the *ttl* of 1.
-U	Forces initial multicast attempts to use unicast instead.
-w *wait*	Sets the time to wait for a trace response to*wait* seconds (default 3 seconds).

Parameters

Item	Description
source	Specifies the host for which the multicast path from a particular receiver is sought. This is a required parameter.
receiver	Specifies the host from which the multicast path is sought for a particular source. Default is the host in which the **mtrace** command is running. This is an optional parameter.
group	Specifies the multicast group. This is an optional parameter.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

In the following example, the two machines, 10.27.41.57 and 10.27.40.20, are on two different subnets separated by a router having two interfaces, 10.27.40.11 and 10.27.41.11. To find the multicast path from 10.27.40.20 to 10.27.41.57, type the following:

```
# mtrace 10.27.41.57 224.2.0.1
```

The following is displayed:

```
Mtrace from 10.27.41.57 to 10.27.40.20 via group 224.2.0.1
Querying full reverse path...
  0  ? (10.27.40.20)

multibos Command

Purpose

Creates, updates, and manages multiple versions of the Base Operating System (BOS) on a `rootvg`.

Syntax

`multibos -s` [`-l` *device* {`-a` | `-f` *file* | `-b` *file* | **-x** *file*}] [`-e` *file*] [`-i` *file*] [`-L` *file*] [`-pntNX`]

`multibos -c -l` *device* {`-a` | `-f` *file* | `-b` *file* | **-x** *file*} [`-pnNX`]

`multibos -m` [`-pnX`]

`multibos -u` [`-pnX`]

`multibos -B` [`-ntX`]

`multibos -S` [`-nX`]

`multibos -R` [`-ptX`]

`multibos -C` [*VG name*]

`multibos` **-s** `-M` *file* [`-pntNX`]

Description

The `multibos` command allows the root user to create an instance of the Base Operating System (BOS) in the `rootvg` volume group.

Note: You cannot use the `multibos` command with a mirrored `rootvg` volume group.

The `multibos` setup operation creates a standby Base Operating System (BOS) that boots from a distinct boot logical volume (BLV). This creates two bootable sets of BOS on a given `rootvg`. The administrator can boot from either instance of BOS by specifying the respective BLV as an argument to the `bootlist` command or using system firmware boot operations. Two bootable instances of BOS can be simultaneously maintained. The instance of BOS associated with the booted BLV is referred to as the *active* BOS. The instance of BOS associated with the BLV that has not been booted is referred to as the *standby* BOS. Currently, only two instances of BOS are supported per `rootvg`.

The `multibos` command allows the administrator to access, install maintenance and technology levels for, update, and customize the standby BOS either during setup or in subsequent customization operations. Installing maintenance and technology updates to the standby BOS does not change system files on the active BOS. This allows for concurrent update of the standby BOS, while the active BOS remains in production.

In addition, the `multibos` command copies or shares logical volumes and file systems. By default, the BOS file systems (currently `/`, `/usr`, `/var`, and `/opt`,) and the boot logical volume are copied. The administrator can make copies of additional BOS objects (using the `-L` flag).

All other file systems and logical volumes are shared between instances of BOS. Separate log device logical volumes (for example, those that are not contained within the file system) are not supported for copy and are shared.

In AIX 5L Version 5.3 with the 5300-09 Technology Level, you can populate the standby instance with a later version such as AIX Version 6.1 with the 6100-02 Technology Level. The function is done by creating a **mksysb** backup of a system at a later version and then using the backup to populate the standby instance. For example, system A is at a level of 5.3.9.0 and system B is at a level of 6.1.2.0. You can create a backup of system B using the `mksysb -M` command and use the **mksysb** backup to populate a standby instance of the operating system on system A.

Notes:

1. While the **multibos** command is running, ensure that system activity is minimal.
2. Any logical volume or file system attributes that are new to the higher level are not implemented when the standby instance is created because the operating system at a lower level has no knowledge of the attributes.
3. Do not keep both an AIX 6.1 instance and an AIX 5.3 instance for an extended period. You might not be able to switch between the instances because of incompatibilities. Commit to one of the instances and remove the other.
4. If your operating system is running with the logical volumes in the active BOS that have the multibos-created `bos_hd*` names, and no standby BOS in the `rootvg` directory, then a preservation or migration type of installation can occur starting with AIX 7200-00. The logical volumes that have the `bos_hd*` names on the system are `bos_hd5`, `bos_hd4`, `bos_hd2`, `bos_hd9var`, and `bos_hd10opt`. The operating system must not have `hd5`, `hd4`, `hd2`, `hd9var`, or `hd10opt` logical volumes. If you created the multibos instance from an `mksysb` image, which was created by using the **mksysb** command with the **-M** flag, the `hd8` logical volume might also have been renamed to `bos_hd8`. You can check this prerequisite with the **lsvg -l rootvg** command. Always back up your system before migrating. Also, copy the `/usr/lpp/bos/pre_migration` file from the media or your network installation manager (NIM) spot of the level to which you are migrating, to the target system and execute the file on the target system to check for any migration warnings.

   Before you perform a migration or a preservation type of operating system installation in this environment, verify that the disk control block has a valid level for your `rootvg`. You can run the **/usr/lpp/bosinst/blvset -d /dev/hdiskN -g level** command, where `hdiskN` is the disk that contains the `bos_hd5` logical volume. If this command returns `0.0` or an unexpected level, run the **bosboot -ad /dev/ipldevice** command to correct it, and rerun the **blvset** command to verify. It must return `6.1` or `7.1`.
5. In addition to the flags mentioned in the syntax section, the **-V** flag performs the verify operation from the inittab during boot. It is important that you do not modify this entry. The verify operation enables the **multibos** utility to synchronize changes in logical volumes and file systems between the active and standby instances. This entry also synchronizes the ODM and devices on initial boot after a **mksysb** restore. Without this operation, both the active and standby instances could become inconsistent with normal file system and logical volume operations.

The file system types (JFS or JFS2) of the **mksysb** backup need to be the same as that of the system where the **multibos** command is to be run. For example, if the **/usr** file system is a JFS2 file system, the **/usr** file system on the **mksysb** backup needs to be a JFS2 file system.

A log is stored in the **/etc/multibos/logs/op.alog** file after you run the **multibos** command. You can view the log file using the **alog -f /etc/multibos/logs/op.alog -o** command.

Note: You can create a backup that contains both instances by first mounting the standby instance (using the `-m` flag), and then creating the backup. However, you can restore the backup onto a disk only by using the **alt_disk_mksysb** command.

Restrictions

- The `multibos` command is supported on AIX 5L Version 5.3 with the 5300-03 Recommended Maintenance package and later.

- The current `rootvg` must have enough space for each BOS object copy. BOS object copies are placed on the same disk or disks as the original.
- The total number of copied logical volumes cannot exceed 128. The total number of copied logical volumes and shared logical volumes are subject to volume group limits.
- Using the **multibos** command in a mirrored `rootvg` volume group is not supported. You can remove the mirror of the `rootvg` volume group by running the **unmirrorvg** command. You can run the **alt_disk_copy** command to have a copy of the `rootvg` volume group that can be upgraded as needed. When you have the required instance of AIX, remove the volume group no longer needed by using the `alt_rootvg_op` operation, and re-mirror the `rootvg` volume group.

Flags

Item	Description
`-a`	Specifies the `update_all` install option. Valid with setup and customization operation.
`-B`	Build boot image operation. The standby boot image is created and written to the standby BLV using the AIX `bosboot` command.
`-b` *file*	Specifies the install bundle to be installed during the setup or customization operation. The install bundle syntax should follow `geninstall` conventions.
`-c`	Performs a customized update of the software in standby BOS.
`-C` *VG name*	Allows you to vary on volume groups for syncing when it is appropriate, as the auto varied off volume groups are not varied on during the reboot, like the rootvg volume group, in order to be synced. The `multibos -C` *VG name* command should be used on auto varied off volume groups after the `multibos` command has created an alternative root volume group (operating system) on the disk and has been booted.
`-e` *file*	Lists active BOS files to be excluded during the setup operation in regular expression syntax.
`-f` *file*	Lists fixes (such as APARs) that are to be installed during the setup or customization operation. The syntax of the list follows `instfix` conventions.
`-i` *file*	Specifies optional `image.data` file to use instead of the default `image.data` file created from the current `rootvg`.
`-L` *file*	Specifies a file that contains a list of additional logical volumes to include in standby BOS.
`-l` *device*	Installs device or directory for software update during the setup or customization operation.
`-m`	Mounts standby BOS.
`-M` *file*	Specifies a file that contains a **mksysb** image. The **mksysb** image must have been created using the `mksysb -M` command beginning with AIX 6.1 with 6100-02.
`-N`	Skips boot image processing. This flag should only be used by experienced administrators that have a good understanding of the AIX boot process.

Item	Description
`-n`	Does not perform cleanup upon failure. This option is useful to retain `multibos` data after a failed operation.
`-p`	Performs a preview of the given operation. Valid with setup, remove, mount, unmount, and customization operations.
`-R`	Removes all standby BOS objects.
`-S`	Initiates an interactive shell with `chroot` access to the standby BOS file systems.
`-s`	Creates an instance of standby BOS.
`-t`	Prevents `multibos` from changing the bootlist.
`-u`	Unmounts standby BOS.
-x *file*	Runs the optional customization script before any other customized parameters, such as, update_all (**-a**), install bundle file (**-b**), and fix list file (**-f**). You must use a full pathname for the script.
`-X`	Allows for automatic file system expansion if space is needed to perform tasks related to `multibos`. It is recommended that all `multibos` operations are executed with this flag.

Exit Status

Item	Description
`0`	All the `multibos` command operations completed successfully.
`>0`	An error occurred.

Security

Only the root user can run the `multibos` command.

Examples

1. To perform a standby BOS setup operation preview, enter the following command:

   ```
   multibos -Xsp
   ```

2. To set up standby BOS, enter the following command:

   ```
   multibos -Xs
   ```

3. To set up standby BOS with optional `image.data` file `/tmp/image.data` and exclude list `/tmp/exclude.list`, enter the following command:

   ```
   multibos -Xs -i /tmp/image.data -e /tmp/exclude.list
   ```

4. To set up standby BOS and install additional software listed as bundle file `/tmp/bundle` and located in the images source `/images`, enter the following command:

   ```
   multibos -Xs -b /tmp/bundle -l /images
   ```

5. To execute a customization operation on standby BOS with the `update_all` install option, enter the following command:

```
multibos -Xac -l /images
```

6. To mount all standby BOS file systems, enter the following command:

```
multibos -Xm
```

7. To perform a standby BOS remove operation preview, enter the following command:

```
multibos -RXp
```

8. To remove standby BOS, enter the following command:

```
multibos -RX
```

9. To use an existing **mksysb** file **/backups/mksysb1** to populate the standby instance of rootvg, enter the following command:

```
multibos -M /backups/mksysb1 -sX
```

Files

Item	Description
`/usr/sbin/multibos`	Contains the `multibos` command.
`/etc/multibos`	Contains `multibos` data and logs.

mv Command

Purpose

Moves files.

Syntax

To Move and Rename a File

mv [**-d**] [**-e**] [**-E**{**force**|**ignore**|**warn**}] [**-i** | **-f**] [**-I**] *SourceFile ... TargetFile*

To Move and Rename a Directory

mv [**-d**] [**-e**] **-E**{**force**|**ignore**|**warn**}] [**-i** | **-f**] [**-I**] *SourceDirectory ... TargetDirectory*

To Move Files or Directories to a Directory Maintaining Original File Names

mv [**-d**] [**-e**] **-E**{**force**|**ignore**|**warn**}] [**-i** | **-f**] [**-I**] *SourceFile/SourceDirectory TargetDirectory*

Description

Attention: The **mv** command can overwrite many existing files unless you specify the **-i** flag. The **-i** flag prompts you to confirm before it overwrites a file. If both the **-f** and **-i** flags are specified in combination, the last flag specified takes precedence.

The **mv** command moves files and directories from one directory to another or renames a file or directory. If you move a file or directory to a new directory, it retains the base file name. When you move a file, all links to other files remain intact, except when you move it to a different file system. When you move a directory into an existing directory, the directory and its contents are added under the existing directory.

When you use the **mv** command to rename a file or directory, the *TargetDirectory* parameter can specify either a new file name or a new directory path name.

If moving the file would overwrite an existing file that does not have write-permission set and if standard input is a workstation, the **mv** command displays the file-permission code and reads a line from standard input. If that line begins with a y or the locale's equivalent of a y, the **mv** command moves the file. If the response is anything other than a y, the **mv** command does nothing to that file and continues with the next specified file. The file-permission code displayed may not fully represent the access permission if the *TargetFile* is associated with an ACL. When the parent directory of the *SourceFile* is writable and has the sticky bit set, one or more of the following conditions are true:

- The user must own the file.
- The user must own the directory
- The user must be a privileged user.
- The file must be writable by the user.

This warning message and prompt for input can be overridden by using the `-f` option.

You can use the **mv** command to move files within the same file system or between file systems. Whether you are working in one file system or across file systems, the **mv** command copies the file to the target and deletes the original file. The **mv** command preserves in the new file the time of the most recent data modification, the time of the most recent access, the user ID, the group ID, the file mode, the extended attributes, and ACLs of the original file. For symbolic links, the **mv** command preserves only the owner and group of the link itself.

If it is unable to preserve the owner and group ID, the **mv** command clears S_ISUID and S_ISGID bits in the target. The **mv** command prints a diagnostic message to stderr if it is unable to clear these bits, though the exit code is not affected.

The **mv** command modifies either the source file or the destination path if the command is prematurely terminated.

Note: The **mv** command supports the **--** (dash, dash) parameter as a delimiter that indicates the end of the flags.

The `mv` command will not move an object if the object is exported as an NFS version 4 referral. The referral object is marked as busy and remains so until it is unexported.

Note: The I/O buffer size for the read and write system calls generated by this command can be configured by using the *AIX_STDBUFSZ* environment variable.

Flags

> **Attention:** The **mv** command can overwrite many existing files unless you specify the **-i** flag. The **-i** flag prompts you to confirm before it overwrites a file. If both the **-f** and **-i** flags are specified in combination, the last flag specified takes precedence.

Item	Description
-d	The source file is stored in decrypted (clear-text) format on target.
-e	The source file is stored in encrypted form, if the target file system is an Encrypted File System (EFS).

Item	Description
-E	The **-E** option requires one of the following arguments. If you omit the **-E** option, **warn** is the default behavior. **force** Fails the **mv** operation on a file if the fixed extent size or space reservation of the file cannot be preserved. **ignore** Ignores any errors in preserving extent attributes. **warn** Issues a warning if the space reservation or the fixed extent size of the file cannot be preserved.
-f	Does not prompt you before overwriting an existing file.
-i	Prompts you before moving a file or directory to an existing path name by displaying the name of the file followed by a question mark. If you answer with a line starting with y or the locale's equivalent of a y, the move continues. Any other reply prevents the move from occurring.
-I	Suppresses the warning message during ACL conversion.

The following table shows the encryption or decryption status of the target file under different conditions:

Explicit flag for the **mv** command	Source file	Target file system	Result
-e (encrypted)	Non-EFS	Non-EFS	Error
-e	Non-EFS	EFS	Encrypted file
-e	EFS	EFS	Encrypted file
-e	EFS	Non-EFS	Error
-d (decrypted)	Non-EFS	Non-EFS	Clear-text file
-d	Non-EFS	EFS	Clear-text file
-d	EFS	Non-EFS	Clear-text file
-d	EFS	EFS	Clear-text file
No explicit flag	Non-EFS	Non-EFS	Clear-text file
No explicit flag	Non-EFS	EFS	If the target file system is EFS activated, the target file is an encrypted file. Else, the target file is a clear-text file.
No explicit flag	EFS	EFS	Encrypted file
No explicit flag	EFS	Non-EFS	Error

Note: It is not permitted to overwrite an encrypted file with a plain-text file and vice versa unless you specify the **-f** flag. The encryption status of the target depends on the **-e** or **-d** flag, the encryption inheritance if you do not specify the **-e** or **-d** flag with the **-f** flag, and the encryption status of the source file if the encryption inheritance is not active.

Examples

1. To rename a file, enter:

   ```
   mv appendix apndx.a
   ```

   This command renames `appendix` to `apndx.a`. If a file named `apndx.a` already exists, its old contents are replaced with those of `appendix`.

2. To move a directory, enter:

   ```
   mv book manual
   ```

   This command moves all files and directories under `book` to the directory named `manual`, if `manual` exists. Otherwise, the directory `book` is renamed `manual`.

3. To move a file to another directory and give it a new name, enter:

   ```
   mv intro manual/chap1
   ```

   This command moves `intro` to `manual/chap1`. The name `intro` is removed from the current directory, and the same file appears as `chap1` in the directory `manual`.

4. To move a file to another directory, keeping the same name, enter:

   ```
   mv chap3 manual
   ```

   This command moves `chap3` to `manual/chap3`

   > **Note:** Examples 1 and 3 name two files, example 2 names two existing directories, and example 4 names a file and a directory.

5. To move several files into another directory, enter:

   ```
   mv chap4 jim/chap5 /home/manual
   ```

   This command moves the `chap4` file to the `/home/manual/chap4` file directory and the `jim/chap5` file to the `/home/manual/chap5` file.

6. To use the **mv** command with pattern-matching characters, enter:

   ```
   mv manual/* .
   ```

   This command moves all files in the `manual` directory into the current directory . (period), retaining the names they had in `manual`. This move also empties `manual`. You must type a space between the asterisk and the period.

   > **Note:** Pattern-matching characters expand names of existing files only. For example, the command `mv intro man*/chap1` does not work if the file `manual/chap1` does not exist.

Exit Status

Item	Description
0	All input files were moved successfully.
>0	An error occurred.

Files

Item	Description
/usr/bin/mv	Contains the **mv** command.

mvdir Command

Purpose

Moves (renames) a directory.

Syntax

mvdir *Directory1 Directory2*

Description

The **mvdir** command renames directories within a file system. To use the **mvdir** command, you must have write permission to *Directory1* and *Directory2* as well as in the parent directories.

The *Directory1* parameter must name an existing directory. If *Directory2* does not exist, *Directory1* is moved to *Directory2*. If *Directory2* exists, *Directory1* becomes a subdirectory of *Directory2*. Neither directory can be a subset of the other.

The **mvdir** Command can also be used to move or rename files. If the *Directory1* parameter is an existing file name and the *Directory2* parameter is an existing directory name, the file specified by *Directory1* is moved to the directory specified by *Directory2*. If the *Directory1* parameter is an existing file name and the *Directory2* parameter does not yet exist, *Directory2* replaces the file name *Directory1*. If both are existing file names, the file specified by *Directory1* is renamed *Directory2*, and the existing *Directory2* is removed.

The **mv** command provides the same functionality as the **mvdir** command.

The `mvdir` command will not rename a directory if the directory is exported for use by NFS version 4, or if the directory leads to a directory exported for use by NFS version 4. NFS version 4-exported directories and directories leading to NFS version 4-exported directories are marked as busy and remain so until unexported.

Example

To rename or move a directory to another location, enter:

```
mvdir appendixes manual
```

If `manual` does not exist, this renames the `appendixes` directory to `manual`.

If a directory named `manual` already exists, this moves `appendixes` and its contents to `manual/appendixes`. In other words, `appendixes` becomes a subdirectory of `manual`.

Files

Item	Description
/usr/sbin/mvdir	Contains the **mvdir** command.

mvfilt Command

Purpose

Moves a filter rule.

Syntax

mvfilt -v 4|6 -p *p_fid* **-n** *n_fid*

Description

Use the **mvfilt** command to change the position of a filter rule in the filter rule table. IPsec filter rules for this command can be configured using the `genfilt` command or IPsec smit (IP version 4 or IP version 6).

Flags

Item	Description
-v	IP version of the filter rule. The value **4** specifies IP version 4 and the value **6** specifies IP version 6.
-p	Filter rule ID. It specifies the previous position of the rule in the filter rule table. For IP version 4, the value of **1** is invalid since the first filter rule is unmoveable.
-n	Filter rule ID. It specifies the new position of the rule in the filter rule table after the move. For IP version 4, the value of **1** is invalid since the first filter rule is reserved and thus is unmoveable.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **`lssecattr`** command or the **`getcmdattr`** subcommand.

mvt Command

Purpose

Typesets English-language view graphs and slides.

Syntax

mvt [**-a**] [**-c**] [**-e**] [**-g**] [**-p**] [**-t**] [**-z**] [**-T***Name* | **-D***Destination*] [*File* ... | **-**]

Description

The **mvt** command typesets its input with the **mv** macro package for view graphs and slides in a manner similar to the **mmt** command. The **mvt** command has flags to specify preprocessing by the **tbl**, **eqn**, **pic**, **cw**, and **grap** commands. The flags you select determine which pipelines, flags, and parameters are generated for the **troff** command and the macro package.

The **mvt** command, unlike the **troff** command, automatically pipes its output to a postprocessor, unless specifically requested not to do so. The user should not specify a postprocessor when using the **mvt** command. The path that the **mvt** command takes is as follows:

1. The **-z** flag (no postprocessor is used).
2. The **-T***Name* flag.
3. The **TYPESETTER** environment variable is read.
4. The default is set to **ibm3816**.

File specifies the file that the **mvt** command formats.

Flags

Flags can occur in any order, but they must be displayed before the *File* parameter. If no file is specified, the **mvt** command prints a list of its flags.

Item	Description
-a	Displays readable **troff** output to the terminal.
-c	Calls the **cw** command.
-e	Calls the **eqn** command; also causes the **eqn** command to read the **/usr/share/lib/pub/eqnchar** file.
-g	Calls the **grap** command, which in turn calls the **pic** command.
-p	Calls the **pic** command.
-t	Calls the **tbl** command.
-z	Calls no output filter (or postprocessor) to process or redirect the output of the **troff** command.
-D*Destination*	Directs the output to the specified device destination. Supported value for the *Destination* variable is **4014**, which is the Tektronix 4014 terminal by way of the **tc** command.
-T*Name*	Creates output for the **troff** device as specified by the *Name* variable. The output is sent through the appropriate postprocessor. The default is **ibm3816**.
-	Forces input to be read from standard input.

Any other parameters or flags that you give the **mvt** command (such as the **-a** flag) are passed to the **troff** command.

The **mvt** command reads standard input when you specify the **-** (minus) flag instead of the *File* parameter.

Use the **-o***List* flag of the **troff** command to specify ranges of pages to be output.

> **Note:** If you call the **mvt** command with one or more of the **-e**, **-c**, **-t**, **-p**, **-g**, or **-** flags, together with the **-o***List* flag of the **troff** command, you may receive a `broken pipe` message. This occurs if you do not specify the last page of the document in the *List* variable. This broken pipe message is not an indication of any problem and can be ignored.

Environment Variables

Item	Description
TYPESETTER	Contains information about a particular printing device.

Files

Item	Description
/usr/share/lib/pub/eqnchar	Contains special character definitions.

mwm Command

Purpose

Runs the AIXwindows Window Manager (MWM).

Syntax

mwm **-display** *Host:Display:ScreenID* **-xrm** *ResourceString* **-multiscreen** **-name** *Name* **-screens** *Name* [*Name* ...]

Description

The **mwm** command runs the AIXwindows Window Manager (MWM) and is often started by a display or session manager. The AIXwindows Window Manager (MWM) is an X Window System client that provides window management functionality and some session management functionality. It provides functions that facilitate control (by the user and the programmer) of elements of window states such as placement, size, icon or normal display, and input-focus ownership. It also provides session management functions such as stopping a client.

The appearance and behavior of the window manager can be altered by changing the configuration of specific resources. Resources are defined under X Defaults .

By default, the **mwm** command manages only the single screen specified by the **-display** option or the **DISPLAY** environment variable (by default, screen 0). If the **-multiscreen** option is specified or if the **multiScreen** resource is True, the **mwm** command tries to manage all the screens on the display.

When the **mwm** command is managing multiple screens, the **-screens** option can be used to give each screen a unique resource name. The names are separated by blanks, for example, **-screens mwm0 mwm1**. If there are more screens than names, resources for the remaining screens are retrieved using the first name. By default, the screen number is used for the screen name.

For information on windows, icons, resources, events, button and key bindings, menus, and variables, see the following sections:

- Windows
- Icons
- Icon Box
- Component Appearance Resources
- General Appearance and Behavior Resources
- Client-Specific Resources
- Window Manager Event Specification
- Button Bindings
- Key Bindings
- Menu Panes
- Environment

Flags

Flag Description

Item	Description
-display *Host*:*Display*:*ScreenID*	Specifies the display to use. The **-display** option has the following parameters: ***Host*** Specifies the host name of a valid system on the network. Depending on the situation, this could be the host name of the user or the host name of a remote system. ***Display*** Specifies the number (usually 0) of the display on the system on which the output is to be displayed. ***ScreenID*** Specifies the number of the screen where the output is to be displayed. This number is 0 for single-screen systems.
-xrm *ResourceString*	Enables the named resources when starting the **mwm** command.
-multiscreen	Causes the **mwm** command to manage all screens on the display. The default is to manage only a single screen.
-name *Name*	Causes the **mwm** command to retrieve its resources using the specified name, as in *Name*Resource*.
-screens *Name* [*Name* [...]]	Specifies the resource names to use for the screens managed by MWM. If MWM is managing a single screen, only the first name in the list is used. If multiple screens are being managed, the names are assigned to the screens in order, starting with screen 0. For example, screen 0 gets the first name and screen 1 gets the second name.

Windows

Default window manager window frames have the following distinct components with associated functions:

Windows Description

Item	Description
title area	In addition to displaying the client's title, the title area is used to move the window. To move the window, place the pointer over the title area, press button 1 and drag the window to a new location. A wire frame is moved during the drag to indicate the new location. When the button is released, the window is moved to the new location.
title bar	The title bar includes the title area, the **Minimize** button, the **Maximize** button, and the **Window Menu** button. In shaped windows, such as round windows, the title bar floats above the window.
Minimize button	To turn the window into an icon, click button 1 on the **Minimize** button (the frame box with a small square in it).
Maximize button	To make the window fill the screen (or enlarge to the largest size allowed by the configuration files), click button 1 on the **Maximize** button (the frame box with a large square in it).

Windows Description *(continued)*

Item	Description
Window Menu button	The **Window Menu** button is the frame box with a horizontal bar in it. To pull down the window menu, press button 1. While pressing the button, drag the pointer on the menu to your selection and release the button when your selection is highlighted. Pressing button 3 in the title bar or resize border handles also posts the window menu. Alternately, you can click button 1 to pull down the menu and keep it posted; then position the pointer and select. You can also post the window menu by pressing the Shift+Esc or Alt+Space key sequence. Double-clicking button 1 with the pointer on the **Window Menu** button closes the window. The following table lists the contents of the window menu:

Default Window Menu

Selection	Accelerator	Description
Restore	Alt+F5	Restores the window to its size before minimizing or maximizing.
Move	Alt+F7	Allows the window to be moved with keys or mouse.
Size	Alt+F8	Allows the window to be resized.
Minimize	Alt+F9	Turns the window into an icon.
Maximize	Alt+F10	Makes the window fill the screen.
Lower	Alt+F3	Moves window to bottom of window stack.
Close	Alt+F4	Causes client to stop.

resize border handles	To change the size of a window, move the pointer over a resize border handle (the cursor changes), press button 1, and drag the window to a new size. When the button is released, the window is resized. While dragging is being done, a rubber-band outline is displayed to indicate the new window size.
matte	An optional matte decoration can be added between the client area and the window frame. A matte is not actually part of the window frame. There is no functionality associated with a matte.

Icons

Icons are small graphic representations of windows. A window can be iconified (minimized) using the **Minimize** button on the window frame. Icons provide a way to reduce clutter on the screen.

Pressing the left mouse button when the pointer is over an icon causes the icon's window menu to open. Releasing the button (press + release without moving mouse = click) causes the menu to stay posted. The menu contains the following selections:

Icon Window Menu		
Selection	**Accelerator**	**Description**
Restore	Alt+F5	Opens the associated window.
Move	Alt+F7	Allows the icon to be moved with keys.
Size	Alt+F8	Inactive (not an option for icons).
Minimize	Alt+F9	Inactive (not an option for icons).
Maximize	Alt+F10	Opens the associated window and makes it fill the screen.
Lower	Alt+F3	Moves icon to bottom of icon stack.
Close	Alt+F4	Removes client from window manager management.

Pressing button 3 over an icon also causes the icon's window menu to open. To make a menu selection, drag the pointer over the menu and release button 3 when the desired item is highlighted.

Double-clicking button 1 on an icon calls the **f.restore_and_raise** function and restores the icon's associated window to its previous state. For example, if a maximized window is iconified, double-clicking button 1 restores it to its maximized state. Double-clicking button 1 on the icon box's icon opens the icon box and allow access to the contained icons. (Double-clicking a mouse button is a quick way to perform a function.) Pressing the Shift+Esc key sequence or the pop-up Menu key causes the icon window menu of the currently selected icon to open.

Icon Box

When icons begin to clutter the screen, they can be packed into an icon box. (To use an icon box, the window manager must be started with the icon box configuration already set.) The icon box is a window manager window that holds client icons. It includes one or more scroll bars when there are more window icons than the icon box can show at the same time.

Icons in the icon box can be manipulated with the mouse. The following button action descriptions summarize the behavior of this interface. Button actions apply whenever the pointer is on any part of the icon. Double-clicking an icon in the icon box calls the **f.restore_and_raise** function.

Icon Box

Button Action	**Description**
Button 1 click	Selects the icon.
Button 1 double-click	Normalizes (opens) the associated window.
Button 1 double-click	Raises an already *open* window to the top of the stack.
Button 1 drag	Moves the icon.
Button 3 press	Causes the menu for that icon to open.
Button 3 drag	Highlights items as the pointer moves across the menu.

Pressing mouse button 3 when the pointer is over an icon causes the menu for that icon to open.

Icon Menu for Icon Box		
Selection	**Accelerator**	**Description**
Restore	Alt+F5	Opens the associated window (if not already open).
Move	Alt+F7	Allows the icon to be moved with keys.
Size	Alt+F8	Inactive.
Minimize	Alt+F9	Inactive.
Maximize	Alt+F10	Opens the associated window (if not already open) and maximizes its size.
Lower	Alt+F3	Inactive.
Close	Alt+F4	Removes client from window manager management.

To pull down the window menu for the icon box itself, press button 1 with the pointer over the menu button for the icon box. The window menu of the icon box differs from the window menu of a client window: The **Close** selection is replaced with the **PackIcons** (Shift+Alt+F7) selection. When selected, the **PackIcons** option packs the icons in the box to achieve neat rows with no empty slots.

You can also post the window menu by pressing the Shift+Esc or Alt+Space key sequence. Pressing the pop-up Menu key causes the icon window menu of the currently selected icon to open.

Input Focus

The **mwm** command supports (by default) a keyboard input focus policy of *explicit selection*. This means when a window is selected to get keyboard input, it continues to get keyboard input until the window is withdrawn from window management, another window is explicitly selected to get keyboard input, or the window is iconified. Several resources control the input focus. The client window with the keyboard input focus has the active window appearance with a visually distinct window frame.

The following table and key action descriptions summarize the keyboard input focus selection behavior:

Input focus		
Button Action	**Object**	**Function Description**
Button 1 press	Window or window frame	Keyboard focus selection
Button 1 press	Icon	Keyboard focus selection

Function Description

Key Action	**Function Description**
Alt+Tab	Moves the input focus to next window in the window stack.
Alt+Shift+Tab	Moves the input focus to the previous window in the window stack (available only in explicit focus mode).

Window Stacking

There are two types of window stacks: global window stacks and an application's local family window stack.

The global stacking order of windows can be changed as a result of setting the keyboard input focus, iconifying a window, or performing a window manager window stacking function. When keyboard focus policy is explicit the default value of the **focusAutoRaise** resource is True. This causes a window to be raised to the top of the stack when it receives input focus, for example, by pressing button 1 on the title bar. The key actions defined in the preceding list raises the window receiving focus to the top of the stack.

In pointer mode, the default value of the **focusAutoRaise** resource is False; that is, the window stacking order is not changed when a window receives keyboard input focus. The following key actions can be used to cycle through the global window stack:

Windows Stacking function description

Key Action	**Function Description**
Alt+Esc	Places top window on bottom of stack.
Alt+Shift+Esc	Places bottom window on top of stack.

By default, a window's icon is placed on the bottom of the stack when the window is iconified; however, the default can be changed by the **lowerOnIconify** resource.

Transient windows (secondary windows such as dialog boxes) stay above their parent windows by default. However, an application's local family stacking order can changed to allow a transient window to be placed below its parent top-level window. The following parameter values show the modification of the stacking order for the **f.lower** function:

Transient windows

Item	Description
f.lower	Lowers the transient window within the family (staying above the parent) and lowers the family in the global window stack.
f.lower [**within**]	Lowers the transient window within the family (staying above the parent) but does not lower the family in the global window stack.
f.lower [**freeFamily**]	Lowers the window separate from its family stack (below the parent), but does not lower the family in the global window stack.

The **within** and **freeFamily** parameter values can also be used with the **f.raise** and **f.raise_lower** functions.

X Defaults

The **mwm** command is configured from its resource database. This database is built from the following sources. They are listed in order of precedence.

1. **mwm** command line options
2. **XENVIRONMENT** variable or **$HOME/.Xdefaults-host**
3. **RESOURCE_MANAGER** root window property or **$HOME/.Xdefaults**
4. **$HOME/Mwm**
5. **/usr/lib/X11/app-defaults/Mwm**.

The **/usr/lib/X11/app-defaults/Mwm** and **$HOME/Mwm** file names represent customary locations for these files. The actual location of the systemwide class resource file might depend on the **XFILESEARCHPATH** environment variable and the current language environment. The actual location of the user-specific class resource file might depend on the **XUSERFILESEARCHPATH** and **XAPPLRESDIR** environment variables and the current language environment.

Entries in the resource database can refer to other resource files for specific types of resources. These include files that contain bitmaps, fonts, and **mwm**-specific resources such as menus and behavior specifications (for example, button and key bindings).

Mwm is the resource class name of the **mwm** command and **mwm** is the resource name used by the **mwm** command to look up resources. (For looking up resources of multiple screens, the **-screens** command-line option specifies resource names such as **mwm_b+w** and **mwm_color**.) In the following discussion of resource specification, "Mwm" and "mwm" (and the aliased **mwm** resource names) can be used interchangeably, but "mwm" takes precedence over "Mwm". The **mwm** command uses the following types of resources:

X Defaults description

Item	Description
component appearance resource set	These resources specify appearance attributes of window manager user-interface components. They can be applied to the appearance of window manager menus, feedback windows (for example, the window reconfiguration feedback window), client window frames, and icons.
frame and icon component resource set	This subset of component appearance resources specifies attributes that are specific to frame and icon components.
general appearance and behavior resource set	These resources specify the **mwm** command appearance and behavior (for example, window management policies). They are not set separately for different **mwm** command user-interface components.

X Defaults description *(continued)*

Item	Description
client-specific resource set	These **mwm** resources can be set for a particular client window or class of client windows. They specify client-specific icon and client window frame appearance and behavior.

Resource identifiers can be either a resource name (for example, **foreground**) or a resource class (for example, **Foreground**). If the value of a resource is a file name and if the file name is prefixed by the ~/ (tilde followed by a slash) characters, it is relative to the path contained in the **HOME** environment variable (generally the user's home directory).

Component Appearance Resources

The syntax for specifying component appearance resources that apply to window manager icons, menus, and client window frames is as follows:

Mwm*ResourceID*

For example, **Mwm*foreground** is used to specify the foreground color for the **mwm** command menus, icons, client window frames, and feedback dialogs.

The syntax for specifying component appearance resources that apply to a particular **mwm** component is as follows:

Mwm*[*Menu*|*Icon*|*Client*|*Feedback*]***ResourceID*

If *Menu* is specified, the resource is applied only to Mwm menus; if *Icon* is specified, the resource is applied to icons; and if *Client* is specified, the resource is applied to client window frames. For example, **Mwm***Icon***foreground** is used to specify the foreground color for the **mwm** command icons, **Mwm***Menu***foreground** specifies the foreground color for the **mwm** command menus, and **Mwm***Client***foreground** is used to specify the foreground color for the **mwm** command client window frames.

The appearance of the title area of a client window frame (including window management buttons) can be separately configured. The syntax for configuring the title area of a client window frame is as follows:

Mwm*Client***Title***ResourceID*

For example, **Mwm***Client***Title*****foreground** specifies the foreground color for the title area. Defaults for title area resources are based on the values of the corresponding client window frame resources.

The appearance of menus can be configured based on the name of the menu. The syntax for specifying menu appearance by name is as follows:

Mwm*Menu***MenuName*****ResourceID*

For example, **Mwm***Menu***MyMenu*****foreground** specifies the foreground color for the menu named MyMenu.

The user can also specify resources for window manager menu components (the gadgets that comprise the menu). These may include, for example, a menu title, a title separator, one or more buttons, and separators. If a menu contains more than one instance of a class, such as multiple **PushButtonGadget** gadgets, the name of the first instance is **PushButtonGadget1**, the second is **PushButtonGadget2**, and so on. The following list identifies the naming conventions used for window manager menu components:

Component Appearance Resources

Item	Description
TitleName	Menu title LabelGadget
TitleSeparator	Menu title SeparatorGadget

Component Appearance Resources *(continued)*

Item	Description
CascadeButtonGadget*n*	CascadeButtonGadget
PushButtonGadget*n*	PushButtonGadget
SeparatorGadget*n*	SeparatorGadget

The following component appearance resources that apply to all window manager parts can be specified.

Component Appearance Resource Set

Component Appearance Resource Set	
Name	**Properties**
background	**Class** Background **Value type** color **Default** varies[1]
backgroundPixmap	**Class** BackgroundPixmap **Value type** string[2] **Default** varies[1]
bottomShadowColor	**Class** Foreground **Value type** color **Default** varies[1]
bottomShadowPixmap	**Class** BottomShadowPixmap **Value type** string[2] **Default** varies[1]
fontList	**Class** FontList **Value type** string[3] **Default** "fixed"

Component Appearance Resource Set *(continued)*	
Name	**Properties**
foreground	**Class** Foreground **Value type** color **Default** varies[1]
saveUnder	**Class** SaveUnder **Value type** True of False **Default** False
topShadowColor	**Class** Background **Value type** color **Default** varies[1]
topShadowPixmap	**Class** TopShadowPixmap **Value type** string[2] **Default** varies[1]
background	**Class** Background **Value type** color **Default** varies[1]
backgroundPixmap	**Class** BackgroundPixmap **Value type** string[2] **Default** varies[1]
bottomShadowColor	**Class** Foreground **Value type** color **Default** varies[1]

Component Appearance Resource Set *(continued)*	
Name	**Properties**
bottomShadowPixmap	**Class** BottomShadowPixmap **Value type** string[2] **Default** varies[1]
fontList	**Class** FontList **Value type** string[3] **Default** "fixed"
foreground	**Class** Foreground **Value type** color **Default** varies[1]
saveUnder	**Class** SaveUnder **Value type** True of False **Default** False
topShadowColor	**Class** Background **Value type** color **Default** varies[1]
topShadowPixmap	**Class** TopShadowPixmap **Value type** string[2] **Default** varies[1]

Note:

1. The default is chosen based on the visual type of the screen.
2. Image name.
3. X Version 11 Release 4 (X11R4) font description.

Background

Item	Description
background (class **Background**)	Specifies the background color. Any legal X color can be specified. The default value is chosen based on the visual type of the screen.
backgroundPixmap (class **BackgroundPixmap**)	Specifies the background pixmap of the **mwm** decoration when the window is inactive (does not have the keyboard focus). The default value is chosen based on the visual type of the screen.
bottomShadowColor (class **Foreground**)	Specifies the bottom shadow color. This color is used for the lower and right bevels of the window manager decoration. Any legal X color can be specified. The default value is chosen based on the visual type of the screen.
bottomShadowPixmap (class **BottomShadowPixmap**)	Specifies the bottom shadow pixmap. This pixmap is used for the lower and right bevels of the window manager decoration. The default is chosen based on the visual type of the screen.
fontList (class **FontList**)	Specifies the font used in the window manager decoration. The character encoding of the font needs to match the character encoding of the strings that are used. The default is the fixed value.
foreground (class **Foreground**)	Specifies the foreground color. The default is chosen based on the visual type of the screen.
saveUnder (class **SaveUnder**)	Controls the repainting of windows that are uncovered after being obscured. This resource indicates whether *save unders* are used for **mwm** components. For this to have any effect, save unders must be implemented by the X server. If save unders are implemented, the X server saves the contents of windows obscured by windows that have the save under attribute set. If the **saveUnder** resource is True, the **mwm** command sets the save under attribute on the window manager frame of any client that has it set. If the **saveUnder** resource is False, save unders is not used on any window manager frames. The default value is False.
topShadowColor (class **Background**)	Specifies the top shadow color. This color is used for the upper and left bevels of the window manager decoration. The default is chosen based on the visual type of the screen.
topShadowPixmap (class **TopShadowPixmap**)	Specifies the top shadow pixmap. This pixmap is used for the upper and left bevels of the window manager decoration. The default is chosen based on the visual type of the screen.

Frame and Icon Component Resource Set

Note: Hyphens in the following table are for readability purposes only. Do not include hyphens within names in programs.

Frame and Icon Component Resource Set	
Name	**Properties**
activeBackground	**Class** Background **Value type** color **Default** varies[1]
activeBackground-Pixmap	**Class** BackgroundPixmap **Value type** string[2] **Default** varies[1]
activeBottomShadow-Color	**Class** Foreground **Value type** color **Default** varies[1]
activeBottomShadow-Pixmap	**Class** BottomShadow-Pixmap **Value type** string[2] **Default** varies[1]
activeForeground	**Class** Foreground **Value type** color **Default** varies[1]
activeTopShadowColor	**Class** Background **Value type** color **Default** varies[1]
activeTopShadowPixmap	**Class** TopShadowPixmap **Value type** string[2] **Default** varies[1]

Frame and Icon Component Resource Set *(continued)*	
Name	**Properties**
activeBackground	**Class** Background **Value type** color **Default** varies[1]
activeBackgroundPixmap	**Class** BackgroundPixmap **Value type** string[2] **Default** varies[1]
activeBottomShadowColor	**Class** Foreground **Value type** color **Default** varies[1]
activeBottomShadowPixmap	**Class** BottomShadowPixmap **Value type** string[2] **Default** varies[1]
activeForeground	**Class** Foreground **Value type** color **Default** varies[1]
activeTopShadowColor	**Class** Background **Value type** color **Default** varies[1]
activeTopShadowPixmap	**Class** TopShadowPixmap **Value type** string[2] **Default** varies[1]

Note:

1. The default is chosen based on the visual type of the screen.
2. Image name.

Background

Item	Description
activeBackground (class **Background**)	Specifies the background color of the **mwm** decoration when the window is active (has the keyboard focus). The default is chosen based on the visual type of the screen.
activeBackgroundPixmap (class **BackgroundPixmap**)	Specifies the background pixmap of the **mwm** decoration when the window is active (has the keyboard focus). The default is chosen based on the visual type of the screen.
activeBottomShadowColor (class **Foreground**)	Specifies the bottom shadow color of the **mwm** decoration when the window is active (has the keyboard focus). The default is chosen based on the visual type of the screen.
activeBottomShadowPixmap (class **BottomShadowPixmap**)	Specifies the bottom shadow pixmap of the **mwm** decoration when the window is active (has the keyboard focus). The default is chosen based on the visual type of the screen.
activeForeground (class **Foreground**)	Specifies the foreground color of the **mwm** decoration when the window is active (has the keyboard focus). The default is chosen based on the visual type of the screen.
activeTopShadowColor (class **Background**)	Specifies the top shadow color of the **mwm** decoration when the window is active (has the keyboard focus). The default is chosen based on the visual type of the screen.
activeTopShadowPixmap (class **TopShadowPixmap**)	Specifies the top shadow pixmap of the **mwm** decoration when the window is active (has the keyboard focus). The default is chosen based on the visual type of the screen.

General Appearance and Behavior Resources

The syntax for specifying general appearance and behavior resources is as follows:

Mwm*ResourceID*

For example, **Mwm*keyboardFocusPolicy** specifies the window manager policy for setting the keyboard focus to a particular client window.

General Appearance and Behavior Resource Set

Note: Hyphens in the following table are for readability purposes only. Do not include hyphens within names in programs.

General Appearance and Behavior Resource Set	
Name	**Properties**
autoKeyFocus	**Class** AutoKeyFocus **Value type** True or False **Default** True
autoRaiseDelay	**Class** AutoRaiseDelay **Value type** millisec. **Default** 500
bitmapDirectory	**Class** BitmapDirectory **Value type** directory **Default** /usr/include/X11/bitmaps
buttonBindings	**Class** ButtonBindings **Value type** string **Default** "DefaultButton-Bindings"
cleanText	**Class** CleanText **Value type** True or False **Default** True
clientAutoPlace	**Class** ClientAutoPlace **Value type** True or False **Default** True
colormapFocusPolicy	**Class** ColormapFocus-Policy **Value type** string **Default** keyboard

General Appearance and Behavior Resource Set *(continued)*	
Name	**Properties**
configFile	**Class** ConfigFile **Value type** file **Default** .mwmrc
defaultSetBehavior	**Class** defaultSetBehavior **Value type** True or False **Default** True
deiconifyKeyFocus	**Class** DeiconifyKeyFocus **Value type** True or False **Default** True
doubleClickTime	**Class** DoubleClickTime **Value type** milliseconds **Default** multiclick time
enableWarp	**Class** enableWarp **Value type** True or False **Default** True
enforceKeyFocus	**Class** EnforceKeyFocus **Value type** True or False **Default** True
fadeNormalIcon	**Class** FadeNormalIcon **Value type** True or False **Default** False

General Appearance and Behavior Resource Set *(continued)*	
Name	**Properties**
feedbackGeometry	**Class** FeedbackGeometry **Value type** string **Default** center on screen
frameBorderWidth	**Class** FrameBorderWidth **Value type** pixels **Default** varies
iconAutoPlace	**Class** IconAutoPlace **Value type** True or False **Default** True
iconBoxGeometry	**Class** IconBoxGeometry **Value type** string **Default** 6x1+0-0
iconBoxName	**Class** IconBoxName **Value type** string **Default** iconbox
iconBoxSBDisplayPolicy	**Class** IconBoxSBDisplayPolicy **Value type** string **Default** all
iconBoxTitle	**Class** IconBoxTitle **Value type** XmString **Default** Icons

General Appearance and Behavior Resource Set *(continued)*	
Name	**Properties**
iconClick	**Class** IconClick **Value type** True or False **Default** True
iconDecoration	**Class** IconDecoration **Value type** string **Default** varies
iconImage-Maximum	**Class** IconImage-Maximum **Value type** width x height **Default** 50x50
iconImageMinimum	**Class** IconImageMinimum **Value type** width x height **Default** 16x16
iconPlacement	**Class** IconPlacement **Value type** string **Default** left bottom
iconPlacementMargin	**Class** IconPlacementMargin **Value type** pixels **Default** varies
interactivePlacement	**Class** InteractivePlacement **Value type** True or False **Default** False

General Appearance and Behavior Resource Set *(continued)*	
Name	**Properties**
keyBindings	**Class** KeyBindings **Value type** string **Default** "DefaultKeyBindings"
keyboardFocusPolicy	**Class** KeyboardFocusPolicy **Value type** string **Default** explicit
limitResize	**Class** LimitResize **Value type** True or False **Default** True
lowerOnIconify	**Class** LowerOnIconify **Value type** True or False **Default** True

Maximum size	
Item	**Description**
maximumMaximuSize	**Class** MaximumMaximuSize **Value type** width x height (pixels) **Default** 2X screen width & height
moveOpaque	**Class** MoveOpaque **Value type** True or False **Default** False

Maximum size *(continued)*	
Item	**Description**
moveThreshold	**Class** MoveThreshold **Value type** pixels **Default** 4
multiScreen	**Class** MultiScreen **Value type** True or False **Default** False
passButtons	**Class** PassButtons **Value type** True or False **Default** False
PassSelectButton	**Class** PassSelectButton **Value type** True or False **Default** True
positionIsFrame	**Class** PositionIsFrame **Value type** True or False **Default** True
positionOnScreen	**Class** PositionOnScreen **Value type** True or False **Default** True
quitTimeout	**Class** QuitTimeout **Value type** milliseconds **Default** 1000

Maximum size *(continued)*	
Item	**Description**
`raiseKeyFocus`	**Class** `RaiseKeyFocus` **Value type** True or False **Default** False
`resizeBorderWidth`	**Class** `ResizeBorderWidth` **Value type** pixels **Default** varies
`resizeCursors`	**Class** `ResizeCursors` **Value type** True or False **Default** True
`screens`	**Class** `Screens` **Value type** string **Default** varies
`showFeedback`	**Class** `ShowFeedback` **Value type** string **Default** all
`startupKeyFocus`	**Class** `StartupKeyFocus` **Value type** True or False **Default** True
`transientDecoration`	**Class** `TransientDecoration` **Value type** string **Default** menu title

Maximum size *(continued)*	
Item	**Description**
`transientFunctions`	**Class** `TransientFunctions` **Value type** string **Default** -minimize -maximize
`useIconBox`	**Class** `UseIconBox` **Value type** True or False **Default** False
`wMenuButtonClick`	**Class** `WMenuButtonClick` **Value type** True or False **Default** True
`wMenuButtonClick2`	**Class** `WMenuButtonClick2` **Value type** True or False **Default** True

AutoKeyFocus

Item	**Description**
autoKeyFocus (class **AutoKeyFocus**)	Controls whether the focus is set to the previous window that had the focus. If the **autoKeyFocus** resource is given a value of True and a window with the keyboard input focus is withdrawn from window management or is iconified, the focus is set to the previous window that had the focus. If the value given is False, there is no automatic setting of the keyboard input focus. It is recommended that both the **autoKeyFocus** resource and the **startupKeyFocus** resource be set to a value of True to work with tear-off menus. The default value is True. This resource is available only when the keyboard input focus policy is set to the explicit value.
autoRaiseDelay (class **AutoRaiseDelay**)	Specifies the amount of time in milliseconds (ms) that the **mwm** command waits before raising a window after it gets the keyboard focus. The default value of this resource is 500 (milliseconds). This resource is available only when the **focusAutoRaise** resource is True and the keyboard focus policy is the pointer value.

Item	Description
bitmapDirectory (class **BitmapDirectory**)	Identifies a directory to be searched for bitmaps referenced by **mwm** resources. This directory is searched if a bitmap is specified without an absolute path name. The default value for this resource is **/usr/include/X11/bitmaps**. The **/usr/include/X11/bitmaps** directory represents the customary locations for this directory. The actual location of this directory may vary on some systems. If the bitmap is not found in the specified directory, the **XBMLANGPATH** environment variable is searched.
buttonBindings (class **ButtonBindings**)	Identifies the set of button bindings for window management functions. The named set of button bindings is specified in the **mwm** resource description file. These button bindings are merged with the built-in default bindings. The default value for this resource is **DefaultButtonBindings**.
cleanText (class **CleanText**)	Controls the display of window manager text in the client title and feedback windows. If the default value of True is used, the text is drawn with a clear (no stipple) background. This makes text easier to read on monochrome systems where a **backgroundPixmap** is specified. Only the stippling in the area immediately around the text is cleared. If False, the text is drawn directly on top of the existing background.
clientAutoPlace (class **ClientAutoPlace**)	Determines the position of a window when the window does not have a user-specified position. With a value of True, windows are positioned with the top left corners of the frames offset horizontally and vertically. A value of False causes the currently configured position of the window to be used. In either case, the **mwm** command attempts to place the windows totally on-screen. The default value is True.
colormapFocusPolicy (class **ColormapFocusPolicy**)	Indicates the colormap focus policy that is to be used. If the resource value is explicit, a colormap selection action is done on a client window to set the colormap focus to that window. If the value is pointer, the client window containing the pointer has the colormap focus. If the value is keyboard, the client window that has the keyboard input focus has the colormap focus. The default value for this resource is keyboard.

AutoKeyFocus *(continued)*

Item	Description
configFile (class **ConfigFile**)	Contains the path name for an **mwm** resource description file. If the path name begins with the ~/ characters, the **mwm** command considers it to be relative to the user's home directory (as specified by the **HOME** environment variable). If the **LANG** environment variable is set, the **mwm** command looks for **$HOME/$LANG/configFile**. If that file does not exist or if **LANG** is not set, **mwm** looks for **$HOME/configFile**. If the **configFile** path name does not begin with the ~/ characters, **mwm** considers it to be relative to the current working directory. If the **configFile** resource is not specified or if that file does not exist, the **mwm** command uses several default paths to find a configuration file. If the **LANG** environment variable is set, the **mwm** command looks for the configuration file first in the **$HOME/$LANG/.mwmrc** file. If that file does not exist or if the **LANG** environment variable is not set, the **mwm** command looks for the **$HOME/.mwmrc** file. If the **$HOME/.mwmrc** file does not exist and if the **LANG** environment variable is set, the **mwm** command next looks for the **/usr/lib/X11/$LANG/system.mwmrc** file. If the **/usr/lib/X11/$LANG/system.mwmrc** file does not exist or if the **LANG** environment variable is not set, the **mwm** command looks for **/usr/lib/X11/system.mwmrc**.
defaultSetBehavior (class **DefaultSetBehavior**)	Determines whether the **mwm** command automatically add key bindings to the **f.set_behavior** function (see .mwmrc file). If the value for the **defaultSetBehavior** resource is **True** (or On), regardless of the key bindings defined in the **.mwmrc** configuration file, `Alt Ctrl<key>1` and `Alt Shift Ctrl<Key>exclam` is bound to the **f.set_behavior** function. If the value for the **defaultSetBehavior** resource is **False** (or Off), the **f.set_behavior** function is bound to a key specified in the **.mwmrc** configuration file. If no key bindings are specified in the configuration file, the **mwm** command uses the default key binding. The default value for the **defaultSetBehavior** resource is **True** (or On).
deiconifyKeyFocus (class **DeiconifyKeyFocus**)	Determines whether a window receives the keyboard input focus when it is deiconified (normalized). The default value is True. This resource applies only when the keyboard input focus policy is set to the explicit value.
doubleClickTime (class **DoubleClickTime**)	Sets the maximum time (in ms) between the clicks (button presses) that make up a double-click. The default value of this resource is the display's multiclick time.

Item	Description
enableWarp (class **EnableWarp**)	Causes the **mwm** command to *warp* the pointer to the center of the selected window during keyboard-controlled resize and move operations. Setting the value to False causes the **mwm** command to leave the pointer at its original place on the screen unless the user explicitly moves it with the cursor keys or pointing device. The default value of this resource is True.
enforceKeyFocus (class **EnforceKeyFocus**)	Determines whether the keyboard input focus is always explicitly set to selected windows even if there is an indication that they are *globally active* input windows. (An example of a globally active window is a scroll bar that can be operated without setting the focus to that client.) If the resource is False, the keyboard input focus is not explicitly set to globally active windows. The default value is True.
fadeNormalIcon (class **FadeNormalIcon**)	Determines whether an icon is unavailable whenever it is normalized (its window is opened). The default value is False.
feedbackGeometry (class **FeedbackGeometry**)	Sets the position of the move and resize feedback window. If this resource is not specified, the default is to place the feedback window at the center of the screen. The value of the resource is a standard window geometry string with the following syntax: [=][{+-}*XOffset*{+-}*YOffset*]
frameBorderWidth (class **FrameBorderWidth**)	Specifies the width in pixels of a client window frame border without resize handles. The border width includes the three-dimensional (3-D) shadows. The default value is based on the size and resolution of the screen.
iconAutoPlace (class **IconAutoPlace**)	Indicates whether the window manager arranges icons in a particular area of the screen or places each icon where the window was when it was iconified. The True value indicates that icons are arranged in a particular area of the screen determined by the **iconPlacement** resource. The False value indicates that an icon is placed at the location of the window when it is iconified. The default is True.
iconBoxGeometry (class **IconBoxGeometry**)	Indicates the initial position and size of the icon box. The value of the resource is a standard window geometry string with the following syntax: [=][*Width*x*Height*][{+-}*XOffset*{+-}*YOffset*] If the offsets are not provided, the **iconPlacement** policy is used to determine the initial placement. The units for width and height are columns and rows. The actual screen size of the icon box window depends on the **iconImageMaximum** (size) and **iconDecoration** resources. The default value for size is (6 times **iconWidth** + padding) wide by (1 times **iconHeight** + padding) high. The default value of the location is +0 -0.
iconBoxName (class **IconBoxName**)	Specifies the name that is used to look up icon box resources. The default name is **iconbox**.

Item	Description
iconBoxSBDisplayPolicy (class **IconBoxSBDisplayPolicy**)	Specifies the scroll bar display policy of the window manager in the icon box. The resource has the following three possible values: all, vertical, and horizontal. The default value, all, causes both vertical and horizontal scroll bars always to be displayed. The vertical value causes a single vertical scroll bar to be displayed in the icon box and sets the orientation of the icon box to horizontal (regardless of the **iconBoxGeometry** specification). The horizontal value causes a single horizontal scroll bar to be displayed in the icon box and sets the orientation of the icon box to vertical (regardless of the **iconBoxGeometry** specification).
iconBoxTitle (class **IconBoxTitle**)	Specifies the name that is used in the title area of the icon box frame. The default value is Icons.
iconClick (class **IconClick**)	Specifies whether the system menu is posted and remains posted when an icon is clicked. The default value is True.
iconDecoration (class **IconDecoration**)	Specifies the general icon decoration. The resource value is label (only the label part is displayed) or image (only the image part is displayed) or label image (both the label and image parts are displayed). A value of activelabel can also be specified to get a label (not truncated to the width of the icon) when the icon is selected. The default icon decoration for icon box icons is that each icon has a label part and an image part (label image). The default icon decoration for standalone icons is that each icon has an active label part, a label part, and an image part (activelabel, label, and image).
iconImageMaximum (class **IconImageMaximum**)	Specifies the maximum size of the icon image. The resource value is *Width* x *Height* (for example, 64x64). The maximum supported size is 128x128. The default value of this resource is 50x50.
iconImageMinimum (class **IconImageMinimum**)	Specifies the minimum size of the icon image. The resource value is *Width* x *Height* (for example, 32x50). The minimum supported size is 16x16. The default value of this resource is 16x16.
iconPlacement (class **IconPlacement**)	Specifies the icon placement scheme to be used. The resource value has the following syntax: *PrimaryLayout SecondaryLayout [Tight]* The layout values are described as one of the following: **top** Lays out the icons from top to bottom. **bottom** Lays out the icons from bottom to top. **left** Lays out the icons from left to right. **right** Lays out the icons from right to left.

Item	Description
	A horizontal (vertical) layout value must not be used for both the *PrimaryLayout* and the *SecondaryLayout* (for example, do not use top for the *PrimaryLayout* and bottom for the *SecondaryLayout*). The *PrimaryLayout* indicates at the time an icon placement is done whether the icon is placed in a row or a column and the direction of placement. The *SecondaryLayout* indicates where to place new rows or columns. For example, the top right value indicates that icons should be placed top to bottom on the screen and that columns should be added from right to left on the screen. The default placement is the left bottom value (icons are placed from left to right on the screen, with the first row on the bottom of the screen, and new rows added from the bottom of the screen to the top of the screen). A tight value places icons with zero spacing between icons. This value is useful for aesthetic reasons, as well as for terminals with small screens. The following is a list of options for **iconPlacement** values: **Icon Placement** **Appropriate Scheme** **From left to right across the top of the screen, new rows below** Left top **From right to left across the top of the screen, new rows below** Right top **From left to right across the bottom of the screen, new rows above** Left bottom **From right to left across the bottom of the screen, new rows above** Right bottom **From bottom to top along the left of the screen, new columns to right** Bottom left **From bottom to top along the right of the screen, new columns to left** Bottom right **From top to bottom along the left of the screen, new columns to right** Top left **From top to bottom along the right of the screen, new columns to left** Top right

AutoKeyFocus *(continued)*

Item	Description
iconPlacementMargin (class **IconPlacementMargin**)	Sets the distance between the edge of the screen and the icons that are placed along the edge of the screen. The value should be greater than or equal to 0. A default value is used if the value specified is invalid. The default value for this resource is equal to the space between icons as they are placed on the screen (this space is based on maximizing the number of icons in each row and column).
interactivePlacement (class **InteractivePlacement**)	Controls the initial placement of new windows on the screen. If the value is True, the pointer shape changes before a new window is placed on the screen to indicate to the user that a position needs to be selected for the upper-left corner of the window. If the value is False, windows are placed according to the initial window configuration attributes. The default value of this resource is False.

Key Bindings

Item	Description
keyBindings (class **KeyBindings**)	Identifies the set of key bindings for window management functions. If specified, these key bindings replace the built-in default bindings. The named set of key bindings is specified in **mwm** resource description file. The default value for this resource is DefaultKeyBindings.
keyboardFocusPolicy (class **KeyboardFocusPolicy**)	Determines the keyboard focus policy. If set to the pointer value, the keyboard focus policy has the keyboard focus set to the client window that contains the pointer (the pointer could also be in the client window decoration that the **mwm** command adds). If set to the explicit value, the policy is to have the keyboard focus set to a client window when the user presses the left mouse button with the pointer on the client window or any part of the associated **mwm** decoration. The default value for this resource is explicit.
limitResize (class **LimitResize**)	Determines whether the user is allowed to resize a window to greater than the maximum size. If this resource is True, the user is not allowed to resize a window to greater than the maximum size. The default value for this resource is True.
lowerOnIconify (class **LowerOnIconify**)	Determines whether a window icon is displayed on the bottom of the window stack when the window is iconified (minimized). A value of False places the icon in the stacking order at the same place as its associated window. The default value of this resource is True.
maximumMaximumSize (class **MaximumMaximumSize**)	Limits the maximum size of a client window as set by the user or client. The resource value is *Width* x *Height* (for example, 1024x1024) where the width and height are in pixels. The default value of this resource is twice the screen width and height.
moveOpaque (class **MoveOpaque**)	Controls whether the actual window is moved or a rectangular outline of the window is moved. A default value of False displays a rectangular outline on move operations.

Key Bindings *(continued)*

Item	Description
moveThreshold (class **MoveThreshold**)	Controls the sensitivity of dragging operations that move windows and icons. The value of this resource is the number of pixels that the locator is moved with a button down before the move operation is initiated. This is used to prevent window and icon movement when you click or double-click and there is unintentional pointer movement with the button down. The default value of this resource is 4 (pixels).
multiScreen (class **MultiScreen**)	Determines whether the **mwm** command manages all the screens on the display. If False, the **mwm** command manages only a single screen. The default value is False.
passButtons (class **PassButtons**)	Indicates whether button press events are passed to clients after they are used to do a window manager function in the client context. If the resource value is False, the button press is not passed to the client. If the value is True, the button press is passed to the client window. The window manager function is done in either case. The default value for this resource is False.
passSelectButton (class **PassSelectButton**)	Indicates whether to pass the select button press events to clients after they are used to do a window manager function in the client context. If the resource value is False, the button press is not passed to the client. If the value is True, the button press is passed to the client window. The window manager function is done in either case. The default value for this resource is True.
positionIsFrame (class **PositionIsFrame**)	Indicates how client window position information (from the **WM_NORMAL_HINTS** property and from configuration requests) is to be interpreted. If the resource value is True, the information is interpreted as the position of the MWM client window frame. If the value is False, it is interpreted as being the position of the client area of the window. The default value of this resource is True.
positionOnScreen (class **PositionOnScreen**)	Indicates that windows should initially be placed (if possible) so that they are not clipped by the edge of the screen (if the resource value is True). If a window is larger than the size of the screen, at least the upper-left corner of the window is on-screen. If the resource value is False, windows are placed in the requested position even if totally off-screen. The default value of this resource is True.
quitTimeout (class **QuitTimeout**)	Specifies the amount of time in milliseconds that the **mwm** command waits for a client to update the **WM_COMMAND** property after the **mwm** command has sent the **WM_SAVE_YOURSELF** message. This protocol is used only for those clients that have a **WM_SAVE_YOURSELF** atom and no **WM_DELETE_WINDOW** atom in the **WM_PROTOCOLS** client window property. The default value of this resource is 1000 (milliseconds). See the **f.kill** function for additional information.

Key Bindings *(continued)*

Item	Description
raiseKeyFocus (class **RaiseKeyFocus**)	Specifies whether a window raised by means of the **f.normalize_and_raise** function also receives the input focus. The default value of this resource is False. This resource is available only when the keyboard input focus policy is set to the explicit value.
resizeBorderWidth (class **ResizeBorderWidth**)	Specifies the width (in pixels) of a client window frame border with resize handles. The specified border width includes the 3-D shadows. The default value is based on the size and resolution of the screen.
resizeCursors (class **ResizeCursors**)	Indicates whether the resize cursors are always displayed when the pointer is in the window size border. If True, the cursors are shown; otherwise, the window manager cursor is shown. The default value is True.
screens (class **Screens**)	Specifies the resource names to use for the screens managed by the **mwm** command. If the **mwm** command is managing a single screen, only the first name in the list is used. If the **mwm** command is managing multiple screens, the names are assigned to the screens in order, starting with screen 0. For example, screen 0 gets the first name and screen 1 gets the second name. Examples of default screen names are 0 and 1.

Item	Description
showFeedback (class **ShowFeedback**)	Controls when feedback information is displayed. It controls both window position and size feedback during move or resize operations and initial client placement. It also controls window manager message and dialog boxes. The value for this resource is a list of names of the feedback options to be enabled or disabled; the names must be separated by a space. If an option is preceded by a minus sign, that option is excluded from the list. The sign of the first item in the list determines the initial set of options. If the sign of the first option is - (a minus sign), the **mwm** command assumes all options are present and starts subtracting from that set. If the sign of the first decoration is + (a plus sign) or is not specified, the **mwm** command starts with no options and builds up a list from the resource. The names of the feedback options are as follows: **all** Shows all feedback (default value). **behavior** Confirms the behavior switch. **kill** Confirms on receipt of the **KILL** signal. **move** Shows position during the move. **none** Shows no feedback. **placement** Shows position and size during initial placement. **quit** Confirms quitting MWM. **resize** Shows size during resize. **restart** Confirms MWM restart. The following command line illustrates the syntax for the **showFeedback** resource: **Mwm*showFeedback: placement resize behavior restart** This resource specification provides feedback for initial client placement and resize, and it enables the dialog boxes to confirm the restart and set behavior functions. It disables feedback for the move function. The default value for this resource is the all value.

Key Bindings *(continued)*

Item	Description
startupKeyFocus (class **StartupKeyFocus**)	Determines whether a window gets the keyboard input focus when the window is mapped (that is, initially managed by the window manager). It is recommended that both the **autoKeyFocus** resource and the **startupKeyFocus** resource be set to a value of True to work with tear-off menus. The default value is True. This resource is available only when the keyboard input focus policy is set to the explicit value.
transientDecoration (class **TransientDecoration**)	Controls the amount of decoration that Mwm puts on transient windows. The decoration specification is exactly the same as for the **clientDecoration** (client-specific) resource. Transient windows are identified by the **WM_TRANSIENT_FOR** property, which is added by the client to indicate a relatively temporary window. The default value for this resource is the menu title value (that is, transient windows have resize borders and a title bar with a window menu button). An application can also specify which decorations the window manager should apply to its windows. If it does so, the window manager applies only those decorations indicated by both the application and the **transientDecoration** resource. Otherwise, the window manager applies only the decorations indicated by the **transientDecoration** resource.
transientFunctions (class **TransientFunctions**)	Indicates which window management functions are applicable (or not applicable) to transient windows. The function specification is exactly the same as for the **clientFunctions** (client-specific) resource. The default value for this resource is **-minimize -maximize**. An application can also specify which functions the window manager should apply to its windows. If it does so, the window manager applies only those functions indicated by both the application and the **transientFunctions** resource. Otherwise, the window manager applies only the functions indicated by the **transientFunctions** resource.
useIconBox (class **UseIconBox**)	Determines whether icons are placed in an icon box. If this resource is given a value of True, icons are placed in an icon box. When an icon box is not used, the icons are placed on the root window (default value).
wMenuButtonClick (class **WMenuButtonClick**)	Indicates whether the window menu is posted and remains posted after a click of the mouse when the pointer is over the **Window Menu** button. If the value given this resource is True, the menu remains posted. True is the default value for this resource.
wMenuButtonClick2 (class **WMenuButtonClick2**)	Indicates whether a double-click action on the **Window Menu** button performs an **f.kill** function. When this resource is given the default value of True, a double-click action on the **Window Menu** button performs an **f.kill** function.

Client-Specific Resources

The syntax for specifying client-specific resources is as follows:

Mwm*ClientNameOrClass******ResourceID*

For example, `Mwm*mterm*windowMenu` is used to specify the window menu to be used with `mterm` clients.

The syntax for specifying client-specific resources for all classes of clients is as follows:

Mwm*ResourceID*

Specific client specifications take precedence over the specifications for all clients. For example, **Mwm*windowMenu** is used to specify the window menu to be used for all classes of clients that do not have a window menu specified.

The syntax for specifying resource values for windows that have an unknown name and class (that is, windows that do not have a **WM_CLASS** property associated with them) is as follows:

Mwm*defaults*ResourceID*

For example, **Mwm*defaults*iconImage** is used to specify the icon image to be used for windows that have an unknown name and class.

Client-Specific Resource Set

Note: Hyphens in the following table are for readability purposes only. Do not include hyphens within names in programs.

Client-Specific Resource Set	
Name	**Properties**
`clientDecoration`	**Class** `ClientDecoration` **Value type** all **Default**
`clientFunctions`	**Class** `ClientFunctions` **Value type** string **Default** all
`focusAutoRaise`	**Class** `FocusAutoRaise` **Value type** True or False **Default** varies

Client-Specific Resource Set *(continued)*	
Name	**Properties**
iconImage	**Class** IconImage **Value type** pathname **Default** (image)
iconImageBackground	**Class** Background **Value type** color **Default** icon background
iconImageBottomShadowColor	**Class** Foreground **Value type** color **Default** icon bottom shadow
iconImageBottomShadowPixmap	**Class** BottomShadowPixmap **Value type** color **Default** icon bottom shadow pixmap
iconImageForeground	**Class** Foreground **Value type** color **Default** varies
iconImageTopShadowColor	**Class** Background **Value type** color **Default** icon top shadow color
iconImageTopShadoPixmap	**Class** TopShadowPixmap **Value type** color **Default** icon top shadow pixmap

Client-Specific Resource Set *(continued)*	
Name	**Properties**
matteBackground	**Class** Background **Value type** color **Default** background
matteBottomShadowColor	**Class** Foreground **Value type** color **Default** bottom shadow color
matteBottomShadowPixmap	**Class** BottomShadowPixmap **Value type** color **Default** bottom shadow pixmap
matteForeground	**Class** Foreground **Value type** color **Default** foreground
matteTopShadowColor	**Class** Background **Value type** color **Default** top shadow color
matteTopShadowPixmap	**Class** TopShadowPixmap **Value type** color **Default** top shadow pixmap
matteWidth	**Class** MatteWidth **Value type** pixels **Default** 0

Client-Specific Resource Set *(continued)*	
Name	**Properties**
`maximumClientSize`	**Class** `MaximumClientSize` **Value type** width x height, vertical, horizontal **Default** fill the screen
`useClientIcon`	**Class** `UseClientIcon` **Value type** True or False **Default** F
`usePPosition`	**Class** `UsePPosition` **Value type** string **Default** nonzero
`windowMenu`	**Class** `WindowMenu` **Value type** string **Default** DefaultWindowMenu

Item	Description
clientDecoration (class **ClientDecoration**)	Controls the amount of window frame decoration. The resource is specified as a list of decorations to specify their inclusion in the frame. If a decoration is preceded by **-** (a minus sign), that decoration is excluded from the frame. The sign of the first item in the list determines the initial amount of decoration. If the sign of the first decoration is a minus sign, the **mwm** command assumes all decorations are present and starts subtracting from that set. If the sign of the first decoration is plus (or not specified), the **mwm** command starts with no decoration and builds up a list from the resource. An application can also specify which decorations the **mwm** command should apply to its windows. If it does so, the **mwm** command applies only those decorations indicated by both the application and the **clientDecoration** resource. Otherwise, the **mwm** command applies the decorations indicated by the **clientDecoration** resource. Following is a list of window frame decorations: **all** Specifies to include all decorations (default value). **border** Specifies the window border. **maximize** Specifies the Maximize button (includes title bar). **minimize** Specifies the Minimize button (includes title bar). **none** Specifies no decorations. **resizeh** Specifies the border resize handles (includes border). **menu** Specifies the Window Menu button (includes title bar). **title** Specifies the title bar (includes border). Following are examples of window frame decoration commands: `Mwm*XClock.clientDecoration: -resizeh -maximize` This removes the resize handles and Maximize button from XClock windows. `Mwm*XClock.clientDecoration: menu minimize border` This removes the resize handles and Maximize button from XClock windows. Note that either `menu` or `minimize` implies title.

Item	Description
clientFunctions (class **ClientFunctions**)	Indicates which **mwm** functions are applicable (or not applicable) to the client window. The value for the resource is a list of functions. If the first function in the list has - (a minus sign) in front of it, the **mwm** command starts with all functions and subtracts from that set. If the first function in the list has a + (plus sign) in front of it, the **mwm** command starts with no functions and builds up a list. Each function in the list must be preceded by the appropriate + (plus) or - (minus) sign and separated from the next function by a space. An application can also specify which functions the **mwm** command should apply to its windows. If it does so, the **mwm** command applies only those functions indicated by both the application and the **clientFunctions** resource. Otherwise, the **mwm** command applies the functions indicated by the **clientFunctions** resource. Following is a list of functions available for this resource: **all** Specifies to include all functions (default value). **none** Specifies no functions. **resize** Specifies **f.resize**. **move** Specifies **f.move**. **minimize** Specifies **f.minimize**. **maximize** Specifies **f.maximize**. **close** Specifies **f.kill**.
focusAutoRaise (class **FocusAutoRaise**)	Determines whether clients are raised when they get the keyboard input focus. If the value is False, the stacking of windows on the display is not changed when a window gets the keyboard input focus. The default value is True when the **keyboardFocusPolicy** is the explicit value and False when the **keyboardFocusPolicy** is the pointer value.
iconImage (class **IconImage**)	Specifies an icon image for a client (for example, **Mwm*myclock*iconImage**). The resource value is a path name for a bitmap file. The value of the (client-specific) **useClientIcon** resource is used to determine whether user-supplied icon images are used instead of client-supplied icon images. The default value is to display a built-in window manager icon image.
iconImageBackground (class **Background**)	Specifies the background color of the icon image that is displayed in the image part of an icon. The default value of this resource is the icon background color (that is, specified by **Mwm*background** or **Mwm*icon*background**).
iconImageBottomShadowColor (class **Foreground**)	Specifies the bottom shadow color of the icon image that is displayed in the image part of an icon. The default value of this resource is the icon bottom shadow color (that is, specified by **Mwm*icon*bottomShadowColor**).
iconImageBottomShadowPixmap (class **BottomShadowPixmap**)	Specifies the bottom shadow pixmap of the icon image that is displayed in the image part of an icon. The default value of this resource is the icon bottom shadow pixmap (that is, specified by **Mwm*icon*bottomShadowPixmap**).
iconImageForeground (class **Foreground**)	Specifies the foreground color of the icon image that is displayed in the image part of an icon. The default value of this resource varies depending on the icon background.
iconImageTopShadowColor (class **Background**)	Specifies the top shadow color of the icon image that is displayed in the image part of an icon. The default value of this resource is the icon top shadow color (that is, specified by **Mwm*icon*topShadowColor**).
iconImageTopShadowPixmap (class **TopShadowPixmap**)	Specifies the top shadow pixmap of the icon image that is displayed in the image part of an icon. The default value of this resource is the icon top shadow pixmap (that is, specified by **Mwm*icon*topShadowPixmap**).
matteBackground (class **Background**)	Specifies the background color of the matte when the **matteWidth** resource is a positive value. The default value of this resource is the client background color (that is, specified by **Mwm*background** or **Mwm*client*background**).

Client Decoration *(continued)*

Item	Description
matteBottomShadowColor (class **Foreground**)	Specifies the bottom shadow color of the matte when the **matteWidth** resource is a positive value. The default value of this resource is the client bottom shadow color (that is, specified by **Mwm*bottomShadowColor** or **Mwm*client*bottomShadowColor**).
matteBottomShadowPixmap (class **BottomShadowPixmap**)	Specifies the bottom shadow pixmap of the matte when the **matteWidth** resource is a positive value. The default value of this resource is the client bottom shadow pixmap (that is, specified by **Mwm*bottomShadowPixmap** or **Mwm*client*bottomShadowPixmap**).
matteForeground (class **Foreground**)	Specifies the foreground color of the matte when the **matteWidth** resource is a positive value. The default value of this resource is the client foreground color (that is, specified by **Mwm*foreground** or **Mwm*client*foreground**).
matteTopShadowColor (class **Background**)	Specifies the top shadow color of the matte when the **matteWidth** resource is a positive value. The default value of this resource is the client top shadow color (that is, specified by **Mwm*topShadowColor** or **Mwm*client*topShadowColor**).
matteTopShadowPixmap (class **TopShadowPixmap**)	Specifies the top shadow pixmap of the matte when the **matteWidth** resource is a positive value. The default value of this resource is the client top shadow pixmap (that is, specified by **Mwm*topShadowPixmap** or **Mwm*client*topShadowPixmap**).
matteWidth (class **MatteWidth**)	Specifies the width of the optional matte. The default value is 0, which effectively disables the matte.
maximumClientSize (class **MaximumClientSize**)	Indicates the client size to be used when an application is maximized. The resource value is specified *Width*x*Height*. The width and height are interpreted in the units that the client uses (for example, this is generally characters for terminal emulators). Alternately, the vertical or horizontal value can be specified to indicate the direction in which the client maximizes. If this resource is not specified, the maximum size from the **WM_NORMAL_HINTS** property is used if set. Otherwise, the default value is the size where the client window with window management borders fills the screen. When the maximum client size is not determined by the **maximumClientSize** resource, the **maximumMaximumSize** resource value is used as a constraint on the maximum size.
useClientIcon (class **UseClientIcon**)	Determines whether a client-supplied icon image takes precedence over a user-supplied icon image. The default value is False, giving the user-supplied icon image higher precedence than the client-supplied icon image.
usePPosition (class **UsePPosition**)	Specifies whether the window manager honors the program-specified position **PPosition** specified in the **WM_NORMAL_HINTS** property in the absence of a user-specified position. Setting this resource to On causes the **mwm** command to always honor the program-specified position. Setting this resource to Off causes the **mwm** command to always ignore the program-specified position. Setting this resource to the default value of nonzero causes the **mwm** command to honor program-specified positions other than (0,0).
windowMenu (class **WindowMenu**)	Indicates the name of the menu pane that is posted when the window menu is opened (usually by pressing button 1 on the Window Menu button on the client window frame). Menu panes are specified in the **mwm** resource description file. Window menus can be customized on a client class basis by specifying resources of the form **Mwm***_ClientNameOrClass_***windowMenu** (See mwm Resource Description File Syntax for more information.) The default value of this resource is DefaultWindowMenu.

Resource Description File

The **mwm** resource description file is a supplementary resource file that contains resource descriptions that are referred to by entries in the defaults files (**.Xdefaults**, **app-defaults/Mwm**). It contains descriptions of resources that are to be used by the **mwm** command and that cannot be easily encoded in the defaults files (a bitmap file is an analogous type of resource description file). A particular **mwm** resource description file can be selected using the **configFile** resource.

The following types of resources can be described in the **mwm** resource description file:

Resource Description

Item	Description
buttons	Window manager functions can be bound (associated) with button events.
keys	Window manager functions can be bound (associated) with key press events.
menus	Menu panes can be used for the window menu and other menus posted with key bindings and button bindings.

mwm Resource Description File Syntax

The **mwm** resource description file is a standard text file that contains items of information separated by blanks, tabs, and new-line characters. Blank lines are ignored. Items or characters can be quoted to avoid special interpretation (for example, the # (comment character) can be quoted to prevent it from being interpreted as the comment character). A quoted item can be contained in " " (double quotation marks). Single characters can be quoted by preceding them with the \ (backslash). All text from an unquoted # (comment character) to the end of the line is regarded as a comment and is not interpreted as part of a resource description. If an ! (exclamation mark) is the first character in a line, the line is regarded as a comment. If a line ends in a \ (backslash), the next line is considered a continuation of that line.

Window manager functions can be accessed with button and key bindings and with window manager menus. Functions are indicated as part of the specifications for button and key binding sets and for menu panes. The function specification has the following syntax:

```
Function = FunctionName [FunctionArguments]
FunctionName = Window Manager Function
FunctionArguments = {QuotedItem | UnquotedItem}
```

The following functions are supported. If a function is specified that is not one of the supported functions, it is interpreted by the **mwm** command as the **f.nop** function.

Resource Description File Syntax

Item	Description
f.beep	Causes a beep.
f.circle_down [*Icon* | *Window*]	Causes the window or icon that is on the top of the window stack to be put on the bottom of the window stack (so that it no longer obscures any other window or icon). This function affects only those windows and icons that obscure other windows and icons or that are obscured by other windows and icons. Secondary windows (that is, transient windows) are restacked with their associated primary window. Secondary windows always stay on top of the associated primary window and there can be no other primary windows between the secondary windows and their primary window. If an *Icon* function argument is specified, the function applies only to icons. If a *Window* function argument is specified, the function applies only to windows.

Item	Description
f.circle_up [*Icon* | *Window*]	Raises the window or icon on the bottom of the window stack (so that it is not obscured by any other windows). This function affects only those windows and icons that obscure other windows and icons or that are obscured by other windows and icons. Secondary windows (that is, transient windows) are restacked with their associated primary window. If an *Icon* function argument is specified, the function applies only to icons. If a *Window* function argument is specified, the function applies only to windows.
f.exec or **!**	Causes the command to be run (using the value of the **MWMSHELL** environment variable if it is set; otherwise, the value of the **SHELL** environment variable if it is set; otherwise, **/usr/bin/sh** is used). The ! notation can be used in place of the **f.exec** function name.
f.focus_color	Sets the colormap focus to a client window. If this function is done in a root context, the default colormap (set up by the X Window System client for the screen where MWM is running) is installed and there is no specific client window colormap focus. This function is treated as **f.nop** if **colormapFocusPolicy** is not set to the explicit value.
f.focus_key	Sets the keyboard input focus to a client window or icon. This function is treated as **f.nop** if **keyboardFocusPolicy** is not set to the explicit value or the function is run in a root context.
f.kill	Stops a client. If the **WM_DELETE_WINDOW** protocol is set up, the client is sent a client message event indicating that the client window needs to be deleted. If the **WM_SAVE_YOURSELF** protocol is set up and the **WM_DELETE_WINDOW** protocol is not set up, the client is sent a client message event indicating that the client needs to prepare to be stopped. If the client does not have the **WM_DELETE_WINDOW** or **WM_SAVE_YOURSELF** protocol set up, this function causes a client's X connection to be stopped (usually resulting in the end of the client). See the description of the **quitTimeout** resource.
f.lower [-*Client* | **within** | **freeFamily**]	Lowers a client window to the bottom of the window stack (where it obscures no other window). Secondary windows (that is, transient windows) are restacked with their associated primary window. The *Client* argument indicates the name or class of a client to lower. If the *Client* argument is not specified, the context, in which the function was started, indicates the window or icon to lower.

Item	Description
f.maximize	Causes a client window to be displayed with its maximum size.
f.menu	Associates a cascading (pull-right) menu with a menu pane entry or a menu with a button or key binding. The **menu_name** function argument identifies the menu to be used.
f.minimize	Causes a client window to be iconified (minimized). When a window is minimized and no icon box is used, its icon is placed on the bottom of the window stack (so that it obscures no other windows). If an icon box is used, the client's icon changes to its iconified form inside the icon box. Secondary windows (that is, transient windows) are minimized with their associated primary window. There is only one icon for a primary window and all its secondary windows.
f.move	Causes a client window to be interactively moved.
f.next_cmap	Installs the next colormap in the list of colormaps for the window with the colormap focus.
f.next_key [*Icon* | *Window* | *Transient*]	Sets the keyboard input focus to the next window or icon in the set of windows and icons managed by the window manager (the ordering of this set is based on the stacking of windows on the screen). This function is treated as **f.nop** if **keyboardFocusPolicy** is not the explicit value. The keyboard input focus is moved only to windows that do not have an associated secondary window that is application-modal. If the *Transient* argument is specified, transient (secondary) windows are crossed (otherwise, if only the *Window* argument is specified, traversal is done only to the last focused window in a transient group). If an *Icon* function argument is specified, the function applies only to icons. If a *Window* function argument is specified, the function applies only to windows.
f.nop	Does nothing. If a function is specified in a type of resource where it is not supported or is started in a context that does not apply, the function is treated as **f.nop**.
f.normalize	Causes a client window to be displayed with its normal size. Secondary windows (that is, transient windows) are placed in their normal state along with their associated primary window.
f.normalize_and_raise	Causes the corresponding client window to be displayed with its normal size and raised to the top of the window stack. Secondary windows (that is, transient windows) are placed in their normal state along with their associated primary window.

Item	Description
f.pack_icons	Causes icons to be packed into the icon grid. This function is used to relay out icons (based on the layout policy being used) on the root window or in the icon box.
f.pass_keys	Enables or disables (toggles) processing of key bindings for window manager functions. When it disables key binding processing, all keys are passed on to the window with the keyboard input focus and no window manager functions are started. If the **f.pass_keys** function is started with a key binding to disable key-binding processing, the same key binding can be used to enable key-binding processing.
f.post_wmenu	Posts the window menu. If a key is used to post the window menu and the Window Menu button is present, the window menu is automatically placed with its top-left corner at the bottom-left corner of the Window Menu button for the client window. If no Window Menu button is present, the window menu is placed at the top-left corner of the client window.
f.prev_cmap	Installs the previous colormap in the list of colormaps for the window with the colormap focus.
f.prev_key [*Icon* | *Window* | *Transient*]	Sets the keyboard input focus to the previous window or icon in the set of windows and icons managed by the window manager (the ordering of this set is based on the stacking of windows on the screen). This function is treated as **f.nop** if **keyboardFocusPolicy** is not the explicit value. The keyboard input focus is moved only to windows that do not have an associated secondary window that is application-modal. If the *Transient* argument is specified, transient (secondary) windows are crossed (otherwise, if only window is specified, traversal is done only to the last focused window in a transient group). If an *Icon* function argument is specified, the function applies only to icons. If a *Window* function argument is specified, the function applies only to windows.
f.quit_mwm	Stops the **mwm** command (but *not* the X Window System client).

Item	Description
f.raise [*-Client* | **within** | **freeFamily**]	Raises a client window to the top of the window stack (where it is obscured by no other window). Raises the secondary window (transient window or dialog box) within the client family. The arguments to this function are mutually exclusive. The *Client* argument indicates the name or class of a client to raise. If the *Client* argument is not specified, the context in which the function was started indicates the window or icon to raise. Specifying **within** raises the secondary window within the family but does not raise the client family in the global window stack. Specifying **freeFamily** raises the window to the top of its local family stack and raises the family to the top of the global window stack.
f.raise_lower [**within** | **freeFamily**]	Raises a primary window to the top of the window stack if it is partially obscured by another window; otherwise, it lowers the window to the bottom of the window stack. The arguments to this function are mutually exclusive. Specifying **within** raises a secondary window within the family (staying above the parent window), if it is partially obscured by another window in the application's family; otherwise, it lowers the window to the bottom of the family stack. It has no effect on the global stacking order. Specifying **freeFamily** raises the window to the top of its local family stack, if obscured by another window, and raises the family to the top of the global window stack; otherwise, it lowers the window to the bottom of its local family stack and lowers the family to the bottom of the global window stack.
f.refresh	Causes all windows to be redrawn.
f.refresh_win	Causes a client window to be redrawn.
f.resize	Causes a client window to be interactively resized.
f.restart	Causes the **mwm** command to be restarted (effectively stopped and restarted).
f.restore	Restores the previous state of an icon's associated window. If a maximized window is iconified, the **f.restore** function restores it to its maximized state. If a normalized window is iconified, the **f.restore** function restores it to its normalized state.

Item	Description
f.restore_and_raise	Restores the previous state of an icon's associated window and raises the window to the top of the window stack. If a maximized window is iconified, the **f.restore_and_raise** function restores it to its maximized state and raises it to the top of the window stack. If a normalized window is iconified, the **f.restore_and_raise** function restores it to its normalized state and raises it to the top of the window stack.
f.screen [**next** | **prev** | **back** | *ScreenNumber*]	Causes the pointer to warp to a specific screen number or to the next, previous, or last visited screen. The arguments to this function are mutually exclusive. The following arguments are available: ***ScreenNumber*** Indicates the screen number to which the pointer is warped. Screens are numbered starting from screen 0. **next** Warps the pointer to the next managed screen (skipping over any unmanaged screens). **prev** Warps the pointer to the previous managed screen (skipping over any unmanaged screens). **back** Warps the pointer to the last visited screen.
f.send_msg *MessageNumber*	Sends a client message of the **_MOTIF_WM_MESSAGES** type with the *MessageType* indicated by the *MessageNumber* function argument. The client message is sent only if *MessageNumber* is included in the client's **_MOTIF_WM_MESSAGES** property. A menu item label is unavailable if the menu item is used to perform the **f.send_msg** function of a message that is not included in the client's **_MOTIF_WM_MESSAGES** property.
f.separator	Causes a menu separator to be put in the menu pane at the specified location (the label is ignored).

Resource Description File Syntax *(continued)*

Item	Description
f.set_behavior	Causes the window manager to restart with the default behavior (if a custom behavior is configured) or revert to the custom behavior. By default this is bound to the Shift+Ctrl+Meta+! key sequence. The Meta+Shift+Ctrl+! key sequence switches (that is, toggles) between the default and custom behaviors. When the user switches to the default MWM behavior, a number of **mwm** resources assume their default values and the **mwm** command restarts. When the user switches back to the custom behavior, the resource values that were changed to default values are reset with the custom values and the **mwm** command restarts. When an **f.set_behavior** function is performed, the following user interaction occurs: 1. A system-modal dialog box is displayed prompting the user for confirmation of the **f.set_behavior** action. 2. The user can cancel the action at this point. 3. The window manager restarts. 4. The window manager applies the new (custom or default) configuration values. 5. Window manager components are mapped. When the default MWM behavior is being set, default resource values are applied and, if specified, client properties that control window manager behavior are applied. This includes the **_MOTIF_WM_HINTS** and **_MOTIF_WM_MENU** properties. These properties might alter default MWM behavior, but it is done in a way that is consistent for all users.
f.title	Inserts a title in the menu pane at the specified location.

Function Contexts

Each function may be constrained as to which resource types can specify the function (for example, menu pane) and also what context the function can be used in (for example, the function is done to the selected client window). The following are the function contexts:

Function contexts

Item	Description
root	No client window or icon is selected as an object for the function.
window	A client window is selected as an object for the function. This includes the window's title bar and frame. Some functions are applied only when the window is in its normalized state (for example, **f.maximize**) or its maximized state (for example, **f.normalize**).
icon	An icon is selected as an object for the function.

If a function's context is specified as **icon**|**window** and the function is started in an icon box, the function applies to the icon box, not to the icons inside.

If a function is specified in a type of resource where it is not supported or is started in a context that does not apply, the function is treated as **f.nop**. The following table indicates the resource types and function contexts in which window manager functions apply:

Function contexts		
Function	**Contexts**	**Resources**
f.beep	root, icon, window	button, key, menu
f.circle_down	root, icon, window	button, key, menu
f.circle_up	root, icon, window	button, key, menu
f.exec	root, icon, window	button, key, menu
f.focus_color	root, icon, window	button, key, menu
f.focus_key	root, icon, window	button, key, menu
f.kill	icon, window	button, key, menu
f.lower	icon, window	button, key, menu
f.maximize	icon, window (normal)	button, key, menu
f.menu	root, icon, window	button, key, menu
f.minimize	window	button, key, menu
f.move	icon, window	button, key, menu
f.next_cmap	root, icon, window	button, key, menu
f.next_key	root, icon, window	button, key, menu
f.nop	root, icon, window	button, key, menu

Normalize item description		
Item	**Description**	
f.normalize	icon, window (maximized)	button, key, menu
f.normalize_and_raise	icon, window	button, key, menu
f.pack_icons	root, icon, window	button, key, menu
f.pass_keys	root, icon, window	button, key, menu
f.post_wmenu	root, icon, window	button, key
f.prev_cmap	root, icon, window	button, key, menu
f.prev_key	root, icon, window	button, key, menu
f.quit_mwm	root, icon, window	button, key, menu (root only)
f.raise	icon, window	button, key, menu
f.raise_lower	icon, window	button, key, menu
f.refresh	root, icon, window	button, key, menu
f.refresh_win	window	button, key, menu
f.resize	window	button, key, menu

Normalize item description *(continued)*		
Item	**Description**	
f.restart	root, icon, window	button, key, menu
f.restore	icon, window	button, key, menu
f.restore_and_raise	icon, window	button, key, menu
f.screen	root, icon, window	button, key, menu
f.send_msg	icon, window	button, key, menu
f.separator	root, icon, window	menu
f.set_behavior	root, icon, window	button, key, menu
f.title	root, icon, window	menu

Window Manager Event Specification

Events are indicated as part of the specifications for button and key-binding sets and for menu panes.

Button events have the following syntax:

```
Button = [ModifierList]<ButtonEventName>
ModifierList = Modifier Name {ModifierName}
```

All modifiers specified are interpreted as being exclusive (this means that only the specified modifiers can be present when the button event occurs). Following is a list that indicates the values that can be used for the *ModifierName* parameter. The Alt key is frequently labeled Extend or Meta. Alt and Meta can be used interchangeably in event specification.

Window Manager Event Specification

Item	**Description**
Modifier	**Description**
Ctrl	Control key
Shift	Shift key
Alt	Alt or Meta key
Meta	Meta or Alt key
Lock	Lock key
Mod1	Modifier1
Mod2	Modifier2
Mod3	Modifier3
Mod4	Modifier4
Mod5	Modifier5

Following is a list that indicates the values that can be used for the *ButtonEventName* parameter.

Button Event Name descriptions

Button	**Description**
Btn1Down	Button 1 press

Button Event Name descriptions *(continued)*

Button	Description
Btn1Up	Button 1 release
Btn1Click	Button 1 press and release
Btn1Click2	Button 1 double click
Btn2Down	Button 2 press
Btn2Up	Button 2 release
Btn2Click	Button 2 press and release
Btn2Click2	Button 2 double click
Btn3Down	Button 3 press
Btn3Up	Button 3 release
Btn3Click	Button 3 press and release
Btn3Click2	Button 3 double click
Btn4Down	Button 4 press
Btn4Up	Button 4 release
Btn4Click	Button 4 press and release
Btn4Click2	Button 4 double click
Btn5Down	Button 5 press
Btn5Up	Button 5 release
Btn5Click	Button 5 press and release
Btn5Click2	Button 5 double click.

Key events that are used by the window manager for menu mnemonics and for binding to window manager functions are single key presses; key releases are ignored. Key events have the following syntax:

```
Key = [ModifierList] <Key> KeyName
ModifierList = ModifierName {ModifierName}
```

All modifiers specified are interpreted as being exclusive (this means that only the specified modifiers can be present when the key event occurs). Modifiers for keys are the same as those that apply to buttons. The *KeyName* parameter is an X11 keysym name. Key symbol names can be found in the **keysymdef.h** file (remove the *XK_* prefix).

The key symbol names will be resolved to a single specific key code by the Window Manager during startup and will not change unless the Window Manager is restarted.

Button Bindings

The **buttonBindings** resource value is the name of a set of button bindings that are used to configure window manager behavior. A window manager function can be used when a button press occurs with the pointer over a framed client window, an icon, or the root window. The context for indicating where the button press applies is also the context for starting the window manager function when the button press is done (significant for functions that are context-sensitive).

Following is the button binding syntax:

```
Buttons BindingsSetName
        {
```

```
Button Context Function
Button Context Function
                .
                .
Button Context Function
        }
```

Following is the syntax for the context specification:

```
Context = Object[|Context]
Object = root | icon | window | title | frame | border | app
```

The *Context* specification indicates where the pointer must be for the button binding to be effective. For example, a context of **window** indicates that the pointer must be over a client window or window management frame for the button binding to be effective. The **frame** context is for the window management frame around a client window (including the border and title bar), the **border** context is for the border part of the window management frame (not including the title bar), the **title** context is for the title area of the window management frame, and the **app** context is for the application window (not including the window management frame).

If an **f.nop** function is specified for a button binding, the button binding is not done.

Key Bindings

The **keyBindings** resource value is the name of a set of key bindings that are used to configure window manager behavior. A window manager function can be done when a particular key is pressed. The context in which the key binding applies is indicated in the key binding specification. The valid contexts are the same as those that apply to button bindings.

Following is the key binding syntax:

```
Keys BindingsSetName
{
Key Context Function
Key Context Function
                .
                .
Key Context Function
}
```

If an **f.nop** function is specified for a key binding, the key binding is not done. If an **f.post_wmenu** or **f.menu** function is bound to a key, the **mwm** command automatically uses the same key for removing the menu from the screen after it is open.

The *Context* specification syntax is the same as for button bindings. For key bindings, the **frame**, **title**, **border**, and **app** contexts are equivalent to the **window** context. The context for a key event is the window or icon that has the keyboard input focus (**root** if no window or icon has the keyboard input focus).

Menu Panes

Menus can be opened using the **f.post_wmenu** and **f.menu** window manager functions. The context for window manager functions that are done from a menu is **root**, **icon**, or **window**, depending on how the menu is opened. In the case of the window menu or menus opened with a key binding, the location of the keyboard input focus indicates the context. For menus opened using a button binding, the context of the button binding is the context of the menu.

Following is the menu pane specification syntax:

```
Menu MenuName
{
Label [Mnemonic] [Accelerator] Function
Label [Mnemonic] [Accelerator] Function
```

```
                .
                .
Label [Mnemonic] [Accelerator] Function
}
```

Each line in the *Menu* specification identifies the label for a menu item and the function to be completed if the menu item is selected. Optionally, a menu button mnemonic and a menu button keyboard accelerator can be specified. Mnemonics are functional only when the menu is posted and keyboard traversal applies.

The label can be a string or a bitmap file. The *Label* specification has the following syntax:

```
Label = Text | BitmapFile
BitmapFile = @FileName
Text = QuotedItem | UnquotedItem
```

The string encoding for labels must be compatible with the menu font that is used. Labels are not available for menu items that use the **f.nop** function, an invalid function, or a function that does not apply in the current context.

A *Mnemonic* specification has the following syntax:

```
Mnemonic = _Character
```

The first matching *Character* in the label is underlined. If there is no matching *Character* in the label, no mnemonic is registered with the window manager for that label. Although the *Character* must exactly match a character in the label, the mnemonic does not perform if any modifier (such as the Shift key) is pressed with the character key.

The *Accelerator* specification is a key event specification with the same syntax that is used for key bindings to window manager functions.

Environment

The **mwm** command does the following:

- Uses the **HOME** environment variable to specify the user's home directory.
- Uses the **LANG** environment variable to specify the user's choice of language for the **mwm** message catalog and the **mwm** resource description file.
- Uses the **XFILESEARCHPATH**, **XUSERFILESEARCHPATH**, **XAPPLRESDIR**, **XENVIRONMENT**, **LANG**, and **HOME** environment variables to determine search paths for resource defaults files. The **mwm** command can also use the **XBMLANGPATH** environment variable to search for bitmap files.
- Reads the **$HOME/.motifbind** file, if it exists, to install a virtual key bindings property on the root window.
- Uses the **MWMSHELL** environment variable (or **SHELL** if **MWMSHELL** is not set) to specify the shell to use when running commands through the **f.exec** function.

Exit Status

This command returns the following exit values:

Exit Status

Item	Description
0	Indicates successful completion.
>1	Indicates an error occurred.

Files

/usr/lib/X11/$LANG/system.mwmrc

/usr/lib/X11/system.mwmrc

/usr/lib/X11/app-defaults/Mwm

$HOME/Mwm

$HOME/.Xdefaults

$HOME/$LANG/.mwmrc

$HOME/.mwmrc

$HOME/.motifbind

n

The following AIX commands begin with the letter *n*.

named Daemon

Purpose

Provides the server function for the Domain Name Protocol.

Syntax

Refer to the syntax for either the **named8** or the **named9** daemon.

Description

AIX 7.1 supports only BIND version 9. By default, named links to nsupdate to nsupdate4, named-xfer to named-xfer4. To use a different version of named, you must relink the symbolic links accordingly for the named and named-xfer daemons.

For example, to use named8:

```
ln -fs /usr/sbin/named8 /usr/sbin/named
ln -fs /usr/sbin/named8-xfer /usr/sbin/named-xfer
```

nsupdate4 can be used with named8, but nsupdate9 must be used with named9 because the security process is different. It does not matter what named-xfer is linked to when using named9 because the daemon does not use it.

Files

Item	Description
/usr/sbin/named	Contains the **named** daemon.
/usr/sbin/named9	Contains the **named9** daemon.
/etc/resolv.conf	Specifies the use of domain name services.
/etc/services	Defines socket service assignments.
/usr/samples/tcpip/named.boot	Contains the sample **named.boot** file with directions for its use.
/usr/samples/tcpip/named.data	Contains the sample DOMAIN data file with directions for its use.
/usr/samples/tcpip/hosts.awk	Contains the sample **awk** script for converting an **/etc/hosts** file to an **/etc/named.rev** file. This file also contains directions for its use.
/usr/samples/tcpip/named.dynamic	Contains a dynamic database setup.

named-checkconf Command

Purpose

Syntax checking tool of a named configuration file.

Syntax

named-checkconf [**-v**] [**-j**] [**-t** *directory*] *filename* [**-z**]

Description

The **named-checkconf** command checks the syntax, but not the semantics, of a named configuration file.

Flags

Item	Description
-j	Reads the journal if it exists when loading a zonefile.
-t *directory*	Changes the present directory to the directory specified so that included directives in the configuration file are processed.
-v	Prints the version of the **named-checkconf** program and exits.
-z	Performs a check and loads the master zone files found in the **named.conf** file.
filename	Specifies the name of the configuration file to be checked. If not specified, the default value is **/etc/named**.

Exit Status

Item	Description
0	Indicates a successful completion.
1	Indicates errors.

named-checkzone, named-compilezone Commands

Purpose

Zone file validity checking or converting tool of a named configuration file.

Syntax

named-checkzone [**-d**] [**-j**] [**-q**] [**-v**] [**-c** *class*] [**-f** *format*] [**-F** *format*] [**-i** *mode*] [**-k** *mode*] [**-m** *mode*] [**-M** *mode*] [**-n** *mode*] [**-o** *filename*] [**-s** *style*] [**-S** *mode*] [**-t** *directory*] [**-w** *directory*] [**-D**] [**-W** *mode*] *zonename filename*

named-compilezone [**-d**] [**-j**] [**-q**] [**-v**] [**-c** *class*] [**-f** *format*] [**-F** *format*] [**-i** *mode*] [**-k** *mode*] [**-m** *mode*] [**-n** *mode*] [**-o** *filename*] [**-s** *style*] [**-t** *directory*] [**-w** *directory*] [**-D**] [**-W** *mode*] *zonename filename*

Description

The **named-checkzone** command checks the syntax and integrity of a zone file. It performs the same checks as the **named** daemon does when loading a zone. This makes the **named-checkzone** command useful for checking zone files before configuring them into a name server.

The **named-compilezone** command is similar to the **named-checkzone** command, but it always dumps the zone contents to a specified file in a specified format. Additionally, it applies stricter check levels by default, since the dump output will be used as an actual zone file loaded by the named daemon. When manually specified otherwise, the check levels must at least be as strict as those specified in the named configuration file.

Flags

Item	Description
-c *class*	Specifies the class of the zone. If not specified, the class is set to "IN" by default.
-d	Enables debugging.
-D	Dumps zone file in canonical format. This is always enabled for the **named-compilezone** command.
-i *mode*	Performs post load zone integrity checks. The *mode* parameter can be one of the following values: **full** Checks if MX records, SRV records, and delegation NS records refer to A or AAAA record (both in-zone and out-of-zone host names). It also checks if glue addresses records in the zone match those advertised by the child. **full-sibling** Disables sibling glue checks but is otherwise the same as mode **full**. **local** Only checks if MX records, SRV records, and delegation NS records refer to in-zone host names or if some required glue exists, that is when the name server is in a child zone. **local-sibling** Disables sibling glue checks but is otherwise the same as mode **local**. **none** Disables the checks.
-j	Reads the journal if it exists when loading the zone file.
-f *format*	Specifies the format of the zone file. Possible formats are "text" (default) and "raw".
-F *format*	Specifies the format of the output file specified. Possible formats are "text" (default) and "raw". This flag does not cause any effects unless it dumps the zone contents.
-k *mode*	Performs "check-names" checks with the specified failure mode. Possible modes are "fail", "warn" (default) and "ignore".
-m *mode*	Specifies whether MX records must be checked to see if they are addresses. Possible modes are "fail", "warn" (default) and "ignore".
-M *mode*	Checks if a MX record refers to a CNAME. Possible modes are "fail", "warn" (default) and "ignore".
-n *mode*	Specifies whether NS records must be checked to see if they are addresses. Possible modes are "fail", "warn" (default) and "ignore".
-o *filename*	Writes zone output to the file specified by the *filename* value.
-q	Indicates quiet mode (exits code only).
-s *style*	Specifies the style of the dumped zone file. Possible styles are "full" (default) and "relative". The "full" format is most suitable for processing automatically by a separate script. On the other hand, the "relative" format is more human-readable and is thus suitable for editing by hand. This flag does not cause any effects unless it dumps the zone contents. It also does not have any meaning if the output format is not text.

Item	Description
-S *mode*	Checks if a SRV record refers to a CNAME. Possible modes are "fail", "warn" (default) and "ignore".
-t *directory*	Changes the directory to the *directory* so that included directives in the configuration file are processed.
-v	Prints the version of the **named-checkzone** command and exits.
-w *directory*	Changes the current directory to the *directory* so that relative file names in master file $INCLUDE directives work. This is similar to the directory clause in the **named.conf** file.
-W *mode*	Specifies whether to check for non-terminal wildcards. Non-terminal wildcards are almost always the result of a failure to understand the wildcard matching algorithm (RFC 1034). Possible modes are "warn" (default) and "ignore".
zonename	Specifies the domain name of the zone being checked.
filename	Specifies the name of the zone file.

Exit Status

Item	Description
0	Indicates a successful completion.
1	Indicates errors.

named8 Daemon

Purpose

Provides the server function for the Domain Name Protocol.

Syntax

/usr/sbin/named8 [**-d** *DebugLevel*] [**-p** *PortNumber*] [**-c** *ConfFile*] [**-w** *WorkingDirectory*] [**-t** *RootDirectory*] [**-q**] [**-r**] [**-f**]

Description

The **/usr/sbin/named8** daemon is the server for the Domain Name Protocol (DOMAIN). The **named8** daemon runs on name server hosts and controls the domain-name resolution function.

Selection of which name server daemon to use is controlled by the **/usr/sbin/named** and **/usr/sbin/named-xfer** symbolic links.

Note: The **named8** daemon can be controlled using the System Resource Controller (SRC) or the System Management Interface Tool (SMIT). Use the **rc.tcpip** file to start the daemon with each system startup.

The **named8** daemon listens for name-server requests generated by resolver routines running on foreign hosts. The daemon listens to the socket defined in the **/etc/services** file; the entry in the **/etc/services** file begins with `domain`. However, this socket assignment can be overridden using the **-p** flag on the command line.

Note: The **/etc/resolv.conf** file tells the local kernel and resolver routines to use the DOMAIN protocol. The **/etc/resolv.conf** file must exist and contain either the local host's address or the loopback address (127.0.0.1) to use the **named8** daemon on the DOMAIN name server host. If the **/etc/resolv.conf** file does not exist, the local kernel and resolver routines use the **/etc/hosts** database. When this occurs, the **named8** daemon does not function properly.

Manipulating the named8 Daemon with the System Resource Controller

The **named8** daemon is a subsystem controlled by the System Resource Controller (SRC). The **named8** daemon is a member of the **tcpip** system group. This daemon is disabled by default and can be manipulated by the following SRC commands:

Item	Description
startsrc	Starts a subsystem, group of subsystems,or a subserver.
stopsrc	Stops a subsystem, group of subsystems, or a subserver.
refresh	Causes the **named8** daemon to reread the **/etc/named.conf** file. Depending on the contents of the file, the **refresh** command may or may not reload the listed databases.
traceson	Enables tracing of a subsystem, group of subsystems, or a subserver.
tracesoff	Disables tracing of a subsystem, group of subsystems, or a subserver.
lssrc	Gets the status of a subsystem, group of subsystems, or a subserver.

Flags

Item	Description
-b | **-c***ConfFile*	Specifies an alternate configuration file.
-d*DebugLevel*	Provides a debugging option. The **-d** flag causes the **named8** daemon to write debugging information to a file named by default **/var/tmp/named.run**. The *DebugLevel* variable determines the level of messages printed, with valid levels from 1 to 11, where level 11 supplies the most information.
-p*PortNumber*	Reassigns the Internet socket where the **named8** daemon listens for DOMAIN requests. If this variable is not specified, the **named8** daemon listens to the socket defined in the **/etc/services** file; the entry in the **/etc/services** file begins with `domain`.
-w*WorkingDirectory*	Changes the working directory of the **named8** daemon. This option can be specified or overridden by the "directory" configuration option.
-t*RootDirectory*	Specifies a directory to be the new root directory for the **named8** daemon using the **chroot** command.
-q	Enables logging of all name service queries.
-r	Disables the server's ability to recurse and resolve queries outside of the server's local databases.
-f	Indicates to run the name server daemon in the foreground rather than becoming a background job.

Signals

The following signals have the specified effect when sent to the **named8** daemon process using the **kill** command:

Item	Description
SIGHUP	The **named8** daemon rereads the **/etc/named.conf**file. Depending on the contents of the file, the **SIGHUP** signal may or may not reload the listed databases.
SIGILL	Dumps statistics data into **named.stats**. Statistics data is appended to the file.

Item	Description
SIGINT	The **named8** daemon dumps the current database to a file named **/var/tmp/named_dump.db**. In the dump file, names with the label **name error** indicate negative cache entries. This happens when a server responds that the specified domain name does not exist. Names labeled as **data error** also indicate negative cache entries. This happens when a server responds that there are no records of the specified type for the (valid) domain name.
SIGUSR1	The **named8** daemon turns on debugging; each subsequent **SIGUSR1** signal increments the debugging level. The debugging information is written to the **/var/tmp/named.run** file.
SIGUSR2	The **named8** daemon turns off debugging.

Examples

1. To start the **named8** daemon normally, enter the following:

   ```
   startsrc -s named
   ```

   This command starts the daemon. You can use this command in the **rc.tcpip** file or on the command line. The **-s** flag specifies that the subsystem that follows is to be started. The process ID of the **named8** daemon is stored in the **/etc/named.pid** file upon startup.
2. To stop the **named8** daemon normally, enter:

   ```
   stopsrc -s named
   ```

   This command stops the daemon. The **-s** flag specifies that the subsystem that follows is to be stopped.
3. To get short status from the **named8** daemon, enter:

   ```
   lssrc -s named
   ```

   This command returns the name of the daemon, the process ID of the daemon, and the state of the daemon (active or inactive).
4. To enable debugging for the **named8** daemon, enter:

   ```
   traceson -s named
   ```

   OR

   ```
   kill -30 `cat /etc/named.pid`
   ```

   The **named8** daemon turns on debugging in response to either of these commands; each subsequent command increments the debugging level. The debugging information is written to the **/var/tmp/named.run** file.
5. To turn off debugging for the **named8** daemon, enter:

   ```
   tracesoff
   ```

   OR

   ```
   kill -31 `cat /etc/named.pid`
   ```

   Either of these commands immediately turns off all debugging.

6. To start the **named8** daemon at the highest debugging level using the **startsrc** command, enter the following:

```
startsrc -s named -a -d11
```

This command writes debugging messages to the **/var/tmp/named.run** file.

Files

Item	Description
/usr/sbin/named8	Contains the **named8** daemon.
/usr/sbin/named8-xfer	Provides the functionality of the worker name server's inbound zone transfer.
/etc/named.conf	Specifies the configuration of the **named8** daemon including some basic behaviors, logging options, and locations of the local databases.
/etc/resolv.conf	Specifies the use of domain name services.
/etc/rc.tcpip	Initializes daemons at each system restart.
/etc/named.pid	Stores process ID.
/etc/services	Defines socket service assignments.
/usr/samples/tcpip/named.conf	Contains the sample **named.conf** file with directions for its use.
/usr/samples/tcpip/named.data	Contains the sample DOMAIN data file with directions for its use.
/usr/samples/tcpip/hosts.awk	Contains the sample **awk** script for converting an **/etc/hosts** file to an **/etc/named.data** file. This file also contains directions for its use.
/usr/samples/tcpip/addrs.awk	Contains the sample **awk** script for converting an **/etc/hosts** file to an **/etc/named.rev** file. This file also contains directions for its use.

named9 Daemon

Purpose

Internet domain name server.

Syntax

named9 [**-4**] [**-6**] [**-c** *config-file*] [**-d** *debug-level*] [**-f**] [**-g**] [**-n** *#cpus*] [**-p** *port*] [**-s**] [**-t** *directory*] [**-u** *user*] [**-v**] [**-x** *cache-file*]

Description

named9 is a Domain Name System (DNS) server, part of the BIND 9 distribution from ISC. For more information on the DNS, see RFCs 1033, 1034, and 1035. When invoked without arguments, the **named9** daemon reads the default configuration file **/etc/named.conf**, reads any initial data, and listens for queries.

Flags

Item	Description
-4	Uses IPv4 only even if the host machine is capable of IPv6. The **-4** and **-6** options are mutually exclusive.
-6	Uses IPv6 only even if the host machine is capable of IPv4. The **-4** and **-6** options are mutually exclusive.
-c *config-file*	Uses *config-file* as the configuration file instead of the default, **/etc/named.conf**. To ensure that reloading the configuration file continues to work after the server has changed its working directory due to a possible directory option in the configuration file, the *config-file* value must be an absolute path name.
-d *debug-level*	Sets the daemon's debug level to the *debug-level* value. Debugging traces from the **named9** daemon become more verbose as the debug level increases.
-f	Runs the server in the foreground.
-g	Runs the server in the foreground and forces all logging to the standard error **stderr**.
-n *#cpus*	Creates *#cpus* worker threads to take advantage of multiple CPUs. If not specified, the **named9** daemon tries to determine the number of CPUs present and creates one thread per CPU. If it is unable to determine the number of CPUs, the **named9** daemon creates a single worker thread.
-p *port*	Listens for queries on port *port*. If not specified, the default is port 53.
-s	Writes memory usage statistics to the standard output **stdout** on exit.
-t *directory*	Changes the present directory to the directory specified after processing the command line arguments, but before reading the configuration file. **Warning:** You must use this option in conjunction with the **-u** option, as changing the present directory of a process running as root does not enhance security on most systems.
-u *user*	Sets the process user ID to the user specified after completing privileged operations, such as creating sockets that listen on privileged ports.
-v	Reports the version number and exit.
-x *cache-file*	Loads data from *cache-file* into the cache of the default view.

Signals

In routine operation, you cannot use signals to control the name server; you must use the **rndc** command.

Item	Description
SIGHUP	Forces a reload of the server.
SIGINT, SIGTERM	Shuts down the server.

The result of sending any other signals to the server is undefined.

Configuration

For a complete description of the **named9** configuration file, refer to the BIND 9 Administrator Reference Manual.

Files

Item	Description
/usr/sbin/named9	Contains the **named9** daemon.
/etc/named.conf	The default configuration file.
/etc/named.pid	The default process-id file.

namerslv Command

Purpose

Directly manipulates domain name server entries for local resolver routines in the system configuration database.

Syntax

To Add a Name Server Entry

namerslv -a { **-i** *IPAddress* | **-D** *DomainName*| **-S** *SearchList*}

To Delete a Name Server Entry

namerslv -d { **-i** *IPAddress* | **-n** | **-l**}

To Delete All Name Server Entries

namerslv -X [**-I**]

To Change a Name Server Entry

namerslv -c *DomainName*

To Display a Name Server Entry

namerslv -s [**-I** | **-n** | **-l**] [**-Z**]

To Create the Configuration Database File

namerslv -b [**-i** *IPAddress* [**-D** *DomainName*] [**-S** *SearchList*]]

To Rename the Configuration Database File

namerslv -E *FileName*

To Move the Configuration Database File to Prevent Name Server Use

namerslv -e

To Import a File into the Configuration Database File

namerslv -B*FileName*

To Change a Search List Entry

namerslv -C*Search List*

Description

The **namerslv** low-level command adds or deletes domain name server entries for local resolver routines in the system configuration database. By default, the system configuration database is contained in the **/etc/resolv.conf** file is moved to the file specified by the *FileName* variable.

Item	Description
-a	Adds an entry to the system configuration database. The **-a** flag must be used with either the **-i** or **-D** flag.
-B *FileName*	Restores the **/etc/resolv.conf** file from the file specified by the **FileName** variable.
-b	Creates the system configuration database, using the **/etc/resolv.conf.sv** file. If the **/etc/resolv.conf.sv** file does not exist, an error is returned. **Note:** The **/etc/resolv.conf.sv** file is not shipped with the system. You have to create the file before the **-b** flag will work.
-C	Changes the search list in the **/etc/resolv.conf** file.
-c *DomainName*	Changes the domain name in the system configuration database.
-D	Indicates that the command deals with the domain name entry.
-d	Deletes an entry in the system configuration database. It must be used with the **-i IPAddress** flag or the **-n** flag. The **-i** flag deletes a name server entry. The **-n** flag deletes the domain name entry.
-E *FileName*	Renames the system configuration database file, so you can stop using a name server. The **/etc/resolv.conf** file is moved to the file specified by the *FileName* variable.
-e	Moves the **/etc/resolv.conf** file to the **/etc/resolv.conf.sv** file, preventing use of a name server.
-I	(Uppercase i) Specifies that the **-s** flag or **-X** flag should print all name server entries.
-i *IPAddress*	Indicates that the command deals with a name server entry. Use dotted decimal format for the given IP address.
-l	(Lowercase L) Specifies that the operation is on the search list. Use this flag with the **-d** and **-s** flag.
-n	Specifies that the operation is on the domain name. Use this flag with the **-d** flag and the **-s** flag.
-S *SearchList*	Changes the search list in the system configuration database.
-s	Shows all domain and name server entries in the configuration system database. If you use the **-i** flag, the **namerslv** command shows all name server entries. If you use the **-n** flag, the **namerslv** command shows the domain name entry found in the database.
-X	Deletes all entries in the database. Use the **-I** flag with this flag to delete all name server entries.

Item	Description
-Z	Generates the output of the query in colon format. This flag is used when the **namerslv** command is called from the SMIT usability interface.

Examples

1. To add a domain entry with a domain name of `abc.aus.century.com`, type:

   ```
   namerslv  -a  -D abc.aus.century.com
   ```

2. To change the `abc.aus.century.com` domain entry to the domain name `xyz.aus.century.com`, type:

   ```
   namerslv xyz.aus.century.com
   ```

3. To add a name server entry with IP address `192.9.201.1`, type:

   ```
   namerslv  -a  -i 192.9.201.1
   ```

4. To show all system configuration database entries related to domain name server information used by local resolver routines, type:

   ```
   namerslv  -s
   ```

   The output is given in the following format:

   ```
   domain xyz.aus.century.com
       name server 192.9.201.1
   ```

5. To rename the **/etc/resolv.conf** file to stop using the name server and specify the new file name, `/etc/resolv.back`, type:

   ```
   namerslv  -E /etc/resolv.back
   ```

Files

Item	Description
/usr/sbin/namerslv	Contains the **namerslv** command.
/etc/html	

ncheck Command

Purpose

Generates path names from i-node numbers.

Syntax

ncheck [[[**-a**] [**-i** *InNumber ...*]] | [**-s**]] [**-o** *Options*] [*FileSystem*]

Description

The **ncheck** command displays the i-node number and path names for filesystem files. It uses question marks (??) displayed in the path to indicate a component that could not be found. Path names displayed with ... (ellipses) at the beginning indicate either a loop or a path name of greater than 10 entries.
The **ncheck** command uses a simple hashing alogrithm to reconstruct the path names that it displays. Because of this, it is restricted to filesystems with less than 50,000 directory entries.

Flags

Item	Description
-a	Lists the . (dot) and .. (dot dot) file names.
-i *InNumber*	Lists only the file or files specified by the *InNumber* parameter.
-o *Options*	Specifies a comma-separated list of implementation-specific options for a virtual file system. The following options are specific to the enhanced journaled file system (JFS2 **-o snapshot=***snapName*): Specifies the name of the internal snapshot subject to the **ncheck** command. The file system owning the snapshot must be mounted.
-s	Lists only special files and files with set-user-ID mode.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To list the i-node number and path name of each file in the default file systems, enter:

   ```
   ncheck
   ```

2. To list all the files in a specified file system, enter:

   ```
   ncheck  -a /
   ```

   This lists the i-node number and path name of each file in the **/** (root) file system, including the .(dot) and .. (dot dot) entries in each directory.

3. To list the name of a file when you know its i-node number, enter:

   ```
   ncheck  -i 690 357 280 /tmp
   ```

   This lists the i-node number and path name for every file in the **/tmp** file system with i-node numbers of 690, 357, or 280. If a file has more than one link, all of its path names are listed.

4. To list special and set-user-ID files, enter:

   ```
   ncheck  -s /
   ```

   This lists the i-node and path name for every file in the **/** (root) file system that is a special file (also called a device file) or that has set-user-ID mode enabled.

nddctl Command

Purpose

Issues commands to network device drivers (NDDs).

Syntax

nddctl { **-r** } *Device*

Description

The **nddctl** command allows the user to control an NDD device at runtime (that is, without having to reconfigure the device driver, which usually entails disruption to the network connection).

Flags

Item	Description
-r	Forces the NDD device to renegotiate its link attributes (speed and duplexity) at runtime. **Note:** Forcing link renegotiation entails resetting the device; this might cause a loss of network connectivity, lasting a few seconds, while the device re-initializes itself.

Parameters

Item	Description
Device	Specifies the NDD device on which to perform the specified command.

Exit Status

Item	Description
0	The command completed successfully.
>0	An error occurred.

Examples

1. To force the device `ent0` to renegotiate its link attributes at runtime, type:

```
nddctl -r ent0
```

Location

/usr/sbin

ndp Command

Purpose

IPv6 neighbor discovery display and control.

Syntax

ndp [**-n**] *hostname*

ndp [**-n**] **-a**

ndp [**-d**] *hostname* | *IpAddress*

ndp [**-i** *interface_index*] **-s** *hostname addr* [**temp**]

Description

The **ndp** program displays and modifies the IPv6-to-Ethernet, IPv6-to-TokenRing, or IPv6-to-InfiniBand address translation tables used by the IPv6 neighbor discovery protocol.

With no flags, the program displays the current **ndp** entry for *hostname*. The host may be specified by name or by number, using IPv6 textual notation.

Flags

Item	Description
- a	Displays all of the current **ndp** entries.
- d	Lets a super-user delete an entry for the host called *hostname* with the **-d** flag.
- i *interface_index*	Specifies the index of the interface to use when an **ndp** entry is added with the **-s** flag (useful with the local-link interface).
- n	Shows network addresses as numbers (normally **ndp** attempts to display addresses symbolically).
- s *hostname addr*	Creates an **ndp** entry for *hostname* with the Hardware address *addr*. The Hardware address is given as six hex bytes separated by colons. The entry is permanent unless the **temp** is specified in the command.

Examples

This is an example output from the **- a** flag:

```
# ndp -a
e-crankv6 (::903:9182) at link#2 0:20:af:db:b8:cf
e-crankv6-11 (fe80:0:100::20:afdb:b8cf) at link#2 0:20:af:db:b8:cf
e-crankv6-11 (fe80::2:c903:1:1e85) at link#5 SQP:0xe SLID0x49 DQP:0x48 DLID:0xf
0:48:fe80::2:c903:1:1e85 [InfiniBand]
# ndp -d e-crankv6-11
e-crankv6-11 (fe80:0:100::20:afdb:b8cf) deleted
# ndp -d fe80::2:c903:1:1e85
```

ndpd-host Daemon

Purpose

Neighbor Discovery Protocol (NDP) daemon for a host.

Syntax

ndpd-host [-d] [-v] [-t] [-c *conffile*][-r [*ValidLifetime PreferredLifetime*]] [-g]

Description

The **ndpd-host** command manages the Neighbor Discovery Protocol (NDP) for nonkernel activities, such as Router Discovery, Prefix Discovery, Parameter Discovery, and Redirects. The **ndpd-host** command handles the default route, which includes the default router, the default interface, and the default interface address. However, the **ndpd-host** command does not overwrite the static default routes that are set on the host. When the daemon is stopped, the daemon cleans up the prefix addresses and the routes that are created during its lifetime.

Interfaces

The **ndpd-host** command knows about IEEE and CTI point to point interfaces. The **ndpd-host** command exchanges packets on all the known interfaces UP with a Link-Local Address. Any change of status of an interface is detected. If an interface goes down or loses its Link-Local address, the NDP processing is stopped on this interface. If an interface goes up, the NDP processing is started.

The IEEE interfaces are configured by using the **autoconf6** command. The PPP interfaces are configured by using the **pppd** daemon. The token negotiation defines the Link-Local addresses. To send the Router Advertisements over a CTI configured tunnel, it must have local and distant Link-Local addresses.

ndpd-host can generate Temporary Addresses as per RFC 4941. You can enable or disable temporary address generation for a particular prefix or interface by configuring the daemon in the `tempaddr.conf` file format. You can set the default preferred and valid lifetimes of Temporary Addresses by using the `-r` option.

Note: For all the up point to point interfaces, **ndpd-host** sets a local route through the `lo0` for local addresses.

Flags

Item	Description
`-c`*conffile*	Specifies the SEND configuration file. By default, the configuration file is the `/etc/ndpd/ndpdh.cnf` file. To enable the SEND option, you must install the `clic.rte` fileset and OpenSSL.
`-d`	Enables debugging (exceptional conditions and dump).
`-g`	Allows the **ndpd-host** command to retain all the static global IPv6 address during initialization.
`-r` [*ValidLifetime PreferredLifetime*]	Enables Temporary Address generation. Along with `-r` flag, user can optionally specify default valid and preferred lifetimes for Temporary Addresses generated. By default, Temporary addresses are not generated, if this flag is not given.
`-t`	Adds a time stamp in each log.
`-v`	Logs all interesting events (`daemon.info` and console).

Signals

Item	Description
SIGUSR1	Turns on verbose.
SIGUSR2	Turns off verbose.
SIGINT	Dumps the current state of **ndpd-host** to **syslog** or **stdout**.
SIGTERM	Cleans up **ndpd-host** and exits.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Files

Item	Description
`/etc/ndpd/ndpdh.cnf`	Specifies the SEND file locations.
`/etc/ndpd/cgaparams.sec`	Specifies the configuration for each interface by using the SEND option.
`/etc/ndpd/sendh_anchor`	Specifies the trusted anchor values necessary for the SEND option.

Item	Description
`/etc/ndpd/tempaddr.conf`	Specifies whether the generation of the Temporary Address for the router prefixes must be denied or allowed. The contents of the file are read only when **ndpd-host** is started with the `-r` flag.

ndpd-router Daemon

Purpose

NDP and RIPng daemon for a router.

Syntax

ndpd-router [**-r**] [**-p**] [**-M**] [**-O**] [**-s**] [**-q**] [**-g**] [**-n**] [**-R**] [**-S**] [**-d**] [**-t**] [**-v**] [**-H**] [**-m**] [**-u** *port*] [**-D** *max*[*min*[**/***life*]]] [**-P** [*invlife*]**/**[*deplife*]] [**-T** [*reachtim*]**/**[*retrans*]**/**[*hlim*]] [**-e** [**off** | **compatible** | **only**]]

Description

The **ndpd-router** daemon manages the Neighbor Discovery Protocol (NDP) for non-kernel activities. It receives Router Solicitations and sends Router Advertisements. It can also exchange routing information using the RIPng protocol.

The **/etc/gateway6** file provides options for **ndpd-router**. This file can be modified while the program is running. The changes are checked before any emission or reception of message, or on reception of the HUP signal. The file contains directives, one by line (with # as comment). All the IPv6 addresses and prefixes in the file must be in numeric form. No symbolic name is allowed. Except for the gateway directive, each line begins with a keyword and is made of options of the form *key=argument*.

Interfaces

The **ndpd-router** daemon knows about IEEE and CTI point to point interfaces. The **ndpd-router** daemon exchanges packets on all the known interfaces UP with a Link-Local Address. Any change of status of an interface is detected. If an interface goes down or loses its Link-Local address, the NDP and RIPng processing is stopped on this interface. If an interface goes up, the NDP and RIPng processing is started.

To send Router Advertisements or RIPng packets or both, local *and* remote Link-Local addresses must be configured.

Flags

Item	Description
-e [**off** | **compatible** | **only**]	Specifies the SEND mode: **off** Implies that the SEND option is not enabled. For example, the router behaves as is prior to RFC 3971/3972. **compatible** Implies that the router complies to RFC 3971/3972 but does not require the options specified in the RFC. The environment can be one where certain nodes are SEND capable while others are not. However, if the SEND options are embedded in the incoming packets, they must be correct. **only** Implies that all message must conform to RFC 3971/3972, or the message will be rejected. In order to enable the SEND option, you must install the clic.rte fileset and OpenSSL.

Item	Description
-H	Enables the system to process NDP features needed to function as a mobile IPv6 home agent
-m	Enables the system to aid movement detection for mobile IPv6 mobile nodes.
-D *max* [*min*[**/***life*]]	Sends Unsolicited Router Advertisements at intervals from *min* to *max* seconds. Default *max* value is 600 seconds, valid range is 4 to 1800 seconds. Default *min* equals to *max* / 3, valid range is from 1 to 0.75 * *max*. The router lifetime is set with *life*, default value is 10 * max. Valid range is 0 to 65535 seconds.
-T [*reachtim*] **/** [*retrans*] **/** [*hlim*]	Sets the BaseReachableTime field to *reachim* seconds, if *reachim* is not zero. If *retrans* is not zero, sets the RetransTime field to *retrans* seconds. If *hlim* is not zero, sets the hop limit field in Router Advertisements to *hlim*.
-M	Sets the **M** flag (stateful configuration) in advertisements.
-O	Sets the **O** flag (other stateful information) in advertisements
-p	Does not offer prefixes (learned from interface configuration).
-P [invlife]/ [deplife]	Sets the invalid life value and the deprecated life value for announced prefixes (in seconds). The default value is 0xffffffff (infinite).
-r	Does not offer to be the default router in Router Advertisements.
-s	Enables the RIPng protocol (the default is: RIPng disabled).
-q	Enables the RIPng protocol, but does not send RIPng packets.
-g	Broadcast a default route in RIPng.
-n	Does not install routes received by RIPng.
-u *port*	Uses UDP port *port* for RIPng. The default is 521.
-R	Uses split horizon without corrupting reverse for RIPng.
-S	Does not use any split horizon for RIPng.
-d	Enables debugging (exceptional conditions and dump).
-v	Logs all interesting events (daemon.info and console).
-t	Adds time stamps in logged messages.

Available directives

The main directives for the **/etc/gateway6** file are:

option [*option-directive* ...]
Sets per-interface/default options.

prefix [*prefix-directive* ...]
Sets per-interface/default prefix processing options.

filter [*filter-directive* ...]
Sets per-interface/default filters.

gateway directives
Sets routes in RIPng packets or in the kernel.

Each of these directives is explained in more detail below.

The option directive

Sets different per-interface options.

Any value settings for the **option** directive which follow the **if** option must appear in a comma-separated list.

Note: At least one option (other than the **if** option) must be specified following the **option** directive. If the **if** option is specified, it must be the first option following the **option** directive. There must be a space between the **if** option and any comma-separated list of options which follow.

Syntax:

option [**if**=*n1*,*n2*] **ripin**=(**y**|**n**),**ripout**=(**y**|**n**|**S**|**R**),**rtadv**=(**y**|**n**|*min*[/*max*]),**flag**=[**M**|**O**],**life**=*Seconds*,**reach**=*Seconds*,**retrans**=*Seconds*

Item	Description
if=*list* **interface=***list*	If there is no keyword, the option directive is a default option. If there is an interface field, the option parameters apply only to the listed interfaces. The list is comma-separated. You can use `le*` to match all the leX interfaces. The default option must be the first line in the **/etc/gateway6** file.
mtu[**=***mtuval*]	Advertises a MTU value of *mtuval* in router advertisements. If there is no *mtuval* argument, the advertised MTU is the MTU of the interface. If *mtuval* is 0, suppress the advertisement of MTU.
ripin=(**n**|**y**)	Does not listen (listen) to incoming RIPng packets. Does not send (send) RIPng packets. With the **-S** flag, do not use split horizon. With the **-R** flag, use split horizon without poisoning reverse.
rtadv=(**n**|**y**|*min* [**/***max*])	Does not send (send) router advertisements. With *min*[**/***max*] option, set the interval (in seconds) between router advertisements.
flag={**M**|**O**}	Sets the stateful mode flags in router advertisements. **M** Uses stateful configuration **O** Uses stateful configuration, but not for addresses
life=*Seconds*	Sets the router life field in router advertisements (in seconds).
reach=*Seconds*	Sets the reachable field in router advertisements (in seconds).
retrans=*Seconds*	Sets the retransmit interval field in router advertisements (in seconds).

The prefix directive

Defines the prefixes announced in Router advertisement directives. If there is no prefix-directive for an interface, the router advertisement contains the list of prefixes deduced from the address list of the interface. If there are prefix-directives, the router advertisement contains the list of prefixes defined by the different prefix directives (in order). No prefix is installed in the kernel. If there is one directive of the form prefix *prefix=none*, no prefix list is advertised.

Syntax:

prefix if=n **prefix**=(**none**|*xxx*::/*PrefixLength*) **flag**=[**L**][**A**] **valid**=*Seconds* **deprec**=*Seconds*

Item	Description
if=*Interface* or **interface**=*Interface*	Specifies the interface on which the directive applies. The **if** keyword is mandatory for the **prefix** directive. It is not an option.
prefix=*xxx*::/*PrefixLength*	The advertised prefix.
flag=[**L**][**A**]	Set the **L** and/or **A** flag for the prefix (the default is **LA**).
deprec=*Seconds*	Set the deprecated time (in seconds) for the prefix.
valid=*Seconds*	Set the validity time (in seconds) for the prefix.

The filter directive

Define a filter pattern for incoming (**filter**=**in**) or outgoing (**filter**=**out**) RIPng packets. There is one incoming and one outgoing filter per interface, and one default incoming and one default outgoing filter for interfaces without explicit filter.

Any received RIPng information is tested against the input filter of the interface, or, if there is none, against the default input filter. The static interface routes are seen as input information coming from the interface and from a gateway with the link local address of the interface. The routes set by a gateway directive with a **gateway** keyword are seen as input information coming from the specified interface and gateway. The default route (**-g** flag) and the routes set by a gateway directive without a **gateway** keyword are seen as input information coming from gateway :: and no interface (the default input filter applies).

Any sent RIPng information is tested against the output filter of the interface, or, if there is none, against the default output filter.

Each filter is a sequence of matching patterns. The patterns are tested in order. Each pattern can test the prefix length, the source gateway (for input filters and that the prefix (padded with zeroes) matches a fixed prefix. If a pattern contains more than one test description, the match is the conjunction of all the tests. The first matching pattern defines the action to perform. If no pattern matches, the default action is accept. The possible actions are accept, reject and truncate/*NumberOfBits*. The truncate/*NumberOfBits* action means: if the pattern matches and if prefix length is greater or equal to *NumberOfBits*, accept the prefix with new length *NumberOfBits*. The accepted prefix is immediately accepted, that is, not checked again against the filters.

For example, the following directive inhibits sending host routes on any interface without an explicit outgoing filter:

```
filter=out length==128 action=reject
```

Syntax:

filter=(**in**|**out**) [**if**=*n1*,*n2*] **prefix**=*xx*::/*NumberOfBits* **gateway**=*xxx* **length**=(=|>=|<=|<|>)*NumberOfBits* **action**=(**accept**|**reject**|**truncate**/*xx*)

Item	Description
if=*list* or **interface**=*list*	If there is no interface keyword, the filter directive is a default option. If there is an interface field, the filter pattern is added at the end of the filters of all specified interfaces. The list is comma-separated. For example, you can specify **interface**=le* to specify all the leX interfaces.
prefix=*xxx*::/*NumberOfBits*	The pattern matches only if *xxx*::/*NumberOfBits* is a prefix of the prefix in the RIPng packet.

Item	Description
gateway=*xxx*	The pattern matches only if the RIPng message comes from source address *xxx*, only in incoming filters.
length=(=|>=|<=|<|>)*NumberOfBits*	The pattern match only if the prefix length in the RIPng message is equal to (or greater than, less than, etc., depending on the operator specified) to *NumberOfBits*.
action=(**accept**|**reject**|**truncate**/*NumberOfBits*)	Specify the action to perform if the pattern matches: accept the message, reject the message, accept but truncate the prefix to *NumberOfBits* bits.

Gateway directives

The gateway directives allow the user to set up routes in RIPng packets and/or in the kernel. These directives must appear at the end of the **/etc/gateway6** file, after the other directives.

Syntax:

xxx::/*NumberOfBits* **metric** *Value*

xxx::/*NumberOfBits* **metric** *Value* **gateway** *IPv6Address ifname*

The second syntax is used to add the route to the kernel.

Examples

The following examples are of the **/etc/gateway6** file.

On a site where all addresses are of the form `5f06:2200:c001:0200:xxxx`, the following example means that only one route, describing all the site, is exported on all the Configured Tunnel Interface (CTI) **ctiX** interfaces. The keyword abbreviations shown are valid.

```
filt=out if=cti* pref=5f06:2200:c001:0200::/64 len=>=64 act=trunc/64
```

Setting a default outgoing route:

```
::/0 metric 2 gateway 5f06:2200:c102:0200::1 cti0
```

Declare that any CTI interface active with RIPng defines a default route:

```
filter=in if=cti* act=trunc/0
```

The following example defines a site with an exterior connection cti0, which aggregates other sites connected through ctiX, and which uses split horizon without poisoned reverse. The order of the lines is important, as all filter descriptions apply to cti0.

```
option if=cti* ripout=R
filter=out if=cti0 prefix=5f06:2200::/24 len=>=24 act=trunc/24
filt=out if=cti* pref=5f06:2200:c001:0200::/64 len=>=64 act=trunc/64
filter=in if=cti0 act=trunc/0
filter=in if=cti* prefix=5f06:2200::/24 len=>=24 act=trunc/64
filter=in if=cti* act=reject
```

Diagnostics

All errors are logged at the **daemon.err** level, unless the debug option is set. This includes all the syntax errors in the **/etc/gateway6** file and configuration mismatches between different routers.

Signals

ndpd-router responds to the following signals:

Item	Description
SIGINT	Dumps its current state to syslog, if syslog is defined. Otherwise, dumped to stdout.
SIGHUP	The **/etc/gateway6** file is read again.
SIGUSR1	Verbosity is incremented.
SIGUSR2	Verbosity is reset.
SIGTERM	Resets to a resonable state and stops.
SIGQUIT	Resets to a resonable state and stops.

Files

Item	Description
/etc/gateway6	
/etc/ndpd/sendr_anchor	The SEND router anchor file for the certificate chain.

ndx Command

Purpose

Creates a subject-page index for a document.

Syntax

ndx [*SubjectFile*] **"** *FormatterCommandLine* **"**

Description

The **ndx** command, given a list of subjects (*SubjectFile*), searches a specified English-language document and writes a subject-page index to standard output.

The document must include formatting directives for the **mm**, **mmt**, **nroff**, or **troff** commands. The formatter command line informs the **ndx** command whether the **troff** command, **nroff** command, **mm** command, or **mmt** command can be used to produce the final version of the document. These commands do the following:

Item	Description
troff or **mmt**	Specifies the **troff** command as the formatting program.
nroff or **mm**	Specifies the **nroff** command as the formatting program.

Parameters

Item	Description
SubjectFile	Specifies the list of subjects that are included in the index. Each subject must begin on a new line and have the following format: *word1*[*word2*...][,*wordk*...] For example: `printed circuit boards` `arrays` `arrays, dynamic storage` `Smith, W.P.` `printed circuit boards, channel-oriented multi-layer` `Aranoff` `University of Illinois` `PL/1` The subject must start in column one.
FormatterCommandLine	Creates the final form of the document. The syntax for this parameter is as follows: *Formatter* [*Flag...*] *File...* **mm -Tlp** File(s) **nroff -mm -Tlp -rW60** File(s) **troff -rB2 -Tibm3816 -r01.5i** File(s) For more information on the formatter command line, see the **mmt** command, **nroff** command, and html

neqn Command

Purpose

Formats mathematical text for the **nroff** command.

Syntax

neqn [**-d** *Delimiter1Delimiter2*] [**-f** *Font*] [**-p** *Number*] [**-s** *Size*] [**—**] [*File* ... | **-**]

Description

The **neqn** command is an **nroff** preprocessor for formatting mathematical text on typewriter-like terminals. Pipe the output of the **neqn** command into the **nroff** command as follows:

neqn [*Flag...*] *File...* **| nroff** [*Flag...*] **|** [*Printer*]

The **neqn** command reads one or more files. If no files are specified for the *File* parameter or the **-** (minus sign) flag is specified as the last parameter, standard input is read by default. A line beginning with the **.EN** macro. These lines are not altered by the **nroff** command, so they can be defined in macro packages to provide additional formatting functions such as centering and numbering.

The **—** (double dash) delimiter indicates the end of flags.

Depending on the target output devices, **neqn** command output formatted by the **nroff** command may need to be post-processed by the **eqn** command gives more information about the input format and keywords used.

Flags

Item	Description
-d*Delimiter1Delimiter2*	Sets two ASCII characters, *Delimiter1* and *Delimiter2,* as delimiters of the text to be processed by the **neqn** command, in addition to input enclosed by the **.EQ** and **.EN** macros. The text between these delimiters is treated as input to the **neqn** command. Within a file, you can also set delimiters for **neqn** text using the **delim** *Delimiter1Delimiter2* request. These delimiters are turned off by the **delim off** request. All text that is not between delimiters or the **.EN** macro is passed through unprocessed.
-f*Font*	Changes font in all the **neqn** command-processed text to the value specified by the *Font* variable. The *Font* value (a font name or position) must be one or two ASCII characters.
-p*Number*	Reduces subscripts and superscripts to the specified number of points in size. The default is 3 points.
-s*Size*	Changes point size in all the **neqn** command-processed text to the value specified by the *Size* variable.
-	Reads from standard input.
—	(double dash) Marks the end of the flags.

Files

Item	Description
/usr/share/lib/pub/eqnchar	Contains special character definitions.

netcd Daemon

Purpose

Launches the network caching (netcd) daemon.

Syntax

netcd [**-l** *file*] [**-c** *file*] [**-d** *level*] [**-h**]

Description

The **netcd** daemon reduces the time taken by the local, DNS, NIS, and user loadable module services to respond to a query by caching the response retrieved from resolvers.

When the **netcd** daemon is running and configured for a resolver (for example, DNS) and a map (for example, hosts), the resolution is first made using the cached answers. If it fails, the resolver is called and the response is cached by the **netcd** daemon.

The type of the maps that are supported for the local, NIS, and user loadable modules resolutions are hosts, services, networks, protocols and netgroup. For DNS, hosts is the only type of map that you can use.

In addition, for the specific case of Yellow Pages, the following maps have been added:

- passwd.byname
- passwd.byuid

- group.byname
- group.bygid
- netid.byname
- passwd.adjunct.byname

You can use a configuration file to specify the resolvers and maps that you want to configure. You can also set other **netcd** parameters using this file. By default, the configuration file used is the **/etc/netcd.conf** file. You can change the path of this configuration file using the **-c** argument of the **netcd** daemon. If the **/etc/netcd.conf** file does not exist, the **netcd** daemon uses the default parameters. You can find a sample of this file under the **/usr/samples/tcpip** file. Do not use this file as a configuration file because it will be overwritten by a new installation of the package containing the file.

You can specify the level of debugging using the **-d** argument. The debugging levels are similar to the one used by the **syslogd** daemon. Log messages are written to the **/var/tmp/netcd.log** file. You can override the default using the netcd configuration file. As with the **syslogd** daemon, you can specify rotation for the netcd log file.

netcd Parameters

When an entry is inserted in a netcd cache, a time-to-live (TTL) is associated to it. You can configure this TTL using the netcd configuration file (cache declarations). For DNS, this TTL is the one contains the response from the DNS.

To clean the caches of outdated entries, you must run two tasks periodically, one to clean local caches and the other to clean the other caches. You can set the frequency of these tasks using the *local_scan_frequency* and *net_scan_frequency* parameters in the netcd configuration file.

Caches are hashed tables. The size of the hash tables can be controlled using the netcd configuration file and the **netcdctrl** command.

To communicate between the applications, the **netcd** daemon uses a socket (**/dev/netcd**). You can configure the size of the message queue using the netcd configuration file.

netcd supports the System Resource Controller

The **netcd** daemon is part of the netcd System Resource Controller (SRC) group. The following are the SRC commands you can use to manage the **netcd** daemon:

- You can start the **netcd** daemon using the **startsrc** command, or stop the **netcd** daemon using the **stopsrc** command.
- The **lssrc** command provides a short status output that includes the Process ID (PID) and the status of the **netcd** daemon.
- The **lssrc -l** command provides a long status output that includes the PID, the status of the **netcd** daemon, the configuration file used when starting the **netcd** daemon, and the configured caches.

Note: You cannot use the **refresh** command with the **netcd** daemon.

Flags

Item	Description
-c *file*	Specifies a configuration file. The default file name is **/etc/netcd.conf**.
-d *level*	Specifies the logging level. The *level* value must be an integer between 0 and 7.
-h	Displays help information.
-l *file*	Loads caches from the specified binary file created by the **netcdctrl** command. The local files (for example, **/etc/hosts**, **/etc/services**) are loaded depending on the configuration file.

Examples

1. To launch the **netcd** daemon using the SRC, enter:

```
startsrc -s netcd
```

2. To display the status of the **netcd** daemon using the SRC, enter:

```
lssrc -s netcd
```

   This command produces the following output:

```
Subsystem         Group            PID          Status
netcd             netcd            299064       active
```

3. To display the status of the **netcd** daemon in long form using the SRC, enter:

```
lssrc -l -s netcd
```

   This command produces the following output:

```
Subsystem         Group            PID          Status
netcd             netcd            299064       active
Configuration File       /etc/netcd.conf
Configured Cache         local services
Configured Cache         local protocols
Configured Cache         local hosts
Configured Cache         local networks
Configured Cache         local netgroup
```

4. To launch the **netcd** daemon without using the SRC, enter:

```
netcd
```

netcdctrl Command

Purpose

Manages the network caching (netcd) daemon caches.

Syntax

netcdctrl [**-t** *type* **-e** *type* [**-a** *file* | **-b** *file* | **-f** | **-s** *file*]] [**-l** *level*] [**-h**]

Description

The **netcdctrl** command provides the following functions:

- Dumps specific caches in ASCII format: provides a readable output of the caches content.
- Dumps specific caches in binary format. The binary format can be used later to reload the caches when starting the **netcd** daemon. Dumping avoids reloading the caches from the beginning.
- Displays statistics on caches use. The caches are tables, and the access to these tables is controlled by a hash algorithm. This output helps you size the table for a given resolution and a given map using the netcd configuration file.
- Flushes specific caches. The content of the specified caches are erased, and local caches are then reloaded. Other caches are reloaded by resolver's responses.
- Changes the logging level dynamically.

Requirement: You must have the root authority to issue the **netcdctrl** command.

Flags

Item	Description
-a *file*	Specifies ASCII dumping of the specified caches.
-b *file*	Specifies binary dumping of the specified caches (local caches are not dumped).
-e *type*	Specifies the map. The *type* parameter can be one of the following values: • hosts • protocols • servers • networks • netgroup • a yellow pages map name (for example passwd.byname or group.bygid) • all Use this flag only with the **-b**, **-a**, **-f** and **-s** flags.
-f	Flushes the specified caches.
-h	Displays help information.
-l *level*	Changes the logging level of the **netcd** daemon. The *level* value must be an integer of 0 through 7.
-s *file*	Provides statistics on caches use.
-t *type*	Specifies the resolution. The *type* parameter can be one of the following values: • local • dns • nis • yp • ulm • a specific module name as provided in the **netcd.conf** file • all Use his flag only with the **-b**, **-a**, **-f** and **-s** flags.

Examples

1. To flush all the caches, enter:

```
netcdctrl -t all -e all -f
```

2. To dump all the NIS caches in binary format, enter:

```
netcdctrl -t nis -e all -b /tmp/netcd_nis_binary_dump
```

3. To dump the local cache for hosts in ASCII format, enter:

```
netcdctrl -t local -e hosts -a /tmp/netcd_dns_hosts
```

4. To set the level of logging to obtain all possible traces, enter:

```
netcdctrl -l 7
```

netpmon Command

Purpose

Monitors activity and reports statistics on network I/O and network-related CPU usage.

Syntax

netpmon [**-o** *File*] [**-d**] [**-T** *n*] [**-P**] [**-t**] [**-v**] [**-r PURR**] [**-O** *ReportType ...*] [**-i** *Trace_File* **-n** *Gensyms_File*] [**-@** [*WparList* | **ALL**]]

Description

The **netpmon** command monitors a trace of system events, and reports on network activity and performance during the monitored interval. By default, the **netpmon** command runs in the background while one or more application programs or system commands are being executed and monitored. The **netpmon** command automatically starts and monitors a trace of network-related system events in real time. By default, the trace is started immediately; optionally, tracing may be deferred until the user issues a **trcon** command. When tracing is stopped by a **trcstop** command, the **netpmon** command generates all specified reports and exits.

The **netpmon** command can also work in offline mode, that is, on a previously generated trace file. In this mode, a file generated by the **gensyms** command is also required. The gensyms file should be generated immediately after the trace has been stopped, and on the same machine. When running in offline mode, the **netpmon** command cannot recognize protocols used by sockets, which limits the level of detail available in the socket reports.

The **netpmon** command reports on the following system activities:

CPU Usage
The **netpmon** command monitors CPU usage by all threads and interrupt handlers. It estimates how much of this usage is due to network-related activities.

Network Device-Driver I/O
The **netpmon** command monitors I/O operations through token-ring and Fiber-Distributed Data Interface (FDDI) network device drivers. In the case of transmission I/O, the command also monitors utilizations, queue lengths, and destination hosts. For receive ID, the command also monitors time in the demux layer.

Internet Socket Calls
The **netpmon** command monitors all **send**, **recv**, **sendto**, **recvfrom**, **read**, and **write** subroutines on Internet sockets. It reports statistics on a per-process basis, for each of the following protocol types:

- Internet Control Message Protocol (ICMP)
- Transmission Control Protocol (TCP)
- User Datagram Protocol (UDP)

NFS I/O
The **netpmon** command monitors **read** and **write** subroutines on client Network File System (NFS) files, client NFS remote procedure call (RPC) requests, and NFS server read or write requests. The command reports subroutine statistics on a per-process or optional per-thread basis and on a per-file basis for each server. The **netpmon** command reports client RPC statistics for each server, and server read and write statistics for each client.

Any combination of the preceding report types can be specified with the command line flags. By default, all the reports are produced.

> **Notes:** The reports produced by the **netpmon** command can be quite long. Consequently, the **-o** flag should usually be used to write the report to an output file. The **netpmon** command obtains performance data using the system trace facility. The trace facility only supports one output stream. Consequently, only one **netpmon** or **trace** process can be active at a time. If

another **netpmon** or **trace** process is already running, the **netpmon** command responds with the message:

```
/dev/systrace: Device busy
```

While monitoring very network-intensive applications, the **netpmon** command may not be able to consume trace events as fast as they are produced in real time. When that happens, the error message:

```
Trace kernel buffers overflowed, N missed entries
```

displays on standard error, indicating how many trace events were lost while the trace buffers were full. The **netpmon** command continues monitoring network activity, but the accuracy of the report diminishes by some unknown degree. One way to avoid overflow is to increase the trace buffer size using the **-T** flag, to accommodate larger bursts of trace events before overflow. Another way to avoid overflow problems all together is to run netpmon in offline mode.

When running in memory-constrained environments (where demand for memory exceeds supply), the **-P** flag can be used to pin the text and data pages of the real-time **netpmon** process in memory so the pages cannot be swapped out. If the **-P** flag is not used, allowing the **netpmon** process to be swapped out, the progress of the **netpmon** command may be delayed such that it cannot process trace events fast enough to prevent trace buffer overflow.

If the **/unix** file and the running kernel are not the same, the kernel addresses will be incorrect, causing the **netpmon** command to exit.

Flags

Item	Description
-d	Starts the **netpmon** command, but defers tracing until the **trcon** command has been executed by the user. By default, tracing is started immediately.
-i *Trace_File*	Reads trace records from the file *Trace_File* produced with the **trace** command instead of a live system. The trace file must be rewritten first in raw format using the **trcpt -r** command. This flag cannot be used without the **-n** flag.
-n *Gensyms_File*	Reads necessary mapping information from the file *Gensyms_File* produced by the **gensyms** command. This flag is mandatory when the **-i** flag is used.
-o *File*	Writes the reports to the specified *File*, instead of to standard output.

Item	Description
-O *ReportType ...*	Produces the specified report types. Valid report type values are: **cpu** CPU usage **dd** Network device-driver I/O. This report is not available inside a workload partition (WPAR) in online mode or in the global WPAR with the '*-@ WparList*' flag. **so** Internet socket call I/O **nfs** NFS I/O (any version) **nfs2** NFS Version 2 I/O **nfs3** NFS Version 3 I/O **nfs4** NFS Version 4 I/O **all** All reports are produced. This is the default value when the **netpmon** command is run in the global WPAR without the **-@** flag.
-P	Pins monitor process in memory. This flag causes the **netpmon** text and data pages to be pinned in memory for the duration of the monitoring period. This flag can be used to ensure that the real-time **netpmon** process does not run out of memory space when running in a memory-constrained environment.
-r PURR	Uses PURR time instead of TimeBase in percent and CPU time calculation. Elapsed time calculations are unaffected.
-t	Prints CPU reports on a per-thread basis.
-T *n*	Sets the kernel's trace buffer size to *n* bytes. The default size is 64000 bytes. The buffer size can be increased to accommodate larger bursts of events, if any. (A typical event record size is on the order of 30 bytes.) **Note:** The trace driver in the kernel uses double buffering, so actually two buffers of size *n* bytes will be allocated. These buffers are pinned in memory, so they are not subject to paging.
-v	Prints extra information in the report. All processes and all accessed remote files are included in the report instead of only the 20 most active processes and files.
-@ [*WparList*|**ALL**]	Specifies that reports are limited to the list of WPARs that are passed as an argument.

Reports

The reports generated by the **netpmon** command begin with a header, which identifies the date, the machine ID, and the length of the monitoring period in seconds. This is followed by a set of summary and detailed reports for all specified report types.

CPU Usage Reports

Process CPU Usage Statistics: Each row describes the CPU usage associated with a process. Unless the verbose option is specified, only the 20 most active processes are listed. At the bottom of the report, CPU usage for all processes is totaled, and CPU idle time is reported.

Process
Process name

PID
Process ID number

CPU Time
Total amount of CPU time used by this process

CPU %
CPU usage for this process as a percentage of total time

Network CPU %
Percentage of total time that this process spent executing network-related code

Thread CPU Usage Statistics
If the **-t** flag is used, each process row described above is immediately followed by rows describing the CPU usage of each thread owned by that process. The fields in these rows are identical to those for the process, except for the name field. (Threads are not named.)

First-Level Interrupt Handler Usage Statistics: Each row describes the CPU usage associated with a first-level interrupt handler (FLIH). At the bottom of the report, CPU usage for all FLIHs is totaled.

FLIH
First-level interrupt handler description

CPU Time
Total amount of CPU time used by this FLIH

CPU %
CPU usage for this interrupt handler as a percentage of total time

Network CPU %
Percentage of total time that this interrupt handler executed on behalf of network-related events

Second-Level Interrupt Handler Usage Statistics: Each row describes the CPU usage associated with a second-level interrupt handler (SLIH). At the bottom of the report, CPU usage for all SLIHs is totaled.

SLIH
Second-level interrupt handler description

CPU Time
Total amount of CPU time used by this SLIH

CPU %
CPU usage for this interrupt handler as a percentage of total time

Network CPU %
Percentage of total time that this interrupt handler executed on behalf of network-related events

Summary Network Device-Driver Reports

Network Device-Driver Statistics (by Device): Each row describes the statistics associated with a network device.

Device
Path name of special file associated with device

Xmit Pkts/s
Packets per second transmitted through this device

Xmit Bytes/s
Bytes per second transmitted through this device

Xmit Util
Busy time for this device, as a percent of total time

Xmit Qlen
Number of requests waiting to be transmitted through this device, averaged over time, including any transaction currently being transmitted

Recv Pkts/s
Packets per second received through this device

Recv Bytes/s
Bytes per second received through this device

Recv Demux
Time spent in demux layer as a fraction of total time

Network Device-Driver Transmit Statistics (by Destination Host): Each row describes the amount of transmit traffic associated with a particular destination host, at the device-driver level.

When hosts are on the same subnet, the destination host name is displayed. When hosts are in a different subnet, the destination host can be bridges, routers, or gateways as resolved by ARP protocol.

Host
Destination host name. An * (asterisk) is used for transmissions for which no host name can be determined.

Pkts/s
Packets per second transmitted to this host

Xmit Bytes/s
Bytes per second transmitted to this host

Summary Internet Socket Reports

- *On-line mode*: **Socket Call Statistics for Each Internet Protocol (by Process)**: Each row describes the amount of **read/write** subroutine activity on sockets of this protocol type associated with a particular process. Unless the verbose option is specified, only the top 20 processes are listed. At the bottom of the report, all socket calls for this protocol are totaled.
- *Off-line mode*: **Socket Call Statistics for Each Process**: Each row describes the amount of **read/write** subroutine activity on sockets associated with a particular process. Unless the verbose option is specified, only the top 20 processes are listed. At the bottom of the report, all socket calls are totaled.

Process
Process name

PID
Process ID number

Read Calls/s or Read Ops/s
Number of **read** , **recv** , and **recvfrom** subroutines per second made by this process on sockets of this type

Read Bytes/s
Bytes per second requested by the above calls

Write Calls/s or Write Ops/s
Number of **write** , **send** , and **sendto** subroutines per second made by this process on sockets of this type

Write Bytes/s
Bytes per second written by this process to sockets of this protocol type

Summary NFS Reports

NFS Client Statistics for Each Server (by File): Each row describes the amount of **read**/**write** subroutine activity associated with a file mounted remotely from this server. Unless the verbose option is specified, only the top 20 files are listed. At the bottom of the report, calls for all files on this server are totaled.

File
Simple file name

Read Calls/s or Read Ops/s
Number of **read** subroutines per second on this file

Read Bytes/s
Bytes per second requested by the above calls

Write Calls/s or Write Ops/s
Number of **write** subroutines per second on this file

Write Bytes/s
Bytes per second written to this file

NFS Client RPC Statistics (by Server): Each row describes the number of NFS remote procedure calls being made by this client to a particular NFS server. At the bottom of the report, calls for all servers are totaled.

Server
Host name of server. An * (asterisk) is used for RPC calls for which no hostname could be determined.

Calls/s or Ops/s
Number of NFS RPC calls per second being made to this server.

NFS Client Statistics (by Process): Each row describes the amount of NFS **read**/**write** subroutine activity associated with a particular process. Unless the verbose option is specified, only the top 20 processes are listed. At the bottom of the report, calls for all processes are totaled.

Process
Process name

PID
Process ID number

Read Calls/s or Read Ops/s
Number of NFS **read** subroutines per second made by this process

Read Bytes/s
Bytes per second requested by the above calls

Write Calls/s or Write Ops/s
Number of NFS **write** subroutines per second made by this process

Write Bytes/s
Bytes per second written to NFS mounted files by this process

NFS Server Statistics (by Client): Each row describes the amount of NFS activity handled by this server on behalf of particular client. At the bottom of the report, calls for all clients are totaled.

Client
Host name of client

Read Calls/s or Read Ops/s
Number of remote read requests per second processed on behalf of this client

Read Bytes/s
Bytes per second requested by this client's read calls

Write Calls/s or Write Ops/s
Number of remote write requests per second processed on behalf of this client

Write Bytes/s
Bytes per second written by this client

Other Calls/s or Ops/s
Number of other remote requests per second processed on behalf of this client

Detailed Reports

Detailed reports are generated for any of the specified report types. For these report types, a detailed report is produced for most of the summary reports. The detailed reports contain an entry for each entry in the summary reports with statistics for each type of transaction associated with the entry.

Transaction statistics consist of a count of the number of transactions of that type, followed by response time and size distribution data (where applicable). The distribution data consists of average, minimum, and maximum values, as well as standard deviations. Roughly two-thirds of the values are between `average - standard deviation` and `average + standard deviation`. Sizes are reported in bytes. Response times are reported in milliseconds.

Detailed Second Level Interrupt Handler CPU Usage Statistics:

SLIH
Name of second-level interrupt handler

Count
Number of interrupts of this type

CPU Time (Msec)
CPU usage statistics for handling interrupts of this type

Detailed Network Device-Driver Statistics (by Device):

Device
Path name of special file associated with device

Recv Packets
Number of packets received through this device

Recv Sizes (Bytes)
Size statistics for received packets

Recv Times (msec)
Response time statistics for processing received packets

Xmit Packets
Number of packets transmitted to this host

Demux Times (msec)
Time statistics for processing received packets in the demux layer

Xmit Sizes (Bytes)
Size statistics for transmitted packets

Xmit Times (Msec)
Response time statistics for processing transmitted packets

Detailed Network Device-Driver Transmit Statistics (by Host):

Host
Destination host name

Xmit Packets
Number of packets transmitted through this device

Xmit Sizes (Bytes)
Size statistics for transmitted packets

Xmit Times (Msec)
Response time statistics for processing transmitted packets

Detailed Socket Call Statistics for Each Internet Protocol (by Process): (*on-line* mode) **Detailed Socket Call Statistics for Each Process**: (*off-line* mode)

Process
Process name

PID
Process ID number

Reads
Number of **read** , **recv** , **recvfrom** , and **recvmsg** subroutines made by this process on sockets of this type

Read Sizes (Bytes)
Size statistics for **read** calls

Read Times (Msec)
Response time statistics for **read** calls

Writes
Number of **write** , **send** , **sendto** , and **sendmsg** subroutines made by this process on sockets of this type

Write Sizes (Bytes)
Size statistics for **write** calls

Write Times (Msec)
Response time statistics for **write** calls

Detailed NFS Client Statistics for Each Server (by File):

File
File path name

Reads
Number of NFS **read** subroutines for this file

Read Sizes (Bytes)
Size statistics for **read** calls

Read Times (Msec)
Response time statistics for **read** calls

Writes
Number of NFS **write** subroutines for this file

Write Sizes (Bytes)
Size statistics for **write** calls

Write Times (Msec)
Response time statistics for **write** calls

Detailed NFS Client RPC Statistics (by Server):

Server
Server host name

Calls
Number of NFS client RPC calls made to this server

Call Times (Msec)
Response time statistics for RPC calls

Detailed NFS Client Statistics (by Process):

Process
Process name

PID
Process ID number

Reads
Number of NFS **read** subroutines made by this process

Read Sizes (Bytes)
Size statistics for **read** calls

Read Times (Msec)
Response time statistics for **read** calls

Writes
Number of NFS **write** subroutines made by this process

Write Sizes (Bytes)
Size statistics for **write** calls

Write Times (Msec)
Response time statistics for **write** calls

Detailed NFS Server Statistics (by Client):

Client
Client host name

Reads
Number of NFS read requests received from this client

Read Sizes (Bytes)
Size statistics for read requests

Read Times (Msec)
Response time statistics for read requests

Writes
Number of NFS write requests received from this client

Write Sizes (Bytes)
Size statistics for write requests

Write Times (Msec)
Response time statistics for write requests

Other Calls
Number of other NFS requests received from this client

Other Times (Msec)
Response time statistics for other requests

Examples

1. To monitor network activity during the execution of certain application programs and generate all report types, type:

   ```
   netpmon
   <run application programs and commands here>
   trcstop
   ```

   The **netpmon** command automatically starts the system trace and puts itself in the background. Application programs and system commands can be run at this time. After the **trcstop** command is issued, all reports are displayed on standard output.

2. To generate CPU and NFS report types and write the reports to the `nmon.out` file, type:

   ```
   netpmon -o nmon.out -O cpu,nfs
   <run application programs and commands here>
   trcstop
   ```

   The **netpmon** command immediately starts the system trace. After the **trcstop** command is issued, the I/O activity report is written to the `nmon.out` file. Only the CPU and NFS reports will be generated.

3. To generate all report types and write verbose output to the `nmon.out` file, type:

   ```
   netpmon -v -o nmon.out
   <run application programs and commands here>
   trcstop
   ```

   With the verbose output, the **netpmon** command indicates the steps it is taking to start up the trace. The summary and detailed reports include all files and processes, instead of just the 20 most active files and processes.

4. To use the **netpmon** command in offline mode, type:

   ```
   trace -a
   run application programs and commands here
   trcoff
   gensyms > gen.out
   trcstop
   netpmon -i tracefile -n gen.out -o netpmon.out
   ```

netrule Command

Purpose

Adds, removes, lists, or queries rules, flags and security labels for interfaces and hosts.

Syntax

netrule hl [**i** | **o** | **io**]

netrule hq { **i** | **o** } *src_host_rule_specification dst_host_rule_specification*

netrule h- [**i** | **o**][**u**] [*src_host_rule_specification dst_host_rule_specification*]

netrule h+ { **i** | **o** } [**u**] *src_host_rule_specification dst_host_rule_specification* [*flags*][*RIPSO/CIPSO options*] *security_label_information*

netrule il

netrule iq *interface*

netrule i- [**u**][*interface*]

netrule i+ [**u**] *interface* [*flags*][*RIPSO/CIPSO options*] *security_label_information*

netrule eq

netrule e { **on** | **off** }

Description

The **netrule** command lists, queries, adds and removes rule specifications for interfaces and hosts. The system default interface rules are set using the interface name. When an interface is removed using the **i-** flag, it will be given these default interface rules. The default interface rules are also set using the **tninit load** command.

Note: Because there must always be an interface rule for an interface, the remove operation sets the interface rule to its default state. All of the command line flags must follow the order as shown in the syntax statements.

Flags

Item	Description
e { **on** | **off** }	Sets the policy for sending the ICMP error response to incoming packets that are not accepted by the system. This setting is off by default and must be set with this flag to be on. You cannot specify the **e** flag when you specify the **h** or **i** flag.
h	Specifies that the object of the **netrule** command is a host. You cannot specify the **h** flag when you specify the **i** or **e** flag.
i	Specifies that the object of the **netrule** command is an interface. You cannot specify the **i** flag when you specify the **h** or **e** flag.
l	Lists all rules for interfaces or hosts.
o	Specifies the host out rules (for host rule only).
q	Queries an interface, a host rule, or the status of the error response setting.
u	Specifies that the **/etc/security/rules.host** and **/etc/security/rules.int** files will be updated after the host or interface rule is successfully added or removed.
+	Adds an interface or a host rule.

Item	Description
-	Removes an interface or a host rule.
interface	Specifies an interface name.
src_host_rule_specification	This parameter takes the following format: `src_host [/ mask][ = proto [:start_port_range [:end_port_range]]]` **Requirement:** There is a space or tab in between each field. **src_host** A source IPv6 address, or an IPv4 address, or a host name. **mask** The subnet mask number indicates how many bits are set, starting from the most significant bit. For example, 24 means 255.255.255.0 for an IPv4 address. **proto** A protocol. **start_port_range** A particular port number or name to begin from. **end_port_range** A particular port number or name to end at.
dst_host_rule_specification	This parameter takes the following format: `dst_host [/ mask][ = proto [:start_port_range [:end_port_range]]]` **Requirement:** There is a space or tab in between each field. **dst_host** A destination IPv6 address, or an IP v4 address, or a host name. **mask** The subnet mask number, which indicates how many bits are set, starting from the most significant bit. For example, 24 means 255.255.255.0 for an IPv4 address. **proto** A protocol. **start_port_range** A particular port number or name to begin in range from. **end_port_range** A particular port number or name to end at.

Item	Description
flags	This parameter takes the following format: `-d drop` ***drop*** AIX Trusted Network can be configured to drop all packets. You can specify one of the following values: **r** Drops all packets **n** Does not drop all packets (interface default). **i** Uses interface default (host default, host only). `-f rflag:tflag` ***rflags*** Security option requirement on incoming (received) packets. You can specify one of the following values: **r** Revised Interconnection Protocol Security Option (RIPSO) only. **c** Commercial Internet Protocol Security Option (CIPSO) only. **e** Either RIPSO or CIPSO. **n** Neither RIPSO or CIPSO (system default). **a** No restrictions. **i** Uses interface or system default (default). ***tflag*** Security option handling on outgoing (transmitted) packets. You can specify one of the following values: **r** Transmits RIPSO. **c** Transmits CIPSO. **n** Does not transmit any security options (interface default). **i** Uses interface default (host default, host only).

Item	Description
RIPSO/CIPSO options	This parameter takes the following format: **-rpafs=*PAF_field*[,*PAF_field*...]** Specifies the PAF fields that are used to receive IPSO packets. This is a list of PAF fields that are accepted. There can be up to 256 fields. ***PAF_field*: NONE | *PAF* [+*PAF*...]** Specifies PAF fields, which are collections of PAFs. The following are the five PAFs that can be included in a single PAF field: • GENSER • SIOP-ESI • SCI • NSA • DOE A PAF field is a combination of these values separated by a plus sign (**+**). For example, a PAF field containing both GENSER and SCI is represented as GENSER+SCI. You can use the PAF field NONE to specify the PAF field without any specified PAFs. **-epaf=*PAF_field*** Specifies the PAF field that is attached to error responses for incoming IPSO packets that were not accepted by the system. **-tpaf=*PAF_field*** Specifies the PAF field that is included in the IPSO options of outgoing packets. **-DOI = *doi*** Specifies the domain of interpretation (DOI) for CIPSO packets. Incoming packets must have this DOI and outgoing packets will be given this DOI. **-tags=*tag*[,*tag*...]** `tag = 1 | 2 | 5` Specifies the set of tags that are accepted and available to be transmitted by CIPSO options. This is a combination of 1, 2 and 5. For example 1,2 would enable tags 1 and 2.
security_label_information	This parameter takes the following format: **+min +max +default | -s input_file** Specifies the standard output (SL) that will apply when adding a rule. You can also specify the **-s** flag and include the SLs in the file in the following order, specifying one per line: • min SL • max SL • default SL You cannot include any comments in the file. Use a backslash (\) at the end of the line if more than one line is needed. If you are not using a file, list the sensitivity labels delimited by a plus sign (+) for the minimum level, the maximum level, and the default or implicit level for unmarked packets.

Security

A user must have the **aix.mls.network.config** and the **aix.mls.network.init** authorizations to run the **netrule** command.

Examples

1. To add in host rule, and update the local database after in host rule is successfully added to kernel, enter:

   ```
   netrule h+iu 9.3.149.25 9.41.86.19 +impl_lo +ts all +pub
   ```

2. To add out host rule, enter:

   ```
   netrule h+o 9.41.86.19  9.3.149.25 -s /tmp/rule
   ```

   or:

   ```
   impl_lo
   ts all
   pub
   ```

   The following are the contents of the input **/tmp/rule** file:

   ```
   impl_lo
   ts \
   all
   pub
   ```

3. To drop all incoming UDP packets from a host, enter:

   ```
   netrule h+i 192.0.0.5 =udp 9.41.86.19 =udp -dr +impl_lo +impl_lo +impl_lo
   ```

4. To remove all host rules and update the local, enter:

   ```
   netrule h-u
   ```

5. To list all host rules, enter:

   ```
   netrule hl
   ```

6. To list all interface rules, enter:

   ```
   netrule il
   ```

7. To add an interface rule, enter:

   ```
   netrule i+ en0 -dn -fa:n +public +ts +secret
   ```

8. To remove a particular host rule, enter:

   ```
   netrule h-i 192.0.0.5 =udp 9.41.86.19 =udp
   ```

9. To add a particular host rule, enter:

   ```
   netrule h+i 9.41.86.19 /24 =tcp :ftp :telnet 9.3.149.6 /28 +public +ts +secret
   ```

10. To set the default interface rule, enter:

    ```
    netrule i+ default -dn -fa:n +impl_lo +ts all +impl_lo
    ```

11. To set the default interface rule to the system drop-all-packets default, enter:

    ```
    netrule i- default
    ```

12. To set the interface to send and only receive CIPSO packets, enter:

```
netrule i+ en0 -fc:c +impl_lo +ts all +impl_lo
```

13. To set the interface to receive either CIPSO or RIPSO packets and send RIPSO packets with PAF values, a CIPSO DOI, and CIPSO flags, enter:

```
netrule i+ en0 -fe:r -rpafs=SCI,NSA+DOE -epaf=SCI -tpaf=NSA -DOI=0x010
-tags=1,2 +impl_lo +ts all +impl_lo
```

14. To set the system-wide policy for sending ICMP responses on incoming packets that are not valid, enter:

```
netrule e on
```

netstat Command

Purpose

Shows network status.

Syntax

To Display Active Sockets for Each Protocol or Routing Table Information

/bin/netstat [**-n**] [{**-A** **-a** } | { **-r** **-C** **-i** **-I** *Interface* }] [**-f** *AddressFamily*] [[**-p** *Protocol*] | [**-@** *WparName*]] [*Interval*]

To Display the Contents of a Network Data Structure

/bin/netstat [**-m** | **-M** | **-s** | **-ss** | **-u** | **-v**] [**-f** *AddressFamily*] [[**-p** *Protocol*] | [**-@** *WparName*]] [*Interval*]

To Display the Virtual Interface Table and Multicast Forwarding Cache

/bin/netstat -g

To Display the Packet Counts Throughout the Communications Subsystem

/bin/netstat -D

To Display the Network Buffer Cache Statistics

/bin/netstat -c

To Display the Data Link Provider Interface Statistics

/bin/netstat -P

To Clear the Associated Statistics

/bin/netstat [**-Zc** | **-Zi** | **-Zm** | **-Zs**]

Description

The **netstat** command symbolically displays the contents of various network-related data structures for active connections. The *Interval* parameter, which is specified in seconds, continuously displays information regarding packet traffic on the configured network interfaces. The *Interval* parameter takes no flags.

Flags

Item	Description
-A	Shows the address of any protocol control blocks associated with the sockets. This flag acts with the default display and is used for debugging purposes.
-a	Shows the state of all sockets. If this flag is not specified, sockets that are used by server processes that are not bound to an interface are not shown.
-c	Shows the statistics of the Network Buffer Cache. The Network Buffer Cache is a list of network buffers that contain data objects that can be transmitted to networks. The Network Buffer Cache grows dynamically as data objects are added to or removed from it. The Network Buffer Cache is used by some network kernel interfaces for performance enhancement on the network I/O. The **netstat -c** command prints the following statistic: `Network Buffer Cache Statistics:` `Current total cache buffer size: 0` `Maximum total cache buffer size: 0` `Current total cache data size: 0` `Maximum total cache data size: 0` `Current number of cache: 0` `Maximum number of cache: 0` `Number of cache with data: 0` `Number of searches in cache: 0` `Number of cache hit: 0` `Number of cache miss: 0` `Number of cache newly added: 0` `Number of cache updated: 0` `Number of cache removed: 0` `Number of successful cache accesses: 0` `Number of unsuccessful cache accesses: 0` `Number of cache validation: 0` `Current total cache data size in private segments: 0` `Maximum total cache data size in private segments: 0` `Current total number of private segments: 0` `Maximum total number of private segments: 0` `Current number of free private segments: 0` `Current total NBC_NAMED_FILE entries: 0` `Maximum total NBC_NAMED_FILE entries: 0`

Item	Description
-C	Shows the routing tables, including the user-configured and current costs of each route. The user-configured cost is set by using the **-hopcount** flag of the **route** command. The current cost can be different than the user-configured cost if Dead Gateway Detection has changed the cost of the route. In addition to the costs of the route, it also shows the weight and policy information associated with each route. These fields are applicable only when the Multipath Routing Feature is used. The policy information displays the routing policy that has been currently selected to choose between the multiple routes available. The policies available are: • Default - Weighted Round Robin (WRR) • Hashed (HSH) • Random (RND) • Weighted Random (WRND) • Lowest Utilization (LUT) If multiple routes are present for the same destination (multipath routes), one of these routes display the policy value of `WRR`, `HSH`, `RND`, `WRND`, or `LUT`. All the other routes in this set display the policy information as `-"-`. This means that all the routes in this set are using the same routing policy displayed by the first route. The weight field is a user-configured weight associated with the route that will be used for Weighted Round-Robin and Weighted Random Policies. For more information about these policies, see the **no** command.
-D	Shows the number of packets received, transmitted, and dropped in the communications subsystem. **Note:** In the statistics output, a `N/A` displayed in a field value indicates the count is not applicable. For the NFS/RPC statistics, the number of incoming packets that pass through RPC are the same packets that pass through NFS, so these numbers are not summed in the `NFS/RPC Total` field, thus the `N/A`. NFS has no outgoing packet or outgoing packet drop counters specific to NFS and RPC. Therefore, individual counts have a field value of `N/A`, and the cumulative count is stored in the `NFS/RPC Total` field.
-f *AddressFamily*	Limits reports of statistics or address control blocks to those items specified by the *AddressFamily* variable. The following address families are recognized: **inet** Indicates the AF_INET address family. **inet6** Indicates the AF_INET6 address family. **unix** Indicates the AF_UNIX address family.
-g	Shows Virtual Interface Table and Multicast Forwarding Cache information. If used in conjunction with the **-s** flag, it will show the multicast routing information.

Item	Description
-i	Shows the state of all configured interfaces. See Interface Display **Note:** The collision count for Ethernet interfaces is not supported.
-I *Interface*	Shows the state of the configured interface specified by the *Interface* variable.
-M	Shows network memory's mbuf cluster pool statistics.
-m	Shows statistics recorded by the memory management routines.
-n	Shows network addresses as numbers. When this flag is not specified, the **netstat** command interprets addresses where possible and displays them symbolically. This flag can be used with any of the display formats.
-o	Used in conjunction with the **-a** flag to display detailed data about a socket, such as socket options, flags, and buffer statistics.
-p *Protocol*	Shows statistics about the value specified for the *Protocol* variable, which is either a well-known name for a protocol or an alias for it. Some protocol names and aliases are listed in the **/etc/networks** file.
-P	Shows the statistics of the Data Link Provider Interface (DLPI). The **netstat -P** command prints the following statistic: `DLPI statistics:` `Number of received packets = 0` `Number of transmitted packets = 0` `Number of received bytes = 0` `Number of transmitted bytes = 0` `Number of incoming pkts discard = 0` `Number of outgoing pkts discard = 0` `Number of times no buffers = 0` `Number of successful binds = 0` `Number of unknown message types = 0` `Status of phys level promisc = 0` `Status of sap level promisc = 0` `Status of multi level promisc = 0` `Number of enab_multi addresses = 0` If DLPI is not loaded, it displays: `can't find symbol: dl_stats`
-r	Shows the routing tables. When used with the **-s** flag, the**-r** flag shows routing statistics. See Routing Table Display.
-s	Shows statistics for each protocol.
-ss	Displays all the non-zero protocol statistics and provides a concise display.
-u	Displays information about domain sockets.
-v	Shows statistics for CDLI-based communications adapters. This flag causes the **netstat** command to run the statistics commands for the **netstat**, **tokstat**, and **fddistat** commands. No flags are issued to these device driver commands. See the specific device driver statistics command to obtain descriptions of the statistical output.
-Zc	Clear network buffer cache statistics.
-Zi	Clear interface statistics.
-Zm	Clear network memory allocator statistics.
-Zs	Clear protocol statistics. To clear statistics for a specific protocol, use -p <protocol>. For example, to clear TCP statistics, type **netstat -Zs -p tcp**.

Item	Description
-@ ***WparName***	Displays the network statistics associated with workload partition (***WparName***). If no ***WparName*** is specified, then show the network statistics for all workload partitions.

Notes:

1. The **-C**, **-D**, **-c**, **-g**, **-m**, **-M**, **-P**, **-r** , **-v**, and **-Z** flags are not supported in the global environment when used in conjunction with the `-@` *WparName* option.
2. The **-C**, **-D**, **-c**, **-g**, **-m**, **-M**, **-P**, **-r** , **-v**, and **-Z** flags are not supported in system workload partitions.

Default Display

The default display for active sockets shows the following items:

- Local and remote addresses
- Send and receive queue sizes (in bytes)
- Protocol
- Internal state of the protocol

Internet address formats are of the form `host.port` or `network.port` if a socket's address specifies a network but no specific host address. The host address is displayed symbolically if the address can be resolved to a symbolic host name, while network addresses are displayed symbolically according to the `/etc/networks` file.

If a symbolic name for a host is not known or if the **-n** flag is used, the address is printed numerically, according to the address family. Unspecified addresses and ports appear as an * (asterisk).

Interface Display (netstat -i)

The interface display format provides a table of cumulative statistics for the following items:

- Errors
- Collisions

  Note: The collision count for Ethernet interfaces is not supported.
- Packets transferred

The interface display also provides the interface name, number, and address as well as the maximum transmission units (MTUs).

Routing Table Display (netstat -r)

The routing table display indicates the available routes and their statuses. Each route consists of a destination host or network and a gateway to use in forwarding packets.

A route is given in the format *A.B.C.D***/***XX*, which presents two pieces of information. *A.B.C.D* indicates the destination address and *XX* indicates the netmask associated with the route. The netmask is represented by the number of bits set. For example, the route `9.3.252.192/26` has a netmask of `255.255.255.192`, which has 26 bits set.

The routing table contains the following fields:

Item	Description
`WPAR`	Displays the name of the workload partition to which this route belongs. This field is only present when the **-@** flag is used with the **-r** flag. For routes belonging to the global system, `Global` is displayed in this column.

Item	Description
Flags	The **flags** field of the routing table shows the state of the route: **A** An Active Dead Gateway Detection is enabled on the route. **U** Up. **H** The route is to a host rather than to a network. **G** The route is to a gateway. **D** The route was created dynamically by a redirect. **M** The route has been modified by a redirect. **L** The link-level address is present in the route entry. **c** Access to this route creates a cloned route. **W** The route is a cloned route. **1** Protocol specific routing flag #1. **2** Protocol specific routing flag #2. **3** Protocol specific routing flag #3. **b** The route represents a broadcast address. **e** Has a binding cache entry. **l** The route represents a local address. **m** The route represents a multicast address. **P** Pinned route. **R** Host or net unreachable. **S** Manually added. **u** Route usable. **s** The Group Routing stopsearch option is enabled on the route. Direct routes are created for each interface attached to the local host.
Gateway	The **gateway** field for these entries shows the address of the outgoing interface.

Item	Description
Refs	Gives the current number of active uses for the route. Connection-oriented protocols hold on to a single route for the duration of a connection, while connectionless protocols obtain a route while sending to the same destination.
Use	Provides a count of the number of packets sent using that route.
PMTU	Gives the Path Maximum Transfer Unit (PMTU). AIX 5.3 does not display the PMTU column.
Interface	Indicates the network interfaces utilized for the route.
Exp	Displays the time (in minutes) remaining before the route expires.
Groups	Provides a list of group IDs associated with that route.
Netmasks	Lists the netmasks applied on the system.
Route Tree for Protocol Family	Specifies the active address families for existing routes. Supported values for this field are: **1** Specifies the UNIX address family. **2** Specifies the Internet address family (for example, TCP and UDP). For more information on other address families, refer to the **/usr/include/sys/socket.h** file.

When the **-@** flag is used with the **netstat -r** command and no *WparName* parameter is specified, all of the routes in the system's route table are displayed. If the *WparName* parameter is specified and the WPAR-specific routing is enabled for that WPAR, only the routes associated with that WPAR are displayed. If the *WparName* parameter is specified and the WPAR specific routing is disabled for that WPAR, the routes associated with the global system are displayed.

When a value is specified for the *Interval* parameter, the **netstat** command displays a running count of statistics related to network interfaces. This display contains two columns: a column for the primary interface (the first interface found during autoconfiguration) and a column summarizing information for all interfaces.

The primary interface may be replaced with another interface by using the **-I** flag. The first line of each screen of information contains a summary of statistics accumulated since the system was last restarted. The subsequent lines of output show values accumulated over intervals of the specified length.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To display routing table information for an Internet interface, enter the following command:

   ```
   netstat -r -f inet
   ```

   This produces the following output:

   ```
   Routing tables
   Destination   Gateway      Flags Refs Use  PMTU If  Exp Groups Netmasks:
   (root node)
   ```

```
(0)0 ffff f000 0
(0)0 ffff f000 0
(0)0 8123 262f 0 0 0 0 0
(root node)

Route Tree for Protocol Family 2:
(root node)
default        129.35.38.47   UG    0  564   -   tr0   -
loopback       127.0.0.1      UH    1  202   -   lo0   -
129.35.32      129.35.41.172  U     4   30   -   tr0   -   +staff
129.35.32.117  129.35.41.172  UGHW  0   13  1492 tr0   30
192.100.61     192.100.61.11  U     1  195   -   en0   -
(root node)

Route Tree for Protocol Family 6:
(root node)
(root node)
```

The `-r -f inet` flags indicate a request for routing table information for all configured Internet interfaces. The network interfaces are listed in the `Interface` column; en designates a Standard Ethernet interface, while `tr` specifies a Token-Ring interface. Gateway addresses are in dotted decimal format.

Note: AIX 5.3 does not display the PMTU column.

2. To display statistics for GRE Protocol, enter the following command:

```
netstat -s -p gre
```

This produces the following output:

```
GRE Interface gre0
        10 number of times gre_input got called
        8 number of times gre_output got called
        0 packets received with protocol not supported
        0 packets received with checksum on
        0 packets received with routing present
        0 packets received with key present
        0 packets received with sequence number present
        0 packets received with strict source route  present
        0 packets received with recursion control present
        0 packets received where reserved0 non-zero
        0 packets received where version non-zero
        0 packets discarded
        0 packets dropped due to network down
        0 packets dropped due to protocol not supported
        0 packets dropped due to error in ip output routine
        0 packets got by NAT
        0 packets got by NAT but not TCP packet
        0 packets got by NAT but with IP options
```

3. To display statistics for the IPv4 over IPv6 tunnel (GIF tunnel), enter the following command:

```
netstat -s -p gif
```

The command produces the following output:

```
GIF Interface gif0
44 total packets received
50 total packets sent
0 packets received with protocol not supported
0 packets received with checksum on
0 packets received with routing present
0 packets received with strict source route present
0 packets received where version non-zero
0 packets discarded
0 packets dropped due to network down
0 packets dropped due to protocol not supported
0 packets dropped due to error in ipv6 output routine
```

4. To display interface information for an Internet interface, enter the following command:

```
netstat -i -f inet
```

This produces the following output:

```
Name Mtu    Network     Address           Ipkts  Ierrs  Opkts  Oerrs  Coll
lo0  16896  Link#1                        5161      0    5193      0     0
lo0  16896  127         localhost         5161      0    5193      0     0
lo0  16896  ::1                           5161      0    5193      0     0
en1  1500   Link#2      8.0.38.22.8.34    221240    0  100284      0     0
en1  1500   129.183.64  infoserv.frec.bul 221240    0  100284      0     0
```

The `-i -f inet` flags indicate a request for the status of all configured Internet interfaces. The network interfaces are listed in the `Name` column; `lo` designates a loopback interface, `en` designates a Standard Ethernet interface, while `tr` specifies a Token-Ring interface.

5. To display statistics for each protocol, enter the following command:

```
netstat -s -f inet
```

This produces the following output:

```
ip:
:
  44485 total packets received
  0 bad header checksums
  0 with size smaller than minimum
  0 with data size < data length
  0 with header length < data size
  0 with data length < header length
  0 with bad options
  0 with incorrect version number
  0 fragments received
  0 fragments dropped (dup or out of space)
  0 fragments dropped after timeout
  0 packets reassembled ok
  44485 packets for this host
  0 packets for unknown/unsupported protocol
  0 packets forwarded
  0 packets not forwardable
  0 redirects sent
  1506 packets sent from this host
  0 packets sent with fabricated ip header
  0 output packets dropped due to no bufs, etc.
  0 output packets discarded due to no route
  0 output datagrams fragmented
  0 fragments created
  0 datagrams that can't be fragmented
  0 IP Multicast packets dropped due to no receiver
  0 successful path MTU discovery cycles
  0 path MTU rediscovery cycles attempted
  0 path MTU discovery no-response estimates
  0 path MTU discovery response timeouts
  0 path MTU discovery decreases detected
  0 path MTU discovery packets sent
  0 path MTU discovery memory allocation failures
  0 ipintrq overflows

icmp:
  0 calls to icmp_error
  0 errors not generated 'cuz old message was icmp
  Output histogram:
    echo reply: 6
  0 messages with bad code fields
  0 messages < minimum length
  0 bad checksums
  0 messages with bad length
  Input histogram:
    echo: 19
  6 message responses generated

igmp:defect
  0 messages received
  0 messages received with too few bytes
  0 messages received with bad checksum
  0 membership queries received
  0 membership queries received with invalid field(s)
  0 membership reports received
  0 membership reports received with invalid field(s)
  0 membership reports received for groups to which we belong
  0 membership reports sent
```

```
tcp:
  1393 packets sent
    857 data packets (135315 bytes)
    0 data packets (0 bytes) retransmitted
    367 URG only packets
    0 URG only packets
    0 window probe packets
    0 window update packets
    170 control packets
  1580 packets received
    790 acks (for 135491 bytes)
    60 duplicate acks
    0 acks for unsent data
    638 packets (2064 bytes) received in-sequence
    0 completely duplicate packets (0 bytes)
    0 packets with some dup. data (0 bytes duped)
    117 out-of-order packets (0 bytes)
    0 packets (0 bytes) of data after window
    0 window probes
    60 window update packets
    0 packets received after close
    0 discarded for bad checksums
    0 discarded for bad header offset fields
  0 connection request
  58 connection requests
  61 connection accepts
  118 connections established (including accepts)
  121 connections closed (including 0 drops)
  0 embryonic connections dropped
  845 segments updated rtt (of 847 attempts)
  0 resends due to path MTU discovery
  0 path MTU discovery terminations due to retransmits
  0 retransmit timeouts
    0 connections dropped by rexmit timeout
  0 persist timeouts
  0 keepalive timeouts
    0 keepalive probes sent
    0 connections dropped by keepalive

udp:
  42886 datagrams received
:
  0 incomplete headers
  0 bad data length fields
  0 bad checksums
  0 dropped due to no socket
  42860 broadcast/multicast datagrams dropped due to no

socket
  0 socket buffer overflows
  26 delivered
  106 datagrams output
```

`ip` specifies the Internet Protocol; `icmp` specifies the Information Control Message Protocol; `tcp` specifies the Transmission Control Protocol; udp specifies the User Datagram Protocol.

Note: AIX 5.3 does not display the PMTU statistics for the IP protocol.

6. To display device driver statistics, enter the following command:

```
netstat -v
```

The `netstat -v` command displays the statistics for each CDLI-based device driver that is up. To see sample output for this command, see the **tokstat** command, the **entstat** command, or the **fddistat** command.

7. To display information regarding an interface for which multicast is enabled, and to see group membership, enter the following command:

```
netstat -a -I interface
```

For example, if an 802.3 interface was specified, the following output will be produced:

```
Name  Mtu  Network Address      Ipkts  Ierrs  Opkts  Oerrs  Coll
et0   1492 <Link>                  0      0      2      0     0
```

```
et0   1492 9.4.37  hun-eth          0      0      2      0     0
                   224.0.0.1
                   02:60:8c:0a:02:e7
                   01:00:5e:00:00:01
```

If instead of **-I** *interface* the flag **-i** is given, then all configured interfaces will be listed. The network interfaces are listed in the Name column; **lo** designates a loopback interface, **et** designates an IEEE 802.3 interface, **tr** designates a Token-Ring interface, while **fi** specifies an FDDI interface.

The address column has the following meaning. A symbolic name for each interface is shown. Below this symbolic name, the group addresses of any multicast groups that have been joined on that interface are shown. Group address 224.0.0.1 is the special *all-hosts-group* to which all multicast interfaces belong. The MAC address of the interface (in colon notation) follows the group addresses, plus a list of any other MAC level addresses that are enabled on behalf of IP Multicast for the particular interface.

8. To display the packet counts in the communication subsystem, enter the following command:

```
netstat -D
```

The following output will be produced:

```
Source                    Ipkts     Opkts     Idrops      Odrops

...................
...................
```

10. To display the routing table, enter the following command:

```
netstat -rn
```

Output similar to the following is displayed:

```
Routing tables
Destination      Gateway           Flags   Refs     Use  If   PMTU Exp Groups

Route Tree for Protocol Family 2 (Internet):
default          9.3.149.65        UG        0       24  en0     -   -
9.3.149.64       9.3.149.88        UHSb      0        0  en0     -   -  =>
9.3.149.64/27    9.3.149.88        U         1        0  en0     -   -
9.3.149.88       127.0.0.1         UGHS      0        1  lo0     -   -
9.3.149.95       9.3.149.88        UHSb      0        0  en0     -   -
127/8            127.0.0.1         U        11      174  lo0     -   -

Route Tree for Protocol Family 24 (Internet v6):
::1              ::1               UH        0        0  lo0     -   -
```

Note: AIX 5.3 does not display the PMTU column.

The character => at the end of the line means the line is a duplicate route of the route on the next line.

The loopback route (9.3.149.88, 127.0.0.1) and the broadcast routes (with the flags field containing b indicating broadcast) are automatically created when an interface is configured. Two broadcast routes are added: one to the subnet address and one to the broadcast address of the subnet. The presence of the loopback routes and broadcast routes improve performance.

11. To display the routing table of a workload partition named `wpar1`, enter the following command:

```
netstat –rn@ wpar1
```

Output similar to the following is displayed:

```
Routing tables
WPAR Destination    Gateway         Flags      Refs      Use    If   Exp  Groups

Route Tree for Protocol Family 2 (Internet):

```

newaliases Command

Purpose

Builds a new copy of the alias database from the mail aliases file.

Syntax

newaliases

Description

The **newaliases** command builds a new copy of the alias database from the **/etc/aliases** file. It must be run each time this file is changed in order for the changes to take effect. Running this command is equivalent to running the **sendmail** command with the **-bi** flag.

Exit Status

Item	Description
0	Exits successfully.
>0	An error occurred.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Files

Item	Description
/usr/sbin/newaliases	Contains the **newaliases** command.
/etc/mail html	

newform Command

Purpose

Changes the format of a text file.

Syntax

newform [**-s**] [**-f**] [**-a** [*Number*]] [**-b** [*Number*]] [**-c** [*Character*]] [**-e** [*Number*]] [**-i** [*TabSpec*]] [**-l** [*Number*]] [**-o** [*TabSpec*]] [**-p** [*Number*]] [*File* ...]

Description

The **newform** command takes lines from the files specified by the *File* parameter (standard input by default) and writes the formatted lines to standard output. Lines are reformatted in accordance with the command-line flags in effect.

Except for the **-s** flag, you can enter command-line flags in any order, repeated, and mixed with the *File* parameter. However, the system processes command-line flags in the order you specify. For example, the

-c flag modifies the behavior of the **-a** and **-p** flags, so specify the **-c** flag before the **-p** or **-a** flag for which it is intended. The **-l** (lowercase L) flag modifies the behavior of the **-a**, **-b**, **-e**, and **-p** flags, so specify the **-l** flag before the flags for which it is intended. For example, flag sequences like **-e**15 **-l**60 yield results that are different from **-l**60 **-e**15. Flags are applied to all files specified on the command line.

An exit value of 0 indicates normal execution; an exit value of 1 indicates an error.

Note:

1. The **newform** command normally only keeps track of physical characters; however, for the **-i** and **-o** flags, the **newform** command keeps track of backspaces to line up tabs in the appropriate logical columns.
2. The **newform** command does not prompt you if the system reads a *TabSpec* variable value from standard input (by use of the **-i-** or **-o-** flag).
3. If you specify the **-f** flag, and the last **-o** flag you specified was **-o-** preceded by either an **-o-** or an **-i-**, the tab-specification format line is incorrect.
4. If the values specified for the **-p**, **-l**, **-e**, **-a**, or **-b** flag are not valid decimal numbers greater than 1, the specified value is ignored and default action is taken.

Flags

Item	Description
-a [*Number*]	Adds the specified number of characters to the end of the line when the line length is less than the effective line length. If no number is specified, the **-a** flag defaults to 0 and adds the number of characters necessary to obtain the effective line length. See also the **-c** [*Character*] and **-p** [*Number*] flags.
-b [*Number*]	Truncates the specified number of characters from the beginning of the line if the line length is greater than the effective line length. If the line also contains fewer characters than specified by the *Number* parameter, the entire line is deleted and a blank line is displayed in its place. See also the **-I** [*Number*] flag. If you specify the **-b** flag with no *Number* variable, the default action truncates the number of characters necessary to obtain the effective line length. This flag can be used to delete the sequence numbers from a COBOL program, as follows: `newform -l1-b7 file-name` The **-l1** flag must be used to set the effective line length shorter than any existing line in the file so that the **-b** flag is activated.
-c [*Character*]	Changes the prefix/add character to that specified by the *Character* variable. Default character is a space and is available when specified before the **-a** and **-p** flags.
-e [*Number*]	Truncates the specified number of characters from the end of the line. Otherwise, the flag is the same as the **-b** [*Number*] flag.
-f	Writes the tab-specification format line to standard output before any other lines are written. The displayed tab-specification format line corresponds to the format specified by the final **-o** flag. If no **-o** flag is specified, the line displayed contains the default specification of -8.

Item	Description
-i [*TabSpec*]	Replaces all tabs in the input with the number of spaces specified by the *TabSpec* variable. This variable recognizes all tab specification forms described in the **tabs** command. If you specify a **-** (minus sign) for the value of the *TabSpec* variable, the **newform** command assumes that the tab specification can be found in the first line read from standard input. The default *TabSpec* value is -8. A *TabSpec* value of -0 expects no tabs. If any are found, they are treated as having a value of -1.
-l [*Number*]	Sets the effective line length to the specified number of characters. If no *Number* variable is specified, the **-l** flag defaults to 72. The default line length without the **-l** flag is 80 characters. Note that tabs and backspaces are considered to be one character (use the **-i** flag to expand tabs to spaces). You must specify the **-l** flag before the **-b** and **-e** flags.
-o [*TabSpec*]	Replaces spaces in the input with a tab in the output, according to the tab specifications given. The default *TabSpec* value is -8. A *TabSpec* value of -0 means that no spaces are converted to tabs on output.
-p [*Number*]	Appends the specified number of characters to the beginning of a line when the line length is less than the effective line length. The default action is to append the number of characters that are necessary to obtain the effective line length. See also the **-c** flag.
-s	Removes leading characters on each line up to the first tab and places up to 8 of the removed characters at the end of the line. If more than 8 characters (not counting the first tab) are removed, the 8th character is replaced by an ***** (asterisk) and any characters to the right of it are discarded. The first tab is always discarded. The characters removed are saved internally until all other specified flags are applied to that line. The characters are then added to the end of the processed line.

Note: The values for the **-a**, **-b**, **-e**, **-l** (lowercase L), and **-p** flags cannot be larger than **LINE_MAX** or 2048 bytes.

Examples

To convert from a file with:

- Leading digits
- One or more tabs
- Text on each line

to a file:

- Beginning with the text, all tabs after the first expanded to spaces
- Padded with spaces out to column 72 (or truncated to column 72)
- Leading digits placed starting at column 73

type the following:

```
newform -s -i -l -a -e filename
```

The **newform** command displays the following error message and stops if the **-s** flag is used on a file without a tab on each line.

```
newform: 0653-457 The file is not in a format supported by the -s flag.
```

newgrp Command

Purpose

Changes a user's real group identification.

Syntax

newgrp [**-**] [**-l**] [*Group*]

Description

The **newgrp** command changes a user's real group identification. When you run the command, the system places you in a new shell and changes the name of your real group to the group specified with the *Group* parameter. By default, the **newgrp** command changes your real group to the group specified in the **/etc/passwd** file.

> **Note:** The **newgrp** command does not take input from standard input and cannot be run from within a script.

The **newgrp** command recognizes only group names, not group ID numbers. Your changes only last for the current session. You can only change your real group name to a group you are already a member of. If you are a root user, you can change your real group to any group regardless of whether you are a member of it or not.

> **Note:** When you run the **newgrp** command, the system always replaces your shell with a new one. The command replaces your shell regardless of whether the command is successful or not. For this reason, the command does not return error codes.

Flags

Item	Description
-	Changes the environment to the login environment of the new group.
-l	Indicates the same value as the **-** flag.

Security

Access Control: This command should be installed as a program in the trusted computing base (TCB). The command should be owned by the root user with the **setuid** (SUID) bit set.

Exit Status

If the **newgrp** command succeeds in creating a new shell execution environment, regardless if the group identification was changed successfully, the exit status will be that of the current shell. Otherwise, the following exit value is returned:

Item	Description
>0	An error occurred.

Examples

1. To change the real group ID of the current shell session to `admin`, enter:

```
newgrp admin
```

2. To change the real group ID back to your original login group, enter:

```
newgrp
```

Files

Item	Description
/etc/passwd	Indicates the password file; contains user IDs.

newkey Command

Purpose

Creates a new key in the **/etc/publickey** file.

Syntax

/usr/sbin/newkey [**-h** *HostName*] [**-u** *UserName*]

Description

The **newkey** command creates a new key in the **/etc/publickey** file. This command is normally run by the network administrator on the Network Information Services (NIS) master machine to establish public keys for users and root users on the network. These keys are needed for using secure Remote Procedure Call (RPC) protocol or secure Network File System (NFS).

The **newkey** command prompts for the login password of the user specified by the *UserName* parameter. Then, the command creates a new key pair in the **/etc/publickey** file and updates the **publickey** database. The key pair consists of the user's public key and secret key and is encrypted with the login password of the given user.

Use of this program is not required. Users may create their own keys using the **chkey** command.

You can use the System Management Interface Tool (SMIT) **smit newkey** fast path to run this command.

Flags

Item	Description
-h *HostName*	Creates a new public key for the root user at the machine specified by the *HostName* parameter. Prompts for the root password of this parameter.
-u *UserName*	Creates a new public key for a user specified by the *UserName* parameter. Prompts for the NIS password of this parameter.

Examples

1. To create a new public key for a user, enter:

```
newkey -u john
```

   In this example, the **newkey** command creates a new public key for the user named `john`.

2. To create a new public key for the root user on host `zeus`, enter:

```
newkey -h zeus
```

In this example, the **newkey** command creates a new public key for the root user on the host named zeus.

Files

Item	Description
/etc/publickey	Stores encrypted keys for users.

news Command

Purpose

Writes system news items to standard output.

Syntax

news [**-a** | **-n** | **-s** | *Item ...*]

Description

The **news** command writes system news items to standard output. This command keeps you informed of news concerning the system. Each news item is contained in a separate file in the **/var/news** directory. Most users run the **news** command followed by the **-n** flag each time they log in by including it in their **$HOME/.profile** file or in the system's **/etc/profile** file. Any user having write permission to this directory can create a news item. It is not necessary to have read permission to create a news item.

If you run the **news** command without any flags, it displays every current file in the **/var/news** file, showing the most recent first. This command, used with the **-a** flag, displays all news items. If you specify the **-n** flag, only the names of the unread news items are displayed. Using the **-s** flag displays the number of unread news items. You can also use the *Item* parameter to specify the files that you want displayed.

Each file is preceded by an appropriate header. To avoid reporting old news, the **news** command stores a currency time. The **news** command considers your currency time to be the date the **$HOME/.news_time** file was last modified. Each time you read the news, the modification time of this file changes to that of the reading. Only news item files posted after this time are considered current.

Pressing the Interrupt (Ctrl-C) key sequence during the display of a news item stops the display of that item and starts the next. Pressing the Ctrl-C key sequence again ends the **news** command.

Note: News items can contain multibyte characters.

Flags

Item	Description
-a	Displays all news items, regardless of the currency time. The currency time does not change.
-n	Reports the names of current news items without displaying their contents. The currency time does not change.
-s	Reports the number of current news items without displaying their names or contents. The currency time does not change.

Examples

1. To display the items that have been posted since you last read the news, enter:

```
news
```

2. To display all the news items, enter:

   ```
   news -a | pg
   ```

   All of the news items display a page at a time (| pg), regardless of whether you have read them yet.
3. To list the names of the news items that you have not read yet, enter:

   ```
   news -n
   ```

   Each name is a file in the **/var/news** directory.
4. To display specific news items, enter:

   ```
   news newusers services
   ```

   This command sequence displays news about `newusers` and `services`, which are names listed by the **news -n** command.
5. To display the number of news items that you have not yet read, enter:

   ```
   news -s
   ```
6. To post news for everyone to read, enter:

   ```
   cp schedule /var/news
   ```

   This copies the `schedule` file into the system **/var/news** directory to create the **/var/news/schedule** file. To do this, you must have write permission to the **/var/news** directory.

Files

Item	Description
/usr/bin/news	Contains the **news** command.
/etc/profile	Contains the system profile.
/var/news	Contains system news item files.
$HOME/.news_time	Indicates the date the **news** command was last invoked.

next Command

Purpose

Shows the next message.

Syntax

next [**+***Folder*] [**-header** | **-noheader**] [**-showproc** *CommandString* | **-noshowproc**]

Description

The **next** command displays the number the system will assign to the next message filed in a Message Handler (MH) folder. The **next** command is equivalent to the **show** command with the **next** value specified as the message.

The **next** command links to the **show** program and passes any switches on to the **showproc** program. If you link to the **next** value and call that link something other than **next**, your link will function like the **show** command, rather than like the **next** command.

The **show** command passes flags it does not recognize to the program performing the listing. The **next** command provides a number of flags for the listing program.

Flags

Item	Description
+*Folder*	Specifies the folder that contains the message you want to show.
-header	Displays a one-line description of the message being shown. The description includes the folder name and message number. This is the default.
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For MH, the name of this flag must be fully spelled out.
-noheader	Prevents display of a one-line description of each message being shown.
-noshowproc	Uses the **/usr/bin/cat** file to perform the listing. This is the default.
-showproc *CommandString*	Uses the specified command string to perform the listing.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To see the next message in the current folder, enter:

   ```
   next
   ```

   The system responds with a message similar to the following:

   ```
   (Message schedule: 10)
   ```

   The text of the message is also displayed. In this example, message `10` in the current folder `schedule` is the next message.
2. To see the next message in the `project` folder, enter:

   ```
   next  +project
   ```

   The system responds with the text of the message and a header similar to the following:

   ```
   (Message project: 5)
   ```

Files

Item	Description
$HOME/.mh_profile	Specifies a user's MH profile.
/usr/bin/next	Contains the **next** command.

nfs.clean Command

Purpose

Stops NFS and NIS operations.

Syntax

```
/etc/nfs.clean [-d][-y][-t nfs|nis]
```

Description

The `/etc/nfs.clean` command is used to shut down operations of NFS, NIS, or both. This script is used by the `shutdown` command but can be used to stop operations of only NFS or NIS. By default, all NFS and NIS daemons are stopped.

This command is recommended instead of using `stopsrc -g nfs` since the `nfs.clean` command shuts daemons down in the correct order. The `stopsrc` command has no notion of stopping daemons of a group in the proper order. This can cause problems if the `statd` and `lockd` daemons are running and the `statd` daemon is stopped before the `lockd` daemon.

Flags

Item	Description
-d	Stops only server-specific daemons. Daemons that can run on clients are not stopped.
-y	Stops only server-specific NIS daemons. This flag is presumed if the `-d` flag is used.
-t	Stops only the specified system. If `-t nfs` is specified, only the NFS daemons are stopped. If `-t nis` is specified, only the NIS daemons are stopped.

Exit Status

Item	Description
0	Command completed successfully.
1	Argument error.

Examples

1. To stop all NFS and NIS daemons, type:

   ```
   /etc/nfs.clean
   ```

2. To stop only NFS, type:

   ```
   /etc/nfs.clean -t nfs
   ```

3. To stop only NFS service daemons, type:

   ```
   /etc/nfs.clean -d -t nfs
   ```

Location

/etc/nfs.clean

nfs4cl Command

Purpose

Displays or modifies current NFSv4 statistics and properties.

Syntax

/usr/sbin/nfs4cl [*subcommand*] [*path*] [*argument*]

Description

Use the **nfs4cl** command to display all the fsid information on the client or modify filesystem options of an fsid.

Note: The **nfs4cl** updates affect newly accessed files in the filesystem. An unmount and remount are required to affect all previously accessed files.

Subcommands

resetfsoptions Subcommand

This subcommand resets all the options for the fsid back to the default options.

Note: The **cio** and **dio** options can be reset with the **resetfsoptions** subcommand, but the **cio** and **dio** behavior is not actually turned off until the NFS filesystem is unmounted and then remounted.

setfsoptions Subcommand

This subcommand will take a path and an argument. The path specifies the target fsid structure and the argument is the file system options. It will set the internal fsid to use the options specified by the argument. Here is the list of possible arguments:

Item	Description
rw	Specifies that the files or directories that bind to this path (fsid) are readable and writable.
ro	Specifies that the files or directories that bind to this path (fsid) are read only.
acdirmax	Specifies the upper limit for the directory attribute cache time out value.
acdirmin	Specifies the lower limit for the directory attribute cache time out value.
acregmax	Specifies the upper limit for the file attribute cache time out value.
acregmin	Specifies the lower limit for the file attribute cache time out value.
cio	Specifies the filesystem to be mounted for concurrent readers and writers. I/O on files in this filesystem behave as if the file was opened with **O_CIO** specified in the **open()** system call.
cior	Specifies to allow read-only files to open in the file system. I/O on files in this filesystem will behave as if they had been opened with **O_CIO | O_CIOR** specified in the **open()** system call.
dio	Specifies that I/O on the filesystem behaves as if all of the files were opened with **O_DIRECT** specified in the **open()** system call.
hard	Specifies that this fsid will use hard mount semantics.
intr	Specifies that the fsid operations are interruptible.

Item	Description
maxpout=*value*	Specifies the pageout level for files on this filesystem at which threads should be slept. If **maxpout** is specified, **minpout** must also be specified. This value must be non-negative and greater than **minpout**. The default is the kernel **maxpout** level.
minpout=*value*	Specifies the pageout level for files on this filesystem at which threads should be readied. If **minpout** is specified, **maxpout** must also be specified. This value must be non-negative. The default is the kernel **minpout** level.
noac	Does not use attribute cache.
nocto	Specifies no close-to-open consistency.
nointr	Specifies that the fsid is non-interruptible.
`prefer=`*servername*	Administratively sets the preferred server to use when data exists at multiple server locations. The server name can be in short name, long name, IPv4, or IPv6 format, but the client must be able to resolve the server name when the `nfs4cl` command is run.
rbr	Utilizes the release-behind-when-reading capability. When sequential reading of a file in this filesystem is detected, the real memory pages used by the file will be released once the pages are copied to internal buffers.
rsize	Specifies the read size for the RPC calls to the server.
retrans	Specifies the number of RPC retransmits to attempt with soft semantics.
soft	Specifies the fsid operation that will use soft mount semantics.
timeo	Specifies the time out value for the RPC calls to the server.
wsize	Specifies the write size for the RPC calls to the server.
nodircache	Does not use directory cache.

showfs Subcommand

This subcommand displays filesystem specific information on the server that is currently accessed by the client. The information includes server address, remote path, fsid, and local path. If path is provided, additional information, such as fs_locations and fsid options, are displayed.

showstat Subcommand

This subcommand shows information similar to what the **df** command prints out for each fsid that exists on the client. The information includes fields such as, Filesystem, 512-blocks, Free, %Used, Iused, %Iused, and Mounted on.

delegreturn Subcommand

This subcommand accepts file path as its input argument. This subcommand will allow a system administrator to instruct NFS v4 client to return delegations on the file specified by the input path name.

help Subcommand

This subcommand prints the usage statement.

Exit Status

Item	Description
0	The command completed successfully.
>0	An error occurred.

Examples

1. To display all the fsid structure on the client, type:

```
nfs4cl showfs
```

2. To set the file system options of **/mnt/usr/sbin** to include only `retrans=3`, type:

```
nfs4cl setfsoptions /mnt/usr/sbin retrns=3
```

3. To reset the filesystem options for **/mnt/use/sbin**, type:

```
nfs4cl resetfsoptions /mnt/user/sbin
```

4. To show **df** command output for **/mnt/usr/sbin**, type:

```
nfs4cl showstat /mnt/usr/sbin
```

5. To make the client failover to server boo when replication occurs in **/mnt/usr/sbin**, type:

```
nfs4cl setfsoptions /mnt/usr/sbin prefer=boo
```

Location

/usr/sbin/nfs4cl

nfs4smctl Command

Purpose

Administers revocation of NFSv4 State.

Syntax

`/usr/sbin/nfs4smctl -r` [*hostname* | *IP_address*]

Description

Administers revocation of NFS v4 State.

Flags

Item	Description
`-r` *hostname IP_address*	Specifies the client of which state is to be revoked using either the *hostname* or *IP_address* parameter.

Files

Item	Description
`/usr/sbin/nfs4smctl`	Location of the `nfs4smctl` command.

nfsauthreset Command

Purpose

Notifies the Network File System (NFS) kernel extension to destroy the appropriate Generic Security Service API (GSSAPI) credentials from the kernel credentials cache.

Syntax

nfsauthreset

Description

To mark the cached context, the **nfsauthreset** command depends on whether a Process Authentication Group (PAG) is set in the process. If a PAG is set in the process, it marks the cached GSSAPI context having the same User ID (UID) and PAG to be destroyed. Otherwise, it marks the cached GSSAPI context having the same UID to be destroyed.

Examples

To destroy the cached kernel credentials after you have specified the **kinit** and the **kdestroy** commands, enter:

```
nfsauthreset
```

Files

Item	Description
/usr/sbin/nfsauthreset	Contains the **nfsauthreset** command.

nfsd Daemon

Purpose

Services client requests for file system operations.

Syntax

/usr/sbin/nfsd [**-a** | **-p** { *tcp* | *udp* }] [**-c** *max_connections*] [-gp on | off] [-gpx *count*] [-gpbypass] [**-w** *max_write_size*] [**-r** *max_read_size*] [-root directory] [-public directory] *nservers*

/usr/sbin/nfsd -getnodes

/usr/sbin/nfsd -getreplicas

Description

The **nfsd** daemon runs on a server and handles client requests for file system operations.

Each daemon handles one request at a time. Assign the maximum number of threads based on the load you expect the server to handle.

The **nfsd** daemon is started and stopped with the following System Resource Controller (**SRC**) commands:

```
startsrc -s nfsd
```

```
stopsrc -s nfsd
```

To change the number of daemons started with the SRC commands, use the **chnfs** command. To change the parameters of an SRC controlled daemon, use the **chssys** command.

Note: If the number of nfsd daemons is not sufficient to serve the client, a nonidempotent operation error is returned to the client. For example, if the client removes a directory, an ENOENT error is returned even though the directory on the server is removed.

Flags

Item	Description
-a	Specifies UDP and TCP transport will be serviced.
-c *max_connections*	Specifies the maximum number of TCP connections allowed at the NFS server.
-gp on|off	Controls the NFSv4 Grace Period enablement. The possible values are on or `off`. If no `-gp` option is specified, the grace period is disabled by default.
-gpbypass	Controls the NFSv4 Grace Period bypass. When this option is specified, the grace period will be bypassed regardless of how the `-gp` option is specified.
-gpx *count*	Controls the NFSv4 Grace Period automatic extension. The *count* parameter specifies the total number of automatic extensions allowed for the grace period. If no `-gpx` option is specified, the number of allowed automatic extensions defaults to 1. A single extension cannot extend the grace period for more than the length of the NFSv4 lease period. The NFSv4 subsystem uses runtime metrics (such as the time of the last successful NFSv4 reclaim operation) to detect reclamation of the state in progress, and extends the grace period for a length of time up to the duration of the given number of iterations.
nservers	Specifies the maximum number of concurrent requests that the NFS server can handle. This concurrency is achieved by dynamic management of threads within the NFS server, up to the maximum. The default maximum is 3891. The **chnfs**, **chssys**, or **nfso** command is used to change the maximum. Changing the maximum setting from the default is not recommended as this may limit server performance.
-p *tcp* or **-p** *udp*	Transports both UDP and TCP to the NFS clients (default). You can only specify UDP or TCP. For example, if **-p** *tcp* is used, the NFS server only accepts NFS client requests using the TCP protocol.
-r *max_read_size*	Specifies for NFS Version 3, the maximum size allowed for file read requests. The default and maximum allowed is 64K.
-w *max_write_size*	Specifies for NFS Version 3, the maximum size allowed for file write requests. The default and maximum allowed is 64K.
`-root directory`	Specifies the directory which should be the root node the NFS version 4 exported filesystem. By default, the root node is `/`. If the root node is set to something other than `/`, use `chnfs -r` to reset the node to `/`. This flag may be used while `nfsd` is running to change the root node, but only if no filesystems are currently exported. This flag might be removed in a future release. Use `chnfs -r` instead.
`-public directory`	Specifies the directory which should be the public node of the NFS version 4 exported filesystem. By default, the public node is the same as the root node. This flag may be use while `nfsd` is running to change the public node. The public node must be a descendant of the root node. This flag might be removed in a future release. Use `chnfs -p` instead.
`-getnodes`	Prints the current root and public nodes for the NFS version 4 server. This option will not cause the NFS server daemon to start.
`-getreplicas`	Prints the current replication enablement mode. If replicas have been specified for the `nfsroot`, they will be displayed.

Examples

1. To start **nfsd** daemons using an **src** command, enter:

   ```
   startsrc -s nfsd
   ```

   In this example, the `startsrc -s nfsd` entry starts the number of daemons specified in the script.
2. To change the number of daemons running on your system, enter:

   ```
   chssys -s nfsd -a 6
   ```

   In this example, the `chssys` command changes the number of `nfsd` daemons running on your system to 6.

nfshostkey Command

Purpose

Configures the host keys for an Network File System (NFS) server.

Syntax

`nfshostkey` `-l` | `-L` | {`-p` *principal* `-f` *file*} | { `-a` -p *principal* `-i` *address* } | { `-d` -p *principal* -i *address*}

Description

An NFS server (or full client) using RPCSEC_GSS RPC security must be able to acquire credentials for its host principal to accept requests. Use the **nfshostkey** command to configure this information.

All full clients and NFS servers must have a primary host principal. The following is the format of the host principal that the **nfshostkey** command sets:

```
nfs/fully_qualified_domain_name
```

After you set the primary host principal, you can use the **nfshostkey** command to set additional host principals for other network addresses. The server searches the list of addresses to find the one that an incoming request was sent to and use the appropriate principal. If none is found, the primary principal is used. The secondary host principals must have entries in the same `keytab` file that was passed in for the primary principal. They will not be used by full clients.

Flags

Item	Description
`-a`	Adds a new secondary host principal.
`-d`	Deletes a secondary host principal.
`-f` *file*	Specifies the path to a `keytab` file for the host principals.
`-i` *address*	Specifies the IP address corresponding to the secondary principal.
`-l`	Lists the primary host principal and keytab.
`-L`	Lists the primary host principal, keytab, and secondary host principals.
`-p` *principal*	Specifies the principal for this host.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges,

see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To set a primary host principal, enter:

```
nfshostkey -p principal -f keytab file
```

2. To add a secondary host principal, enter:

```
nfshostkey -a -p principal -i ip address
```

3. To delete a host principal, enter:

```
nfshostkey -d -p principal -i ip address
```

nfshostmap Command

Purpose

Manage mapping from hosts to principals for an nfs client.

Syntax

/usr/sbin/nfshostmap -a *hostname alias1 alias2* | -d *hostname* | -e *hostname alias1 alias2* | -l

Description

All hosts defined as aliases will be mapped to the host defined as a *hostname* when constructing a kerberos request to the server. This is useful if, for example, a server has interfaces wizard.sub.austin.ibm.com and wizard.austin.ibm.com; if this server's kerberos principal is wizard.austin.ibm.com, nfshostmap -a wizard.austin.ibm.com wizard.sub.austin.ibm.com run on the client will take care of this problem.

This modifies /etc/nfs/princmap, which is read by the gssd daemon on startup.

Flags

Item	Description
-a *hostname alias1 alias2*	Adds a mapping from the aliases to *hostname*,
-d *hostname*	Deletes all aliases for *hostname*.
-e *hostname alias1 alias2*	Removes all previous mappings for *hostname* and replaces them with the given alias list.
-l	Prints the existing state of the respective files on the system.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

nfso Command

Purpose

Manages Network File System (NFS) tuning parameters.

Syntax

nfso [**-p** | **-r**] [**-c**] { **-o** *Tunable*[**=***newvalue*] }

nfso [**-p** | **-r**] { **-d** *Tunable* }

nfso [**-p** | **-r**] **-D**

nfso [**-p** | **-r**] **-a** [**-F**] [**-c**]

nfso -h [*Tunable*]

nfso -l [*hostname*]

nfso [**-F**] **-L** [*Tunable*]

nfso [**-F**] **-x** [*Tunable*]

nfso [**-@** *WparName*] [**-p** | **-r**] **-a** [**-c**]

nfso [**-@** *WparName*] [**-p** | **-r**] [**-c**] { **-o** *Tunable*[**=***newvalue*] }

nfso -H {*ha operation*}

Note: Multiple flags **-o**, **-d**, **-x**, and **-L** are allowed.

Description

Use the **nfso** command to configure Network File System tuning parameters. The **nfso** command sets or displays current or next boot values for Network File System tuning parameters. This command can also make permanent changes or defer changes until the next reboot. Whether the command sets or displays a parameter is determined by the accompanying flag. The **-o** flag performs both actions. It can either display the value of a parameter or set a new value for a parameter.

Understanding the Effect of Changing Tunable Parameters

Extreme care should be taken when using this command. If used incorrectly, the **nfso** command can make your system inoperable.

Before modifying any tunable parameter, you should first carefully read about all its characteristics in the Tunable Parameters section below, and follow any Refer To pointer, in order to fully understand its purpose.

You must then make sure that the Diagnosis and Tuning sections for this parameter truly apply to your situation and that changing the value of this parameter could help improve the performance of your system.

If the Diagnosis and Tuning sections both contain only "N/A", you should probably never change this parameter unless specifically directed by AIX development.

Flags

Item	Description
-a	Displays the current, reboot (when used in conjunction with **-r**) or permanent (when used in conjunction with **-p**) value for all tunable parameters, one per line in pairs *Tunable* **=** *Value*. For the permanent options, a value is only displayed for a parameter if its reboot and current values are equal. Otherwise NONE displays as the value.

Item	Description
-c	Changes the output format of the **nfso** command to colon-delineated format.
-d *Tunable*	Sets the *Tunable* variable back to its default value. If a *Tunable* needs to be changed that is, . it is currently not set to its default value) and is of type Bosboot or Reboot, or if it is of type Incremental and has been changed from its default value, and **-r** is not used in combination, it will not be changed but a warning displays instead.
-D	Sets all *Tunable* variables back to their default value. If *Tunable*s needing to be changed are of type Bosboot or Reboot, or are of type Incremental and have been changed from their default value, and the **-r** flag is not used in combination, they will not be changed but warnings display instead.
-F	Forces restricted tunable parameters to be displayed when the options **-a**, **-L** or **-x** are specified on the command line. If you do not specify the **-F** flag, restricted tunables are not included, unless they are specifically named in association with a display option.
-h [*Tunable*]	Displays help about *Tunable* parameter if one is specified. Otherwise, displays the **nfso** command usage statement.
-H {ha operation}	Runs an high availability (HA) operation. HA operations follow: **enable_ha** Turns on the HA function. **disable_ha** Turns off the HA function. **sm_register <hostname>** PowerHA SystemMirror registers this host. **sm_unregister <hostname>** PowerHA SystemMirror unregisters this host. **sm_gethost** PowerHA SystemMirror gets the host. **dump_dupcache <log device>** Dumps HA dupcache.
-l *hostname*	Allows a system administrator to release NFS file locks on an NFS server. The *hostname* variable specifies the host name of the NFS client that has file locks held at the NFS server. The **nfso -l** command makes a remote procedure call to the NFS server's **rpc.lockd** network lock manager to request the release of the file locks held by the *hostname* NFS client. If there is an NFS client that has file locks held at the NFS server and this client has been disconnected from the network and cannot be recovered, the **nfso -l** command can be used to release those locks so that other NFS clients can obtain similar file locks. **Note:** The **nfso** command can be used to release locks on the local NFS server only.

Item	Description
-L [*Tunable*]	Lists the characteristics of one or all *Tunable*, one per line, using the following format:

```
NAME                      CUR    DEF    BOOT   MIN    MAX
UNIT           TYPE
     DEPENDENCIES
------------------------------------------------------------------------------
------
portcheck                 0      0      0      0      1
On/Off            D
------------------------------------------------------------------------------
------
udpchecksum               1      1      1      0      1
On/Off            D
------------------------------------------------------------------------------
------
nfs_socketsize            600000 600000 600000 40000  1M
Bytes             D
------------------------------------------------------------------------------
------
nfs_tcp_socketsize        600000 600000 600000 40000  1M
Bytes             D
------------------------------------------------------------------------------
------
...
where:
    CUR = current value
    DEF = default value
    BOOT = reboot value
    MIN = minimal value
    MAX = maximum value
    UNIT = tunable unit of measure
    TYPE = parameter type: D (for Dynamic),
           S (for Static), R (for Reboot),B (for Bosboot), M (for Mount),
           I (for Incremental), C (for Connect), and d (for Deprecated)
    DEPENDENCIES = list of dependent tunable parameters, one per line
```

-o *Tunable*[**=***newvalue*]	Displays the value or sets *Tunable* to *newvalue*. If a tunable needs to be changed (the specified value is different than current value), and is of type Bosboot or Reboot, or if it is of type Incremental and its current value is bigger than the specified value, and **-r** is not used in combination, it will not be changed but a warning displays instead. When **-r** is used in combination without a new value, the nextboot value for the *Tunable* displays. When **-p** is used in combination without a *newvalue*, a value displays only if the current and next boot values for the *Tunable* are the same. Otherwise NONE displays as the value.
-p	Makes changes apply to both current and reboot values, when used in combination with **-o**, **-d** or **-D**, that is, it turns on the updating of the **/etc/tunables/nextboot** file in addition to the updating of the current value. These combinations cannot be used on Reboot and Bosboot type parameters because their current value cannot be changed. When used with **-a** or **-o** without specifying a new value, values are displayed only if the current and next boot values for a parameter are the same. Otherwise NONE displays as the value.
-r	Makes changes apply to reboot values when used in combination with **-o**, **-d** or **-D**, that is, it turns on the updating of the **/etc/tunables/nextboot** file. If any parameter of type Bosboot is changed, the user is prompted to run bosboot. When used with **-a** or **-o** without specifying a new value, next boot values for tunables display instead of current values.

Item	Description
-x [*Tunable*]	Lists characteristics of one or all tunables, one per line, using the following (spreadsheet) format: `tunable,current,default,reboot,min,max,unit,type,{dtunable }` `where:` `  current = current value` `  default = default value` `  reboot = reboot value` `  min = minimal value` `  max = maximum value` `  unit = tunable unit of measure` `TYPE = parameter type: D (for Dynamic),` `  S (for Static), R (for Reboot),B (for Bosboot), M (for Mount),` `  I (for Incremental), C (for Connect), and d (for Deprecated)` `  dtunable = space separated list of dependent tunable parameters`
-@ *WparName*	Sets or displays tunables for the specified workload partition. The **-@** flag can only be used when the **nfso** command is run in the global partition.

If you make any change (with **-o**, **-d** or **-D**) to a restricted tunable parameter, it results in a warning message that a tunable parameter of the restricted-use type has been modified. If you also specify the **-r** or **-p** options on the command line, you are prompted for confirmation of the change. In addition, at system reboot, the presence of restricted tunables in the **/etc/tunables/nextboot** file, which were modified to a value that is different from their default value (using a command line specifying the **-r** or **-p** options), results in an error log entry that identifies the list of these modified tunables.

If you make any change (with **-o**, **-d**, or **-D**) to a parameter of type Mount, it results in a warning message that the change is only effective for future mountings.

If you make any change (with **-o**, **-d** or **-D**) to a parameter of type Connect, it results in **inetd** being restarted, and a warning message that the change is only effective for future socket connections.

If you make any change (with **-o**, **-d**, or **-D**) to a parameter of type Bosboot or Reboot without **-r**, it results in an error message.

If you make any change (with **-o**, **-d**, or **-D** but without **-r**) to the current value of a parameter of type Incremental with a new value smaller than the current value, it results in an error message.

Note: Tunable variables that apply to the entire system can not be modified within a workload partition.

Note: When the **nfso** command is run within a workload partition (or if the **-@** flag is specified), only the following tunables can be set with the **-o** flag:

- **nfs_dynamic_retrans**
- **nfs_iopace_pages**
- **nfs_use_reserved_port**
- **nfs_v4_fail_over_timeout**
- **utf8_validation**
- **nfs_auth_rbr_trigger**
- **client_delegation**

Tunable Parameters Type

All the tunable parameters manipulated by the tuning commands (**no**, **nfso**, **vmo**, **ioo**, **schedo**, and `raso`) have been classified into these categories:

Item	Description
Dynamic	If the parameter can be changed at any time
Static	If the parameter can never be changed

Item	Description
Reboot	If the parameter can only be changed during reboot
Bosboot	If the parameter can only be changed by running bosboot and rebooting the machine
Mount	If changes to the parameter are only effective for future file systems or directory mounts
Incremental	If the parameter can only be incremented, except at boot time
Connect	If changes to the parameter are only effective for future socket connections
Deprecated	If changing this parameter is no longer supported by the current release of AIX.

For parameters of type Bosboot, whenever a change is performed, the tuning commands automatically prompt the user to ask if they want to execute the **bosboot** command. For parameters of type Connect, the tuning commands automatically restart the **inetd** daemon.

Note that the current set of parameters managed by the **nfso** command only includes Dynamic, Mount, and Incremental types.

Compatibility Mode

When running in pre 5.2 compatibility mode (controlled by the **pre520tune** attribute of **sys**0, see AIX 5.2 compatibility mode), reboot values for parameters, except those of type Bosboot, are not really meaningful because in this mode they are not applied at boot time.

In pre 5.2 compatibility mode, setting reboot values to tuning parameters continues to be achieved by imbedding calls to tuning commands in scripts called during the boot sequence. Parameters of type **Reboot** can therefore be set without the **-r** flag, so that existing scripts continue to work.

This mode is automatically turned ON when a machine is MIGRATED to AIX 5L Version 5.2. For complete installations, it is turned OFF and the reboot values for parameters are set by applying the content of the **/etc/tunables/nextboot** file during the reboot sequence. Only in that mode are the **-r** and **-p** flags fully functional. See Kernel Tuning in the *Performance Tools Guide and Reference* for details about the new 5.2 mode.

Tunable Parameters

For default values and range of values for tunables, refer the **nfso** command help (**-h** <*tunable_parameter_name*>).

Note: Starting with AIX Version 6.1 with the 6100-02 Technology Level, the following parameters are obsolete because the network file system (NFS) and the virtual memory manager (VMM) dynamically tunes the number of **buf** structures and page device tables (PDTs) based on workload:

- nfs_v2_pdts
- nfs_v2_vm_bufs
- nfs_v3_pdts
- nfs_v3_vm_bufs
- nfs_v4_pdts
- nfs_v4_vm_bufs

Item	Description
client_delegation	**Purpose:** Determine if the NFS version 4 client will accept delegations for open files. **Tuning:** A value of 0 disables delegations. A value of 1 enables delegations.
nfs_hang_log	**Purpose:** Sets the priority at which the NFS mount messages that are hung get logged to the `syslog` log file. **Tuning:** The values are in the range 1 - 7. • 1: LOG_ALERT • 2: LOG_CRIT • 3: LOG_ERR • 4: LOG_WARNING • 5: LOG_NOTICE • 6: LOG_INFO • 7: LOG_DEBUG The default value is 6.
nfs_max_read_size	**Purpose:** Allows the system administrator to control the NFS RPC sizes at the server. **Tuning:** Useful when all clients must have changes in the read sizes, and when the clients cannot be changed. Use the values of the client mount as the default value. The default value is required to reduce the V3 read sizes when the mounts cannot be manipulated directly on the clients, in particular during the NIM installations on networks where the network is dropping packets with the default read sizes. In this case, set the maximum size of 512 KB to a smaller value such that the value works on the network. This parameter is also useful when the network devices are dropping packets and a generic change is desired for communications with the server. The default value is 64 KB and the maximum value is 512 KB.
nfs_max_write_size	**Purpose:** Allows the system administrator to control the NFS RPC sizes at the server. **Tuning:** Useful when all clients must have changes in the write sizes, and when the clients cannot be changed. Use the values of the client mount as the default value. The default value is required to reduce the V3 read sizes when the mounts cannot be manipulated directly on the clients, in particular during the NIM installations on networks where the network is dropping packets with the default write sizes. In this case, set the maximum size of 512 KB to a smaller value such that the value works on the network. This parameter is also useful when the network devices are dropping packets and a generic change is desired for communications with the server. The default value is 64 KB and the maximum value is 512 KB.

Item	Description
nfs_rfc1323	**Purpose:** Enables very large TCP window size negotiation (greater than 65535 bytes) to occur between systems. **Tuning:** If using the TCP transport between NFS client and server, and both systems support it, this allows the systems to negotiate a TCP window size in a way that will allow more data to be in-flight between the client and server. This increases the throughput potential between client and server. Unlike the **rfc1323** option of the no command, this only affects NFS and not other applications in the system. Value of 0 means this is disabled, and value of 1 means it is enabled. If the no command parameter **rfc1323** is already set, this NFS option does not need to be set.
nfs_securenfs_authtimeout	**Purpose:** Sets the number of seconds for which a DES credential. **Tuning:** Value of 0 disables DES credential timeouts.
nfs_server_base_priority	**Purpose:** Sets the base priority of **nfsd** daemons. **Tuning:** By default, the **nfsd** daemons run with a floating process priority. Therefore, as they increase their cumulative CPU time, their priority will change. This parameter can be used to set a static parameter for the **nfsd** daemons. The value of 0 represents the floating priority (default). Other values within the acceptable range will be used to set the priority of the **nfsd** daemon when an NFS request is received at the server. This option can be used if the NFS server is overloading the system (lowering or making the **nfsd** daemon less favored). It can also be used if you want the **nfsd** daemons be one of the most favored processes on the server. Use caution when setting the parameter because it can render the system almost unusable by other processes. This situation can occur if the NFS server is very busy and will essentially lock out other processes from having run time on the server.

Item	Description
nfs_server_clread	**Purpose:** This option allows the NFS server to be very aggressive about the reading of a file. The NFS server can only respond to the specific NFS-read request from the NFS client. However, the NFS server can read data in the file which exists immediately after the current read request. This is normally referred to as read-ahead. The NFS server does read-ahead by default. **Tuning:** May be useful in cases where server memory is low and a lot of disk-to-memory activity is going on. With the **nfs_server_clread** option enabled, the NFS server becomes very aggressive about doing read-ahead for the NFS client. If value is 1, then aggressive read-ahead is done; If value is 0, normal system default read-ahead methods are used. Normal system read-ahead is controlled by VMM (for JFS file systems) and JFS2 (for JFS2 file systems). This more aggressive top-half read-ahead enabled via the nfs_server_clread option is less susceptible to read-ahead breaking down due to out-of-order requests (which are typical in the NFS server case). When the mechanism is activated, it will read an entire cluster (128 KB, the LVM logical track group size) at a time.
nfs_server_close_delay	**Purpose** Determines if the NFS version 4 server must avoid sending an NFS4ERR_DELAY response if the expected delay is not too long. If NFS clients are used that pause applications for a long time when encountering a NFS4ERR_DELAY response from the server, the server attempts to processes the delay on the server by using the **nfs_server_close_delay** option, which avoids pausing the application. **Tuning** A value of 0 turns off this feature. The default value is 0. A value of 1 enables local processing of short delays on the server side.
nfs_use_reserved_ports	**Purpose:** Specifies using non-reserved IP port number. **Tuning:** Value of 0 will use non-reserved IP port number when the NFS client communicates with the NFS server.
nfs_v3_server_readdirplus	**Purpose:** Determines if READDIRPLUS calls are supported by the server. **Tuning:** Value of 0 disables READDIRPLUS processing.

Item	Description
nfs_v4_fail_over_timeout	**Purpose:** Specifies a time out period which the NFS version 4 client operation will fail over to the replica provided by the NFS version 4 server. Measured in seconds. **Tuning:** If value of 0 is specified, the timeout value will be the timeout value for tcp multipled by 4. Values from 1 to 4 are reserved and the NFS version 4 client will treat it as 0. NFS version 4 allows client to fail over to other replica server if the main server is not responding. This value will determine how long a client has to wait for a respond from the server before it switch all the NFS version 4 request for that **fsid** to other replica server.
portcheck	**Purpose:** Checks whether an NFS request originated from a privileged port. **Tuning:** Value of 0 disables the port-checking that is done by the NFS server. A value of 1 directs the NFS server to do port checking on the incoming NFS requests. This is a configuration decision with minimal performance consequences.
server_delegation	**Purpose:** Determine if the NFS version 4 server will issue read delegations for open files. **Tuning:** A value of 0 disables delegation granting. A value of 1 enables delegation granting.
utf8_validation	**Purpose:** Determine if the NFS version 4 client and server will check string data for UTF-8 correctness. **Tuning:** A value of 0 disables the UTF-8 checking. A value of 1 enables the UTF-8 checking.
gss_window	**Purpose:** Enable or disable GSS window size checking. **Tuning:** A value of 0 disables GSS window size checking. A value of 1 enables GSS window size checking. The default value is 1.

Examples

1. To set the **portcheck** tunable parameter to a value of zero, type:

```
nfso -o portcheck=0
```

2. To set the **udpchecksum** tunable parameter to its default value of 1 at the next reboot, type:

```
nfso -r -d udpchecksum
```

3. To print, in colon-delimited format, a list of all tunable parameters and their current values, type:

```
nfso -a -c
```

4. To list the current and reboot value, range, unit, type and dependencies of all tunables parameters managed by the **nfso** command, type:

```
nfso -L
```

5. To display help information on **nfs_tcp_duplicate_cache_size**, type:

```
nfso -h nfs_tcp_duplicate_cache_size
```

6. To permanently turn off **nfs_dynamic_retrans**, type:

```
nfso -p -o nfs_dynamic_retrans=0
```

7. To list the reboot values for all Network File System tuning parameters, type:

```
nfso -r -a
```

8. To list (spreadsheet format) the current and reboot value, range, unit, type and dependencies of all tunables parameters managed by the **nfso** command, type:

```
nfso -x
```

nfsrgyd daemon

Purpose

Services translation requests between names and ids from servers and clients using NFS V4 or RPCSEC-GSS.

Syntax

`nfsrgyd` [`-f`] [`-T` *heartBeatInt*]

Description

The `nfsrgyd` daemon provides a name translation service for NFS servers and clients. This daemon must be running in order to perform translations between NFS string attributes and UNIX numeric identities.

The environment variables `NFS_NOBODY_USER` and `NFS_NOBODY_GROUP` affect the anonymous user and group owner strings used in the name translations. If these environment variables are not set, their default values of `nobody` will be used. They may be set in the file `/etc/environment`, or on the command line before `nfsrgyd` is started.

The local NFS domain must be set before running the `nfsrgyd` daemon. This may be set by using the `chnfsdom` command.

Note: The `nfsrgyd` daemon uses an ephemeral port.

Flags

Item	Description
`-f`	Creates a new process to flush the name translation cache and exits.
`-T`	Specifies the time interval between subsequent LDAP server reconnections. The valid values are 60-3600 seconds. The default value is 300.

Examples

1. The nfsrgyd daemon is started from the /etc/rc.nfs file. Using the following System Resource Controller (SRC) commands, you can start and stop the nfsrgyd daemon:

```
startsrc -s nfsrgyd
stopsrc -s nfsrgyd
```

2. To change the parameters passed to the nfsrgyd daemon using the chssys command, enter:

```
chssys -s nfsrgyd -a "-T 360"
```

Tip: The change does not take effect until the daemon is restarted. The value of the *heartBeatInt* interval will then be persistent after the nfsrgyd daemon is restarted.

Security

Users must have root authority.

Files

Item	Description
/etc/environment	Contains NFS environment variables.

nfsstat Command

Purpose

Displays statistical information about the Network File System (NFS) and Remote Procedure Call (RPC) calls.

Syntax

/usr/sbin/nfsstat [**-@** *WparName*] [**-c**] [**-d**] [**-s**] [**-n**] [**-r**] [**-m** [**-i**]] [-4] [**-z**] [**-t**] [**-b**] [-g]

Description

The **nfsstat** command displays statistical information about the NFS and Remote Procedure Call (RPC) interfaces to the kernel. You can also use this command to reinitialize this information. If no flags are given, the default is the **nfsstat -csnr** command. With this option, the command displays everything, but reinitializes nothing.

RPC Server Information

The server RPC display includes the following fields:

Item	Description
calls	Total number of RPC calls received. This number includes the NFS version 4 calls if the -4 flag is used. Otherwise, only the version 2 and version 3 total is displayed.
badcalls	Total number of calls rejected by the RPC layer. This number includes the NFS version 4 calls if the -4 flag is used. Otherwise, only the version 2 and version 3 total is displayed.
nullrecv	Number of times an RPC call was not available when it was thought to be received.
badlen	Number of RPC calls with a length shorter than a minimum-sized RPC call.
xdrcall	Number of RPC calls whose header could not be XDR decoded.
dupchecks	Number of RPC calls that looked up in the duplicate request cache.

Item	Description
dupreqs	Number of duplicate RPC calls found.

RPC Client Information

Item	Description
calls	Total number of RPC calls made
badcalls	Total number of calls rejected by the RPC layer
badxid	Number of times a reply from a server was received that did not correspond to any outstanding call
timeouts	Number of times a call timed out while waiting for a reply from the server
newcreds	Number of times authentication information had to be refreshed
badverfs	The number of times the call failed due to a bad verifier in the response.
timers	The number of times the calculated time-out value was greater than or equal to the minimum specified timed-out value for a call.
cantconn	The number of times the call failed due to a failure to make a connection to the server.
nomem	The number of times the calls failed due to a failure to allocate memory.
interrupts	The number of times the call was interrupted by a signal before completing.
retrans	The number of times a call had to be retransmitted due to a time-out while waiting for a reply from the server. This is applicable only to RPC over connection-less transports
dupchecks	The number of RPC calls that looked up in the duplicate request cache.
dupreqs	The number of duplicate RPC calls found.

NFS Server Information

The NFS server displays the number of NFS calls received (`calls`) and rejected (`badcalls`), as well as the counts and percentages for the various kinds of calls made.

NFS Client Information

The NFS client information displayed shows the number of calls sent and rejected, as well as the number of times a CLIENT handle was received (`clgets`), the number of times the client handle had no unused entries (`clatoomany`), and a count of the various kinds of calls and their respective percentages.

NFS Registry Daemon Information

The NFS registry daemon display shows the number of requests from the client and server to translate between UID/GID and string names.

-m Information

The **-m** flag displays information about **mount** flags set by **moun**t options, **mount** flags internal to the system, and other **mount** information. See the **mount** command for more information.

The following **mount** options are set by **mount** flags:

Item	Description
auth	Provides one of the following values: **none** No authentication. **unix** UNIX style authentication (UID, GID). **des** des style authentication (encrypted timestamps).
hard	Hard mount.
soft	Soft mount.
intr	Interrupts allowed on hard mount.
nointr	No interrupts allowed on hard mount.
noac	Client is not caching attributes.
rsize	Read buffer size in bytes.
wsize	Write buffer size in bytes.
retrans	NFS retransmissions.
nocto	No close-to-open consistency.
llock	Local locking being used (no lock manager.
grpid	Group ID inheritance.
vers	NFS version.
proto	Protocol.

The following **mount** options are internal to the system:

Item	Description
printed	Not responding message printed.
down	Server is down.
dynamic	Dynamic transfer size adjustment.
link	Server supports links.
symlink	Server supports symbolic links.
readdir	Use **readdir** instead of **readdirplus**.

-t Information

The `-t` flag displays information relating to translation requests of the NFS identity mapping subsystem.

Item	Description
ids_to_strings	The number of id-to-string translation requests.
strings_to_ids	The number of string-to-id translation requests.
resolve_errors	The number of failed translation requests due to missing data.
badowners	The number of failed translation requests due to invalid inputs.

Item	Description
`cache_hits`	The number of translation requests handled by the translation cache.
`cache_misses`	The number of translation requests not handled by the translation cache.
`cache_entries`	The number of entries in the translation cache.
`cache_recycles`	The number of entries in the translation cache that have expired.

Flags

Item	Description
-@ *WparName*	Displays statistics for the specified workload partition. The **-@** flag can only be used when the **nfsstat** command is executed in the global partition. If the **-@** flag is not used when the **nfsstat** command is executed from a workload partition, the statistics for the current workload partition are displayed. If the **-@** flag is not used when the **nfsstat** command is executed from the global partition, the sum statistics of all active workload partitions (and the global partition) are displayed. **Note:** If you use the **-@** *WparName* flag together with the **-m** flag, the **nfsstat** command displays statistics for the global partition instead of the specified workload partition.
-b	Displays additional statistics for the NFS version 4 server.
-c	Displays client information. Only the client side NFS and RPC information is printed. Allows the user to limit the report to client data only. The **nfsstat** command provides information about the number of RPC and NFS calls sent and rejected by the client. To print client NFS or RPC information only, combine this flag with the **-n** or **-r** option.
-d	Displays information related to NFS version 4 delegations.

Item	Description
-g	Displays RPCSEC_GSS information. The RPCSEC_GSS information sections contain: **activegss** Active RPCSEC_GSS contexts **discardgss** Discarded RPCSEC_GSS messages **krb5est** Established krb5 contexts **krb5iest** Established krb5i contexts **krb5pest** Established krb5p contexts **expgss** Expired RPCSEC_GSS contexts **badaccept** gss_accept_sec_context failures **badverify** gss_verify_mic failures **badgetmic** gss_get_mic failures **badwrap** gss_wrap failures **badunwrap** gss_unwrap failures
-m	Displays statistics for each NFS file system mounted along with the server name, mount flags, current read and write sizes, retransmission count, and the timers used for dynamic retransmission. **Note:** If you provide the **-m** option when you use the **nfsstat** command, you always get statistics for the global partition.
-i	When used along with **-m**, it prints the server's ip address as well. This flag is valid only along with the **-m** flag.
-n	Displays NFS information . Prints NFS information for both the client and server. To print only the NFS client or server information, combine this flag with the **-c** and **-s** options.
-r	Displays RPC information.
-s	Displays server information.
-t	Displays statistics related to translation requests of the NFS identity mapping subsystem. To print only the NFS client or server information, combine with the -c and -s options.
-4	When combined with the **-c**, **-n**, **-s**, or **-z** flags, includes information for the NFS version 4 client or server, in addition to the existing NFS version 2 and version 3 data. Without this option, the output is identical to output from the **nfsstat** command in AIX versions prior to version 5.3.
-z	Re-initializes statistics. This flag is for use by the root user only and can be combined with any of the above flags to zero particular sets of statistics after printing them.

Examples

1. To display information about the number of RPC and NFS calls sent and rejected by the client, enter:

```
nfsstat -c
```

2. To display and print the client NFS call-related information, enter:

```
nfsstat -cn
```

3. To display statistics for each NFS mounted file system, enter:

```
nfsstat -m
```

4. To display and print RPC call-related information for the client and server, enter:

```
nfsstat -r
```

5. To display information about the number of RPC and NFS calls received and rejected by the server, enter:

```
nfsstat -s
```

6. To reset all call-related information to zero on the client and server, enter:

```
nfsstat -z
```

   Note: You must have root user authority to use the **-z** flag.

7. To display information about the NFS client statistics for workload partition **abc**, enter:

```
nfsstat -@ abc -cn
```

nice Command

Purpose

Runs a command at a lower or higher priority.

Syntax

nice [**-** *Increment*| **-n** *Increment*] *Command* [*Argument ...*]

Description

The **nice** command lets you run a command at a priority lower than the command's normal priority. The *Command* parameter is the name of any executable file on the system. If you do not specify an *Increment* value the **nice** command defaults to an increment of 10. You must have root user authority to run a command at a higher priority. The priority of a process is often called its nice value.

The nice value can range from -20 to 19, with 19 being the lowest priority. For example, if a command normally runs at a priority of 10, specifying an increment of 5 runs the command at a lower priority, 15, and the command runs slower. The **nice** command does not return an error message if you attempt to increase a command's priority without the appropriate authority. Instead, the command's priority is not changed, and the system starts the command as it normally would.

The nice value is used by the system to calculate the current priority of a running process. Use the **ps** command with the **-l** flag to view a command's nice value. The nice value appears under the **NI** heading in the **ps** command output.

> **Note:** The **csh** command contains a built-in command named **nice**. The **/usr/bin/nice** command and the **csh** command's **nice** command do not necessarily work the same way. For information on the **csh** command's **nice** command, see the **csh** command.

Flags

Item	Description
-*Increment*	Increments a command's priority up or down. You can specify a positive or negative number. Positive increment values reduce priority. Negative increment values increase priority. Only users with root authority can specify a negative increment. If you specify an increment value that would cause the nice value to exceed the range of -20 to 19, the nice value is set to the value of the limit that was exceeded. This flag is equivalent to the **-n** *Increment* flag.
-n *Increment*	This flag is equivalent to the **-***Increment* flag.

Exit Status

If the command specified by the *Command* parameter is started, the exit status of the **nice** command is the exit status of the command specified by the *Command* parameter. Otherwise, the **nice** command exits with one of the following values:

Item	Description
1-125	An error occurred in the **nice** command.
126	The command specified by the *Command* parameter was found but could not be invoked.
127	The command specified by the *Command* parameter could not be found.

Examples

1. To specify a very low priority, enter:

   ```
   nice -n 15 cc -c *.c &
   ```

   This example runs the **cc** command in the background at a lower priority than the default priority set by the **nice** command.

2. To specify a very high priority, enter:

   ```
   nice --10 wall <<end
   System shutdown in 2 minutes!
   end
   ```

   This example runs the **wall** command at a higher priority than all user processes, which slows down everything else running on the system. The <<end and end portions of the example define a *here document*, which uses the text entered before the end line as standard input for the command.

   > **Note:** If you do not have root user authority when you run this command, the **wall** command runs at the normal priority.

3. To run a command at low priority, enter:

   ```
   nice cc -c *.c
   ```

   This example runs the **cc** command at low priority.

   > **Note:** This does not run the command in the background. The workstation is not available for doing other things.

4. To run a low-priority command in the background, enter:

   ```
   nice cc -c *.c &
   ```

   This example runs the **cc** command at low priority in the background. The workstation is free to run other commands while the **cc** command is running. Refer to the **Shells** in *Operating system and device management*for more information on background (asynchronous) processing.

Files

Item	Description
/usr/bin/nice	Contains the **nice** command.

nim Command

Purpose

Performs operations on Network Installation Management (NIM) objects.

Syntax

nim { **-o** *Operation*} [**-F**] [**-t** *Type*] [**-a** *Attribute*=*Value* . . .] *{ObjectName}*

Description

The **nim** command performs an operation on a NIM object. The type of operation that is performed is dependent on the type of object that is specified by the *ObjectName* parameter. Possible operations include initializing environments and managing resources. You can use the **lsnim** command to display the list of supported operations.

Flags

Item	Description
-a *Attribute* **=** *Value* . . .	Assigns the specified value to the specified attribute. Use the **lsnim -q** *Operation* **-t** *Type* command to get a list of valid attributes for a specific operation.
-F	Overrides some safety checks.

Item	Description
-o *Operation*	Specifies an operation to perform on a NIM object. The possible operations are: **activate** Starts a managed system. **allocate** Allocates a resource for use. **alt_disk_install** Performs an alternate disk installation. **alt_disk_mig** Creates a copy of **rootvg** to a free disk (or disks) and simultaneously upgrades it to a new version or release level of AIX. **bos_inst** Performs a BOS installation. **change** Changes an object's attributes. **check** Checks the status of a NIM object. **chwpar** Changes the characteristics of managed workload partitions. **create** Creates an instance of a managed system. **cust** Performs software customization. **deactivate** Stops a managed system. **deallocate** Deallocates a resource. **define** Defines an object. **destroy** Removes an instance of a managed system. **diag** Enables a system to boot a diagnostic image. **dkls_init** Initializes a diskless environment of a system. **dtls_init** Initializes a dataless environment of a system. **fix_query** Lists the fix information for an APAR or keyword. **linux_inst** Installs the Linux operating system on stand-alone clients. **lppchk** Verifies installed filesets on NIM systems and SPOTs. **lppmgr** Eliminates unnecessary software images in an **lpp_source**. **lslpp** Lists licensed program information about an object. **lswpar** Shows the characteristics of managed workload partitions. **maint** Performs software maintenance. **maint_boot** Enables a system to boot in maintenance mode. **reboot** Reboots a NIM client system.

Item	Description
-o *Operation* (Continued)	**remove** Removes an object. **reset** Resets an object's NIM state. **restvg** Performs a **restvg** operation. **select** Includes and excludes group members from operations that are performed on the group. **showlog** Displays a NIM client's installation, boot or customization log, or a SPOT's installation log from the NIM master. **showres** Displays the contents of a NIM resource. **sync** Synchronizes the NIM database with an alternate master. **sync_roots** Synchronizes root directories for diskless and dataless clients for a specific Shared Product Object Tree (SPOT). **syncwpar** Synchronizes the managed workload partition software with the managing system. **takeover** Allows a machine that is configured as an **alternate_master** to take control of the NIM environment. **unconfig** Unconfigures the NIM master fileset. **update** Adds software to an **lpp_source** or removes software from an **lpp_source**. **updateios** Performs software customization and maintenance on a virtual input-output server (VIOS) management server that is of the **vios** or **ivm** type. Use the **lsnim -POt** *Type* command to get a list of the valid operations for a specific type.

Item	Description
-t *Type*	Specifies the type of the NIM object for define operations. The possible types are: **resource types:** **adapter_def** Directory containing secondary adapter definition files. **boot** An internally managed NIM resource that is used to indicate that a boot image is allocated to a client. **bosinst_data** Configure file that is used during base system installation. **devexports** Device exports the file for workload partitions. **dump** Parent directory for client dump files. **exclude_files** Contains files to be excluded from a **mksysb** image. **fb_script** Executable script that is run during the first reboot of a machine. **fix_bundle** Fix (keyword) input file for the **cust** or **fix_query** operation. **home** Parent directory for client **/home** directories. **image_data** Configure file that is used during base system installation. **installp_bundle** **Installp** bundle file. **ios_mksysb** Represents a backup image that is taken from a VIOS management server that is of the **vios** or **ivm** type. **linux_source** Represents the Linux installation media. **log** Captures log data during a network installation. **lpp_source** Source device for optional product images. **mksysb** **mksysb** image. **nas_filer** A network-attached storage (NAS) device. **nim_script** An internally managed NIM resource that is used to indicate that NIM must run a script as a part of a NIM operation. **paging** Parent directory for the paging files of the client. **root** Parent directory for client **/** (root) directories. **resolv_conf** Name server configuration file. **savevg** A **savevg** image. **savewpar** Workload partition backup image. **script** Executable file that is run on a client. **secattrs** Security attributes file for workload partitions.

Item	Description
-t *Type* (Continued)	Specifies the type of the NIM object for define operations. The possible types are: **shared_home** /home directory that is shared by clients. **shared_root** / (root) directory that is shared by clients **spot** Shared Product Object Tree (SPOT) - equivalent to **/usr** file system. **tmp** Parent directory for client **/tmp** directories. **vg_data** Configuration file that is used during volume group restoration. **wpar_spec** Specification file for creating workload partitions. **machine types:** **alternate_master** A system that is reserved as a backup in case the primary NIM master ceases to function properly. **diskless** All file systems and resources remote. **dataless** Local paging, dump; remote **/**,**/usr**; others remote or local. **standalone** Local file systems and resources. **master** System that controls the NIM environment. **wpar** Workload partition hosted by the managing system. **management types:** **bcmm** A blade management module hardware. **cec** A central electronic complex hardware. **hmc** A Hardware Management Console system. **ivm** An integrated virtual management system. **vios** A Virtual I/O Server. **network types:** **tok** Token-Ring network. **ent** Ethernet network. **fddi** FDDI network. **atm** ATM network. **generic** Other TCP/IP networks. **hfi** Host Fabric Interface (HFI) network. **group types:** **mac_group** Group of machines. **res_group** Group of resources.

Security

Access Control: You must have root authority to run the **nim** command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges,

see Privileged Command Database in *Security*. For a list of privileges and the authorizations that are associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

The following examples are grouped by operation.

activate

1. To start the managed wpar1 workload partition, type:

```
nim -o activate wpar1
```

2. To start the managed wpar1 workload partition with additional **startwpar** command flags with verbose output, type:

```
nim -o activate -a cmd_flags="-v" wpar1
```

allocate

1. To allocate resources to a diskless workstation with the name syzygy and SPOT attribute value of spot1, type:

```
nim -o allocate -a spot=spot1 syzygy
```

2. To perform a base system installation on the system that is named krakatoa, resources must be allocated initially by entering:

```
nim -o allocate -a spot=myspot -a lpp_source=images krakatoa
```

   The NIM environment can be initialized to support the installation by performing the **bos_inst** operation, type:

```
nim -o bos_inst krakatoa
```

3. To install the software product, adt, into a standalone system,stand1, given that the installable option, adt, in the **lpp_source**, images, type:

```
nim -o allocate -a lpp_source=images stand1
```

   Then type:

```
nim -o cust -a filesets="adt" stand1
```

4. To install software products into a standalone system, stand1, such that the image for the installable option, adt, in the **lpp_source**, images, and the **installp_bundle**, bundle1, contains the name of the installable option, type:

```
nim -o allocate -a lpp_source=images \
-a installp_bundle=bundle1 stand1
```

   Then type:

```
nim -o cust stand1
```

5. To automatically configure a machine with name resolution services after a BOS installation, create the /exports/resolv.conf file, with contents similar to the following:

```
nameserver      129.35.143.253
nameserver      9.3.199.2
domain          austin.ibm.com
```

   then type:

```
nim -o define -t resolv_conf -a location=/exports/resolv.conf \
-a server=master rconf1
```

Prior to issuing the **bos_inst** operation, allocate this resource with other required and optional resources by typing:

```
nim -o allocate -a spot=spot1 -a lpp_source=images1 \
-a bosinst_data=bid1 -a resolv_conf=rconf1 client1
```

6. To allocate all resources applicable to standalone machines from the NIM resource group `res_grp1`, to the machine `mac1`, type:

```
nim -o allocate -a group=res_grp1 mac1
```

alt_disk_install

1. To install a **mksysb** resource `all_devices_mysysb` to client `roundrock`, on hdisk4 and hdisk5, using the **image_data** resource `image_data_shrink`, with debug turned on, type:

```
nim -o alt_disk_install -a source=mksysb\
-a image_data=image_data_shrink\
-a debug=yes\
-a disk='hdisk4 hdisk5' roundrock
```

2. To clone a **rootvg** on client `austin` to hdisk2, but only run phase1 and phase2 (leaving the **/alt_inst** file systems mounted), type:

```
nim -o alt_disk_install -a source=rootvg\
-a disk='hdisk2'\
-a phase=12 austin
```

bos_inst

1. To install the machine `blowfish`, using the resources `spot1`, `images1`, `bosinst_data1`, and `rconf1`, first allocate the resources by typing:

```
nim -o allocate -a spot=spot1 -a lpp_source=images1 \
-a bosinst_data=bosinst_data1 -a resolv_conf=rconf1 blowfish
```

Then, perform the BOS installation by typing:

```
nim -o bos_inst blowfish
```

2. To install the machine `blowfish` while allocating the resources `spot1`, `images1`, `bosinst_data1`, and `rconf1` automatically when the **bos_inst** operation starts, type:

```
nim -o bos_inst -a spot=spot1 -a lpp_source=images1 \
-a bosinst_data=bosinst_data1 -a resolv_conf=rconf1 blowfish
```

3. To use the default resources when installing the machine `mac1`, type:

```
nim -o bos_inst mac1
```

4. To install a machine, `deadfish`, with `spot1` and `lpp_source1` and use an **adapter_def** resource, `adapter_def1`, to configure secondary adapters, type:

```
  nim -o bos_inst -a spot=spot1 -a lpp_source=lpp_source1 \
  -a adapter_def=adapter_def1 deadfish
```

5. To install the machine blowfish and accept software license agreements, type:

```
nim -o bos_inst -a spot=spot1 -a lpp_source=images1 \
-a accept_licenses=yes -a resolv_conf=rconf1 blowfish
```

change

1. Machines on the BLDG905 network use the gateway905 gateway to reach the 0Z network. Machines on the 0Z network use the gateway0Z gateway to reach the BLDG905 network. To add a route between two networks named BLDG905 and 0Z, type:

```
nim -o change -a routing1="0Z gateway905 gateway0Z" BLDG905
```

2. The adapter that is identified by the host name sailfish2.austin.ibm.com is attached to a token ring network. To define a secondary interface for this adapter on the NIM master and instructing NIM to locate the NIM network representing the attached ethernet network and, if not found, have NIM define a NIM network with subnetmask 255.255.255.128, type:

```
nim -o change -a if2="find_net sailfish2.austin.ibm.com 0" \
-a net_definition="tok 255.255.255.128" -a ring_speed2=16 master
```

   Note: A default name is generated for the network, and no routing information is specified for the new network.

3. To define default routes for the networks net1 and net2 that use default gateways gw1 and gw2 respectively, type the following two commands:

```
nim -o change -a routing1="default gw1" net1
nim -o change -a routing1="default gw2" net2
```

4. To designate the resources that are defined by the resource group res_grp1 as the set of resources that are always allocated by default during any operation in which these resources are applicable, type:

```
nim -o change -a default_res=res_grp1 master
```

check

1. To have NIM check on the usability of a SPOT named myspot, type:

```
nim -o check myspot
```

2. To check the status of an **lpp_source** named images, type:

```
nim -o check images
```

chwpar

To add rset rs/cpus23 to the resource control attributes for the wpar1 workload partition, type:

```
nim -o chwpar -a cmd_flags="-R rset=rs/cpu23" wpar1
```

create

1. To create the wpar1 workload partition with host name and specification file resource basic_wpar, type:

```
nim -o create -a wpar_spec=basic_wpar wpar1
```

2. To create the wpar1 workload partition with the wpar-specification file resource wpar1_spec, type:

```
nim -o create -a wpar_spec=wpar1_spec wpar1
```

3. To create the wpar1 workload partition from the **savewpar** backup image resource wpar1_backup, type:

```
nim -o create -a savewpar=wpar_backup wpar1
```

cust

1. To install a software product into a spot, spot1, such that the image for the installable option,adt, resides in the **lpp_source**, images, type:

```
nim -o cust -a lpp_source=images -a filesets=adt spot1
```

2. To install a software product into a spot, spot1, such that the image for the installable option,adt, resides in the **lpp_source**,images, and the **installp_bundle**, bundle1, contains the name of the installable option, type:

```
nim -o cust -a lpp_source=images -a installp_bundle=bundle1 spot1
```

3. To install a software product into a spot, spot1, such that the image for the installable option,adt, resides on a tape that is in the tape drive that is local to the machine where the spot resides, type:

```
nim -o cust -a lpp_source=/dev/rmt0 -a filesets=adt spot1
```

4. To install a software product into a spot, spot1, such that the image for the installable option, adt, resides on a tape that is in the tape drive that is local to the machine where the spot resides, type:

```
nim -o cust -a lpp_source=/dev/rmt0 -a filesets=adt spot1
```

5. To install all fileset updates associated with APAR IX12345, residing on the tape **/dev/rmt0** into spot1 and any diskless or dataless clients to which spot1 is currently allocated, type:

```
nim -F -o cust -afixes=IX12345 -a lpp_source=/dev/rmt0 spot1
```

6. To update all software installed on the client Standalone1, with the latest updates in the **lpp_source** named updt_images, type:

```
nim -o allocate -a lpp_source=updt_images Standalone1
nim -o cust -afixes=update_all Standalone1
```

7. To install the machine catfish with the contents of the **installp_bundle** bundle1, first allocate the resources by typing:

```
nim -o allocate -a installp_bundle=bundle1 \
-a lpp_source=images1 catfish
```

   Then, perform the cust operation by typing:

```
nim -o cust catfish
```

8. To update all software that is installed on the client Standalone1, with the latest updates in the **lpp_source** named updt_images, type:

```
nim -o cust -a lpp_source=updt_images -a fixes=update_all \
Standalone1
```

9. To install the machine catfish with the contents of the **installp_bundle** bundle1, while allocating this resource and the **lpp_source** images1 when the **cust** operation runs, type:

```
nim -o cust -a installp_bundle=bundle1 -a lpp_source=images1 \
catfish
```

10. To configure secondary adapters on a client machine, deadfish, by using the secondary adapter configuration file in the **adaper_def** resource, adapter_def1, type:

```
  nim -o cust -a adapter_def=adapter_def1 deadfish
```

deactivate

1. To stop the managed wpar1 workload partition, type:

```
nim -o deactivate wpar1
```

2. To force the stop of the managed wpar1 workload partition, type:

```
nim -Fo deactivate wpar1
```

3. To stop the managed wpar1 workload partition with more **stopwpar** command flags to halt after 85 seconds, type:

```
nim -o deactivate -a cmd_flags="-t 85" wpar1
```

deallocate

To deallocate an **lpp_source** named images from the standalone machine client1, type:

```
nim -o deallocate -a lpp_source=images client1
```

define

1. To define a resource that is a directory that contains installable images that is on the server altoid and has a path name of /usr/sys/inst.images, and name that resource images, type:

```
nim -o define -t lpp_source -a server=altoid \
-a location=/usr/sys/inst.images images
```

2. To create a new SPOT resource named myspot on the NIM master in the /export/exec directory, by using an **lpp_source** named image, type:

```
nim -o define -t spot -a server=master -a location=/export/exec \
-a source=images myspot
```

3. To define a network object named BLDG905, with a subnetmask of 255.255.240.0 and an address of 129.35.129.0, type:

```
nim -o define -t tok -a snm=255.255.240.0 \
-a net_addr=129.35.129.0 BLDG905
```

4. To define a **mksysb** resource, mksysb1, from an existing mksysb image that is located in /resources/mksysb.image on the master, type:

```
nim -o define -t mksysb -a server=master \
-a location=/resources/mksysb.image mksysb1
```

5. To define a NIM network named ATMnet with a subnet mask of 255.255.240 and an address of 129.35.101.0 to represent an ATM network, use the generic network type as follows:

```
nim -o define -t generic -a snm=255.255.240.0 \
-a net.addr=129.35.101.0 ATMnet
```

6. To define a machine group named DisklsMacs1 with members that are NIM diskless machines named diskls1, diskls2, and diskls3, type:

```
nim -o define -t mac_group -a add_member=diskls1 \
-a add_member=diskls2 -a add_member=diskls3 DisklsMacs1
```

7. To define a resource group named DisklsRes1 with resources spot1, root1, dump1, paging1, home1, tmp1, type:

```
nim -o define -t res_group -a spot=spot1 -a root=root1 \
-a dump=dump1 -a paging=paging1 -a home=home1 -a tmp=tmp1 \
DisklsRes1
```

8. To display the space that is required to define a **mksysb** resource, mksysb2, and create a mksysb image of the client, client1, during the resource definition where the image is located in /resources/mksysb.image on the master, type:

Note: This action shows the space that is required for the operation, **mksysb**, or resource creation does NOT take place.

```
nim -o define -t mksysb -a server=master \
-a location=/resources/mksysb.image -a source=client1 \
-a mk_image=yes -a size_preview=yes mksysb2
```

9. To define a **mksysb** resource, `mksysb2`, and create the mksysb image of the client, `client1`, during the resource definition where the image is in `/resources/mksysb.image` on the master, type:

```
nim -o define -t mksysb -a server=master \
-a location=/resources/mksysb.image -a source=client1 \
-a mk_image=yes mksysb2
```

10. To define a **mksysb** resource, `mksysb2`, and create a mksysb image of the client, `client1`, during the resource definition where the mksysb flags used to create the image are **-em**, and the image is in `/resources/mksysb.image` on the master, type:

```
nim -o define -t mksysb -a server=master \
-a location=/resources/mksysb.image -a source=client1 \
-a mk_image=yes -a mksysb_flags=em mksysb2
```

11. To define an **exclude_files** resource, `exclude_file1`, located in `/resources/mksysb.image` on the master, type:

```
nim -o define -t exclude_files -a server=master \
-a location=/resources/exclude_file1 exclude_file1
```

12. A machine that is called `redfish`, hostname `redfish_t.lab.austin.ibm.com`, has its primary interface that is attached to a token-ring network with ring speed of 16 Megabits. To define `redfish` as a standalone machine in the NIM environment and instructing NIM to locate the name of the network that the machine's primary interface is attached, type:

```
nim -o define -t standalone  -a if1="find_net \
redfish_t.lab.austin.ibm.com 0" -a ring_speed1=16 redfish
```

13. A machine that is called `bluefish`, hostname is `bluefish_e.lab.austin.ibm.com`, has its primary interface that is attached to an ethernet network with **cable_type** of **bnc**. To define `bluefish` as a diskless machine in the NIM environment and instructing NIM to locate the name of the network that the machine's primary interface is attached, and if not found, have NIM define a NIM network with the name `ent_net`, subnetmask of `255.255.255.128` and default route by using the gateway with hostname `lab_gate`, type:

```
nim -o define -t diskless -a if1="find_net \
bluefish_e.lab.austin.ibm.com 0" -a net_definition="ent \
255.255.255.128 lab_gate 0 ent_net" -a cable_type=bnc bluefish
```

    Note: Specify 0 in place of the master gateway in the **net_definition** attribute if a default route for the master exists, otherwise you must specify the master gateway.

14. To define the **/export/nim/adapters** directory as an **adapter_def** resource, `adapter_def1`, on the master, type:

```
  nim -o define -t adapter_def -a server=master \
  -a location=/export/nim/adapters adapter_def1
```

    To populate the **adapter_def** resource with secondary adapter configuration files, run the **nimadapters** command.

15. To display the space that is required to define a **savevg** resource, `savevg2`, and create a **savevg** image of the client, `client1`, during the resource definition where the image is in `/export/nim/savevg` on the master and the **volume_group** to to backup is `myvg`, type:

```
nim -o define -t savevg -a server=master \
  -a location=/export/nim/savevg/savevg2 -a source=client1 \
  -a mk_image=yes -a size_preview=yes -a volume_group=myvg savevg2
```

    Note: This action shows the space that is required for the operation. **savevg** or resource creation does not take place.

16. To define a **savevg** resource, savevg2, and create the **savevg** image of the client, client1, during the resource definition where the image is in /export/nim/savevg on the master and the **volume_group** to backup is myvg, type:

```
nim -o define -t savevg -a server=master \
-a location=/export/nim/savevg -a source=client1 \
-a mk_image=yes -a volume_group=myvg savevg2
```

17. To define a **savevg** resource, savevg2, and create a **savevg** image of the client, client1, during the resource definition where the **savevg** flags used to create the image are **-em**, and the image is in /export/nim/savevg on the master, type:

```
nim -o define -t savevg -a server=master \
-a location=/export/nim/savevg -a source=client1 \
-a mk_image=yes -a volume_group=myvg -a savevg_flags=em savevg2
```

18. To define a **vg_data** resource, my_vg_data, on the master at the location /export/nim, type:

```
nim -o define -t vg_data -a server=master -a location=/export/nim/my_vg_data my_vg_data
```

19. To define the wpar1 workload partition that is managed by the yogi managing standalone machine with wpar1 as both the host name and the name of the workload partition on the managing system, type:

```
nim -o define -t wpar -a mgmt_profile1="yogi wpar1" -a if1="find_net wpar1 0" wpar1
```

20. To define a **savewpar** resource named wpar1backup and create the **savewpar** image of the yogi workload partition on the sterling server, type:

```
nim -o define -t savewpar \
   -a server=sterling -a location=/resources/wpar1.image \
   -a source=wpar1 -a mk_image=yes wpar1backup
```

21. To define a **savewpar** resource named wpar1backup and create the **savewpar** image of the yogi workload partition on the sterling server, excluding file patterns in the **exclude_files** resource wparexclude, and passing the flag to the **savewpar** resource to exclude files and creates a **image.data** file, type:

```
nim -o define -t savewpar \
   -a server=sterling -a location=/resources/wpar1.image -a source=wpar1 \
   -a exclude_files=wparexclude -a cmd_flags="-ei" mk_image=yes wpar1backup
```

22. To define a **ios_mksysb** resource such as **ios_mksysb1**, and create the **ios_mksysb** image of the **vios** client as **vios1**, during the resource definition where the image is located in /export/nim/ios_mksysb on the master, type:

```
nim -o define -t ios_mksysb -a server=master \
-a location=/export/nim/ios_mksysb -a source=vios1 \
-a mk_image=yes ios_mksysb1
```

destroy

1. To remove the managed wpar1 workload partition from its managing system, type:

```
nim -o destroy wpar1
```

2. To force the removal of the managed wpar1 workload partition, type:

```
nim -Fo destroy wpar1
```

dkls_init

1. To initialize the environment for a diskless workstation with the name of syzygy, by using the resources spot1, root1, dump1, and paging1, you must allocate the resources by typing:

```
nim -o allocate -a spot=spot1 -a root=root1 -a dump=dump1 \
-a paging=paging1 syzygy
```

Then initialize the resources for the client machine by typing:

```
nim -o dkls_init syzygy
```

2. To initialize the environment for a diskless workstation with the name of `syzygy`, type:

```
nim -o dkls_init syzygy
```

3. To exclude the member named `diskls2` from operations on the machine group `DisklsMacs1`, and then initialize the remaining members while allocating the diskless resources defined by the resource group named `DisklsRes1`, type the following two commands:

```
nim -o select -a exclude=diskls2 DisklsMacs1
nim -o dkls_init -a group=DisklsRes1 DisklsMacs1
```

4. To initialize the group of diskless machines that are defined by the machine group `dtgrp1`, while allocating the required and optional resources defined by the resource group `dk_resgrp1`, when the **dkls_init** operation runs, type:

```
nim -o dkls_init -a group=dtgrp1 dk_resgrp1
```

dtls_init

1. To initialize the environment for a dataless workstation with the name of `syzygy`, using the resources `spot1`, `root1`, and `dump1`, first allocate the resources by typing:

```
nim -o allocate -a spot=spot1 -a root=root1 -a dump=dump1 syzygy
```

Then initialize the resources for the client machine by typing:

```
nim -o dtls_init syzygy
```

2. To initialize the environment for a dataless workstation with the name of `syzygy`, type:

```
nim -o dtls_init syzygy
```

3. To exclude the member named `dataless1` from operations on the machine group `DatalsMacs1`, and then initialize the remaining members while allocating the dataless resources defined by the resource group named `DatalsRes1`, type the following two commands:

```
nim -o select -a exclude=datals2 DatalsMacs1
nim -o dtls_init -a group=DatalsMacs1 DatalsRes1
```

4. To initialize the group of dataless machines defined by the machine group `DatalsMacs1`, while allocating the required and optional resources defined by the resource group `DatalsRes1`, when the **dtls_init** operation runs, type:

```
nim -o dtls_init -a group=DatalsMacs1 DatalsRes1
```

fix_query

To list information about fixes installed on client `Standalone1` for 20 APAR numbers, create the file `/tmp/apar.list` with one APAR number per line, as shown:

```
IX123435
IX54321
IX99999
...
```

then type:

```
nim -o define -t fix_bundle -alocation=/tmp/apar.list \
                -aserver=master fix_bun
nim -o allocate -a fix_bundle=fix_bun Standalone1
nim -o fix_query Standalone1
```

lppchk

1. To check fileset version and requisite consistency on the SPOT spot1, type:

   ```
   nim -o lppchk spot1
   ```

2. To verify the file checksums for all packages beginning with the name bos on NIM targets in the group of standalone machines macgrp1, and displaying detailed error information and updating the software database to match the actual file checksum when inconsistencies are found, type:

   ```
   nim -o lppchk -a lppchk_flags='-c -m3 -u' \
   -a filesets='bos*' macgrp1
   ```

   Because the **lppchk** operation runs in the background on group members by default, to view the output from the **lppchk** operation type:

   ```
   nim -o showlog -a log_type=lppchk macgrp1
   ```

lppmgr

1. To list the names of duplicate base level filesets which should be removed from lpp_source1 with space usage information, type:

   ```
   nim -o lppmgr -a lppmgr_flags="-lsb" lpp_source1
   ```

2. To remove duplicate base and update filesets and superseded updates from lpp_source1, type:

   ```
   nim -o lppmgr -a lppmgr_flags="-rbux" lpp_source1
   ```

3. To remove all non-SIMAGES (filesets that are not required for a bos install) from lpp_source1, type:

   ```
   nim -o lppmgr -a lppmgr_flags="-rX" lpp_source1
   ```

4. To remove all language support except 'C' from lpp_source1, type:

   ```
   nim -o lppmgr -a lppmgr_flags="-r -k C" lpp_source1
   ```

lswpar

1. To list the characteristics of the managed wpar1 workload partition, type:

   ```
   nim -o lswpar wpar1
   ```

2. To list the network characteristics of the managed wpar1 workload partition, type:

   ```
   nim -o lswpar -a cmd_flags="-N" wpar1
   ```

3. To list the general characteristics of the workload partitions managed by the global1 standalone system, type:

   ```
   nim -o lswpar -a cmd_flags="-G" global1
   ```

maint

1. To cleanup from an interrupted software installation on a spot, spot1, type:

   ```
   nim -o maint -a installp_flags="-C" spot1
   ```

2. From the master, to clean up from an interrupted software installation on a standalone machine, stand1, type:

```
nim -o maint -a installp_flags="-C" stand1
```

maint_boot

To enable the NIM standalone client, `stand1`, to boot in maintenance mode, type:

```
nim -o maint_boot stand1
```

This sets up the maintenance boot operation, but you must initiate the network boot locally from `stand1`.

remove

To remove a resource named `dump_files`, type:

```
nim -o remove dump_files
```

showlog

To view the boot logs of the machines that are defined by the group `DisklsMacs1`, type:

```
nim -o showlog -a log_type=boot DisklsMacs1
```

showres

1. To show the contents of the configure `script1` script , type:

```
nim -o showres script1
```

2. To show the contents of the bosinst.data resource `bosinst_data1`, type:

```
nim -o showres bosinst_data1
```

3. To list all the filesets in the lpp_source `lpp_source1`, type:

```
nim -o showres lpp_source1
```

4. To list all the filesets in the lpp_source `lpp_source1` relative to what is installed on the machine `machine1`, type:

```
nim -o showres -a reference=machine1 lpp_source1
```

5. To list all the problems that are fixed by software on the lpp_source `lpp_source1`, use:

```
nim -o showres -a instfix_flags="T" lpp_source1
```

6. To show the contents of the secondary adapter configuration file in the **adapter_def** resource, `adapter_def1`, for client, `deadfish`, type:

```
nim -o showres -a client=deadfish adapter_def1
```

7. To show the contents of every secondary adapter configuration file in the **adapter_def** resource, `adapter_def1`, type:

```
nim -o showres adapter_def1
```

8. To show the contents of the **savevg** resource, `savevg1`, type:

```
nim -o showres savevg1
```

syncwpar

1. To synchronize the software of the managed `wpar1` workload partition with its managing system, type:

```
nim -o syncwpar wpar1
```

2. To synchronize the software of all the workload partitions managed by the `global1` standalone system, type:

```
nim -o syncwpar -a cmd_flags="-A" global1
```

update

1. To add all the filesets on `/dev/cd0` to `lpp_source1`, type:

```
nim -o update -a packages=all -a source=/dev/cd0 lpp_source1
```

2. To add the `bos.games 7.1.0.0` and `bos.terminfo` filesets to `lpp_source1`, type:

```
nim -o update -a packages="bos.games 7.1.0.0 bos.terminfo" \
  -a source=/dev/cd0 lpp_source1
```

3. To remove `bos.games` from `lpp_source1`, type:

```
nim -o update -a rm_images=yes -a packages="bos.games" lpp_source1
```

4. To recover the missing SIMAGES for `lpp_source1` from the AIX Installation CD, type:

```
nim -o update -a recover=yes -a source=/dev/cd0 lpp_source1
```

updatios

1. To install fixes or to update VIOS with the *vioserver1* NIM object name to the latest maintenance level, type:

```
nim -o updateios -a lpp_source=lpp_source1 -a preview=no vioserver1
```

   The updates are stored in `lpp_source` and `lpp_source1` files.

   Note: The **updateios** operation runs a preview during installation. Running the **updateios** operation from NIM runs a preview unless the preview flag is set to no. During the installation, you must run a preview when you use the **updateios** operation with **updatios_flags=-install**. With the preview, you can check whether the preview installation is running accurately before you proceed with the VIOS update.

2. To reject fixes for a VIOS with the *vioserver1* NIM object name, type:

```
nim -o updateios -a updateios_flags=-reject vioserver1
```

3. To clean up partially installed updates for a VIOS with the *vioserver1* NIM object name, type:

```
nim -o updateios -a updateios_flags=-cleanup vioserver1
```

4. To commit updates for a VIOS with the *vioserver1* NIM object name, type:

```
nim -o updateios -a updateios_flags=-commit vioserver1
```

5. To remove a specific update such as `update1` for a VIOS with the *vioserver1* NIM object name, type:

```
nim -o updateios -a updateios_flags=-remove-a filesets="update1" vioserver1
```

6. To remove updates for a VIOS with the *vioserver1* NIM object name by using an *installp_bundle bundle1*, where *bundle1* contains the updates to be removed, type:

```
nim -o updateios -a updateios_flags=remove -a installp_bundle=bundle1 vioserver1
```

Files

Item	Description
/etc/niminfo	Contains variables that are used by NIM.

nim_clients_setup Command

Purpose

Define clients and initialize BOS install operation on NIM client objects.

Syntax

`nim_clients_setup` [`-m` *mksysb_resource*] [`-n`] [`-c`] [`-r`] [`-v`] *client_object(s)*

Description

The `nim_clients_setup` command defines new client objects and initializes the BOS install operation for clients in the NIM environment by performing the following tasks:

- Exports the environment variable NIM_LICENSE_ACCEPT=yes.
  - Used for accepting software license agreement during network install.
- Adds variable entry NSORDER=local,bind in `/etc/environment`.
  - Necessary for name resolution when hosts only exist in `/etc/host`.
- Defines client objects using `client.defs` file (if `-c` flag specified).
  - User must edit stanzas in `/export/nim/client.defs` file prior to using `nim_clients_setup`.
- Prepares client objects for install.
  - If `-c` flag is used, defined clients are initialized for install.
  - If client objects are given, specified clients are initialized for install.
  - If `-c` or client objects are omitted, all existing NIM clients are initialized for install.
- Resources contained in the group name `basic_res_grp` are used as resources during the BOS install operation.

Note: The`basic_res_grp` resource group is populated with resources created during `nim_master_setup` command execution. If this group is not present, it must be defined with NIM install resources prior to using the `nim_clients_setup` command.

Flags

Item	Description
`-m` *mksysb_resource*	Specifies an alternate backup image to restore during BOS install. The value for *mksysb_resource* may specify a NIM object name or absolute path location used for defining a new `mksysb` resource. By default, the `mksysb` resource is assigned from the `basic_res_grp` NIM resource group.
`-n`	Enables native (`rte`) install and ignores restoring backup image (`mksysb`) during BOS install. By default, `mksysb restore` is performed during BOS install.
`-c`	Defines client objects from the `client.defs` file. The `/export/nim/client.defs` file must exist and have valid client definition information. The `client.defs` file is created during `nim_master_setup` command execution. If the file is not present, a sample `client.defs` file may be copied from `/usr/samples/nim/client.defs` and edited by the user.
`-r`	Reboots client objects after initiating BOS install operation. By default, clients are not rebooted. Resources are assigned for install and clients may be rebooted when desired.
`-v`	Enables verbose debug output during command execution.

Security

Access Control: You must have root authority to run the `nim_clients_setup` command.

Location

`/usr/sbin/nim_clients_setup`

Examples

1. To define client objects from `/export/nim/client.defs` file, initialize the newly defined clients for BOS install using resources from the `basic_res_grp` resource group, and reboot the clients to begin install, type:

   ```
   nim_clients_setup -c -r
   ```

2. To initialize clients client1 and client2 for BOS install, using the backup file `/export/resource/NIM/530mach.sysb` as the restore image, type:

   ```
   nim_clients_setup -m /export/resource/NIM/530mach.sysb \ client1 client2
   ```

3. To initialize all clients in the NIM environment for native (`rte`) BOS install using resources from the `basic_res_grp` resource group, type:

   ```
   nim_clients_setup -n
   ```

Files

Item	Description
`/etc/niminfo`	Contains variables used by NIM.

nim_master_recover Command

Purpose

Restores a backup of the Network Installation Management (NIM) database to a different machine and updates the database to reflect this change.

Syntax

`nim_master_recover` [`-f` *mstr_fileset_dir*]

[`-n` *nimdef_file*]

[`-r` *nimdb_file*]

[`-i` *mstr_interface*]

[`-D`] [`-R`] [`-S`] [`-p`] [`-s`] [`-u`] [`-v`]

[**`-N`** *mstr_net_info* [**`-t`** *net_def*]]

Description

The `nim_master_recover` command can restore and update the NIM database from a backup tar file. To backup the NIM database on the old master, run the `smit nim_backup_db` command. This creates a tar file named `/usr/objrepos/nimdb.backup` by default. Once the `nimdb.backup` is copied to the new master, pass the `-r` flag with the full path to the file. If the path to the tar file is `/usr/objrepos/nimdb.backup`, then pass `-r /usr/objrepos/nimdb.backup` to the `nim_master_recover` script.

The script updates the master definition in the NIM database based on the master's primary network interface. The `-i` flag specifies the primary interface to use for the master. To use `en0`, pass `-i en0` to the `nim_master_recover` script.

Note: A restored NIM database may be incorrect if you restore from a database that has network definitions containing static routes. The `nim_master_recover` command removes all the interfaces in the old master definition before adding the primary interface for the new master. Check that the routing information is correct after running the `nim_master_recover` command, by running `lsnim -lc networks`. If all the NIM network definitions in the restored database contain dynamic routes, then you should not run into this situation.

Along with restoring and updating the NIM database, the script performs several other optional functions. One is to install the `bos.sysmgt.nim.master` fileset if the `-f` flag is passed with the location of the `bos.sysmgt` package. For instance, if the `bos.sysmgt` package is located in the `/export/latest/installp/ppc` directory, then you would pass `-f /export/latest/installp/ppc` to the `nim_master_recover` script.

The script always resets each client. If the `-u` flag is passed, the script attempts to unexport NIM resources that the database states are allocated to clients. Each client stores the hostname of its NIM master in its `/etc/niminfo` file. To update the `niminfo` file on each client, pass the `-s` flag.

Note: Any NIM client that is not running, does not have a network connection, does not allow the new master `rhost` permissions, or does not have at least the `bos.sysmgt.nim.client 5.1.0.10` package, will not have its `niminfo` updated. The `nim_master_recover` script will report any clients which fail to have their `niminfo` files updated.

New clients can be added to the environment by specifying a `nimdef` file with the `-n` flag. Consult the AIX Installation Guide for more information on `nimdef` files.

Finally, the script will check to see if the resources in the NIM database exist. The script deletes resources that don't exist. For example if the new master is unable to communicate with a NIM server, then the resources defined on that server will be removed from the NIM database. Passing the `-R` flag prevents the script from checking resources.

Note: Resources that were defined on the master where the database was backed up, will not be available once the database is restored unless the resources were copied to the new master before running `nim_master_recover`.

All output will be logged to `/var/adm/ras/nim.recover`. Once the script is complete you should verify that no errors were logged.

The **nim_master_recover** command behaves differently when it is called with the **-N** flag. This allows the master to have its hostname, IP address, and NIM network changed in its if1 attribute. Optionally, a new NIM network may be created if the **-t** flag is provided with the **-N** flag. The command should be run with these flags before the master's network name or address is actually changed so that the NIM environment will work properly once the change actually takes place. When the master's NIM attributes are changed, the command will attempt to update **/.rhosts** and **/etc/niminfo** of each standalone client defined in the environment. Any clients for which this attempt fails must have its NIM master information updated manually. Also, after a standalone client has had its NIM master's network name changed, it will not be able to execute any NIM operations until the master is up and running with its new network name.

Flags

Item	Description
`-D`	Deletes all client definitions from the restored database.
`-f` *directory*	Directory containing the `bos.sysmgt.nim.master` fileset to install.
`-i` *interface*	Primary network interface of the machine where you are running the command.
`-n` *nimdef*	Optional *nimdef* file that will be used to define new machines.

Item	Description
-N *mstr_net_info*	Changes the master's if1 attribute and attempts to update each standalone client defined in the environment with the master's new network information. The *mstr_net_info* variable consists of the following: "`nim_net_name [hostname] [cable_type]`"; where *hostname* and *cable_type* are optional.
`-p`	Print the machine states before the script resets the machines.
`-r` *nimdb.backup*	The NIM database backup tar file that will be restored.
`-R`	Do not check the resources to see if each one exists. The default behavior is for the script to check each resource and if it does not exist, remove its definition from the database.
`-S`	Do not check the SPOT resources. The default behavior is for the script to check every SPOT to ensure it is ready to support an install. For example, the check ensures the boot images are created.
`-s`	Attempt to update the `niminfo` file on each client. Any NIM client that is not running, does not have a network connection, does not allow the new master rhost permissions, or does not have at least the `bos.sysmgt.nim.client 5.1.0.10` package installed, will not have its `niminfo` updated.
-t *net_def*	Creates a new NIM network if the master's IP address changes and there is no existing NIM network that could contain the master. This flag is only valid when the **-N** flag is also specified. The *net_def* variable consists of the following: "`nim_net_name net_type net_addr net_snm default_route`"; where *net_type* can be `ent`, `tok`, `atm`, or `fddi`.
`-u`	Unexport all resources that are listed as allocated in the restored database. The default behavior is for the script to delete the allocation from the NIM database without attempting to deallocate the resource.
`-v`	Enables verbose debug output during command execution.

Location

`/usr/sbin/nim_master_recover`

Exit Status

Returns zero (0) upon success.

Security

Access Control: You must have root authority to run the `nim_master_recover` command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To recover the NIM master using the `/export/nim/nimdb.backup` file and the primary interface en0, type:

```
nim_master_recover -r /usr/objrepos/nimdb.backup -i en0
```

2. To install the `bos.sysmgt.nim.master` fileset from `/export/lpp_source/installp/ppc` before recovering the NIM master, type:

```
nim_master_recover -f /export/lpp_source/installp/ppc \
          -r /usr/objrepos/nimdb.backup -i en0
```

3. To recover the NIM master without checking if each resource exists and without checking the SPOTs to rebuild boot images, type:

```
nim_master_recover -R -S -r /usr/objrepos/nimdb.backup -i en0
```

4. To recover the NIM master while unexporting any resources that are allocated and printing the state of the clients before each one is reset, type:

```
nim_master_recover -u -p -r /usr/objrepos/nimdb.backup -i en0
```

5. To recover the NIM master and update the `/etc/niminfo` file on each client, type:

```
nim_master_recover -s -r /usr/objrepos/nimdb.backup -i en0
```

6. To recover the NIM master, delete each client from the database, and define new clients from the `nimdef` file `/export/nim/nimdef`, type:

```
nim_master_recover -D -n /export/nim/nimdef -r /usr/objrepos/nimdb.backup -i en0
```

7. To change the master's hostname to `newhost.domain.com` and move it to a different existing NIM network, called `net2`, but preserve the value of the current *cable_type* attribute, type:

```
nim_master_recover -N "net2 newhost.domain.com"
```

8. To change the master's hostname to `newhost.domain.com`, change its *cable_type* to `bnc`, and move it to a new NIM ethernet network called `new_nim_net` whose address is `192.168.1.0`, subnet mask is `255.255.255.0`, and default gateway is `192.168.1.1`, type:

```
nim_master_recover -N "new_nim_net newhost.domain.com bnc" \
    -t "new_nim_net ent 192.168.1.0 255.255.255.0 192.168.1.1"
```

Files

Item	Description
`/etc/niminfo`	Contains variables used by NIM.
`/var/adm/ras/nim.recover`	Contains log information from command execution.

nim_master_setup Command

Purpose

Initializes the Network Installation Management (NIM) master fileset, configures the NIM master, and creates the required resources for installation.

Syntax

`nim_master_setup` [-a [mk_resource={yes|no}] [file_system=*fs_name*] [volume_group=*vg_name*] [disk=*disk_name*] [device=*device*]] [-B] [-F] [-L] [-v]

Description

The `nim_master_setup` command initializes the NIM master fileset and configures the NIM environment. Once initialized, the `nim_master_setup` command configures the NIM environment by performing the following tasks:

- Determines which volume group and file system will contain the NIM resources.
- If necessary, creates the volume group and file system.
- Creates a NIM `mksysb` of the master.
  - Backup image.
- Creates a NIM `lpp_source` resource.
  - Source for product images.
- Creates a NIM spot resource.
  - Shared Product Object Tree (SPOT) - equivalent to `/usr` file system.
- Creates a NIM `bosinst_data` resource.
  - `config` file used during BOS installation.
- Creates a NIM `resolv_conf` resource.
  - Name-server configuration file.
- Defines a default resource group for use during install. The default resource group will contain all NIM resources defined during command execution.
- Copies a sample `client.defs` configuration file into the defined NIM file system.
  - Sample file which may be edited for adding clients in the NIM environment.

Flags

Item	Description
`-a`	Assigns the following `attribute=`*value* pairs: **mk_resource={yes|no}** Specifies if NIM resources should be created. If set to no, NIM resources will not be created during command execution. By default, the value is yes. **file_system=*fs_name*** Specifies the absolute path location for creating NIM resources. If *fs_name* does not exist, a logical volume will be created in the volume group defined from *vg_name*. By default, *fs_name* is `/export/nim`. **volume_group=*vg_name*** Specifies the volume group name used for creating new logical volumes. If *vg_name* does not exist, a volume group will be created using the physical volume (disk) defined from *disk_name*. By default, *vg_name* is `rootvg`. **disk=*disk_name*** Specifies the physical volume used when creating the *vg_name* volume group. If *disk_name* is not specified, the next available (empty) physical volume will be used. **device=*device*** Specifies the absolute path location for install images used during NIM master fileset installation and resource creation. By default, `device` is `/dev/cd0`.
`-B`	Disables the creation of the backup image.
`-F`	Disables the creation of the file system.
`-L`	Disables the creation of the `lpp_source` resource.
`-v`	Enables verbose debug output during command execution.

Location

`/usr/sbin/nim_master_setup`

Exit Status

Returns zero (0) upon success.

Security

Access Control: You must have root authority to run the `nim_master_setup` command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To install the NIM master fileset and initialize the NIM environment using install media located in device `/dev/cd1`, type:

   ```
   nim_master_setup -a device=/dev/cd1
   ```

2. To initialize the NIM environment without creating NIM install resources, type:

   ```
   nim_master_setup -a mk_resource=no
   ```

3. To initialize the NIM environment, create NIM install resources without creating a backup image, using install media located under mount point `/cdrom`, type:

   ```
   nim_master_setup -a device=/cdrom -B
   ```

4. To define NIM resources in an existing NIM environment, using install media located in device `/dev/cd0`, and create a new file system named `/export/resources/NIM` under volume group `nimvg`, type:

   ```
   nim_master_setup -a volume_group=nimvg  \
               -a file_system=/export/resources/NIM
   ```

Note: If the file system `/export/resources/NIM` does not currently exist, then it will be created under the volume group `nimvg`. If the `nimvg` volume group does not exist, it will be created using the next empty physical volume (disk) since the disk attribute was not specified.

`/etc/niminfo`	Contains variables used by NIM.
`/var/adm/ras/nim.setup`	Contains log information from command execution.

nim_move_up Command

Purpose

Facilitates the enablement of new hardware in AIX environments.

Syntax

nim_move_up {[-S] | [-K [-h *control_host*]] | [-r [-R] [-u]]} | { [-c *NIM_client*] [-i *target_ip* [*-ending_ip*]] [-s *subnet_mask*] [-g *gateway*] [-h *control_host*] [-m *managed_sys*] [-V *vio_server* [-e] [-D]] [-I *img_src*] [-l *resource_dir*] [-t *seconds*] [-p *loops*] [-j *nimadm_vg*] [-L *lpp_source*] [-U *spot*] [-B *bosinst_data*] [-E *exclude_files*] [-C *script_resource*] [-b *installp_bundle*] [-f *fix_bundle*] {{[-n] [-d]} | -O} [-q] [-T] [-M *manual_configuration_filenames*]}

Description

The nim_move_up command enables users of existing AIX environments to take advantage of the capabilities available on new POWER servers. The command provides an interface that migrates an existing AIX system onto an LPAR residing on a POWER server. The level of AIX on the original machine is raised to a level that supports operation on newer hardware. The original system's hardware resources are closely replicated on the newer hardware. By the end of the migration, the same system is fully running on the new LPAR.

In addition, nim_move_up can use the Virtual I/O capabilities of POWER servers by optionally migrating a client onto virtualized hardware, such as virtual disks and virtual Ethernet.

The nim_move_up command relies on the functionality of NIM and the NIM master's capability of remotely managing and installing NIM clients on the network. The nim_move_up command attempts to use the NIM master and the nimadm command to complete the following actions on an existing NIM client:

1. Create a system backup of the client
2. Migrate the backup's level of AIX
3. Install the backup onto an LPAR that resides on the new POWER server, which is be represented in the NIM environment as a new standalone client.

Before the new hardware is installed, the NIM master (on which the **nim_move_up** command is run) and the NIM clients on the existing hardware must be configured. The clients are the starting point of the migration and eventually turn into the new LPAR.

After a successful migration, the following conditions are true:

- The NIM master remains the same.
- The LPAR on the new POWER server correspond to the original NIM clients and are controlled by the NIM master.
- An HMC controls the LPAR on the new POWER servers by communicating with the NIM master through SSH.
- The original NIM clients remain unaffected and still in control of the NIM master.

The entire migration takes place without any downtime required on the part of the original client. The process can be completed in phases executed sequentially, which allows more control over the process, or can be executed all at once, so that no user interaction is required. The command is delivered as part of the bos.sysmgt.nim.master fileset and requires a functional NIM environment in order to run.

Required Flags

Item	Description
-c *NIM_client*	Specifies either a NIM standalone client (standalone object type) or a NIM machine group (mac_group object type). The client indicated must be reachable using the network from the NIM master and must allow the NIM master to run commands on them. If a NIM machine group is specified in this argument, it must reside in the same NIM network. The client is the target machine that will be migrated onto the new LPAR on a POWER server.
-g *gateway*	Specifies the IP address of the default gateway that the clients will be configured with after the migration to the POWER server.
-h *control_host*	Specifies the host name or IP address of the HMC that is used for hardware control of the POWER server.
-i *target_ip*[-*ending_ip*]	Specifies the IP address that the new migrated client will be configured with after it is installed on the POWER server. If a NIM machine group is supplied to the -c option, a range of IP addresses must be supplied here and there must be enough addresses in the range to enumerate the amount of clients that are to be migrated.
-I *img_src*	Specifies the path to the source of the installation images used to create the NIM resources required for migration and installation. This path can be a device (such as dev/cd0 if using AIX product media) or a path to a location on the file system containing the installation images.
-l *resource_dir*	Specifies the path to a location on the file system that will contain any new NIM resources created through the nim_move_up command. The location must have enough space to accommodate an LPP_Source and a spot unless existing resources were provided through the -L and -U options.
-m *managed_sys*	Specifies the name of the managed system corresponding to the POWER server as tracked by the HMC.
-s *subnet_mask*	Specifies the subnet mask that the clients will be configured with after the migration to the POWER server.

Execution and Control Flags

Item	Description
-d	Executes nim_move_up in the background and returns control of the terminal to the caller. The progress of nim_move_up can be tracked through the -S flag.

Item	Description
-K	Configures SSH keys on the specified HMC. This allows the unattended remote execution of commands from the NIM master without password prompts. This flag cannot be used with any other options except the -h option.
-n	Runs only the next phase of the nim_move_up migration process. The nim_move_up command exits when the phase completes or fails. If this flag is not provided, all the subsequent phases are run and nim_move_up exits when they have all run or one of them has failed.
-O	Saves only supplied values. Save values provided through other options and then exits without executing any phases. This flag cannot be used with any other of the Execution and Control Flags.
-q	Specifies quiet mode. No output is displayed to the terminal (but is instead kept in the logs). This flag has no effect if nim_move_up runs with the -d flag.
-r	Unconfigures nim_move_up. This resets all saved data, including saved options, phase-specific data, and current phase information. This operation must be run if the migration process is to be started over for the migration of a new client or set of clients.
-R	Removes all NIM resources created by nim_move_up in addition to unconfiguring the environment. This flag can only be used with the -r option.
-S	Displays the status of the current phase or the next phase to be run. All saved values are displayed as well. The nim_move_up command exits immediately after displaying the information. This flag cannot be used with any other options.

Optional Flags

Item	Description
-b *installp_bundle*	Specifies an existing installp_bundle NIM resource whose software are installed on each of the newly migrated LPAR in phase 10 (post-installation customization) if the option is provided.
-B *bosinst_data*	Specifies an existing bosinst_data NIM resource used by nim_move_up to install the new clients onto the new LPAR. If this option is not provided, nim_move_up generates a bosinst_data resource with default unattended installation values.
-C *script_resource*	Specifies an existing script NIM resource that, if provided, nim_move_up will execute in phase 10 (post-installation customization) on all of the new migrated LPAR.

Item	Description
`-D`	Forces the use of physical storage controllers instead of virtual SCSI adapters in creating the new LPAR on the POWER server when a Virtual I/O server LPAR is specified. This flag is only valid when used with the `-V` option.
`-e`	Forces the use of physical network adapters instead of shared Ethernet adapters in creating the new LPAR on the POWER server when a Virtual I/O server LPAR is specified. This flag is only valid when used with the `-V` option.
`-E` *exclude_files*	Specifies an existing `exclude_files` NIM resource that `nim_move_up` uses to create a `mksysb` of the original clients. If this option is not provided, `nim_move_up` generates an `exclude_files` resource that excludes the contents of `/tmp` from the backup.
`-f` *fix_bundle*	Specifies an existing `fix_bundle` NIM resource whose APARs are installed on each of the newly migrated LPARin phase 10 (post-installation customization) if the option is provided.
`-j` *nimadm_vg*	Specifies the volume group to be used by the underlying `nimadm` call for data caching. If this option is not provided, the default value is `rootvg`.
`-L` *lpp_source*	Specifies an existing LPP_Source NIM resource to whose AIX level the target clients will be migrated to. If this option is not provided, `nim_move_up` attempts to create a new LPP_Source from the installation image source provided through the `-I` option.
`-M` *manual_configuration_filenames*	Specifies **phase4** to use these manual configuration files to the associated back-level AIX machines. This flag is effective only in **phase4** of the **nim_move_up** command. For more information about this flag, see the Advanced usage section.
`-p` *loops*	Specifies the number of times to execute system analysis tools on the target NIM clients in analyzing resource utilization. The final resource usage data will be the average of the values obtained from each loop. This data will be taken into account when determining the equivalent POWER server resources from which the migrated LPAR will be derived. If this option is not provided, the default is 1 loop.
`-t` *seconds*	Specifies the number of seconds each loop runs for. If this option is not provided, the default is 10 seconds.
`-T`	Transports user-defined volume groups from the original clients to the new migrated LPAR.
`-u`	Enables `nim_move_up` to completely "roll back" entire `nim_move_up` migration. Must be used with the `-r` flag.

Item	Description
-U *spot*	Specifies an existing spot NIM resource that will be used in the migration and installation of the clients. If this option is not provided, a new spot is created from the *lpp_source* NIM resource provided by the -L and -I options.
-V *vio_server*	Specifies the LPAR name of a Virtual I/O server that resides on the POWER server denoted by the -m flag.

Exit Status

Item	Description
0	Successful completion.
nonzero	An error occurred.

Security

Only the root user can run this command.

Examples

1. To run the first phase and configure all the required options (nim_move_up must not be already configured and running), type:

```
nim_move_up -c client1 -i 192.168.1.100 -s 255.255.255.0 -g 192.168.1.1 -h hmc1.mydomain.com
-m \
my-p5 -l /big/dir -I /dev/cd0 -n
```

2. To display the status of the nim_move_up command's environment, including all saved configuration input and which phase is to be executed next, type:

```
nim_move_up -S
```

3. To change the saved host name to a new name and run the next phase while suppressing output, type:

```
nim_move_up -h hmc2.mydomain.com -n -q
```

4. To run all remaining phases in the background, save your agreement to accept all licenses, and have the prompt returned after the phases begin running, type:

```
nim_move_up -Y -d
```

5. To unconfigure nim_move_up, discard all saved input, and reset the command to run phase 1, type:

```
nim_move_up -r
```

   All NIM resources previously created by nim_move_up remain unaffected in the NIM environment and will be used by nim_move_up as necessary to migrate another client.

Restrictions

The following NIM master requirements must be met before running the nim_move_up application:

- Running AIX 5L Version 5.3 with the 5300-03 Recommended Maintenance package, or later.
- Perl 5.6 or later.
- OpenSSH (from the Linux Toolbox CD)
- At least one standalone NIM client running AIX 4.3.3 update or later in the environment

- Product media version AIX 5L Version 5.2 with the 5200-04 Recommended Maintenance package or later, or product media version AIX 5.3 or later (the equivalent LPP_Source and spot NIM resources can also be used).

In addition, the following prerequisites must be available:

- A POWER server with sufficient hardware resources to support the target clients' equivalent POWER server configuration.
- An installed and configured Virtual I/O server is, if virtual resources will be used to migrate the clients.
- An HMC controlling the POWER server, along with sufficient privileges to power-on, power-off, and create LPAR.

The `nim_move_up` command will fail to execute properly if all of the preceding requirements are not met or if the command is executed by a non-root user.

Implementation Specifics

The `nim_move_up` command takes a phased approach to migrating an existing client onto a new LPAR. The following phases make up the process:

1. **Create NIM resources.** The NIM resources required to perform the migration steps are created if they do not already exist.
2. **Assess premigration software.** An assessment of which software is installed and which software cannot be migrated is performed on each target client. Any software missing from the LPP_Source is added from the source of the installation images (such as product media) that is provided to `nim_move_up`.
3. **Collect client hardware and usage data.** Data about each target client's hardware resources are gathered. Also, an attempt to assess the average use of those resources over a given amount of time is made.
4. **Collect POWER server resource availability data and translate client resource data.** The managed system that is provided is searched for available hardware resources. The data gathered in the previous phase is used to derive an equivalent LPAR configuration that uses the managed system's available resources. If a Virtual I/O server LPAR was provided to work with, the derived client LPAR is created with virtual I/O resources instead of physical I/O resources. The appropriate adapters and configuration are created on the Virtual I/O server as needed.
5. **Create system backups of target clients.** After NIM performs a `mksysb` of each target client, the corresponding `mksysb` NIM resources are created.
6. **Migrate each system backup.** Using the NIM resources designated by `nim_move_up`, each `mksysb` resource is migrated to the new level of AIX by the `nimadm` command. The original `mksysb` NIM resources are preserved and new mksysb NIM resources are created for the new migrated `mksysb` resources.
7. **Allocate NIM resources to new LPAR.** NIM standalone client objects are created for each new derived LPAR created in phase 4 using the network information provided to `nim_move_up`. Appropriate NIM resources are allocated and a `bos_inst` pull operation is run on each NIM client (NIM does not attempt to boot the client).
8. **Initiate installation on LPAR.** Each LPAR is rebooted using the control host (HMC) and the installation is initiated. The phase's execution stops after the installation has begun (that is, the progress of the installation is not monitored).
9. **Assess post-migration software.** After each installation has completed, the overall success of the migration is assessed, and a report of software problems encountered during migration is generated. If any filesets failed to migrate, the errors reported for that fileset must be corrected manually.
10. **Customize post-installation.** If an alternate LPP_Source, fileset list, or customization script was provided, a customized NIM operation is performed on each client with the values provided. This allows for the optional installation of additional software applications or for any additional customization.

In order to successfully migrate a NIM client onto a new LPAR, each of these phases (with the exception of phase 10, which is optional) must be executed completely successfully. If all phases completed successfully, a new NIM client object will be present in the NIM environment that represents the migrated LPAR, which will be running the level of AIX supplied through the `nim_move_up` source of installation resources.

After all prerequisites needed to run `nim_move_up` have been satisfied, the `nim_move_up` command runs in two phases: configuration and phase execution.

Configuration

Before the `nim_move_up` command can begin its phases, input must be provided to the application. The required input includes a list of the NIM clients to be migrated, TCP/IP configuration information of the new migrated LPAR, and the POWER server name. For a complete list of required `nim_move_up` configuration options, refer to the Required Flags (they also are denoted by a * (asterisk) in the `nim_move_up_config` SMIT menu). Optional input, such as whether a Virtual I/O server is specified, also affects the behavior of `nim_move_up` and the end result of the migration process (if a Virtual I/O server is specified, virtual I/O resources are used to create the migrated LPAR).

To populate the required and optional input through the SMIT interface, enter one of the following commands:

```
smitty nim_move_up_config
```

or

```
smitty nim_move_up
```

and select the `Configure nim_move_up Input Values` option.

At the menu, fill in the options with values that reflect the requirements of your environment. For further information about the `nim_move_up` command's SMIT interface, see the SMIT usage section below.

After the `nim_move_up` command's environment has been configured with the needed input, those values are remembered through subsequent runs of the `nim_move_up` command until the `nim_move_up` command environment is unconfigured. The values can be changed at any time through the SMIT menu interface or by providing the new values through command line flags. The command line interface can also be used to configure the `nim_move_up` command environment.

Note:

If you use the command line interface, the `nim_move_up` command, by default, also attempts to execute phases whenever configuration values are provided to it. To prevent phases from being executed when calling the command directly, use the `-0` flag.

Phase Execution

After all input is supplied, phase execution begins at phase 1 and continues sequentially. If a phase encounters an error, `nim_move_up` attempts to execute the failed phase the next time it runs. Optionally, you can specify that `nim_move_up` start only the next phase or attempt all remaining phases.

To start `nim_move_up` phases through the SMIT interface, type one of the following commands:

```
smitty nim_move_up_exec
```

or

```
smitty nim_move_up
```

and select the `Execute the nim_move_up Phases` option. Answer the `Execute All Remaining Phases?` option and press Enter. The phases begin executing.

To specify that nim_move_up execute only the next phase using the command line, type the following command:

```
nim_move_up -n
```

To specify that nim_move_up execute all remaining phases, type the following command:

```
nim_move_up
```

In addition to executing phases, this command can also modify saved configuration options if the appropriate flag is supplied.

SMIT Usage

The nim_move_up SMIT menus can be accessed using the nim_move_up fastpath. To invoke the root menu of nim_move_up, type the following command:

```
smitty nim_move_up
```

The following SMIT screens are accessible through the root menu:

Display the Current Status of nim_move_up
Equivalent to running nim_move_up with the -S flag. The next phase to be executed and a listing of all the saved options are displayed.

Configure nim_move_up Input Values
Through this screen, all required and optional input to nim_move_up can be configured. All values entered into the fields are saved and are remembered through subsequent runs of nim_move_up and through subsequent uses of this SMIT screen. This screen can be used at any time to modify saved values after phases have been run.

Execute nim_move_up Phases
Provides a simple interface to execute nim_move_up phases. The phases can be executed one at a time or all at once, depending on how the questions in this phase are answered.

Configure SSH Keys on Target HMC
Provides a simple interface for setting up SSH keys on the remote control host (HMC). This does the equivalent work of passing the -K flag on the command line. Configuring SSH keys on the remote control host enables the unattended remote execution of commands from the NIM master, which is necessary for completing all the phases (some of which remotely execute commands on this system).

Unconfigure nim_move_up
Provides an interface to unconfigure the nim_move_up command's environment. This removes all state information, including which phase to execute next, saved data files generated as a result of the execution of some phases, and all saved input values. Optionally, all NIM resources created through nim_move_up can be removed as well. This screen does the equivalent work of the -r command line option.

Advanced Usage: Understanding the mig2p5 Framework

The mig2p5 framework consists of the /var/mig2p5 directory and serves as a means for nim_move_up to remember its state between subsequent invocations. Its existence and its use by nim_move_up is completely transparent to the user: the directory is created by nim_move_up and its values are initialized if it does not exist. It is removed when nim_move_up is unconfigured. The contents of this directory are easily readable and can be very helpful in troubleshooting problems with nim_move_up; the directory contains all of the logs generated in the phases and contains editable files that affect the behavior of nim_move_up in ways that are not allowed by the command line (such as forcing nim_move_up to run a certain phase out of order).

The following list describes the purpose and contents of each file in the /var/mig2p5 directory:

config_db
Contains all of the saved configuration options passed to `nim_move_up` through the command line arguments or the `nim_move_up_config` SMIT menu. Each line in the file takes the following form:

```
option_name:value
```

current_phase
Contains the number of the phase that will be executed at the next invocation of `nim_move_up`. Before running this phase, `nim_move_up` ensures that all previous phases have run successfully. This information is also maintained elsewhere with the `mig2p5` framework.

global_log
Contains the output of all phases that have been run since the last time the `mig2p5` framework was initialized.

client_data/
Contains files that are generated by `nim_move_up` during phases 3 and 4, in which each of the original clients' system resources and utilization are monitored and quantified into configuration files. The available resources in the POWER server are also quantified into corresponding text files. All the data in these files will be taken into account when determining the hardware profile of the newly derived LPAR on the POWER server. These files are intended to be machine-readable data files for the `nim_move_up` command's internal use. Do not manually modify or create them.

phase#/
Contains data specific to the corresponding phase denoted by the number in its name (#). Every phase has a directory (for example, `phase1/` , `phase2/` , and so on).

phase#/log
Contains all output displayed during a phase's run. If a phase runs multiple times (such as after an error has been corrected), all new output is appended to any text already existing in the file. This log is helpful in investigating failures related to this phase after they have occurred. The `global_log` file is composed of all the phases' log files, and all output in that file is arranged in the order that it was originally displayed.

phase#/status
Indicates whether this phase succeeded or failed when it was last run. This file is used by `nim_move_up` to determine whether a subsequent phase can be run. A phase can run only if all of the previous phases' `status` files contain the string `success`. The `status` file contains the `failure` string if the phase encountered an error that caused it to fail the last time it was run.

pid
Contains the `nim_move_up` process ID number when `nim_move_up` is running in the background. This file and is cleaned up when the process finishes. As long as this file exists and contains a process ID, `nim_move_up` cannot run phases because concurrent runs of `nim_move_up` are not supported.

With the exception of the log files and the contents of the `client_data/` directory, the files in `/var/mig2p5` that comprise the `mig2p5` framework can be read and modified so that `nim_move_up` performs tasks that it would not do through its command line and SMIT interfaces. Users are encouraged to manipulate the `mig2p5` environment to make `nim_move_up` meet any specific need and to aid in the troubleshooting of any problems that might arise during the migration process.

Note: Customizing the `mig2p5` framework is considered advanced usage and can yield unsatisfactory results if done incorrectly. The `mig2p5` environment should only be directly modified by users who understand the changes being performed and their effect on the behavior of the `nim_move_up` application.

What is the manual configuration file and why is it needed?

During **phase4** of the **nim_move_up** command, the tool calculates various resource requirements based on the back-level AIX machine and appropriately creates an LPAR on a target POWER server. When you meet any of the following situations, you can specify what modifications you need in the manual configuration file in a predefined format and run the **nim_move_up** command:

- There is a need for more memory than that determined by the **nim_move_up** command.

- There is a virtual SCSI adapter (vhost#) created on a Virtual I/O server that you want to use for a Volume Group.
- You want to use a different Virtual Local Area Network (VLAN) ID than the one generated by the **nim_move_up** tool.

After the successful completion of the **nim_move_up** command, the manual configuration is applied on the target LPAR.

How do I write a manual configuration file?

Note: You must create the manual configuration file before initiating the **nim_move_up** command. You can create these files for each of the clients to be migrated and specify these files as arguments to the **-M** flag to enable the **nim_move_up** command to use the manual configuration. The file name must be of the form *path*/manual_cfginfo_*client_host_name*. The *path* value is the directory where the manual configuration file is located, and the *client_host_name* value is the host name of the client machine to be migrated.

For each client that is migrated to a POWER platform, the **nim_move_up** command does all of the hardware configuration-related calculations by default. This file enables you to alter or tune the configuration of the target machine as you choose.

You can change the amount of memory, the size of the volume groups and the Virtual I/O server resources to be used. For example, you can change the VSCSI server adapter to be used for the volume groups created for the target LPAR. You can also change the VLAN IDs to be used for the Ethernet adapters created for the target LPAR.

The following is a sample of the manual configuration file:

```
# manual_cfgfile_dennis file
# MEMORY = min_MB desired_MB max_MB
MEMORY = 256 512 1024
# VIO_VG_INFO = vgname_src, size_in_MB, vhost_to_use
#    Where vgname_src is the VG name in source machine, and
#    vhost_to_use is the virtual adapter to be used for
#    the VG specified in the VIO Server.
VIO_VG_INFO = rootvg,15344,vhost4
# VIO_VLAN_INFO = vlan_id, lpar_name, slot_number
VIO_VLAN_INFO = 1,VIO-server,2
```

The file can have any blank lines. You can add comments to the file with a # at the beginning of the line.

All of the *min_MB*, *desired_MB*, and *max_MB* values must be in megabytes (MB). There is no restriction on the number of spaces between these numbers.

min_MB
The minimum memory required for AIX to run.

desired_MB
The amount of memory that you want the logical partition to have when activated.

max_MB
The maximum memory when dynamic logical-partitioning operations are performed on the partition.

The values of the VIO_VG_INFO field must be comma separated. The *vgname_src* value is the Volume Group in the source machine for which the manual data must be given. The *size_in_MB* value is the size of the Volume Group on the target machine and the *vhost_to_use* value is the vhost* (virtual SCSI server adapter) to be used for this Volume Group on the target POWER server.

Similarly, the values of the VIO_VLAN_INFO field must be comma separated. The *vlan_id* value is used instead of the one used by the **nim_move_up** command for the target LPAR's Ethernet adapter. The *lpar_name* value is the LPAR name of the Virtual I/O server having the shared Ethernet adapter (SEA), and the *slot_number* value is the slot number of this SEA on the Virtual I/O server.

It is not necessary to provide all of these values. The **nim_move_up** command receives the specified values from the manual file and generates the rest based on the client configuration.

Files

Item	Description
/usr/sbin/nim_move_up	Contains the nim_move_up command.

nim_update_all Command

Purpose

Updates NIM resources and customizes NIM clients.

Syntax

nim_update_all [-d *device*] [-l *lpp_source resource*] [-s *spot resource*] [-B] [-u] [-v] *client object(s)*

Description

The nim_update_all command updates the install resources and clients in the NIM environment. Flags may be used for specifying which NIM resources need updating and also to disable the updating of NIM clients. The nim_update_all command updates the NIM environment by performing the following tasks:

- Exports the environment variable NIM_LICENSE_ACCEPT=yes.
  - Used for accepting software license agreement during update install.
- Adds variable entry NSORDER=local,bind in /etc/environment.
  - Necessary for name resolution when hosts only exist in /etc/host.
- Obtains the update level information from the media.
  - The default media location is /dev/cd0.
  - The media location may be modified by using the -d flag.
- Updates the lpp_source, spot, and mksysb resources.
  - The lpp_source resource name may be specified by using the -l flag.
  - The spot resource name may be specified by using the -s flag.
  - The mksysb resource name is obtained from the mksysb resource contained in the basic_res_grp resource group. Specify the -B flag to disable updating the mksysb resource.
- Performs an update_all operation on NIM clients.
  - If client objects are given, specified clients are updated.
  - If client objects are omitted, all existing NIM clients are updated.
  - If -u flag is used, no clients are updated.

Flags

Item	Description
-d *device*	Specifies the absolute path location for update images used during command execution. By default, *device* is /dev/cd0.
-l *lpp_source resource*	Specifies the object name for the *lpp_source resource* to update. By default, the resource name is obtained from basic_res_grp.
-s *spot resource*	Specifies the object name for the *spot resource* to update. By default, the resource name is obtained from basic_res_grp.

Item	Description
-B	Disables the updating of the backup image contained in basic_res_grp.
-u	Disables the updating of client objects.
-v	Enables verbose debug output during command execution. Security

Location

/usr/sbin/nim_update_all

Exit Status

Returns zero (0) upon success.

Security

Access Control: You must have root authority to run the nim_update_all command.

Examples

1. To update install resources 520lpp_res (lpp_source), 520spot_res (spot), and master_sysb (mksysb) contained in the basic_res_grp resource group, using update images located in device /dev/cd2, and update all clients in the NIM environment, type:

```
nim_update_all -d /dev/cd2
```

2. To update install resources lpp1 (lpp_source), spot1 (spot), and disable updating the mksysb image, using update images located in device /dev/cd0, and update the client object machine1 in the NIM environment, type:

```
nim_update_all -l lpp1 -s spot1 \
          -B machine1
```

3. To update install resources 520lpp_res (lpp_source), 520spot_res (spot), and disable updating the mksysb image contained in the basic_res_grp resource group, using update images located in device /dev/cd0, and disable updating clients in the NIM environment, type:

```
nim_update_all -B -u
```

Files

Item	Description
/etc/niminfo	Contains variables used by NIM.
/var/adm/ras/nim.update	Contains log information from command execution.

nimadapters Command

Purpose

Defines Network Installation Management (NIM) secondary adapter definitions from a stanza file.

Syntax

nimadapters {-p | -d | -r } -f SecondaryAdapterFileName *adapter_def_name*

or

nimadapters {-p | -d | -r }-a client=*Client* [-a info=*AttributeList*] *adapter_def_name*

Description

The nimadapters command parses a secondary adapters stanza file to build the files required to add NIM secondary adapter definitions to the NIM environment as part of an *adapter_def* resource. The nimadapters command does not configure secondary adapters. The actual configuration takes place during a nim -o bos_inst or nim -o cust operation that references the *adapter_def* resource.

Note: Before using the nimadapters command, you must configure the NIM master. For more information, see **Configuring the NIM Master and Creating Basic Installation Resources** in *Installation and migration* guide.

Secondary Adapters File Rules

The format of the secondary adapters file must comply with the following rules:

- After the stanza header, follow attribute lines of the form: Attribute = *Value*
- If you define the value of an attribute multiple times within the same stanza, only the last definition is used.
- If you use an invalid attribute keyword, that attribute definition is ignored.
- Each line of the file can have only one header or attribute definition.
- More than one stanza can exist in a definition file for each machine host name.
- Each stanza for a machine host name represents a secondary adapter definition on that NIM client. No two secondary adapter definitions for the same machine host name can have the same location or interface_name. There should be only one definition per adapter or interface on a given NIM client.
- If the stanza header entry is the keyword default, this specifies to use that stanza for the purpose of defining default values.
- You can specify a default value for any secondary adapter attribute. However, the netaddr and secondary_hostname attribute must be unique. Also, the location and interface_name must be unique on a NIM client.
- If you do not specify an attribute for a secondary adapter but define a default value, the default value is used.
- You can specify and change default values at any location in the definition file. After a default value is set, it applies to all definitions following it.
- To turn off a default value for all following machine definitions, set the attribute value to nothing in a default stanza.
- To turn off a default value for a single machine definition, set the attribute value to nothing in the machine stanza.
- You can include comments in a client definition file. Comments begin with the # character.
- Tab characters and spaces are ignored when parsing the definition file for header and attribute keywords and values.

Note: During a nim -o bos_inst or nim -o cust operation, if NIM examines the configuration data on the client and determines that a secondary adapter is already configured with precisely the attributes requested in the *adapter_def* resource, this secondary adapter is not reconfigured.

Secondary Adapter File Keywords

The secondary adapter file uses the following keywords to specify machine attributes:

Required Attributes

machine_type = secondary | etherchannel | install
Specifying the machine_type attribute as secondary clearly distinguishes the nimadapters input from nimdef input. If a secondary adapters file is mistakenly passed to the nimdef command, the error can be easily detected. Stanzas with a machine_type of install will be ignored.

netaddr
Specifies the network address for the secondary adapter.

network_type = en | et | sn | ml | vi
Specifies the type of network interface, which can be one of en, et, sn, ml, or vi. This attribute replaces the deprecated network_type attribute.

subnet_mask
Specifies the subnet mask used by the secondary adapter.

Optional Attributes

adapter_attributes
Blank-separated list of physical adapter attributes and values (for example, "Attribute1=Value1 Attribute2=Value2"). To see the list of attributes that can be set for the requested physical adapter, run the command `lsattr -E -l` ***AdapterName***.

interface_attributes
Blank-separated list of interface attributes and values (for example, "Attribute1=Value1 Attribute2=Value2"). To see the list of attributes that can be set for the requested interface, run the command `lsattr -E -l` ***InterfaceName***. This attribute replaces the **attributes** attribute.

cable_type
Specifies the cable type (optional if network_type is en or et).

comments
Specifies a comment to include in the secondary adapter definition. Enclose the comment string in double quotes (").

interface_name
Specifies the name of the network interface for the secondary adapter (for example, en1, sn0, ml0). Do not specify both location and interface_name.

Note: The interface_name must be consistent with the interface_type.

location
Specifies the physical location of the adapter corresponding to this network interface. Do not specify both location and interface_name.

Note: Except for the multilink pseudo-device, use of the location is highly recommended. If the location is not specified and the user adds multiple adapters or adds an adapter at the same time that the operating system is reinstalled, the adapter and network interface names might be reassigned by the operating system in unexpected ways.

multiple_physloc
This attribute can be used with etherchannel or VIPA stanzas to specify the physical adapters to associate with the interface.

media_speed
Specifies the media speed (optional if network_type is en or et).

secondary_hostname
Host name to save in the `/etc/hosts` file with the netaddr attribute. This host name will not be set using the `hostname` command or `uname -S` command.

bos_preconfig
Specifies that the **tunchange** command is to change the value of tuning parameters. With the **bos_preconfig** attribute, you can change tunable parameters that have been set by the **/usr/lpp/bos.sysmgt/nim/methods/c_cfgadptrs** script with default values. The **bos_preconfig** attribute is used for the **nim -o bos_inst** command. For more information about the valid stanza and the respected stanza commands for tunable values, see the **tunchange** command.

The format for the **bos_preconfig** attribute is as follows:

```
bos_preconfig="tunchange -f nextboot -t Stanza [ -o tunable=value ... ]"
```

Requirement: You must restart the system in order for any new setting you made using the **bos_preconfig** attribute to take effect.

cust_preconfig
Specifies that the **vmo** command is to change the value of tuning parameters. With the **cust_preconfig** attribute, you can change tunable parameters that have been set by the **/usr/lpp/bos.sysmgt/nim/methods/c_cfgadptrs** script with default values. The **cust_preconfig** attribute is used for the **nim -o cust** command. For more information about valid tunable parameters, see the **vmo** command.

The format for the **cust_preconfig** attribute is as follows:

```
cust_preconfig="vmo -r [ -o tunable=value ... ]"
```

Note: You must restart the system to use the **cust_preconfig** attribute to set tunable parameters.

route
Specifies the route value to be added into network routing tables. You must specify the following values, or leave a blank space for any value that you do not want to specify:

Destination IP
The host or network for directing the route to. Specify the value as a numeric address.

Destination subnet mask
The mask for determining which network the destination IP belongs to. Specify the value as a numeric address.

Gateway IP
The network to which the packets are sent. Specify the value as a numeric address.

Each value must be separated by a double colon (::), and each additional set of the three values must be separated by a comma (,). The format for the route attribute is as follows:

```
route="DestHostA::MaskHostA::GatewayHostA, DestHostB::MaskHostB::GatewayHostB, ..."
```

For values that do not apply, you can leave it as blank but they still must be separated by a double colon as in the following example:

```
route="1.2.3.4::::5.6.7.8"
```

When you add the route attribute, using the **nimadapters** command with the **-a info** flag, you must separate the value for route with a double colon, and you must separate each additional set of three values with a space.

Secondary Adapter File Stanza Errors

A secondary adapter stanza causes an error under any of the following conditions:

- The host name that was used in the stanza header for the definition cannot be resolved.
- A required attribute is missing.
- An invalid value was specified for an attribute.
- An attribute mismatch occurs. For example, if the interface_type is not en or et, you cannot specify cable_type=bnc or media_speed=1000_Full_Duplex.
- The stanza contains both a location attribute and an interface_name attribute.
- Secondary adapter definitions occur multiple times for the same adapter location and the same host name.
- Secondary adapter definitions occur multiple times for the same interface_name and the same host name.

If a secondary adapter stanza is incorrect, the errors are reported, the stanza is ignored, and the following input is processed without regard to the incorrect stanza.

Example Secondary Adapter File

The following is an example of how a secondary adapter file can look:

```
# Set default values.

 default:

     machine_type  = secondary

     subnet_mask   = 255.255.240.0

     network_type  = en

     media_speed   = 100_Full_Duplex

 # Define the machine "lab1"

 # Take all defaults and specify 2 additional attributes.

 # Unlike the case of the client definitions that are input to the

 # nimdef command, the secondary adapter definition includes at least

 # one required field that cannot be defaulted.

 lab1:

     netaddr = 9.53.153.233

     location = P2-I1/E1

 # Change the default "media_speed" attribute.

 default:

     media_speed   = 100_Half_Duplex

 # define the machine "test1"

 # Take all defaults and include a comment.

 test1:

     comments      = "This machine is a test machine."

# define a machine with a VIPA interface that uses interfaces en2 and en3.
 lab2:
     machine_type         = secondary
     interface_type       = vi
     interface_name       = vi0
     netaddr              = 9.53.153.235
     subnet_mask          = 255.255.255.0
     secondary_hostname   = lab3
     interface_attributes = "interface_names=en2,en3"

 # define a machine with an etherchannel adapter that uses the adapters at
 # the following location codes P1-I4/E1 and P1/E1
 lab4:
     machine_type         = etherchannel
     interface_type       = en
     interface_name       = en2
     netaddr              = 9.53.153.237
     subnet_mask          = 255.255.255.0
     multiple_physloc     = P1-I4/E1,P1/E1

 # define a machine with an etherchannel adapter that uses the
 # ent2 and ent3 adapters and uses mode 8023ad.
 lab6:
     machine_type         = etherchannel
     interface_type       = en
     interface_name       = en2
     netaddr              = 9.53.153.239
     subnet_mask          = 255.255.255.0
     adapter_attributes = "adapter_names=ent2,ent3 mode=8023ad"
```

Flags

Item	Description
`-a`	Assigns the following attribute=value pairs: **client=nim_*client_name*** Specifies the NIM client that will have a secondary adapter definition added or removed. This option allows you to define one secondary adapter for a client. To define multiple secondary adapters, use a stanza file. **info=*AttributeList*** When previewing or defining a secondary adapter, the info attribute must be used when the client attribute is specified. *AttributeList* is a list of attributes separated by commas. The attributes must be specified in the following order:interface_type,location,interface_name,cable_type,media_speed,netaddr,subnet_mask, interface_attributes, secondary_hostname, machine_type, adapter_attributes, multiple_physloc,bos_preconfig, cust_preconfig, route.Use lowercase n/a to specify that a value will not be used.
`-d`	Defines secondary adapters. A `Client.adapter` file is created in the *adapter_def* location for each valid secondary adapter definition. If the `nimadapters` command encounters existing secondary adapter definitions for a NIM client, the existing definitions are replaced.
`-f`	*SecondaryAdapterFileName* Specifies the name of the secondary adapter file.
`-p`	Displays a preview operation to identify any errors. This flag processes the secondary adapter file or info attribute but does not add adapter definitions to the NIM environment. The preview shows the following: • All complete and valid secondary adapter stanzas. • All invalid secondary adapter stanzas and the reason for failure. **Note:** Specify the `-p` flag to verify that all stanzas are correct before using the secondary adapter file for configuring secondary adapters.
`-r`	Removes the secondary adapter definitions of a specific client or all the clients listed in a secondary adapter stanza file. If the client attribute or secondary adapter stanza file are not specified, then all the secondary adapter definitions in the *adapter_def* resource will be removed.

Parameters

Item	Description
adapter_def	This parameter is required to run the `nimadapters` command. Specifies the *adapter_def* NIM resource that is the directory containing secondary adapter definition files. An *adapter_def* resource must be defined using the `nim -o define` operation before the *adapter_def* can be used with the `nimadapters` command.

Exit Status

0
The command completed successfully.

>0
An error occurred.

Security

Access Control: You must have root authority to run the `nimadapters` command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To add the NIM secondary adapters described in the secondary adapters definition file secondary_adapters.defs to the my_adapter_def resource, type:

```
nimadapters -d -f secondary_adapters.defs my_adapter_def
```

2. To preview the client definition file secondary_adapters.defs, type:

```
nimadapters -p -f secondary_adapters.defs my_adapter_def
```

3. To define a NIM secondary adapter for a client called pilsner, type:

```
     nimadapters -d \

     -a info="en,P2-I1/E1,n/
a,bnc,1000_Full_Duplex,9.53.153.233,255.255.254.0,n/a,n/a,n/a,n/a,n/a" \

     -a client=pilsner my_adapter_def
```

4. To remove the NIM secondary adapter definitions for a client called pilsner from the my_adapter_def resource, type:

```
nimadapters -r -a client=pilsner my_adapter_def
```

5. To remove the NIM secondary adapter definitions for clients defined in the file `secondary_adapters.defs`, type:

```
nimadapters -r -f secondary_adapters.defs my_adapter_def
```

6. To remove all the NIM secondary adapter definitions from the my_adapter_def resource, type:

```
nimadapters -r my_adapter_def
```

Files

Item	Description
`/usr/sbin/nimadapters`	Contains the `nimadapters` command.

nimadm Command

Purpose

The **nimadm** (Network Install Manager Alternate Disk Migration) command is a utility that allows the system administrator to do the following actions:

- Create a copy of rootvg to a free disk (or disks) and simultaneously migrate it to a new version or release level of AIX.
- Using a copy of rootvg, create a new NIM mksysb resource that has been migrated to a new version or release level of AIX.

- Using a NIM mksysb resource, create a new NIM mksysb resource that has been migrated to a new version or release level of AIX.
- Using a NIM mksysb resource, restore to a free disk (or disks) and simultaneously migrate to a new version or release level of AIX.

The **nimadm** command uses NIM resources to perform these functions.

Syntax

Perform Alternate Disk Migration:

nimadm -l *lpp_source* **-c** *NIMClient* **-s** *SPOT* **-d** *TargetDisks* [**-a** *PreMigrationScript*] [**-b** *installp_bundle*] [**-z** *PostMigrationScript*] [**-e** *exclude_files*] [**-i** *image_data*] [-j *VGname*] [**-m** *NFSMountOptions*] [**-o** *bosinst_data*] [**-P** *Phase*] [-j *VGname*] [**-Y**] [**-F**] [**-D**] [**-E**] [**-V**] [{ **-B** | **-r** }]

Cleanup Alternate Disk Migration on client:

nimadm -C -c *NIMClient* **-s** *SPOT* [**-F**] [**-D**] [**-E**]

Wake-up Volume Group:

nimadm -W -c *NIMClient* **-s** *SPOT* **-d** *TargetDisks* [**-m** *NFSMountOptions*] [**-z** *PostMigrationScript*] [**-F**] [**-D**] [**-E**]

Put-to-sleep Volume Group:

nimadm -S -c *NIMClient* **-s** *SPOT* [**-F**] [**-D**] [**-E**]

Synchronize Alternate Disk Migration Software:

nimadm -M -s *SPOT* -l *lpp_source* [-d *device*] [-P] [-F]

mksysb to Client Migration:

nimadm -T *NIMmksysb* -c *NIMClient* -s *SPOT* -l *lpp_source* -d *TargetDisks* -j *VGname* -Y [-a *PreMigrationScript*] [-b *installpBundle*] [-z *PostMigrationScript*] [-i *ImageData*] [-m *NFSMountOptions*] [-o *bosinst_data*] [-P *Phase*] [-F] [-D] [-E] [-V] [-B | -r]

mksysb to mksysb Migration:

nimadm -T *NIMmksysb* -O *mksysbfile* -s *SPOT* -l *lpp_source* -j *VGname* -Y [-N *NIMmksysb*] [-a *PreMigrationScript*] [-b *installp_bundle*] [-z *PostMigrationScript*] [-i *image_data*] [-m *NFSMountOptions*] [-o *bosinst_data*] [-P *Phase*] [-F] [-D] [-E] [-V]

Client to mksysb Migration:

nimadm -c *nim_client* -O *mksysbfile* -s *SPOT* -l *lpp_source* -j *VGname* -Y [-N *NIMmksysb*] [-a *PreMigrationScript*] [-b *installp_bundle*] [-z *PostMigrationScript*] [-i *image_data*] [-m *NFSMountOptions*] [-o *bosinst_data*] [-P *Phase*] [-e *exclude_files*] [-F] [-D] [-E] [-V]

Description

The **nimadm** command is a utility that allows the system administrator to create a copy of **rootvg** to a free disk (or disks) and simultaneously migrate it to a new version or release level of AIX. The **nimadm** command uses NIM resources to perform this function.

There are several advantages to using the nimadm command over a conventional migration:

1. Reduced downtime. The migration is performed while the system is up and functioning normally. There is no requirement to boot from install media, and the majority of processing occurs on the NIM master.
2. The **nimadm** command facilitates quick recovery in the event of migration failure. As the **nimadm** command uses **alt_disk_install** to create a copy of **rootvg**, all changes are performed to the copy (altinst_rootvg). In the event of serious migration installation failure, the failed migration is cleaned up and there is no need for the administrator to take further action. In the event of a problem with the new (migrated) level of AIX, the system can be quickly returned to the pre-migration operating system by booting from the original disk.

3. The **nimadm** command allows a high degree of flexibility and customization in the migration process. This is done with the use of optional NIM customization resources: image_data, bosinst_data, exclude_files, pre-migration script, installp_bundle, and post-migration script.

Please note that this document provides information pertaining to the **nimadm** command. For complete coverage of **alt_disk_install**, NIM, migration, and other related install issues, refer to the latest editions of the following publications:

- "*Installation and migration* in guide"
- "*AIX Version 4.3 to 5L Migration Guide*", an IBM Redbooks publication

nimadm Local Disk Caching

Local disk caching allows the NIM master to avoid having to NFS write to the client, which can be useful if the `nimadm` operation is not performing optimally due to an NFS write bottle neck. If this function is invoked with the `-j` *VGname* flag, the `nimadm` command creates file systems on the specified volume group (on the NIM master) and uses streams to cache all of the data from the client to these file systems.

The advantages and disadvantages to this function are as follows:

`Advantages:`

1. Improved performance for **nimadm** operations that are on relatively slow networks.
2. Improved performance for **nimadm** operations that are bottle necked in NFS writes (NFS writes are very expensive).
3. Decreased CPU usage on the client.
4. Client file systems are not exported.

`Disadvantages:`

1. Cache file systems take up space on the NIM master (you must have enough space to host the client's `rootvg` file systems and migration space for each client)
2. Increased CPU usage on the master.
3. Increased I/O on the master (for optimal performance use a volume group (disk) that does not contain the NIM resource being used in the operation).

How to execute disk caching:

1. Make sure you are at the latest level of `bos.alt_disk_install.rte` on the NIM master.
2. Add the `-j` *VGName* flag to any `nimadm` operations. For example:

   ```
   nimadm -j rootvg ...
   ```

   or

   ```
   nimadm -j cachevg
   ```

You can exclude specific file systems (which are not involved in the migration) from being cached over the network (they are still copied locally to `altinst_rootvg` on the client). To specify a list of file systems to be excluded from network caching, you must create a file in the location of the SPOT resource that is used for the migration. To get the exact location of the SPOT path, enter:

```
# lsnim -a location SpotName
```

You must name the file in the following format:

```
Nim_Client.nimadm_cache.excl
```

Note: This file applies to the NIM client specified in *Nim_Client*. The full path should be:

```
Spot_Location/Nim_Client.nimadm_cache.excl
```

For example: `/nim_resources/520spot/usr/myclient.nimadm_cache.excl`.

To exclude a file system from caching, enter one file system (to be excluded) per line in this file. While excluding a file system, ensure that you:

1. Do not exclude any file systems that are involved in the migration process. In other words, these file systems contain software files that are migrated. This can lead to unpredictable results.
2. Do not (cannot) exclude the following AIX file systems: `/, /usr, /var, /opt, /home, and /tmp`.

With disk caching, the `nimadm` command changes the following four phases (all other phases remain the same) :

`Phase 2:` The NIM master creates local cache file system in specified target volume group (on the NIM master).

`Phase 3:` The NIM master populates the cache file systems with the client's data.

`Phase 9:` The NIM master writes all migrated data to the client's alternate `rootvg`.

`Phase 10:` The NIM master cleans up and removes the local cache file systems.

nimadm Requirements

The **nimadm** requirements are:

1. The NIM master must have the same level of **bos.alt_disk_install.rte** installed in its **rootvg** and the SPOT which is used to perform the migration. (Note: it is not necessary to install the **alt_disk_install** utilities on the client).
2. The selected **lpp_source** NIM resource, and selected SPOT NIM resource must match the AIX level to which you are migrating.
3. The NIM master must be at the same or higher AIX level then the level being migrated to.
4. The client (the system to be migrated) must be at AIX 4.3.3 or higher.
5. The client must have a disk (or disks) large enough to clone the **rootvg** and an additional 500 Megs (approximately) of free space for the migration. The total amount of required space depends on original system configuration and **nimadm** customization.
6. The target client must be a registered with the master as a standalone NIM client (see the **niminit** command for more information). The NIM master must be able to execute remote commands on the client using the **rshd** protocol.
7. The NIM master must be able to execute remote commands on the client using the **rshd** protocol.
8. The NIM master and client must both have a minimum of 128 megabytes of RAM.
9. A reliable network, which can facilitate large amounts of NFS traffic, must exist between the NIM master and the client. The NIM master and client must be able to perform NFS mounts and read/write operations.
10. The client's hardware and software must support the AIX level that is being migrated to and meet all other conventional migration requirements.
11. All application and database servers, such as DB2 and LDAP, must be stopped before you run the **nimadm** command to clone the rootvg of a client system. Otherwise, the application servers and the database servers do not start normally after the **nimadm** command operations are complete.

Note: If you cannot meet requirements 1-10, you must perform a conventional migration. If you cannot meet requirement 11, then migration is not possible.

Attention: Before performing a **nimadm** migration you must agree to all software license agreements for software to be installed. You can do this by specifying the **-Y** flag as an argument to the **nimadm** command or setting the **ADM_ACCEPT_LICENSES** environment variable to "yes".

nimadm Limitations

The following limitations apply to the **nimadm** command:

1. If the trusted computing base (TCB) is turned on in the client's **rootvg**, you must disable it (permanently), use the disk caching option (**-j**), or perform a conventional migration. This limitation

exists because TCB must access the file metadata, which is not accessible through network file system (NFS).

2. All NIM resources used by the **nimadm** command must be local to the NIM master.
3. Although there is almost no interference with the client's active **rootvg** volume group during the migration, the client might experience minor reduction in performance due to increased disk I/O, `biod` activity, and CPU usage associated with cloning the **alt_disk_install** command.
4. You might need to tune the NFS to optimize the **nimadm** performance.

NIM resources used by nimadm:

SPOT resource (-s flag)
The NIM spot resource is required for all **nimadm** operations (migration, cleanup, wake-up, sleep). All **nimadm** and **alt_disk_install** utilities that are used by the client are installed in this resource. It is not necessary to install **nimadm** software on the client. The NIM cust operation must be used to install the following file sets into the spot:

- Required: **bos.alt_disk_install.rte** (must match the NIM master's level).
- Optional message catalog: **bos.msg.*$LANG*.alt_disk_install.rte**

lpp_source resource (-l flag)
This NIM resource is the source of install images that are used to migrate the system. It is required for **nimadm** migration operations. The **lpp_source** must contain all system images for the level being migrated to (check the lpp_source images attribute in **lsnim -l lpp_source** output). It must also contain any optional `installp` images that need to be migrated.

pre-migration
This script resource that is run on the NIM master, but in the environment of the client's `alt_inst` file system that is mounted on the master (this is done by using the **chroot** command). This script is run before the migration begins.

post-migration
This script resource is similar to the **pre-migration** script, but it is executed after the migration is complete.

image_data
Specifies an **image_data** resource that is passed to **alt_disk_install** (as arguments to the **-i** flag). NIM allocates and mount this resource on the client before calling **alt_disk_install**.

exclude_files
Specifies an **exclude_files** resource that is passed to **alt_disk_install** (as an argument to the `-e` flag). NIM allocates and mount this resource on the client before calling **alt_disk_install**.

installp_bundle
This NIM resource specifies any additional software that the **nimadm** command installs after completing the migration.

bosinst_data
This NIM resource specifies various install settings that may be used by the **nimadm** command.

The nimadm Migration Process

The **nimadm** command performs migration in 12 phases. Each phase can be executed individually by using the **-P** flag. The **nimadm** phases must be run sequentially. The **nimadm** phases are as follows:

1. The master issues an **alt_disk_install** command to the client that makes a copy of the **rootvg** volume group to the target disks (coincidentally this is Phase 1 of the **alt_disk_install** process). In this phase **altinst_rootvg** (alternate rootvg) is created. If a target **mksysb** is specified, the **mksysb** is used to create a **rootvg** volume group by using local disk caching on the NIM master.
2. The master runs remote client commands to export all the **/alt_inst** file systems to the master. The file systems are exported as read/write with root access to the master. If a target **mksysb** is specified, the cache file systems are created based on the image data from the **mksysb**.
3. The master NFS mounts the file systems exported in Phase 2. If a target **mksysb** is specified, the **mksysb** archive is restored in the cache file systems that was created in phase 2.

4. If the pre-migration script resource is specified, the script is executed at this time.
5. System configuration files are saved. Initial migration space is calculated and appropriate file system expansions are made. "bos" is restored and the device database is merged (similar to a conventional migration). The migration merge methods are executed and some miscellaneous processing takes place.
6. The file sets of the system are migrated by using the **installp**. Any required RPM images are installed during this phase.
7. If the **post-migration** script resource is specified, the script is executed at this time.
8. **bosboot** is executed to create a client boot image that is written to the client's boot logical volume (**hd5**).
9. The mounts that are made on the master in phase 3 are removed.
10. The client exports that are created in phase 2 are removed.
11. The **alt_disk_install** is called again (phase 3 of **alt_disk_install**) to make final adjustments and place **altinst_rootvg** to sleep. The bootlist is set to the target disk (unless the `-B` flag is used). If an output **mksysb** is specified, the cache is archived into a **mksysb** file and made into a NIM **mksysb** resource.
12. Cleanup is executed to end the migration. The client is rebooted, if the `-r` flag is specified.

Note: The **nimadm** command supports migrating several clients simultaneous.

nimadm Cleanup Operation

This operation, indicated with the "**-C**" flag, is designed to clean up after a failed migration that for some reason did not perform a cleanup it self. It can also be used to clear a previous migration in order to perform a new migration.

nimadm Wake-up and Sleep

After a migration completes, the **nimadm** command can be used to "wake-up" the migrated **altinst_rootvg** or the original **rootvg** (if booted from the migrated disk). The **nimadm** wake-up (**-W** flag) performs an **alt_disk_install** wake-up, NFS exports the **/alt_inst** file systems, and mounts them on the NIM master. The **nimadm** sleep function (**-S** flag) reverses the wake-up by unmounting the NIM master mounts, unexporting the **/alt_inst** file systems, and executing the **alt_disk_install** sleep function on the client.

Flags

Item	Description
-a *PreMigrationScript*	Specifies the pre-migration NIM script resource.
-b *installp_bundle*	Specifies the installp_bundle NIM resource.
-B	Specifies not running **bootlist** after the **nimadm** migration. If set, then **-r** flag cannot be used.
-c *ClientDisks*	Specifies the NIM defined client which is the target of this **nimadm** operation. This flag is required for all **nimadm** operations.
-C	Performs **nimadm** cleanup.
-d *TargetDisks*	Specifies the client target disk which is used to create **altinst_rootvg** (the volume group that is migrated).
-D	Sets the **nimadm** command into debug mode. This function must only be used to debug **nimadm** related problems and is not set by default.
-e *exclude_files*	Specifies the **exclude_files** NIM resource. This resource is used by the **alt_disk_install** command during Phase 1.
-E	Enters the **nimadm** debugger if a serious migration error occurs.

Item	Description
-F	Forces a client to unlock. Normally, the **nimadm** command locks a client to perform various operations. While the client is locked, other **nimadm** or NIM operations cannot be performed. This flag must ONLY be used in the unusual condition that a client is incorrectly locked (this can happen if for some reason the **nimadm** command could not call cleanup after a failure).
-i *image_data*	Specifies the **image_data** NIM resource. This resource is used by the **alt_disk_install** command during Phase 1 and 11.
`-j` *VGname*	Creates file systems on the specified volume group (on the NIM master) and uses streams to cache all of the data from the client to these file systems.
-l *lpp_source*	Specifies the lpp_source NIM resource to be used for this **nimadm** operation. This flag is required for migration operations.
-m *NFSMountOptions*	Specifies arguments that are passed to the mount command that **mounts** client resources on the master. This flag can be used to tune **nimadm** related NFS performance.
`-M`	Verifies that the levels of the alt_disk_install software (bos.alt_disk_install) on the NIM master, SPOT, lpp_source, and optional device are synchronized (match). If there is no match, the `nimadm` command installs the highest level found in the lpp_source or optional device.
`-N` *NIMmksysb*	Specifies the unique new NIM mksysb resource to create. If the `-N` flag is specified, the `-0` flag must be specified.
-o *bosinst_data*	Specifies **bosinst_data** NIM resource.
`-0` *mksysbfile*	Specifies the file pathname for the migrated mksysb. If the `-0` flag is specified, the `-j` flag and either the `-c` or `-T` flag must be specified.
-P *Phase*	The phase to execute during this invocation of the **nimadm** command. If there is more then one phase, the phases must be separated by spaces or commas. Valid phases are 1 through 12.
-r	Specifies that the client must reboot after **nimadm** migration is complete.
-s *SPOT*	Specifies the **SPOT** NIM resource to be used for this **nimadm** operation. This flag is required for all **nimadm** operations.
-S	Performs the **nimadm** "sleep" function. This function must be executed to end a **nimadm** "wake-up".
`-T` *NIMmksysb*	Specifies an existing NIM mksysb resource to migrate. If the `-T` flag is specified, the `-j` flag and either the `-0` or `-c` flag must be specified.
-V	Turns on verbose output.
-W	Performs the **nimadm** "wake-up" function.
-Y	Agrees to required software license agreements for software to be installed.
-z *PostMigrationScript*	Specifies the post-migration NIM script resource.

Exit Status

0
All the **nimadm** command related operations completed successfully.

>0
An error occurred.

Security

Access Control: You must have root authority to run the `nimadm` command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To execute **nimadm** migration to target NIM client aix1, using NIM **SPOT** resource spot1, NIM **lpp_source** resource lpp1, and target disks hdisk1 & hdisk2. Note that the **-Y** flag agrees to all required software license agreements for software to be installed, enter the following:

   ```
   nimadm -c aix1 -s spot1 -l lpp1 -d "hdisk1 hdisk2" -Y
   ```

2. To execute the same operation as in the example above to hdisk2, and also run pre-migration script nimscript1 and post-migration script nimscript2, type the following:

   ```
   nimadm -c aix1 -s spot1 -a nimscrip1 -z nimscript2 -l lpp1 -d hdisk1 -Y
   ```

3. To execute **nimadm** cleanup on client aix1, using NIM **SPOT** resource spot1, type the following:

   ```
   nimadm -C -c aix1 -s spot1
   ```

4. To create a migrated new mksysb resource of a client with the filename nim1, type the following:

   ```
   nimadm -c aix1 -s spot1 -l lpp1 -O /export/mksysb/mksysb1 -j vg00 -Y -N nim1
   ```

5. To create a new migrated mksysb resource with the filename nim3 from an existing NIM mksysb resource, type the following:

   ```
   nimadm -s spot1 -l lpp1 -j vg00 -Y -T nim2 -O /export/mksysb/m2 -N nim3
   ```

6. To migrate an existing NIM resource and put it on a client, type the following:

   ```
   nimadm -c aix1 -s spot1 -l lpp1 -d hdisk1 -j vg00 -T nim2 -Y
   ```

   Note: No changes are made to the nim2 NIM mksysb resource.

Files

Item	Description
/usr/sbin/nimadm	Contains the **nimadm** command.

nimclient Command

Purpose

Allows Network Installation Management (NIM) operations to be performed from a NIM client.

Syntax

To Enable or Disable the NIM Master's Push Permissions

nimclient { **-p** } | { **-P** }

To Enable or Disable Cryptographic Authentication for NIM Master Push Operations

nimclient { **-c** } | { **-C** }

To List Information about the NIM Environment

nimclient -l *LsnimParameters*

To Set the Date and Time to That of the NIM Master

nimclient -d

To Perform a NIM Operation

nimclient -o *Operation* [**-a** *Attribute*=*Value*] ...

Description

The **nimclient** command is used by workstations that are NIM clients to pull NIM resources. This command can enable or disable the NIM master server's ability to initiate workstation installation and customization for the workstation. The **nimclient** command can be used to generate a list of available NIM resources or display the NIM resources that have already been allocated to the client. A limited set of NIM operations can also be performed by the **nimclient** command using the **-o** flag.

Flags

Item	Description
-a A*ttribute*=*Value*	Passes information to NIM operations. **From the master** Use the **lsnim -q** *Operation* **-t** *Type* command to get a list of valid attributes for a specific operation. **From the client** Use the **nimclient -l -q** *Operation* **-t** *Type* command to get a list of valid attributes for a specific operation.
-c	Enables SSL authentication during NIM master push operations. **Note:** OpenSSL certificates must be configured on the NIM master using the **nimconfig -c** command. The SSL certificate is copied from the NIM master when **nimclient -c** is executed.
-C	Disables SSL authentication and uses standard nimsh security during NIM master push operations.
-d	Sets the client's date and time to that of the master.
-l *Lsnim parameters*	Executes the **lsnim** command on the master using the **lsnim** parameters that you specify. All the parameters which you use with this option must adhere to the syntax rules of the **lsnim** command. Note that some **lsnim** syntax requires the use of a NIM object name. To find out what the NIM name is for your machine, look in the **/etc/niminfo** file.

Item	Description
-o *Operation*	Performs the specified operation. The possible operations are: **allocate** Allocates a resource for use. **bos_inst** Performs a BOS installation. **change** Changes an object's attributes. **check** Checks the status of a NIM object. **cust** Performs software customization. **deallocate** Deallocates a resource. **diag** Enables a machine to boot a diagnostic image. **maint_boot** Enables a machine to boot in maintenance mode. **reset** Resets an object's NIM state. **showres** Displays the contents of a NIM resource.
-p	Enables the NIM master to push commands.
-P	Removes the NIM master's permissions to push commands. **Note:** The master can override this restriction by using the **-F** flag.

Security

Access Control: You must have root authority to run the **nimclient** command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To list all the NIM resources which are available to this machine when its NIM name is `pluto`, enter:

   ```
   nimclient -l -L pluto
   ```

2. To list all the Shared Product Object Trees (SPOTs) which are available to this machine when its NIM name is `pluto`, enter:

   ```
   nimclient -l -L -t spot pluto
   ```

3. To list the operations which may be initiated from this machine, enter:

   ```
   nimclient -l -p -s pull_ops
   ```

4. To prevent the NIM master from running commands locally on the client, enter:

```
nimclient -P
```

5. To allocate a spot resource named `myspot`, an **lpp_source** resource named `images`, and an **installp** bundle file name `dept_bundle`, enter:

```
nimclient -o allocate -a spot=myspot -a lpp_source=images \
-a installp_bundle=dept_bundle
```

6. To perform a base system installation after the required resources have been allocated, enter:

```
nimclient -o bos_inst
```

7. From a standalone client, to allocate an **lpp_source** and install a software product such that the image for the installable option, `adt`, is contained in the **lpp_source**, `images`, enter:

```
nimclient -o allocate -a lpp_source=images
```

Then enter:

```
nimclient -o cust -a filesets="adt"
```

8. From a standalone client, to allocate an **lpp_source** and install a software product such that the image for the installable option, `adt`, is contained in the **lpp_source**, `images`, and the name of the installable option is contained in the **installp_bundle**, `bundle3`, enter:

```
nimclient -o allocate -a lpp_source=images \
-a installp_bundle=bundle3
```

Then enter:

```
nimclient -o cust
```

9. To install all fileset updates associated with APAR `IX12345`, residing in the **lpp_source** `updt_images`, enter:

```
nimclient -o allocate -a lpp_source=updt_images
nimclient -o cust -afixes=IX12345
```

10. From the NIM stand-alone, to run a live update for an APAR `IX12345`, residing in the **lpp_source** `lpp_source1`, enter:

```
nimclient -o allocate -a lpp_source=lpp_source1
nimclient -o cust -a live_update=yes -a filesets=IX12345
```

11. To update all installed software on the client with the latest updates from the `updt_images` **lpp_source**, enter:

```
nimclient -o allocate -a lpp_source=updt_images
nimclient -o cust -afixes=update_all
```

12. To enable the system to boot in maintenance mode using a SPOT resource named `spot1`, enter:

```
nimclient -o maint_boot -a spot=spot1
```

This sets up the maintenance boot operation, but you must initiate the network boot locally.

13. To show the contents of the config script `script1`, enter:

```
nimclient -o showres -a resource=script1
```

14. To show the contents of the bosinst.data resource `bosinst_data1`, enter:

```
nimclient -o showres -a resource=bosinst_data1
```

15. To list all the filesets in the lpp_source `lpp_source1` relative to what is currently installed on the machine `machine1`, from the NIM client machine `machine1`, enter:

```
nimclient -o showres -a resource=lpp_source1
```

    The **reference** attribute is automatically supplied by the **nimclient** command.

16. To list all problems fixed by software on the lpp_source `lpp_source1`, use:

```
nimclient -o showres -a instfix_flags="T" -a resource=lpp_source1
```

17. To install the filesets listed in the NIM **installp_bundle** `client_bundle` using the **lpp_source** `client_images`, while automatically allocating these resources during the installation operation, enter:

```
nimclient -o cust -a installp_bundle=client_bundle \
-a lpp_source=client_images
```

18. To perform a base system installation while automatically allocating all applicable resources from the NIM resource group named `client_grp`, enter:

```
nimclient -o bos_inst -a group=client_grp
```

19. To perform a base system installation while automatically allocating all applicable resources from the NIM group defined as the default resource group on the master, enter:

```
nimclient -o bos_inst
```

20. To copy an SSL certificate and enable SSL authentication, type:

```
nimclient -c
```

    Note: OpenSSL must be installed on the NIM client prior to using this command option.

Files

Item	Description
/etc/niminfo	Contains variables used by NIM.

nimconfig Command

Purpose

Initializes the Network Installation Management (NIM) master package.

Syntax

To Initialize the NIM master package

nimconfig -a pif_name=*Pif* **-a netname=***Objectname* [**-a master_port=***PortNumber*] [**-a platform=***Value*] [**-a registration_port=***PortNumber*] [**-a ring_speed=***Speed* | **-a cable_type=***CableType*]

To Configure SSL for the NIM Environment

nimconfig -c

To Rebuild the /etc/niminfo file:

nimconfig -r

Description

The **nimconfig** command initializes the NIM master package. You must initialize the package before any other NIM commands can be used. When you use the **-a** flag to supply the proper attributes, the **nimconfig** command initializes the NIM environment by performing the following tasks:

- Defines a network object specified by the *ObjectName* parameter to represent the network to which the NIM master's primary interface, specified by the *Pif* parameter, is connected.
- Completes the definition of the NIM master by connecting it to the newly defined network object.
- Defines a resource object to represent the network boot resource, which is managed automatically by NIM.
- Defines a resource object to represent the customization scripts that NIM automatically builds to perform customization.
- Starts the **NIM** communications daemon, **nimesis**.

Flags

Item	Description

-a Assigns the following attribute=value pairs:

pif_name=*Pif*
Designates the primary network interface for the NIM master. This value must be a logical interface name (such as tr0 or en0) is in the available state.

master_port=*PortNumber*
Specifies the port number of the **nimesis** daemon used for NIM client communication.

platform=*Value*
Specifies the platform. The supported platforms are:

rs6K
Micro Channel-based, uniprocessor models for AIX 5.1 and earlier

rs6ksmp
Micro Channeled-based, symmetric multiprocessor models for AIX 5.1 and earlier

rspc
PowerPC PCI bus-based, uniprocessor models for AIX 5.1 and earlier

rspcsmp
PowerPC PCI bus-based, symmetric multiprocessor models for AIX 5.1 and earlier

netname=*ObjectName*
Specifies the name you want the **nimconfig** command to use when creating the network object to represent the network to which the master's primary interface connects.

ring_speed=*Speed*
Speed in Mbps. When the **pif_name** refers to a token ring network, this value must be given. Acceptable values are:

4

16

cable_type=*CableType*
Specifies the ethernet cable type. When the **pif_name** refers to an ethernet network, this value must be given. Acceptable values are:

bnc

dix

N/A

registration_port=*PortNumber*
Specifies the port number used for NIM client registration.

Note: If you do not specify port numbers on the command line, the port numbers in the **/etc/services** file for NIM are used. If the **/etc/services** file does not contain entries for the NIM ports `nim` and `nimreg`, the default values of 1058 for **master_port** and 1059 for **registration_port** are used.

-c When OpenSSL is installed on the NIM master, this option creates SSL keys and certificates for use during NIM client communication. The SSL certificates are later copied to NIM clients using the **nimclient -c** command.

-r Rebuilds the **/etc/niminfo** file on the master using the information already exists in the NIM database. Note that if the **bos.sysmgt.nim.master** package has not been configured on this machine, this option will fail. This option is provided in case the **/etc/niminfo** file is accidentally removed by a user.

Security

Access Control: You must have root authority to run the **nimconfig** command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To initialize the NIM environment using token ring and the default NIM ports for network communications, type:

```
nimconfig -a pif_name=tr0 -a netname=net1 -a ring_speed=16
```

2. To initialize the NIM environment using ethernet and the default NIM ports, type:

```
nimconfig -a pif_name=en0 -a master_port=1058 \
-a netname = net2 -a cable_type=bnc
```

3. To rebuild the **/etc/niminfo** file on the NIM master when that machine has already been correctly configured as a master, type:

```
nimconfig -r
```

4. To initialize the NIM master using an ATM network interface, type:

```
nimconfig -a pif_name=at0 -a master_port=1058 -a netname=ATMnet
```

   Note: Because an interface to an ATM network does not currently support booting over the network, this operation will define a generic network object corresponding to the master's subnet.

5. To initialize the NIM environment using TCP/IP port 1060 for NIM client communications and TCP/IP port 1061 for NIM client registration, type:

```
nimconfig -a pif_name=tr0 -a netname=net2 -a master_port=1060 \
-a registration_port=1061 -a ring_speed=16
```

6. To create SSL keys and certificates for NIM communication, type:

```
nimconfig -c
```

   Note: OpenSSL must be installed on the NIM master prior to using this command option.

Files

Item	Description
/etc/niminfo	Contains variables used by NIM.

nimdef Command

Purpose

Defines Network Installation Management (NIM) clients from a stanza file.

Syntax

nimdef [**-p** | **-d** | **-c**] **-f** *Name*

Description

The **nimdef** command parses a definition stanza file to build the commands required to add NIM client definitions to the NIM environment.

The **nimdef** command can also create NIM networks and NIM machine groups automatically in the NIM environment to support the new client definitions.

> **Note:** Before using the **nimdef** command, you must configure the NIM master. (See **Basic NIM operations and configuration** in *Installation and migration* for more information.)

Client Definition File Rules

The format of the client definition file must comply with the following rules:

- After the stanza header, follow attribute lines of the form *Attribute* = *Value.*
- If you define an attribute value multiple times within the same stanza, only the last definition is used unless the attribute is **machine_group**. If you specify multiple **machine_group** attributes, all are applied to the machine definition.
- If you use an invalid attribute keyword, then that attribute definition is ignored.
- Each line of the file can have only one header or attribute definition.
- Only one stanza may exist in a definition file for each machine hostname.
- If the stanza header entry is the keyword **default**, this specifies to use it for the purpose of defining default values.
- You can specify a default value for any machine attribute except the machine hostname. If you do not specify an attribute for a machine but define a default value, then the default value is used.
- You can specify and change default values at any location in the definition file. After a default value is set, it applies to all definitions following it.
- To turn off a default value for all following machine definitions, set the attribute value to **nothing** in a default stanza.
- To turn off a default value for a single machine definition, set the attribute value to **nothing** in the machine stanza.
- You can include comments in a client definition file. Comments begin with the pound (**#**) character.
- When parsing the definition file for header/attribute keywords and values, tab characters and spaces are ignored.

Client Definition File Keywords

The client definition file uses the following keywords to specify machine attributes:

Required Attributes

Item	Description
cable_type	Specifies the cable type of the machine. Required if **network_type** is **ent**.
gateway	Specifies the hostname or IP address of the default gateway used by the machine. If the machine does not use a gateway, then specify the value **0** (zero) for this attribute.
machine_type	Specifies the type of the machine: **standalone**, **diskless**, or **dataless**.
network_type	Specifies the type of the machine's network adapter: **ent** or **tok**.
ring_speed	Specifies the ring speed of the machine. Required if **network_type** is **tok**.
subnet_mask	Specifies the subnet mask used by the machine.

Optional Attributes

Item	Description
nim_name	Specifies the NIM name to use for a machine. Use this attribute if something other than the hostname is used for the NIM name. By default, the NIM name given to a machine is the hostname of the machine with any domain information stripped off. If you use non-unique hostnames in different domains, a conflict occurs because the same NIM name is used for both machines. In such an environment, define this attribute for the affected machine definitions.
platform	Specifies the machine hardware platform. If you do not specify this attribute, default is **rs6k** through AIX 5.1 only.
net_adptr_name	Specifies the name of the network adapter used by the machine (**tok0**, **ent0**, etc.).
netboot_kernel=*NetbootKernelType*	Specifies the type of kernel to use when booting the client over the network. The **netboot_kernel** values are **up** or **mp**.
ipl_rom_emulation	Specifies the device to use for IPL ROM emulation (**/dev/fd0**, **/dev/rmt0**, etc.).
primary_interface	Specifies the hostname used for the original machine definition. Use this attribute if the current stanza is only to define an additional interface to a machine that is defined in the NIM environment.
master_gateway	Specifies the gateway that the NIM master uses to reach this machine if this machine is on a different network. This attribute is not necessary if this machine is defined on a network that is already defined in the NIM environment, or if the NIM master network has a default gateway specified.
machine_group	Specifies the group or groups to add the machine to when it is defined.
comments	Specifies a comment to include in the machine definition. The comment string should be in double quotes (**"**).

Client Definition File Stanza Errors

A definition stanza is incorrect under any of the following conditions:

- The hostname used in the stanza header for the definition is unresolvable.
- A required attribute is missing.
- You specify an invalid value for an attribute.
- An attribute mismatch occurs. For example, you can not specify **network_type=tok** and **cable_type=bnc** in the same stanza.
- A group-type mismatch occurs. For example, you can not specify a group for a machine if the group includes standalone machines and you specify **machine_type=diskless**.
- Machine definitions occur multiple times for the same hostname.
- A machine definition occurs for a machine that is already defined in the NIM environment.
- The **primary_interface** value in a machine definition does not match the hostname of any defined machine or stanza definition.
- The **primary_interface** value in a machine definition matches the hostname of another machine definition, but that definition is incorrect.

Sample Client Definition File

These default values are for AIX 5.1 and earlier.

```
# Set default values.
default:
    machine_type  = standalone
    subnet_mask   = 255.255.240.0
    gateway       = gateway1
    network_type  = tok
    ring_speed    = 16
    platform      = rs6k
    machine_group = all_machines

# Define the machine "lab1"
# Take all defaults.
lab1:

# Define the machine "lab2"
# Take all defaults and specify 2 additional attributes.
# The machine "lab2" uses IPL ROM emulation, and will be added to
# the machine groups "all_machines" and "lab_machines".
lab2:
    ipl_rom_emulation = /dev/fd0
    machine_group     = lab_machines

# Define the machine "lab3"
# Take all defaults, but do not add the machine to the default
# group.
lab3:
    machine_group=

# Define the machine "lab4"
# Take all defaults, but do not add "lab4" to the default group
# "all_machines".
# Instead add it to the groups "lab_machines" and "new_machines".
lab4:
    machine_group =
    machine_group = lab_machines
    machine_group = new_machines

# Change the default "platform" attribute.
default:
    platform = rspc

# define the machine "test1"
# Take all defaults and include a comment.
test1:
    comments = "This machine is a test machine."
```

Flags

Item	Description
-c	Generates commands from a client definition file. This flag processes the definition file and generates the commands to add the definitions. The commands are not invoked but displayed as a KSH script that you can redirect to a file and invoke at a later time.
-d	Defines machines from a client definition file. This flag processes the definition file and invokes the commands to add the definitions to the NIM environment.
-f *Name*	Specifies the name of the client definition file.

Item	Description
-p	Displays a preview of the client definition file. This flag processes the definition file but does not add machines to the NIM environment. Displays the following: All complete and valid NIM definition stanzas. All additional interfaces that will be defined for machines. All invalid definitions stanzas and the reason for failure. All new machine groups and the members to add. All existing machine groups and the members to add. All network definitions to add to the NIM environment. The commands to invoke to add each new machine. The commands to invoke to add each additional machine interface. The commands to invoke to create new machine groups and add their members. The commands to invoke to add new members to existing machine groups. **Note:** We recommend that you specify the **-p** flag on a client definition file to verify that all stanzas are correct before using it for adding machines.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
!0	An error occurred.

Security

Access Control: You must have root authority to run the **nimdef** command.

Auditing Events: N/A

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To preview the client definition file **client.defs**, enter:

```
nimdef -p -f client.defs
```

2. To add the NIM clients described in the client definition file **client.defs**, enter:

```
nimdef -d -f client.defs
```

3. To create a kshell script called **client.add** to add the NIM clients described in the client definition file **client.defs**, enter:

```
nimdef -c -f client.defs > client.add
```

Files

Item	Description
/usr/sbin/nimdef	Contains the **nimdef** daemon/command.

niminit Command

Purpose

Configures the Network Installation Management (NIM) client package.

Syntax

To Configure the NIM Client Package

niminit{**-a name=***Name* **-a pif_name=***Pif* **-a master=***Hostname*} [**-a master_port=***PortNumber*] [**-a registration_port=***PortNumber*] [**-a cable_type=***Type* | **-a ring_speed=***Speed*] [**-a iplrom_emu=***Device*] [**-a platform=***PlatformType*] [**-a netboot_kernel=***NetbootKernelType*] [**-a adpt_add=***AdapterAddress*] [**-a is_alternate=** yes | no] [**-a connect=***value*] [**-a vlan_tag=***value*] [**-a vlan_pri=***value*]

To Rebuild the /etc/niminfo File

niminit {**-a name=***Name* **-a master=***Hostname* **-a master_port=***PortNumber*}

Description

The **niminit** command configures the NIM client package. This must be done before the **nimclient** command can be used. When the required attributes are supplied to the **niminit** command, a new machine object will be created to represent the machine where the **niminit** command is being executed. When the **niminit** command completes successfully, the machine will be able to participate in the NIM environment.

After the NIM client package has been successfully configured, the **niminit** command can be run again to rebuild the **/etc/niminfo** on the client. The **/etc/niminfo** file is used by the **nimclient** command and must be rebuilt if it is accidentally removed by a user.

This command configures an `alternate_master` when the `is_alternate` attribute is set to `yes`. The `bos.sysmgt.nim.master` fileset must be installed prior to configuring an `alternate_master`. Once the configuration of an `alternate_master` is successful, the master that it registered with will be able to run `alternate_master` operations on this machine.

Flags

Item	Description	Attribute Description
-a	Specifies up to five different attributes for the **niminit** command. All of the following attribute=value pairs are preceded by the **-a** flag:	
	name=*Name*	Specifies the name that NIM will use to identify the workstation. This value is required.
	pif_name=*Pif*	Defines the name of the network interface for all NIM communications. This value is required.

Item	Description	Attribute Description
	master=*Hostname*	Specifies the hostname of the NIM master. The client must have the ability to resolve this hostname to an Internet Protocol (IP) address. This value is required.
	master_port=*PortNumber*	Specifies the port number of the **nimesis** daemon used for NIM communications.
	cable_type=*CableType*	Specifies the ethernet cable type. When the **pif_name** refers to an ethernet network, this value must be given. Acceptable values are: **bnc**, **dix**, and **N/A**.
	ring_speed=*Speed*	Speed in Mbps. When the **pif_name** refers to a token ring network, this value must be given. Acceptable values are: **4** and **16**.
	iplrom_emu=*Device*	Specifies a device that contains a ROM emulation image. This image is required for models that do not have internal support for booting via network interface.
	platform=*PlatformType*	Specifies the platform that corresponds to the client's machine type. If this attribute is not specified, the default, **chrp**, will be used. The supported platforms are: **chrp** PowerPC Common Hardware Reference Platform (CHRP) architecture-based machines **rs6k** Micro Channel-based, uniprocessor models for AIX 5.1 and earlier **rs6ksmp** Micro Channel-based, symmetric multiprocessor models for AIX 5.1 and earlier **rspc** PowerPC PCI bus-based, uniprocessor machines for AIX 5.1 and earlier **rspcsmp** PowerPC PCI bus-based, symmetric multiprocessor machines for AIX 5.1 and earlier
	adpt_add=*AdapterAddress*	Specifies the hardware address that corresponds to the network adapter.
	registration_port=*PortNumber*	Specifies the port number used for NIM client registration. **Note:** 1. If you do not specify port numbers on the command line, the port numbers in the **/etc/services** file for NIM is used. If the **/etc/services** file does not contain entries for the NIM ports `nim` and `nimreg`, the default values of 1058 for **master_port** and 1059 for **registration_port** are used. 2. The values used for **master_port** and **registration_port** should match the values used by the NIM master. To display the values used by the NIM master, run the command **lsnim -l master** on the NIM master.

Item	Description	Attribute Description
	netboot_kernel= *NetbootKernelType*	Specifies the type of kernel to use when booting the client over the network. The **netboot_kernel** values are: **up** Kernel for uniprocessor machines **mp** Kernel for multiprocessor machines The default is **up**.
	`is_alternate=[yes|no]`	Set this to yes if this machine is to be configured as an `alternate_master`.
	connect=*value*	Specifies the communicating service used by the NIM client for remote execution of NIM commands. Value options are `shell` (for rsh) and `nimsh`. The default setting is `connect=shell`. This attribute is optional. If the is_alternate attribute is set to yes then `nimsh` is the default setting, and is the only valid value. Using the is_alternate attribute is optional.
	vlan_tag=*value*	Specifies the virtual logical area network (VLAN) identifier that is used for VLAN tagging. The ID is used to identify the VLAN to which the Ethernet frame must belong. The ID allows the network administrator to organize the client's communication logically rather than assigning the network to the subnet. The VLAN tagging value is used by NIM to perform a network boot of a client. The configuration of the VLAN tag communication must be handled outside of NIM before using the value. Valid values are 0 - 4094.
	vlan_pri=*value*	Specifies the virtual logical area network (VLAN) priority that is used for VLAN tagging. The priority value, along with the VLAN tag, is used to identify the VLAN to which the Ethernet frame must belong. The priority allows the network administrator to organize the client's communication logically rather than assigning the network to the subnet. The VLAN tagging value is used by NIM to perform a network boot of a client. The configuration of the VLAN tag communication must be handled outside of NIM before using the value. Valid values are 0 - 7.

Security

Access Control: You must have root authority to run the **niminit** command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To configure the NIM client package on a machine that has a BOOTP-enabled IPL ROM such that it will be known as `scuba` in the NIM environment, using `en0` as its primary interface and an ethernet cable type of `bnc`, and specifying that it communicates with the NIM master using the master's hostname of `manta` and the default NIM ports located in **/etc/services** for network install communications, type:

```
niminit -a name=scuba -a pif_name=en0 -a cable_type=bnc \
-a master=manta
```

2. To rebuild the **/etc/niminfo** file when it has accidentally been removed by a user, using a hostname of superman for the master's hostname and a port number of 1058, type:

```
niminit -a name=robin -a master=superman -a master_port=1058
```

3. To configure the NIM client package for AIX 5.1 and earlier on a machine that is a PowerPC PCI bus-based, uniprocessor system that has a BOOTP-enabled IPL ROM such that it will be known as starfish in the NIM environment, using en0 as its primary interface and an Ethernet cable type of dix, and specifying that it communicates with the NIM master using the master's host name of whale and a port number of 1058, type:

```
niminit -a name=starfish -a pif_name=en0 -a cable_type=dix \
-a master=whale -a master_port=1058 -a platform=rspc
```

4. To configure the NIM client, on a machine to be known as bluefish in the NIM environment, using at0 as its primary interface and specifying that it communicates with the NIM master using the master's host name redfish and a port number of 1058, type:

```
niminit -a name=bluefish -a pif_name=at0 -a master=redfish \
-a master_port=1058
```

   Note: Because an interface to an ATM network does not currently support booting over the network, this operation will define a machine object on the NIM master if a Generic network object corresponding to the client's subnet is already defined.

5. To configure the NIM client for AIX 5.1 and earlier on a machine that is a PowerPC PCI bus-based, symmetric multiprocessor system that has a BOOTP-enabled IPL ROM such that it will be it will be known as jellyfish in the NIM environment, using en0 as its primary interface and an Ethernet cable type of dix, and specifying that it communicates with the NIM master using the master's host name of whale and a port number of 1058, type:

```
niminit -a name=jellyfish -a pif_name=en0 -a cable_type=dix \
-a master=whale -a master_port=1058 -a platform=rspcsmp
```

6. To configure the NIM client package on a machine that will use an IPL ROM emulation in device /dev/fd0, such that it will be known as octopus in the NIM environment and uses tr0 as its primary interface and a ring speed of 16, and communicates with the NIM master using the master's hostname of dolphin and a port number of1700 for client communications and 1701 for client registration, type:

```
niminit -a iplrom_emu=/dev/fd0 -a name=octopus -a pif_name=tr0 \
-a ring_speed=16 -a master=dolphin -a master_port=1700 \
-a registration_port=1701
```

7. To configure this machine as an alternate_master with the NIM master dolphin and communicate over interface en0, type:

```
niminit -a is_alternate=yes -a name=octopus -a pif_name=en0 \
-a cable_type=bnc -a master=dolphin
```

Files

Item	Description
/etc/niminfo	Contains variables used by NIM.

niminv Command

Purpose

Allows system administrators to gather, conglomerate, compare, and download fixes based on installation inventory of NIM objects.

Syntax

To get installation inventory:

`niminv -o invget -a targets=`*object1,object2,...* [`-a location=`*path*] [`-a colonsep=yes|no`]

To conglomerate installation inventory:

`niminv -o invcon -a targets=`*object1,object2,...* [`-a base=highest|lowest`] [`-a location=`*path*] [`-a colonsep=yes|no`]

To compare installation inventory:

`niminv -o invcmp -a targets=`*object1,object2,...* [`-a base=object|any`] [`-a location=`*path*]

To get fixes based on conglomerate inventory:

`niminv -o fixget -a targets=`*object1,object2,...* [`-a download=yes|no`] [`-a lp_source=`*object*] [`-a location=`*path*] `-a newlppname=`*name*

Description

The `niminv` command (Network Install Manager Inventory) allows system administrators to accomplish the following tasks:

- Gather installation inventory of several NIM objects.
- Conglomerate installation inventory of several NIM objects.
- Compare installation inventory of several NIM objects.
- Download fixes base on the installation inventory of several NIM objects.

The `niminv` command can use any NIM object that contains installation information. Examples of such objects include standalone client objects, SPOT objects, `lpp_source` objects and `mksysb` objects.

Using the `niminv` command has the following advantages:

- Hardware installation inventory is gathered alongside the software installation inventory.
- Data files are saved with a naming convention that is easily recognizable.
- All NIM objects that have installation inventory can be used.
- The command provides a holistic view of all managed NIM objects.

The information displayed by `niminv` can be limited by any of the following factors:

- Only software installation inventory is provided for objects that do not actually have physical devices (such as SPOT objects, `lpp_source` objects, and `mksysb` objects).
- Software and hardware installation inventory on client objects are limited to what commands on the remote system can provide.
- The recognition of fixes to download is based on the fix backend server. For more details, see **Using the Software Service Management menu (including SUMA)**.

Flags

Item	Description
-a *attribute=value*	Specifies the attribute and value. The supported attributes and values are based on the operation.
-o *operation*	Specifies the operation. The following operations are currently supported: **fixget** Gathers the latest fixes based on the installation inventory. This operation supports the following attributes: **targets** (required) A comma-separated list of NIM objects to base the gathering of fixes. **lpp_source** (optional) The NIM `lpp_source` object to use as a filter for downloading fixes. If the location and `newlppname` attributes are not used, this `lpp_source` object will also be where any fixes are downloaded to. **location** (optional) A directory to store the fixes. Use this attribute only if the fixes should not be downloaded to the object supplied to the `lpp_source` attribute. This attribute can only be used with the `newlppname` attribute. **newlppname** (optional) The NIM object name of the `lpp_source` to create at location. This attribute can only be used with the `location` attribute. The value supplied must be distinct and currently unused in the NIM environment. **download** (optional) Instructs the command whether or not to download the fixes. If no `lpp_source` or `location` field is specified and the value of this attribute is `yes`, fixes will be downloaded to the default location through the `suma` command. **Note:** The `suma` command will increase the file system space according to the `MaxFSSize` field in the `suma` configuration.

Item	Description
-o *operation (Continued)*	**invcmp** Compares installation inventory. This operation supports the following attributes: **targets** (required) A comma-separated list of NIM objects to compare installation inventory. **base** (required) The NIM object to use as the comparison base, or the keyword `any`. If the NIM object is supplied, the installation inventory in the object is the sole determinate of the data displayed, and only inventory in the base object is compared against inventory in the target objects. The keyword `any` forces the command to use any installation inventory of the targets. **location** (optional) A directory to store the data files. If this option is used, each inventory is saved with the format `conglomerate`*base_object*.*target_object_list*.*timestamp*, where *base_object* is the NIM name of the base object used for comparison (or the keyword `any`), *target_object_list* is a colon-separated and sorted list of the NIM name of the objects, and *timestamp* is the time the command was run (*year month day hour minute second*). If the directory does not exist, it will be created. The default is to display the data to the screen.

Item	Description
-o *operation (Continued)*	**invcon** Conglomerates installation inventory. This operation supports the following attributes: **targets** (required) A comma-separated list of NIM objects to conglomerate installation inventory. **base** (optional) Specifies whether the conglomerate inventory is based on the highest or lowest software levels. **location** (optional) A directory to store the data files. If this option is used, each inventory is saved with the format `base`.*target_object_list*.*timestamp*, where `base` indicates wther the conglomerate is based on the highest or lowest levels, *target_object_list* is a colon-separated and sorted list of the NIM name of the objects, and *timestamp* is the time that the command was run (*year month day hour minute second*). If the directory does not exist, it will be created. The default is to display the data to the screen. **colonsep** (optional) Instructs the command whether or not to produce colon-separated output. The default is no. **invget** Gathers installation inventory. This operation supports the following attributes: **targets** (required) A comma-separated list of NIM objects to gather installation inventory. **location** (optional) A directory to store the data files. If this option is used, each inventory is saved with the format `conglomerate`.*target_object_name*.*timestamp*, where *target_object_name* is the NIM name of the object, and *timestamp* is the time that the command was run (*year month day hour minute second*). If the directory does not exist, it will be created. The default is to display the data to the screen. **colonsep** (optional) Instructs the command whether or not to produce colon-separated output. The default is no.

Exit Status

Item	Description
`0`	The command completed successfully.
`>0`	An error occurred.

Security

Access Control: You must have root authority to run the `niminv` command.

Attention RBAC users and Trusted AIX users: The **rbacqry** command grants execute (x) access to the root user. The **rbacqry** command is a privileged command that is used to run privilege operations. You must activate a role that has the authorization to run the command successfully.

Examples

1. To gather installation inventory of a two clients and save the output to /tmp/inventory, enter:

   ```
   niminv -o invget -a targets=client1,client2 -a location=/tmp/inventory
   ```

   Output similar to the following is displayed:

   ```
   Installation Inventory for client1 saved to
       /tmp/inventory/inventory.client1.060406140453.
   Installation Inventory for client2 saved to
       /tmp/inventory/inventory.client2.060406140453.
   ```

   The information in the files is similar to the output of lslpp -L
2. To conglomerate installation inventory of two clients and save the output to /tmp/inventory, enter:

   ```
   niminv -o invcon -a targets=client1,client2 -a location=/tmp/inventory
   ```

   Output similar to the following is displayed:

   ```
   Installation Inventory for client1 saved to
       /tmp/inventory/conglomerate.client1:client2.060406140500.
   ```

   The information in the files is similar to the output of lslpp -L.
3. To compare installation inventory of a mksysb, SPOT, and lpp_source to what's currently installed on the master, and save the output to /tmp/inventory, enter:

   ```
   niminv -o invcon -a targets=mksysb1,spot1,lpp_source1 -a base=master -a \
   location=/tmp/inventory
   ```

   Output similar to the following is displayed:

   ```
   Installation Inventory for client1 saved to
       /tmp/inventory/comparison.master.mksysb1:spot1:lpp_source1.060406140610.
   ```

   The information in the file is listed in column format. The comparison only includes installation inventory on the master.
4. To do the same comparison as in the preceding example but also include software on any of the objects, enter:

   ```
   niminv -o invcon -a targets=mksysb1,spot1,lpp_source1,master -a base=any -a \
   location=/tmp/inventory
   ```

   Output similar to the following is displayed:

   ```
   Installation Inventory for client1 saved to
       /tmp/inventory/comparison.any.mksysb1:spot1:lpp_source1.060406140733.
   ```

   The information in the file is listed in column format. The comparison includes any installation inventory in any of the target objects.
5. To see the fixes that can be downloaded based on the lowest installations in a mksysb, SPOT and lpp_source, enter:

   ```
   niminv -o fixget -a targets=mksysb1,spot1,lpp_source1
   ```

   Output similar to the following is displayed:

   ```
   ****************************************
   Performing preview download.
   ****************************************
   ```

```

       0 skipped
```

6. To download the latest fixes based on the lowest installations in a mksysb, SPOT and lpp_source, enter:

```
niminv -o fixget -a targets=mksysb1,spot1,lpp_source1 -a download=yes
```

   Output similar to the following is displayed:

```
Extending the /usr filesystem by 30 blocks.
File System size changed to 8126464

Download SUCCEEDED: /usr/sys/inst.images/installp/ppc/Java14.debug.1.4.1.0.bff
Download SUCCEEDED: /usr/sys/inst.images/installp/ppc/Java14.debug.1.4.1.7.bff
Download SUCCEEDED: /usr/sys/inst.images/installp/ppc/devices.pci.00100100.com.5.2.0.50.bff
Download SUCCEEDED: /usr/sys/inst.images/installp/ppc/devices.pci.00100300.diag.5.2.0.75.bff
Download SUCCEEDED: /usr/sys/inst.images/installp/ppc/devices.pci.00100f00.rte.5.2.0.85.bff
Download SUCCEEDED: /usr/sys/inst.images/installp/ppc/devices.pci.13100560.rte.5.2.0.85.bff

Summary:
       6 downloaded
       0 failed
       0 skipped
```

   Note: Any installations already contained in the default download path (as specified by the suma command) will not be downloaded again. The default download path in this example was /usr/sys/inst.images. Refer to the suma command for specifics on where the default download path will be.

7. To download the latest fixes based on the lowest installations in a mksysb, SPOT and lpp_source to an existing lpp_source, enter:

```
niminv -o fixget -a targets=mksysb1,spot1,lpp_source1 -a download=yes -a \
lpp_source=lpp_source2
```

   Output similar to the following is displayed:

```
Download SUCCEEDED: /nim/lpps/lpp_source2/installp/ppc/Java14.debug.1.4.1.0.bff
Download SUCCEEDED: /nim/lpps/lpp_source2/installp/ppc/Java14.debug.1.4.1.7.bff

Summary:
       2 downloaded
       0 failed
       0 skipped
```

   Note: Any installations already contained in lpp_source2 will not be downloaded again. In this example, the filesets device already existed in the lpp_source2.

8. To download the latest fixes based on the lowest installations in a mksysb, SPOT and lpp_source to a newlpp_source while filtering filesets in an existing lpp_source, enter:

```
niminv -o fixget -a targets=mksysb1,spot1,lpp_source1 -a download=yes -a \
location=/nim/lpps/newlpp1 -a newlppname=newlpp1
```

   Output similar to the following is displayed:

```
Download SUCCEEDED: /nim/lpps/newlpp1/installp/ppc/Java14.debug.1.4.1.0.bff
Download SUCCEEDED: /nim/lpps/newlpp1/installp/ppc/Java14.debug.1.4.1.7.bff

Summary:
       2 downloaded
       0 failed
       0 skipped
```

Note: Any installations already contained in `lpp_source2` will not be downloaded again. In this example, the `filesets` device already existed in the `lpp_source2`.

9. To download the latest fixes based on the lowest installations in a `mksysb`, SPOT and `lpp_source` to a new`lpp_source`, enter:

```
niminv -o fixget -a targets=mksysb1,spot1,lpp_source1 -a download=yes -a \
location=/nim/lpps/newlpp2 -a newlppname=newlpp2
```

Output similar to the following is displayed:

```
Download SUCCEEDED: /nim/lpps/newlpp2/installp/ppc/Java14.debug.1.4.1.0.bff
Download SUCCEEDED: /nim/lpps/newlpp2/installp/ppc/Java14.debug.1.4.1.7.bff
Download SUCCEEDED: /nim/lpps/newlpp2/installp/ppc/devices.pci.00100100.com.5.2.0.50.bff
Download SUCCEEDED: /nim/lpps/newlpp2/installp/ppc/devices.pci.00100300.diag.5.2.0.75.bff
Download SUCCEEDED: /nim/lpps/newlpp2/installp/ppc/devices.pci.00100f00.rte.5.2.0.85.bff
Download SUCCEEDED: /nim/lpps/newlpp2/installp/ppc/devices.pci.13100560.rte.5.2.0.85.bff

Summary:
       6 downloaded
       0 failed
       0 skipped
```

Location

`/usr/sbin/niminv`

nimol_backup Command

Purpose

Creates NIMOL install resources from an AIX client.

Note: This command is used only for Virtual I/O Server (VIOS) or Integrated Virtualization Management (IVM) from the Hardware Management Console (HMC).

Syntax

nimol_backup **-c** *client_hostname* [**-t** *directory*] [**-m** *remote_access_method*] [**-L** *label*] [**-D**]

Description

The **nimol_backup** command creates NIMOL install resources from a configured NIMOL client using the specified remote access method, which is **/usr/bin/rsh** by default, to call the nimol_mk_resources method on the client. When configuring a NIMOL server using the **nimol_config** command, the user can set the default remote access method to something other than **/usr/bin/rsh**, such as **/usr/bin/ssh**. A machine is considered a NIMOL client when it has been installed using the **nimol_install** command without the **-n** flag.

The command creates the target directory and label on the NIMOL server. The directory is then exported. The default label is `default`. For example, if the command is passed **-t /export/aix -L aix530**, then the command creates the **/export/aix/aix530** directory on the NIMOL server.

The command then uses the remote access method to run the **nimol_mk_resources** command. The **nimol_mk_resources** command creates the necessary install resources in the target directory.

Flags

Item	Description
-c *client_hostname*	Specifies the NIMOL client hostname on which to execute the **geninstall** command.

Item	Description
-D	Runs the command in debug mode.
-L *label*	Specifies the label or name to create for the created resources.
-m *remote_access_method*	Specifies the remote access method to use to run the **geninstall** command. The default **/usr/bin/rsh**. Another option is **/usr/bin/ssh**.
-t *directory*	Specifies the target directory where the AIX install resources will be created from the NIMOL client. The default directory is **/export/aix**.

Exit Status

Item	Description
0	The command completed successfully.
> 0	Error returned.

Security

To run the **nimol_backup** command on a NIMOL client, the client must provide remote access permissions to the NIMOL server. Using **/usr/bin/ssh** is a more secure remote acces method than **/usr/bin/rsh**.

Examples

1. To create install resources from client `myclient` in the **/export/aix** directory and named 530, type:

```
nimol_backup -c myclient -L 530 -t /export/aix
```

2. To execute `nimol_mk_resources` using `ssh`, type:

```
nimol_backup -c myclient -m ssh
```

Location

/usr/sbin/nimol_backup

Files

Item	Description
/etc/nimol.conf	Stores configuration information for the command.

nimol_config Command

Purpose

Configures a Linux server to network install a machine with AIX by configuring services and copying install resources.

Note: This command is used only for Virtual I/O Server (VIOS) or Integrated Virtualization Management (IVM) from the Hardware Management Console (HMC).

Syntax

nimol_config [**-d** *DirectoryContainingAIXResources*] [**-t** *TargetDirectoryToCopyResources*] [**-L** *InstallResourcesLabel*] [**-s** *NIMOLServerHostname*] [**-m** *RemoteAccessMethod*] [**-C**] [**-e**] [**-l**] [**-r**] [**-S**] [**-U**] [**-D**]

Description

The **nimol_config** command configures a Linux server to network install a machine with AIX. The command performs the following configuration.

1. First, the command obtains the hostname and IP address of the Linux server. If no hostname is specified with the **-s** flag, the command uses the hostname of the local machine and the IP address associated with the hostname. If a hostname and IP address are specified, then the pair is added to the **/etc/hosts** file, if it does not already exist.
2. The command then starts the portmap service and nfs server.
3. The command stores the remote access method in the **/etc/nimol.conf** file if specified with the **-m** flag. The default remote access command is **/usr/bin/rsh**, which is used to communicate with NIMOL clients that have been installed without specifying the **-n** flag to the **nimol_install** command.
4. Next, tftpboot is configured. The **/tftpboot** directory is created if it does not exist and the **/etc/xinetd.d/tftp** file is created if it does not exist. Then the command sets disable equal to no in the **/etc/xinetd.d/tftp** file and restarts xinetd so that the tftp server can handle incoming requests.
5. The **nimol_config** command also sets up syslog to accept incoming messages from other machines. Clients pass back status while installing to the syslog server. The **/etc/sysconfig/syslog** file is modified to include the **-r** flag in the SYSLOGD_OPTIONS or SYSLOGD_PARAMS variable. Then the command searches **/etc/syslog.conf** for the first available local log and sets it to write messages to **/var/log/nimol.log**. Clients write status to this log file, which can be monitored during a client installation. After the changes are made to the syslog configuration files, the service is restarted.
6. Next, the command sets up the DHCP server to receive bootp requests from AIX clients. The subnet of the NIMOL server is determined and added to the **dhcpd.conf** file. The options `allow bootp`, `not authoritative`, and `ddns-update-style none` are added if they do not already exist. Existing settings for these options will be overwritten.
7. Once the services have been configured, the **nimol_config** command attempts to copy AIX install resources locally, if the **-C** flag was not passed to the command. The command copys resources from the source directory specified with the **-d** flag (**/mnt/cdrom** by default) to the target directory (**/export/aix** by default). A directory is created (name that matches the LABEL name specified with the **-L** flag 'default' by default). The command looks in the source directory for the following resources:
   - a SPOT (Source Product Object Tree) directory named **/SPOT** and a SPOT directory named **ispot.tar.Z**
   - an lpp_source directory named **/lpp_source**
   - a mksysb named **mksysb** or **mksysb.bff**
   - a boot image named **booti.chrp.mp.ent**
   - a bosinst.data file named **bosinst.data**
   - an image.data file named **image.data**
   - a customization script named **cust.script**
   - a resolv.conf file named **resolv.conf**

   A SPOT, boot image, and either mksysb or lpp_source are required.
8. The target directory is then globally exported unless the **-e** flag is specified.
9. If a target directory and label are specified that contain resources, then these resources will be used and no resources will be copied. For example, if the command is passed **-t /export/aix -L aix530** and the directory **/export/aix/aix530** contains resource, then the command will not attempt to copy resources from the source directory.

10. After the NIMOL server has been configured, the **nimol_config** command will not attempt to reconfigure services on the NIMOL server when defining new resource labels.
11. The command also lists defined resource labels with the **-l** flag.
12. Resource labels can be removed by specifying the **-r** flag with a resource label. The command unexports the directory, if exported, and deletes the directory of the resource label.
13. When the **-U** flag is passed, the command attempts to undo any configuration that it has done, such as unconfiguring services.

Flags

Item	Description
-C	Specifies that the server should only configure services without copying install resources.
-d *directory*	Specifies the source directory that contains the AIX install resources. The default directory is **/mnt/cdrom**.
-D	Runs the command in debug mode.
-e	Instructs the command not to globally export the directory of newly created resource label.
-l	Lists the defined resource labels available to install a client.
-L *label*	Specifies the label or name to create for the copied resources.
-m *method*	Specifies the remote access method to use when running commands on clients that have been installed without specifying the **-n** flag to the **nimol_install** command.
-r	Instructs the command to remove the specified resource label.
-s *hostname*	The hostname to use for the NIMOL server. The default is to determine the hostname by running the **hostname** command.
-S	Instructs the command to not configure the syslog service. No status will be logged when clients are installing.
-t *directory*	Specifies the target directory where the AIX install resources will be copied from the source directory. The default directory is **/export/aix**.
-U	Instructs the command to unconfigure the NIMOL server. The command will attempt to undo any configuration that it performed.

Exit Status

Item	Description
0	The command completed successfully.
> 0	Error returned.

Security

Configuring the syslog service to accept messages from remote clients can be a security issue. Configure your firewall to only accept syslog messages from known clients.

Examples

1. To configure the NIMOL server without copying resources, type:

```
nimol_config -C
```

2. To configure the NIMOL server, copy resources from **/mnt/aix** to **/export/aix**, and label the resource `aix530`, type:

```
nimol_config -d /mnt/aix -t /export/aix -L aix530
```

3. To configure the NIMOL server and copy resources without configuring syslog and without globally exporting the resource label directory, type:

```
nimol_config -S -e
```

4. To list defined resource labels, type:

```
nimol_config -l
```

5. To remove the `aix530` resource label, type:

```
nimol_config -L aix530 -r
```

Location

/usr/sbin/nimol_config

Files

Item	Description
/etc/nimol.conf	Stores configuration information for the command.

nimol_install Command

Purpose

Sets up a configured NIMOL server to install AIX to a specific client machine.

Note: This command is used only for Virtual I/O Server (VIOS) or Integrated Virtualization Management (IVM) from the Hardware Management Console (HMC).

Syntax

nimol_install -c *client_hostname* [**-g** *gateway*] [**-m** *mac_address*] [**-p** *ip_address*] [**-s** *subnet_mask*] [**-L** *label*] [**-n**] [**-r**] [**-D**]

Description

The **nimol_install** command sets up a configured NIMOL server to network install a machine with AIX. The command peforms the following configuration.

1. The command determines the IP address of the client hostname if the client IP address isn't specified. If the client hostname isn't resolvable and a client IP address is specified, then the pair will be added to the **/etc/hosts** file if it does not exist.
2. The client is added to the **/etc/nimol.conf** file.
3. The directory of the resource label is exported to the client if it is not already globally exported.
4. A stanza for the client is added to the **/etc/dhcpd.conf** file. The client's subnet will also be added to the **/etc/dhcpd.conf** file if it does not exist. If the client or its subnet already exist in the **/etc/dhcpd.conf** file, an error is displayed.
5. A symbolic link to the boot image is created in the **/tftpboot** directory for the client.
6. A static `arp` entry is added if the client is on the same subnet as the NIMOL server.

7. The command will turn off the firewall rules to a client that is installing if the **iptables** command exists by running:

   ```
   iptables -I INPUT 1 -s client_hostname -j ACCEPT
   ```

   This allows the various services used by NIMOL to succeed. When a client is removed, the **nimol_install** command will run the following command to delete the rule: `iptables -D INPUT -s client_hostname`.
8. The command ensures that the required resources exist in the resource label's directory.
9. A nim_script is created in the scripts subdirectory of the resource label's directory if a **resolv.conf** or customization script was specified or if the client will remain a client of the NIMOL server after the installation. The **nimol_install** command will look for a general customization script in the resource label's directory named `cust.script` or a specific customization script for the client named *client_name*`.script`.
10. An information file is created in the **/tftpboot** directory that will be used during the installation of the operating system.
11. If the **-l** flag is specified, the command will list clients set up for an installation. A client will be removed if the **-r** flag is specified with a client name.
12. Once the client has been set up to install, the client must be told to perform a network install. If the client has AIX installed and is running, then use the **bootlist** command. For example, if the NIMOL server is `192.168.1.20` and the AIX client is `192.168.1.30`, then to boot off `ent0` run:

    ```
    bootlist -m normal -ent0 bserver=192.168.1.20 \\
      gateway=0.0.0.0 client=192.168.1.30
    ```

    then reboot by running:

    ```
    shutdown -Fr
    ```
13. If the client is not running, then boot into the SMS menus and specify the network boot parameters and the network boot device. If the client is on the same subnet as the NIMOL server, then the client will be able to do a broadcast **bootp** install. A broadcast **bootp** does not require the IP parameters to be set; the bserver, gateway and client would be `0.0.0.0` on a broadcast bootp install.

Flags

Item	Description
-c *client_hostname*	Specifies the client hostname that will be set up for an install or will be removed.
-D	Runs the command in debug mode.
-g *gateway*	Specifies the gateway that will be configured after the client has installed AIX. This is required when installing a client.
-l	Lists the clients set up to install.
-L *label*	Specifies the label or name of resources with which to install the client. The default is `default`.
-m *mac_address*	Specifies the MAC address of the network interface the client will install over. This is required when installing a client. The MAC address must contain colons (for example `00:60:08:3F:E8:DF`).
-n	Specifies not to configure the machine to remain a client of the NIMOL server after the installation has completed. If this option is specified, the client will not have its network configured after the installation.
-p *ip_address*	Specifies the IP address of the client. Use this flag if the client's hostname is not resolvable.

Item	Description
-r	Removes the client. The client will not be able to install AIX until it is reconfigured. This flag requires a client hostname.
-s *subnet_mask*	Specifies the subnet mask of the client interface. This flag is required when installing a client.

Exit Status

Item	Description
0	The command completed successfully.
> 0	Error returned.

Security

If the machine remains a client of the NIMOL server (the **-n** flag is not specified), then it will give the NIMOL server **/usr/bin/rsh** permissions so it can run commands on the client.

Examples

1. To setup client `myclient` to install the `aix530` resource label with gateway `192.168.1.1`, MAC address `00:60:08:3F:E8:DF`, and subnet mask `255.255.255.0`, type:

   ```
   nimol_install -c myclient -g 192.168.1.1 \\
     -m 00:60:08:3F:E8:DF -s 255.255.255.0 -L aix530
   ```

2. To setup client `myclient` and not have it remain a client to the NIMOL server after the installation, type:

   ```
   nimol_install -n -c myclient -g 192.168.1.1 \\
     -m 00:60:08:3F:E8:DF -s 255.255.255.0 -L aix530
   ```

3. To list the clients configured to be installed, type:

   ```
   nimol_install -l
   ```

4. To remove client `myclient`, type:

   ```
   nimol_config -c myclient -r
   ```

Location

/usr/sbin/nimol_install

Files

Item	Description
/etc/nimol.conf	Stores configuration information for the command.

nimol_lslpp Command

Purpose

Runs the **lslpp** command on a NIMOL client.

Note: This command is used only for Virtual I/O Server (VIOS) or Integrated Virtualization Management (IVM) from the Hardware Management Console (HMC).

Syntax

nimol_lslpp -c *client_hostname* [**-m** *remote_access_method*] [**-f** *lslpp_flags*] [**-D**]

Description

The **nimol_lslpp** command executes the **lslpp** command on a configured NIMOL client using the specified remote access method, which is **/usr/bin/rsh** by default. When configuring a NIMOL server using the **nimol_config** command, the user can set the default remote access method to something other than **/usr/bin/rsh**, such as **/usr/bin/ssh**. A machine is considered a NIMOL client when it has been installed using the **nimol_install** command without the **-n** flag.

The command runs the **lslpp** command with **-L -c** as the default flags. The **lslpp** command flags can be specified with the **-f** flag.

Flags

Item	Description
-c *client_hostname*	Specifies the NIMOL client hostname on which to execute the **lslpp** command.
-D	Runs the command in debug mode.
-f *lslpp_flags*	Specifies the **lslpp** command flags to pass to the **lslpp** command.
-m *remote_access_method*	Specifies the remote access method to use to run the **lslpp** command. The default is **/usr/bin/rsh**. Another option is **/usr/bin/ssh**.

Exit Status

Item	Description
0	The command completed successfully.
> 0	Error returned.

Security

To run the **nimol_lslpp** command on a NIMOL client, the client must provide remote access permissions to the NIMOL server. Using **/usr/bin/ssh** is a more secure remote access method than **/usr/bin/rsh**.

Examples

1. To run the **lslpp** command on client `myclient`, with the default flags **-Lc**, type:

   ```
   nimol_lslpp -c myclient
   ```

2. To run the **lslpp** command on client `myclient`, with the flags **-i bos.rte**, type:

   ```
   nimol_lslpp -c myclient -f "-i bos.rte"
   ```

3. To run the **lslpp** command on client `myclient`, using `ssh` as the remote access method, type:

   ```
   nimol_lslpp -c myclient -m ssh
   ```

Location

/usr/sbin/nimol_lslpp

Files

Item	Description
/etc/nimol.conf	Stores configuration information for the command.

nimol_update Command

Purpose

Runs geninstall on a NIMOL client to perform software maintenance.

Note: This command is used only for Virtual I/O Server (VIOS) or Integrated Virtualization Management (IVM) from the Hardware Management Console (HMC).

Syntax

nimol_update -c *client_hostname* [**-L** *label*] [**-f** *geninstall_flags*] [**-m** *remote_access_method*] [**-p** *package_list*] [**-D**]

Description

The **nimol_update** command executes the **geninstall** command on a configured NIMOL client using the specified remote access method, which is **/usr/bin/rsh** by default. When configuring a NIMOL server using the **nimol_config** command, the user can set the default remote access method to something other than **/usr/bin/rsh**, such as **/usr/bin/ssh**. A machine is considered a NIMOL client when it has been installed using the **nimol_install** command without the **-n** flag.

The command runs the **geninstall** command with **-acgX** as the default flags. Use the **-f** flag to specify **geninstall** command flags. The software packages to pass the **geninstall** command are specified with the **-p** flag.

When installing filesets using the **nimol_update** command, you must specify a resource label that has an lpp_source. Run **nimol_config -l -L *label*** to determine if a resource label contains an lpp_source. The command will export the resource label directory if it is not already globally exported. The client will mount the directory and use it as the source directory during an installation.

Flags

Item	Description
-c *client_hostname*	Specifies the NIMOL client hostname on which to execute the **geninstall** command.
-D	Runs the command in debug mode.
-f *geninstall_flags*	Specifies the flags to pass to the **geninstall** command. The default flags are **-acgX**.
-L *label*	Specifies the name of the resource label that will be used as the source for install images.
-m *remote_access_method*	Specifies the remote access method to use to run the **geninstall** command. The default is **/usr/bin/rsh**. Another option is **/usr/bin/ssh**.
-p *package_list*	Specifies the name of software packages to pass to the **geninstall** command. The default is `all`.

Exit Status

Item	Description
0	The command completed successfully.
> 0	Error returned.

Security

To run the **nimol_update** command on a NIMOL client, the client must provide remote access permissions to the NIMOL server. Using **/usr/bin/ssh** is a more secure remote access method than **/usr/bin/rsh**.

Examples

1. To install all packages in resource label 530 to client `myclient`, type:

```
nimol_update -c myclient -L 530
```

2. To apply an update for `bos.games` on client `myclient`, type:

```
nimol_update -c myclient -L 530 -f "-a" -p "bos.games"
```

3. To remove `bos.games` from client `myclient`, type:

```
nimol_update -c myclient -f "-u" -p "bos.games"
```

4. To execute the **geninstall** command using `ssh`, type:

```
nimol_update -c myclient -L 530 -m ssh
```

Location

/usr/sbin/nimol_update

Files

Item	Description
/etc/nimol.conf	Stores configuration information for the command.

nimquery Command

Purpose

Query a system in the Network installation management (NIM) environment for system information and create client objects in the environment.

Syntax

`nimquery`{{ `-a` host=*hostname* [`-a` name=*client obj*[`-d`] [`-a` hmc=*obj name*[`-d`] [`-a` cec=*obj name* [`-a` bcmm=*obj name* [`-a` ivm=*obj name*} [`-p`] [`-q`] [`-v`]

Description

The `nimquery` command queries a machine for system information when using the `-a` host parameter. The information is used for defining a new client object in the NIM environment. System information is provided from systems that use the NIM service handler (nimsh).

The `nimquery` command can also be used to query logical partitions (LPARs) , central electronics complex (CEC) and blades information when pointing to a Hardware Management Console (HMC) , CEC, Integrated Virtualization Manager (IVM) or Blade Center Management Module (BCMM) object. To do so, the **openssh.base.client** must be installed on the NIM master.

Flags

Item	Description
`-a`	Assigns the following parameter attribute=value pairs.
`-d`	Defines a new client object (requires the name attribute when `-a` host is used).
`-p`	Enables print format.
`-q`	Shows an attribute list for `nimquery` command.
`-v`	Enables verbose debug output during command execution.

Parameters

Item	Description
`host=`*hostname*	Specifies the host name of the system to query. This attribute is required.
`name=`*client_obj*	Specifies the name to assign the client object when creating a new definition in the NIM database.
`hmc=`*objname*	Specifies the object name of the HMC system to query. This attribute is required.
`cec=`*objname*	Specifies the object name of the CEC system to query. This attribute is required.
`ivm=`*objname*	Specifies the object name of the IVM system to query. This attribute is required.
`bcmm=`*objname*	Specifies the object name of the BCMM system to query. This attribute is required.

Exit Status

0
Returns zero on success.

Security

You must have root authority to run the `nimquery` command.

Examples

1. To query machine buckey for system information, type:

   ```
   nimquery -a host=buckey
   ```

2. To query machine buckey for system information and to provide detailed output information, type:

   ```
    nimquery -a host=buckey -p
   ```

3. To define machine buckey.austin.ibm.com using name client6 as the NIM object name, type:

   ```
   nimquery -a name=client6 -a host=buckey -d
   ```

4. To query Management Module bcmm2 for blade system information, type:

```
nimquery -a bcmm=bcmm2
```

5. To define CEC objects managed by HMC hmc1, type:

```
nimquery -a hmc=hmc1 -d
```

6. To query LPARs attached to cec1 buckey for system information, type:

```
nimquery -a cec=cec1
```

Files

Item	Description
`/usr/sbin/nimquery`	The location of `nimquery` command.

nistoldif Command

Purpose

Exports user, group, name resolution, and rpc data to rfc 2307-compliant form.

Syntax

nistoldif **-d** *Suffix* [**-a** *BindDN* **-h** *Host* **-p** *Password* [**-n** *Port*]] [**-f** *Directory*] [**-y** *domain*] [-S *Schema*] [**-k** *KeyPath* **-w** *SSLPassword*] [**-s** *Maps*] [**-m** *ldap_mapname*]

Description

The **nistoldif** command converts the data from **passwd**, **group**, **hosts**, **services**, **protocols**, **rpc**, **networks**, **netgroup**, and **automount** into forms compliant with rfc2307. It will first attempt to read data from NIS, and if it cannot find a NIS map it will fall back to the flat files.

If the server information (the **-a**, **-h**, and **-p** flags) is given on the command line, data will be written directly to the server. If any data conflicts with an entry already on the server, either because the entry already exists, or because the **uid** or **gid** already exists, a warning will be printed. If the server information is not given, the data will be written to **stdout** in LDIF. In either case, **nistoldif** does not add an entry for the suffix itself; if that entry does not exist, attempts to add data to the server will fail. This entry will be added during server setup, usually by the **mksecldap** command.

Translation is not exact. Because of the limitations of the rfc2307 definitions, some attributes are defined in a case-insensitive way; for example, TCP, Tcp, and tcp are all the same protcol name to the LDAP server. Uids and gids greater than 2^31-1 will be translated to their negative twos complement equivalent for storage.

The **nistoldif** command reads the **/etc/security/ldap/sectoldif.cfg** file to determine what to name the sub-trees that the passwd, group, hosts, services, protocols, rpc, networks and netgroup data will be exported to. The names specified in the file will be used to create sub-trees under the base DN specified with the **-d** flag. For more information, see the **/etc/security/ldap/sectoldif.cfg** file documentation.

Flags

Item	Description
-a	Specifies the administrative bind DN used to connect to the LDAP server. If this flag is used, **-h** and **-p** must also be used, and data will be written directly to the LDAP server.
-d	Specifies the suffix that the data should be added under.

Item	Description
-f	Specifies the directory to look for flat files in, or the name of the automount map file. If this flag is not used, **nistoldif** will look for files in **/etc**. This flag is required for automount maps.
-h	Specifies the host name which is running the LDAP server. If this flag is used, **-a** and **-p** must also be used, and data will be written directly to the LDAP server. This flag will be ignored for automount data.
-k	Specifies the SSL key path. If this flag is used, **-w** must also be used.
-m	Specifies the automount map on the LDAP server.
-n	Specifies the port to connect to the LDAP server on. If this flag is used, **-a**, **-h** and **-p** must also be used; if it is not used, the default LDAP port is used.
-p	Specifies the password used to connect to the LDAP server. If this flag is used, **-a** and **-h** must also be used, and data will be written directly to the LDAP server.
-s	Specifies a set of maps to be written to the server. This flag should be followed by a list of letters representing the maps that should be migrated. If this flag is not used, all maps will be migrated. The letters are: **a** for automount, **e** for netgroup, **g** for group, **h** for hosts, **n** for networks, **p** for protocols, **r** for rpc, **s** for services, and **u** for passwd.
-S	Specifies the LDAP schema to use for users and groups. This can be either RFC2307 or RFC2307AIX; RFC2307AIX gives extended AIX schema support. If this flag is not used, RFC2307 is the default.
-w	Specifies the SSL password. If this flag is used, **-k** must also be used.
-y	Specifies the NIS domain to read maps from. If this flag is not used, the default domain will be used.

Exit Status

This command returns the following exit values:

0
No errors occurred. Note that failure to find a map is not considered an error.

>0
An error occurred.

Security

Access Control: Only the root user can run this command.

Examples

1. To export the NIS maps from the domain **austin.ibm.com** (falling back to the flat files in **/tmp/etc**) to LDIF under the suffix **cn=aixdata**, type:

```
nistoldif -d cn=aixdata -y austin.ibm.com -f /tmp/etc > ldif.out
```

2. To export the hosts and services maps from the default domain (falling back to the flat files in **/etc**) to the LDAP server **ldap.austin.ibm.com** with administrator bind DN**cn=root** and password `secret` under the suffix **cn=aixdata**, type:

```
nistoldif -d cn=aixdata -h ldap.austin.ibm.com -a cn=root -p secret -s hs
```

3. To convert the **/etc/auto_master** automount map file into LDIF, type:

```
nistoldif -s a -f /etc/auto_master > ldif.out
```

4. In order to remove automount data, the LDIF file must be created manually. For example, suppose the user `user1` was erroneously added to the `auto_home` automount map in the `dc=austin,dc=ibm,dc=com` suffix, and needs to be deleted. Create the following LDIF:

```
# cat /tmp/del_user1.ldif
dn: automountKey=user1,automountMapName=auto_home,dc=austin,dc=ibm,dc=com
changetype: delete
```

   Then run the following command:

```
ldapmodify -f /tmp/del_user1.ldif
```

5. In order to edit automount data, the LDIF file must be created manually. For example, suppose the user `user2` was given the wrong mount point in the `auto_home` automount map in the `dc=austin,dc=ibm,dc=com` suffix, and needs to be changed to the correct location of `/home/user2`. Create the following LDIF:

```
# cat /tmp/ch_user2.ldif
dn: automountKey=user2,automountMapName=auto_home,dc=austin,dc=ibm,dc=com
changetype: modify
replace: automountInformation
automountInformation: /home/user2
```

   The run the following command:

```
ldapmodify -f /tmp/ch_user2.ldif
```

Files

Item	Description
/usr/sbin/nistoldif	Contains the **nistoldif** command.

nl Command

Purpose

Numbers lines in a file.

Syntax

nl [**-b** *Type*] [**-f** *Type*] [**-h** *Type*] [**-l** *Number*] [**-d** *Delimiter*] [**-i** *Number*] [**-n** *Format*] [**-v** *Number*] [**-w** *Number*] [**-p**] [**-s** *Separator*] [*File*]

Description

The **nl** command reads the *File* parameter (standard input by default), numbers the lines in the input, and writes the numbered lines to standard output. In the output, the **nl** command numbers the lines on the left according to the flags you specify on the command line.

The input text must be written in logical pages. Each logical page has a header, a body, and a footer section (you can have empty sections). Unless you use the **-p** flag, the **nl** command resets the line numbers at the start of each logical page. You can set line-numbering flags independently for the header, body, and footer sections (for example, the header and footer lines can be numbered while the text lines are not).

Signal the start of logical-page sections with lines in the file that contain only the following delimiter characters:

Line Contents	Start Of
\:\:\:	Header

Line Contents	Start Of
\:\:	Body
\:	Footer

You can name only one file on the command line. You can list the flags and the file name in any order.

Flags

All the parameters are set by default. Use the following flags to change these default settings. Except for the **-s** flag, enter a **-n** flag without a variable to see its default value.

Item	Description
-b *Type*	Chooses which body section lines to number. Recognized values for the *Type* variable are: **a** Numbers all lines **t** Does not number lines that are blank or lines that contain any non-graphic character such as a tab within them. (default) **n** Does not number any lines **p*Pattern*** Numbers only those lines specified by the *Pattern* variable.
-d *Delimiter*	Uses the two characters specified by the *Delimiter* variable as the delimiters for the start of a logical page section. The default characters are \: (backslash, colon). You may specify two ASCII characters, two 1-byte extended characters, or one extended character. If you enter only one 1-byte character after the **-d** flag, the second character remains the default (a colon). If you want to use a backslash as a delimiter, enter two backslashes (\\).
-f *Type*	Chooses which logical-page footer lines to number. The possible values for the *Type* variable are the same as the **-b** flag. The default value of the *Type* variable is **n** (no lines numbered).
-h *Type*	Chooses which logical-page header lines to number. The possible values for the *Type* variable are the same as the **-b** flag. The default value of the *Type* variables **n** (no lines numbered).
-i *Number*	Increments logical-page line numbers by the number specified in the *Number* variable. The default value of the *Number* variable is 1. The range of the *Number* variable is from 1 to 250.
-l *Number*	(Lowercase L) Uses the value specified in the *Number* parameter as the number of blank lines to count as one. For example, `-l3` numbers every third blank line in a series. The default value of the *Number* variable is 1. This flag works when the **-ha**, **-ba**, or **-fa** option is set. The range of the *Number* variable is from 1 to 250.
-n *Format*	Uses the value of the *Format* variable as the line numbering format. Recognized formats are: **ln** Left-justified, leading zeros suppressed **rn** Right-justified, leading zeros suppressed (default) **rz** Right-justified, leading zeros kept

Item	Description
-p	Does not restart numbering at logical page delimiters.
-s *Separator*	Separates the text from its line number with the character specified in the *Separator* variable. The default value of the *Separator* variable is a tab character.
-v *Number*	Sets the initial logical-page line number to the value specified by the *Number* variable. The default value of the *Number* variable is 1. The range of the *Number* variable is from 0 to 32767.
-w *Number*	Uses the value specified by the *Number* variable as the number of characters in the line number. The default value of the *Number* variable is 6. The range of the *Number* variable is from 1 to 20.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To number only the non-blank lines, enter:

   ```
   nl  chap1
   ```

   This displays a numbered listing of `chap1`, numbering only the non-blank lines in the body sections. If `chap1` contains no \:\:\+:, or \: delimiters, then the entire file is considered the body.

2. To number all lines:

   ```
   nl  -ba  chap1
   ```

   This numbers all the lines in the body sections, including blank lines. This form of the **nl** command is adequate for most uses.

3. To specify a different line number format, enter:

   ```
   nl  -i10  -nrz  -s::  -v10  -w4  chap1
   ```

   This numbers the lines of `chap1` starting with ten (`-v10`) and counting by tens (`-i10`). It displays four digits for each number (`-w4`), including leading zeros (`-nrz`). The line numbers are separated from the text by two colons (`-s : :`).

   For example, if `chap1` contains the text:

   ```
   A  not-so-important
   note  to  remember:

   You  can't  kill  time
   without  injuring  eternity.
   ```

   then the numbered listing is:

   ```
   0010::A  not-so-important
   0020::note  to  remember

   0030::You  can't  kill  time
   0040::without  injuring  eternity.
   ```

Note that the blank line was not numbered. To do this, use the **-ba** flag as shown in example 2.

Files

Item	Description
/usr/bin/nl	Contains the **nl** command.

nlssrc Command

Purpose

Gets the status of a subsystem or a group of subsystems in canonical form.

Syntax

nlssrc [**-h** *host*] **-a**

nlssrc [**-h** *host*] **-g** *group_name*

nlssrc [**-h** *host*] [**-l**] [**-c**] **-s** *subsystem_name*

nlssrc [**-h** *host*] [**-l**] [**-c**] **-p** *subsystem_pid*

The syntax for the first two usages of `nlssrc` will generate the exact same output as `lssrc`. The syntax for the last two usages will generate the output in the canonical form as `lssrc`.

Description

Use the `nlssrc` command to get the status of a subsystem or a group of subsystems in canonical form. For the AIX platform, use the `nlssrc -c` command to get language-independent output for supported subsystems from the `lssrc` command. The status is displayed in English regardless of the installed language locale. If the `-c` flag is not present, the `nlssrc` command will invoke the `lssrc` command that uses the daemon's locale.

Flags

Item	Description
-a	Lists the current status of all defined subsystems
-c	Requests the canonical `lssrc` output of the supported subsystems.
-g *group_name*	Specifies a group of subsystems to get status for. The command is unsuccessful if the *group_name* parameter is not contained in the subsystem object class.
-h *host*	Specifies the foreign host on which this status action is requested. The local user must be running as root. The remote system must be configured to accept remote System Resource Controller (SRC) requests. That is, the `srcmstr` daemon (see `/etc/inittab`) must be started with the `-r` flag and the `/etc/hosts.equiv` file or the `.rhosts` file must be configured to allow remote requests.

Item	Description
-l	Requests that a subsystem send its current status in long form. Long status requires that a status request be sent to the subsystem; it is the responsibility of the subsystem to return the status.
-p *subsystem_pid*	Specifies a particular instance of the *subsystem_pid* parameter to get status for, or a particular instance of the subsystem to which the status subserver request is to be taken.
-s *subsystem_name*	Specifies a subsystem to get status for. The *subsystem_name* parameter can be the actual subsystem name or the synonym name for the subsystem. The command is unsuccessful if the *subsystem_name* parameter is not contained in the subsystem object class.

Security

You do *not* need `root` authority to run this command.

Exit Status

0
Command has run successfully.

1
Command was not successful.

Restrictions

This command applies to the `cthags` and `cthats` subsystems only.

Standard Output

When the `-h` flag is specified, this command's usage statement is written to standard output.

Standard Error

Error messages are written to standard error (and to the `ctsnap.`*host_name*`.nnnnnnnn.log` file).

Examples

1. To get `nlssrc` output in English from a subsystem called `ctsubsys`, enter:

```
nlssrc -c -ls ctsubsys
```

2. The following example shows the same information in different formats:

```
nlssrc -ls ctsubsys (locale-dependent)

Subsystem  Group     PID   Status
ctsubsys   ctsubsys  6334  active
2 locally-connected clients.  Their PIDs:
15614 23248
HA Subsystem domain information:
Domain established by node 5
Number of groups known locally: 1
                    Number of          Number of local
Group Name          providers          providers/subscribers
ha_filesys             7                  1        0
```

```
nlssrc -ls ctsubsys -c (canonical form)

Number of local clients: 2
PIDs: 15614 23248
HA Subsystem domain information:
Domain established by node 5.
Number of known local groups: 1
Group Name: ha_filesys
     Providers: 7
     Local Providers: 1
     Local Subscribers: 0
```

Location

/opt/rsct/bin/nlssrc
Contains the `nlssrc` command

Files

/tmp/ctsupt
Location of the default directory that contains the output files.

/tmp/ctsupt/ctsnap.*host_name.nnnnnnnn*.log
Location of the log file of the command execution, where *nnnnnnnn* is a timestamp and *host_name* is the name of the host on which the command is running.

tmp/ctsupt/ctsnap.*host_name.nnnnnnnn*.tar.Z
Location of the compressed tar file that contains the collected data, where *nnnnnnnn* is a timestamp and *host_name* is the name of the host on which the command is running.

nm Command

Purpose

Displays information about symbols in object files, executable files, and object-file libraries.

Syntax

nm [**-A**] [**-C**] [**-X** {**32**|**64**|**32_64**|**d64**| **any**}] [**-f**] [**-h**] [**-l**] [**-p**] [**-r**] [**-T**] [**-v**] [**-B** | **-P**] [**-e** | **-g** | **-u**] [**-d** | **-o** | **-x** | **-t** *Format*] *File* ...

Description

The **nm** command displays information about symbols in the specified *File*, which can be an object file, an executable file, or an object-file library. If the file contains no symbol information, the **nm** command reports the fact, but does not interpret it as an error condition. The **nm** command reports numerical values in decimal notation by default.

The **nm** command writes the following symbol information to standard output:

- **Library** or **Object Name**

  The **nm** command reports either the library or the object name associated with the file only if you specify the **-A** option.
- **Symbol Name**
- **Symbol Type**

  The **nm** command represents the file's symbol type with one of the following characters (with weak symbols represented by the same characters as global symbols):

Item	Description
A	Global absolute symbol.
a	Local absolute symbol.
B	Global bss symbol.
b	Local bss symbol.
D	Global data symbol.
d	Local data symbol.
f	Source file name symbol.
L	Global thread-local symbol (TLS).
l	Static thread-local symbol (TLS).
T	Global text symbol.
t	Local text symbol.
U	Undefined symbol.

- **Value**
- **Size**

  The **nm** command reports the size associated with the symbol, if applicable.

Flags

Item	Description
-A	Displays either the full path name or library name of an object on each line.
-B	Displays output in the Berkeley Software Distribution (BSD) format: `value type name`
-C	Suppresses the demangling of C++ names. The default is to demangle all C++ symbol names. **Note:** Symbols from C++ object files have their names demangled before they are used.
-d	Displays a symbol's value and size as a decimal. This is the default.
-e	Displays only static and external (global) symbols.
-f	Displays full output, including redundant .text, .data, and .bss symbols, which are normally suppressed.
-g	Displays only external (global) symbols.
-h	Suppresses the display of output header data.

Item	Description
-l	Distinguishes between WEAK and GLOBAL symbols by appending a * to the key letter for WEAK symbols. If used with the **-P** option, the symbol type for weak symbols is represented as follows: **V** Weak Data Symbol **W** Weak Text Symbol **w** Weak Undefined Symbol **Z** Weak bss Symbol
-o	Displays a symbol's value and size as an octal rather than a decimal number.
-P	Displays information in a standard portable output format: `library/object name name type value size` This format displays numerical values in hexadecimal notation, unless you specify a different format with the **-t**, **-d**, or **-o** flags. The **-P** flag displays the **library/object name** field only if you specify the **-A** flag. Also, the **-P** flag displays the **size** field only for symbols for which size is applicable.
-p	Does not sort. The ouput is printed in symbol-table order.
-r	Sorts in reverse order.
-t *Format*	Displays numerical values in the specified format, where the *Format* parameter is one of the following notations: **d** Decimal notation. This is the default format for the **nm** command. **o** Octal notation. **x** Hexadecimal notation.
-T	Truncates every name that would otherwise overflow its column, making the last character displayed in the name an asterisk. By default, **nm** displays the entire name of the symbols listed, and a name that is longer than the width of the column set aside for it causes every column after the name to be misaligned.
-u	Displays only undefined symbols.
-v	Sorts output by value instead of alphabetically.
-x	Displays a symbol's value and size as a hexadecimal rather than a decimal number.

Item	Description
-X *mode*	Specifies the type of object file **nm** should examine. The *mode* must be one of the following: **32** Processes only 32-bit object files **64** Processes only 64-bit object files **32_64** Processes both 32-bit and 64-bit object files **d64** Examines discontinued 64-bit XCOFF files (magic number == U803XTOCMAGIC). **any** Processes all of the supported object files. The default is to process 32-bit object files (ignore 64-bit objects). The *mode* can also be set with the **OBJECT_MODE** environment variable. For example, **OBJECT_MODE=64** causes **nm** to process any 64-bit objects and ignore 32-bit objects. The **-X** flag overrides the **OBJECT_MODE** variable.

Note: The **nm** command supports the **—** (double hyphen) flag. This flag distinguishes a *File* operand if the file name can be misinterpreted as an option. For example, to specify a file name that begins with a hyphen, use the **—** flag.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To list the static and external symbols of the object file a`.out`, enter:

```
nm -e a.out
```

2. To display symbol sizes and values as hexadecimal and sort the symbols by value, enter:

```
nm -xv a.out
```

3. To display symbol of all 64-bit objects in **libc.a**, ignoring all 32-bit objects:

```
nm -X64 /usr/lib/libc.a
```

Files

Item	Description
/usr/ccs/bin/nm	Contains the **nm** command.

nmon Command

Purpose

Displays local system statistics in interactive mode and records system statistics in recording mode.

Syntax

Interactive mode

nmon [**-h**]

nmon [**-s** < *seconds* >] [**-c** < *count* >] [**-b**] [**-B**] [**-g** < *filename* >] [**-k** *disklist*] [**-C** < process1:process2:...:processN >] [**-i**]

Recording mode

nmon [**-f** | **-F** *filename* | **-x** | **-X** | **-z**] [**-r** < *runname* >] [**-t** | **-T** | **-Y**] [**-s** *seconds*] [**-c** *number*] [**-w** *number*] [**-l** *dpl*] [**-d**] [**-g** *filename*] [**-k** *disklist*] [**-C** <process1:process2:...:processN >] [**-G**] [**-K**] [**-o** *outputpath*] [**-D**] [**-E**] [**-J**] [**-V**] [**-P**] [**-M**] [**-N**] [**-W**] [**-S**] [**-^**] [**-O**] [**-L**] [**-I** *percent*] [**-A**] [**-m** < *dir* >] [**-Z** *priority*] [**-i**] [**-y** *options*]

Note: In recording mode, specify only one of the **-f**, **-F**, **-z**, **-x**, or **-X** flags as the first argument.

Description

The **nmon** command displays and records local system information. The command can run either in interactive or recording mode. If you specify any of the **-F**, **-f**, **-X**, **-x**, and **-Z** flags, the **nmon** command is in recording mode. Otherwise, the **nmon** command is in interactive mode.

The **nmon** command provides the following views in interactive mode:

- Adapter I/O statistics (pressing the **a** key)
- AIO processes view (pressing the **A** key)
- Detailed Page Statistics (pressing the **M** key)
- Disk busy map (pressing the **o** key)
- Disk groups (pressing the **g** key)
- Disk statistics (pressing the **D** key)
- Disk statistics with graph (pressing the **d** key)
- ESS vpath statistics view (pressing the **e** key)
- Fibre Channel adapter statistics (pressing the **^** key)
- JFS view (pressing the **j** key)
- Kernel statistics (pressing the **k** key)
- Long term processor averages view (pressing the **l** key)
- Large page analysis (pressing the **L** key)
- Memory and paging statistics (pressing the **m** key)
- Network interface view (pressing the **n** key)
- NFS panel (pressing the **N** key)
- Paging space (pressing the **P** key)
- Process view (pressing the **t** and **u** keys)
- Processor usage small view (pressing the **c** key)
- Processor usage large view (pressing the **C** key)
- Shared Ethernet adapter statistics (pressing the **O** key)

- Shared-processor logical partition view (pressing the **p** key)
- System resource view (pressing the **r** key)
- Thread level statistics (pressing the **i** key)
- Verbose checks OK/Warn/Danger view (pressing the **v** key)
- Volume group statistics (pressing the **V** key)
- WLM view (pressing the **W** key)

In the recording mode, the command generates the **nmon** files. You can view these files directly by opening them or with post-processing tools such as nmon analyzer. The **nmon** tool disconnects from the shell during the recording so that the command continues running even if you log out.

If you use the same set of keys every time you start the **nmon** command, you can place the keys in the NMON shell variable. For example, you can run the following command:

```
export NMON=mcd
```

Then run the **nmon** command.

To stop the **nmon** command from the command line, use the **kill -USR2** with the nmon process ID.

To print the background process IDs of the nmon recording, run the **nmon** command with the **-p** flag.

To limit the processes that the **nmon** command lists (online and to a file), you can utilize the following options:

- Set the program names in environment variables from **NMONCMD0** to **NMONCMD63**
- Use the **-C** flag with *cmd:cmd:cmd* parameter. For example, you can enter the following command:

```
nmon -C ksh:vi:syncd
```

To limit the disks that the **nmon** lists to a maximum of 64 (online only), use the **-k** flag with the *diskname* parameter. For example, you can enter the following command:

```
nmon -k hdisk2,hdisk0,hdisk3
```

The **nmon** tool disconnects from the shell during the recording, ensuring that the command continues running even if you log out. This function is not true in the case of recordings triggered using the on-demand recording facility.

Recording or monitoring journaled file system (JFS) statistics in nmon can prevent unloading a file system because the file system is in use while collecting statistics.

Inside workload partitions (WPAR), the **nmon** command shows global values for processors and memory statistics. The rest of the values are WPAR specific. The following statistics cannot be retrieved inside a WPAR, and the **nmon** screen does not support them inside a WPAR:

- Disks, disk I/O graphs, disk busy map, disk groups
- Disk adapters
- Paging space
- Volume group
- ESS/vpaths
- Fibre Channel adapters
- VIOS Shared Ethernet adapters

Note: The dynamic configuration changes applied to the system are not reflected in the current **nmon** recording. The nmon tool must be restarted for the new configuration changes to take effect.

Flags in Interactive Mode

You can use the following flags in the interactive mode.

Item	Description
-s < *seconds* >	Time interval between refreshing the screen. The default value is 2 seconds.
-c < *count* >	Number of times the screen must be refreshed.
-g < *filename* >	A file that contains user-defined disk groups that can be specified using the *filename* parameter. Each line in the file begins with a group name. The list of hard disks follows the group name and is separated by spaces. The file can contain a maximum of 64 disk groups. A hard disk can belong to various disk groups.
-b	Displays the view in black and white mode.
-B	Does not include boxes in the view. By default, the command displays boxes.
-h	Displays help information.
-k < *disklist* >	Reports only the disks in the disk list.
-i	Reports top thread level CPU utilization.

Flags in Recording Mode

Item	Description
-A	Includes the Asynchronous I/O section in the view.
-c	Specifies the number snapshots that must be taken by the command. The default value is 10000000.
-d	Includes the Disk Service Time section in the view.
-D	Skips the Disk Configuration section.
-E	Skips the ESS Configuration section.
-f	Specifies that the output is in spreadsheet format. By default, the command takes 288 snapshots of system data with an interval of 300 seconds between each snapshot. The name of the output file is in the format of *hostname_YYMMDD_HHMM***.nmon**.
-F	Specifies that the output is in spreadsheet format and the name of the output file is *filename*. The *filename* parameter specifies the name of the output file.
-g	Specifies the file that contains the user-defined disk groups, using the *filename* parameter. Each line in the file begins with a group name. The list of disks follows the group name and is separated with spaces. The file can contain a maximum of 64 disk groups. A disk can belong to various disk groups.
-G	Uses Greenwich mean time (GMT) instead of local time. This method is helpful when you compare nmon files from many LPARof 1 system for processor view but the LPARare in different time zones.
-i	Reports thread level statistics.
-I	Specifies the percentage of process threshold at which the command ignores the TOP processes statistics. The default percentage is zero. The command does not save the TOP processes statistics if the process is using less processor power than the specified percentage.
-J	Skips the JFS section.
-k	Specifies a list of disks to be recorded.

Item	Description
-K	Includes the RAW Kernel section and the LPAR section in the recording file. The **-K** flag dumps the raw numbers of the corresponding data structure. The memory dump is readable and can be used when the command is recording the data.
-l	Specifies the number of disks to be listed on each line. By default, 150 disks are listed per line. For EMC disks, specify a value of 64.
-L	Includes the large page analysis section.
-m	Changes the directory before the command saves the data to a file.
-M	Includes the MEMPAGES section in the recording file. The MEMPAGES section displays detailed memory statistics per page size.
-N	Includes the NFS section in the recording file. To collect the NFSv4 statistics, specify **-NN**.
-o	Specifies the file name or directory to which the recorded file is to be stored.
-O	Includes the Shared Ethernet adapter (SEA) VIOS sections in the recording file.
-P	Includes the Paging Space section in the recording file.
-r	Specifies the value for the *runname* field written to the spreadsheet file. By default, the value is the hostname.
-s	Specifies the interval in seconds between 2 consecutive recording snapshots.
-S	Includes WLM sections with subclasses in the recording file.
-t	Includes the top processes in the output. You cannot specify the **-t**, **-T**, or **-Y** flags with each other.
-T	Includes the top processes in the output and saves the command-line arguments into the UARG section. You cannot specify the **-t**, **-T**, or **-Y** flags with each other.
-V	Includes disk volume group section.
-w	Specifies the size of timestamp (Tnnnn) to be recorded. The timestamp is recorded in the **.csv** file. The value of the *number* parameter ranges from 4 through 16. For NMON analyzer, use the values 4 or 8.
-W	Includes the WLM sections into the recording file.
-x	Specifies the sensible spreadsheet recording for duration of 1 day for capacity planning. By default, the recording is done every 900 seconds for 96 times. This flag is equivalent to **-ft -s 900 -c 96**.
-X	Specifies the sensible spreadsheet recording for duration of 1 hour for capacity planning. By default, the recording is done every 30 seconds for 120 times. This flag is equivalent to **-ft -s 30 -c 120**.

Item	Description
-y options	Controls the nmon recording sections. The values of the **options** parameter must be separated by commas. The following values are valid for the **options** parameter: **sub=sea** Records the SEA Bridged adapters statistics. **sub=ssp** Records the shared storage pool (SSP) statistics. **PCPU=[on | off]** Enables or disables recording of Physical CPU (PCPU) sections, which are nothing but metrics that start with PCPU. These metrics are based on Processor Utilization of Resources Register (PURR). The default value is off. You can specify the following values for the PCPU section: **on** Enables recording of the PCPU section. **off** Disables recording of the PCPU section. **SCPU=[on | off]** Enables or disables recording of Scaled CPU (SCPU) sections, which are metrics that start with SCPU. These metrics are based on Scaled Processor Utilization of Resources Register (SPURR). Default value is off. You can specify the following values for the SCPU section: **on** Enables recording of the SCPU section. **off** Disables recording of the SCPU section. **dfreq=[on | off]** Enables or disables frequency sections, which are metrics that start with CPUMHZ. These metrics are based on the POWER options that are set. Default value is off. You can specify the following values for the dfreq section: **on** Enables recording of the CPUMHZ section. **off** Disables recording of the CPUMHZ section. **Note:** The value reported in the currentMHz column in CPUMHZ can vary slightly from the actual processor speed depending on conditions such as system load. The latest values of the **options** parameter override the previous values if the same value is used more than once in the command line. **Example:** If you run the command "`nmon -f -y PCPU=on -y PCPU=off`", the value *off* is used for the PCPU option.
-Y	Includes the top process in the recording with all of the commands of the same name added and recorded. You cannot specify the **-t**, **-T**, or **-Y** flags together.
-z	Specifies the sensible spreadsheet recording for duration of 1day for capacity planning. By default, the recording is done every 900 seconds for 96 times. This flag is equivalent to **-f -s 900 -c 96**.

Item	Description
-Z	Specifies the priority of the **nmon** command that is running. A value of -20 means important. A value of 20 means not important. Only root user can specify negative value.
-^	Includes the Fibre Channel (FC) sections.

Parameters

Item	Description
disklist	Specifies a list of disks.
dir	Specifies a directory.
dpl	Specifies the number of disks to list on each line.
filename	Specifies a file that contains the disk group you select.
number	Specifies the number of refreshes.
count	Specified the number of times to record.
percent	Specifies the percentage of processor usage.
priority	Specifies the priority of processes to be run.
runname	Specifies the value for the *runname* field in the spreadsheet file to be run.
seconds	Specifies the interval, in seconds, of refreshing the snapshot.
outputpath	Specifies the path for the output file.

Subcommands

Item	Description
space	Refreshes the screen immediately.
.	Displays only busy disks and processes.
~	Switches to the **topas** screen.
^	Displays the Fibre Channel adapter statistics
+	Doubles the screen refresh time.
-	Decreases the screen refresh time by half.
0	Resets the peak values of statistics (displayed on the screen) to zero. Applicable only for panels that display peak values.
a	Displays the I/O statistics of the adapters.
A	Summarizes the Async I/O (AIO server) processes.
b	Displays the view in black and white mode.
c	Displays processor statistics with bar graphs.
C	Displays processor statistics. It is useful for comparison when the number of processors ranges from 15 to 128.
d	Displays the I/O information of disks. To display specific disks only, specify the **-k** flag.
D	Displays the I/O statistics of disks. To get additional statistics of the disks, press the **D** key more than once.

Item	Description
e	Displays the I/O statistics of the ESS virtual path logical disks.
g	Displays the I/O statistics of the Disk Group. You must specify the **-g** flag with this key.
h	Displays the online help information.
j	Displays the JFS statistics.
k	Displays the internal statistics of the kernel.
l	Displays the processor statistics in long format. More than 75 snapshots are displayed with bar graphs.
m	Displays the memory and paging statistics.
M	Displays multiple page size statistics in pages. If you press the **M** key twice, the statistics are displayed in megabytes.
n	Displays the network statistics.
N	Displays the statistics of the NFS Network file system. If you press the **N** key twice, you see the NFSv4 statistics.
o	Displays the map of Disk I/O.
O	Displays only the Shared Ethernet adapter VIOS.
p	Displays the statistics of the partitions.
P	Displays the statistics of the paging space.
q	Quits. You can also use the **x**, or Ctrl+C key sequence.
r	Displays the resource type, system name, cache details, AIX version, and the LPAR information.
S	Displays the WLM with subclasses.
t	Displays the statistics of top processes. You can press the following keys with this subcommand: • 1: Displays basic details. • 2: Displays accumulated process information. • 3: Sorts the view by processor. • 4: Sorts the view by size. • 5: Sorts the view by I/O information.
u	Displays the top processes with the command arguments. To refresh the arguments for new processes, press the **u** key twice.
U	Displays the top processes with the command arguments, and the workload class or workload partitionworkload partition information.
v	Highlights status of pre-defined system resources and categorizes them as either danger, warnings, or normal.
V	Displays the statistics of the Disk Volume Group.
w	Displays the wait processes when used with the top processes.
W	Displays the statistics of the Workload Manager (WLM).
[	Triggers a custom on-demand recording. The recording initiated exits along with the interactive **nmon** if not stopped earlier.
]	Stops a custom recording triggered by **]** .

Output Details

This section provides explanations to the metrics that are displayed on nmon screen.

System resources view

This view provides general information about the system resources. To display this view, press the **r** key. It contains information about the following resources:

- The number of processors in the system.
- The number of online processors that are active in the system.
- The frequency of the processors.
- The version of AIX and its technical level.
- The type of the running kernel.
- The logical partition.
- The power savings mode of the logical partition.
- The model of the hardware.
- The processor architecture of the system.
- The type of the platform bus.
- The cache information of processors.
- The number of active events.
- The old serial number. This number is the system ID of the partition before the dynamic configuration event.
- The current serial number. This number is the current system ID or the system ID of the partition after the dynamic configuration event.
- The local time of the last dynamic reconfiguration event. This information is labeled with the "When" keyword.
- The sub processor mode of the logical partition.

AIO Processes View

The AIO processes view provides information about the asynchronous I/O (AIO) processes. To display this view, press the **A** key. The following columns are displayed on the screen:

Item	Description
Total AIO Processes	The total number of AIO processes.
Actually in use	The number of AIO processes that uses more than 0.1% of the processor.
CPU Used	The percentage of the processor that is used by all of the kernel processes.
All time peak	The maximum number of kernel processes that are running since the system starts.
Recent peak	The recent maximum number of kernel processes that use more than 0.1% of the processor.
Peak	The maximum percentage of the processor that is used by all of the kernel processes.

Process View

The **Process View** provides details of the processes in the system. To display this view, press the **t** key or the **v** key. It contains the following columns are displayed on the screen:

Item	Description
pid	The ID of the process.

Item	Description
ppid	The ID of the parent process.
User	The user ID of the process.
Proc Group	The ID of the process group.
Nice	The initial priority of a process. This value is set by the **nice** command.
Priority	The base schedule priority of a process.
Status	The status of a program.
Proc_Flag	The flag of a process.
Thrds	The number of threads.
Files	The maximum file index that is in use.
Foreground	Foreground process or background process.
Command	The name of the command.
Time Start	The time when the command started.
CPU-Total	The total time that the process takes since it starts.
Child Total	The total time that the child process takes since it starts.
Delta-Total	The total time taken by the process in the interval.
%CPU Used	The percentage of the processor that is used in the last interval.
Size KB	The size of the pages in kilobytes.
Res Size	The sum of real-memory data (resident set) and real-memory (resident set) text size of the process.
Res Set	The sum of real-memory data (resident set) and real-memory (resident set) text size of the process.
Res Text	The real-memory text size of the process.
Res Data	The real-memory data size of the process.
Char I/O	The number of I/O characters per second from the last interval.
RAM Use	The percentage of the RAM that is used.
Paging I/O	The I/O page faults per second in the last interval.
Paging Other	The non-I/O page faults per second in the last interval.
Paging Repages	The number of repage faults per second in the last interval.
Class	The Workload Manager class name of the process.

Processor Usage Small View

The Processor Usage Small View provides a brief summary of the user, system, idle, and wait time of logical processors, the corresponding entitlement, and the virtual processor used. You can generate the Processor Usage Small View by pressing the **c** key.

Processor Usage Large View

The Processor Usage Large View displays the use of logical processor in a graph. To display this view, you can press the **C** key.

The following labels are used to identify time that is spent in different modes:

- **s**: Labels the percentage of time that is spent in system mode
- **u**: Labels the percentage of time that is spent in user mode

Shared-Processor Logical Partition View

The Shared-Processor Logical Partition View includes flags that indicate the following information of a partition:

- Whether the partition is an LPAR or not
- Whether the partition can be an LPAR or not
- Whether the partition is shared or dedicated
- Whether the SMT is turned on or off
- Whether the shared-partition is capped or uncapped
- Whether LPAR is SMT bound or enabled
- Whether the LPAR flags are set, and whether they are set to display a value greater than AVG=lp

If the flags are set, the **nmon+C** graph contains information about the Cpu_user and the Avg_user, respectively. You can view the graph in the right column.

To display this view, you can press the **p** key.

Processors:

The following metrics of the processor status are displayed in this view:

Item	Description
Max Phys in Sys	Maximum number of physical processors in the system
Phys CPU in system	Number of physical processors in the system
Virtual Online	Number of online virtual processors
Logical online	Number of online logical processors
Physical pool	Number of shared physical processors in the shared pool ID that this partition is assigned to
SMT threads/CPU	Number of SMT threads per processor

Capacity:

The following information displays the processor capacity:

Item	Description
Cap. Processor Min	Minimum number of processing units that are defined for this LPAR
Cap. Processor Max	Maximum number of processing units that are defined for this LPAR
Cap. Increment	Granularity at which changes to the entitled capacity can be made
Cap. Unallocated	Sum of the number of processor units that are unallocated from shared LPARin an LPAR group
Cap. Entitled	Entitled capacity
MinReqVirtualCPU	Minimum required virtual processors for the LPAR

ID Memory:

The following metrics of the ID memory are displayed:

Item	Description
LPAR ID Group:Pool	ID of an LPAR group and its pool ID
Memory (MB/GB) Min:Max	Minimum and maximum memory that is defined for this LPAR in megabytes or gigabytes
Memory(MB/GB) Online	Online real memory in megabytes or gigabytes

Item	Description
Memory Region LMB	Size in bytes of one logical memory block (LMB)

Time (in seconds):

Item	Description
Time Dispatch Wheel	Interval during which each virtual processor receives its entitlement
MaxDispatch Latency	Maximum latency in seconds between the dispatch of the LPAR on the physical processors
Time Pool Idle	Time in seconds that the shared processor pool is idle
Time Total Dispatch	Total time in seconds that the LPAR dispatches

Minimum and Maximum Values of Processors

The following minimum and maximum values of processors are displayed:

Item	Description
Virtual CPU (Min - Max)	Minimum number and maximum number of virtual processors in the LPAR definition
Logical CPU (Min - Max)	Minimum number and maximum number of logical processors

Weight

The following information about the weight of the processor is displayed:

Item	Description
Weight Variable	Variable weight of the processor capacity
Weight Unallocated	Unallocated variable weight available for this partition

NFS Panel

The NFS Panel provides information about the Network File System (NFS). To display this view, press the **N** key. The following metrics are included in the view:

Item	Description
Root	NFS V2 server and client root requests
Wrcache	NFS server and client write cache requests
Null	NFS server and client write cache requests
Getattr	NFS server and client get attributes requests
Setattr	NFS server and client set attributes requests
Lookup	NFS server and client filename lookup requests
Readlink	NFS server and client read link requests
Read	NFS server and client read requests
Write	NFS server and client write requests
Create	NFS server and client file creation requests
Mkdir	NFS server and client directory creation requests
Symlink	NFS server and client symbolic link creation requests
Remove	NFS server and client file removal requests

Item	Description
Rmdir	NFS server and client directory removal requests
Rename	NFS server and client file renaming requests
Link	NFS server and client link creation requests
Readdir	NFS server and client read-directory requests
Fsstat	NFS server and client file-status requests
Access	NFS V3 server and client access requests
Mknod	NFS V3 server and client **mknod** creation requests
readdir+	NFS V3 server and client read-directory plus requests
Fsinfo	NFS V3 server and client file information requests
Pathconf	NFS V3 server and client path configuration requests
Commit	NFS server and client commit requests
Bad calls	NFS server and client failed calls
Calls	NFS server and client requests

The following NFS V4 client/server statistics are printed when you press the **N** key twice.

Item	Description
Access	NFS V4 server and client access requests
acl_read	NFS V4 client reading access control list (ACL)
acl_stat_l	NFS V4 client that is retrieving long ACL information
acl_write	NFS V4 client write access control list (ACL)
Clntconfirm	NFS V4 client confirm operations
Close	NFS V4 client closing files
Commit	NFS V4 server and client committed
Compound	NFS V4 server compound calls
Create	NFS V4 server and client that is creating a non-regular object
Delegpurge	NFS V4 server purge delegations that is awaiting recovery
Delegreturn	NFS V4 server and client that is returning delegation
Finfo	NFS V4 client that is obtaining file information
getattr	NFS V4 server and client retrieving attributes
getfh	NFS V4 server retrieving file handles
Link	NFS V4 server and client that is linking operations
Lock	NFS V4 server and client that is locking operations
lockt/test	NFS V4 server that is testing the specified lock or NFS V4 client lock test
locku/unlock	NFS V4 server or NFS V4 client unlock operations
lookup	NFS V4 server and client that is looking up filenames
lookupp	NFS V4 server that is looking up parent directories
mkdir	NFS V4 client that is creating directories
mknod	NFS V4 client that is creating special files

Item	Description
Null	NFS V4 server null calls or NFS V4 client null calls
nverify	NFS V4 server verifying difference in attributes
openattr	NFS V4 server opening named attribute directories
openconfirm	NFS V4 server and client that is confirming the open for usage
opendowngrade	NFS V4 server and client that is downgrading the access for a specified file
Open	NFS V4 server and client open operations
operations	NFS V4 server and client operations
pcl_read	NFS V4 client extracting numeric data from printer control language (PCL) files
pcl_readstat_l	NFS V4 client **pcl_stat** long operations
pcl_stat	NFS V4 client **pcl_stat** operations
pcl_write	NFS V4 client **pcl_write** operations
putfh	NFS V4 server setting current file handles
putpubfh	NFS V4 server setting public file handles
putrootfh	NFS V4 server setting root file handles
readdir	NFS V4 server and client reading directories
readlink	NFS V4 server and client reading symbolic links
Read	NFS V4 server and client reading data from files
release	NFS V4 server and client **release_lock** operations
remove	NFS V4 server and client removing file system object
rename	NFS V4 server and client renaming object names
renew	NFS V4 server and client renewing leases
replicate	NFS V4 client replicate operations
restorefh	NFS V4 server restoring file handles
rmdir	NFS V4 client removing directories
savefh	NFS V4 server saving file handles
secinfo	NFS V4 server and client obtaining security information
setattr	NFS V4 server and client setting object attributes
setclient	NFS V4 server and client **setclient** operations
statfs	NFS V4 client file statistics requests
symlink	NFS V4 client symbolic link operations
verify	NFS V4 client verifying same attributes
write	NFS V4 server and client writing to files

Network Interface View

The Network Interface View shows the statistics errors for the network. You can view this information by pressing the **n** key.

If the screen is updated three times with no network errors, the Network Interface View does not contain the network error statistics.

The following metrics are displayed in this view:

Item	Description
I/F Name	Interface name
Recv-KB/s	Data that are received in kilobytes per second in the interval
Trans-KB/s	Data that are transmitted in kilobytes per second in the interval
Packin	Number of packets that are received in the interval
Packout	Number of packets that are sent in the interval
Insize	Average size of packet that is received in the interval
Outsize	Average size of packet that is sent in last interval
Peak->Recv	Peak value of received data in kilobytes per second
Peak->Trans	Peak value of sent data in kilobytes per second
Total Recv	Total received data in megabytes per second
Total Sent	Total sent data in megabytes per second
MTU	Maximum size of transport unit in bytes
Ierror	Number of input errors
Oerror	Number of output errors
Collision	Number of collisions
Mbits/s	Adapter bit rate in megabits (Mbits) per second. If the network adapter is larger than 10Gb, the adapter bit rate is shown as 10240 Mbits per second.
Description	Description of the interface

WLM View

The WLM View shows the information about workload management. You can open this view by pressing the **W** key. To turn on the subclasses section, press the **S** key from WLM View. To turn off the subclasses section, press the **S** key again.

The following metrics are displayed in this view:

Item	Description
CPU	Percentage of processor use of the class.
MEM	Percentage of physical memory use of the class.
BIO	Percentage of disk I/O bandwidth use for the class.
Process (Procs)	Number of processes in the class.
Tier (T)	Tier number. The value ranges from zero through nine.
Inheritance (I)	Values of the inheritance attribute. A value of zero means no. A value of one means yes.
Location	Values of location. A value of one means avoiding transfer of segments to shared classes. Otherwise, a value of zero is displayed.

Disk Busy Map

The Disk Busy Map shows the use statistics of disks. To display this map, press the **o** key. A maximum of 100 disks is shown per screen. Only the disks with the names that range from hdisk0 through hdisk100 are displayed. The following table shows the symbols for the ranges of names.

Symbols	Names
_	Less than 5

Symbols	Names
.	Less than 10
-	Less than 20
+	Less than 30
o	Less than 40
0	Less than 50
O	Less than 60
8	Less than 70
X	Less than 80
#	Less than 90
@	Less than 100 and equal to 100

Disk Groups

Multiple disks can be monitored by placing them in groups. To display this view, press the **g** key.

You must create a group configuration file that contains the lines as shown in the following example:

```
<Group_name1> <disk_name1> <disk_name2> ....
<Group_name2> <disk_nameA> <disk_nameB> ...
```

In the example, <Group_name1> is the name of the first disk in the group; <disk_name1> and <disk_name2> are the first and second disks in the group.

To see the Disk Group I/O, run the **nmon** command with the **-g** flag and a group file, and then press the **g** key. The following metrics are shown in this view:

Item	Description
Name	Disk Group name. You can specify a maximum of 64 groups. A disk can be in multiple groups.
Disks	Number of disks in the group.
Read/Write-KB/s	Data transfer rate of read and written data in kilobytes per second in the interval.
TotalMB/s	Sum of read and written data in megabytes per second in the interval.
Xfers/s	Number of read and written data transfers per second in the interval.
BlockSizeKB	Block size in kilobytes read or written per transfer operation.

ESS Vpath Statistics View

This view provides the ESS Vpath Statistics. To display this view, press the **e** key. The following metrics are included in this view:

Item	Description
Name	Name of the virtual path.
Size	Size of the ESS path.
AvgBusy	Average busy use of the disk.
Write-KB/s	Transfer rate of written data in kilobytes per second in the interval.
Read-KB/s	Transfer rate of read data in kilobytes per second in the interval.
Xfers/s	Number of read and write transfers per second.

Item	Description
Total vpaths	Number of virtual paths.

JFS View

This view provides the Journaled File System (JFS) statistics. To display this view, press the **j** key. The following statistics are recorded in this view:

Item	Description
FileSystem	Name of the file system.
Size (MB)	Size in megabytes for the file system.
Free (MB)	Available free space in megabytes in the file system.
%Used	Percent of file system used.
%Inodes	Percent of file system that is used by i-nodes.
Mount point	Local mount point.

Kernel Statistics

This view contains the statistics of the kernel. To display this view, press the **k** key. The following statistics are displayed in this view:

Item	Description
runqueue	Average number of threads that are ready to run but are waiting for an available processor.
pswitch	Number of processor switches per second in the interval.
fork	Number of forks per second in the interval.
exec	Number of execs per second in the interval.
msg	Number of interprocess communication (IPC) messages that are sent and received per second in the interval.
sem	Number of semaphore operation system calls per second in the interval.
hw intrp	Number of device interrupts per second in the interval.
sw intrp	Number of off-level handlers that are called per second in the interval.
Swapin	Number of processes in swap queue per second in the interval.
Syscall	Number of system calls per second in the interval.
read	Number of read calls per second in the interval.
write	Number of write calls per second in the interval.
readch	Number of characters that are transferred through read system call per second in the interval.
Writech	Number of characters that are transferred through write system call per second in the interval.
R + W (MB/s)	Number of read and write characters in megabytes per second in the interval.
Uptime	Time duration for which the system is up.
iget	Number of inode lookups per second in the interval.
dirblk	Number of 512-byte block reads by the directory search routine to locate an entry for a file per second in the interval.
namei	Number of vnode lookup from a path name per second in the interval.

Item	Description
ksched	Number of kernel processes that are created per second in the interval.
koverf	Number of kernel process creation attempts where the user forked to the maximum limit or the configuration limit of processes that are reached per second in the interval.
kexit	Number of kernel processes that become zombies per second in the interval.

Long Term Processor Averages View

This view provides information about the instantaneous system. To display this view, press the **l** key. You can use the following labels to identify the time that is spent in different modes:

- **s**: Labels the percentage of the time that is spent in system mode.
- **u**: Labels the percentage of the time that is spent in user mode.
- **w**: Labels the percentage of the time that is spent in wait mode.

The following metrics are displayed on this view:

Item	Description
EntitledCPU	Entitled capacity of the partition.
UsedCPU	Number of physical processors that are used by the partition.

Large Page Analysis

This view provides analysis of the large page. To display this view, press the **L** key. The following information is displayed:

Item	Description
Count	Number of large pages and their total size.
Free	Percentage of free large pages and their size.
In Use	Percentage of large pages in use and their size.
Size	Size of a large page.
High water mark	Large page high watermark.

Paging Space

This view prints the paging-space statistics. To display this view, press the **p** key. The following metrics are displayed in the view:

Item	Description
PagingSpace	Number of paging spaces.
Volume-Group	Number of volume groups.
Type	Type of logical volumes. The types can be NFS or LV.
LPs	Size of logical partitions.
MB	Size in megabytes.
Used	Percentage of use for volume groups.
IOpending	Number of pending I/O in the paging space.
Active/Inactive	Active or inactive paging space.
Auto/NotAuto	Indicates whether the paging space is auto that is loaded or not.

Volume Group Statistics

This view provides statistics for the volume group. To display this view, press the **V** key. The following information is displayed in the view:

Item	Description
Name	Volume group name.
Disks	Number of disks in the group.
AvgBusy	Average busy of the disks in the volume group.
Read/Write-KB/s	Data transfer rate of read and written data in kilobytes per second in the interval.
TotalMB/s	Sum of read and written data in megabytes per second in the interval.
Xfers/s	Number of read and written transfers per second in the interval.
BlockSizeKB	Block size that is read or written per transfer in kilobytes per second in the interval.

Disk Statistics

This view provides statistics for disks. To display this view, press the **D** key. You can press the **D** key for the following times to view various metrics:

- Once: Shows disk numbers
- Twice: Shows disk descriptions
- Three times: Shows service times
- Four times: Shows disk statistics with graphs similar to the graph shown on pressing the **d** key

Disk Numbers (pressing the **D** key once)

The following metrics are shown in this view:

Item	Description
Name	Name of the disks.
Busy	Average busy of the disks.
Read-KB/s	Data transfer rate of read data in kilobytes per second in the interval.
Write-KB/s	Data transfer rate of written data in kilobytes per second in the interval.
Transfers/sec	Number of read and written transfer per second in the interval.
SizeKB	Block size that is read or written per transfer in kilobytes per second in the interval.
Peak	Peak percentage of average busy.
Peak KB/s	Peak that is read and written data in kilobytes per second.
qDepth	Number of requests that are sent to disk and are not completed.
Totals Size (GB)	Total size of disks in gigabytes.
Totals Free (GB)	Total free space that is left in disks in gigabytes.
Totals Read (MB/s)	Total data transfer rate of read data from all disks in megabytes per second.
Totals Write (MB/s)	Total data transfer rate of written data to all disks in megabytes per second.

Disk Descriptions (Pressing the **D** key twice)

The following metrics are shown in this view:

Item	Description
Name	Disk names.
Size (GB)	Size of disks in gigabytes.
Free (GB)	Free space that is left in disk in gigabytes.
Disk Paths	Number of paths that are defined to the disk.
Disk Adapter	Name of disk adapters.
Volume Group	Volume group that the disk belongs to.
Disk Description	Description of the disk.
Totals Size (GB)	Total size of disks in gigabytes.
Totals Free (GB)	Total free space that is left in disks in gigabytes.
Totals Read (MB/s)	Total data transfer rate of read data from all disks in megabytes per second.
Totals Write (MB/s)	Total data transfer rate of written data to all disks in megabytes per second.

Service Times (Pressing the **D** key three times)

The following metrics are displayed in the view:

Item	Description
Disk	Name of the disk.
Service (in msecs)	Average service time per request in milliseconds.
Wait (in msecs)	Average waiting time per request in milliseconds.
ServQ size	Average number of requests in service queue.
WaitQ size	Average number of requests that is waiting to be accomplished.
ServQ Full	Number of times the disk is not accepting any coming requests.
Totals Size (GB)	Total size of disks in gigabytes.
Totals Free (GB)	Total free space that is left in disks in gigabytes.
Totals Read (MB/s)	Total data transfer rate of read data from all disks in megabytes per second.
Totals Write (MB/s)	Total data transfer rate of written data to all disks in megabytes per second.

Disk Statistics With Graphs (Pressing the **D** key four times)

This view displays disk statistics with graphs. To display this view, press the **d** key. The following metrics are displayed in this view:

Item	Description
Name	Name of the disk.
Busy	Average percentage of busy for the disk.
Read-KB/s	Data transfer rate of read data in kilobytes per second.
Write-KB/s	Data transfer rate of written data in kilobytes per second.

Memory and Paging Statistics

The view provides information about the memory and paging statistics. To display this view, press the **m** key. The following metrics are included in this view:

Item	Description
%Used	Percentage of used space in physical memory and paging space.
%Free	Percentage of free space in physical memory and paging space.
MB Used	Physical memory and paging space that are used in megabytes.
MB Free	Physical memory and paging space that are free in megabytes.
Pages/sec to Paging Space	Number of I/O pages that are transferred to or from the paging space per second.
Pages/sec to file system	Number of I/O pages that are transferred to or from the file system per second.
Page Scans	Number of page scans by clock.
Page Faults	Number of page faults.
Page Cycles	Number of page replacement cycles.
Page Steals	Number of pages steals.
Numperm	Number of frames that are used for files (in 4-KB pages).
Process	Percentage of real memory that is used by process segments.
System	Percentage of real memory that is used by system segments.
Free	Percentage of real memory that is free.
Total	Percentage of total real memory used.
Min/Maxperm	The **minperm** and **maxperm** values for page steals.
Min/Maxfree	The **minfree** and **maxfree** pages free list.
Min/Maxpgahead	Minimum and maximum number of page ahead pages.
Total Virtual	Total virtual memory.
Accessed Virtual	Active virtual memory.
Numclient	Number of client frames.
Maxclient	Maximum number of client frames.
User	Real memory that is used by non-system segments.
Pinned	Real memory that is pinned.

The AMS statistics are displayed in the **topas_nmon** memory panel. To display this view, press the **m** key. The following metrics are included in this view:

Item	Description
Pool	AMS pool ID of the pool that the logical partition (LPAR) belongs to.
Weight	Weight of the variable memory.
pMem	Physical memory currently backing up the logical memory partition (in MB).
hpi	Number of hypervisor page-ins.
hpit	Time that is spent in hypervisor page-ins (in seconds).

Logical unit information:

Item	Description
Size (MB)	Total size that is allocated for the logical unit.

Item	Description
Lu Udid	Logical unit identifier.

Adapter I/O Statistics View

This view provides the adapter I/O statistics. To display this view, press the **a** key. The following metrics are displayed in this view:

Item	Description
Adapter	Name of the adapter.
Busy%	Bandwidth use of the adapter. This is the aggregate **Busy%** of the disks connected to this adapter. The value might exceed 100% if more than one disk is connected to the adapter.
Read-KB/s	Data transfer rate of read data in kilobytes per second.
Write-KB/s	Data transfer rate of written data in kilobytes per second.
Transfers	Number of read and write transfers.
Disks	Number of disks.
Adapter-Type	Type of the adapter.

Shared Ethernet adapter

This view provides shared Ethernet adapter statistics in a Virtual I/O Server (VIOS). To display this view, press the **O** key. The following metrics are displayed in this view:

Item	Description
Number	Serial number.
Name	Name of the shared Ethernet adapter.
Recv-KB/s	Data transfer rate of received data in kilobytes per second.
Trans-KB/s	Data transfer rate of sent data in kilobytes per second.
Packin	Number of packets that are received per second in the interval.
Packout	Number of packets that are sent per second in the interval.
Insize	Average size per second for received packet in the interval.
Outsize	Average size per second for outgoing packet in the interval.

Verbose Checks OK/Warn/Danger

This view prints the statistics for processor, memory, and disks. It also prints the status message, such as OK, Warn, or Danger, which is based on the system metrics that exceed the pre-defined threshold values. To display this view, press the **v** key.

Detailed Page Statistics

This view provides page statistics. To display this view, press the **M** key.

If you press the **M** key once, the view contains the statistics in pages. If you press the **M** key twice, the page statistics are shown in megabytes.

The following metrics are shown in this view:

Item	Description
Numframes	Number of real memory frames of the page size.
Numfrb	Number of pages on free list.

Item	Description
Numclient	Number of client frames.
Numcompress	Number of frames in compressed segments.
Numperm	Number of frames in non-working segments.
Numvpages	Number of accessed virtual pages.
Minfree	Minimum free list.
Maxfree	Maximum free list.
Numpout	Number of page-outs.
Numremote	Number of remote page-outs.
Numwseguse	Number of pages in use for working segments.
Numpseguse	Number of pages in use for persistent segments.
Numclseguse	Number of pages in use for client segments.
Numwsegpin	Number of pages that are pinned for working segments.
Numpsegpin	Number of pages that are pinned for persistent segments.
Numclsegpin	Number of pages that are pinned for client segments.
numpgsp_pgs	Number of allocated page spaces.
numralloc	Number of remote allocations.
pfrsvdblks	Number of system reserved blocks.
Pfavail	Number of pages available for pinning.
Pfpinavail	Application level number pages available for pinning.
system_pgs	Number of pages on segment control blocks (SCB) that are marked with **V_SYSTEM.**
nonsys_pgs	Number of pages on SCBs not marked with **V_SYSTEM.**
Numpermio	Number of pageouts in non-working storage.
Pgexct	Number of page faults.
Pgrclm	Number of pages reclaims.
Pageins	Number of paged-in pages.
Pageouts	Number of paged-out pages.
Pgspgins	Number of paged-in pages from page space.
Pgspgouts	Number of paged-out pages from page space.
Numsios	Number of I/O started.
Numiodone	Number of I/O completed.
Zerofills	Number of zero-filled pages.
Exfills	Number of exec-filled pages.
Scans	Number of page scans by clock.
Cycles	Number of clock hand cycles.
pgsteals	Number of pages steals.

Fibre Channel Adapter Statistics

This view contains information about the Fibre Channel adapter. You can see this view by pressing the caret (**-^**) key. The following metrics are included in this view:

Note: If the N_Port Virtualization (NPIV) is configured on the VIOS, use the -^ option in the **nmon** command to record the NPIV related statistics.

Item	Description
Number	Serial number.
Name	Name of the Fibre Channel adapter.
Receive-KB/s	Data transfer rate of received data in kilobytes per second.
Transmit-KB/s	Data transfer rate of sent data in kilobytes per second.
Requests In	Number of requests that are received per second in the interval.
Requests Out	Number of requests that are sent per second in the interval.
Outsize	Average outgoing packet size per second in the interval.

Thread level statistics

This view contains information about thread level statistics. To display this view, press the **-i** key. The following metrics are included in this view:

Item	Description
PID	Process ID to which the thread belongs.
TID	Top thread ID that uses higher CPU. Sorting is based on CPU utilization in descending order.
%CPU	Percentage of CPU used by the specific thread.
BOUND CPU ID	Bounded CPU ID if the thread has been bound to any processor.

Environment Variables

Environment variables **NMON_START**, **NMON_END**, **NMON_SNAP**, and **NMON_ONE_IN** are used for collecting external data while recording in nmon format.

Item	Description
NMONCMD0, NMONCMD1, ..., NMONCMD63	You can monitor only the processes that are set in these variables when these environment variables are set. Alternatively, you can use the **-C** flag to restrict the commands in the process listing of the **nmon** command. For example, you can run the **nmon -C db2:nmon:topas** command.
NMON	Contains the set of key strokes corresponding to the initial set of panels to be displayed when the **nmon** command is started.

Item	Description
NMON_TIMESTAMP	You can specify the **NMON_TIMESTAMP** variable to the following values: **NMON_TIMESTAMP = 0** The recorded lines contain the nmon Tnnnn timestamps at the beginning of the line and work with the nmon data file. **NMON_TIMESTAMP = 1** The lines contains timestamps that have the hours, minute, seconds, day, month, and year. This value can be used if you do not want to merge the data with the nmon file for analysis.
NMON_START	External command to be started when the **nmon** recording begins.
NMON_END	External command to be started when the **nmon** recording ends.
NMON_SNAP	External command to be started periodically to record metrics.
NMON_ONE_IN	You can specify the **NMON_ONE_IN** variable to the following values: **NMON_ONE_IN=1** Runs the **snap** command every time the recording is done. **NMON_ONE_IN=*n*** Runs the **snap** command after the number of recordings that are specified by the *n* parameter is done.

Examples

1. To generate the **nmon** recording in the current directory for two hours, capturing data every 30 seconds, enter the following command:

   ```
   nmon -f -s 30 -c 240
   ```

2. To display the memory and processor statistics immediately after the **nmon** command is started, do the following steps:

   a. Enter the following command:

   ```
   export NMON=mc
   ```

   b. Run the **nmon** command.

3. To run the **nmon** command for 20 seconds with the screen that is refreshed at 10 seconds, enter the following command:

   ```
   nmon -c 10 -s 2
   ```

4. To run nmon in black and white mode, enter the following command:

   ```
   nmon -b
   ```

5. To view the process information, do the following steps:

   a. Run the **nmon** command.

b. Press the **t** key.

6. To view the list of views that **nmon** command provides, press the key **h**.
7. The following sample explains the steps to collect external data. In the sample, the `mystart` file, the `mysnap` file, and the `myend` file are executable and are in the path that the $PATH defines.

   a. Set the environment variables as indicated in the following example:

   ```
   $export NMON_TIMESTAMP=0
   $export NMON_START="mystart"
   $export NMON_SNAP="mysnap"
   $export NMON_END="myend"
   $export NMON_ONE_IN=1
   ```

   In the previous example, the value of one is the default value for the NMON_ONE_IN environment variable. It generates one set of external recorded data for every snapshot of nmon recording.

   b. Modify the content of the `mystart` file as the following:

   ```
   ps -ef >start_ps.xt
   echo "PROCCOUNT,Process Count, Procs" >ps.csv
   ```

   c. Modify the content of the `mysnap` file as the following:

   ```
   echo PROCCOUNT,$1,`ps -ef | wc -l` >>ps.csv
   ```

   d. Modify the content of the `myend` file as the following:

   ```
   echo PROCCOUNT,$1,`ps -ef | wc -l` >>ps.csv
   ```

   e. Run the **nmon** command as follows:

   ```
   nmon -f -s 2 -c 10
   ```

   The recording finishes in 20 seconds.

   The output of the `ps.csv` file is similar to the following sample:

   ```
   PROCCOUNT,Process Count, Procs
   PROCCOUNT,T0001, 43
   PROCCOUNT,T0002, 43
   PROCCOUNT,T0003, 43
   PROCCOUNT,T0004, 43
   PROCCOUNT,T0005, 43
   PROCCOUNT,T0006, 43
   PROCCOUNT,T0007, 43
   PROCCOUNT,T0008, 43
   PROCCOUNT,T0009, 44
   PROCCOUNT,T0010, 44
   PROCCOUNT,T0010, 44
   ```

   To concatenate the generated nmon file with the `ps.csv` file that is generated by external recording, enter the following command:

   ```
   cat  filename.nmon ps.csv > c.csv
   ```

   To get the graph, open the `c.csv` file in **nmon** analyzer.

8. To view the hdisk details, enter the **nmon** command with `-k` flag:

   ```
   nmon -k hdisk1,hdisk2
   ```

   The previous command shows the disk details for hdisk1 and hdisk2. For hdiskpower devices, enter the following command:

   ```
   nmon -k hdiskpower or
   nmon -k power
   ```

   Note: The `nmon -k hdisk` matches all the hdisk devices on the LPAR and does not match the hdiskpower devices.

All hdiskpower devices display as power in interactive and recording modes. For example, `nmon -k hdiskpower1` matches the device hdiskpower1 and `nmon -k hdiskpower` matches all hdiskpower devices on the LPAR.

Note: The output of the **lsconf** and **lspv** commands in the **nmon** recording file is not affected by the changes to the **nmon -k** command.

Location

`/usr/bin/nmon`

`/usr/bin/topasrec`

no Command

Purpose

Manages the tuning parameters of the network.

Syntax

no [**-p** | **-r**] { **-o** *Tunable*[**=***NewValue*] }

no [**-p** | **-r**] {**-d** *Tunable* }

no [**-p** | **-r**] { **-D** }

no [**-p** | **-r**] [**-F**] **-a**

no -h [*Tunable*]

no [**-F**] **-L** [*Tunable*]

no [**-F**] **-x** [*Tunable*]

Note: Multiple flags **-o**, **-d**, **-x**, and **-L** are allowed.

Description

Use the **no** command to configure parameters that used to tune the network. The **no** command sets or displays current or next system boot values for network tuning parameters. This command can also make permanent changes or defer changes until the next system reboot. Whether the command sets or displays a parameter, is determined by the accompanying flag. The **-o** flag does both these actions. It can either display the value of a parameter or set a new value for a parameter. When the **no** command is used to modify a network option, it logs a message to the syslog by using the LOG_KERN facility.

Understanding the Effect of Changing Tunable Parameters

Be careful when you use this command. If used incorrectly, the **no** command can cause your system to become inoperable.

Before you modify any tunable parameter, you must read about all its characteristics in the Tunable Parameters section, and follow the Refer To pointer instructions to understand the purpose. Ensure that the Diagnosis and Tuning sections for this parameter apply to the situation, and changing the value of this parameter helps to improve the performance of your system.

If the Diagnosis and Tuning sections both contain N/A, you must not change this parameter unless directed by AIX development.

Flags

Item	Description
-a	Displays current, reboot (when used with **-r**) or permanent (when used with **-p**) value for all tunable parameters, one per line in pairs *Tunable* **=** *Value*. For the permanent options, a value displays for a parameter if its reboot and current values are equal. Otherwise NONE displays as the value.
-d *Tunable*	Resets *Tunable* to its default value. If *Tunable* must be changed when, it is set to one of the following values: • The tunable is not set to its default value and it is of type Bosboot or reboot • The tunable is of type Incremental and must be changed from its default value. and **-r** is not used in combination. The tunable parameter is not changed but a warning message is displayed.
-D	Resets all tunable parameters to their default value. If a tunable parameter that must be changed, is of one of the following types: • Bosboot or Reboot • Incremental type and is changed from its default value and if either **-p** nor **-r** flag are used in combination, the parameter is not changed but a warning message is displayed.
-F	Forces restricted tunable parameters to be displayed when the options **-a**, **-L** or **-x** are specified on the command line. If you do not specify the **-F** flag, restricted tunables are not included, unless they are named in association with a display option.
-h [*Tunable*]	Displays help about *Tunable* parameter if one is specified. Otherwise, displays the **no** command usage statement.

Item	Description
-L [*Tunable*]	Lists the characteristics of one or all *Tunable*s, one per line, by using the following format:

```
NAME              CUR    DEF    BOOT   MIN
MAX    UNIT       TYPE
 DEPENDENCIES
------------------------------------------------------
-----------------
General Network
Parameters
------------------------------------------------------
-----------------
sockthresh        85     85     85     0
100    %_of_thewall  D
------------------------------------------------------
-----------------
fasttimo          200    200    200    50
200    millisecond   D
------------------------------------------------------
-----------------
inet_stack_size   16     16     16
1             kbyte         R
------------------------------------------------------
-----------------
...
where:
    CUR = current value
    DEF = default value
    BOOT = reboot value
    MIN = minimal value
    MAX = maximum value
    UNIT = tunable unit of measure
    TYPE = parameter type: D (for Dynamic),
           S (for Static), R (for Reboot),B (for
Bosboot), M (for Mount),
           I (for Incremental), C (for Connect),
and d (for Deprecated)
    DEPENDENCIES = list of dependent tunable
parameters, one per line
```

-o *Tunable* [**=***NewValue*]	Displays the value or sets the *Tunable* to *NewValue*. If a tunable must be changed, that is the specified value is different from current value, and is one of the following types: • Bosboot or Reboot • Incremental and its current value is more than the specified value and **-r** is not used in combination, it is not changed but a warning message is displayed. When **-r** is used in combination without a new value, the nextboot value for *Tunable* is displayed. When **-p** is used in combination without a new value, a value displays only if the current and next boot values for tunable are the same Otherwise NONE displays as the value.

Item	Description
-p	Changes are applied to both current and reboot values when used in combination with **-o**, **-d** or **-D**, that is turns on updating of the /etc/tunables/nextboot file in addition to updating of the current value. These combinations cannot be used on Reboot and Bosboot type parameters because their current value cannot be changed. When used with **-a** or **-o** without specifying a new value, the values are displayed when the current and next boot values for a parameter are the same. Otherwise NONE displays as the value.
-r	Changes are applied to reboot values when used in combination with **-o**, **-d**, or **-D** flags, that is it turns on updating the /etc/tunables/nextboot file. If any parameter of type Bosboot is changed, the user is prompted to run bosboot. When used with **-a** or **-o** without specifying a new value, next boot values for tunables display instead of the current values.
-x [*Tunable*]	Lists characteristics of one or all tunables, one per line, by using the following (spreadsheet) format: `tunable,current,default,reboot,min,max,unit,type,` `{dtunable }` `where:` `  current = current value` `  default = default value` `  reboot = reboot value` `  min = minimal value` `  max = maximum value` `  unit = tunable unit of measure` `  TYPE = parameter type: D (for Dynamic),` `  S (for Static), R (for Reboot),B` `(for Bosboot), M (for Mount),` `  I (for Incremental), C (for Connect),` `and d (for Deprecated)` `  dtunable = space separated list of` `dependent tunable parameters`

If you change by using the **-o**, **-d** or **-D** flag to a restricted tunable parameter, it results in a warning message that a tunable parameter of the restricted-use type is modified. If you also specify the **-r** or **-p** options on the command line, you are prompted for confirmation of the change. During system reboot, the presence of restricted tunables in the /etc/tunables/nextboot file that were modified to a value different from their default value by using a command line and by specifying the **-r** or **-p** options, results in an error log entry that identifies the list of these modified tunables.

If you change by using the **-o**, **-d**, or **-D** flag to a parameter of type Mount, it results in a warning message that the change is effective for future mountings.

If you change to a parameter of type Connect by using the **-o**, **-d** or **-D** flag, it results in starting the **inetd** and displays a warning message that the change is effective for future socket connections.

If you change to a parameter of type Bosboot or Reboot by using the **-o**, **-d**, or **-D** flag and without using the **-r** flag, it results in an error message.

If you change the current value of a parameter of type Incremental with a new value that is smaller than the current value by using the **-o**, **-d**, or **-D** flag and without using the **-r** flag, it results in an error message.

Tunable Parameters Type

All the tunable parameters that are manipulated by the tuning commands such as **no**, **nfso**, **vmo**, **ioo**, **schedo**, and **raso** commands are classified into the following categories:

Item	Description
Dynamic	If the parameter can be changed at any time
Static	If the parameter can never be changed
Reboot	If the parameter can be changed during reboot
Bosboot	If the parameter can be changed by running bosboot and rebooting the machine
Mount	If changes to the parameter are only effective for future file systems or directory mounts
Incremental	If the parameter can be incremented, except at boot time
Connect	If changes to the parameter are only effective for future socket connections
Deprecated	If this parameter cannot be changed and is no longer supported by the current release of AIX.

For parameters of type Bosboot, whenever there is a change, the tuning commands automatically prompt the user to ask if they want to run the **bosboot** command. For parameters of type Connect, the tuning commands automatically restart the **inetd** daemon if pre520tune is disabled.

Note: The current set of parameters that are managed by the **no** command includes Reboot, Static, Dynamic, Incremental, and Connect types.

Tunable Parameters

For default values and range of values for tunables, refer the **no** command help (**-h** <*tunable_parameter_name*>).

Item	Description
arpqsize	**Purpose:** Specifies the maximum number of packets to queue while waiting for Address Resolution Protocol (ARP) responses. **Tuning:** This attribute is supported by Ethernet, 802.3, Token Ring and FDDI interfaces.
arpt_killc	**Purpose:** Specifies the time in minutes before a complete ARP entry will be deleted. **Tuning:** To reduce ARP activity in a stable network, you can increase **arpt_killc**.
arptab_bsiz	**Purpose:** Specifies Address Resolution Protocol (ARP) table bucket size. **Tuning:** **netstat -p arp** will show the number of ARP packets sent and the number of ARP entries purged from the ARP table. If large number of entries are being purged, the ARP table size should be increased. Use arp -a to show the ARP table hashing distribution.

Item	Description
arptab_nb	**Purpose:** Specifies the number of ARP table buckets. **Tuning:** **netstat -p arp** will show the number of ARP packets sent and the number of ARP entries purged from the ARP table. If large number of entries are being purged, the ARP table size should be increased. Use arp -a to show the ARP table hashing distribution. Increase this value for systems that have a large number of clients or servers. The default provides for 149 x 7 = 1043 ARP entries, but assumes an even hash distribution.
bcastping	**Purpose:** Allows response to ICMP echo packets to the broadcast address. **Tuning:** A value of **0** disables it; while a value on **1** enables it. The default is to not respond to echo packets to a broadcast address. This prevents so called 'broadcast storms' on the network that can result when multiple machines respond to a broadcast address.
clean_partial_conns	**Purpose:** Specifies whether or not we are avoiding SYN attacks. If non-zero, **clean_partial_conns** specifies how many partial connections to be removed randomly to make room for new non-attack connections. **Tuning:** A value of **0** disables this option. This option should be turned on for servers that need to protect against network attacks.
delayack	**Purpose:** Delays ACKs for certain TCP packets and attempts to piggyback them with the next packet sent instead. **Tuning:** This action will only be performed for connections whose destination port is specified in the list of the **delayackports** attribute. This can be used to increase the performance when communicating with an HTTP server by reducing the total number of packets sent. The parameter can have one of following four values: **0** No delays, normal operation **1** Delays the ACK for the server's SYN **2** Delays the ACK for the server's FIN **3** Delay both the ACKs for the SYN and FIN

Item	Description
delayackports	**Purpose:** Specifies the list of destination ports for which the operation defined by the `delayack` port option is performed. **Tuning:** The attribute takes a maximum of 10 ports, which are separated by commas and enclosed in curly braces. For example: `no -o delayackports={80,30080}.` To clear the list, set the option to {}.
dgd_flush_cached_route	**Purpose:** Flushes the cached routes of sockets when Dead Gateway Detection detects a previous dead gateway back online. The connections are forced to reacquire the route before the data is sent. **Tuning:** A value of 1 enables the DGD to flush the cached routes. A value of 0 disables it.
dgd_packets_lost	**Purpose:** Specifies how many consecutive packets must be lost before Dead Gateway Detection decides that a gateway is down.
dgd_ping_time	**Purpose:** Specifies the seconds that must pass between pings of a gateway by Active Dead Gateway Detection.
dgd_retry_time	**Purpose:** Specifies the minutes a route's cost must remain raised when it is raised by Passive Dead Gateway Detection. After this many minutes pass, the route's cost is restored to its user-configured value. The unit specified is in numeric.
directed_broadcast	**Purpose:** Specifies whether a directed broadcast to a gateway must be allowed or not. **Tuning:** The value of 1 allows packets to be directed to a gateway that must be broadcast on a network on the other side of the gateway.
fasttimo	**Purpose:** Allows to set the millisecond delay for the TCP fast timeout timer. This timeout controls how often the system scans the TCP control blocks to send delayed acknowledgments. **Tuning:** Reducing this timer value can improve performance with some non-IBM systems. However, this parameter can result in slightly increased system utilization.

Item	Description
hstcp	**Purpose:** Enables the HighSpeed TCP as specified in RFC 3649. This parameter modifies the congestion control mechanism for use with TCP connections with large congestion windows to improve the average throughput. **Tuning:** A value of 1 enables the HighSpeed TCP enhancements on a system-wide scale. A value of 0 disables it.
icmp6_errmsg_rate	**Purpose:** Specifies the upper limit for the number of ICMP v6 error messages that can be sent per second. This parameter prevents excessive bandwidth from being used by ICMP v6 error messages.
icmpaddressmask	**Purpose:** Specifies whether the system responds to an ICMP address mask request. **Tuning:** If the value 0 is set, the network silently ignores any ICMP address mask request that it receives.
icmptimestamp	**Purpose:** Specifies whether the system responds to an ICMP timestamp request. **Tuning:** If the value of 0 is set, the network ignores any ICMP timestamp request that it receives.
ie5_old_multicast_mapping	**Purpose:** Specifies IP multicasts on token ring that must be mapped to the broadcast address rather than a functional address when value 1 is used.
ifsize	**Purpose:** Specifies the maximum number of network interface structures per interface of a single type. This limit does not apply to ethernet interface structures for which the infrastructure expands dynamically to handle any number of ethernet interface structures. **Tuning:** The **ifsize** parameter must be large on systems that supports hotplug adapters and on DLPAR configurations because adapters can be added as required. The static interface tables must be large enough to accept the large number of adapters that is added for this system or partition. If the system detects at the start, that more adapters of a type are present than that is allowed by the current value of **ifsize**, it automatically increases the value to support the number of adapters present.
ip6_defttl	**Purpose:** Specifies the default hop count that is used for IP version 6 packets if no other hop count is specified.
ip6_prune	**Purpose:** Specifies how often to check the IP version 6 routing table for expired routes, in seconds.

Item	Description
ip6forwarding	**Purpose:** Specifies whether the kernel must forward the IP version 6 packets. **Tuning:** The default value of 0 prevents forwarding of ipv6 packets when they are not for the local systems. A value of 1 enables forwarding.
ip6srcrouteforward	**Purpose:** Specifies whether the system forwards source-routed IP version 6 packets. **Tuning:** A value of 1 allows the forwarding of source-routed packets. A value of 0 causes all source-routed packets that are not at their destinations to be discarded.
ip_ifdelete_notify	**Purpose:** Specifies when an interface address is deleted. All the existing TCP connections that were bound locally to the interface address and were deleted must be notified with error **ENETDOWN**. **Tuning:** Existing FTP/Telnet connections are disconnected when the ENETDOWN error is returned.
ip_ifdelete_no_retrans	**Purpose:** Specifies that when an interface address is deleted, the existing TCP connections that were bound locally to the interface address must not retransmit data. **Tuning** No further retransmission of data occurs over the existing SSH connections.
ip_nfrag	**Purpose:** Specifies the maximum number of fragments of an IP packet that can be kept on IP reassembly queue at a time.
ipforwarding	**Purpose:** Specifies whether the kernel must forward packets. **Tuning:** Set this parameter to 1, if the system is acting as an IP router.
ipfragttl	**Purpose:** Specifies the time to live for IP fragments in half-seconds. **Tuning:** Check for fragments that dropped after timeout (netstat -p ip). If the value of IP, that is the fragments dropped after timeout is nonzero, increases the **ipfragttl** parameter, it can reduce retransmissions.
ipignoreredirects	**Purpose:** Specifies whether to process redirects that are received. **Tuning:** A value of 0 processes redirects as usual. A value of 1 ignores redirects.

Item	Description
ipqmaxlen	**Purpose:** Specifies the number of received packets that can be queued on the IP protocol input queue. **Tuning:** Examine if `ipintrq` overflows (netstat -s) or use crash to access IP input queue overflow counter. Increase size if system is using many loopback sessions. Most operating system network drivers call IP directly and do not use the IP queue. Increasing the **ipqmaxlen** parameter on these devices has no effect.
ipoutqueues	**Purpose** Specifies whether to queue User Datagram Protocol (UDP) packets that are sent over IPv4. These UDP packets are handled by a separate kernel thread. **Tunning** The default value is 0 and it specifies the UDP to transmit the packet immediately without queuing. A non-zero value specifies the number of queues to be created and used. For example, to create a single queue that is used by the UDP, enter the following command: `no -o ipoutqueues=1`
ipsendredirects	**Purpose:** Specifies whether the kernel must send redirect signals. **Tuning:** This parameter is a configuration decision with performance consequences.
ipsrcrouteforward	**Purpose:** Specifies whether the system forwards source routed packets. **Tuning:** The default value of 1 allows the forwarding of source-routed packets. A value of 0 causes all source-routed packets that are not at their destinations to be discarded.
ipsrcrouterecv	**Purpose:** Specifies whether the system accepts source routed packets. **Tuning:** The default value of 0 causes all source-routed packets that are destined for this system to be discarded. A value of 1 allows source-routed packets to be received.
ipsrcroutesend	**Purpose:** Specifies whether applications can send source routed packets. **Tuning:** The default value of 1 allows source-routed packets to be sent. A value of 0 causes **setsockopt()** to return an error if an application attempts to set the source routing option, and removes any source routing options from the outgoing packets.

Item	Description
limited_ss	**Purpose:** Enables the Limited SlowStart as specified in RFC 3742. This limits the number of segments by which the congestion window is increased for one window during slow-start. This enhancement improves the performance for TCP connections with large congestion windows. **Tuning:** A value from 1 to 100 enables the Limited SlowStart enhancements on a system-wide scale and sets it as the number of segments to the value of the maximum SlowStart threshold. A value of 0 disables it. The default value is 0.
llsleep_timeout	**Purpose:** Specifies timeout value in seconds for link local timeouts (used when multi_homed=1).
lo_perf	**Purpose:** Specifies whether you want to utilize a separate queue per CPU to improve loopback performance. **Tuning:** A value of 1 enables a separate queue per CPU. A value of 0 disables this option.
lowthresh	**Purpose:** Specifies the maximum number of bytes that can be allocated by using the **allocb** call for the **BPRI_LO** priority. **Tuning:** When the total amount of memory that is allocated by the **net_malloc** call reaches this threshold, then the **allocb** request for the **BPRI_LO** priority returns 0. The lowthresh attribute represents a percentage of the **thewall** attribute and you can set its value from 0 to 100.
main_if6	**Purpose:** Specifies the interface to use for link local addresses.
main_site6	**Purpose:** Specifies the interface to use for site local address routing.
maxnip6q	**Purpose:** Specifies the maximum number of IP version 6 packet reassembly queues.
maxttl	**Purpose:** Specifies the time to live (in seconds) for RIP packets.
medthresh	**Purpose:** Specifies the maximum number of bytes that can be allocated by using the **allocb** call for the **BPRI_MED** priority. **Tuning:** When the total amount of memory that is allocated by the **net_malloc** call reaches this threshold, then the **allocb** request for the **BPRI_MED** priority returns 0. The **medthresh** attribute represents a percentage of the **thewall** attribute. A typical setting of 95 represents 95% of **thewall** attribute.

Item	Description
mpr_policy	**Purpose:** Specifies the policy to be used for Multipath Routing. **Tuning:** The following are the available routing policies: **Weighted Round-Robin (1)** Based on user-configured weights that are assigned to the multiple routes (through the route command) round-robin is applied. If no weights are configured then, it behaves identical to plain round-robin. **Random (2)** Chooses a route at random. **Weighted Random (3)** Chooses a route that is based on user-configured weights and a randomization routine. The policy adds up the weights of all the routes and picks a random number between 0 and total weight. Each of the individual weights is removed from the total weight until this number is zero. This picks a route in the range of the total number of routes available. **Lowest Utilization (4)** Chooses a route with the minimum number of current connections going through it. **Hash-based (5)** Hash-based algorithm chooses a route by hashing based on the destination IP address.
multi_homed	**Purpose:** Specifies the level of multi-homed IP version 6 host support. **Tuning:** Tuning is performed for connections whose destination port is specified in the list of the `delayackports` parameter. This parameter can be used to increase performance when communicating with an HTTP server. The parameter can have one of four values: **0** Indicates the original functionality in AIX 4.3. **1** Indicates that link local addresses is resolved by querying each interface for the link local address. **2** Indicates that link local addresses is examined for the interface that is defined by `main_if6`. **3** Indicates that link local addresses is examined for the interface that is defined by `main_if6` and site local addresses are routed to the `main_site6` interface.

Item	Description
nbc_limit	**Purpose:** Specifies the total maximum amount of memory that can be used for the Network Buffer Cache. **Tuning:** This attribute is in number of Kilobytes. When the cache grows to this limit, the rarely used cache objects are flushed out of the cache to make room for the new ones.
nbc_max_cache	**Purpose:** Specifies the maximum size of the cache object that is allowed in the Network Buffer Cache without using the private segments. **Tuning:** This parameter is in number of bytes. A data object bigger than this size is either cached in a private segment or is not cached at all.
nbc_min_cache	**Purpose:** Specifies the minimum size of the cache object that is allowed in the Network Buffer Cache. **Tuning:** This attribute is in number of bytes. A data object smaller than this size is not put into the NBC. This attribute applies for **send_file()** API and some web servers that use the get engine in the kernel.
nbc_ofile_hashsz	**Purpose:** Specifies the size of the hash table that is used for hashing cache objects in the Network Buffer Cache. **Tuning:** This hash table size applies to only opened file entries that is, entries that cache files from the file system. Since this attribute resizes the hash table size and affects the hashing of all existing entries, this attribute can be modified when the Network Buffer Cache is empty.
nbc_pseg	**Purpose:** Specifies the maximum number of private segments that can be created for the Network Buffer Cache. **Tuning:** When this option is set at nonzero0, a data object between the size that is specified in **nbc_max_cache** and the segment size (256MB) is cached in a private segment. A data object bigger than the segment size is not cached. When the maximum number of private segments exist, cache data in private segments can be flushed for new cache data so that the number of private segments do not exceed the limit. When **nbc_pseg** is set to 0, all cache in private segments is flushed.

Item	Description
nbc_pseg_limit	**Purpose:** Specifies the maximum amount of cached data size allowed in private segments in the Network Buffer Cache. **Tuning:** This value is expressed in Kilobytes. Since data cached in private segments are pinned by the Network Buffer Cache, **nbc_pseg_limit** controls the amount of pinned memory that is used for the Network Buffer Cache in addition to the network buffers in global segments. When the amount of cached data reaches this limit, cache data in private segments can be flushed for new cache data so that the total pinned memory size does not exceed the limit. When **nbc_pseg_limit** is set to 0, all cache in private segments is flushed.
ndd_event_name	**Purpose:** Specifies the list of interface names for **ns_alloc** and **ns_free** events to be captured, when the trace of **ns_alloc/ns_free** events is enabled by setting the `ndd_event_tracing` option.
ndd_event_tracing	**Purpose:** Specifies the size of the `ns_alloc/ns_free` trace buffer. **Tuning:** If the value of this option is non-zero all **ns_alloc/ns_free** events are traced in a kernel buffer. A value of zero disables this event tracing. If the values of `ndd_event_tracing` are larger than 1024 it allocates as many items in the kernel buffer for tracing.
ndp_mmaxtries	**Purpose:** Specifies the maximum number of Multicast NDP Neighbor Discovery Protocol (NDP) packets to send.
ndp_umaxtries	**Purpose:** Specifies the maximum number of Unicast Neighbor Discovery Protocol (NDP) packets to send.
ndpqsize	**Purpose:** Specifies the number of packets to hold waiting on completion of a Neighbor Discovery Protocol (NDP) entry that is used by IP version 6.
ndpt_down	**Purpose:** Specifies the time, in half seconds, to hold down an NDP entry.
ndpt_keep	**Purpose:** Specifies the time, in half seconds, to keep a Neighbor Discovery Protocol (NDP) entry.
ndpt_probe	**Purpose:** Specifies the time in half seconds, to delay before the first Neighbor Discovery Protocol (NDP) probe is sent .
ndpt_reachable	**Purpose:** Specifies the time, in half seconds, to test if a Neighbor Discovery Protocol (NDP) entry is still valid.
ndpt_retrans	**Purpose:** Specifies the time, in half seconds, to wait before an NDP request is retransmitted.

Item	Description
net_buf_size	**Purpose:** Specifies a list of buffer sizes for `net_malloc/net_free` events to be captured. **Tuning:** The **net_buf_size** strings represent a list of sizes. If this attribute is not of value all, only `net_malloc/net_free` events of those sizes are captured. A value of all means that the events of any size are captured.
net_buf_type	**Purpose:** Specifies a list of buffer types for `net_malloc/net_free` events to be captured. **Tuning:** The **net_buf_type** string represents a list of types. If the string is not empty and different from all, only `net_malloc/net_free` events of that type is captured.
net_malloc_frag_mask	**Purpose:** It is used as boolean attribute for mask with each bucket that requests similar fragments to be promoted to full pages. **Tuning:** Allows promotion of allocations smaller than 1 page to full pages for better detection of memory overwrite problems. It is a mask for each bucket size that requests such fragments to be promoted to full pages. Enabling this option for memory fragments results in lower performance.
netm_page_promote	**Purpose:** Specifies whether to allow promotion of a fragment to page size. **Tuning:** This option allows promotion of fragment sizes that are specified in `net_malloc_frag_mask` to page size. Setting this option to 0, disables the page promotion irrespective of the sizes that are set in `net_malloc_frag_mask`.
nonlocsrcroute	**Purpose:** Tells the Internet Protocol that strictly source-routed packets can be addressed to hosts outside the local network. **Tuning:** A value of 0 disallows addressing to outside hosts. A value of 1 allows packets to be addressed to outside hosts. Loosely source routed packets are not affected by this attribute.
nstrpush	**Purpose:** Specifies the maximum number of modules that you can push onto a single stream. The minimum value is 8. **Tuning:** This parameter is read-only. This attribute can be set when loading the operating system in the `/etc/pse_tune.conf` file.

Item	Description
passive_dgd	**Purpose:** Specifies whether Passive Dead Gateway Detection is enabled. **Tuning:** A value of 0 disables **passive_dgd**, and a value of 1 enables it for all gateways in use.
pmtu_default_age	**Purpose:** This option is now unused because UDP applications are now required to always set **IP_DONTFRAG** socket option to be able to detect decreases in Path MTU. **Tuning:** A value of zero allows no aging. The default value is 10 minutes. The **pmtu_default_age** value can be overridden by UDP applications. **pmtu_default_age** is a runtime attribute.
pmtu_expire	**Purpose:** Specifies the default amount of time (in minutes) before which the path MTU entries with reference count of zero are deleted. **Tuning:** A value of 0 suggests that the **pmtu** entries does not expire.
pmtu_rediscover_interval	**Purpose:** Specifies the default amount of time (in minutes) before the path MTU value for UDP and TCP paths are checked for a higher value. **Tuning:** A value of 0 allows no path MTU rediscovery.
psebufcalls	**Purpose:** Specifies the maximum number of **bufcalls** to allocate by Streams. **Tuning:** The Stream subsystem allocates certain number of **bufcall** structures at initialization, so that when the **allocb** call fails, the user can register their requests for the **bufcall**. You are not allowed to lower this value until the system is restarted. During restart, the parameter returns to its default value.
psecache	**Purpose:** Controls the number of stream buffers.
psetimers	**Purpose:** Specifies the maximum number of timers to allocate by Streams. **Tuning:** The Stream subsystem allocates certain a number of timer structures at initialization so that the streams driver or module can register their timeout calls. You are not allowed to lower this value until the system is restarted. During restart, the parameter returns to its default value.
rfc1122addrchk	**Purpose:** Performs address validation as specified by RFC1122, Requirements for Internet Hosts-Communication Layers. **Tuning:** A value of 0 does not perform address validation. A value of 1 performs address validation.

Item	Description
rfc1323	**Purpose:** Enables TCP enhancements as specified by RFC 1323, TCP Extensions for High Performance. **Tuning:** A value of 0 disables the RFC enhancements on a system-wide scale. A value of 1 specifies that all TCP connections attempts to negotiate the RFC enhancements. The SOCKETS application can override the default behavior on individual TCP connections, by using the **setsockopt** subroutine. The **rfc1323** network option can also be set on a per interface basis through the **ifconfig** command.
rfc2414	**Purpose:** Enables the increasing of TCP's initial window as described in RFC 2414. **Tuning:** When it is on, the initial window depends on setting the **tcp_init_window** tunable.
route_expire	**Purpose:** Specifies whether the route expires. **Tuning:** A value of 0 allows no route expiration. Negative values are not allowed for this option.
routerevalidate	**Purpose:** Specifies that each cached route of a connection must be validated when a new route is added to the routing table. **Tuning:** This option ensures that applications that keep the same connection open for long periods of time (for example NFS) uses the correct route after routing table changes occur. A value of 0 does not revalidate the cached routes. Turning on this option can cause some performance degradation.
rto_high	**Purpose:** Specifies the TCP Retransmit Time out high value that is used in calculating factors, and the allowable maximum retransmits that is used in TCP data segment retransmits. **Tuning:** **rto_high** is the high factor.
rto_length	**Purpose:** Specifies the TCP Retransmit Time Out length value that is used in calculating factors, and the allowable maximum retransmits that is used in TCP data segment retransmits. **Tuning:** **rto_length** is the total number of time segments.
rto_limit	**Purpose:** Specifies the TCP Retransmit Time out limit value that is used in calculating factors, and the allowable maximum retransmits that is used in TCP data segment retransmits. **Tuning:** **rto_limit** is the number of time segments from **rto_low** to **rto_high**.

Item	Description
rto_low	**Purpose:** Specifies the TCP Retransmit Time Out low value that is used in calculating factors, and the allowable maximum retransmits that is used in TCP data segment retransmits. **Tuning:** **rto_low** is the low factor.
sack	**Purpose:** Enables TCP Selective Acknowledgment as described in RFC 2018. **Tuning:** A value of 1 makes all TCP connections negotiate sack. Default is zero, which disables the negotiation. sack feature needs support from the peer TCP. The negotiation phase during connection initiation determines that. When out of order segments are received , Selective Acknowledgments from the receiver informs the sender of the data that is received so that the sender can retransmit only the missing segments. This results in less unnecessary retransmitted segments. Sack is useful for recovering fast from multiple packet drops in a window of data.
sb_max	**Purpose:** Specifies the maximum buffer size that is allowed for a TCP and UDP socket. Limits **setsockopt**, **udp_sendspace**, **udp_recvspace**, **tcp_sendspace**, and **tcp_recvspace**. **Tuning:** Increase size, preferably to multiple of 4096. Must be approximately two to four times the largest socket buffer limit.
send_file_duration	**Purpose:** Specifies the cache validation duration for all the file objects that system call send_file accessed in the network buffer cache. **Tuning:** This attribute is in number of seconds. A value of 0 means that the cache is validated for every access.
site6_index	**Purpose:** Specifies the maximum interface number for site local routing.
sockthresh	**Purpose:** Specifies the maximum amount of network memory that can be allocated for sockets. Used to prevent new sockets or TCP connections from exhausting all MBUF memory and reserve the remaining memory for the existing sockets or TCP connections. **Tuning:** When the total amount of memory that is allocated by the **net_malloc** subroutine reaches the **sockthresh** threshold, the socket and **socketpair** system calls fail with an error of ENOBUFS. Incoming connection requests are silently discarded. Existing sockets can continue to use more memory. The **sockthresh** attribute represents a percentage of the **thewall** attribute.
sodebug	**Purpose:** Specifies whether the newly created sockets has SO_DEBUG flag on.

Item	Description
sodebug_env	**Purpose:** Specifies whether SODEBUG process environment variable is checked for the newly created sockets; if so, these sockets has the SO_DEBUG flag on.
somaxconn	**Purpose:** Specifies the maximum listen backlog. **Tuning:** Increase this parameter on busy web servers to handle peak connection rates.
soreuseport_lb	**Purpose:** Specifies whether the SO_REUSEPORT socket option is enabled or disabled for load balancing. **Tuning:** This tunable parameter can have the following values: • **1** - Enables the SO_REUSEPORT socket option. • **0** - Disables the SO_REUSEPORT socket option.
strctlsz	**Purpose:** Specifies the maximum number of bytes of information that a single system call can pass to a Stream to place into the control part of a message (in an **M_PROTO** or **M_PCPROTO** block). **Tuning:** The **putmsg** call with a control part that exceeds this size fails with **ERANGE**.
strmsgsz	**Purpose:** Specifies the maximum number of bytes of information that a single system call can pass to a Stream to place into the data part of a message (in **M_DATA** blocks). **Tuning:** Any write call that exceeds this size is broken into multiple messages. The **putmsg** call with a data part that exceeds this size fails with **ERANGE**.
strthresh	**Purpose:** Specifies the maximum number of bytes Streams are normally allowed to allocate. **Tuning:** When the threshold is passed, **strthresh** does not allow users without the appropriate privilege to open Streams, push modules, or write to Stream devices, and returns ENOSR. The threshold applies to the output and does not affect the data coming into the system (for example, console continues to work properly). A value of zero means that there is no threshold. The **strthresh** attribute represents a percentage of the **thewall** attribute. The **thewall** attribute indicates the maximum number of bytes that can be allocated by Streams and Sockets by using the **net_malloc** call.

Item	Description
strturncnt	**Purpose:** Specifies the maximum number of requests that are handled by the current running thread for Module or Elsewhere level Streams synchronization. **Tuning:** The Module level synchronization works in a way that only one thread can run in the module at any time and all other threads, which try to acquire the same module enqueues their requests and leave. After the current running thread completes its work, it dequeues all the previously enqueued requests one by one and runs them. If there are many requests that are enqueued in the list, then the current running thread has to serve everyone and will always be busy serving others and starves itself. To avoid this situation, the current running thread serves only the **strturncnt** number of threads after that a separate kernel thread activates and runs all the pending requests.
subnetsarelocal	**Purpose:** Specifies whether all subnets that match the subnet mask are to be considered local for purposes of establishing, for example, the TCP maximum segment size. **Tuning:** This parameter is used by the **in_localaddress** subroutine. The default value, **1** specifies that addresses that match the local network mask are local. If the value is 0, addresses that match the local subnetwork are local. This is a configuration decision with performance consequences. If all the subnets do not have the same MTU, fragmentation at bridges can degrade performance. If the subnets do have the same MTU, and **subnetsarelocal** is 0, TCP sessions can use a small MSS.
tcp_bad_port_limit	**Purpose:** Specifies the number of TCP segments to a port, which does not have a socket connection, within the time duration of half a second. TCP stops sending TCP reset segments in response after this time. **Tuning:** If the value is set to 0, TCP indicates a bad port number error by sending TCP reset segments. A value greater than 0 indicates the number of TCP segments received by a port, which does not have a socket connection, within the time duration of half a second before TCP stops sending TCP reset segments.
tcp_cwnd_modified	**Purpose:** Allows the TCP IP applications with specific socket options to adjust the network congestion window. This parameter might be used only in a specific wide area network (WAN) environment. **Tuning:** Default value is 0, which disables the tuning parameter. Tuning it to a value of 1 allows to adjust the network congestion window.

Item	Description
tcp_ecn	**Purpose:** Enables TCP level support for Explicit Congestion Notification as described in RFC 2481. **Tuning:** Default is off (0). Turning it on (1) makes all connections negotiate ECN capability with the peer. For this feature to work, you need support from the peer TCP and also IP level ECN support from the routers in the path.
tcp_ephemeral_high	**Purpose:** Specifies the largest port number to allocate for TCP ephemeral ports. **Tuning:** The number of ephemeral sockets is determined by **tcp_ephemeral_high** minus **tcp_ephemeral_low**. For maximum number of ephemeral sockets, set **tcp_ephemeral_high** to 65535 and **tcp_ephemeral_low** to 1024.
tcp_ephemeral_low	**Purpose:** Specifies the smallest port number to allocate for TCP ephemeral ports. **Tuning:** The number of ephemeral sockets is determined by **tcp_ephemeral_high** minus **tcp_ephemeral_low**. For maximum number of ephemeral sockets, set **tcp_ephemeral_high** to 65535 and **tcp_ephemeral_low** to 1024.
tcp_fastlo	**Purpose:** Allows the TCP loopback traffic to cutoff the entire TCP/IP stack protocol and interface to achieve better performance. **Tuning:** A value of 1 enables the TCP loopback traffic to cutoff the entire TCP/IP stack. A value of 0 disables this option.
tcp_finwait2	**Purpose:** Specifies the length of time to wait in the FIN_WAIT2 state before closing the connection, measured in half seconds.
tcp_icmpsecure	**Purpose:** Specifies whether or not ICMP (Internet Control Message Protocol) attacks on TCP are avoided. **Tuning:** This option should be turned on to protect TCP connections against ICMP attacks. The ICMP attacks may be of the form of ICMP source quench attacks and PMTUD (Path MTU Discovery) attacks. If this network option is turned on, the system does not react to ICMP source quench messages. This will protect against ICMP source quench attacks. Also, if this network option is enabled, the payload of the ICMP message is tested to determine if the sequence number of the TCP header portion of the payload is within the range of acceptable sequence numbers. This will mitigate PMTUD attacks to a large extent.

Item	Description
tcp_init_window	**Purpose:** This value is used only when rfc2414 is turned on (ignored otherwise). **Tuning:** If rfc2414 is on and this value is zero, then the initial window computation is done according to rfc2414. If this value is non-zero, the initial (congestion) window is initialized a number of maximum sized segments equal to **tcp_init_window**. Changing f**tcp_init_window** allows you to tune the TCP slow start to control the number of TCP segments (packets) outstanding before an ACK is received. For example, setting this value to 6 would allow 6 packets to be sent initially, instead of the normal 2 or 3 packets, thus speeding up the initial packet rate.
tcp_inpcb_hashtab_siz	**Purpose:** Specifies the size of the inpcb hash table for TCP connections. **Tuning:** This table holds the **inpcbs** required for connection management and is implemented as a table of hash chains. A larger table means that the linked hash chains will be smaller and lower traversal time on the average but the memory footprint will be larger. This value should be a prime number. This option impacts performance and should be used with extreme caution. Please consult a performance analyst in case it is felt that the value needs to be changed. The execution environment could have an influence on the value. It is strongly encouraged to maintain the system defined defaults as they tend to execute optimally in most environments.
tcp_keepcnt	**Purpose:** **tcp_keepcnt** represents the number of keepalive probes that could be sent before terminating the connection.
tcp_keepidle	**Purpose:** Specifies the length of time to keep the connection active, measured in half seconds.
tcp_keepinit	**Purpose:** Sets the initial timeout value for a TCP connection, which is measured in half seconds.
tcp_keepintvl	**Purpose:** Specifies the interval, which is measured in half seconds, between packets that are sent to validate the connection. **Tuning:** For example, 150 half seconds results in 75 seconds between validation probes. This allows TCP to know that a connection is still valid and keep the connection open when it is otherwise idle. This is a configuration decision with minimal performance consequences. No change is recommended. If the interval were shortened significantly, processing and bandwidth costs might become significant.

Item	Description
tcp_limited_transmit	**Purpose:** Enables the feature that enhances TCP's loss recovery as described in the RFC 3042. **Tuning:** A value of 1 enables this option and zero disables the option.
tcp_low_rto	**Purpose:** Specifies the TCP retransmit timeout (RTO) in milliseconds for connections that are experiencing packet drops. **Tuning:** A tick is 10 ms (one 100th of a second). The option `timer_wheel_tick` must be set to non-zero value before setting the `tcp_low_rto` option. Also, `tcp_low_rto` can be equal to zero or a multiple of ten times the `timer_wheel_tick` value. This tunable allows TCP to use smaller timeout values for packet timeout and retransmit on high speed networks. Normal TCP retransmit timeout is 1.5 seconds.
tcp_maxburst	**Purpose:** Specifies the number of back-to-back packets that TCP can send before pausing to allow those packets to be forwarded to their destination. **Tuning:** This can be useful if routers are unable to handle large bursts of TCP packets and are dropping some of them. A value of 0 means no limitation for back-to-back packets before pausing.
tcp_maxqueuelen	**Purpose:** Specifies the maximum number of TCP segments that can be processed in the reassembly queue. **Tuning:** Values for this tunable parameter are in the range 0 - 32767. A value of 0 means unlimited queue length. The default value is 1000.
tcp_mssdflt	**Purpose:** Default maximum segment size that is used in communicating with remote networks. **Tuning:** **tcp_mssdflt** is only used if path MTU discovery is not enabled or path MTU discovery fails to discovery a path MTU. The **tcp_mssdflt** network option can also be set on a per interface basis (see the documentation for ISNO options). Limiting data to (MTU - 40) bytes ensures that, where possible, only full packets are sent.
tcp_nagle_limit	**Purpose:** This is the Nagle algorithm threshold in bytes, which can be used to disable Nagle. **Tuning:** The default is Nagle turned on. To disable Nagle, set this value to 0 or 1. TCP disables Nagle for data segments larger than or equal to this threshold value.

Item	Description
tcp_nagleoverride	**Purpose:** Setting the option tcp_nagle_limit turns off the Nagle algorithm system wide and setting tcp_nodelay option for a socket turns off the Nagle algorithm for that specific connection whereas setting tcp_nagleoverride disables the Nagle algorithm only for certain situations during the connection. **Tuning:** The value of 1 disables Nagle algorithm only for certain TCP packets in a connection.
tcp_ndebug	**Purpose:** Specifies the number of **tcp_debug** structures.
tcp_newreno	**Purpose:** Enables the modification to TCP's Fast Recovery algorithm as described in RFC 2582. **Tuning:** This fixes the limitation of TCP's Fast Retransmit algorithm to recover fast from dropped packets when multiple packets in a window are dropped. sack also achieves the same thing but sack needs support from both ends of the TCP connection; the NewReno modification is only on the sender side.
tcp_nodelayack	**Purpose:** Turning this parameter on causes TCP to send immediate acknowledgement (Ack) packets to the sender. When **tcp_nodelayack** is disabled, TCP delays sending Ack packets by up to 200ms. This allows the Ack to be piggy-backed onto a response and minimizes system overhead. **Tuning:** This option can be used to overcome bugs in other implementations of the TCP nagle algorithm. Setting this option to 1 will cause slightly more system overhead, but can result in much higher performance for network transfers if the sender is waiting on the receiver's acknowledgement.
tcp_pmtu_discover	**Purpose:** Enables or disables path MTU discovery for TCP applications. **Tuning:** A value of 0 disables path MTU discovery for TCP applications, while a value of 1 enables it.
tcp_recvspace	**Purpose:** Specifies the system default socket buffer size for receiving data. This affects the window size used by TCP. **Tuning:** The optimum buffer size is the product of the media bandwidth and the average round-trip time of a packet. The **tcp_recvspace** network option can also be set on a per interface basis (reference documentation on Interface Specific Network Options (ISNO)). Most interfaces now have this tunable set in the ISNO defaults. The **tcp_recvspace** attribute must specify a socket buffer size less than or equal to the setting of the **sb_max** attribute.

Item	Description
tcp_sendspace	**Purpose:** Specifies the system default socket buffer size for sending data. **Tuning:** The optimum buffer size is the product of the media bandwidth and the average round-trip time of a packet: `optimum_window=bandwidth * average_round_trip_time`. The **tcp_sendspace** network option can also be set on a per interface basis (reference documentation on Interface Specific Network Options (ISNO)). Most interfaces now have this tunable set in the ISNO defaults. The **tcp_sendspace** attribute must specify a socket buffer size less than or equal to the setting of the **sb_max** attribute.
tcp_syn_rto	**Purpose:** Specifies the TCP retransmission timeout (RTO) value, in interval of half-seconds, for a connection experiencing packet drops before the connection is established. **Tuning:** The value of the **tcp_syn_rto** tunable parameter will be set as the initial retransmission timeout value for retransmissions that occur before the connection is established. The values are in the range 0 - 32767. The default value is 0.
tcp_tcpsecure	**Purpose:** Specifies whether connection reset attacks and data corruption attacks on TCP are avoided. **Tuning:** This option is used to protect TCP connections from one or more of the following three vulnerabilities. The first vulnerability involves sending of a fake SYN to an established connection to abort the connection. A **tcp_tcpsecure** value of 1 provides protection from this vulnerability. The second vulnerability involves the sending of a fake RST to an established connection to abort the connection. A **tcp_tcpsecure** value of 2 provides protection from this vulnerability. The third vulnerability involves injecting fake data in an established TCP connection. A **tcp_tcpsecure** value of 4 provides protection from this vulnerability. Values for **tcp_tcpsecure** can range from a minimum of 0 (this is the default value and provides no protection from these vulnerabilities) to a maximum value of 7. Values of 3, 5, 6, or 7 protects the connection from combinations of these three vulnerabilities.
tcp_timewait	**Purpose:** The **tcp_timewait** option is used to configure how long connections are kept in the **timewait** state. **Tuning:** It is given in 15 second intervals. Increasing this value degrades performance of web servers or applications that open and close many TCP connections.
tcp_ttl	**Purpose:** Specifies the time to live for TCP packets, expressed in ticks. **Tuning:** A tick is 0.6 seconds (there are 100 ticks per minutes).

Item	Description
tcprexmtthresh	**Purpose:** Specifies the number of consecutive duplicate acknowledgements, which cause TCP to goto fast retransmit phase. **Tuning:** Increase this parameter if TCP performance is low due to an increased number of duplicate acknowledgements but the network is not congested. Be aware that setting a high value for this option can cause TCP to time out and retransmit.
tcptr_enable	**Purpose:** Enables TCP traffic regulation that is defined by policies that created by using the tcptr command. A value of 0 means disabled. Any non-zero value means traffic regulation is enabled. **Tuning:** A value of 0 disables this option. This option must be turned on for servers that must protect against network attacks.
thewall	**Purpose:** Specifies the maximum amount of memory, in kilobytes, that is allocated to the memory pool. **Tuning:** Cannot be set anymore.
timer_wheel_tick	**Purpose:** Specifies the slot interval of the timer wheel, in ticks, where a tick=1000/HZ=10ms. **Tuning:** This attribute is used with `tcp_low_rto` attribute to reduce the TCP timeout values to smaller units.
tn_filter	**Purpose:** The option is valid for Trusted AIX environment only. If the option is disabled in this environment, the MAC checks are bypassed at the IP layer.
udp_bad_port_limit	**Purpose:** Specifies the number of UDP packets to a port with no socket that can be received in a 500-millisecond period before UDP stops sending ICMP errors in response to such packets. **Tuning:** If set to 0, ICMP errors will always be sent when UDP packets are received for a bad port number. If greater than 0, it specifies the number of packets to be received before UDP stops sending ICMP errors.
udp_ephemeral_high	**Purpose:** Specifies the largest port number to allocate for UDP ephemeral ports.
udp_ephemeral_low	**Purpose:** Specifies the smallest port number to allocate for UDP ephemeral ports.

Item	Description
udp_inpcb_hashtab_siz	**Purpose:** Specifies the size of the inpcb hash table for UDP connections. This table holds the inpcbs that is required for connection management and is implemented as a table of hash chains. A larger table means that the linked hash chains is smaller and lower traversal time on the average but the memory footprint is larger. **Tuning:** This value must be a prime number. This option impacts performance and must be used with extreme caution. Consult a performance analyst in case it is felt that the value must be changed. The execution environment can have an influence on the value. It is encouraged to maintain the system defined defaults as they tend to run optimally in most environments.
udp_pmtu_discover	**Purpose:** Enables or disables path MTU discovery for UDP applications. **Tuning:** UDP applications must be written to use path MTU discovery. A value of 0 disables the feature, while a value of 1 enables it.
udp_recvspace	**Purpose:** Specifies the system default socket buffer size for receiving UDP data. **Tuning:** Change when nonzero n in **netstat -s** report of udp: n socket buffer overflows. The **udp_recvspace** parameter must specify a socket buffer size less than or equal to the setting of the **sb_max** parameter. Increase size, preferably to multiple of 4096.
udp_send_perf	**Purpose** Improves the UDP Transmit performance by caching address information and Memory Buffers (**mbufs**) that are used to transmit packets over a network. **Tunning** The default value is 0 and it disables caching. To enable caching, specify a value of 1. For example, to enable caching, enter the following command: `no -o udp_send_perf=1`
udp_sendspace	**Purpose:** Specifies the system default socket buffer size (in bytes) for sending UDP data. **Tuning:** The **udp_sendspace** attribute must specify a socket buffer size less than or equal to the setting of the **sb_max** attribute. **udp_sendspace** must be at least as large as the largest datagram size that the application sends. Increase size, preferably to multiple of 4096.
udp_ttl	**Purpose:** Specifies the time to live (in seconds) for UDP packets.

Item	Description
udpcksum	**Purpose:** Allows UDP checksum to be turned on/off. **Tuning:** A value of 0 turns it off; while a value of 1 turns it on.
use_sndbufpool	**Purpose:** Enables caching of mbuf clusters to improve performance. **Tuning:** If this value is disabled, then to allocate a mbuf cluster, AIX allocates a cluster buffer and also a mbuf buffer to point to it, thus requiring two buffer allocation operations. Likewise, to free the cluster, two buffer free operations are required. With this option enabled, AIX maintains a cache of clusters for each cluster size that is being used. This improves performance by reducing overhead to allocate and free mbuf clusters. The default value of 1 enables this option on a system-wide scale. The mbuf cluster cache can be displayed by using the **netstat -M** command.

Compatibility Mode

When running in pre 5.2 compatibility mode that is controlled by the **pre520tune** attribute of **sys**0, see **AIX 5.2 compatibility mode**. The reboot values for parameters, except those of type Bosboot, are not applicable because in the pre 5.2 compatibility mode they are not applied during boot.

In pre 5.2 compatibility mode, setting reboot values to tuning parameters continues to be achieved by embedding calls to tuning commands in scripts that are called during the boot sequence. Parameters of type **Reboot** can therefore be set without the **-r** flag, so that existing scripts continue to work.

This mode is automatically turned ON when a machine is MIGRATED to AIX 5L Version 5.2. For complete installations, it is turned OFF and the reboot values for parameters are set by applying the content of the **/etc/tunables/nextboot** file during the reboot sequence. Only in that mode are the **-r** and **-p** flags fully functional. See **Kernel Tuning** in the *Performance Tools Guide and Reference* for details.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To display the maximum size of the mbuf pool, type:

```
no -o thewall
```

2. To reset the time to live for UDP packets its default size, type:

```
no -d udp_ttl
```

3. To change the default socket buffer sizes on your system, type:

```
no -r -o tcp_sendspace=32768
no -r -o udp_recvspace=32768
```

4. To use a system as an internet work router over Internet Protocol networks, type:

```
 no -o ipforwarding=1
```

5. To list the current and reboot value, range, unit, type and dependencies of all tunable parameters that are managed by the **no** command, type:

```
no -L
```

6. To display the help information about the udp_ephemeral_high option, type:

```
no -h udp_ephemeral_high
```

7. To permanently turn off the ip6srcrouteforward option, type:

```
no -p -o ip6srcrouteforward=0
```

8. To list the reboot values for all Network tuning parameters, type:

```
no -r -a
```

9. To list (spreadsheet format) the current and reboot value, range, unit, type and dependencies of all tunable parameters that are managed by the **no** command, type:

```
no -x
```

10. To log all allocations and frees of type mbuf or socket that are size 256 or 4096, type:

```
no -o net_buf_type={mbuf:socket} -o net_buf_size={256:4096} -o net_malloc_police=1
```

11. To log all allocations and frees of type mbuf, type:

```
no -o net_buf_type={mbuf} -o net_buf_size={all} -o net_malloc_police=1
```

12. To log all **ns_alloc**s and **ns_free**s for en0 or en3 by using a 2000 events buffer size, type:

```
no -o ndd_event_name={en0:en3} -o ndd_event_tracing=2000
```

13. To log all **ns_alloc**s and **ns_free**s for all en adapters by using a 2000 events buffer size, type:

```
no -o ndd_event_name={en} -o ndd_event_tracing=2000
```

14. To log all **ns_alloc**s and **ns_free**s for all adapters, type:

```
no -o ndd_event_name={all} -o ndd_event_tracing=1
```

nohup Command

Purpose

Runs a command without hangups.

Syntax

nohup { -p *pid* | *Command* [*Arg* ...] [**&**] }

Description

The **nohup** command runs the command specified by the *Command* parameter and any related *Arg* parameters, ignoring all hang up signals (SIGHUP) or modifies the process specified with the **-p** option to ignore all SIGHUP signals. SIGHUP is a signal that is sent to a process when the controlling terminal of the process is closed.

The **nohup** command can also be used to run programs in the background after logging off. To run a nohup command in the background, add an & (ampersand) to the end of the command.

If the standard error is displayed on the terminal and if the standard output is neither displayed on the terminal, nor sent to the output file specified by the user (the default output file is `nohup.out`), both the `./nohup.out` and `$HOME/nohup.out` files are not created or opened for appending the error message. The **nohup** command does not execute the parameter utility that is specified with the **nohup** command and exits with exit status 127.

Note: The **-p** *pid* and *Command* options can not be specified together.

When the **-p** *pid* flag is used, the output of the specified process will not be re-directed to the `nohup.out` file.

Flags

Item	Description
-p *pid*	*pid* is the process-id of a running process. The nohup command modifies the specified process, to ignore all hangup (SIGHUP) signals.

Exit Status

This command returns the following exit values:

Item	Description
126	The command specified by the *Command* parameter was found but could not be invoked.
127	An error occurred in the nohup command or the command specified by the *Command* parameter could not be found.

Otherwise, the exit status of the nohup command is that of the command specified by the *Command* parameter.

Examples

1. To run a command in the background after you log off, enter:

   ```
   $ nohup find / -print &
   ```

   After you enter this command, the following is displayed:

   ```
   670
   $ Sending output to nohup.out
   ```

   The process ID number changes to that of the background process started by & (ampersand). The message `Sending output to nohup.out` informs you that the output from the **find / -print** command is in the **nohup.out** file. You can log off after you see these messages, even if the `find` command is still running.
2. To run a command in the background and redirect the standard output to a different file, enter:

   ```
   $ nohup find / -print >filenames &
   ```

   This example runs the **find / -print** command and stores its output in a file named `filenames`. Now only the process ID and prompt are displayed:

   ```
   677
   $
   ```

   Wait before logging off because thenohup command takes a moment to start the command specified by the *Command* parameter. If you log off too quickly, the command specified by the *Command* parameter may not run at all. Once the command specified by the *Command* parameter starts, logging off does not affect it.
3. To run more than one command, use a shell procedure. For example, if you write the shell procedure:

```
neqn math1 | nroff > fmath1
```

and name it the `nnfmath1` file, you can run the nohup command for all of the commands in the `nnfmath1` file with the command:

```
nohup sh nnfmath1
```

4. If you assign execute permission to the `nnfmath1` file, you get the same results by issuing the command:

```
nohup nnfmath1
```

5. To run the `nnfmath1` file in the background, enter:

```
nohup nnfmath1
&
```

6. To run the `nnfmath1` file in the Korn shell, enter:

```
nohup ksh nnfmath1
```

7. To make a running process ignore all hangup signals, enter:

```
nohup -p 161792
```

enotifyevent Command, notifyevent Command

Purpose

Mails event information generated by the event response resource manager (ERRM) to a specified user ID.

Syntax

`enotifyevent` [`-h`] [*user-ID*]

`notifyevent` [`-h`] [*user-ID*]

Description

The `enotifyevent` script always return messages in English. The language in which the messages of the `notifyevent` script are returned depend on the locale settings.

These scripts capture event information that is posted by the event response resource manager (ERRM) in environment variables that are generated by the ERRM when an event occurs. These scripts can be used as actions that are run by an event response resource. They can also be used as templates to create other user-defined actions.

Event information is returned about the ERRM environment variables, and also includes the following:

Local Time
Time when the event or rearm event is observed. The actual environment variable supplied by ERRM is ERRM_TIME. This value is localized and converted to readable form before being displayed.

In AIX, these scripts use the `mail` command to send event information to the specified user ID. When a user ID is specified, it is assumed to be valid, and it is used without verifying it. If a user ID is not specified, the user who is running the command is used as the default.

user-ID is the optional ID of the user to whom the event information will be mailed. If *user-ID* is not specified, the user who is running the command is used as the default.

Flags

-h
Writes the script's usage statement to standard output.

Parameters

log_file
Specifies the name of the file where event information is logged. An absolute path for the *log_file* parameter should be specified.

For AIX, the *log_file* is treated as a circular log and has a fixed size of 64KB. When *log_file* is full, new entries are written over the oldest existing entries.

For other platforms, the size of the *log_file* is not limited, and it will not overwrite itself. The file size will increase indefinitely unless the administrator periodically removes entries.

If *log_file* already exists, event information is appended to it. If *log_file* does not exist, it is created so that event information can be written to it.

Exit Status

0
Command has run successfully.

Restrictions

1. These scripts must be run on the node where the ERRM is running.
2. The `mail` command is used to read the file.

Standard Output

When the `-h` flag is specified, the script's usage statement is written to standard output.

Examples

1. You can use the **mail** command to read the contents of the event information. The following example shows how a warning event for the `/var` file system (a file system resource) is formatted and logged:

```
============================================================================
Event reported at Sun Mar 26 16:38:03 2002

Condition Name:                      /var space used
Severity:                   Warning
Event Type:                    Event
Expression:                    PercentTotUsed>90

Resource Name:                    /var
Resource Class Name:                IBM.FileSystem
Data Type:                   CT_UINT32
Data Value:                   91
```

Location

/opt/rsct/bin/enotifyevent
Contains the `enotifyevent` script

/opt/rsct/bin/notifyevent
Contains the `notifyevent` script

nroff Command

Purpose

Formats text for printing on typewriter-like devices and line printers.

Syntax

nroff [**-e**] [**-h**] [**-i**] [**-q**] [**-z**] [**-o** *List*] [**-n** *Number*] [**-s** *Number*] [**-r** *ANumber*] [**-u** *Number*] [**-T** *Name*] [**-man**] [**-me**] [**-mm**] [**-mptx**] [**-ms**] [*File* ... | **-**]

Description

The **nroff** command reads one or more files for printing on typewriter-like devices and line printers. If no file is specified or the **-** (minus sign) flag is specified as the last parameter, standard input is read by default. The *File* variable specifies files to be printed on a typewriter-like device by the **nroff** command. The default is standard input.

The **col** command may be required to postprocess **nroff** command output in certain cases.

Flags

Item	Description
-e	Produces equally spaced words in adjusted lines, using the full resolution of a particular terminal.
-h	Uses output tabs during horizontal spacing to speed output and reduce the output character count. Tab settings are assumed to be every eight nominal character widths.
-i	Reads standard input after reading all specified files.
-man	Selects the **man** macro processing package.
-me	Selects the **me** macro processing package.
-mm	Selects the **mm** macro processing package.
-mptx	Selects the **mptx** macro processing package.
-ms	Selects the **ms** macro processing package.
-n *Number*	Assigns the specified number to the first printed page.
-o *List*	Prints only those pages specified by the *List* variable, which consists of a comma-separated list of page numbers and ranges, as follows: • A range of *Start-Stop* means print pages *Start* through *Stop.* For example, 9-15 prints pages 9 through 15. • An initial *-Stop* means print from the beginning to page *Stop.* • A final *Start-* means print from page *Start* to the end. • A combination of page numbers and ranges prints the specified pages. For example, -3, 6-8,10,12- prints the beginning through page 3, pages 6 through 8, page 10, and page 12 to the end. **Note:** When the **-o***List* flag is used in a pipeline (as with one or more of the **eqn** or **tbl** commands) you may receive a `broken pipe` message if the last page in the document is not specified in the *List* parameter. This broken pipe message is not an indication of any problem and can be ignored.

Item	Description
-q	Calls the simultaneous input/output mode of the **.rd** request.
-r *ANumber*	Sets register *A* to the specified number. The value specified by the *A* variable must have a one-character ASCII name.
-s *Number*	Stops every specified number of pages (the default is 1). The **nroff** command halts every specified number of pages to allow paper loading or changing, then resumes upon receipt of a linefeed or new-line character. This flag does not work in pipelines (for example, with the **mm** command). When the **nroff** command halts between pages, an ASCII BEL character is sent to the workstation.
-T *Name*	Prepares the output for the specified printing device. Typewriter-like devices and line printers use the following *Name* variables for international extended character sets, as well as English-language character sets, digits, and symbols: **hplj** Hewlett-Packard LaserJet II and other models in the same series of printers. **ibm3812** 3812 Pageprinter II. **ibm3816** 3816 Pageprinter. **ibm4019** 4019 LaserPrinter. **Note:** The 4019 and the HP Laser Jet II printer both have nonprintable areas at the top and bottom of a page. If a file is targeted for these printers, be sure to define top and bottom margins (for example, by formatting with the **-mm** flag) so that all output can be positioned within the printable page. **37** Teletype Model 37 terminal (default) for terminal viewing only. This device does not support extended characters that are inputted by the \[N] form. Inputting Extended Single-Byte Characters provides more information. **lp** Generic name for printers that can underline and tab. All text sent to the **lp** value using reverse linefeeds (for example, text that includes tables) must be processed with the **col** command. This device does not support extended characters that are inputted by the \[N] form. Inputting Extended Single-Byte Characters provides more information. **ppds** Generic name for printers that support the personal printer data streams such as the Quietwriter III, Quickwriter, and Proprinters. **ibm5575** 5575 Kanji Printer. **ibm5577** 5577 Kanji Printer. **Note:** For completeness of the text formatting system, the following devices are shipped *as is* from the AT&T Distribution center. No support is provided for these tables.

Item	Description
-T *Name* (Continued)	**2631** Hewlett-Packard 2631 printer in regular mode. **2631-c** Hewlett-Packard 2631 printer in compressed mode. **2631-e** Hewlett-Packard 2631 printer in expanded mode. **300** DASI-300 printer. **300-12** DASI-300 terminal set to 12 characters per inch. **382** DTC-382. **4000a** Trendata 4000a terminal (4000A). **450** DASI-450 (Diablo Hyterm) printer. **450-12** DASI-450 terminal set to 12 characters per inch. **832** Anderson Jacobson 832 terminal. **8510** C.ITOH printer. **tn300** GE Terminet 300 terminal. **X** Printers equipped with a TX print train. **300s** DASI-300s printer (300S). **300s-12** DASI-300s printer set to 12 characters per inch (300S-12).
-u *Number*	Sets the bold factor (number of character overstrokes) for the third font position (bold) to the specified number, or to 0 if the *Number* variable is missing.
-z	Prints only messages generated by **.tm** (workstation message) requests. **Note:** See the Macro Packages for Formatting Tools in the **troff** command for information about the macros.
-	Forces input to be read from standard input.

Files

Item	Description
/usr/share/lib/tmac/tmac.*	Contains pointers to standard macro files.
/usr/share/lib/macros/*	Contains standard macro files.
/usr/share/lib/nterm/*	Contains the terminal driving tables for the **nroff** command.
/usr/share/lib/pub/terminals	Contains a list of supported terminals.

nslookup Command

Purpose

Queries internet domain name servers interactively.

Syntax

nslookup [- option] [name | -] [server]

Description

The **nslookup** command queries internet domain name servers in two modes. Interactive mode allows you to query name servers for information about various hosts and domains, or to print a list of the hosts in a domain. In noninteractive mode, the names and requested information are printed for a specified host or domain.

The **nslookup** command enters interactive mode when no arguments are given, or when the first argument is a - (minus sign) and the second argument is the host name or internet address of a name server. When no arguments are given, the command queries the default name server. The **nslookup** command enters non-interactive mode when you give the name or internet address of the host to be looked up as the first argument. The optional second argument specifies the host name or address of a name server. You can specify options on the command line if they precede the arguments and are prefixed with a hyphen. For example, to change the default query type to host information, and the initial timeout to 10 seconds, enter the following command:

```
nslookup -query=hinfo  -timeout=10
```

Interactive commands

Item	Description
host [*server*]	Looks up information for the host using the current default server or using server, if specified. If the host is an Internet address and the query type is **A** or **PTR**, the **nslookup** command returns the name of the host. If the host is a name and does not have a trailing period, the search list is used to qualify the name. To look up a host not in the current domain, append a period to the name.
server *Domain* **lserver** *Domain*	Changes the default server to the value specified by the *Domain* parameter. The **lserver** subcommand uses the initial server to look up information about the domain. The **server** subcommand uses the current default server. If an authoritative answer cannot be found, the names of any additional servers that might have the answer are returned.
exit	Exits the program.

Item	Description
set *Keyword*[**=***Value*]	Changes state information that affects lookups. You can specify the following keywords: **all** Prints the current values of the frequently used options to **set**. Information about the current default server and host is also printed. **class=*value*** Changes the query class to one of the following value. The class specifies the protocol group of the information. The default is **IN**. **IN** The Internet class. **CH** The Chaos class. **HESIOD** The Hesiod class. **ANY** Wildcard (any of the above). **[no]debug** Turns debugging mode on. The default is **nodebug**. **[no]d2** Turns comprehensive debugging on. The default is **nod2**. **domain=*name*** Changes the default domain name to the name specified by the *name* parameter. **[no]search** Appends the domain names in the domain search list to the request until an answer is received, if the lookup request contains a period other than a trailing period. The default is **search**. **port=*value*** Changes the default TCP/UDP name server port to the number specified by the *value* parameter. The default value is 53. **querytype=*value*type=*value*** Changes the type of the information query to the type specified by the *value* parameter. The default value is A. **[no]recurse** Tells the name server to query other servers if it does not have the information. The default is **recurse**. **retry=*number*** Sets the number of retries to the number specified by the *number* parameter. **timeout=*number*** Changes the initial timeout interval for waiting for a reply to the seconds specified by the *number* parameter. **[no]vc** Always uses a virtual circuit when sending requests to the server. The default is **novc**. **[no]fail** Tries the next name server if a name server responds with SERVFAIL or a referral (**nofail**) or terminate query (**fail**) on such a response. The default is **nofail**.

Files

Item	Description
/etc/resolv.conf	Contains the initial domain name and nameserver addresses.

nsupdate Command

Purpose

Updates a DNS server.

Syntax

Refer to the syntax for the **nsupdate4**, **nsupdate8**or **nsupdate9** command.

Description

AIX 7.1 supports only BIND version 9. BIND 8 application code is removed from AIX 7.1 and the **named** daemon links to **named9** now, and **nsupdate** to **nsupdate4**. To use a different version of **nsupdate**, you must relink the symbolic links accordingly to the **nsupdate** command.

For example, to use **nsupdate9**, type:

```
ln -fs /usr/sbin/nsupdate9 /usr/sbin/nsupdate
```

nsupdate4 can be used with **named8** (which is now removed from AIX 7.1), but **nsupdate9** must be used with **named9** because the security process is different.

Files

/usr/sbin/named
Contains a symbolic link to the version of **named** being used on the system.

/usr/sbin/nsupdate
Contains a symbolic link to the version of **nsupdate** being used on the system.

/usr/sbin/nsupdate4
Contains the BIND version 4 **nsupdate** command.

/usr/sbin/nsupdate8
Contains the BIND version 8 **nsupdate** command.

/usr/sbin/nsupdate9
Contains the BIND version 9 **nsupdate** command.

nsupdate4 Command

Purpose

Updates a DNS server.

Syntax

nsupdate4 [**-a**] [**-g**] [**-i**] [**-q**] [**-v**] [**-?**] [**-k** *KeyFile*] [**-h** *HostName*] [**-d** *DomainName*] [**-p** *PrimaryName*] [**-r** *IPAddress*] [**-s** "*CommandString*"]

Description

The **nsupdate4** command updates the DNS server. The **nsupdate4** command runs in either interactive mode or command mode. If a command string is provided, the **nsupdate4** command runs the command string and then exits. The return code is dependent upon the successfulness of the command string.

The valid internal commands for the command string or interactive modes are:

Item	Description
r	Reset update packets. This must be first.
d	Delete a record. Following this command are questions for a record type and the value to delete.
a	Add a record. Following this command are questions for a record type and the value to add.
n	Add a record only if it doesn't exist yet. Following this command are questions for a record type and the value to add.
e	Add a record only if it already exists. Following this command are questions for a record type and the value to add.
t	Sets the default time to live value for the updated records.

Item	Description
s	Signs the update. Depending on if the **-a** or **-g** flags were specified, a key will be generated and the update will be signed.
x	Transmit the update packet to the server specified by the **-p** flag.
v	Turns on or off verbose mode.
i	Returns the information passed in by the parameters.
p	Prints the update packet in record format.
q	Exits the command

The **-g** flag allows you to generate a set of keys to distribute to clients for use in secure mode. This flag takes the hostname and the primary name and generates a public and a private key. For secure mode zone operation, the public is entered into the DNS server's database for the data to secure and the private key is placed on the client so that it can update that information at a later time.

The **-a** flag allows you to enter administrative mode. The zone may be secured by a zone key. This key gives the user full access to the zone. The **-a** flag tries to use the zone key for update signatures instead of the individual records key.

Flags

Item	Description
-a	Administrative mode. Attempts to use zone key instead of individual records key.
-d *DomainName*	Specifies the name of the domain to apply the update to. This is used with all records except PTR records.
-g	Generation mode. Used to generate a key pair for a primary name and a hostname.
-h *HostName*	Specifies the name of the record to update. This is used with all records except PTR records.
-i	Ignores errors and runs all the commands in the string.
-k *KeyFile*	Specifies the name of the default keyfile. This is the file for keys.
-p *PrimaryName*	Specifies the name or IP address of a DNS server. The primary DNS server is prefered.
-q	Turns off output.
-r *IPAddress*	Specifies the IP Address of the record to update. This is used only with PTR records.
-s "*CommandString*"	A set of internal commands separated by spaces or colons.
-v	Turns on verbose output.
-?	Command line options list

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.

Item	Description
>0	An error occurred.

Security

Access Control: Any User

Example

To initialize a packet, delete all A records for the specified hostname, add an A record for the hostname to 9.3.145.2 association, signed and valid for 300 seconds with a default KEY pad of 3110400, transmit the packet, and quit, enter: (where ";" is pressing the enter key)

```
r;d;a;*;a;a;9.3.145.2;s;300;3110400;x;q
```

If any one of the items had failed, a message would be printed. In command line mode, an error would cause the program to exit and return 1.

Files

Item	Description
/usr/sbin/nsupdate4	Contains the **nsupdate4** command.
/usr/sbin/named	Contains the DNS server.

nsupdate8 Command

Purpose

Generates a DNS update packet readable by a BIND 8 nameserver.

Syntax

nsupdate8 [**-v**] [**-d**] [*Filename*]

Description

The **nsupdate8** command can read from a file specified on the command line, from stdin for pipes or redirected input from a file, or interactively from a tty. All three methods use the same format specified below. The input defines a DNS update packet that can be used to update a ZONE. There are two sections to an update, a prerequisite section and an update section. The DNS name server verifies that all the prerequisites are true before processing the update section.

Flags

Item	Description
-d	Causes **nsupdate8** to generate additional debug information about its actions.
-v	Tells **nsupdate8** to use a virtual circuit (TCP connection), instead of the usual UDP connection.

The input format is defined as a set of update packets. Each packet is a set of strings terminated with a newline. The last string in the input stream may end with an EOF. If the stream is to contain multiple update packets, each packet must be separated from the next packet by a blank line (single newline

character). The semi-colon is used a comment character. Anything after it is ignored and thrown out of the update packet.

The input format for nsupdate8 is a follows:

```
section opcode  name [ttl] [class] [type] [data]
```

This is the general form. Each value of *section* and *opcode* modify what is required for later arguments.

Item	Description
section	Defines the section of the update this record is for. Values are: **prereq** Indicates the record is for the prerequisites section. **update** Indicates the record is for the update section.
opcode	Defines the operation to do with this record. **Values are:** **Prerequisite operations:** **nxdomain** Indicates that the name should be checked for non-existance. The ttl must be a non-zero value to indicate for how long it shouldn't exist. An optional class can be specified to restrict the search to only that class. The type of T_ANY is used as a wildcard to match any record type. **nydomain** Indicates that the name should be checked for existance. The ttl must be a non-zero value to indicate for how long the name should continue to exist. An optional class is allowed to restrict the search to only that class. The record type is T_NONE. This forces the check to make sure the name exists. **nxrrset** Indicates that the record of a specific type doesn't exist for the name. An optional class and ttl are allowed to restrict the search. A type is mandatory. **nyrrset** Indicates that the record of a specific type must exist for the name. The ttl and class are optional to restrict the search. The type and data are mandatory. Data may be a wild card. If the data is not a wildcard, it must match the format for the type specified. **Values are:** **Update operations:** **add** Indicates that the record should be added to the zone. The type and data are mandatory. Wildcards are not allowed as data. The ttl is mandatory and must be non-zero. The class is optional. **delete** Indicates that the record should be deleted from the zone. The type and data are optional. A wildcard is allowed for data. data defaults to the NULL string and type defaults to T_ANY. ttl and class are optional. If ttl is specified, it is reset to 0.
name	The name of the DNS entry that one is testing or modifying.
[*ttl*]	Optional time-to-live for the record being added. In some forms, this is not optional.

Item	Description
[*class*]	Class of the record to be added to the zone. Values are IN, HESIOD, and CHAOS. The default for all messages is IN.
[*type*]	The type of the record to be added to or checked against the zone. Values are A, NS, CNAME, SOA, MB, MR, NULL, WKS, PTR, HINFO, MINFO, MX, TXT, RP, AFSDB, X25, ISDN, RT, NSAP, NSAP_PTR, PX, and LOC. NOTE: The CNAME type may only be added with TSIG and TKEY records which are not currently supported in BIND 8.
[*data*]	The data to be added or checked against the zone. The data should be valid for the specified type and in the DOMAIN data file format of a DNS server zone file. For prerequisite checking, an asterik (*) is used to match any value. This can also be used to delete all records of a particular type.

Here are the specific format cases:

```
prereq nxdomain <name> <ttl != 0> [class]
prereq nydomain <name ttl != 0> [class]
prereq nxrrset <name> [ttl] [class] <type>
prereq nyrrset <name> [ttl] [class] <type> <data>
update delete <name> [ttl] [class] [type] [data]
update add <name> <ttl != 0> [class] <type> <data>
```

Diagnostics

Messages indicating the different actions done and/or problems encountered by the program.

nsupdate9 Command

Purpose

Dynamic DNS update utility.

Syntax

nsupdate9 [**-d**] [**-y** [*hmac:*] *keyname: secret* | **-k** *keyfile*] [**-t** *timeout*] [**-u** *udptimeout*] [**-r** *udpretries*] [**-v**] [*filename*]

Description

The **nsupdate9** command is used to submit Dynamic DNS Update requests as defined in RFC2136 to a name server. This allows resource records to be added or removed from a zone without manually editing the zone file. A single update request can contain requests to add or remove more than one resource record.

Zones that are under dynamic control via **nsupdate9** or a DHCP server should not be edited by hand. Manual edits could conflict with dynamic updates and cause data to be lost.

The resource records that are dynamically added or removed with **nsupdate9** have to be in the same zone. Requests are sent to the zone's master server. This is identified by the MNAME field of the zone's SOA record.

The **-d** option makes **nsupdate9** operate in debug mode. This provides tracing information about the update requests that are made and the replies received from the name server.

Transaction signatures can be used to authenticate the Dynamic DNS updates. These use the TSIG resource record type described in RFC2845 or the SIG(0) record described in RFC3535 and RFC2931. The signatures rely on a shared secret that should only be known to **nsupdate9** and the name server. Currently, the only supported encryption algorithm for TSIG is HMAC-MD5, which is defined in RFC 2104. Once other algorithms are defined for TSIG, applications will need to ensure they select the

appropriate algorithm as well as the key when authenticating each other. For instance suitable key and server statements would be added to **/etc/named.conf** so that the name server can associate the appropriate secret key and algorithm with the IP address of the client application that will be using TSIG authentication. SIG(0) uses public key cryptography. To use a SIG(0) key, the public key must be stored in a KEY record in a zone served by the name server. **nsupdate9** does not read **/etc/named.conf.**

nsupdate9 uses the **-y** or **-k** option to provide the shared secret needed to generate a TSIG record for authenticating Dynamic DNS update requests. The default type is HMAC-MD5. These options are mutually exclusive. With the **-k** option, **nsupdate9** reads the shared secret from the file *keyfile*, whose name is of the form **K{name}.+157.+{random}.private**. For historical reasons, the file **K{name}.+157.+{random}.key** must also be present. When the **-y** option is used, a signature is generated from [*hmac*:] *keyname:secret*. *keyname* is the name of the key, and *secret* is the base64 encoded shared secret. Use of the **-y** option is discouraged because the shared *secret* is supplied as a command line argument in clear text. This may be visible in the output from ps(1) or in a history file maintained by the user's shell.

You can also use the **-k** flag to specify a SIG(0) key used to authenticate Dynamic DNS update requests. In this case, the key specified is not an HMAC-MD5 key.

By default **nsupdate9** uses UDP to send update requests to the name server unless they are too large to fit in a UDP request in which case TCP is used. The **-v** option makes **nsupdate9** use a TCP connection. This may be preferable when a batch of update requests is made.

Flags

Item	Description
-d	Makes **nsupdate9** operate in debug mode.
-k *keyfile*	Reads the shared secret from the file *keyfile*.
-r *udpretries*	Sets the number of UDP retries. The default is 3. If zero, only one update request is made.
-t *timeout*	Sets the maximum time a update request can take before it is aborted. The default is 300 seconds. You can use zero to disable the timeout.
-u *udptimeout*	Sets the UDP retry interval. The default is 3 seconds. If zero, the interval is computed from the timeout interval and number of UDP retries.
-v	Makes **nsupdate9** use a TCP connection.
-y [*hmac:*] *keyname:secret*	Generates a signature from keyname:*secret*.

Parameters

Item	Description
filename	File to be updated.

Input Format

nsupdate9 reads input from the file *filename* or standard input. Each command is supplied on exactly one line of input. Some commands are for administrative purposes. The others are either update instructions or prerequisite checks on the contents of the zone. These checks set conditions that some name or set of resource records (RRset) either exists or is absent from the zone. These conditions must be met if the entire update request is to succeed. Updates will be rejected if the tests for the prerequisite conditions fail.

Every update request consists of zero or more prerequisites and zero or more updates. This allows a suitably authenticated update request to proceed if some specified resource records are present or missing from the zone. A blank input line (or the **send** command) causes the accumulated commands to be sent as one Dynamic DNS update request to the name server.

The command formats and their meaning are as follows:

Item	Description
server [*servername*] [*port*]	Sends all dynamic update requests to the name server *servername*. When no **server** statement is provided, **nsupdate9** will send updates to the master server of the correct zone. The MNAME field of that zone's SOA record will identify the master server for that zone. *port* is the port number on *servername* where the dynamic update requests get sent. If no *port* number is specified, the default DNS port number of 53 is used.
local [*address*] [*port*]	Sends all dynamic update requests using the local address. When no local statement is provided, **nsupdate9** will send updates using an *address* and *port* choosen by the system. *port* can additionally be used to make requests come from a specific port. If no port number is specified, the system will assign one.
zone [*zonename*]	Specifies that all updates are to be made to the zone *zonename*. If no zone statement is provided, **nsupdate9** will attempt determine the correct zone to update based on the rest of the input.
key [*name*] [*secret*]	Specifies that all updates are to be TSIG signed using the *keyname keysecret* pair. The key command overrides any key specified on the command line via **-**y or **-k**.
prereq nxdomain [*domain-name*]	Requires that no resource record of any type exists with name *domain-name*.
prereq yxdomain [*domain-name*]	Requires that *domain-name* exists (has as at least one resource record, of any type).
prereq nxrrset [*domain-name*] [*class*] [*type*]	Requires that no resource record exists of the specified *type*, *class* and *domain-name*. If class is omitted, IN (internet) is assumed.
prereq yxrrset [*domain-name*] [*class*] [*type*]	This requires that a resource record of the specified *type*, *class* and *domain-name* must exist. If class is omitted, IN (internet) is assumed.
prereq yxrrset [*domain-name*] [*class*] [*type*] [*data...*]	The data from each set of prerequisites of this form sharing a common *type*, *class*, and *domain-name* are combined to form a set of RRs. This set of RRs must exactly match the set of RRs existing in the zone at the given *type*, *class*, and *domain-name*. The *data* are written in the standard text representation of the resource record's RDATA.
update delete [*domain-name*] [*ttl*] [*class*] [*type*] [*data...*]	Deletes any resource records named *domain-name*. If *type* and *data* is provided, only matching resource records will be removed. The internet *class* is assumed if class is not supplied. The *ttl* is ignored, and is only allowed for compatibility.
update add [*domain-name*] [*ttl*] [*class*] [*type*] [*data...*]	Adds a new resource record with the specified *ttl*, *class* and *data*.
show	Displays the current message, containing all of the prerequisites and updates specified since the last send.
send	Sends the current message. This is equivalent to entering a blank line.
answer	Displays the answer.

Lines beginning with a semicolon are comments and are ignored.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

Note: The **nsupdate9** command does not sort two updates combined in one update into different zones. Two updates need to be made individually by inserting a blank line or the **send** command between them.

The examples below show how **nsupdate9** could be used to insert and delete resource records from the example.com zone. Notice that the input in each example contains a trailing blank line so that a group of commands are sent as one dynamic update request to the master name server for example.com.

```
# nsupdate9
> update delete oldhost.example.com A
> update add newhost.example.com 86400 A 172.16.1.1
>
```

Any A records for oldhost.example.com are deleted. and an A record for newhost.example.com it IP address 172.16.1.1 is added. The newly-added record has a 1 day TTL (86400 seconds)

```
# nsupdate9
> prereq nxdomain nickname.example.com
> update add nickname.example.com CNAME somehost.example.com
> send
```

The prerequisite condition gets the name server to check that there are no resource records of any type for **nickname.example.com**. If there are, the update request fails. If this name does not exist, a CNAME for it is added. This ensures that when the CNAME is added, it cannot conflict with the long-standing rule in RFC1034 that a name must not exist as any other record type if it exists as a CNAME. (The rule has been updated for DNSSEC in RFC2535 to allow CNAMEs to have SIG, KEY and NXT records.)

```
# nsupdate9
> update delete 61.26.31.9.in-addr.arpa 0 IN PTR
> update add 61.26.31.9.in-addr.arpa 86400 IN PTR newhost.example.com.
```

Any PTR records for IP address 9.31.26.61 are deleted and a PTR record for IP address 9.31.26.61 and hostname **newhost.example.com** is added. The newly-added record has a 1 day-TTL (86400 seconds).

Files

Item	Description
/etc/resolv.conf	Used to identify default name server
K{name}.+157.+{random}.key	Base-64 encoding of HMAC-MD5 key created by **dnssec-keygen**(8).
K{name}.+157.+{random}.private	Base-64 encoding of HMAC-MD5 key created by **dnssec-keygen**(8).

ntpd4 Daemon

Purpose

Network Time Protocol (NTP) Daemon.

Syntax

ntpd4 [**-4**] [**-6**] [**-a**] [**-A**] [**-b**] [**-c** *conffile*] [**-d**] [**-D** *level*] [**-f** *driftfile*] [**-g**] [**-i** *jaildir*] [**-k** *keyfile*] [**-l** *logfile*] [**-L**] [**-n**] [**-N**] [**-p** *pidfile*] [**-P** *priority*] [**-q**] [**-r** *broadcastdelay*] [**-s** *statsdir*] [**-t** *key*] [**-u** *user[:group]*] [**-U** *interface update interval*] [**-v** *variable*] [**-V** *variable*] [**-x**]

Description

The **ntpd** program is an operating system daemon that sets and maintains the system time-of-day in synchrony with the Internet Standard Time servers. The **ntpd** program is a complete implementation of the Network Time Protocol (NTP) version 4, and also retains compatibility with version 3, as defined by the RFC-1305, and version 1 and 2, as defined by RFC-1059 and RFC-1119. The **ntpd** program generally computes in 64-bit floating point arithmetic mode. If a precision of 232 picoseconds needs to be maintained, then **ntpd** computes in 64-bit fixed-point mode. The ultimate precision of 232 picoseconds is not achievable with existing workstations and networks, however, this precision may be required with future Gigahertz CPU clocks and Gigabit LANs.

Frequency discipline

The **ntpd** behavior at startup depends on the frequency file, usually **ntp.drift**. This file contains the latest estimate of clock frequency error. When the **ntpd** daemon is started and the file does not exist, the **ntpd** enters a special mode designed to quickly adapt to the particular system clock oscillator time and frequency error. This takes approximately 15 minutes, after which the time and frequency are set to nominal values and the **ntpd** enters normal mode of operation, where the time and frequency are continuously tracked relative to the server. After one hour the frequency file is created and the current frequency offset is written to this file. When the **ntpd** is started and the file does exist, the **ntpd** frequency is initialized from the file and **ntpd** enters the normal mode of operation. After that the current frequency offset is written to the file at hourly intervals.

Operating modes

The **ntpd** program can operate in any of the several modes, including symmetric active/passive, client/server, and broadcast/multicast. The **ntpd** normally operates continuously while monitoring for small changes in frequency and trimming the clock for the ultimate precision. The **ntpd** can operate in a one-time mode where the time is set from an external server and frequency is set from a previously recorded frequency file. A broadcast or multicast client can discover remote servers, compute server-client propagation delay correction factors and configure itself automatically. This makes it possible to deploy a fleet of workstations without specifying configuration details specific to the local environment.

By default, **ntpd** runs in continuous mode where each of the possibly several external servers are polled at intervals determined by an intricate state machine. The state machine measures the incidental roundtrip delay jitter and the oscillator frequency wander and determines the best poll interval using a heuristic algorithm. Ordinarily, and in most operating environments, the state machine starts with 64-seconds intervals and eventually increases in steps to 1024 seconds. A small amount of random variation is introduced in order to avoid bunching at the servers. In addition, should a server become unreachable for some time, the poll interval is increased in steps to 1024 seconds in order to reduce network overhead.

In some cases, it might not be practical for **ntpd** to run continuously. A common workaround has been to run the **ntpdate** program from a **cron** job at designated times. However, this program does not have the crafted signal processing, error checking and mitigation algorithms of **ntpd**. The **-q** option is intended for this purpose. Setting this option will cause **ntpd** to exit just after setting the clock for the first time. The procedure for initially setting the clock is the same as in continuous mode; most applications specify the **iburst** command with the server configuration command. With this command a volley of messages are exchanged to groom the data and the clock is set in to about 10 second. If no response is received, after a couple of minutes, the daemon times out and exits. After a certain period if no response is received, the **ntpdate** program is stopped.

Flags

Item	Description
-4	Forces DNS resolution of hostnames to the IP version 4 namespace.
-6	Force DNS resolution of hostnames to the IP version 6 namespace.
-a	Requires cryptographic authentication for broadcast client, multicast client and symmetric passive associations. This is the default value.
-A	Does not require cryptographic authentication for broadcast client, multicast client, and symmetric passive associations.
-b	Enables the client to synchronize to broadcast servers.
-c *conffile*	Specifies the name and path of the configuration file, default `/etc/ntp.conf`.
-d	Specifies debugging mode. This option may occur more than once, with each occurrence indicating greater detail of display.
-D *level*	Specifies the debugging level directly.
-f *driftfile*	Specifies the name and path of the frequency file, default **/etc/ntp.drift**. This is the same operation as the **driftfile driftfile** configuration command.
-g	Allows the time to be set to any value without restriction; this can happen only once. The **ntpd** command exits with a message to the system log if the offset exceeds the panic threshold, which is 1000 seconds by default. If the threshold is exceeded after that, **ntpd** will exit with a message to the system log. This option can be used with the **-q** and **-x** options.
-i *jaildir*	The **chroot** command directs the server to the directory **jaildir**. This option also implies that the server attempts to drop root privileges at startup (otherwise, **chroot** gives little additional security), and it is only available if the operating system supports to run the server without full root privileges. You must specify a **-u** option.
-k *keyfile*	Specifies the name and path of the symmetric key file, default `/etc/ntp.keys`. This is the same operation as the keys keyfile configuration command.
-l *logfile*	Specifies the name and path of the log file. The default is the system log file. This is the same operation as the **logfile** configuration command.
-L	Does not listen to virtual IPs. The default is to listen.
-n	Does not fork.
-N	Runs the **ntpd** at the highest priority level to the extent permitted by the operating system.
-p *pidfile*	Specifies the name and path of the file used to record the **ntpd** process ID. This is the same operation as the **pidfile pidfile** configuration command.
-P *priority*	Runs the **ntpd** at the specified priority to the extent permitted by the operating system.
-q	Exits the **ntpd** just after the first time the clock is set. This behavior mimics that of the **ntpdate** program, which is to be retired. The **-g** and **-x** options can be used with this option. **Note:** The kernel time discipline is disabled with this option.
-r *broadcastdelay*	Specifies the default propagation delay from the broadcast/multicast server to the client. This is necessary only if the delay cannot be computed automatically by the protocol.
-s *statsdir*	Specifies the directory path for files created by the statistics facility. This is the same operation as the **statsdir** configuration command.
-t *key*	Adds a key number to the trusted key list. This option can occur more than once.

Item	Description
-u *user[:group]*	Specifies an user, and optionally a group, to switch. This option is only available if the operating system supports running the server without complete root privileges.
-U *interface update interval*	Specifies the number of seconds to wait between the interface list scans to pick up new and deleted network interface. Set to 0 to disable dynamic interface list updating. The default is to scan every 5 minutes.
-v *variable*	Adds a system variable listed by default.
-V *variable*	
-x	Slews the time if the offset is less than the step threshold, which is 128 milliseconds by default, and steps up if above the threshold. This option sets the threshold to 600 seconds, which is well within the accuracy window to set the clock manually.

Exit Status

This command returns the following exit values:

0
Successful completion.

> 0
An error occurred.

Security

Access Control : You must have root authority to run this command.

Auditing Events : N/A

Examples

By default, the symbolic link `/usr/sbin/xntpd` points to NTP version 3 daemon (`/usr/sbin/ntp3/xntpd`). To run NTP version 4 daemon (`/usr/sbin/ntp4/ntpd4`), modify the symbolic link so that it points to the version 4 daemon.

```
/usr/sbin/xntpd-->
/usr/sbin/ntp4/ntpd4
```

1. To start the **xntpd** daemon, enter:

   ```
   startsrc -s xntpd
   ```

2. To stop the **xntpd** daemon, enter:

   ```
   stopsrc -s xntpd
   ```

By default, the NTP symbolic link `/usr/sbin/xntpd` points to the NTP version 3 daemon (`/usr/sbin/ntp3/xntpd`). To run the NTP version 4 daemon (`/usr/sbin/ntp4/ntpd4`), switch to the NTP version 4 binaries by using the following command:

```
/usr/sbin/ntp_ssw -v4
```

After you run the **ntp_ssw** command successfully, all NTP symbolic links point to NTP version 4 binaries as shown in the following example:

```
/usr/sbin/ntpq -> /usr/sbin/ntp4/ntpq4
/usr/sbin/sntp -> /usr/sbin/ntp4/sntp4
/usr/sbin/ntptrace -> /usr/sbin/ntp4/ntptrace4
/usr/sbin/xntpd -> /usr/sbin/ntp4/ntpd4
/usr/sbin/ntpdate -> /usr/sbin/ntp4/ntpdate4
/usr/sbin/ntp-keygen -> /usr/sbin/ntp4/ntp-keygen4
```

Files

Item	Description
`/usr/sbin/ntp4/ntpd4`	Contains the **ntpd4** daemon. Default symbolic link to NTP version 3 binary from `/usr/sbin` directory. `/usr/sbin/xntpd --> /usr/sbin/ntp3/xntpd`
`/etc/ntp.conf`	Contains the default configuration file.
`/etc/ntp.drift`	Contains the default drift file.

ntpdate Command

Purpose

Sets the date and time using the Network Time Protocol (NTP).

Syntax

ntpdate [**-b**] [-c] [**-d**] [**-s**] [**-u**] [**-a** *Keyid*] [**-e** *AuthenticationDelay*] [**-k** *KeyFile*] [**-o** *Version*] [**-p** *Samples*] [**-t** *TimeOut*] *Server ...*

Description

The **ntpdate** command sets the local date and time by polling the NTP servers specified to determine the correct time. It obtains a number of samples from each server specified and applies the standard NTP clock filter and selection algorithms to select the best of the samples.

The **ntpdate** command makes time adjustments in one of the following ways:

- If it determines that the clock is off by more than 0.5 seconds, it steps the clock's time by calling the **settimeofday** subroutine. This is the preferred method at boot time.
- If it determines that the clock is off by less than 0.5 seconds, it slews the clock's time by calling the **adjtime** subroutine with the offset. This method tends to keep a badly drifting clock more accurate, though at some expense to stability. When running the **ntpdate** command on a regular basis from the **cron** command instead of running a daemon, doing so once every hour or two results in precise enough timekeeping to avoid stepping the clock.

  Notes:

  1. The **ntpdate** command's reliability and precision improves dramatically with a greater number of servers. Although you can use a single server, you obtain better performance by providing at least three or four servers.
  2. If an NTP server daemon like the **xntpd** daemon is running on the same host, the **ntpdate** command will decline to set the date.
  3. You must have root authority on the local host to run this command.

Flags

Item	Description
-a *Keyid*	Enable the authentication function and authenticate all packets using *Keyid*. By default, the authentication function is disabled.
-b	Step the clock's time by calling the **settimeofday** subroutine.
-c	Slew the clock's time by calling the **adjtime** subroutine.
-d	Specifies debug mode. Determines what results the **ntpdate** command produces without actually doing them. The results appear on the screen. This flag uses unprivileged ports.
-e *AuthenticationDelay*	Specifies the amount of time in seconds to delay the authentication processing. Typical values range from 0.0001 to 0.003.
-k *KeyFile*	Specifies a different name for the file containing the keys when not using the default **/etc/ntp.keys** file. See ... for the description of the *KeyFile*.
-o *Version*	Specifies the NTP version implementation to use when polling its outgoing packets. The values for *Version* can be 1, 2 or 3. The default is 3.
-p *Samples*	Specifies the number of samples to acquire from each server. The values for *Samples* can be between 1 and 8 inclusive. The default is 4.
-s	Specifies the use of the syslog facility to log actions instead of using standard output. Useful when running the **ntpdate** command with the **cron** command.
-t *TimeOut*	Specifies the amount of time to wait for a response. The value given for *TimeOut* is rounded to a multiple of 0.2 seconds. The default is 1 second.
-u	Specifies the use of an unprivileged port to send the packets from. Useful when you are behind a firewall that blocks incoming traffic to privileged ports, and you want to synchronize with hosts beyond the firewall. A firewall is a system or machine that controls the access from outside networks to a private network.

Parameters

Item	Description
Server ...	Specifies the servers to poll.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Access Control: You must have root authority to run this command.

Auditing Events: N/A

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

To set the local date and time by polling the NTP servers at address `9.3.149.107`, enter:

```
/usr/sbin/ntpdate 9.3.149.107
```

Output similar to the following appears:

```
28 Feb 12:09:13 ntpdate [18450]: step time server 9.3.149.107
offset 38.417792 sec
```

Files

Item	Description
/usr/sbin/ntpdate	Contains the **ntpdate** command.
/etc/ntp.keys	Contains the default key file.

ntpdate4 Command

Purpose

Sets the date and time using the Network Time Protocol (NTP).

Syntax

ntpdate4 [**-4**] [**-6**] [**-a** *key*] [**-B**] [**-b**] [**-d**] [**-e** *authdelay*] [**-k** *keyfile*] [**-o** *version*] [**-p** *samples*] [**-q**] [**-s**] [**-t** *timeout*] [**-u**] [**-v**] *server* [...]

Description

The **ntpdate** command sets the local date and time by polling the Network Time Protocol (NTP) server(s) given as the server arguments to determine the correct time. The **ntpdate** must be run as root on the local host. Samples are obtained from each of the servers specified and a subset of the NTP clock filter and selection algorithms are applied to select the best. Note that the accuracy and reliability of **ntpdate** depends on the number of servers, the number of polls each time it is run and the interval between runs.

The **ntpdate** can be run manually as necessary to set the host clock, or it can be run from the host startup script to set the clock at boot time. This is useful in some cases to set the clock initially before starting the NTP daemon **ntpd**. It is also possible to run **ntpdate** from a **cron** script. However, it is important to note that **ntpdate** with contrived **cron** scripts is not a substitute for the NTP daemon, which uses complex algorithms to maximize accuracy and reliability while minimizing resource use. Finally, since **ntpdate** does not tune the host clock frequency as does ntpd, the accuracy using **ntpdate** is limited.

Time adjustments are made by **ntpdate** in one of two ways. If **ntpdate** determines that the clock is in error of more than 0.5 seconds it will simply step the time by calling the system **settimeofday()** routine. If the error is less than 0.5 seconds, it will slew the time by calling the system **adjtime** () routine. The latter technique is less disruptive and more accurate when the error is small, and works quite well when **ntpdate** is run by **cron** every hour or two.

The **ntpdate** will decline to set the date if an NTP server daemon (**ntpd**) is running on the same host. When running **ntpdate** on a regular basis from **cron** as an alternative to running a daemon, doing so once every hour or two will result in precise enough timekeeping to avoid stepping the clock.

Note: Where a host name is expected, a -4 qualifier preceding the host name forces DNS resolution to the IP version 4 namespace, while a -6 qualifier forces DNS resolution to the IP version 6 namespace.

Flags

Item	Description
- 4	Forces DNS resolution of following host names on the command line to the IP v4 namespace
- 6	Forces DNS resolution of following host names on the command line to the IP v6 namespace.
- a *key*	Enables the authentication function and specifies the key identifier to be used for authentication as the argument **keyntpdate**. The keys and key identifiers must match in both the client and server key files. The default is to disable the authentication function.
- B	Forces the time to be slewed using the **adjtime** () system call, even if the measured offset is greater than + or - 128 millisecond. The default is to step the time using **settimeofday** () if the offset is greater than + or -128 millisecond. Note that, if the offset is much greater than + or -128 millisecond in this case, that it can take a long time (hours) to slew the clock to the correct value. During this time the host should not be used to synchronize clients.
- b	Forces the time to be stepped using the **settimeofday** () system call, rather than slewed (default) using the **adjtime** () system call. This option should be used when called from a startup file at boot time.
- d	Enables the debugging mode, in which **ntpdate** will go through all the steps, but not adjust the local clock. Information useful for general debugging is also printed.
- e *authdelay*	Specifies the processing delays to perform an authentication function as the value *authdelay*, in seconds and fraction (See the ntpd for more details). This number is usually small enough to be negligible for most purposes, though specifying a value may improve timekeeping on very slow CPUs.
- k *keyfile*	Specifies the path for the authentication key file as the string keyfile. The default is `/etc/ntp.keys`.
- o *version*	Specifies the NTP version for outgoing packets as the integer version, which can be 1 or 2. The default is 3. This allows **ntpdate** to be used with older NTP versions.
- p *samples*	Specifies the number of samples to be acquired from each server as integer samples, with values from 1 to 8 inclusive. The default value is 4.
- q	Specifies the query. Does not set the clock.
- s	Diverts logging output from the standard output (default) to the system **syslog** facility. This is designed primarily for convenience of **cron** scripts.
- t *timeout*	Specifies the maximum time waiting for a server response as the value timeout, in seconds and fraction. The value is rounded to a multiple of 0.2 seconds. The default is 1 second, a value suitable for polling across a LAN.
- u	Directs **ntpdate** to use an unprivileged port or outgoing packets. You can use this option when behind a firewall that blocks incoming traffic to privileged ports, and you want to synchronize with hosts beyond the firewall. Note that the **-d** option always uses unprivileged ports.
- v	Verbose output. This option causes the **ntpdate** version identification string to be logged.

Parameters

Item	Description
Server...	Specifies the servers to poll

Exit Status

This command returns the following exit values:

Item	Description
`0`	Successful completion.
`>0`	An error occurred.

Security

Item	Description
`Access Control`	You must have root privilege to run this command.
`Auditing Events`	N/A

Examples

1. To set the local date and time by polling the NTP servers at address 9.41.254.24, enter:

   ```
   ntpdate 9.41.254.24
   ```

   Output similar to the following appears:

   ```
   address: ::
   address: 0.0.0.0
   25 Feb 12:19:41 ntpdate[434262]: adjust time server 9.41.254.24 offset -0.005270  sec
   ```

Files

Item	Description
`/usr/sbin/ntp4/ntpdate4`	Contains the **ntpdate** command for NTP version 4. Default Symbolic link to NTP version 3 binary from `/usr/sbin` directory. `/usr/sbin/ntpdate --> /usr/sbin/ntp3/ntpdate`
`/etc/ntp.keys`	Encryption keys used by **ntpdate**.

ntpdc4 Command

Purpose

Starts the query or control program for the Network Time Protocol (NTP) daemon, **ntpd**.

Syntax

ntpdc [**-4**] [**-6**] [**-d**] [**-i**] [**-l**] [**-n**] [**-p**] [**-s**] [**-c** *command*] [*host*] [...]

Description

The **ntpdc** command is used to query the **ntpd** daemon about its current state and to request changes in the state. The program may be run either in interactive mode or controlled using command line arguments. Extensive state and statistics information is available through the **ntpdc** interface. In addition, all the configuration options which can be specified at startup using **ntpd**'s configuration file might also be specified at run time using **ntpdc**.

If one or more request options are included in the command line when **ntpdc** is executed, each of the requests will be sent to the NTP servers running on each of the hosts given as command line arguments, or on localhost by default. If no request options are given, **ntpdc** will attempt to read commands from the standard input and execute these on the NTP server running on the first host given on the command line, again defaulting to localhost when no other host is specified. **ntpdc** will prompt for commands if the standard input is a terminal device.

ntpdc uses NTP mode 7 packets to communicate with the NTP server, and hence can be used to query any compatible server on the network which permits it. Note that since NTP is a UDP protocol this communication will be somewhat unreliable, especially over large distances in terms of network topology. **ntpdc** makes no attempt to retransmit requests, and will time requests out if the remote host is not heard from within a suitable timeout time.

The operation of **ntpdc** are specific to the particular implementation of the ntpd daemon and can be expected to work only with this and maybe some previous versions of the daemon. Requests from a remote **ntpdc** program that affects the state of the local server must be authenticated, which requires both the remote program and local server share a common key and key identifier.

Note that in contexts where a host name is expected, a -4 qualifier preceding the host name forces DNS resolution to the IP version 4 namespace, while a -6 qualifier forces DNS resolution to the IP version 6 namespace.

Specifying a command line option other than **-i** or **-n** will cause the specified query (queries) to be sent to the indicated host(s) immediately. Else, **ntpdc** will attempt to read interactive format commands from the standard input.

Flags

Item	Description
-4	Forces DNS resolution of following host names on the command line to the IP version 4 namespace.
-6	Forces DNS resolution of following host names on the command line to the IP version 6 namespace.
-c *command*	The following argument is interpreted as an interactive format command and is added to the list of commands to be executed on the specified host(s). You can run multiple **-c** options.
-d	Enables debugging mode. You can use this option more than once.
-i	Forces **ntpdc** to operate in interactive mode. Prompts will be written to the standard output and commands read from the standard input.
-l	Obtains a list of peers, which are known to the server(s). This switch is equivalent to **-c** *listpeers*.
-n	Outputs all host addresses in dotted-quad numeric format rather than converting them to the canonical host names.
-p	Prints a list of the peers known to the server as well as a summary of their state. This is equivalent to **-c** *peers*.

Item	Description
-s	Prints a list of the peers known to the server as well as a summary of their state. The print format is different from the **-p** switch. This is equivalent to **-c** *dmpeers*.

Parameters

Item	Description
Host...	Specifies the hosts.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Access Control: You must be part of the system group to run this command.

Auditing Events: N/A

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To start the query/control program for the Network Time Protocol daemon, enter:

```
ntpdc
```

2. To print a list of the peers known to the server as well as a summary of their state, enter:

```
ntpdc -p
```

Output similar to the following appears:

```
     remote              local        st   poll reach  delay     offset   disp
==============================================================================
ausgsa.austin.ibm.com 9.124.101.190    2   64    1    0.29128 -0.013381 2.81735
```

ntpdc Internal Commands

Interactive Commands

Interactive format commands consist of a keyword followed by zero to four arguments. Only enough characters of the full keyword to uniquely identify the command need be typed. The output of a command is normally sent to the standard output, but optionally the output of individual commands may be sent to a file by appending a <, followed by a file name, to the command line.

A number of interactive format commands are executed entirely within the ntpdc program itself and do not result in NTP mode 7 requests being sent to a server. The following list describes the interactive commands.

Item	Description
? [command_keyword] or **help [command_keyword]**	A question mark (?) by itself prints a list of all the command keywords known to this incarnation of **ntpq**. A question mark (?) followed by a command keyword will print function and the use of the command.
delay milliseconds	Specifies a time interval to be added to timestamps included in requests which require authentication. This is used to enable (unreliable) server reconfiguration over long delay network paths or between machines whose clocks are unsynchronized.
host hostname	Sets the host to which future queries will be sent. Hostname may be either a host name or a numeric address.
hostnames [yes | no]	If yes is specified, host names are printed in information displays. If no is specified, numeric addresses are printed instead. The default is yes, unless modified using the command line **-n** switch.
keyid keyid	Allows the specification of a key number to be used to authenticate configuration requests from **ntpdc** to the host(s). This must correspond to a key number which the host/server has been configured to use for this purpose (server options: trustedkey, and requestkey). If authentication is not enabled on the host(s) for **ntpdc** commands, the command **keyid 0** should be given, else the keyid of the next subsequent addpeer/addserver/broadcast command will be used.
quit	Exits **ntpdc**.
passwd	Prompts you to type in a password (which will not be echoed) which will be used to authenticate configuration requests. The password must correspond to the key configured for use by the NTP server for this purpose if such requests are to be successful.
timeout milliseconds	Specifies a timeout period for responses to server queries. The default is about 8000 milliseconds. **Note: ntpdc** retries each query once after a timeout, and hence the total waiting time for a timeout will be twice the timeout value set.

Control Message Commands

Query commands result in NTP mode 7 packets containing requests for information being sent to the server. These are read-only commands do not make any modification to the server configuration state.

Item	Description
listpeers	Obtains and prints a brief list of the peers for which the server is maintaining state. These should include all configured peer associations as well as those peers whose stratum is such that they are considered by the server to be possible future synchronization candidates.

Item	Description
peers	Obtains a list of peers for which the server is maintaining state, along with a summary of that state. Summary information includes the address of the remote peer, the local interface address (0.0.0.0 if a local address has yet to be determined), the stratum of the remote peer (a stratum of 16 indicates the remote peer is unsynchronized), the polling interval, in seconds, the reachability register, in octal, and the current estimated delay, offset and dispersion of the peer, all in seconds. The character in the left margin indicates the mode this peer entry is operating in. A + denotes symmetric active, a - indicates symmetric passive, a = means the remote server is being polled in client mode, a ^ indicates that the server is broadcasting to this address, a ~ denotes that the remote peer is sending broadcasts and a * marks the peer the server is currently synchronizing to. The contents of the host field may be one of four forms. It may be a host name, an IP address, a reference clock implementation name with its parameter or REFCLK(implementation number, parameter). On hostnames no only IP-addresses will be displayed.
dmpeers	A slightly different peer summary list. Identical to the output of the peers command, except for the character in the leftmost column. Characters only appear beside peers which were included in the final stage of the clock selection algorithm. A . indicates that this peer was cast off in the falseticker detection, while a + indicates that the peer made it through. A * denotes the peer the server is currently synchronizing with.
showpeer peer_address [...]	Shows a detailed display of the current peer variables for one or more peers. Most of these values are described in the NTP Version 2 specification.
pstats peer_address [...]	Displays per-peer statistic counters associated with the specified peer(s).
clockinfo clock_peer_address [...]	Obtains and print information concerning a peer clock. The values obtained provide information on the setting of fudge factors and other clock performance information.
kerninfo	Obtains and print kernel phase-lock loop operating parameters. This information is available only if the kernel has been specially modified for a precision timekeeping function.
loopinfo [oneline | multiline]	Prints the values of selected loop filter variables. The loop filter is the part of NTP which deals with adjusting the local system clock. The offset is the last offset given to the loop filter by the packet processing code. The frequency is the frequency error of the local clock in parts-per-million (ppm). The time_const controls the stiffness of the phase-lock loop and thus the speed at which it can adapt to oscillator drift. The watchdog timer value is the number of seconds which have elapsed since the last sample offset was given to the loop filter. The oneline and multiline options specify the format in which this information is to be printed, with multiline as the default.

Item	Description
sysinfo	Print a variety of system state variables, i.e., state related to the local server. All except the last four lines are described in the NTP Version 3 specification, RFC-1305. The system flags show various system flags, some of which can be set and cleared by the enable and disable configuration commands, respectively. These are the auth, bclient, monitor, pll, pps and stats flags. See the ntpd documentation for the meaning of these flags. There are two additional flags which are read only, the kernel_pll and kernel_pps. These flags indicate the synchronization status when the precision time kernel modifications are in use. The kernel_pll indicates that the local clock is being disciplined by the kernel, while the kernel_pps indicates the kernel discipline is provided by the PPS signal. The stability is the residual frequency error remaining after the system frequency correction is applied and is intended for maintenance and debugging. In most architectures, this value will initially decrease from as high as 500 ppm to a nominal value in the range .01 to 0.1 ppm. If it remains high for some time after starting the daemon, something may be wrong with the local clock, or the value of the kernel variable tick may be incorrect. The broadcastdelay shows the default broadcast delay, as set by the broadcastdelay configuration command. The authdelay shows the default authentication delay, as set by the authdelay configuration command.
sysstats	Prints statistics counters maintained in the protocol module.
memstats	Prints statistics counters related to memory allocation code.
iostats	Prints statistics counters maintained in the input-output module.
timerstats	Prints statistics counters maintained in the timer/event queue support code.
reslist	Obtains and print the server's restriction list. This list is printed in sorted order and may help to understand how the restrictions are applied.
ifstats	Lists interface statistics for interfaces used by ntpd for network communication.
ifreload	Forces the scan of current system interfaces. Outputs interface statistics for interfaces that could possibly change. Marks unchanged interfaces with ., added interfaces with + and deleted interfaces with -.
monlist [version]	Obtains and prints traffic counts collected and maintained by the monitor facility. The version number should not normally need to be specified.
clkbug clock_peer_address [...]	Obtains debugging information for a reference clock driver. This information is provided only by some clock drivers and cannot be decoded without a copy of driver source.

Runtime Configuration Requests

All requests which cause state changes in the server are authenticated by the server using a configured NTP key (the facility can also be disabled by the server by not configuring a key). The key number and the corresponding key must also be made known to **ntpdc**. This can be done using the **keyid** and **passwd** commands, the latter of which will prompt at the terminal for a password to use as the encryption key. You will also be prompted automatically for both the key number and password the first time a command which would result in an authenticated request to the server is given. Authentication not only provides verification that the requester has permission to make such changes, but also gives an extra degree of protection again transmission errors.

Authenticated requests always include a timestamp in the packet data, which is included in the computation of the authentication code. This timestamp is compared by the server to its receive time stamp. If they differ by more than a small amount the request is rejected. This is done for two reasons. First, it makes simple replay attacks on the server, by someone who might be able to overhear traffic on your LAN, much more difficult. Second, it makes it more difficult to request configuration changes to your server from topologically remote hosts. While the reconfiguration facility will work well with a server on the local host, and may work adequately between time-synchronized hosts on the same LAN, it will work very poorly for more distant hosts. As such, if reasonable passwords are chosen, care is taken in the distribution and protection of keys and appropriate source address restrictions are applied, the run time reconfiguration facility should provide an adequate level of security.

The following commands run authenticated requests.

Item	Description
addpeer peer_address [keyid] [version] [minpoll# | prefer | iburst | burst | minpoll N | maxpoll N [...]] **addpeer peer_address [prefer | iburst | burst | minpoll N | maxpoll N | keyid N | version N [...]]**	Add a configured peer association at the given address and operating in symmetric active mode. Note that an existing association with the same peer may be deleted when this command is executed, or may simply be converted to conform to the new configuration, as appropriate. If the **keyid** is nonzero, all outgoing packets to the remote server will have an authentication field attached encrypted with this key. If the value is 0 (or not given) no authentication will be done. If **ntpdc**'s key number has not yet been set (e.g., by the **keyid** command), it will be set to this value. The **version#** can be 1 through 4 and defaults to 3. The remaining options are either a numeric value for **minpoll** or literals prefer, **iburst**, **burst**, **minpoll N**, **keyid N**, **version N**, or **maxpoll N** (where N is a numeric value), and have the action as specified in the peer configuration file command of ntpd. Each flag (or its absence) replaces the previous setting. The prefer keyword indicates a preferred peer (and thus will be used primarily for clock synchronization if possible). The preferred peer also determines the validity of the PPS signal - if the preferred peer is suitable for synchronization so is the PPS signal.
addserver peer_address [keyid] [version] [minpoll# | prefer | iburst | burst | minpoll N | maxpoll N [...]] **addserver peer_address [prefer | iburst | burst | minpoll N | maxpoll N | keyid N | version N [...]]**	Identical to the **addpeer** command, except that the operating mode is client.
broadcast peer_address [keyid] [version] [prefer]	Identical to the **addpeer** command, except that the operating mode is broadcast. In this case a valid non-zero key identifier and key are required. The **peer_address** parameter can be the broadcast address of the local network or a multicast group address assigned to NTP. If a multicast address, a multicast-capable kernel is required.
unconfig peer_address [...]	This command causes the configured bit to be removed from the specified peer(s). In many cases this will cause the peer association to be deleted. When appropriate, however, the association may persist in an unconfigured mode if the remote peer is willing to continue on in this fashion.
fudge peer_address [time1] [time2] [stratum] [refid]	This command provides a way to set certain data for a reference clock. See the source listing for further information.

Item	Description
enable [auth | bclient | calibrate | kernel | monitor | ntp | pps | stats]	These commands operate in the same way as the enable and disable configuration file commands of **ntpd**.
disable [auth | bclient | calibrate | kernel | monitor | ntp | pps | stats]	
restrict address mask flag [flag]	This command operates in the same way as the restrict configuration file commands of **ntpd**.
unrestrict address mask flag [flag]	Removes the restriction of the matching entry from the restrict list.
delrestrict address mask [ntpport]	Deletes the matching entry from the restrict list.
readkeys	Causes the current set of authentication keys to be purged and a new set to be obtained by reading the keys file again (which must have been specified in the **ntpd** configuration file). This allows encryption keys to be changed without restarting the server.
trustedkey keyid [...]	These commands operate in the same way as the **trustedkey** and **untrustedkey** configuration file commands of **ntpd**.
untrustedkey keyid [...]	
authinfo	Returns information concerning the authentication module, including known keys and counts of encryptions and decryptions which have been done.
traps	Displays the traps set in the server. See the source listing for further information.
addtrap [address [port] [interface]	Sets a trap for asynchronous messages. See the source listing for further information.
clrtrap [address [port] [interface]	Clears a trap for asynchronous messages. See the source listing for further information.
reset	Clears the statistics counters in various modules of the server. See the source listing for further information.

Files

Item	Description
/usr/sbin/ntp4/ntpdc4	Contains the **ntpdc** command. The default symbolic link to NTP version 3 binaries from the `/usr/sbin` directory. `/usr/sbin/ntpdc --> /usr/sbin/ntp3/xntpdc`

ntp-keygen4 Command

Purpose

Generate public and private keys.

Syntax

ntp-keygen [**-d**] [**-e**] [**-G**] [**-g**] [**-H**] [**-I**] [**-M**] [**-P**] [**-T**] [**-c** [*RSA-MD2* | *RSA-MD5* | *RSA-SHA* | *RSA-SHA1* | *RSA-MDC2* | *RSA-RIPEMD160* | *DSA-SHA* | *DSA-SHA1*]] [**-i** *name*] [**-m** *modulus*] [**-p** *password*] [**-q** *password*] [**-S** [*RSA* | *DSA*]] [**-s** *name*] [**-v** *nkeys*] [**-V** *params*]

Description

The **ntp-keygen4** command generates cryptographic data files used by the NTP version 4 authentication and identification schemes. It generates MD5 key files used in symmetric key cryptography. In addition, if the OpenSSL software library has been installed, it generates keys, certificate and identity files used in public key cryptography. These files are used for cookie encryption, digital signature and challenge/response identification algorithms compatible with the Internet standard security infrastructure.

By default, files are not encrypted by ntp-keygen. The **-p** *password* option specifies the write password and **-q** *password* option the read password for previously encrypted files. The **ntp-keygen** program prompts for the password if it reads an encrypted file and the password is missing or incorrect. If an encrypted file is read successfully and no write password is specified, the read password is used as the write password by default.

The **ntpd** configuration command crypto **pw** password specifies the read password for previously encrypted files. The daemon expires on the spot if the password is missing or incorrect. For convenience, if a file has been previously encrypted, the default read password is the name of the host running the program. If the previous write password is specified as the host name, these files can be read by that host with no explicit password.

All files are in PEM-encoded printable ASCII format, so they can be embedded as MIME attachments in mail to other sites and certificate authorities. File names begin with the prefix `ntpkey_` and end with the postfix `_hostname.filestamp`, where hostname is usually the string returned by the UNIX **gethostname()** routine, and filestamp is the NTP seconds when the file was generated, in decimal digits. This both guarantees uniqueness and simplifies maintenance procedures, since all files can be quickly removed by a **rm ntpkey*** command or all files generated at a specific time can be removed by a **rm *filestamp** command. To further reduce the risk of misconfiguration, the first two lines of a file contain the file name and generation date and time as comments.

All files are installed by default in the keys `/usr/local/etc` directory , which is normally in a shared filesystem in NFS-mounted networks. The actual location of the keys directory and each file can be overridden by configuration commands, but this is not recommended. Normally, the files for each host are generated by that host and used only by that host, although exceptions exist as noted later on this page.

Normally, files containing private values, including the host key, sign key and identification parameters, are permitted root read/write-only; while others containing public values are permitted world readable. Alternatively, files containing private values can be encrypted and these files permitted world readable, which simplifies maintenance in shared file systems. Since uniqueness is insured by the hostname and file name extensions, the files for a NFS server and dependent clients can all be installed in the same shared directory.

The recommended practice is to keep the file name extensions when installing a file and to install a soft link from the generic names specified elsewhere on this page to the generated files. This allows new file generations to be activated simply by changing the link. If a link is present, **ntpd** follows it to the file name to extract the filestamp. If a link is not present, **ntpd** extracts the filestamp from the file itself. This allows clients to verify that the file and generation times are always current. The **ntp-keygen** program uses the same extension for all files generated at one time, so each generation is distinct and can be readily recognized in monitoring data.

Running the program

The safest way to run the ntp-keygen program is logged in directly as root. The recommended procedure is change to the keys directory, usually `/ust/local/etc`, then run the program. When run for the first time, or if all **ntpkey** files have been removed, the program generates a RSA host key file and matching RSA-MD5 certificate file, which is all that is necessary in many cases. The program also generates soft

links from the generic names to the respective files. If run again, the program uses the same host key file, but generates a new certificate file and link.

The host key is used to encrypt the cookie when required and so must be RSA type. By default, the host key is also the sign key used to encrypt signatures. When necessary, a different sign key can be specified and this can be either RSA or DSA type. By default, the message digest type is MD5, but any combination of sign key type and message digest type supported by the OpenSSL library can be specified, including those using the MD2, MD5, SHA, SHA1, MDC2 and RIPE160 message digest algorithms. However, the scheme specified in the certificate must be compatible with the sign key. Certificates using any digest algorithm are compatible with RSA sign keys; however, only SHA and SHA1 certificates are compatible with DSA sign keys.

Private/public key files and certificates are compatible with other OpenSSL applications and very likely other libraries as well. Certificates or certificate requests derived from them should be compatible with extant industry practice, although some users might find the interpretation of X509v3 extension fields somewhat liberal. However, the identification parameter files, although encoded as the other files, are probably not compatible with anything other than Autokey.

Running the program as other than root and using the UNIX su command to assume root may not work properly, since by default the OpenSSL library looks for the random seed file .rnd in the user home directory. However, there should be only one .rnd, most conveniently in the root directory, so it is convenient to define the $RANDFILE environment variable used by the OpenSSL library as the path to /.rnd.

Installing the keys as root might not work in NFS-mounted shared file systems, as NFS clients may not be able to write to the shared keys directory, even as root. In this case, NFS clients can specify the files in another directory such as /etc using the keysdir command. There is no need for one client to read the keys and certificates of other clients or servers, as these data are obtained automatically by the Autokey protocol.

Ordinarily, cryptographic files are generated by the host that uses them, but it is possible for a trusted agent (TA) to generate these files for other hosts; however, in such cases files should always be encrypted. The subject name and trusted name default to the hostname of the host generating the files, but can be changed by command line options. It is convenient to designate the owner name and trusted name as the subject and issuer fields, respectively, of the certificate. The owner name is also used for the host and sign key files, while the trusted name is used for the identity files.

Flags

Item	Description
-c [*RSA-MD2* | *RSA-MD5* | *RSA-SHA* | *RSA-SHA1* | *RSA-MDC2* | *RSA-RIPEMD160* | *DSA-SHA* | *DSA-SHA1*]	Selects certificate message digest/signature encryption scheme. Note that RSA schemes must be used with a RSA sign key and DSA schemes must be used with a DSA sign key. The default without this option is RSA-MD5.
-d	Enables debugging. This option displays the cryptographic data produced in eye-friendly billboards.
-e	Writes the IFF client keys to the standard output. This is intended for automatic key distribution by mail.
-G	Generates parameters and keys for the GQ identification scheme, obsoleting any that may exist.
-g	Generates keys for the GQ identification scheme using the existing GQ parameters. If the GQ parameters do not yet exist, create them first.
-H	Generates new host keys, obsoleting any that may exist.
-I	Generates parameters for the IFF identification scheme, obsoleting any that may exist.

Item	Description
-i name	Sets the subject name to name. This is used as the subject field in certificates and in the file name for host and sign keys.
-M	Generates MD5 keys, obsoleting any that may exist.
-m *modulus*	Sets prime modulus size in bits (256 - 2048). Default size is 512.
-P	Generates a private certificate. By default, the program generates public certificates.
-p *password*	Encrypts generated files containing private data with password and the DES-CBC algorithm.
-q *password*	Sets the password for reading files to password.
-S *[RSA | DSA]*	Generates a new sign key of the designated type, obsoleting any that may exist. By default, the program uses the host key as the sign key.
-s *name*	Sets the issuer name to name. This is used for the issuer field in certificates and in the file name for identity files.
-T	Generates a trusted certificate. By default, the program generates a non-trusted certificate.
-V *nkeys*	Generates parameters and keys for the Mu-Varadharajan (MV) identification scheme.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Access Control: You must be part of the system group to run this command.

Auditing Events: N/A

Examples

1. To generate RSA-SHA cryptographic keys, enter:

```
ntp-keygen -c RSA-SHA
```

2. To print a list of the peers known to the server as well as a summary of their state, enter:

```
ntpdc -p
```

Output similar to the following appears:

```
            Using OpenSSL version 90804f
            Generating RSA keys (512 bits)...
            RSA                                             3 1 2
            Generating new host file and link
            ntpkey_host_aixfvt12->ntpkey_RSAkey_aixfvt12.3444540821
            Using host key as sign key
```

```
Generating certificate RSA-SHA
X509v3 Basic Constraints: critical,CA:TRUE
X509v3 Key Usage: digitalSignature,keyCertSign
Generating new cert file and link
ntpkey_cert_aixfvt12->ntpkey_RSA-SHAcert_aixfvt12.3444540821
```

Files

Item	Description
/usr/sbin/ntp4/ntp-keygen4	Contains the **ntp-keygen** command. The default symbolic link to the NTP version 4 binary from `/usr/sbin` directory. `/usr/sbin/ntp-keygen --> /usr/sbin/ntp4/ntp-keygen4`

ntp_ssw Command

Purpose

Switches the symbolic links for Network Time Protocol (NTP) between NTP version 3 and NTP version 4.

Syntax

```
ntp_ssw [-v4|-v3]
```

Description

For NTP version 3, the `xntpd` and NTP executable files are linked to the NTP version 3 files. To switch to NTP version 4, all NTP executable files must be linked to the NTP version 4 files. You can switch between NTP version 3 and NTP version 4 by using the **ntp_ssw** command.

When the AIX LPAR is running with NTP version 3, the symbolic links are as follows:

```
/usr/sbin/xntpdc -> /usr/sbin/ntp3/xntpdc
/usr/sbin/ntpq -> /usr/sbin/ntp3/ntpq
/usr/sbin/ntptrace -> /usr/sbin/ntp3/ntptrace
/usr/sbin/ntpdate -> /usr/sbin/ntp3/ntpdate
/usr/sbin/sntp -> /usr/sbin/ntp3/sntp
```

To switch to NTP version 4, run the **ntp_ssw** command with the **-v4** flag. After you run the **ntp_ssw** command, the NTP symbolic links are updated as follows:

```
/usr/sbin/ntpq -> /usr/sbin/ntp4/ntpq4
/usr/sbin/sntp -> /usr/sbin/ntp4/sntp4
/usr/sbin/ntptrace -> /usr/sbin/ntp4/ntptrace4
/usr/sbin/xntpd -> /usr/sbin/ntp4/ntpd4
/usr/sbin/ntpdate -> /usr/sbin/ntp4/ntpdate4
/usr/sbin/ntp-keygen -> /usr/sbin/ntp4/ntp-keygen4
```

Flags

-v4
Switches the NTP symbolic links to NTP version 4 binary files.

-v3
Switches the NTP symbolic links to NTP version 3 binary files.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

- To switch the NTP symbolic links from NTP version 3 to NTP version 4, enter the following command:

```
/usr/sbin/ntp_ssw -v4
```

- To switch the NTP symbolic links from NTP version 4 to NTP version 3, enter the following command:

```
/usr/sbin/ntp_ssw -v3
```

Files

/usr/sbin/ntp_ssw
Contains the **ntp_ssw** command.

ntpq Command

Purpose

Starts the standard Network Time Protocol (NTP) query program.

Syntax

ntpq [**-i**] [**-n**] [**-p**] [**-c** *SubCommand*] [*Host ...*]

Description

The **ntpq** command queries the NTP servers running on the hosts specified which implement the recommended NTP mode 6 control message format about current state and can request changes in that state. It runs either in interactive mode or by using command-line arguments. You can make requests to read and write arbitrary variables, and raw and formatted output options are available. The **ntpq** command can also obtain and print a list of peers in a common format by sending multiple queries to the server.

If you enter the **ntpq** command with one or more flags, the NTP servers running on each of the hosts specified (or defaults to local host) receive each request. If you do not enter any flags, the **ntpq** command tries to read commands from standard input and run them on the NTP server running on the first host specified or on the local host by default. It prompts for subcommands if standard input is the terminal.

The **ntpq** command uses NTP mode 6 packets to communicate with the NTP server and can query any compatible server on the network which permits it.

The **ntpq** command makes one attempt to retransmit requests, and will time-out requests if the remote host does not respond within a suitable time.

Specifying a flag other than **-i** or **-n** sends the queries to the specified hosts immediately. Otherwise, the **ntpq** command attempts to read interactive format subcommands from standard input.

Flags

Item	Description
-c *SubCommand*	Specifies an interactive format command. This flag adds *SubCommand* to the list of commands to run on the specified hosts. You can enter multiple **-c** flags.
-i	Specifies interactive mode. Standard output displays prompts and standard input reads commands.
-n	Displays all host addresses in dotted decimal format (x.x.x.x) rather than the canonical host names.
-p	Displays a list of the peers known to the server and a summary of their state. Same as using the **peers** subcommand.

Parameters

Item	Description
Host ...	Specifies the hosts.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Access Control: You must be part of the system group to run this command.

Auditing Events: N/A

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To start the Network Time Protocol query program in interactive mode, type:

```
ntpq -i
```

2. To add a time interval of 1000 milliseconds to timestamps, type:

```
ntpq -c "delay 1000"
```

ntpq Internal Subcommands

The following subcommands can only be used while running the **ntpq** query program.

Interactive Format Subcommands

Interactive format subcommands consist of a keyword followed by zero to four arguments. You only need to type enough characters of the full keyword to uniquely identify the subcommand. The output of a

subcommand goes to standard output, but you can redirect the output of individual subcommands to a file by appending a > (greater than sign), followed by a file name, to the command line.

Some interactive format subcommands run entirely within the **ntpq** query program and do not result in sending NTP mode 6 requests to a server.

The data carried by NTP mode 6 messages consists of a list of items of the form:

```
Variable=Value
```

where *Value* is ignored, and can be omitted, in requests to the server to read variables. The **ntpq** query program maintains an internal list where data to be included in control messages can be assembled and sent using the **readlist** and **writelist** control message subcommands.

Item	Description
? [*SubCommand*]	Displays command usage information. When used without *SubCommand*, displays a list of all the **ntpq** command keywords. When used with *SubCommand*, displays function and usage information about the subcommand.
addvars *Variable* [=*Value*] [,...]	Specifies the variables and their optional values to be added to the internal data list. If adding more than one variable, the list must be separated by commas and not contain spaces.
authenticate yes | **no**	Specifies whether to send authentication with all requests or not. Normally the **ntpq** query program does not authenticate requests unless they are write requests.
clearvars	Removes all variables from the internal data list.
cooked	Displays all results received from the remote server reformatted. A trailing ? (question mark) marks variables that do not have decodable values.
debug more | **less** | **off**	Turns the **ntpq** query program debugging on or off. The **more** and **less** options control the verbosity of the output. If you enter this subcommand without an argument, it prints the current setting for this subcommand.
delay *MilliSeconds*	Specifies the time interval to add to timestamps included in requests which require authentication. This subcommand enables unreliable server reconfiguration over long delay network paths or between machines whose clocks are unsynchronized. If you enter this subcommand without an argument, it prints the current setting for this subcommand.
host *HostName*	Specifies the host to send queries to. *HostName* may be either a host name or a numeric address. If you enter this subcommand without an argument, it prints the current setting for this subcommand.
hostnames yes | **no**	Specifies whether to output the host name (**yes**) or the numeric address (**no**). Defaults to **yes** unless the **-n** flag is used. If you enter this subcommand without an argument, it prints the current setting for this subcommand.
keyid *Number*	Specifies the server key number to use to authenticate configuration requests. If you enter this subcommand without an argument, it prints the current setting for this subcommand.
ntpversion 1 | **2** | **3**	Specifies the NTP version implementation to use when polling its packets. The default is 3. If you enter this subcommand without an argument, it prints the current setting for this subcommand. **Note:** Mode 6 control messages and modes did not exist in NTP version 1.
passwd	Prompts you to type in the NTP server authentication password to use to authenticate configuration requests.
quit	Exits the **ntpq** query program.
raw	Displays all results received from the remote server without formatting. Only transforms non-ascii characters into printable form.
rmvars *Variable* [=*Value*] [,...]	Specifies the variables and their optional values to be removed from the internal data list. If removing more than one variable, the list must be separated by commas and not contain spaces.
timeout *MilliSeconds*	Specifies the time-out period for responses to server queries. The default is 5000 milliseconds. If you enter this subcommand without an argument, it prints the current setting for this subcommand. **Note:** Because **ntpq** query program retries each query once after a time-out, the total waiting time for a time-out is twice the time-out value set.

Control Message Subcommands

Each peer known to an NTP server has a 16-bit integer association identifier assigned to it. NTP control messages which carry peer variables must identify the peer that the values correspond to by including its association ID. An association ID of 0 is special and indicates the variables are system variables whose names are drawn from a separate name space.

The **ntpq** control message subcommands result in one or more NTP mode 6 messages sent to the server, and outputs the data returned in some format. Most subcommands currently implemented send a single message and expect a single response. The current exceptions are the **peers** subcommand, which sends a preprogrammed series of messages to obtain the data it needs, and the **mreadlist** and **mreadvar** subcommands, which iterate over a range of associations.

Item	Description
associations	Obtains and prints a list of association identifiers and peer statuses for in-spec peers of the server being queried. The list is printed in the following columns: • First column contains the index numbering the associations from 1 for internal use. • Second column contains the actual association identifier returned by the server. • Third column contains the status word for the peer. • Remaining columns contain data decoded from the status word. **Note:** The data returned by the **associations** subcommand is cached internally in the **ntpq** query program. When dealing with servers that use difficult association identifiers, use the index as an argument, in the form `&index`, as an alternative to the association identifier.
clockvar [*AssocID*] [*Variable* [=*Value*], ...] or **cv** [*AssocID*] [*Variable* [=*Value*], ...]	Displays a list of the server's clock variables. Servers which have a radio clock or other external synchronization respond positively to this. To request the system clock variables, leave *AssocID* blank or type `0`. If the server treats clocks as pseudo-peers and can possibly have more than one clock connected at once, referencing the appropriate peer association ID shows the variables of a particular clock. Omitting the variable list causes the server to return a default variable display.
lassociations	Displays a list of association identifiers and peer statuses for all associations for which the server is maintaining state. This subcommand differs from the **associations** subcommand only for servers which retain state for out-of-spec client associations.
lpassociations	Displays data for all associations, including out-of-spec client associations, from the internally cached list of associations.
lpeers	Displays a summary of all associations the server maintains state for Similar to the **peers** subcommand. This may produce a longer list of peers from out-of-spec client servers.
mreadvar *AssocID AssocID* [*Variable* [=*Value*], ...] or **mrv** *AssocID AssocID* [*Variable* [=*Value*], ...]	Displays the values of the specified peer variables for each server in the range of given nonzero association IDs. The association list cached by the most recent associations command determines the range.
mreadlist *AssocID AssocID* or **mrl** *AssocID AssocID*	Displays the values of the specified peer variables in the internal variable list for each server in the range of given nonzero association IDs. The association list cached by the most recent associations command determines the range.
opeers	An old form of the **peers** subcommand. Replaces the reference ID with the local interface address.
passociations	Displays association data concerning in-spec peers from the internally cached list of associations. This subcommand works like the **associations** subcommand except that it displays the internally stored data rather than making a new query.

Item	Description
peers	Displays a list of in-spec peers of the server and a summary of each peer's state. Summary information includes the following: • Address of the remote peer • Reference ID (0.0.0.0 for an unknown reference ID) • Stratum of the remote peer (a stratum of 16 indicates the remote peer is unsynchronized) • Type of peer (local, unicast, multicast, *or* broadcast) • Time the last packet was received, the polling interval (seconds) • Polling interval (seconds) • Reachability register (octal) • Current estimated delay, offset and dispersion of the peer (milliseconds) The character in the left margin indicates the fate of this peer in the clock selection process: **space** Discarded due to high stratum and/or failed sanity checks. **x** Designated falseticker by the intersection algorithm. **.** Culled from the end of the candidate list. **-** Discarded by the clustering algorithm. **+** Included in the final selection set. **#** Selected for synchronization but distance exceeds maximum. ***** Selected for synchronization. **o** Selected for synchronization, **pps** signal in use. The contents of the host field may be a host name, an IP address, a reference clock implementation name with its parameter or REFCLK (*ImplementationNumber*, *Parameter*). Only IP addresses display when using **hostnames no**. **Note:** The **peers** subcommand depends on the ability to parse the values in the responses it gets. It may fail to work from time to time with servers that poorly control the data formats. The **peers** subcommand is non-atomic and may occasionally result in spurious error messages about invalid associations occurring and terminating the command.
pstatus *AssocID*	Displays the names and values of the peer variables of the server with the given association by sending a read status request. The output displays the header preceding the variables, both in hexadecimal and in English.

Item	Description
readlist [*AssocID*] or **rl** [*AssocID*]	Displays the values of the peer variables in the internal variable list of the server with the given association. To request the system variables, leave *AssocID* blank or type `0`. If the internal variable list is empty, the server returns a default variable display.
readvar [*AssocID*] [*Variable* [=*Value*], ...] or **rv** [*AssocID*] [*Variable* [=*Value*], ...]	Displays the values of the specified peer variables of the server with the given association by sending a read variables request. To request the system variables, leave *AssocID* blank or type `0`. Omitting the variable list causes the server to return a default variable display.
writevar [*AssocID*] [*Variable* [=*Value*], ...]	Writes the values of the specified peer variables to the server with the given association by sending a write variables request.
writelist [*AssocID*]	Writes the values of the peer variables in the internal variable list of the server with the given association.

Files

Item	Description
/usr/sbin/ntpq	Contains the **ntpq** command.

ntpq4 Daemon

Purpose

Starts the standard Network Time Protocol (NTP) query program.

Syntax

ntpq [**-4** **-6** **-d** **-i** **-n** **-p**] [**-c** command] [host] [...]

Description

The **ntpq** program is used to monitor the NTP daemon, the **ntpd** operations, and determine performance. It uses the standard NTP version 3 mode 6 control message formats defined by RFC 1305. The same formats are used in NTP version 4.

The program can be run either in interactive or controlled mode using command line arguments. The raw and printed output options enables you to assemble the requests to read and write arbitrary variables. The **ntpq** program can also obtain and print a list of peers in a common format by sending multiple queries to the server.

If one or more request options are included in the command line when the **ntpq** program is executed, each request will be sent to the NTP servers running on the hosts given by the command line arguments, or on localhost by default. If no request options are given, the **ntpq** utility will attempt to read commands from the standard input and execute them on the NTP server running on the first host given by the command line, again defaulting to localhost when no other host is specified. The **ntpq** utility will prompt for commands if the standard input is a terminal device.

The **ntpq** utility uses NTP mode 6 packets to communicate with the NTP server, and hence can be used to query any compatible server on the network which permits it.

In the instance where a host name is expected, and when you add a **-4** qualifier preceding the host name, the utility forces the DNS resolution to the IP version 4 namespace. Similarly, and a **-6** qualifier forces DNS resolution to the IP version 6 namespace.

Specifying a command line option other than **-i** or **-n** will cause the specified query or queries to be sent to the indicated host or hosts immediately. Otherwise, the **ntpq** utility will attempt to read interactive format commands from the standard input.

Flags

Item	Description
-4	Forces DNS resolution of the host names on the command line to the IP version 4 namespace.
-6	Forces DNS resolution of the host names on the command line to the IP version 6 namespace.
-c	The following argument is interpreted as an interactive format command and is added to the list of commands to be executed on the specified host or hosts. Multiples of the **-c** options might be added.
-d	Enables the debugging mode.
-i	Forces the **ntpq** utility to operate in interactive mode. The results will be written to the standard output and the commands are read from the standard input.
-n	Outputs all host addresses in dotted-quad numeric format rather than converting to the canonical host names.
-p	Prints a list of peers known to the server as well as a summary of their state. This is equivalent to the peers interactive command.

Parameters

Item	Description
Host...	Specifies the hosts.

Exit Status

This command returns the following exit values:

0
Successful completion.

> 0
An error occurred.

Security

Access Control : You must have root authority to run this command.

Auditing Events : N/A

Examples

1. To start the Network Time Protocol query program in interactive mode, enter:

   ```
   ntpq -i
   ```

2. To print a list of peers known to the server and the summary of their state, enter:

   ```
   ntpq -p
   ```

Output similar to the following is displayed:

```
     remote           refid             st  t   when poll reach   delay        offset    jitter
==============================================================================================
ausgsa.austin.ibm.com 9.41.253.167     2 u   19      64  377      285.962   -8.792   2.989
```

ntpq Internal Commands

Interactive Format Commands

Interactive format commands consist of a keyword followed by a maximum of 4 arguments. You must type only the required number of characters of the keyword to uniquely identify the command. The output of a command is normally sent to the standard output. You can also opt to send the output of individual commands by appending a greater than symbol (>), followed by a file name, to the command line. A number of interactive format commands are executed entirely within the **ntpq** program and do not send the NTP mode 6 requests to a server.

Item	Description
? [command_keyword] or **help [command_keyword]**	A question mark (?) by itself will print a list of all the command keywords known to this incarnation of ntpq. A question mark (?) followed by a command keyword will print function and the use of the command.
addvars variable_name [= value] [...] or **rmvars variable_name [...]** or **clearvars**	The data carried by the NTP mode 6 messages consists of a list of items of the form *variable_name = value*, where the equals symbol (=) value is ignored, and can be omitted, in requests to the server to read variables. The **ntpq** program maintains an internal list in which data to be included in control messages can be assembled, and sent using the **readlist** and **writelist** commands described below. The **addvars** command allows variables and their optional values to be added to the list. If more than one variable is to be added, the list must be separated by using commas, and must not contain any white space. The **rmvars** command can be used to remove individual variables from the list, while the **clearlist** command removes all variables from the list.
cooked	Causes the output from query commands to be cooked, so that variables which are recognized by the **ntpq** command will have their values reformatted for human consumption. The **ntpq** program marks the variables with a trailing question mark symbol (?) when the variable value cannot be decoded.
debug more | less | no	Adjusts the level of **ntpq** debugging. The default is **debug no**.
delay milliseconds	Specifies a time interval to be added to timestamps included in requests which require authentication. This is used to enable server reconfiguration over long delay network paths or between machines whose clocks are not synchronized.
host hostname	Sets the host to which future queries will be sent. Hostname may be either a host name or a numeric address.
hostnames [yes | no]	If **yes** is specified, host names are printed in the information display. If **no** is specified, numeric addresses are printed. The default is yes, unless modified using the command line **-n** switch.
keyid keyid	Specifies the key number to be used to authenticate configuration requests. This must correspond to a key number the server has been configured to use for this purpose.

Item	Description
ntpversion 1 | 2 | 3 | 4	Sets the NTP version number which **ntpq** claims in packets. The default is 2. The mode 6 control messages did not exist in NTP version 1.
passwd	Prompts for a password that will not be echoed, and which will be used to authenticate configuration requests. The password must correspond to the key configured for NTP server for this purpose.
quit	Exits **ntpq**.
raw	Prints the output of query commands received from the remote server. The only formatting done on the data is transforming non-ASCII data to a printable form.
timeout millseconds	Specifies a timeout period for responses to server queries. The default is 5000 milliseconds. Since **ntpq** retries each query once after a timeout, the total waiting time for a timeout will be twice the timeout value set.

Control Message Commands

Each association known to an NTP server has a 16 bit integer association identifier. The NTP control messages that carry peer variables must identify the corresponding peer values, which are its association ID. An association ID 0 indicates that the variables are system variables, and their names are drawn from a separate name space.

Control message commands result in one or more NTP mode 6 messages being sent to the server, and cause the data returned to be printed in a format. Most commands currently implemented send a single message and expect a single response. The current exceptions is the **peers** command, which will send a pre-programmed series of messages to obtain the data it needs, and the **mreadlist** and **mreadvar** commands, which will iterate over a range of associations.

Item	Description
associations	Obtains and prints a list of association identifiers and peer statuses for in-spec peers of the server being queried. The list is printed in columns. The first column indicates the index numbering of associations from 1. The second column specifies the actual association identifier returned by the server, and the third column indicates the status word for the peer. This is followed by a number of columns containing data decoded from the status word. See the peers command for a decode of the condition field. **Note:** 1. The data returned by the associations command is cached internally in **ntpq**. 2. The index in the form **&index** is used when dealing with servers that use association identifiers wherein the subsequent commands require an association identifier as an argument.

Item	Description
clockvar [assocID] [variable_name [= value [...]] [...] **cv [assocID] [variable_name [= value [...]][...]**	Requests the server to send a list of the server's clock variables. Servers, which have a radio clock or other external synchronization will respond positively to this. If the association identifier is omitted or is a zero, you are requesting for the system clock variables and will get a positive response from all servers with a clock. If the server treats clocks as pseudo-peers, and hence can possibly have more than one clock connected at once, referencing the appropriate peer association ID will show the variables of a particular clock. Omitting the variable list will cause the server to return a default variable display.
lassociations	Obtains and prints a list of association identifiers and peer statuses for all associations for which the server is maintaining state. This command differs from the associations command only for servers which retain state for out-of-spec client associations (i.e., fuzzballs). Such associations are normally omitted from the display when the associations command is used, but are included in the output of lassociations.
lpassociations	Prints data for all associations, including out-of-spec client associations, from the internally cached list of associations. This command differs from passociations only when dealing with fuzzballs.
lpeers	Similar to R peers, except that a summary of states of all associations that the server is maintaining are printed. This can produce a much longer list of peers from fuzzball servers.
mreadlist assocID assocID **mrl assocID assocID**	Similar to the **readlist** command, except that the query is done for a range of (nonzero) association IDs. This range is determined from the association list cached by the most recent associations command.
mreadvar assocID assocID [variable_name [= value[...] **mrv assocID assocID [variable_name [= value[...]**	Similar to the **readvar** command, except that the query is done for a range of (nonzero) association IDs. This range is determined from the association list cached by the most recent associations command.
opeers	An old form of peers command with the reference ID replaced by the local interface address.
passociations	Displays association data concerning in-spec peers from the internally cached list of associations. This command performs identically to the associations except that it displays the internally stored data rather than making a new query.
peers	Obtains a current list peers of the server, along with a summary of each peer's state. Summary information includes the address of the remote peer, the reference ID (0.0.0.0 if this is unknown), the stratum of the remote peer, the type of the peer (local, unicast, multicast or broadcast), when the last packet was received, the polling interval, in seconds, the reachability register, in octal, and the current estimated delay, offset and dispersion of the peer, all in milliseconds.
pstatus assocID	Sends a read status request to the server for the given association. The names and values of the peer variables returned will be printed. Note that the status word from the header is displayed preceding the variables, both in hexadecimal and in pidgeon English.

Item	Description
readlist [assocID] **rl [assocID]**	Requests that the values of the variables in the internal variable list be returned by the server. If the association ID is omitted or is 0 the variables are assumed to be system variables. Otherwise they are treated as peer variables. If the internal variable list is empty a request is sent without data, which should induce the remote server to return a default display.
readvar assocID variable_name [= value] [...] **rv assocID [variable_name [= value] [...]**	Requests that the values of the specified variables be returned by the server by sending a read variables request. If the association ID is omitted or is given as zero the variables are system variables, otherwise they are peer variables and the values returned will be those of the corresponding peer. Omitting the variable list will send a request with no data which should induce the server to return a default display. The encoding and meaning of the variables derived from NTPv3 is given in RFC-1305; the encoding and meaning of the additional NTPv4 variables are given later in this page.
writevar assocID variable_name [= value [...]	Similar to the **readvar** request, except that the specified variables are written.
writelist [assocID]	Similar to the **readlist** request, except that the internal list of variables are written.

Files

Item	Description
`/usr/sbin/ntp4/ntpq4`	Contains the **ntpq** command. The default symbolic link to NTP version 3 binary file from the `/usr/sbin` directory. `/usr/sbin/ntpq --> /usr/sbin/ntp3/ntpq`

ntptrace Command

Purpose

Traces a chain of Network Time Protocol (NTP) hosts back to their master time source.

Syntax

ntptrace [**-d**] [**-n**] [**-v**] [**-r** *Retries*] [**-t** *TimeOut*] [*Server*]

Description

The **ntptrace** command determines where a given NTP server gets its time, and follows the chain of NTP servers back to their master time source. For example, stratum 0 server.

Flags

Item	Description
-d	Turns on debugging output.
-n	Outputs host IP addresses instead of host names.
-r *Retries*	Specifies the number of retransmission attempts for each host. The default is 5.

Item	Description
-t *TimeOut*	Specifies the retransmission timeout in seconds. The default is 2 seconds.
-v	Specifies verbose mode.

Parameters

Item	Description
Server	Specifies the server. The default is the local host.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Access Control: You must be part of the system group to run this command.

Auditing Events: N/A

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

To trace where the local host NTP server gets its time from, enter:

```
ntptrace
```

Output similar to the following appears:

```
localhost: stratum 4, offset 0.0019529, sync distance 0.144135
server2.bozo.com: stratum 2, offset 0.0124263, sync distance 0.115784
usndh.edu: stratum 1, offset 0.0019298, sync distance 0.011993, refid
'WWVB'
```

On each line, the fields are:

1. the host's stratum,
2. the time offset between that host and the local host, as measured by the **ntptrace** command, (this is why it is not always zero for localhost).
3. the host's synchronization distance, which is a measure of the quality of the clock's time, and
4. the reference clock ID This only applies to stratum-1 servers.

All times are given in seconds.

Files

Item	Description
/usr/sbin/ntptrace	Contains the **ntptrace** command.

ntptrace4 Command

Purpose

Traces a chain of Network Time Protocol (NTP) hosts back to their master time source.

Syntax

ntptrace [**-n**] [**server**]

Description

The **ntptrace** command determines the time source for the Network Time Protocol (NTP) server and follows the chain of NTP servers back to their master time source. If no arguments are provided, it starts with localhost. Following is an example of the output of the **ntptrace** command:

```
% ntptrace
localhost: stratum 4, offset 0.0019529, sync distance 0.144135
server2ozo.com: stratum 2, offset 0.0124263, sync distance 0.115784
usndh.edu: stratum 1, offset 0.0019298, sync distance 0.011993, refid 'WWVB'
```

On each line, the fields from left to right are host name, host stratum, time offset between that host and the local host as measured by the **ntptrace** command. This is why it is not always zero for "localhost", host synchronization distance, and (applies only for the stratum-1 servers) the reference clock ID. All times are given in seconds. Note that the stratum is the server hop count to the primary source, while the synchronization distance is the estimated error relative to the primary source. These terms are precisely defined in RFC-1305.

Flags

Item	Description
-n	Turns off the printing of host names; instead, host IP addresses are printed. This may be useful if a nameserver is down.

Parameters

Item	Description
Server	Specifies the server. The default is the local host.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion
>0	An error occurred

Security

Access Control: You must be part of the system group to run this command.

Auditing Events: N/A

Examples

1. To trace the time source for the local host NTP server, enter:

```
ntptrace
```

Output similar to the following appears:

```
            loopback: stratum 5, offset 0.000076, synch distance 0.18291
            ganga08.in.ibm.com: stratum 4, offset -0.001854, synch distance 0.30600
            ganga10.in.ibm.com: stratum 3, offset 0.000251, synch distance 0.30550
            ausgsa.austin.ibm.com: stratum 2, offset -0.010158, synch distance 0.01921
            gsantp.austin.ibm.com: stratum 1, offset 0.016067, synch distance 0.00000, refid
          'GPS'
```

Files

Item	Description
/usr/sbin/ntp4/ntptrace4	Contains the **ntptrace** command. Default Symbolic link to NTP version 3 binary from `/usr/sbin` directory. `/usr/sbin/ntptrace --> /usr/sbin/ntp3/ntptrace`

nulladm Command

Purpose

Creates active accounting data files.

Syntax

/usr/sbin/acct/nulladm [*File ...*]

Description

The **nulladm** command creates the file specified by the *File* parameter, gives read (r) and write (w) permission to the file owner, and group and read (r) permission to other users, and ensures that the file owner and group are **adm**. Various accounting shell procedures call the **nulladm** command. A user with administrative authority can use this command to set up the active data files, such as the **/var/adm/wtmp** file.

> **Note:** You should not share accounting files among nodes in a distributed environment. Each node should have its own copy of the various accounting files.

Security

Access Control: This command should grant execute (x) access only to members of the adm group.

Files

Item	Description
/usr/sbin/acct	Contains the accounting commands.
/var/adm/acct/sum	Contains accounting data files.

number Command

Purpose

Displays the written form of a number.

Syntax

number

Description

The **number** command translates the numerical representation of an entered number to the written form. The largest number it can translate accurately contains 66 digits. For example:

```
12345678
twelve million.
three hundred forty five thousand.
six hundred seventy eight.
```

In the above example, you entered 12345678 and the computer translated it to `twelve million three hundred forty five thousand six hundred seventy eight`.

The **number** command does not prompt you for a number. Once started, it simply waits for input. To exit the program, press the Interrupt (Ctrl-C) or End Of File **(**Ctrl-D) key sequence.

Files

Item	Description
/usr/games	Contains the system games.

nxstat Command

Purpose

The **nxstat** command displays usage statistics of on-chip hardware accelerators that can implement GZIP functions.

Syntax

```
nxstat {-S | [-AUWT] [-a accel_type] [-u unit_index ] [-w window_index] [-t window_type]
interval [count]}
```

Description

Applications in an AIX logical partition use the `zlibNX` library to open a communication channel with the GZIP accelerator. This communication channel is also known as a *window*. For more information about the type of communication channels, see Nest Accelerators.

The low-level usage statistics per window might include a large amount of data that might not be relevant for a system administrator. The **nxstat** command can aggregate the usage statistics to provide global usage statistics for a specific accelerator type or for a specific hardware accelerator unit based on the options and arguments that are specified with the command.

The following values are displayed in the usage statistics for each aggregation level along with the window type and corresponding credits:

- Opens: Number of open and close operations on a window.

- `Bytes`: Number of bytes processed by the hardware accelerator unit.
- `Faults`: Number of page faults that are detected by the hardware accelerator unit.
- `Intrs`: Number of completion interrupts. This value is optional for accelerator operations.
- `Polls`: Number of completion interrupts that are detected during the polling phase of the **nxstat** command.
- `Waits`: Number of operations that were completed after the caller was actually blocked. The total of `Polls` and `Waits` values represent the total number of operations that were completed during the specific time interval.

The kernel service that waits for completion of active GZIP operations, first polls a `completion` bit for a period of time before blocking the thread. Total count of `Polls` and `Waits` values provide insight about efficiency and usefulness of the polling phase.

The **nxstat** command aggregates the usage statistics of a specific accelerator type during a specified time interval. The **nxstat** command can also display the accelerator usage statistics for successive time intervals. The **-A**, **-U**, **-T**, and **-W** flags determine the aggregation levels. If more than one flags are specified, for example, **-AU**, the **nxstat** command displays usage statistics for both aggregation levels. The **-a**, **-u**, **-t**, **-w** flags are used to limit the statistics data to specific objects such as accelerator unit, window, and window type.

Flags

-s

Displays types of accelerators that are available.

-A

Displays usage statistics for a specific type of accelerator. This is the default option.

-U

Displays usage statistics for a specific hardware accelerator unit.

-T

Displays usage statistics for a specific window type.

-W

Displays usage statistics for each window.

-a

Specifies the accelerator type for which the usage statistics is displayed. The **-a** flag value for the GZIP accelerator is 0. Currently, the only supported value for the **-a** flag is 0. Therefore, if you do not specify the **-a** flag, the default value of 0 is applied.

-u

Specifies the accelerator unit for which the usage statistics is displayed. You must specify the **-u** flag only with the **-U** flag. The accelerator unit index value for this flag is a number between zero and the number of accelerator units minus 1. For example, if the AIX logical partition has access to three accelerator units, valid values that can be specified for this flag are 0, 1, and 2.

If the **-u** flag is not specified along with the **-U** flag, the **nxstat** command displays the data for all the hardware accelerator units that can be accessed by the logical partition.

-w

Specifies a specific window for which the usage statistics is displayed. If the logical partition has access to **n** windows, the windows are numbered from 0 to n-1. You can specify the **-w** flag only with the **-W** flag.

-t

Specifies a specific window type (0 for Quality of Service (QoS), 1 for default) for which the usage statistics is displayed. You can specify the **-t** flag only with the **-T** flag.

Note: The **-u**, **-w** and **-t** flags are mutually exclusive.

interval
Specifies the time interval, in seconds, during which the usage statistics must be captured. This flag is mandatory. By default, the kernel service captures usage statistics every 2 seconds, so you must specify a time interval more than 2 seconds to display useful data.

count
Specifies the number of successive time intervals for which you want to display the usage statistics. The default value is 1.

Examples

- To display total usage statistics for all the accelerator type and for all window types, run the following command:

```
nxstat 10 4
```

An output that is similar to the following example is displayed:

```
Accelerator GZIP:   Window Types:  2    Units:  1   Credits:   72
Type Cred   Opens          Bytes   Faults      Intrs         Polls         Waits
 ALL   72  266826      35.747 GB        0      17281        222795         61223
 ALL   72  262812      35.638 GB        0      17524        220368         59641
 ALL   72  300647      33.583 GB        0      15990        257351         58969
 ALL   72  259405      35.557 GB        0      17111        216629         60048

 ** Average **
 ALL   72  272422      35.131 GB        0      16976        229285         59970
```

- To display accelerator level statistics by window type, run the following command:

```
nxstat -AT 10
```

An output that is similar to the following example is displayed:

```
Accelerator GZIP:   Window Types:  2    Units:  4   Credits:   92
Type Cred   Opens          Bytes   Faults      Intrs         Polls         Waits
 QOS   12         0    49.892 GB        0      28695          4998         52476
 DEF   80         0     4.406 GB        0       2561           422          4654
```

- To display unit level statistics by accelerator unit, run the following command:

```
nxstat -U 10 4
```

An output that is similar to the following example is displayed:

```
  Unit Index  0:   SRAD ID         0  Window Types:  2    Credits:   23
Type Cred   Opens          Bytes   Faults      Intrs         Polls         Waits
 ALL   23       0      16.735 GB        0       9589          1551         17728

  Unit Index  1:   SRAD ID         1  Window Types:  2    Credits:   23
Type Cred   Opens          Bytes   Faults      Intrs         Polls         Waits
 ALL   23       0      12.438 GB        0       7219          1270         13058

  Unit Index  2:   SRAD ID         2  Window Types:  2    Credits:   23
Type Cred   Opens          Bytes   Faults      Intrs         Polls         Waits
 ALL   23       0      12.427 GB        0       7131          1310         13006

  Unit Index  3:   SRAD ID         3  Window Types:  2    Credits:   23
Type Cred   Opens          Bytes   Faults      Intrs         Polls         Waits
 ALL   23       0      12.430 GB        0       7230          1383         12935
```

- To display types of accelerators that are available, run the following command:

```
nxstat -S
```

An output that is similar to the following example is displayed:

```
GZIP accelerator available
```

o

The following AIX commands begin with the letter *o*.

od Command

Purpose

Displays files in a specified format.

Syntax

To Display Files Using a Type-String to Format the Output

od [**-v**] [**-A** *AddressBase*] [**-N** *Count*] [**-j** *Skip*] [**-t** *TypeString* ...] [*File* ...]

To Display Files Using Flags to Format the Output

od [**-a**] [**-b**] [**-c**] [**-C**] [**-d**] [**-D**] [**-e**] [**-f**] [**-F**] [**-h**] [**-H**] [**-i**] [**-I**] [**-l**] [**-L**] [**-o**] [**-O**] [**-p**] [**-P**] [**-s**] [**-v**] [**-x**] [**-X**] [[**-S** [*N*]] [**-w** [*N*]] [*File*] [[**+**] *Offset* [**.** | **b** | **B**] [**+**] *Label* [**.** | **b** | **B**]] [*File* ...]

Description

The **od** command displays the file specified by the *File* parameter in the format specified. If the *File* parameter is not given, the **od** command reads standard input. Multiple types can be specified by using multiple -bcCDdFfOoSstvXx options.

In the first syntax format, the output format is specified by the **-t** flag. If no format type is specified, **-t o2** is the default.

In the second syntax format, the output format is specified by a combination of flags. The *Offset* parameter specifies the point in the file where the file output begins. By default, the *Offset* parameter is interpreted as octal bytes. If the **.** (dot) suffix is appended, the parameter is interpreted as a decimal; if the parameter begins with a leading x or 0x, it is treated as a hexadecimal. If the **b** suffix is added to the parameter, it is interpreted in blocks of 512 bytes; if the **B** suffix is added to the parameter, it is interpreted in blocks of 1024 bytes.

The *Label* parameter is interpreted as a pseudo-address for the first byte displayed. If used, it is given in **( )** (parentheses) following the *Offset* parameter. The suffixes have the same meanings as for the *Offset* parameter.

When the **od** command reads standard input, the *Offset* parameter and the *Label* parameter must be preceded by a **+** (plus sign).

The setting of environment variables such as **LANG** and **LC_ALL** affects the operation of the **od** command.

The **od** command copies each input file sequentially, writes them to the standard output and transforms the input data according to the types of output that are specified by using the **-t** flag. The default number of bytes in the input data correspond to the size of the type specifier characters **d, o, u,** or **x**. These type specifier characters allow you to specify an optional number of bytes in the input data that corresponds to the number of bytes in the **char**, **short**, **int**, and **long** data types in the C programming language. The number of bytes can also be specified by using an application (any program or use case that uses the **od** command) in which the character **C** is used for **char** data type, character **S** is used for **short** data type, character **I** is used for **int** data type, and character **L** is used for **long** data type. The type specifier characters supports the values 1, 2, 4 and 8 even though the data type as per the C programming language is not specified for the size of the input data. The type specifier characters also supports the decimal value similar to the **long long** data type in the C programming language.

Flags

The flags for the first format are:

Item	Description
-A *AddressBase*	Specifies the input offset base. The *AddressBase* variable is one of the following characters: **d** Offset base is written in decimal. **o** Offset base is written in octal. **x** Offset base is written in hexadecimal. **n** Offset base is not displayed. Unless **-A n** is specified, the output line will be preceded by the input offset, cumulative across input files, of the next byte to be written. In addition, the offset of the byte following the last byte written will be displayed after all the input data has been processed. Without the **-A** address_base option and the [offset_string] operand, the input offset base is displayed in octal.
-j *Skip*	Jumps over the number of bytes given by the *Skip* variable before beginning to display output. If more than one file is specified, the **od** command jumps over the designated number of bytes of the concatenated input files before displaying output. If the combined input is not at least the length of the skip bytes, the **od** command will write a diagnostic message to standard error and exit non-zero status. By default, the value of the *Skip* variable is interpreted as a decimal number. With a leading 0x or 0X, the offset is interpreted as a hexadecimal number; otherwise, with a leading 0, the offset shall be interpreted as an octal number. If the characters **b**, **k**, or **m** are appended to the number contained by the *Skip* variable, the offset is equal to the value, in bytes, of the *Skip* variable multiplied by 512, 1024, or 1024*1024, respectively.
-N *Count*	Formats no more than the number of input bytes specified by the *Count* variable. By default, the value of the *Count* variable is interpreted as a decimal number. With a leading 0x or 0X, it is treated as a hexadecimal number. If it begins with a 0, it is treated as an octal number. The base of the address displayed is not implied by the base of the *Count* option-argument.

Item	Description
-t *TypeString*	Specifies the output type. The *TypeString* variable is a string specifying the types to be used when writing out data. Multiple types can be concatenated within the same *TypeString* variable, and the **-t** flag can be specified more than once. Output lines are written for each type specified, in the order in which the type specification characters are given. The *TypeString* variable can consist of the following characters: **a** Displays bytes as named characters. Bytes with the least seven bits in the range of 0 through 01777 are written using the corresponding names for those characters. **c** Displays bytes as characters. The number of bytes transformed by the **c** type string is determined by the **LC_CTYPE** local category. Printable multibyte characters are written in the area corresponding to the first byte of the character; the two character sequence ** is written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. The following nongraphic characters are used as C-language escape sequences: **** Backslash **\a** Alert **\b** Backspace **\f** Form-feed **\n** New-line character **\0** Null **\r** Carriage return **\t** Tab **\v** Vertical tab **d** Displays bytes as signed decimals. By default, the **od** command transforms the corresponding number of bytes in the C-language type **int**. The **d** type string can be followed by an unsigned decimal integer that specifies the number of bytes to be transformed by each instance of the output type. An optional **C**, **I**, **L**, or **S** character can be appended to the **d** option, indicating that the conversion should be applied to an item of type **char**, **int**, **long**, or **short**, respectively. **f** Displays bytes as floating points. By default, the **od** command transforms the corresponding number of bytes in the C-language type **double**. The **f** type string can be followed by an unsigned decimal integer that specifies the number of bytes to be transformed by each instance of the output type. An optional **F**, **D**, or **L** character can be appended to the **f** option, indicating that the conversion should be applied to an item of type **float**, **double**, or **long double**, respectively. **o** Displays bytes as octals. By default, the **od** command transforms the corresponding number of bytes in the C-language type **int**. The **o** type string can be followed by an unsigned decimal integer that specifies the number of bytes to be transformed by each instance of the output type. An optional **C**, **I**, **L**, or **S** character can be appended to the **o** option, indicating that the conversion should be applied to an item of type **char**, **int**, **long**, or **short**, respectively.

Item	Description
	u Display bytes as unsigned decimal. By default, the **od** command transforms the corresponding number of bytes in the C-language type **int**. The **u** type string can be followed by an unsigned decimal integer that specifies the number of bytes to be transformed by each instance of the output type. An optional **C**, **I**, **L**, or **S** character can be appended to the **u** option, indicating that the conversion should be applied to an item of type **char**, **int**, **long**, or **short**, respectively.
	x Display bytes as hexadecimal. By default, the **od** command transforms the corresponding number of bytes in the C-language type **int**. The **x** type string can be followed by an unsigned decimal integer that specifies the number of bytes to be transformed by each instance of the output type. An optional **C**, **I**, **L**, or **S** character can be appended to the **x** option, indicating that the conversion should be applied to an item of type **char**, **int**, **long**, or **short**, respectively.
-v	Writes all input data. By default, output lines that are identical to the immediately preceding output lines are not printed, but are replaced with a line containing only an * (asterisk). When the **-v** flag is specified, all the lines are printed.

The flags for the second format are:

Item	Description
-a	Displays bytes as characters and displays them with their ASCII names. If the **-p** flag is also given, bytes with even parity are underlined. The **-P** flag causes bytes with odd parity to be underlined. Otherwise, parity is ignored.
-b	Displays bytes as octal values.
-c	Displays bytes as ASCII characters. The following nongraphic characters appear as C-language escape sequences: **** Backslash **\a** Alert **\b** Backspace **\f** Form-feed **\n** New-line character **\0** Null **\r** Carriage return **\t** Tab **\v** Vertical tab Others appear as three-digit octal numbers.
-C	Displays extended characters as standard printable ASCII characters (using the appropriate character escape string) and displays multibyte characters in hexadecimal form.
-d	Displays 16-bit words as unsigned decimal values.
-D	Displays long words as unsigned decimal values.
-e	Displays long words as double-precision, floating point. (same as the **-F** flag)
-f	Displays long words as floating points.
-F	Displays long words as double-precision, floating point. (same as the **-e** flag)
-h	Displays 16-bit words as unsigned hexadecimal.
-H	Displays long words as unsigned hexadecimal values.

Item	Description
-i	Displays 16-bit words as signed decimal.
-I	(Uppercase i) Displays long words as signed decimal values.
-l	(Lowercase L) Displays long words as signed decimal values.
-L	Displays long words as signed decimal values.
-o	Displays 16-bit words as unsigned octal.
-O	Displays long words as unsigned octal values.
-p	Indicates even parity on **-a** conversion.
-P	Indicates odd parity on **-a** conversion.
-s	Displays 16-bit words as signed decimal values.
-S[*N*]	Searches for strings of characters ending with a null byte. The *N* variable specifies the minimum length string to be recognized. If the *N* variable is omitted, the minimum length defaults to 3 characters.
-v	Writes all input data. By default, output lines that are identical to the immediately preceding output lines are not printed, but are replaced with a line containing only an * (asterisk). When the **-v** flag is specified, all the lines are printed.
-w [*N*]	Specifies the number of input bytes to be interpreted and displayed on each output line. If the **-w** flag is not specified, 16 bytes are read for each display line. If the **-w** flag is specified without the *N* variable, 32 bytes are read for each display line. The maximum input value is 4096 bytes. Input values greater than 4096 bytes will be reassigned the maximum value.
-x	Displays 16-bit words as hexadecimal values.
-X	Displays long words as unsigned hexadecimal values. (same as the **-H** flag)

Note: The flags **-I** (uppercase i), **-l** (lowercase L), and **-L** are identical.

Exit Status

This command returns the following exit values:

Item	Description
0	All input files were processed successfully.
>0	An error occurred.

Examples

1. To display a file in octal, a page at a time, enter:

   ```
   od a.out | pg
   ```

   This command displays the a.out file in octal format and pipes the output through the **pg** command.
2. To translate a file into several formats at once, enter:

   ```
   od -t cx a.out > a.xcd
   ```

   This command writes the contents of the a.out file, in hexadecimal format (**x**) and character format (**c**), into the a.xcd file.
3. To start displaying a file in the middle (using the first syntax format), enter:

```
od -t acx -j 100 a.out
```

This command displays the a.out file in named character (**a**), character (**c**), and hexadecimal (**x**) formats, starting from the 100th byte.

4. To start in the middle of a file (using the second syntax format), enter:

```
od -bcx a.out +100.
```

This displays the **a.out** file in octal-byte (**-b**), character (**-c**), and hexadecimal (**-x**) formats, starting from the 100th byte. The **.** (period) after the offset makes it a decimal number. Without the period, the output would start from the 64th (100 octal) byte.

Files

Item	Description
/usr/bin/od	Contains the **od** command.

odmadd Command

Purpose

Adds objects to created object classes.

Syntax

odmadd [*InputFile* ...]

Description

The **odmadd** command takes as input one or more *InputFile* files and adds objects to object classes with data found in the stanza files. Each *InputFile* file is an ASCII file containing the data that describes the objects to be added to object classes. If no file is specified, input is taken from stdin (standard input).

The classes to be added to are specified in the ASCII input file. The file is in the following general format:

```
class1name:
        descriptor1name = descriptor1value
        descriptor2name = descriptor2value
        descriptor3name = descriptor3value

class2name:
        descriptor4name = descriptor4value
.
.
.
```

The input file can contain the **** (backslash), which is handled as it is in C language. String and method values in the input file must be enclosed in " " (double-quotation marks). A descriptor value can span more than one line.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

An ASCII input file used by the **odmadd** command looks like the following:

```
Fictional_Characters:
Story_Star       = "Cinderella"
Birthday         = "Once upon a time"
Age              = 19
Friends_of       = Cinderella
Enemies_of       = "Cinderella"

Friend_Table:
Friend_of        = "Cinderella"
Friend           = "Fairy godmother"

Friend_Table:
Friend_of        = "Cinderella"
Friend           = "Mice"

Enemy_Table:
Enemy_of         = "Cinderella"
Enemy            = "Wicked sisters"

Enemy_Table:
Enemy_of         = "Cinderella"
Enemy            = "Mean stepmother"
```

If the preceding file is named `NewObjects`, the following command adds the objects to existing object classes:

```
odmadd NewObjects
```

See html

odmchange Command

Purpose

Changes the contents of a selected object in the specified object class.

Syntax

odmchange -o *ObjectClass* [**-q** *Criteria*] [*InputFile*]

Description

The **odmchange** command, given the object class to modify, the search criteria, and the new object (only for attributes that need to change), modifies all objects that satisfy the search criteria. The *InputFile* file has the same format as the *InputFile* file (the ASCII input file) for the **odmadd** command.

Flags

Item	Description
-o *ObjectClass*	Specifies the object class to modify.
-q *Criteria*	Specifies the criteria used to select objects from the object class. For information on qualifying criteria, see html

odmcreate Command

Purpose

Produces the **.c** (source) and **.h** (include) files necessary for ODM application development and creates empty object classes.

Syntax

odmcreate [**-p**] [**-c** | **-h**] *ClassDescriptionFile*

Description

The **odmcreate** command is the ODM class compiler. The command takes as input an ASCII file that describes the objects a user wishes to use in a specific application. The **odmcreate** command can create empty object classes as part of its execution.

The output of the **odmcreate** command is a **.h** file (an include file) that contains the C language definitions for the object classes defined in the ASCII *ClassDescriptionFile* file. The resulting include file is used by the application for accessing objects stored in ODM. The **odmcreate** command also produces a **.c** file that must be compiled and bound in with the application. The **.c** file contains structures and definitions that are used internally by ODM at run time.

The *ClassDescriptionFile* parameter specifies an ASCII file that contains descriptions of one or more object classes. The general syntax for the *ClassDescriptionFile* parameter is as follows:

Item	Description
file	: classes
classes	: class | classes class
class	: head body tail
head	: **struct** *ClassName* **{**
tail	: **}**
body	: elements
elements	: elements | elements element
element	:**char** *DescriptorName* **[** *DescriptorSize* **];**
	vchar *DescriptorName* **[** *DescriptorSize* **];**
	binary *DescriptorName* **[** *DescriptorSize* **];**
	short *DescriptorName* **;**
	long *DescriptorName* **;**
	long64 or **int64** or **ODM_LONG_LONG** *DescriptorName* **;**
	method *DescriptorName* **;**
	link *StdClassName StdClassName ColName DescriptorName* **;**

The default suffix for a *ClassDescriptionFile* file is **.cre**. If no suffix is specified on the **odmcreate** command, then a **.cre** suffix is appended. The file can have C language comments if run with the **-p** flag, and can include **#define** and **#include** lines that can be preprocessed if the **-p** flag is used to run the C language preprocessor on the file.

> **Note:** ODM databases are 32-bit databases. The long type, when used in the class description file is a 32-bit data item. The long64 or int64 type, when used in the class description file

is a 64-bit data item. The generated files will function the same for both 32- and 64-bit applications.

Flags

Item	Description
-c	Creates empty object classes only; does not generate the C language **.h** and **.c** files.
-h	Generates the **.c** and **.h** files only; does not create empty classes.
-p	Runs the C language preprocessor on the *ClassDescriptionFile* file.

Example

Assuming that a *ClassDescriptionFile* file named `FileName.cre` exists, the following command creates object classes:

```
odmcreate FileName.cre
```

Below is the `FileName.cre` source file and the resulting **.h** file:

```
/* This is an example odmcreate input file */
/* FileName.cre */

       class Class2 {
            char keys[32];
            method card;
            long cash;
            };
      class TstObj {
            long a;
            char b[80];
            link Class2 Class2 card Class2Ln;
            };

/* End of FileName.cre */

/* This is the generated header file FileName.h */

#include <odmi.h>

struct Class2 {
     long _id;         /* unique object id within object class */
     long _reserved;   /* reserved field */
     long _scratch;    /* extra field for application use */
     char keys[32];
     char card[256];   /* method */
     long cash;
     };
#define Class2_Descs 3

extern struct Class Class2_CLASS[];
#define get_Class2_list (a,b,c,d,e) (struct Class2 * ) odm_get_list (a,b,c,d,e)

struct TstObj {
     long _id;         /* unique object id within object class */
     long _reserved;   /* reserved field */
     long _scratch;    /* extra field for application use */
     long a;
     char b[80];
     struct Class2 *Class2Ln;  /* link */
     struct objlistinfo *Class2Ln_info; /* link */
     char Class2Ln_Lvalue[256];        /* link */
     };
#define TstObj_Descs 3

extern struct Class TstObj_CLASS[];
#define get_TstObj_list (a,b,c,d,e) (struct TstObj * ) odm_get_list (a,b,c,d,e)

/* End of generated header file FileName.h */
```

odmdelete Command

Purpose

Deletes selected objects from a specified object class.

Syntax

odmdelete -o *ObjectClass* [**-q** *Criteria*]

Description

The **odmdelete** command, given the object class to delete from and the search criteria, deletes all objects that meet those criteria.

Flags

Item	Description
-o *ObjectClass*	Specifies the object class to delete from.
-q *Criteria*	Specifies the criteria used to select objects from the object class. For information on qualifying criteria, see html

odmdrop Command

Purpose

Removes an object class.

Syntax

odmdrop -o *ClassName*

Description

The **odmdrop** command removes an entire object class and all of its objects. No checking is done to see if other object classes are linked to this one.

Flags

Item	Description
-o *ClassName*	Specifies the object class to remove.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Example

Assuming that an object class named `MyObjectClass` exists, the following command removes the object class:

```
odmdrop -o MyObjectClass
```

odmget Command

Purpose

Retrieves objects from the specified object classes into an **odmadd** input file.

Syntax

odmget [**-q** *Criteria*] *ObjectClass* ...

Description

The **odmget** command takes as input a search criteria and a list of object classes, retrieves the selected objects from the specified object classes, and writes an ASCII **odmadd** input file to standard output.

Flags

Item	Description
-q *Criteria*	Specifies the search criteria used to select objects from the object class or classes.

Examples

1. To display information about the Customized Device Drivers (CuDvDr) or the major (value1) and minor (value2) numbers of a device that has a logical name, $logical_name, enter the following command:

   ```
   # odmget -q "resource='devno' and value3='$logical_name'" CuDvDr
   ```

   The output might be similar to the following example:

   ```
   CuDvDr:
           resource = "devno"
           value1 = "19"
           value2 = "8"
           value3 = "hdisk0"
   ```

2. To display information about the Customized Devices (CuDv) and the corresponding Predefined Devices (PdDv) of a device that has a logical name, $logical_name, enter the following command:

   ```
   # odmget -q uniquetype=$(odmget -q name=$logical_name CuDv | tee /dev/tty | grep PdDvLn |
   cut -d'"' -f2) PdDv

   # logical_name=hdisk0

   # odmget -q uniquetype=$(odmget -q name=$logical_name CuDv | tee /dev/tty | grep PdDvLn |
   cut -d'"' -f2) PdDv
   ```

   The output might be similar to the following example:

   ```
   CuDv:
           name = "hdisk0"
           status = 1
           chgstatus = 2
           ddins = "scsidisk"
           location = "C5-T1-01"
           parent = "fscsi1"
           connwhere = "W_2"
           PdDvLn = "disk/fcp/mpioapdisk"

   PdDv:
           type = "mpioapdisk"
           class = "disk"
           subclass = "fcp"
   ```

```
        prefix = "hdisk"
        devid = ""
        base = 1
        has_vpd = 1
        detectable = 1
        chgstatus = 0
        bus_ext = 0
        fru = 1
        led = 1574
        setno = 2
        msgno = 0
        catalog = "scdisk.cat"
        DvDr = "scsidisk"
        Define = "/usr/lib/methods/define"
        Configure = "/usr/lib/methods/cfgscsidisk"
        Change = "/usr/lib/methods/chgdisk"
        Unconfigure = "/usr/lib/methods/ucfgdevice"
        Undefine = "/usr/lib/methods/undefine"
        Start = ""
        Stop = ""
        inventory_only = 0
        uniquetype = "disk/fcp/mpioapdisk"
```

3. To display information about the CuDv and Customized Attribute (CuAt) of a device that has a logical name, $logical_name, enter the following command:

```
# logical_name=vio0

# odmget -q "name='$logical_name'" CuDv CuAt
```

The system displays the following output:

```
CuDv:
        name = "vio0"
        status = 1
        chgstatus = 2
        ddins = "vdev_busdd"
        location = ""
        parent = "sysplanar0"
        connwhere = "vdevice"
        PdDvLn = "bus/chrp/vdevice"

CuAt:
        name = "vio0"
        attribute = "bus_id"
        value = "0x90000340"
        type = "R"
        generic = "D"
        rep = "n"
        nls_index = 5
```

odmshow Command

Purpose

Displays an object class definition on the screen.

Syntax

odmshow *ObjectClass*

Description

The **odmshow** command takes as input an object class name (*ObjectClass*) and displays the class description on the screen. The class description is in the format taken as input to the **odmcreate** command.

Example

Assuming that an object class named `MyObjectClass` exists, the following command displays the description of `MyObjectClass` on the screen:

```
odmshow MyObjectClass
```

Also, see the **odmcreate** command or **ODM Example Code and Output** in *General Programming Concepts: Writing and Debugging Programs* for an example of the output listing.

on Command

Purpose

Executes commands on remote systems.

Syntax

/usr/bin/on [**-i**] [**-d**] [**-n**] *Host Command* [*Argument ...*]

Description

The **on** command executes commands on other systems in an environment that is similar to the one running the program. The **on** command passes the local environment variables to the remote machine, thus preserving the current working directory. When using the **on** command, both users must have the same user identification. Relative path names work only if they are within the current file system. Absolute path names can cause problems since commands are issued at one machine and executed on another.

The standard input is connected to the standard input of the remote command. The standard output and standard error from the remote command are sent to the corresponding files for the **on** command. The root user cannot execute the **on** command.

> **Attention:** When the working directory is remotely mounted over the Network File System (NFS), the Ctrl-Z key sequence causes the window to hang.

Flags

Item	Description
-d	Specifies debug mode. Displays status messages as work progresses.
-i	Specifies interactive mode. Uses remote echoing and special character processing. This option is needed for programs that expect to be talking to a terminal. All terminal modes and window size changes are increased.
-n	Specifies no input. This option causes the remote program to get an end-of-file (EOF) message when it reads from standard input. This flag is necessary when running commands in the background with job control.

Example

To execute the **ls -al** command on another machine and display the in-progress status messages on your terminal, enter:

```
on  -d zorro ls -al
```

In this example, the **on** command executes the **ls** command on a workstation named `zorro`.

Files

Item	Description
/etc/inetd.conf	Defines how the **inetd** daemon handles Internet service requests.

openpts Command

Purpose

Allows enrolling and certifying a remote system.

Syntax

openpts [**-i** [**-f**] | [**-v**] | **-r** | **-D**] [**-h**] [**-V**] [**-u**] [**-l** *username*] [**-p** *port*] [**-c** *configfile*] **host**

Description

The **openpts** command allows the system (the verifier) to connect to a remote **host** (the collector) to determine whether the collector has performed a trusted boot. A machine is considered to have performed trusted boot when the contents of the collector's trusted platform module (TPM) is interrogated for consistency against a reference set of measurements (reference manifest) maintained by the verifier. To acquire the set of reference measurements, the verifier must first enroll the collector by using the **-i** option. After enrollement, the verifier can attest the collector with the default **-v** option that compares the current values represented in the integrity report against the reference set. The success or failure of this operation is reported to you along with the reason of failure. Examples of operations that may cause a failed certification include booting from a different device, changing the boot flags, and modifying the boot image.

If updates are pending to the state of the collector (for example, an OS upgrade that affects the next boot operation) these updates are reported during an attestation. The user is prompted to accept or reject the new values. Updates can be automatically accepted by using the **-u** option. The attestation request uses secure shell (SSH) as the communication mechanism between the collector and the verifier. The **openpts** command uses parameters such as **-l** for ssh command username and **-p** for port.

Flags

Item	Description
-c *configfile*	Specifies the configuration file to use. The default is ~/.openpts/openpts.conf.
-D	Displays the configuration settings of the target and all the options.
-h	Displays the command usage information.
-i [*-f*]	Enrolls a new collector partition or forces the enrollment of an existing collector.
-l *username*	Specifies the ssh command username.
-p *port*	Specifies the ssh command port number.
-r	Removes all information about a target system.
-u	Allow the command to accept updates to the manifest from the collector without prompting the **yes** option. The default is no.
-v (**default**)	Verifies a collector against its existing reference manifest.
-V	Displays the information in verbose mode. Multiple **-V** options increase the verbosity. This is used for debugging the data.

Files

Item	Description
~/.openpts/	This directory is the default location for all configuration and remote host information.
~/.openpts/openpts.conf	The configuration of the verifier.
~/.openpts/uuid	The UUID file of the verifier.
~/.openpts/UUID/ir.xml	The last integrity report received from the remote host.
~/.openpts/UUID/ newrm_uuid	The UUID file of the new reference manifest (for example, for the next boot operation after a system update).
~/.openpts/UUID/ policy.conf	The policy to verify the properties of a remote host.
~/.openpts/UUID/rm_uuid	The UUID file of the reference manifest.
~/.openpts/UUID/UUID/ rmN.xml	The reference manifests of the remote host.
~/.openpts/UUID/ target.conf	The configuration of the remote host.
~/.openpts/UUID/ vr.properties	The platform properties of the remote host derived from the integrity report.

OS_install Command

Purpose

Performs network installation operations on `OS_install` objects.

Syntax

Traditional usage:

`OS_install` [**-K** *keyfile_path_name*]{ `-o` *Operation* } [**-F**] [-a`-` *attr=value...*] {*ObjectName*}

For system plan installations (System Plan mode):

`OS_install` [**-K** *keyfile_path_name*] `-i sysplan` { `-x` *sysplan.xml* } [`-d`] [**-F**]

For listing `OS_install` objects (List mode):

`OS_install -l` [`-v`] [`-t` *object_type* | *object_name*]

For managing network daemons:

`OS_install` **-S** | **-U**

Description

The `OS_install` command performs a network installation operation on an `OS_install` object. The type of operation is dependent on the type of object specified by the *ObjectName* parameter. The object pointed to by the *ObjectName* parameter can be one of four types: `Client`, `OS_Resource`, `Remote_Resource` or `Control_Host`. Command operations involve the creation and management of `OS_install` objects that enable network installation to install an operation system on a client system.

`OS_install` can also be run in System Plan mode by passing the `-i sysplan` flag instead of specifying an operation. This operation provides the ability to combine multiple `OS_install` operations into a single XML document.

The operations involving Remote_Resource objects require configuring an SSH key that is generated with the ssh-keygen command. The SSH key is required to run ssh commands on the local platform and remote resource server. On an HMC, the default name of the file *keyfile_path_name* containing the SSH key is /home/hscroot/ssh_keys. This file name can be overridden with the **-K** option. On other platforms, there is no default file name for the SSH key file. If the **-K** option is not specified on other platforms, the standard path names of SSH key files must be accessible to the OS_install command process.

The List mode of OS_install is used to list the current configuration of objects in the OS_install environment.

The HMC or IVM network daemons can be started and stopped with the **S** and **U** options, without modifying the OS_install objects.

Flags

Item	Description
-a *attr=value*	Assigns the specified value to the specified attribute. Operations lists the required and optional attributes for a specific operation.
-d	Deletes all OS_install objects created during System Plan mode after all operations are completed.
-F	Authorizes a reset of the existing remote server client system objects if required, during an OS_install allocate operation or system plan installation.
-i sysplan	Specifies System Plan mode.
-K *keyfile_path_name*	Specifies the absolute path name of the file where the SSH keys are generated.
-l	Lists all OS_install objects in the environment by default.
-o *Operation*	Specifies an operation to perform on an OS_install object.
-S	Starts the network daemons without modifying the OS_install objects.
-t *object_type* | *object_name*	Narrows the list returned by the -l flag to only objects of type *object_type* or to the single OS_install object specified by *object_name*.
-U	Stops the network daemons without modifying the OS_install objects.
-v	Displays the list returned by the -l flag.
-x *sysplan.xml*	Specifies the XML file that contains the system plan.

Operations

Operation	Description	Required Attributes	Optional Attributes
`define_client` [-a *attr=value*...] {*ClientObjectName*}	Defines a new client object.	**ip_addr** Client's IP address. **mac_addr** MAC address of the network interface of the client system. **gateway** IP gateway address of the client system. **subnet_mask** IP subnet mask of the client system. **lpar** LPAR name to install client (required attribute for the netboot operation). **profile** LPAR profile to use for the client (required attribute for the netboot operation). **managed_system** Name of the managed system that contains LPAR (required attribute for the netboot operation). **ctrl_host** Name of the Hardware Control Host object for this client (required attribute for the netboot operation).	**adapter_speed** Speed of the network adapter of the client system. **adapter_duplex** Duplex setting of the network adapter of the client system. **disk_location** Location of the disk to install client. **vlan_tag** Specifies the virtual logical area network (VLAN) tag to be used for tagging Ethernet frames during network installation for virtual network communication. Valid values are 0 - 4094. **vlan_pri** Specifies the virtual logical area network (VLAN) tag to be used for tagging Ethernet frames during network installation for virtual network communication. Valid values are 0 - 7.
`define_resource` [-a *attr=value*...] {*ResourceObjectName*}	Defines a new `OS_Resource` object.	**type** AIX or VIOS. **version** OS version. **location** Absolute path where `OS_Resource` resides. **source** Source of installation images.	**configfile** Install configuration file.

Operation	Description	Required Attributes	Optional Attributes
`define_remote_resource` [-a *attr=value*...] {*ResourceObjectName*}	Defines a new `Remote_Resource` object.	**server** Host name of the remote resource server. **type** AIX or Linux. **remote_identifier** Name of the resource or resource set on the remote resource server.	**communication_method** Supports ssh communication method.
`define_ctrl_host` [-a *attr=value*...] {*ControlHostObjectName*}	Defines a new Hardware Control_Host object.	**communication_method** Supports ssh communication method. **hostname** Host name of control host (the host name localhost can be specified if `OS_install` is run on the HMC control host). **type** hmc or ivm.	None.
`allocate` [-F][-a *attr=value*...] {*ClientObjectName*}	Allocates an `OS_Resource` or `Remote_Resource` to a client object. Both objects must exist in the `OS_install` environment. An error occurs if the client object has an `OS_Resource` or `Remote_Resource` already allocated to it.	**os_resource** Existing `OS_Resource` or `Remote_Resource` object to allocate to the client object. **remote_resource** Existing `Remote_Resource` object to allocate to the client object. **install_resource** Existing `OS_Resource` or `Remote_Resource` object to allocate to the client object.	**config_file** Install configuration file (applies for an `OS_Resource` object).
`netboot` {*ClientObjectName*}	Instructs the hardware control host of the client object to initiate a network boot.	None.	None.
`monitor_installation` {*ClientObjectName*}	Monitors the installation status of the client object.	None.	None.

Operation	Description	Required Attributes	Optional Attributes
`deallocate` {*ClientObjectName*}	Deallocates the `OS_Resource` or `Remote_Resource` that was allocated to the client object by an allocate operation.	None.	None.
`remove` {*ObjectName*}	Removes the object from the `OS_install` environment.	None.	None.

Exit Status

Item	Description
`0`	The command completed successfully.
`>0`	An error occurred.

Examples

1. To define a client object, enter a command similar to the following:

   ```
   OS_install -o define_client -a ip_addr=128.0.64.117 -a mac_addr=ab:cc:de:10:23:45 -a \
   gateway=128.0.64.1 -a subnet_mask=255.255.255.0 -a ctrl_host=myhmc -a lpar=AIX1 -a \
   profile=AIX1 -a managed_system=myMngSys myclient01
   ```

   The preceding client object is a logical partition in a managed system.
2. To define an `OS_Resource` object, enter a command similar to the following:

   ```
   OS_install -o define_resource -a location=/images/AIX/53ML3 -a type=AIX -a version=53ML3
   my53resource
   ```
3. To define a `Remote_Resource` object (using the `OS_install` default SSH key file for HMC), enter a command similar to the following:

   ```
   OS_install -o define_remote_resource -a server=MyNimServer -a type=AIX
     -a remote_identifier=NimResGrp1 myRemoteResource
   ```
4. To define a `Remote_Resource` object (using a previously generated ssh-keygen key located in /home/hscroot/id_dsa file), enter the following:

   ```
   OS_install -K /home/hscroot/id_dsa -o define_remote_resource -a server=MyNimServer -a
   type=AIX -a
   remote_identifier=NimResGrp1 myRemoteResource
   ```
5. To allocate the `OS_Resource` object defined in example 2 to a client object, enter a command similar to the following:

   ```
   OS_install -o allocate -a os_resource=my53resource myclient01
   ```

   or

   ```
   OS_install -o allocate -a install_resource=my53resource myclient01
   ```
6. To allocate the `Remote_Resource` object defined in example 3 to a client object and authorize reset on an existing client, enter a command similar to the following:

   ```
   OS_install -o allocate -F -a remote_resource=myRemoteResource myclient01
   ```

   or

```
OS_install -o allocate -F -a install_resource=myRemoteResource myclient01
```

7. To deallocate the `my53resource` client object that was allocated in the example 5, enter:

```
OS_install -o deallocate myclient01
```

8. To define a `Control_Host` object to be specified for the `ctrl_host` attribute of a Client object, enter a command similar to the following:

```
OS_install -o define_ctrl_host -a type=hmc -a hostname=hmc_hostname -a
communication_method=ssh myhmc
```

   Although the preceding example shares the same name of the `ctrl_host` attribute in the first example, the `define_client` operation allows an undefined `Control_Host` object to be specified for the `ctrl_host` attribute. In that case the controlling host of the Client object must be the HMC or IVM on which the `netboot` operation for the client is executed.

9. To execute a `netboot` operation, enter:

```
OS_install -o netboot myclient01
```

10. To view a `myclient01` installation, enter:

```
OS_install -o monitor_installation myclient01
```

11. To remove the definition of the `my53resource` object, enter:

```
OS_install -o remove my53resource
```

12. To remove the definition of the `myclient01` object, enter:

```
OS_install -o remove myclient01
```

    If an `OS_Resource` object is specified, the `remove` operation removes OS images that exist in the file system directory specified by the `location` attribute of the object.

Configuring SSH

- Generate SSH Rivest-Shamir-Adleman (RSA) keys and place them in an accessible ssh_keys file in the HMC HOME directory, by entering the command:

```
ssh-keygen -t rsa -f /home/hscroot/ssh_keys
```

- On the remote resource server, append or copy the content of the /home/hscroot/ssh_keys.pub file that is generated by using the **ssh-keygen** command to the resource server's .ssh/authorized_keys file.
- If `OS_install` command is used to run a netboot operation on a target client of a remote HMC control host, append the content of the /home/hscroot/ssh_keys.pub file that is generated by using the **ssh-keygen** command to the remote HMC hscroot user's .ssh/authorized_keys2 file, by entering the following command as a hscroot user on the remote HMC:

```
mkauthkeys -a '<content_of_ssh_keys.pub>'
```

Location

Item	Description
`/usr/sbin/OS_install`	
`/opt/osinstall`	Directory containing the `OS_install` Perl module files.

Files

Item	Description
`/var/osinstall`	Directory containing configuration files for the `OS_install` environment.
`/home/hscroot/ssh_keys`	Default file name for SSH keys on an HMC.

oslevel Command

Purpose

Reports the latest installed level (technology level, maintenance level and service pack) of the system.

Syntax

oslevel [**-l** *Level* | **-g** *Level* | **-q**] [**-r** | **-s**] [**-f**]

Description

The **oslevel** command reports the technology level and service pack of the operating system using a subset of all filesets installed on your system. These filesets include the Base Operating System (BOS), base devices, base printers, and X11.

The **oslevel** command also prints information about the technology level and service pack, including which filesets are not at a specified technology level or service pack.

Flags

Item	Description
-l *Level*	Lists filesets that are earlier (less) than the technology level or service pack specified by the *Level* parameter.
-f	Forces the **oslevel** command to rebuild the cache for this operation.
-g *Level*	Lists filesets that are later (greater) than the technology level or service pack specified by the *Level* parameter.
-q	Lists names of known technology levels (when used with the **-r** flag) or service packs (when used with the **-s** flag) that can be specified using the **-l** or **-g** flag.
-r	Applies all flags to technology levels.
-s	Applies all flags to service packs. The service pack level returned is in the format 6100-00-01-0748, where 6100 refers to base level 6.1.0.0; 00 refers to technology level 0; 01 refers to service pack 1; and 0748 is the build sequence identifier, which is used to determine valid technology levels and service packs that can be applied to the current level. Attempts to apply a technology level or service pack with a lower build sequence identifier will fail.

If no flags are specified, the base system software is entirely at or above the level that is listed in the output of the **oslevel** command.

Examples

1. To determine the base level of the system, type:

   ```
   oslevel
   ```

   The output will be similar to the following:

```
6.1.0.0
```

2. To determine the highest technology level reached for the current version of AIX on the system, type:

```
oslevel -r
```

3. To list all known technology levels on the system, type:

```
oslevel -rq
```

The levels returned can be used with the [**-r -l**] or [**-r -g**] flags, and will be similar to the following:

```
Known Recommended Maintenance Levels
------------------------------------
5300-02
5300-01
5300-00
```

4. To list which software is below AIX Version 5.3 technology level 1, type:

```
oslevel -r -l 5300-01
```

5. To list which software is at a level later than AIX Version 5.3 technology level 1, type:

```
oslevel -r -g 5300-01
```

6. To determine the highest service pack reached for the current technology level on the system, type:

```
oslevel -s
```

7. To list the known service packs on a system, type:

```
oslevel -sq
```

The levels returned can be used with the [**-s -l**] or [**-s -g**] flags, and will be similar to the following:

```
Known Service Packs
-------------------
6100-00-02-0750
6100-00-01-0748
6100-00-00-0000
```

8. To list which software is below AIX Version 6.1 technology level 0, service pack 1, type:

```
oslevel -s -l 6100-00-01-0748
```

9. To list which software is at a level later than AIX Version 6.1 technology level 0, service pack 1, type:

```
oslevel -s -g 6100-00-01-0748
```

Files

Item	Description
/usr/bin/oslevel	Contains the **oslevel** command.

ospf_monitor Command

Purpose

Monitors the OSPF gateways.

Syntax

ospf_monitor *mon_db_file*

Description

The **ospf_monitor** command is used to query OSPF routers. The **ospf_monitor** command operates in interactive mode. It allows the user to query the various OSPF routers to provide detailed information on I/O statistics, error logs, link-state data bases, AS external data bases, the OSPF routing table, configured OSPF interfaces, and OSPF neighbors.

Specify the complete pathname of a database composed of records configuring destinations for **ospf_monitor** remote commands with *mon_db_file*. Each destination record is a single-line entry which lists the destination IP address, the destination hostname, and an OSPF authentication key (if authentication is activated by the destination). Since authentication keys may be present in the destination records, it is recommended that general access to this database be restricted.

Refer to RFC-1583 (OSPF Specification, version 2) for details about OSPF database and packet formats.

Commands

Upon entering interactive mode, **ospf_monitor** presents the `'[ # ] dest command params >'` prompt, at which you can enter any of **ospf_monitor**'s interactive commands. Interactive commands can be interrupted at any time with a keyboard interrupt.

Note: The command line length must be less than 200 characters.

Local Commands

Item	Description
?	Displays all local commands and their functions.
?R	Displays all remote commands and their functions.
d	Displays all configured destinations. This command displays *dest_index* , the IP address, and the hostname of all potential **ospf_monitor** command destinations configured in *mon_db_file*.
h	Displays the command history buffer showing the last 30 interactive commands.
x	Exits the **ospf_monitor** program.
@ *remote_command*	Sends *remote_command* to the same (previous) destination.
@*dest_index remote_command*	Sends *remote_command* to configured destination *dest_index*.
F *filename*	Sends all **ospf_monitor** output to *filename*.
S	Sends all **ospf_monitor** output to stdout.

Remote Commands

Item	Description
a *area_id type ls_id adv_rtr*	Displays link state advertisement. *Area_id* is the OSPF area for which the query is directed. *adv_rtr* is the router-id of the router which originated this link state advertisement. *Type* specifies the type of advertisement to request and should be specified as follows: **1** Request the router links advertisements. They describe the collected states of the router's interfaces. For this type of request, the *ls_id* field should be set to the originating router's Router ID. **2** Request the network links advertisements. They describe the set of routers attached to the network. For this type of request, the *ls_id* field should be set to the IP interface address of the network's Designated Router. **3** Request the summary link advertisements describing routes to networks. They describe inter-area routes, and enable the condensing of routing information at area borders. For this type of request, the *ls_id* field should be set to the destination network's IP address. **4** Request the summary link advertisements describing routes to AS boundary routers. They describe inter-area routes, and enable the condensing of routing information at area borders. For this type of request, the *ls_id* field should be set to the Router ID of the described AS boundary router. **5** Request the AS external link advertisements. They describe routes to destinations external to the Autonomous System. For this type of request, the *ls_id* field should be set to the destination network's IP address.
c	Displays cumulative log. This log includes input/output statistics for monitor request, hello, data base description, link-state request, link-state update, and link-state ack packets. Area statistics are provided which describe the total number of routing neighbors and number of active OSPF interfaces. Routing table statistics are summarized and reported as the number of intra-area routes, inter-area routes, and AS external data base entries.
e	Displays cumulative errors. This log reports the various error conditions which can occur between OSPF routing neighbors and shows the number of occurrences for each.
h	Displays the next hop list. This is a list of valid next hops mostly derived from the SPF calculation.
l [*retrans*]	Displays the link-state database (except for ASE's). This table describes the routers and networks making up the AS. If *retrans* is non-zero, the retransmit list of neighbors held by this lsdb structure will be printed.
A [*retrans*]	Displays the AS external data base entries. This table reports the advertising router, forwarding address, age, length, sequence number, type, and metric for each AS external route. If *retrans* is non-zero, the retransmit list of neighbors held by this lsdb structure will be printed.

Item	Description
o [*which*]	Displays the OSPF routing table. This table reports the AS border routes, area border routes, summary AS border routes, networks, summary networks and AS external networks currently managed via OSPF. If *which* is omitted, all of the above will be listed. If specified, the value of *which* (between 1 and 63) specifies that only certain tables should be displayed. The appropriate value is determined by adding up the values for the desired tables from the following list: **1** Routes to AS border routers in this area. **2** Routes to area border routers for this area. **4** Summary routes to AS border routers in other areas. **8** Routes to networks in this area. **16** Summary routes to networks in other areas. **32** AS routes to non-OSPF networks.
I	Displays all interfaces. This report shows all interfaces configured for OSPF. Information reported includes the area, interface IP address, interface type, interface state, cost, priority, and the IP address of the DR and BDR for the network.
N	Displays all OSPF routing neighbors. Information reported includes the area, local interface address, router ID, neighbor IP address, state, and mode.
V	Displays Gated version information.

p

The following AIX commands begin with the letter *p*.

pac Command

Purpose

Prepares printer/plotter accounting records.

Syntax

/usr/sbin/pac [**-c**] [**-m**] [**-p***Price*] [**-P***Printer*] [**-q***File*] [**-r**] [**-s**] [*Name ...*]

Description

The **pac** command prepares printer/plotter accounting records for each user of the selected printer or for the users specified by the *Name* parameter. For printer choices, see the **-P** flag.

The unit of measure is the number of pages, with the exception of raster devices, for which feet of paper is measured. Output is expressed both as the number of units used and the charge in dollars. For information on the charge (price) per unit, see the **-p** flag.

The accounting file specified in the **/etc/qconfig** file and the file created to contain the summary information must grant read and write permissions to the root user or printq group. The **pac** command generates the summary file name by appending **_sum** to the path name specified by the `acctfile =` clause in the **/etc/qconfig** file. For example, if the **qconfig** file reads:

```
acctfile = /var/adm/1p0acct
```

The **pac** command expects the summary file to be named **/var/adm/1p0acct_sum**.

Flags

Item	Description
-c	Sorts the output by price instead of alphabetically by user.
-m	Groups all the printing charges for a user, regardless of the host machine.
-p*Price*	Specifies the price, in dollars, charged per unit of output. By default, the system charges $0.02 per unit.
-P*Printer*	Specifies the printer for which accounting records are prepared. By default, the system selects the printer named by the **PRINTER** environment variable or the default value **lp0**. **Note:** When the **LPDEST** environment variable is set, it takes precedence over the **PRINTER** environment variable, which has an identical function. Any destination options issued from the command line override both the **LPDEST** and **PRINTER** environment variables.
-q*File*	Specifies the queue configuration file. The default value is the **/etc/qconfig** file.
-r	Reverses the sorting order, so that records are sorted alphabetically from z to a, or in descending order by price.
-s	Summarizes the accounting information in a summary file. This flag is needed for busy systems.

Examples

1. To produce printer/plotter accounting information for all users of the `lp0` printer, enter:

   ```
   /usr/sbin/pac
   ```

   The command displays the number of printed pages and the charge, sorted by user. This example assumes that there is no **PRINTER** environment variable.
2. To collect printer/plotter accounting records in a summary file, enter:

   ```
   /usr/sbin/pac  -s
   ```
3. To produce printer/plotter accounting information for `smith`, `jones`, and `greene` from the `lp12` printer, enter:

   ```
   /usr/sbin/pac  -Plp12 smith jones greene
   ```

   Note: Do not place a space between a flag and its variable; for example, the **-p***Price,* **-P***Printer*, and **-q***File.*

Files

Item	Description
/usr/sbin/pac	Contains the **pac** command.
/etc/qconfig	Specifies the path to the file.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

pack Command

Purpose

Compresses files.

Syntax

pack [**-f**] [**-**] *File ...*

Description

The **pack** command stores the file specified by the *File* parameter in a compressed form. The input file is replaced by a packed file with the same name and the suffix **.z** appended. If the invoking process has appropriate privileges, the packed file maintains the same access modes, access and modification dates, and owner as the original file. The input file name can contain no more than 253 bytes to allow space for the added **.z** suffix. If the **pack** command is successful, the original file is removed. Packed files can be restored to their original form using the **compress** command.

The exit value of the **pack** command is the number of files that it could not pack. The **pack** command does not pack under any of the following conditions:

- The file is already packed.
- The input file name has more than 253 bytes.

- The file has links.
- The file is a directory.
- The file cannot be opened.
- No storage blocks are saved by packing.
- A file called *File***.z** already exists.
- The **.z** file cannot be created.
- An I/O error occurred during processing.

Flags

Item	Description
-f	Forces packing of the file specified by the *File* parameter. This is useful for packing an entire directory, even if some of the files will not benefit.

Parameters

Item	Description
File	Specifies the file to be packed.
-	Displays statistics about the file specified by the *File* parameter. The statistics are calculated from a Huffman minimum redundancy code tree built on a byte-by-byte basis. Additional occurrences of the **-** (minus sign) parameter on the command line toggles this function for the next specified file. See example 2.

Exit Status

This command returns the following exit values:

Item	Description
0	Specifies that the file was successfully packed.
>0	Specifies that an error occurred.

Examples

1. To compress the files named chap1 and chap2 and display the revised file names, enter:

   ```
   pack chap1 chap2
   ```

   The compressed versions are renamed chap1.z and chap2.z. The **pack** command displays the percent decrease in size for each file compressed.
2. To display statistics about the amount of compression done, enter:

   ```
   pack - chap1 - chap2
   ```

   This compresses the files named chap1 and chap2 and displays statistics about the file named chap1, but not about the file named chap2. The first **-** (minus sign) parameter turns on the statistic display, and the second **-** parameter turns it off.

Files

Item	Description
/usr/bin/pack	Contains the **pack** command.

packf Command

Purpose

Compresses the contents of a folder into a file.

Syntax

packf [**+***Folder*] [*Messages*] [**-file** *File*]

Description

The **packf** command compresses the messages in a folder into a specified file. By default, the **packf** command compresses messages from the current folder and places them in the **msgbox** file. If the file does not exist, the system prompts you for permission to create it. Each message in the file is separated with four Ctrl-A characters and a new-line character.

Note: You can use the **inc** command to unpack compressed messages.

Flags

Item	Description
-file *File*	Specifies the file in which to put compressed messages. The default is the **./msgbox** file. If the file exists, the **packf** command appends the messages to the end of the file. Otherwise, the system prompts you for permission to create the file.
+*Folder*	Identifies the folder containing the messages you want to pack.
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For Message Handler (MH), the name of this flag must be fully spelled out.

Item	Description
Messages	Specifies what messages to pack. The *Messages* parameter can specify several messages, a range of messages, or a single message. If several messages are specified, the first message packed becomes the current message. Use the following references to specify messages: ***Number*** Number of the message. When specifying several messages, separate each number with a space. When specifying a range, separate the first and last numbers in the range with a hyphen. ***Sequence*** A group of messages specified by the user. Recognized values include: **all** All the messages in the folder. This is the default. **cur or . (period)** Current message. **first** First message in a folder. **last** Last message in a folder. **next** Message immediately after the current message. **prev** Message immediately before the current message.

Profile Entries

The following entries are entered in the *UserMhDirectory***/.mh_profile** file:

Item	Description
`Current-Folder:`	Sets your default current folder.
`Msg-Protect:`	Sets the protection level for your new message files.
`Path:`	Specifies the user's MH directory.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To pack all the messages in the current folder and place the resulting text in the **schedule** file, enter:

   ```
   packf  -file schedule
   ```

   The system responds with a message similar to the following:

   ```
   Create file "/home/mary/schedule"?
   ```

   Enter y to create the file.

2. To pack the range of messages from 3 to 7 from the **test** folder into an existing **msgbox** file, enter:

   ```
   packf  +test 3-7
   ```

   The system responds with the `shell` prompt when the command is complete.
3. To pack the current, first, and last message in the **inbox** folder into an existing **msgbox** file, enter:

   ```
   packf cur first last
   ```

Files

Item	Description
$HOME/.mh_profile	Specifies the MH user profile.
/usr/bin/packf	Contains the **packf** command.

pagdel Command

Purpose

Removes any existing PAG association within the current process' credentials.

Syntax

paginit [**-R** *module_name*] [*username*]

Description

The **pagdel** command will remove the PAG identifier from the current process' credentials structure. If the **-R** option is omitted, the registry attribute will be used as the **module_name**.

Flags

Item	Description
-R *module_name*	Specifies a load module found in **/usr/lib/security/modules.cfg**. The **load_module** will be asked to delete any PAG currently associated with the process.

Security

Access Control: This command should grant execute (x) access only to the `root` user and members of the security group. This command should be installed as a program in the trusted computing base (TCB). The command should be owned by the `root` user with the **setuid** (SUID) bit set.

Auditing

USER_PagDelete

Example

To remove the PKI authentication certificate associated with the current process, type:

```
pagdel -R FPKI
```

pagesize Command

Purpose

Displays the system page size.

Syntax

pagesize [**-a**] [-f]

Description

The **pagesize** command prints the size, in bytes, of a page of memory, as returned by the **getpagesize** subroutine. Provided for system compatibility, this command is useful when constructing portable shell scripts.

If the **-a** flag is specified, the **pagesize** command prints all of the page size values (in bytes) supported on the system.

Flags

-a
Prints all of the page size values (in bytes) supported on the system.

-f
Prints the formatted page sizes with an alphabetical suffix rather than the page size in bytes (for example, 4K)

Example

1. To obtain the size system page, enter:

   ```
   pagesize
   ```

   The system returns the number of bytes, such as 4096.
2. To print the formatted page size, enter:

   ```
   pagesize -f
   ```

   The system returns the formatted page size (for example, 4K).
3. To print all of the supported page size with an alphabetical suffix, enter:

   ```
   pagesize -af
   ```

   The system returns all of the supported page sizes. For example:

   ```
   4K
   64K
   16M
   ```

Files

Item	Description
/usr/bin/pagesize	Contains the **pagesize** command.

paginit Command

Purpose

Authenticate a user and create a PAG association.

Syntax

paginit [**-R** *module_name*] [*username*]

Description

The **paginit** command authenticates *username* (by default, the user issuing the command) and creates an association between the *username* and a kernel token called a Process Authentication Group entry (PAG). A new login shell is spawned by this command.

If the **-R** flag is not given, **paglist** queries the user's registry attribute and use that value for *module_name*.

To associate the *username* with an alternate Identification and Authentication (I&A) mechanism, the **-R** flag can be used to specify the I&A load module used to create the user. Load modules are defined in the **/usr/lib/security/methods.cfg** file.

Flags

Item	Description
-R *module_name*	Specifies the loadable I&A module used to authenticate the user.

Parameters

Item	Description
username	Specifies the user. This parameter defaults to the user issuing the command. Only the **root** user may override the default.

Security

Access Control: This command should be executable by all. It should be owned by **root** and should be **setuid**.

Auditing

USER_Paginit

Example

```
paginit -R FPKI
```

The user is authenticated using the registry FPKI, which is defined in the **/usr/lib/security/methods.cfg** file. A PAG is associated with the current process credentials.

paglist Command

Purpose

Lists authentication information associated with the current process.

Syntax

paglist [**-R** *module_name*]

Description

The **paglist** command queries the current process' credentials to display its authentication certificate.

If the **-R** option is not given, **paglist** will query the user's registry attribute and use that value for **module_name**.

Flags

Item	Description
-R *module_name*	Specifies that the load module *module_name* is to list its authentication certificate associated with the current process.

Security

Access Control: This command runs with the ID of the invoking user, without any elevated privileges. It should be owned by `root`, but executable by all.

Example

```
paglist -R FPKI
```

This example will list the PAG associated with the current process within the FPKI registry.

panel20 Command

Purpose

Diagnoses activity between an HIA and the 5080 Control Unit.

Syntax

panel20 [**HIA0** | **HIA1** | **HIA2**]

Description

Use the **panel20** command as a diagnostic tool to determine whether the Host Interface Adapter (HIA) is correctly installed and communicating with the 5088 Graphics Channel Control Unit (GCCU).

The **panel20** command displays a diagnostic screen with the following columns: `Device Name`, `Channel Address`, `Link Address`, `Link Status`, `Poll Counter`, `SNRM Counter`.

If the HIA is correctly installed and the host operating system is correctly configured to support 3270 devices on the 5088, the entries in the Set Normal Response Mode (`SNRM Counter`) column will be increasing. If the entries in `SNRM Counter` are not increasing, refer to problem determination procedures for the HIA and verify that the host operating system is correctly configured.

Examples

To start the **panel20** command, enter:

```
panel20
```

By default, the **panel20** command will monitor HIA0. To monitor HIA1 or HIA2, enter:

```
panel20 HIA1
```

OR

```
panel20 HIA2
```

passwd Command

Purpose

Changes a user's password.

Syntax

passwd [**-R** *load_module*] [**-f** | **-s** **-a**] [*User*]

Description

The **passwd** command sets and changes passwords for users. Use this command to change your own password or another user's password. You can also use the **passwd** command to change the full name (gecos) associated with your login name and the shell you use as an interface to the operating system.

Depending on how the user is defined, the user's password can exist locally or remotely. Local passwords exist in the **/etc/security/passwd** database. Remote passwords are stored in the database provided by the remote domain.

To change your own password, enter the **passwd** command. The **passwd** command prompts the nonroot user for the old password (if one exists) and then prompts for the new password twice. (The password is never displayed on the screen.) If the two entries of the new password do not match, the **passwd** command prompts for the new password again.

Note: The **passwd** command uses only the first eight characters of your password for local and NIS passwords. Only 7-bit characters are supported in passwords. For this reason, globalization code points are not allowed in passwords. You can set a password of up to 255 characters.

To change another user's password, enter the **passwd** command and the user's login name (the *User* parameter). Only the root user or a member of the security group is permitted to change the password for another user. The **passwd** command prompts you for the old password of the user as well as the new password. For local passwords, the **passwd** command does not prompt the root user for either the old user password or the root password. For remote passwords, by default the root user will be prompted to input the old password so the remote domain can make the decision to use the password or ignore it. To change this behavior, see the **rootrequiresopw** option in the **/usr/lib/security/methods.cfg** file. The **passwd** command does not enforce any password restrictions upon the root user.

The **/etc/passwd** file records your full name and the path name of the shell that you use. To change your recorded name, enter the **passwd -f** command. To change your login shell, enter the **passwd -s** command.

Construct locally-defined passwords according to the password restrictions in the **/etc/security/user** configuration file. This file contains the following restrictions:

Item	Description
dictionlist	Specifies the list of dictionary files checked when a password is changed.
histexpire	Specifies the number of weeks that a user cannot reuse a password.
histsize	Specifies the number of previous passwords that the user cannot reuse.
maxage	Specifies the maximum age of a password. A password must be changed after a specified amount of time measured in weeks.

Item	Description
maxexpired	Specifies the maximum number of weeks beyond the `maxage` value that a password can be changed by the user.
maxrepeats	Specifies the maximum number of times a single character can be used in a password.
minalpha	Specifies the minimum number of alphabetic characters.
minother	Specifies the minimum number of other characters.
minlen	Specifies the minimum number of characters. **Note:** This value is determined by either the `minalpha` value plus the `minother` value or the `minlen` value, whichever is greater.
mindiff	Specifies the minimum number of characters in the new password that are not in the old password. **Note:** This restriction does not consider position. If the new password is `abcd` and the old password is `edcb`, the number of different characters is `1`.
minage	Specifies the minimum age at which a password can be changed. Passwords must be kept for a minimum period. This value is measured in weeks.
minloweralpha	Specifies the minimum number of lower case alphabetic characters.
minupperalpha	Specifies the minimum number of upper case alphabetic characters.
mindigit	Specifies the minimum number of digits.
minspecialchar	Specifies the minimum number of special characters.
pwdchecks	Specifies the list of external password restriction methods invoked when a password is changed.

If the root user adds the **NOCHECK** attribute to your flags entry in the **/etc/security/passwd** file, your password does not need to meet these restrictions. Also, the root user can assign new passwords to other users without following the password restrictions.

If the root user adds the **ADMIN** attribute to your flags entry or if the **password** field in the **/etc/passwd** file contains an * (asterisk), only the root user can change your password. The root user also has the exclusive privilege of changing your password if the **password** field in **/etc/passwd** contains an ! (exclamation point) and the **password** field in the **/etc/security/passwd** file contains an * (asterisk).

If the root user changes your password, the **ADMCHG** attribute is automatically added to your flags entry in the **/etc/security/passwd** file. In this case, you must change the password the next time you log in.

If the user's **registry** value in the **/etc/security/user** file is either DCE or NIS, the password change can only occur in the specified database.

The **passwd** command creates the user keystore, if the keystore does not exist and if the **efs_keystore_access** attribute value of the user is not **none**. The keystore is created with the Encrypted File System (EFS) attributes that are found in the **/etc/security/user** file. If the old password can open the keystore, it also changes the keystore password. That is to say, if the login and keystore passwords are same, then the **passwd** command changes both of the passwords. If the file system is an Encrypted File System (EFS), then the command performs as though the **-a** flag is specified. If you specify the **-a** flag, the result is that the EFS password is not synchronized with user login password after a password change. Therefore, the keystore is not be loaded automatically on next logins.

Flags

Item	Description
-a	Changes a user's password in all modules (compat, LDAP, NIS, and so on).

Item	Description
-f	Changes the user information accessed by the **finger** command. You can use this flag to provide your full name in the **/etc/passwd** file.
-s	Changes the login shell.
-R *load_module*	Specifies the loadable I&A module used to change a user's password.

Security

The **passwd** command is a PAM-enabled application with a service name of passwd. System-wide configuration to use PAM for authentication is set by modifying the value of the **auth_type** attribute, in the usw stanza of **/etc/security/login.cfg**, to PAM_AUTH as the root user.

The authentication mechanisms used when PAM is enabled depend on the configuration for the passwd service in **/etc/pam.conf**. The **passwd** command requires **/etc/pam.conf** entries for the password module type. Listed below is a recommended configuration in **/etc/pam.conf** for the passwd service:

```
#
# AIX passwd configuration
#

passwd password required /usr/lib/security/pam_aix
```

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To change your password, type:

   ```
   passwd
   ```

   The **passwd** command prompts you for your old password, if it exists and you are not the root user. After you enter the old password, the command prompts you twice for the new password.

2. To change your full name in the **/etc/passwd** file, type:

   ```
   passwd -f
   ```

   The **passwd** command displays the name stored for your user ID. For example, for login name sam, the **passwd** command could display this message:

   ```
   sam's current gecos:
                "Sam Smith"
   Change (yes) or no)? >
   ```

   If you type a Y for yes, the **passwd** command prompts you for the new name. The **passwd** command records the name you enter in the **/etc/passwd** file.

3. To use a different shell the next time you log in, type:

   ```
   passwd -s
   ```

   The **passwd** command lists the path names of the available shells and the shell you are currently using. The command also displays a prompt:

   ```
   Change (yes) or (no)? >
   ```

   If you type a Y for yes, the **passwd** command prompts you for the shell to use. The next time you log in, the system provides the shell that you specify here.

Files

Item	Description
/usr/bin/passwd	Contains the **passwd** command.
/etc/passwd	Contains user IDs, user names, home directories, login shell, and finger information.
/etc/security/passwd	Contains encrypted passwords and security information.

paste Command

Purpose

Joins the lines of different files.

Syntax

paste [**-s**] [**-d** *List*] *File1* ...

Description

The **paste** command reads input from the files specified on the command line. The command reads from standard input if a **-** (minus sign) appears as a file name. The command concatenates the corresponding lines of the given input files and writes the resulting lines to standard output.

By default, the **paste** command treats each file as a column and joins them horizontally with a tab character (parallel merging). You can think of the **paste** command as the counterpart of the **cat** command (which concatenates files vertically, that is, one file after another).

With the **-s** flag, the **paste** command combines subsequent lines of the same input file (serial merging). These lines are joined with the tab character by default.

Notes:

1. The **paste** command supports up to 32767 input files (the **OPEN_MAX** constant).
2. The action of the **pr -t -m** command is similar to that of the **paste** command, but creates extra spaces, tabs, and lines for a nice page layout.
3. Input files should be text files, but may contain an unlimited number of line lengths.

Flags

Item	Description
-d *List*	Changes the delimiter that separates corresponding lines in the output with one or more characters specified in the *List* parameter (the default is a tab). If more than one character is in the *List* parameter, then they are repeated in order until the end of the output. In parallel merging, the lines from the last file always end with a new-line character instead of one from the *List* parameter. The following special characters can also be used in the *List* parameter: **\n** New-line character **\t** Tab **** Backslash **\0** Empty string (not a null character) **c** An extended character You must put quotation marks around characters that have special meaning to the shell.
-s	Merges subsequent lines from the first file horizontally. With this flag, the **paste** command works through one entire file before starting on the next. When it finishes merging the lines in one file, it forces a new line and then merges the lines in the next input file, continuing in the same way through the remaining input files, one at a time. A tab separates the lines unless you use the **-d** flag. Regardless of the *List* parameter, the last character of the file is forced to be a new-line character.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To paste several columns of data together, enter:

```
paste names places dates > npd
```

This creates a file named npd that contains the data from the `names` file in one column, the `places` file in another, and the `dates` file in a third. If the `names`, `places`, and `dates` file look like:

```
names           places          dates
rachel          New York        February 5
jerry           Austin          March 13
mark            Chicago         June 21
marsha          Boca Raton      July 16
scott           Seattle         November 4
```

then the npd file contains:

```
rachel          New York        February 5
jerry           Austin          March 13
mark            Chicago         June 21
marsha          Boca Raton      July 16
scott           Seattle         November 4
```

A tab character separates the name, place, and date on each line. These columns do not always line up because the tab stops are set at every eighth column.

2. To separate the columns with a character other than a tab, enter:

```
paste  -d"!@" names places dates > npd
```

This alternates ! and @ as the column separators. If the `names`, `places`, and `dates` files are the same as in example 1, then the npd file contains:

```
rachel!New York@February 5
jerry!Austin@March 13
mark!Chicago@June 21
marsha!Boca Raton@July 16
scott!Seattle@November 4
```

3. To display the standard input in multiple columns, enter:

```
ls | paste - - - -
```

This lists the current directory in four columns. Each `-` (minus) tells the **paste** command to create a column containing data read from the standard input. The first line is put in the first column, the second line in the second column, and so on.

This is equivalent to:

```
ls | paste  -d"\t\t\t\n" -s -
```

This example fills the columns across the page with subsequent lines from the standard input. The `-d"\t\t\t\n"` defines the character to insert after each column: a tab character (`\t`) after the first three columns, and a new-line character (`\n`) after the fourth. Without the **-d** flag, the **paste -s -** command would display all of the input as one line with a tab character between each column.

Files

Item	Description
/usr/bin/paste	Contains the **paste** command.

patch Command

Purpose

Applies changes to files.

Syntax

patch [**-b** [**-B** *Prefix*]] [**-f**] [**-l**] [**-N**] [**-R**] [**-s**] [**-v**] [**-c** | **-e** | **-n** | **-u**] [**-d** *Directory*] [**-D** *Define*] [**-F** *Number*] [**-i** *PatchFile*] [**-o** *OutFile*] [**-p** *Number*] [**-r** *RejectFile*] [**-x** *Number*] [*File*]

Description

The **patch** command reads a source file's instructions on how to change a file, then applies the changes. The source file contains difference listings (or *diff* listings) produced by the **diff -c** or **-u** command, and one or more sets of **diff** command output, customarily called *hunks*.

The **patch** command skips any leading text in a patch file, applies the actual diff listing, and skips any trailing text. Thus, you could use as a patch file or message that includes a diff listing, and the **patch** command would still work. In such a case, if the entire diff listing is indented by a consistent amount, the **patch** command will also adjust for that spacing.

To change a line range within the original file, each hunk within a patch must be a separate diff listing. The line numbers for successive hunks within a patch must occur in ascending order.

File Name Determination

If no *File* parameter is specified, the **patch** command performs the following steps to obtain the name of the file to edit:

1. In the header of a context diff listing,
   - If the type of the diff is copied context, the file name is determined from lines beginning with *** (three asterisks) or —- (three dashes). A line beginning with *** indicates the name of the file from which the patches were taken, while a line beginning with —- indicates the name of the file to which the patches should be applied. The shortest name of an existing file is selected.
   - If the type of the diff is unified context, the file name is determined from lines beginning with --- (three dashes) or +++ (three pluses). A line beginning with --- indicates the name of the file from which the patches were taken, while a line beginning with +++ indicates the name of the file to which the patches should be applied. The shortest name of an existing file is selected.
2. If there is an `Index:` line in the leading text, the **patch** command tries to use the file name from that line.
3. A context diff header takes precedence over an `Index:` line.
4. If no file name can be determined from the leading text, the **patch** command prompts you for the name of the file to patch.
5. If the original file cannot be found, but a suitable SCCS or RCS file is available, the **patch** command attempts to get or check out the file.
6. If the leading text contains a `Prereq:` line, the **patch** command takes the first word from the prerequisites line (normally a version number) and checks the input file to see if that word can be found. If not, the **patch** command prompts you for confirmation before proceeding.

Patch Application

If the patch file contains more than one patch, the **patch** command tries to apply each diff listing as if it came from a separate patch file. In this case, the name of the file to patch is determined for each diff listing, and the header text before each diff listing is examined for information such as file name and revision level.

If you specify the **-c**, **-e**, **-n**, or **-u** flag, the **patch** command interprets information within each hunk as a copied context difference, an ed editor difference, a normal difference, or a unified context difference respectively. Otherwise, the **patch** command determines the type of difference based on the format of the information within the hunk.

The **patch** command searches for the place to apply each hunk by taking the first line number of the hunk and adding or subtracting any line offset caused by applying the previous hunk. If an exact match is not possible at this line location, the **patch** command scans both forward and backward for a set of lines matching the hunk's content exactly.

If no such place is found, and if the **patch** command is applying a context diff listing, the **patch** command can search for a less exact match. A *fuzz factor* specifies how many lines can be inexactly matched. If the fuzz factor is set to 1 or more, the **patch** command performs a second scan, this time ignoring the first and last line of context. If no match results, and the maximum fuzz factor is set to 2 or more, the **patch** command performs a third scan, this time ignoring the first two lines and the last two lines of the context. (The default maximum fuzz factor is 2.) If no match is found, the **patch** command places the hunk in a reject file. The reject file is created with the same name as the output file and the suffix **.rej**. This naming convention can be overridden by using the **-r** flag.

The rejected hunk is written in copied context diff listing form, regardless of the format of the patch file. If the input was a normal or ed editor style difference, the reject file may contain differences with zero lines of copied context format. The line numbers on the hunks in the reject file may be different from the line numbers in the patch file. This is because the reject file line numbers reflect the approximate locations for the failed hunks in the new file rather than the old one.

As each hunk is completed, the **patch** command tells you whether the hunk succeeded or failed. You are also informed of the new line number assumed for each hunk. If this is different from the line number specified in the diff listing, you are notified of the offset. The **patch** command also tells you if a fuzz factor was used to make the match.

> **Note:** A single large offset may be an indication that a hunk was installed in the wrong place. Use of a fuzz factor may also indicate bad placement.

Preparing Patches for Other Users

Programmers preparing patches that will be shipped to other users should consider the following additional guidelines:

- If you try to apply the same patch twice, the **patch** command assumes the second application should be a reverse patch and prompts you for confirmation of this reversal. Therefore, avoid sending out reversed patches, since this makes users wonder whether they already applied the patch.
- It is recommended that you keep a **patchlevel.h** file that is updated with the latest patch level. The patch level can then be used as the first diff listing in the patch file you send out. If your patch includes a `Prereq:` line, users cannot apply patches out of order without receiving a warning.
- Make sure you specify the file names correctly, either in a context diff listing header or with an `Index:` line. If you are patching something in a subdirectory, be sure to tell the patch user to specify a **-p** flag as needed.
- You can create a file by sending out a diff listing that compares a null file to the file you want to create. However, this only works if the file you want to create does not already exist in the target directory.
- While you may be able to put many diff listings into one file, it is advisable to group related patches into separate files.
- The **patch** command cannot tell if the line numbers are incorrect in an ed script, and can only detect bad line numbers in a normal diff listing when it finds a change or a delete command. A context diff listing using a fuzz factor of 3 may have the same line-number problem. Until a suitable interactive interface is added, use a context diff listing in such cases to check the changes for accuracy. Compilation without errors usually means that the patch worked, but it is not an infallible indicator.
- The results of the **patch** command are guaranteed only when the patch is applied to exactly the same version of the file from which the patch was generated.
- If the code has been duplicated, for example:

```
#ifdef
... NEWCODE
#else
... OLDCODE
# endif
```

  the **patch** command is incapable of patching both versions. If the **patch** command succeeds, it may have patched the wrong version and return a successful exit status.

Flags

Item	Description
-b	Saves a copy of each modified file before the differences are applied. The copied original is filed with the same name and the suffix **.orig**. If a file by that name already exists, it is overwritten. If multiple patches are applied to the same file, only one copy is made of the original file at the time of the first patch. If the **-o** *OutFile* flag is also specified, the **.orig** file is not created. But if the specified out file already exists, *OutFile***.orig** is created.
-B *Prefix*	Specifies a prefix to the backup file name. This flag only works in conjunction with the **-b** flag.
-c	Interprets the patch file as a copied context diff listing (the output of the **diff -c** or **diff -C** command). This flag cannot be used with the **-e**, **-n**, or **-u** flag.
-d *Directory*	Changes the current directory to the specified directory before processing.
-D *Define*	Marks changes with the following C preprocessor construct: `#ifdef Define` `...  (NEWCODE)` `#else` `...  (OLDCODE)` `#endif /* Define */` The *Define* variable is used as the differentiating symbol. This flag only works when the normal or context form of diff listing is used as a patch file.
-e	Interprets the patch file as an ed editor script. This flag cannot be used with the **-c**, **-n**, or **-u** flag.
-f	Suppresses queries to the user. To suppress commentary, use the **-s** flag.
-F *Number*	Sets the maximum fuzz factor. This flag applies to context diff listings only and causes the **patch** command to ignore the specified number of lines when determining where to install a hunk. If the **-F** flag is not specified, the default fuzz factor is 2. The factor may not be set to more than the number of lines of content in the context diff listing (ordinarily 3). **Note:** A larger fuzz factor increases the odds of a faulty patch.
-i *PatchFile*	Reads the patch information from the specified file, rather than from standard input.
-l	(lowercase L) Causes any sequence of blank characters in the diff listing script to match any sequence of blank characters in the input file. Other characters are matched exactly.
-n	Interprets the script as a normal diff listing. This flag cannot be used with the **-c**, **-e**, or **-u** flag.
-N	Ignores patches where the differences have already been applied to the file. By default, already-applied patches are rejected.
-o *OutFile*	Copies the files to be patched, applies the changes, then writes the modified version to the specified output file. Multiple patches for a single file are applied to the intermediate versions of the file created by any previous patches. Therefore, multiple patches result in multiple, concatenated versions of the output file.

Item	Description
-p *Number*	Sets the path name strip count, which controls how path names found in the patch file are treated. This flag is useful if you keep your files in a directory different from the specified path. The strip count specifies how many slashes are stripped from the front of the path name. Any intervening directory names are also stripped. For example, assume a patch file specified `/u/leon/src/blurf1/blurf1.c`: • **-p 0** leaves the entire path name unmodified. • **-p 1** removes the leading slash, leaving `u/leon/src/blurf1/blurf1.c`. • **-p 4** removes four slashes and three directories, leaving `blurf1/blurf1.c`. If the **-p** flag is not specified, only the base name (the final path name component) is used. This flag works only when the *File* parameter is not specified.
-r *RejectFile*	Overrides the default reject file name. The default reject file name is formed by appending the suffix **.rej** to the original file name.
-R	Reverses the sense of the patch script. For example, if the diff listing was created from new version to old version, using the **-R** flag causes the **patch** command to reverse each portion of the script before applying it. Rejected differences are saved in swapped format. The **-R** flag cannot be used with ed scripts, because there is too little information to reconstruct the reverse operation. If the **-R** flag is not specified, the **patch** command attempts to apply each portion in its reversed sense as well as in its normal sense, until a portion of the patch file is successfully applied. If the attempt is successful, the user is prompted to determine if the **-R** flag should be set. **Note:** This method cannot detect a reversed patch if used with a normal diff listing where the first command is an append (that is, would have been a delete). Appends always succeed because a null context matches anywhere. Fortunately, most patches add or change lines rather than delete lines. Therefore most reversed normal diff listings begin with a delete, causing a failure and triggering heuristics.
-s	Patches silently unless an error occurs.
-u	Interprets the patch file as a unified context difference (the output of the **diff** command when you specify the **-u** or **-U** flag). You cannot specify this flag with the **-c**, **-e**, or **-n** flag.
-v	Prints the revision header and patch level. If the **-v** flag is used with other flags, the other flags are ignored.
-x *Number*	Sets internal debugging flags. This flag is only for **patch** command developers.

Exit Status

The following exit values are returned:

Item	Description
0	Successful completion.
1	An error occurred and one or more lines are written to the rejected file.
>1	An error occurred.

Examples

1. To apply diff listings in the `difflisting` file to the `prog.c` file, enter:

   ```
   patch -i difflisting prog.c
   ```

2. To save the original version of the `prog.c` file, enter:

   ```
   patch -b -i difflisting prog.c
   ```

   This applies changes to `prog.c` and saves the original contents of `prog.c` in the file `prog.c.orig`.

3. To patch the `prog.c` file without altering the original version, enter:

   ```
   patch -i difflisting -o prog.new prog.c
   ```

   This uses `prog.c` as a source file, but the changed version is written to a file named `prog.new`.

Files

Item	Description
/usr/bin/patch	Contains the **patch** command.

pathchk Command

Purpose

Checks path names.

Syntax

pathchk [-p] [-P] *pathname...*

Description

The **pathchk** command checks that one or more path names are valid and portable. By default, the **pathchk** command checks each component of each path name specified by the *pathname* parameter based on the underlying file system. An error message is sent for each path name that meets the following criteria:

- The byte length of the full path name is longer than allowed by the system.
- The byte length of a component is longer than allowed by the system.
- Search permission is not allowed for a component.
- A character in any component is not valid in its containing directory.

It is not an error if one or more components of a path name do not exist. If a file that matches the path name specified by the *pathname* parameter can be created and it must not violate any of the above criteria.

More extensive portability checks are run when the `-p` flag is specified.

Flags

Item	Description
`-p`	Checks the path name based on POSIX portability standards. An error message is sent for each path name that meets the following criteria: • The byte length of the full path name is longer than allowed by POSIX standards. • The byte length of a component is longer than allowed by POSIX standards. • A character in any component is not in the portable file name character set.
`-P`	Checks the *pathname* operand and returns an error message if the *pathname* operand meets the following criteria: • The *pathname* operand contains a component whose first character is the hyphen character. • The *pathname* operands are empty.

Exit Status

This command returns the following exit values:

Item	Description
`0`	All *pathname* operands passed all of the checks.
`>0`	An error occurred.

Examples

1. To check the validity and portability of the `/home/bob/work/tempfiles` path name on your system, enter:

```
pathchk /home/bob/work/tempfiles
```

2. To check the validity and portability of the `/home/bob/temp` path name for POSIX standards, enter:

```
pathchk -p /home/bob/temp
```

Files

Item	Description
`/usr/bin/pathchk`	Contains the **pathchk** command.

pax Command

Purpose

Extracts, writes, and lists members of archive files; copies files and directory hierarchies.

Syntax

To List Member Files of Archived Files

pax [**-c** | **-n**] [**-d**] [-U] [**-v**] [**-H** | **-L**] [**-f** *Archive*] [**-s** *ReplacementString*...] [**-x** *Format*] [**-o** *Options*] [**-Z**] [*Pattern*...]

To Extract Archive Files Using the -r Flag

pax -r [**-c** | **-n**] [**-d**] [**-i**] [**-k**] [-U] [**-u**] [**-v**] [**-H** | **-L**] [**-f** *Archive*] [**-o** *Options*] [**-p** *String*...] [**-s** *ReplacementString*...] [**-x** *Format*] [**-Z**] [*Pattern* ...]

To Write Archive Files Using the -w Flag

pax -w [**-d**] [**-i**] [**-t**] [-U] [**-u**] [**-v**] [**-X**] [**-H** | **-L**] [**-E**] [**-b** *Blocking*] [[**-a**] **-f** *Archive*] [**-o** *Options*] [**-s** *ReplacementString*...] [**-x** *Format*] [**-Z**] [*File*...]

To Copy Files Using the -r and -w Flags

pax -r -w [**-d**] [**-i**] [**-k**] [**-l**] [**-t**] [-U] [**-u**] [**-v**] [**-X**] [**-H** | **-L**] [**-p** *String*...] [**-o** *Options*] [**-s** *ReplacementString*...] [**-x** *Format*] [**-Z**] [*File* ...] *Directory*

Description

pax stands for portable archive interchange. The **pax** command extracts and writes member files of archive files; writes lists of the member files of archives; and copies directory hierarchies. The **-r** and **-w** flags specify the type of archive operation.

Note: pax actively sparse files that are being restored. If a file blocks an aligned and sized areas that are NULL populated, **pax** does not cause physical space for those file system blocks to be allocated. The file size in bytes remains the same, but the actual space that is taken within the file system is for the non-NULL areas.

Listing Member Files of Archived Files (List Mode)

When the **-r** flag or the **-w** flag is not specified, the **pax** command lists all the member files of the archive file that is read from standard input. If the *Pattern* parameter is specified, only the member files with path names that match the specified patterns are written to standard output. If a named file is a directory, the file hierarchy that is contained in the directory is also written. When the **-r** flag or the **-w** flag is not specified, the **-c**, **-d**, **-f**, **-n**, **-s**, and **-v** flags, and the *Pattern* parameter can be specified.

Extracting Archive Files Using the -r Flag (Read Mode)

When the **-r** flag is specified, but the **-w** flag is not, the **pax** command extracts all the member files of the archive files that are read from standard input. If the *Pattern* parameter is specified, only the member files with path names that match the specified patterns are written to standard output. If a named file is a directory, the file hierarchy that is contained in the directory is also extracted. The **-r** flag can be specified with the **-c**, **-d**, **-f**, **-i**, **-k**, **-n**, **-s**, **-u**, and **-v** flags, and with the *Pattern* parameter.

The access and modification times of the extracted files are the same as the archived files. The file modes of the extracted files are the same as when they were archived, unless they are affected by the user's default file creation mode (**umask**). The **S_ISUID** and **S_ISGID** bits of the extracted files are cleared.

If intermediate directories are necessary to extract an archive member, the **pax** command creates the directories with access permissions set as the bitwise inclusive OR of the values of the **S_IRWXU**, **S_IRWXG**, and **S_IRWXO** masks.

If the selected archive format supports the specification of linked files, it is an error if these files cannot be linked when the archive is extracted.

Writing Archive Files Using the -w Flag (Write Mode)

When the **-w** flag is specified and the **-r** flag is not, the **pax** command writes the contents of the files that are specified by the *File* parameter to standard output in an archive format. If no *File* parameter is specified, a list of files to copy, one per line, is read from the standard input. When the *File* parameter specifies a directory, all of the files that are contained in the directory are written. The **-w** flag can be specified with the **-a**, **-b**, **-d**, **-f**, **-i**, **-o**, **-s**, **-t**, **-u**, **-v**, **-x**, and **-X** flags and with *File* parameters.

Copying Files Using the -r and -w Flags (Copy Mode)

When both the **-r** and **-w** flags are specified, the **pax** command copies the files that are specified by the *File* parameters to the destination directory specified by the *Directory* parameter. If no files are specified, a list of files to copy, one per line, is read from the standard input. If a specified file is a directory, the file hierarchy that is contained in the directory is also copied. The **-r** and **-w** flags can be specified with the

-d, **-i**, **-k**, **-l**, **-o**, **-p**, **-s**, **-t**, **-u**, **-v**, and **-X** flags and with *File* parameters. The *Directory* parameter must be specified.

Copied files are the same as written to an archive file and are later extracted, except that there are hard links between the original and the copied files.

Modifying the Archive Algorithm Using the -o Flag

Use the **-o** flag to modify the archive algorithm according to keyword-value pairs. The keyword-value pairs must adhere to a correct archive format. A list of valid keywords and their behavior is given in the subsequent description of the **-o** flag.

Further notes

In read or copy modes, if intermediate directories are necessary to extract an archive member, the **pax** command does actions similar to the **mkdir()** subroutine with the intermediate directory used as the path argument and the value **S_IRWXU** as the mode argument.

If any specified pattern or file operands are not matched by at least one file or archive member, **pax** writes a diagnostic message to standard error for each one that did not match and exits with an error status.

In traversing directories, the **pax** command detects the infinite loops by entering a previously visited directory that is an ancestor of the last file visited. Upon detection of an infinite loop, the **pax** command writes a diagnostic message to standard error and terminates.

When **pax** command is in read mode or list mode, by using the **-x pax** archive format, a file name, link name, owner name, or any other field in an extended header record cannot be converted from the **pax** UTF8 code set format to the current code set and locale. The **pax** command writes a diagnostic message to standard error, processes the file as described for the **-o invalid=** option, and then processes the next file in the archive.

For AIX 5.3 the pax command ignores the extended attributes by default. The -U option informs pax to archive or restore extended attributes, which include ACLs. The -pe option preserves ACLs. When the -pe option is specified and if pax fails to preserve the ACLs, a diagnostic message is written to the standard error but the extracted file is not deleted. A nonzero exit code is returned. A new record type is required for extended attribute entries in the pax archive files.

Variables

Item	Description
Directory	Specifies the path of a destination directory when copying files.
File	Specifies the path of a file to be copied or archived. If no file matches the *File* parameter, the **pax** command detects the error, exits, and writes a diagnostic message.
Pattern	Specifies a pattern that matches one or more paths of archive members. A / (backslash) character is not recognized in the *Pattern* parameter and it prevents the subsequent character from having any special meaning. If no *Pattern* parameter is specified, all members are selected in the archive. If a *Pattern* parameter is specified, but no archive members are found that match the pattern that is specified, the **pax** command detects the error, exits, and writes a diagnostic message.

Flags

Item	Description
-a	Appends files to the end of an archive. **Note:** Streaming tape devices do not allow the append function.

Item	Description
-b *Blocking*	Specifies the block size for output. The *Blocking* parameter specifies a positive decimal integer value that specifies the number of bytes per block. Application conforming to POSIX2 must not specify a blocksize value greater than 32256. Devices and archive formats might impose restrictions on blocking. Blocking is automatically determined on input. Default blocking when the archives are created depends on the archive format. (See the **-x** flag definition.) The *Blocking* parameter accepts one of the following values: ***Integer* b** Specifies that the block size, in bytes, be the value of the positive decimal integer that is specified by the *Integer* parameter that is multiplied by 512. ***Integer* k** Specifies that the block size, in bytes, be the value of the positive decimal integer that is specified by the *Integer* parameter that is multiplied by 1024. ***Integer* m** Specifies that the block size, in bytes, be the value of the positive decimal integer that is specified by the *Integer* parameter that is multiplied by 1024 x 1024. ***Integer+Integer*** Specifies that the block size, in bytes, be the sum of the positive decimal integers that are specified by the *Integer* parameters.
-c	Matches all file or archive members except the files that are specified by the *Pattern* parameter.
-d	Causes directories being copied, archived, or extracted, to match the directory and not the contents of the directory.
-E	Avoids truncation of the long user and group names during addition of files to a new or existing archive.
-f *Archive*	Specifies the path of an archive file to be used instead of standard input (when the **-w** flag is not specified) or standard output (when the **-w** flag is specified but the **-r** flag is not). When specified with the **-a** flag option, any files that are written to the archive are appended to the end of the archive.
-H	If a symbolic link that refers to a directory is specified on the command line, **pax** archives the file hierarchy that is rooted in the directory that is referenced in the link, by using the name of the link as the name of the file hierarchy. By default, **pax** archives the symbolic link itself.
-i	Renames files or archives interactively. For each archive member that matches the *Pattern* parameter or file that matches a *File* parameter, a prompt is written to the display device that contains the name of a file or archive member. A line is then read from the display device. If this line is empty, the file or archive member is skipped. If this line consists of a single period, the file or archive member is processed with no modification to its name. Otherwise, its name is replaced with the contents of the line.
-k	Prevents the **pax** command from writing over existing files.
-l	Links files when copying files. Hard links are established between the source and destination file hierarchies whenever possible.

Item	Description
-L	If a symbolic link that refers to a directory is specified on the command line or encountered during the traversal of a file hierarchy, **pax** archives the file hierarchy that is rooted in the directory that is referenced in the link, by using the name of the link as the name of the file hierarchy. By default, **pax** archives the symbolic link itself.
-n	Selects the first archive member that matches each *Pattern* parameter. No more than one archive member is matched for each pattern.

Item	Description
-o *Options*	Modifies the archiving algorithm according to the keyword-value pairs specified in the *Options* parameter. The keyword-value pairs must be in the following format: *keyword:=value,keyword:=value,...* Some keywords apply only to certain file formats, as indicated with each description. Use of keywords that are inapplicable to the file format being processed will be ignored by **pax**. Keywords can be preceded with white space. The *value* field consists of zero or more characters; within *value*, any literal comma must be preceded with a backslash (\). A comma as the final character, or a comma that is followed by white space as the final character, in *Options* is ignored. Multiple **-o** options can be specified. If keywords given to these multiple **-o** options conflict, the keywords and values that appear later in the command-line sequences take precedence. The earlier values are ignored. The following keyword-value pairs are supported for the indicated file formats: **datastream**=*pathname*,**datastr_size**=*size* (Applicable to all file formats.) The **datastream** keyword indicates that the incoming archive file is not in a file format; instead, it is a DataStream from the standard input device. Consequently, the data must be archived as a regular file in a format that is recognized by the **-x** flag. The file name of the DataStream must be specified in the *pathname* parameter and must include the identification of the person who invoked the command, the group identification, and the **umask** for the file mode. **Note:** The **datastream** keyword does not have a default variable size. You must specify one. The **datastr_size** keyword denotes the size of the DataStream input in bytes by using decimal digits. If the **pax** command reaches the end of file (EOF) character before it reads the *size* parameter, it pads the archive file with null values. The null values make the archive file the same size as specified by the *size* parameter. If the data in the archive file exceeds the size that is specified, the **pax** command truncates the archive file to the size specified by the *size* parameter. The **pax** command also stops taking input and closes the archive file. **Note:** You can specify multiple instances of keyword pairs. If you assign different values to the same keyword, the **pax** command uses the last value that is assigned to the keyword to run the **-o** flag. **delete**=*pattern* (Applicable only to the **-x pax** format.) When used in write or copy mode, **pax** omits any keywords matching *pattern* from the extended header records that it produces. When used in read or list mode, **pax** ignores any keywords matching *pattern* in the extended header records. In all cases, matching is done using standard shell pattern-matching notation. For example, `-o delete=security.*` suppresses security-related information.

Item	Description
-o *Options (Continued)*	

exthdr.name=*string* (Applicable only to the **-x pax** format.)

This keyword allows user control over the name written into the **ustar** header blocks for the extended header records. The name is the contents of *string* after the following character substitutions have been made:

***string* includes:**
Replaced by:

%d
The directory name of the file, equivalent to the result of the **dirname** utility on the transformed path name

%f
The filename of the file, equivalent to the result of the **basename** utility on the transformed path name

%%
A %% character

Any other % characters in *string* produce undefined results. If this keyword-value pair is not specified in the **-o** *Options* list, the default value of the name is:

%d/PaxHeaders/%f

globexthdr.name=*string* (Applicable only to the **-x pax** format.)

When used in write or copy mode with the appropriate options, **pax** creates global extended header records with **ustar** header blocks that will be treated as regular files by previous versions of **pax**. This keyword allows user control over the name that is written into the **ustar** header blocks for global extended header records. The name is the contents of *string* after the following character substitutions have been made:

***string* includes:**
Replaced by:

%n
An integer that represents the sequence number of the global extended header record in the archive starting at 1

%%
A % character

Any other % characters in *string* produce undefined results. If this keyword-value pair is not specified in the **-o** *Options* list, the default value of the name is

$TMPDIR/GlobalHead.%n

where **$TMPDIR** is either the value of the **TMPDIR** environment variable or **/tmp** if **TMPDIR** is unset.

invalid=*action* (Applicable only to the **-x pax** format.)

This keyword allows user control over the action **pax** takes upon encountering values in an extended header record that:

- in read or copy mode, are invalid in the destination hierarchy, or
- in list mode, cannot be written in the code set and current locale.

Item	Description
-o *Options (Continued)*	**pax** recognizes these invalid values: • In read or copy mode, a file name or link name that contains character encodings invalid in the destination hierarchy. (For example, the name may contain embedded NULLs.) • In read or copy mode, a file name or link name that is longer than the maximum allowed in the destination hierarchy (for either a path name component or the entire path name). • In list mode, any character string value (file name, link name, username, and so on) that cannot be written in the code set and current locale. These mutually exclusive values of the *action* argument are supported: • **bypass** In read or copy mode, **pax** bypasses the file, causing no change to the destination hierarchy. In list mode, **pax** writes all requested valid values for the file, but its method for writing invalid values is unspecified. • **rename** In read or copy mode, **pax** acts as if the **-i** flag is in effect for each file with invalid file name or link name values, allowing the user to provide a replacement name interactively. In list mode, **pax** behaves identically to the **bypass** action. • **UTF8** When used in read, copy, or list mode and a file name, link name, owner name, or any other field in an extended header record cannot be translated from the **pax UTF8** code set format to the current code set and locale, **pax** uses the actual UTF8 encoding for the name. • **write** In read or copy mode, **pax** writes the file, translating or truncating the name, regardless of whether this may overwrite an existing file with a valid name. In list mode, **pax** behaves identically to the **bypass** action. If no **-o invalid=***action* is specified, **pax** acts as if the **bypass** action is specified. Any overwriting of existing files that may be allowed by the **-o invalid=***actions* is subject to permission (**-p**) and modification time (**-u**) restrictions, and is suppressed if the **-k** flag is also specified. **linkdata** (Applicable only to the **-x pax** format.) In write mode, the **pax** command writes the contents of a file to the archive, even when that file is a hard link to a file whose contents are written to the archive.

Item	Description
-o *Options (Continued)*	**listopt**=*format* (Applicable to all file formats.) This keyword specifies the output format of the table of contents that are produced when the **-v** option is specified in list mode. To avoid ambiguity, this keyword-value pair must be used as the only or final keyword-value pair following the **-o** flag; all characters in the remainder of the option-argument are considered part of the format string. If multiple **-o listopt=format** options are specified, the format strings are considered to be a single, concatenated string, evaluated in command-line order. See the **List-Mode Format Specifications** section for more information. **times** (Applicable only to the **-x pax** format.) When used in write or copy mode, **pax** includes atime, ctime, and mtime extended header records for each file.

Extended header keywords

(Applicable only to the **-x pax** format.)

If the **-x pax** format is specified, the keywords and values that are defined in the list below can be used as parameters to the **-o** flag, in either of two modes:

keyword=value

When used in write or copy mode, these keyword-value pairs are written into the global extended header records of the new archive. When used in read or list mode, these keyword-value pairs act as if they were present in the global extended header records of the archive that is being read. In both cases, the given value is applied to all files that do not have a value that is assigned in their individual extended header records for the specified keyword.

*keyword***:=***value*

When used in write or copy mode, these keyword-value pairs are written into the extended header records of each file in the new archive. When used in read or list mode, these keyword-value pairs act as if they were present in the extended header records of each file in the archive that is being read. In both cases, the given value overrides any value for the specified keyword that is found in global or file-specific extended header records.

atime

The file access time for the following files, equivalent to the value of the st_atime member of the stat structure for a file.

charset

The name of the character set to encode the data in the following files. The entries in this table are defined to refer to known standards:

value	**Formal Standard**
"ISO-IR 646 1990"	ISO/IEC 646 IRV
"ISO-IR 8859 1 1987"	ISO 8859-1
"ISO-IR 8859 2 1987"	ISO 8859-2
"ISO-IR 10646 1993"	ISO/IEC 10646
"ISO-IR 10646 1993 UTF8"	ISO/IEC 10646, UTF8 encoding
"BINARY"	None

The encoding is included in an extended header for information only; when **pax** is used as described, it does not translate the file data into any other encoding. The BINARY entry indicates binary data that is not encoded.

comment

A series of characters used as a comment. All characters in the value field are ignored by **pax**.

ctime

The file creation time for the following file(s), equivalent to the value of the st_ctime member of the stat structure for a file.

gid

The group ID of the group that owns the file, expressed as a decimal number by using digits from ISO/IEC 646. This record overrides the *gid* field in the following header block(s). When used in write or copy mode, **pax** includes a gid extended header record for each file whose group ID is greater than 99,999,999.

gname

The group of the following file(s), formatted as a group name in the group database. This record overrides the *gid* and *gname* fields in the following header blocks, and any *gid* extended header record. When used in read, copy, or list mode, **pax** translates the name from the UTF8 encoding in the header record to the character set appropriate for the group database on the receiving system. If any of the UTF8 characters cannot be translated, and if the **-o invalid=UTF8** option is not specified, the results are undefined. When used in write or copy mode, **pax** includes a gname extended header record for each file whose group name cannot be represented entirely with the letters and digits of the portable character set.

hdrcharset

The name of the character set that is used to encode the value field of the `gname`, `linkpath`, `path`, and `uname` extended header records. The entries in the following table are defined to refer to the known standards. Additional names might be agreed between the originator and the recipient.

value	**Formal Standard**
ISO-IR106462000UTF-8	ISO/IEC 10646, UTF-8 encoding
BINARY	None

If the `hdrcharset` extended header record is not specified, the default character set (ISO/IEC 10646-1:2000 standard UTF-8 encoding) is used to encode all values in the extended header records.

The **BINARY** entry indicates that all the values that are recorded in the extended headers for affected files are unencoded binary data from the underlying system.

linkpath

The path name of a link that is created to another file, of any type, previously archived. This record overrides the *linkname* field in the following **ustar** header block(s).

The following **ustar** header block determines the type of link that is created, whether hard or symbolic. In the latter case, the linkpath value is the contents of the symbolic link. **pax** translates the name of the link (contents of the symbolic link) from the UTF8 encoding to the character set appropriate for the local file system.

When used in write or copy mode, **pax** includes a link path extended header record for each link whose path name cannot be represented entirely with the members of the portable character set other than NULL.

mtime

The file modification time of the following file(s), equivalent to the value of the st_mtime member of the stat structure for a file. This record overrides the *mtime* field in the following header block(s). The modification time is restored if the process has the appropriate privilege to do so.

path

The pathname of the following file(s). This record overrides the *name* and *prefix* fields in the following header block(s). **pax** translates the path name of the file from the UTF8 encoding to the character set appropriate for the local file system. When used in write or copy mode, **pax** includes a path extended header record for each file whose path name cannot be represented entirely with the members of the portable character set other than NULL.

realtime.*any*

The keywords that are prefixed by real time are reserved for future POSIX real-time standardization. **pax** recognizes but silently ignores them.

security.*any*

The keywords that are prefixed by security are reserved for future POSIX security standardization. **pax** recognizes but silently ignores them.

size

The size of the file in octets, expressed as a decimal number using digits from ISO/IEC 646. This record overrides the *size* field in the following header block(s). When used in write or copy mode, **pax** includes a size of extended header record for each file with a size value greater than 999,999,999,999.

uid

The user ID of the user that owns the file, expressed as a decimal number using digits from ISO/IEC 646.. This record overrides the *uid* field in the following header block(s). When used in write or copy mode, **pax** includes a uid extended header record for each file whose owner ID is greater than 99,999,999.

uname

The owner of the following file(s), formatted as a user name in the user database. This record overrides the *uid* and *uname* fields in the following header block(s), and any *uid* extended header record. When used in read, copy, or list mode, **pax** translates the name from the UTF8 encoding in the header record to the character set appropriate for the user database on the receiving system. If any of the UTF8 characters cannot be translated, and if the **-o invalid=UTF8** option is not specified, the results are undefined. When used in write or copy mode, **pax** includes a uname extended header record for each file whose user name cannot be represented entirely with the letters and digits of the portable character set.

If the *value* field is zero length, it deletes any header block field, previously entered extended header value, or global extended header value of the same name.

If a keyword in an extended header record (or in a **-o** option-argument) overrides or deletes a corresponding field in the **ustar** header block, **pax** ignores the contents of that header block field.

Extended header keyword precedence

(Applicable only to the **-x pax** format.)

This section describes the precedence in which the various header records and fields and command-line options are selected to apply to a file in the archive. When **pax** is used in read or list modes, it determines a file attribute in this sequence:

1. If **-o delete**=*keyword-prefix* is used, the affected attribute is determined from step (7) if applicable, or ignored otherwise.
2. If **-o keyword**:=NULL is used, the affected attribute is ignored.
3. If **-o keyword**:=*value* is used, the affected attribute is assigned the value.
4. If *value* exists in a file-specific extended header record, the affected attribute is assigned the value. When extended header records conflict, the last one given in the header takes precedence.
5. If **-o keyword**=*value* is used, the affected attribute is assigned the value.
6. If a value exists in a global extended header record, the affected attribute is assigned the value. When global extended header records conflict, the last one given in the global header takes precedence.
7. Otherwise, the attribute is determined from the **ustar** header block.

Item	Description
-p *String*	Specifies one or more file characteristics to be retained or discarded on extraction. The *String* parameter consists of the characters **a**, **e**, **m**, **o**, and **p**. Multiple characteristics can be concatenated within the same string and multiple **-p** flags can be specified. The specifications have the following meanings: **a** Does not retain file-access times. **e** Retains the user ID, group ID, file mode, access time, modification time, and ACLs. **m** Does not retain file-modification times. **o** Retains the user ID and the group ID. **p** Retains the file modes. If neither the **-e** nor the **-o** flag is specified, or the user ID and group ID are not preserved for any reason, the **pax** command does not set the **S_ISUID** and **S_ISGID** bits of the file mode. If the retention of any of these items fails, the **pax** command writes a diagnostic message to standard error. Failure to retain any of the items affects the exit status, but does not cause the extracted file to be deleted. If specification flags are duplicated or conflict with each other, the last flag that is specified takes precedence. For example, if `-p eme` is specified, file-modification times are retained.
-r	Reads an archive file from the standard input.
-s *ReplacementString*	Modifies file or archive-member names that are specified by the *Pattern* or *File* parameters according to the substitution expression *ReplacementString*, by using the syntax of the **ed** command. The substitution expression has the following format: **-s /*old*/*new*/[gp]** where (as in the **ed** command), *old* is a basic regular expression and *new* can contain an **&** (ampersand), **n* (**n** is a digit) back references, or subexpression matching. The *old* string can also contain new-line characters. Any non-null character can be used as a delimiter (the / (backslash) is the delimiter in the example). Multiple **-s** flag expressions can be specified; the expressions are applied in the order specified, terminating with the first successful substitution. The optional trailing g character performs as in the **ed** command. The optional trailing p character causes successful substitutions to be written to standard error. File or archive-member names that substitute to the empty string are ignored when reading and writing archives.
-t	Causes the access times of input files to be the same as they were before being read by the **pax** command.

Item	Description
-U	Performs archival and extraction of ACL and Extended Attributes. Attributes include Access control list (ACL) also. If the ACL type is not supported on the *Target* filesystem then it is converted to the ACL type supported by the *Target* filesystem. If the EA is not supported on the filesystem then it is not copied. When listing members of the archive this option will list the names of any named extended attributes and the type of any ACLs associated with each file that are part of the archive image.
-u	Ignores files that are older than a preexisting file or archive member with the same name. • When extracting files, an archive member with the same name as a file in the file system is extracted if the archive member is newer than the file. • When writing files to an archive file, an archive member with the same name as a file in the file system is superseded if the file is newer than the archive member. If the **-a** flag is specified this is accomplished by appending to the archive. Otherwise it is unspecified if this is accomplished by actual replacement in the archive or by appending to the archive. • When copying files to a destination directory, the file in the destination hierarchy is replaced by the file in the source hierarchy or by a link to the file in the source hierarchy if the file in the source hierarchy is newer.
-v	Writes information about the process. If neither the **-r** or **-w** flags are specified, the **-v** flag produces a verbose table of contents; otherwise, archive member path names are written to standard error.
-w	Writes files to the standard output in the specified archive format.

Item	Description
-x *Format*	Specifies the output archive format with the default format being **ustar**. The **pax** command recognizes the following formats: **pax** The **pax** interchange format. The default blocking value for this format for character-special archive files is 10240. Blocking values of 512 - 32256 in increments of 512 are supported. **cpio** Extended **cpio** interchange format. The default blocking value for this format for character-special archive files is 5120. Blocking values of 512 -32256 in increments of 512 are supported. **ustar** Extended **tar** interchange format. The default blocking value for this format for character-special archive files is 10240. Blocking values of 512 -32256 in increments of 512 are supported. • **Filename**: The **pax** command supports the length of the path and the file name until the PATH_MAX limit that is defined by the system is reached. If the length of the path and the file name input exceeds the PATH_MAX limit, then the values are not archived. • **gid or uid**: The **pax** command supports the values of gid and uid until the UINTMAX limit is reached. Values greater than the UINTMAX limit are truncated. If you attempt to append an archive file with a format that is different from the existing archive format causes the **pax** command to exit immediately with a nonzero exit status. In copy mode, if no **-x** format is specified, **pax** behaves as if **-x pax** were specified.
-X	When traversing the file hierarchy specified by a pathname, the **pax** command does not descend into directories that have a different device ID.
-Z	Archives the Encrypted File System (EFS) information of encrypted files or directories. The EFS information is extracted by default. When members of the archive are listed, an **e** indicator is displayed after the file mode for encrypted files and directories that were archived with the **-Z** flag, and a hyphen (-) is displayed for other files. **Note:** Archives created with the **-Z** flag can be restored only on AIX 6.1 or later releases.

Flag Interaction and Processing Order

The flags that operate on the names of files or archive members (**-c**, **-i**, **-n**, **-s**, **-u**, and **-v**) interact as follows:

- When extracting files, archive members are selected according to the user-specified *pattern* parameters as modified by the **-c**, **-n**, and **-u** flags. Then, any **-s**, and **-i** flags modify, in that order, the names of the selected files. The **-v** flag writes the names resulting from these modifications.
- When writing files to an archive file, or when copying files, the files are selected according to the user-specified pathnames as modified by the **-n** (this option is not valid for Copy Mode) and **-u** flags. Then, any **-s**, and **-i** flags modify, in that order, the names resulting from these modifications. The **-v** flag writes the names resulting from the modification.

- If both the **-u** and **-n** flags are specified, the **pax** command does not consider a file selected unless it is newer than the file to which it is compared.

List Mode Format Specifications

In list mode with the **-o listopt=***format* option, the format argument is applied for each selected file. **pax** appends a newline character to the **listopt** output for each selected file. The format argument is used as the format string described in **printf()**, with the following exceptions:

1. The sequence *keyword* can occur before a format conversion specifier. The conversion argument is defined by the value of *keyword*. The following keywords are supported:
   - Any of the field name entries for **ustar** and **cpio** header blocks.
   - Any keyword defined for the extended header or provided as an extension within the extended header.

   For example, the sequence `%(charset)s` is the string value of the name of the character set in the extended header.

   The result of the keyword conversion argument is the value from the applicable header field or extended header, without any trailing NULLs.

   All keyword-values used as conversion arguments are translated from the UTF8 encoding to the character set appropriate for the local file system, user database, etc., as applicable.
2. An additional conversion character, **T**, specifies time formats. The **T** conversion character can be preceded by the sequence *keyword=subformat*, where *subformat* is a date format allowed by the **date** command. The default keyword is **mtime** and the default subformat is: %b %e %H:%M %Y.
3. An additional conversion character, **M**, specifies the file mode string as displayed by the **ls -l** command. If *keyword* is omitted, the **mode** keyword is used. For example, %.1M writes the single character corresponding to the *entry type* field of the **ls -l** command.
4. An additional conversion character, **D**, specifies the device for block or special files, if applicable. If not applicable and *keyword* is specified, then this conversion is equivalent to %*keyword* u. If not applicable and *keyword* is omitted, this conversion is equivalent to <space>.
5. An additional conversion character, **F**, specifies a pathname. The **F** conversion character can be preceded by a sequence of comma-separated keywords:

   keyword,keyword...

   The values for all the non-null keywords are concatenated together, each separated by a /. The default is *path* if the keyword path is defined; otherwise, the default is *prefix,name*.
6. An additional conversion character, **L**, specifies a symbolic link expansion. If the current file is a symbolic link, then %L expands to:

   "%s -> %s", *value_of_keyword*, *contents_of_link*

   Otherwise, the %L conversion character is equivalent to %F.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To copy the `olddir` directory hierarchy to `newdir`, enter:

   ```
   mkdir newdir
   ```

   ```
   pax -rw olddir newdir
   ```

2. To copy the contents of the current directory to the tape drive, enter:

   ```
   pax -wf /dev/rmt0
   ```

3. To archive the file `xxx` as XXX and display the successful substitution, enter one of the following commands:

   - ```
     pax -wvf/dev/rfd0 -s /xxx/XXX/p xxx
     ```
   - ```
     pax -wvf/dev/rfd0 -s/x/X/gp xxx
     ```

4. To read a file from a standard input and dump it to a datastream file with a specified size, enter:

   ```
   dd if=/dev/hd6 bs=36b count=480 | pax -wf /dev/rfd0 -o
   datastream=_filename_,datastr_size=_size_
   ```

5. To list the files in an archive `pax.ar` in a specified format, enter:

   ```
   pax -v -o listopt="start %F end" -f pax.ar
   ```

6. To create an archive `pax.ar` in `pax` format, enter :

   ```
   pax -wf pax.ar -x pax file1
   ```

7. To extract a file from an archive `pax.ar` in `pax` format with a new path, enter :

   ```
   pax -rvf pax.ar -x pax -o path=newfilename
   ```

8. To copy the contents of a symbolic link from source to destination, enter:

   ```
   pax -rwL srclink destdir
   ```

9. To extract files from the archive with group name as `bin`, enter:

   ```
   pax -rvf pax.ar -x pax -o gname=bin
   ```

10. To ignore the path name from the archive in `pax` format during extraction, enter:

    ```
    pax -rvf pax.ar -o delete=path
    ```

11. To avoid the truncation of long user and group names while creating the archive, enter:

    ```
    pax -wEf file.pax file
    ```

12. To copy the `olddir` directory hierarchy to `newdir` with ACL and EA associated with the files, enter:

    ```
    mkdir newdir
    pax -rUw olddir newdir
    ```

Files

Item	Description
/usr/bin/pax	Contains the **pax** command.

pcat Command

Purpose

Unpacks files and writes them to standard output.

Syntax

pcat *File* ...

Description

The **pcat** command reads the files designated by the *File* parameter, unpacks them, and writes them to standard output. Whether or not the specified file ends in the **.z** characters, the **pcat** command assumes that the file is packed and unpacks it.

The exit value of the **pcat** command is the number of files it was unable to unpack. A file cannot be unpacked if any of the following occurs:

- The file name (exclusive of **.z**) has more than 253 bytes.
- The file cannot be opened.
- The file is not a packed file.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To display compressed files, enter:

   ```
   pcat chap1.z chap2 | pg
   ```

   This command sequence displays the compressed files `chap1.z` and `chap2.z` on the screen in expanded form, a page at a time (`| pg`). Note that the **pcat** command accepts files with and without the `.z` characters.

2. To use a compressed file without expanding the copy stored on disk, enter:

   ```
   pcat chap1.z | grep 'Greece'
   ```

   This command sequence prevents the **pcat** command from displaying the contents of `chap1.z` in its expanded form and pipes it to the **grep** command.

File

Item	Description
/usr/bin/pcat	Contains the **pcat** command.

pdelay Command

Purpose

Enables or reports the availability of delayed login ports.

Syntax

pdelay [**-a**] [*Device*]

Description

The **pdelay** command enables delayed ports. Delayed ports are enabled like shared ports, except that the login herald is not displayed until you type one or more characters (usually carriage returns). If a port is directly connected to a remote system or connected to an intelligent modem, it is enabled as a delayed port to prevent the **getty** command from talking to a **getty** on the remote side or to the modem on a local connection. This action conserves system resources and is equivalent to **pdelay enabled=delay**. If you do not specify a *Device* parameter, the **pdelay** command reports the names of the currently enabled ports.

Use the *Device* parameter to specify the ports to be enabled. Permitted values include:

- Full device name, such as the **/dev/tty1** device
- Simple device name, such as the **tty1** device
- A number (for example, 1 to indicate the **/dev/tty1** device)

Note: You must have root user authority to run this command.

Flags

Item	Description
-a	Enables all ports as delayed.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Example

To display the names of the delayed ports that are currently enabled, enter:

```
pdelay
```

Files

Item	Description
/etc/locks	Contains **lock** files for the **pshare** and **pdelay** commands.

Item	Description
/usr/sbin/pdelay	Contains the **pdelay** command.

pdisable Command

Purpose

Disables login ports.

Syntax

pdisable [**-a**] [*Device*]

Description

The **pdisable** command disables a specific port, even if a user is logged in at that port. The system disables a port by updating an entry in the **/etc/inittab** file and then sending a signal to the **init** process**.** When the **init** process receives the signal and reads the updated status entry, it takes the appropriate action.

Use the *Device* parameter to specify the ports to be disabled. Permitted values include:

- A full device name, such as the **/dev/tty1** device
- A simple device name, such as the **tty1** device
- A number (for example, 1 to indicate the **/dev/tty1** device).

If you do not specify a *Device* parameter, the **pdisable** command reports the names of currently disabled ports in its set.

Note: You must have root user authority to run this command.

Flag

Item	Description
-a	Disables all ports that are currently enabled.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To display the names of all ports currently disabled, enter:

   ```
   pdisable
   ```

2. To disable all ports that are enabled, even if users are logged in, enter:

   ```
   pdisable -a
   ```

3. To disable the workstation attached to the **/dev/tty8** port, enter:

   ```
   pdisable tty8
   ```

Files

Item	Description
/etc/locks	Contains **lock** files for the **pshare** and **delay** commands.
/usr/sbin/pdisable	Contains the **pdisable** command.

pdlink Command

Purpose

Links files in partitioned sub directories.

Syntax

pdlink *dirname filename ...*

Description

The **pdlink** command allows you to make a file that exists under a partitioned subdirectory accessible to the processes running at different SLs. The file corresponds to the sensitivity label (SL) of the invoking process. The directory name that you specify using the *dirname* parameter must a partitioned directory, and the file name that you specify using the *filename* parameter must be a file name (not a path name) under that named directory. You can specify multiple file names.

The **pdlink** command creates a hard link to the file specified, with the following qualifications:

- The link is only created in the partitioned subdirectories.
- Each partitioned subdirectory must exist at the time the **pdlink** command is running.
- The link is only created in partitioned subdirectories that have an SL that is higher than the minimum SL of the file specified by the *filename* parameter.

Security

Only authorized users can run the **pdlink** command.

Item	Description
aix.mls.pdir.link	Required to create links in partitioned sub directories with this command.

Exit Status

The **pdlink** command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To create a link of the **sample.c** file, present in the partitioned directory called **partdir**, enter:

```
pdlink partdir sample.c
```

Files

Item	Description
/usr/sbin/pdlink	Contains the **pdlink** command.

pdmkdir Command

Purpose

Creates partitioned directories.

Syntax

pdmkdir [**-m** *Mode*] [**-u** *Owner*] [**-g** *Group*] *dirname* ...

Description

The **pdmkdir** command creates partitioned directories that you specify using the *dirname* parameter. Normal users can create partitioned directories if the Discretionary Access Control (DAC), the Mandatory Access Control (MAC) and the Mandatory Integrity Control (MIC) permissions allow the user to create the new directory. Users with the **aix.mls.pdir.mkdir** authorization can override the DAC, MAC and MIC permissions.

Flags

Item	Description
-g *Group*	Sets the group of the newly-created directories. You can specify either a group name or group ID. Users with the **aix.mls.pdir.mkdir** authorization can change the group of the directory to a group that they are not members of.
-m *Mode*	Sets the permission bits for the newly created directories to the value that is specified by the *Mode* variable. Specify the *Mode* variable as a numeric value.
-u *Owner*	Sets the owner of the newly created directories. You can specify either the owner name or owner ID. Users with the **aix.mls.pdir.mkdir** authorization can change the owner of the directory.

Note: The *Mode*, *Owner* or *Group* variable that is set is applied to the partitioned directory and the partitioned subdirectory created based on the processes Sensitivity Level (SL) which ran the command. If another process with a different SL accesses the partitioned directory, the partitioned subdirectory that is created cannot be governed by these flags.

Security

All users can run the **pdmkdir** command. To successfully perform specific functions, users need the following authorization:

Item	Description
aix.mls.pdir.mkdir	Required to change the owner or group using the **-u** or **-g** flag. This authorization is also required to create directories in a path that ignores the DAC, MAC and MIC permissions of the parent directory.

Exit Status

The **pdmkdir** command returns the following exit values:

Item	Description
0	The command ran successfully and made all requested changes.
>0	An error occurred.

Examples

1. To create a partitioned directory, enter:

```
pdmkdir partdir
```

2. To create a partitioned directory with the permission "755", user "joe", group "staff", enter:

```
pdmkdir –m 755 –u joe –g staff partdir
```

Files

Item	Description
/usr/sbin/pdmkdir	Contains the **pdmkdir** command.

pdmode Command

Purpose

Invokes a command in the virtual or real partitioned, directory-access mode.

Syntax

pdmode [[**-r**] *command* [*arg* ...]]

Description

The **pdmode** command allows you to invoke a command that you specify using the *command* parameter in the virtual or real partitioned directory access mode. When invoked without any argument, the **pdmode** command returns the partitioned directory access mode of the process which invoked this command.

If you run the **pdmode** command followed by the *command* parameter without any flag, the command is run in the virtual mode. A user can run a command in the real partitioned directory access mode by using the **-r** flag.

Flags

Item	Description
-r *command* [*arg*...]	Sets the new process's partitioned directory access mode to the real mode. In this mode, partitioned directories are not transparent, and you must be aware of partitioned directories to navigate the subtree at a partitioned directory. To successfully run the command with this option, users need the **aix.mls.pdir.mode** authorization.

Security

All users can run the **pdmode** command. To successfully perform specific functions, you need the following authorization:

Item	Description
aix.mls.pdir.mode	Required to use the **pdmode** command with the **-r** flag.

Exit Status

The **pdmode** command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To get the partitioned directory access mode, enter:

   ```
   pdmode
   ```

2. To run the **ls** command in the virtual mode, enter:

   ```
   pdmode ls -l
   ```

3. To run the **ls** command in the real mode, enter:

   ```
   pdmode –r ls -l
   ```

Files

Item	Description
/usr/sbin/pdmode	Contains the **pdmode** command.

pdrmdir Command

Purpose

Deletes partitioned directories.

Syntax

pdrmdir *dirname* ...

Description

The **pdrmdir** command deletes partitioned directories that you specify using the *dirname* parameter. Normal users can delete partitioned directories if the Discretionary Access Control (DAC), the Mandatory Access Control (MAC) and the Mandatory Integrity Control (MIC) permissions allow the user to delete the directory. Authorized users with the **aix.mls.pdir.rmdir** authorization can override the DAC, MAC and MIC permissions.

The **pdrmdir** command removes only empty partitioned subdirectories and does not remove files or directories within partitioned subdirectories. The partitioned directory is removed after all the partitioned subdirectories are removed and the directory is empty. The removal of partitioned directory fails if a file exists.

Security

All users can execute the **pdrmdir** command. To successfully perform specific functions, users need the following authorization:

Item	Description
aix.mls.pdir.rmdir	Required to remove directories in a path ignoring the DAC, MAC and MIC permissions.

Exit Status

The **pdrmdir** command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To delete a partitioned directory, enter:

```
pdrmdir partdir
```

Files

Item	Description
/usr/sbin/pdrmdir	Contains the **pdrmdir** command.

pdset Command

Purpose

Converts normal directories to partitioned directories.

Syntax

pdset *dirname* ...

Description

The **pdset** command converts normal directories that you specify using the *dirname* parameter to partitioned directories.

The directory names that you specify cannot be a partitioned subdirectory or a partitioned sub-subdirectory. Existing subdirectories or files under this directory can only be accessible in the real mode of the partitioned directory.

Security

Only authorized users can run the **pdset** command.

Item	Description
aix.mls.pdir.set	Required for converting normal directories to partitioned directories.

Exit Status

The **pdset** command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To convert a directory to a partitioned directory, enter:

```
pdset testdir
```

Files

Item	Description
/usr/sbin/pdset	Contains the **pdset** command.

penable Command

Purpose

Enables or reports the availability of login ports.

Syntax

penable [**-a**] [*Device*]

Description

The **penable** command enables normal ports. Normal ports are asynchronous and only allow users to log in. No outgoing use of the port is allowed while it is enabled. The system enables a port by updating an entry in the **/etc/inittab** file and then sending a signal to the **init** process. After receiving the signal and reading the updated status entry, the process takes the appropriate action.

Use the *Device* parameter to specify the ports to be enabled. Permitted values include:

- Full device name, such as the **/dev/tty1** device
- Simple device name, such as the **tty1** device
- A number (for example, 1 to indicate the **/dev/tty1** device).

If you do not specify a *Device* parameter, the **penable** command reports the names of the currently enabled normal ports.

Note: You must have root user authority to run this command.

Flags

Item	Description
-a	Enables all normal ports.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Example

To enable all normal ports listed in the **/etc/inittab** file, enter:

```
penable -a
```

Files

Item	Description
/etc/locks	Contains **lock** files for the **pshare** and **pdelay** commands.
/usr/sbin/penable	Contains the **penable** command.

perfwb Command

Purpose

Starts the Performance Workbench to monitor system activity

Syntax

perfwb

Note: The DISPLAY environment variable must be set.

Description

The **perfwb** command is used to start the Performance Workbench. It is a graphical interface to monitor the system activity and processes.

A panel shows the partition configuration and the CPU and memory consumptions.

Another panel lists the top processes that can be sorted on the different provided metrics. A filtering device is also provided to restrict the list to particular processes.

Exit Status

Item	Description
0	The command completed successfully.
>0	An error occurred.

Location

/usr/bin/perfwb

Files

Item	Description
/usr/bin/perfwb	Contains the **perfwb** command.

Item	Description
$HOME/workspace	Contains the **perfwb** working directory that contains preferences.

pg Command

Purpose

Formats files to the display.

Syntax

pg [**-** *Number*] [**-c**] [**-e**] [**-f**] [**-n**] [**-p** *String*] [**-r**] [**-s**] [**+***LineNumber*] [**+**/*Pattern***/**] [*File ...*]

Description

The **pg** command reads a file name from the *File* parameter and writes the file to standard output one screen at a time. If you specify a **-** (dash) as the *File* parameter, or run the **pg** command without options, the **pg** command reads standard input. Each screen is followed by a prompt. If you press the Enter key, another page is displayed. Subcommands used with the **pg** command let you review or search in the file.

To determine workstation attributes, the **pg** command scans the file for the workstation type specified by the **TERM** environment variable. The default type is **dumb**.

When the **pg** command pauses and issues a prompt, you can issue a subcommand. Some of these subcommands change the display to a particular place in the file, some search for specific patterns in the text, and others change the environment in which the **pg** command works.

Changing Location Within the File

The following subcommands display a selected place in the file:

Item	Description
Page	Displays the page specified by the *Page* parameter.
+*Number*	Displays the page obtained by adding the *Number* value to the current page.
-*Number*	Displays the page as specified by the *Number* value before the current page.
l	(Lowercase L) Scrolls the display one line forward.
*Number***l**	Displays at the top of the screen the line specified by the *Number* parameter.
+*Number***l**	Scrolls the display forward for the specified number of lines.
-*Number***l**	Scrolls the display backward for the specified number of lines.
d	Scrolls half a screen forward. Pressing the Ctrl-D key sequence functions the same as the **d** subcommand.
-d	Scrolls half a screen backward. Pressing the **-**Ctrl-D key sequence functions the same as the **-d** subcommand.
Ctrl-L	Displays the current page again. A single . (dot) functions the same as the **Ctrl-L** key sequence subcommand.
$	Displays the last page in the file. Do not use this when the input is from a pipeline.

Searching for Text Patterns

The following subcommands search for text patterns in the text. (You can also use the patterns described in the **ed** command.) They must always end with a new-line character, even if the **-n** flag is used.

In an expression such as `[k.a-z]k.`, the minus implies a range, as in a through z, according to the current collating sequence. A collating sequence defines equivalence classes for use in character ranges.

Item	Description
[*Number***]/***Pattern***/**	Searches for the occurrence of the *Pattern* value as specified by the *Number* variable. The search begins immediately after the current page and continues to the end of the current file, without wraparound. The default for the *Number* variable is 1.
*Number***?***Pattern***?**	

Item	Description
*Number***^***Pattern***^**	Searches backward for the occurrence of the *Pattern* value as specified by the *Number* variable. The searching begins immediately before the current page and continues to the beginning of the current file, without wraparound. The default for the *Number* variable is 1. The ^ notation is useful for Adds 100 terminals which will not properly handle the ? notation.

After searching, the **pg** command displays the line with the matching pattern at the top of the screen. You can change the position of the display by adding the **m** or **b** suffix to the search command. The **m** suffix displays the line with the matching pattern in the middle of the screen for all succeeding subcommands. The **b** suffix displays the line with the matching pattern at the bottom of the screen for all succeeding subcommands. The **t** suffix displays the line with the matching pattern at the top of the screen again.

Changing the pg Environment

You can change the **pg** command environment with the following subcommands:

Item	Description
[*Number***]n**	Begins examining the next file in the command line, as specified by the *Number* variable. The default for the *Number* variable is first.
[*Number***]p**	Begins examining the previous file on the command line, as specified by the *Number* variable. The default for the *Number* variable is first.
[*Number***]w**	Displays another window of text. If the *Number* variable is specified, sets the window size to the number of lines it specifies. This subcommand is the same as the **[***Number***]z** subcommand.
[*Number***]z**	Displays another window of text. If the *Number* variable is specified, sets the window size to the number of lines it specifies. This subcommand is the same as the **[***Number***]w** subcommand.
s *File*	Saves the input in the specified file. Only the current file being examined is saved. This command must always end with a new-line character, even if you specify the **-n** flag.
h	Displays an abbreviated summary of available subcommands.
q or **Q**	Quits the **pg** command.
!*Command*	Sends the specified command to the shell named in the **SHELL** environment variable. If this is not available, the default shell is used. This command must always end with a new-line character, even if the **-n** flag is used.

Attention:

1. Some output is lost when you press the QUIT WITH DUMP (Ctrl-\) or INTERRUPT (Ctrl-C) key sequence because any characters waiting in the output queue are purged when the **QUIT** signal is received.
2. If workstation tabs are not set every eight positions, unpredictable results can occur.

At any time output is being sent to the workstation, you can press the QUIT WITH DUMP or INTERRUPT key sequence. This causes the **pg** command to stop sending output and displays the prompt. Then you can enter one of the preceding subcommands at the command prompt.

If standard output is not a workstation, the **pg** command acts like the **cat** command, except that a header is displayed before each file.

While waiting for workstation input, the **pg** command stops running when you press the INTERRUPT key sequence. Between prompts these signals interrupt the current task and place you in the prompt mode.

Flags

Item	Description
-c	Moves the cursor to the home position and clears the screen before each page. This flag is ignored if the `clear_screen` field is not defined for your workstation type in the **terminfo** file.
-e	Does not pause at the end of each file.
-f	Does not split lines. Normally, the **pg** command splits lines longer than the screen width.
-n	Stops processing when a **pg** command letter is entered. Normally, commands must end with a new-line character.
-p *String*	Uses the specified string as the prompt. If the *String* contains a **%d** value, that value is replaced by the current page number in the prompt. The default prompt is **:** (colon). If the specified string contains spaces, you must enclose the string in quotation marks.
-r	Prevents shell escape when the **"!"** subcommand is used.
-s	Highlights all messages and prompts.
+*LineNumber*	Starts at the specified line number.
-*Number*	Specifies the number of lines in the window. On workstations that contain 24 lines, the default is 23.
+/*Pattern***/**	Starts at the first line that contains the specified pattern.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Example

To look at the contents of a file one page at a time, enter:

```
pg filename
```

Files

Item	Description
/usr/bin/pg	Contains the **pg** command.
/usr/share/lib/terminfo/*	Contains the **terminfo** file that defines terminal types.

Item	Description
/tmp/pg*	Contains the temporary file created when using **pg** command.

phold Command

Purpose

Disables or reports the availability of login ports on hold.

Syntax

phold [**-a**] [*Device*]

Description

The **phold** command disables a set of login ports. The **phold** command allows logged-in users to continue, but does not allow any more users to log in. A user cannot log in on a disabled port. The system disables a port by updating an entry in the **/etc/inittab** file and then sending a signal to the **init** process. When the **init** process receives the signal and reads the updated status entry, it takes the appropriate action.

Use the *Device* parameter to specify the ports to be disabled. Permitted values include:

- A full device name, such as the **/dev/tty1** device
- A simple device name, such as the **tty1** device
- A number (*e.g.*, 1 to indicate the **/dev/tty1** device)

If you do not specify a *Device* parameter, the **phold** command reports the names of currently disabled ports in its set.

Note: You must have root user authority to run this command.

Flags

Item	Description
-a	Holds all ports that are currently enabled.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Example

To list the ports that are currently on hold, enter:

```
phold
```

Files

Item	Description
/etc/locks	Contains **lock** files for the **pshare** and **pdelay** commands.
/etc/phold	Contains the **phold** command.

pic Command

Purpose

Preprocesses **troff** command input for the purpose of drawing pictures.

Syntax

pic [**-T** *Name*] [**-** | *File* ...]

Description

The **pic** command is a **troff** command preprocessor for drawing simple figures on a typesetter. The basic objects are a box, circle, ellipse, line, spline, arrow, arc, and the text specified by the *Text* variable. The top-level object is the picture.

Item	Description
File	Specifies the output from a **troff** command that is processed by the **pic** command to draw pictures.

Pictures

The top-level object in the **pic** command is the picture.

.PS *OptionalWidth OptionalHeight*

ElementList

.PE

If the **.PF** macro is used instead of the **.PE** macro, the position after printing is restored to what it was upon entry.

Item	Description
OptionalWidth	Specifies the width of the picture (in inches), if present, regardless of any dimensions used internally. The maximum value is 8.5.
OptionalHeight	Specifies a height value, in inches, different from the default, which is scaled to the same proportion. The maximum value is 14.

Item	Description
ElementList	Represents the following list of elements: ***Shape AttributeList*** *For Statement* ***Placename: Element*** *If Statement* ***Placename: Position*** *Copy Statement* ***Variable = Expression*** Print Statement ***Direction*** Plot Statement **{ *List of Elements* }** sh *X Commandline X* **[*List of Elements*]** *troff-command*

Variable names begin with a lowercase letter, followed by zero or more letters or numbers. Place names begin with an uppercase letter, followed by zero or more letters or numbers. Place and variable names retain their values from one picture to the next.

Elements in a list must be separated by new-line characters or ; (semicolon); a long element can be continued by ending the line with a \ (backslash). Comments are introduced by a # character and ended by a new-line character.

Primitives

The primitive objects are as follows:

box

circle

ellipse

arc

line

arrow

spline

move

Text-List

The **arrow** object is the same as the **line** object with the **->** attribute.

Attributes

An *AttributeList* element is a sequence of zero or more attributes; each attribute consists of a keyword, perhaps followed by a value.

Attribute	Attribute
h(eigh)t *Expression*	**wid(th)** *Expression*
rad(ius) *Expression*	**diam(eter)** *Expression*
up *OptionalExpression*	**down** *OptionalExpression*
right *OptionalExpression*	**left** *OptionalExpression*
from *Position*	**to** *Position*

Attribute	**Attribute**
at *Position*	**with** *Corner*
by *Expression, Expression*	**then**
dotted *OptionalExpression*	**dashed** *OptionalExpression*
chop *OptionalExpression*	**-> <- <->**
invis	**same**
Text-list	

Missing attributes and values are filled in from defaults. Not all attributes make sense for all primitives; irrelevant ones are not processed. The following are the currently meaningful attributes:

Item	**Description**
Primitives	**Attributes**
box	**h(eigh)t**, **wid(th)**, **at**, **same**, **dotted**, **dashed**, **invis**, *Text*
circle, **ellipse**	**rad(ius)**, **diam(eter)**, **h(eigh)t**, **wid(th)**, **at**, **same**, **invis**, *Text*
arc	**up**, **down**, **left**, **right**, **h(eigh)t**, **wid(th)**, **from**, **to**, **at**, **rad(ius)**, **invis**, **ccw**, **cw**, **<-**, **->**, **<->**, *Text*
line, **arrow**	**up**, **down**, **left**, **right**, **h(eigh)t**, **wid(th)**, **from**, **to**, **by**, **then**, **at**, **same**, **dotted**, **dashed**, **invis**, **<-**, **->**, **<->**, *Text*
spline	**up**, **down**, **left**, **right**, **h(eigh)t**, **wid(th)**, **from**, **to**, **by**, **then**, **at**, **same**, **invis**, **<-**, **->**, **<->**, *Text*
move	**up**, **down**, **left**, **right**, **to**, **by**, **same**, *Text*
Text-list	**at**, *Text-item*

The **at** attribute implies placing the geometrical center at the specified place. For lines, splines, and arcs, the **h(eigh)t** and **wid(th)** attributes refer to arrowhead size.

The *Text-item* variable is usually an attribute of some primitive; by default, it is placed at the geometrical center of the object. Stand-alone text is also permitted. A *Text-list* primitive is a list of text items; a text item is a quoted string optionally followed by a positioning request, as follows:

"..."

"..." **center**

"..." **ljust**

"..." **rjust**

"..." **above**

"..." **below**

If there are multiple text items for some primitives, they are centered vertically except as qualified. Positioning requests apply to each item independently.

Text items can contain **troff** commands that control, for example, size and font changes and local motions. Make sure these commands are balanced so that the entering state is restored before exiting.

Item	Description
Positions/Places	A position is ultimately an *X,Y* coordinate pair, but it can also be specified in the following ways: *Place* (*Position*) *Expression, Expression* (*Position*) [**+/-** (*Expression, Expression*)] (*Position*) [**+/-** *Expression, Expression*] (*Place1, Place2*) (*Place1.X, Place2.Y*) *Expression* **<** *Position, Position* **>** *Expression* [**of the way**] **between** *Position* **and** *Position* *Placename* [*Corner*] *Corner Placename* **Here** *Corner* **of** *Nth Shape* *Nth shape* [*Corner*] **Note:** A *Corner* variable designates one of the eight compass points or the center, beginning, or end of a primitive, as follows: **.n .e .w .s .ne .se .nw .sw** **.t .b .r .l** **c .start .end**

Each object in a picture has an ordinal number; *Nth* refers to this, as follows:

- *Nth*
- *Nth* last

The **pic** command is flexible enough to accept names like **1***th* and **3***th*. Usage like **1***st* and **3***st* are accepted as well.

Variables

The built-in variables and their default values are as follows:

Item	Description
boxwid	0.75
boxht	0.5
circlerad	0.25
arcrad	0.25
ellipsewid	0.75
ellipseht	0.5
linewid	0.5
lineht	0.5
movewid	0.5

Item	Description
moveht	0.5
arrowwid	0.05
arrowht	0.1
textwid	0
textht	0
dashwid	0.5
scale	1

These default values can be changed at any time, and the new values remain in force from picture to picture until changed again.

The **textht** and **textwid** variables can be set to any value to control positioning. The width and height of the generated picture can be set independently from the **.PS** macro line. Variables changed within the [(left bracket) delimiter and the] (right bracket) delimiter revert to their previous value upon exit from the block. Dimensions are divided by **scale** during output.

Note: The **pic** command has an eight inch by eight inch limitation on picture sizes generated and sent to the **troff** command, even when the **.ps** (size) line specifies a size greater than eight inches.

Expressions

The following **pic** command expressions are evaluated in floating point. All numbers representing dimensions are taken to be in inches.

Expression + *Expression*

Expression - *Expression*

Expression * *Expression*

Expression / *Expression*

Expression % *Expression* (modulus)

- *Expression*

(*Expression*)

variable

number

Place **.x**

Place **.y**

Place **.ht**

Place **.wid**

Place **.rad**

sin(*Expression*) **cos**(*Expression*) **atan2**(*Expression, Expression*) **log**(*Expression*) **sqrt**(*Expression*) **int**(*Expression*) **max**(*Expression, Expression*) **min**(*Expression,Expression*) **rand**(*Expression*)

Logical Operators

The **pic** command provides the following operators for logical evaluation:

Item	Description
!	Not
>	Greater than

Item	Description
<	Less than
>/=	Greater than or equal to
</=	Less than or equal to
&&	And
|	Or
==	Equal to
!=	Not equal to

Definitions

The following **define** statement is not part of the grammar:

define *Name* **X** *Replacement text* **X**

Occurrences of values such as **$1** and **$2** in the *Replacement text* variable are replaced by the corresponding options if the *Name* variable is called, as follows:

Name(*Option1, Option2*, ...)

Non-existent options are replaced by null strings. The *Replacement text* variable can contain newline characters.

copy and copy thru Statements

The **copy** statement includes data from a file or values that immediately follow, such as:

```
copy File
```

```
copy thru Macro
```

```
copy File thru Macro
```

```
copy File thru Macro until String
```

The *Macro* parameter value can be either the name of a defined macro or the body of a macro enclosed in some character not part of the body. If no file name is given, the **copy** statement copies the input until the next **.PE** macro line.

for Loops and if Statements

The **for** and **if** statements provide for loops and decision-making, as follows:

```
Variable=Expression to Expression by Expression do X anything X
```

```
if Expression then X anything X else X anything X
```

The **by** and **else** clauses are optional. The *Expression* variable in an **if** statement can use the usual relational operators or the *String1* **==** (or **!=**) *String2* string tests.

Miscellaneous Information

The **sh** command runs a command line, as follows:

```
sh X Commandline X
```

It is possible to plot the value of an expression, as follows:

```
plot Expression OptionalFormat Attributes
```

The *Expression* variable value is evaluated and converted to a string (using the format specification, if provided).

The state of fill or no-fill mode is preserved with respect to pictures.

Input numbers can be expressed in **E** (exponential) notation.

Flags

Item	Description
-T*Name*	Prepares the output for the specified printing device. Possible values for *Name* are: **ibm3812** 3812 Pageprinter. **ibm3816** 3816 Pageprinter. **hplj** Hewlett-Packard LaserJet II. **ibm5587G** 5587-G01 Kanji Printer multi-byte language support. **psc** PostScript printer. **X100** AIXwindows display. **X100K** AIXwindows display for multi-byte character support. The default is **ibm3816**. **Note:** It is possible to set the **TYPESETTER** environment variable to one of the preceding values instead of using the **-T** *Name* flag of the **troff** command.
-	Reverts to standard input.

pick Command

Purpose

Selects messages by content and creates and modifies sequences.

Syntax

pick [**+***Folder*] [*Messages*] [**-datefield** *Field*] [**-not**] [**-lbrace**] [**-after** *Date*] [**-before** *Date*] [**-cc** *"Pattern"*] [**-date** *"Pattern"*] [**-from** *"Pattern"*] [**-search** *"Pattern"*] [**-to***"Pattern"*] [**—***Component "Pattern"*] [**-rbrace**] [**-and**] [**-or**] [**-sequence** *Name* [**-zero** | **-nozero**] [**-public** | **-nopublic**] [**-list** | **-nolist**]

Description

The **pick** command selects messages containing particular character patterns or particular dates. You can use the **-and**, **-or**, **-not**, **-lbrace**, and **-rbrace** flags to construct compound conditions for selecting messages.

Flags

Item	Description
-after *Date*	Selects messages with dates later than that specified by the *Date* variable. Use the following specifications for the *Date* variable: **yesterday** **today** **tomorrow** **sunday** **monday** **tuesday** **wednesday** **thursday** **friday** **saturday** **-**Days SystemDate The **pick** command treats the days of the week as days in the past. For example, **monday** means last Monday, not today or next Monday. You can use the **-***Days* argument to specify a number of days in the past. For example, -31 means 31 days ago. For the *SystemDate* argument, you can specify any valid format defined for your system.
-and	Forms a logical AND operation between two message-selecting flags; for example, `pick -after Sunday -and -from mark`. The **-and** flag has precedence over the **-or** flag, but the **-not** flag has precedence over the **-and** flag. Use the **-lbrace** and **-rbrace** flags to override this precedence.
-before *Date*	Selects messages with dates earlier than the specified date. See the **-after** flag on how to specify *Date*.
-cc "*Pattern***"**	Selects messages that contain the character string specified by the **"***Pattern***"** variable in the `cc:` field.
-date "*Pattern***"**	Selects messages that contain the character string specified by the **"***Pattern***"** variable in the `Date:` field.
-datefield *Field*	Specifies which dated field is parsed when the **-after** and **-before** flags are given. By default, the **pick** command uses the `Date:` field.
+*Folder*	Identifies the folder that contains the messages you wish to pick. By default, the system uses the current folder.
-from "*Pattern***"**	Selects messages that contain the character string specified by the **"***Pattern***"** variable in the `From:` field.
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For MH, the name of this flag must be fully spelled out.
-lbrace	Groups **-and**, **-or**, and **-not** operations. Operations between the **-lbrace** and **-rbrace** flags are evaluated as one operation. You can nest the **-lbrace** and **-rbrace** flags.
-list	Sends a list of selected message numbers to standard output. This allows you to use the **pick** command to generate message numbers to use as input for other commands. For example, to scan all messages in the current folder that were sent after Tuesday, you would enter the following: `scan 'pick -after tuesday -list'` If you do not specify a sequence, the **-list** flag is the default.

Item	Description
Messages	Specifies the messages to search. You can specify several messages, a range of messages, or a single message. Use the following to specify messages: ***Number*** Number of the message. ***Sequence*** A group of messages specified by the user. Recognized values include: **all** All of the messages in the folder. This is the default. **cur or . (period)** Current message. **first** First message in a folder. **last** Last message in a folder. **new** New message that is created. **next** Message following the current message. **prev** Message preceding the current message.
-nolist	Prevents the **pick** command from generating a list of the selected message numbers. If a sequence is specified, the **-nolist** flag is the default.
-nopublic	Restricts a sequence to your usage. The **-nopublic** flag does not restrict the messages in a sequence, only the sequence itself. This option is the default if the folder is write-protected from other users.
-not	Forms a logical NOT operation on a message-selecting flag; for example, `pick -not -from george`. This construction evaluates all messages not chosen by the message-selecting flag. The **-not** flag has precedence over the **-and** flag, and the **-and** flag has precedence over the **-or** flag. Use the **-lbrace** and **-rbrace** flags to override this precedence.
-nozero	Appends the selected messages to the specified sequence.
-or	Forms a logical OR operation on two message-selecting flags; for example, `pick -from amy -or -from mark`. The **-not** flag has precedence over the **-and** flag, and the **-and** flag has precedence over the **-or** flag. Use the **-lbrace** and **-rbrace** flags to override this precedence.
-public	Allows other users access to a sequence. The **-public** flag does not make protected messages available, only the sequence itself. This option is the default if the folder is not write-protected from other users.
-rbrace	Groups **-and**, **-or**, and **-not** operations. Operations between the **-lbrace** and **-rbrace** flags are evaluated as one operation. You can nest the **-lbrace** and **-rbrace** flags.
-search "*Pattern***"**	Selects messages that contain the character string specified by the **"***Pattern***"** variable anywhere in the message.

Item	Description
-sequence *Name*	Stores the messages selected by the **pick** command in the sequence specified by the *Name* variable.
-to "*Pattern***"**	Selects messages that contain the character string specified by the **"***Pattern***"** variable in the `To:` field.
-zero	Clears the specified sequence before placing the selected messages into the sequence. This flag is the default.
—*Component* **"***Pattern***"**	Selects messages that contain the character string specified by the **"***Pattern***"** variable in the heading field specified by the *Component* variable; for example, `pick —reply-to amy`.

Profile Entries

The following profile entries are part of the *UserMHDirectory*/**.mh_profile** file:

Item	Description
`Current-Folder:`	Sets the default current folder.
`Path:`	Specifies the user's MH directory.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To get a list of message numbers in the current folder that are from user `jones`, enter:

   ```
   pick  -from jones
   ```

   The system responds with a message similar to the following:

   ```
   12
   15
   19
   ```

2. To see a list of message numbers in the `schedule` folder received within the last 30 days, enter:

   ```
   pick  + schedule  -after -30
   ```

   The system responds with a message similar to the following:

   ```
   5
   8
   21
   30
   ```

Files

Item	Description
$HOME/.mh_profile	Contains the user's MH profile.
/usr/bin/pick	Contains the **pick** command.

ping Command

Purpose

Sends an echo request to a network host.

Syntax

ping [**-d**] [**-D**] [**-n**] [**-q**] [**-r**] [**-v**] [**-R**] [**-a** *addr_family*] [**-c** *Count*] [**-w** *timeout*] [**-f** | **-i** *Wait*] [**-l** *Preload*] [**-p** *Pattern*] [**-s** *PacketSize*] [**-S** *hostname/IP addr*] [**-L**] [**- I** *a.b.c.d.*] [**-o** *interface*] [**-T** *ttl*] *Host* [*PacketSize*] [*Count*]

Description

The **/usr/sbin/ping** command sends an Internet Control Message Protocol (ICMP) ECHO_REQUEST to obtain an ICMP ECHO_RESPONSE from a host or gateway. The **ping** command is useful for:

- Determining the status of the network and various foreign hosts.
- Tracking and isolating hardware and software problems.
- Testing, measuring, and managing networks.

If the host is operational and on the network, it responds to the echo. Each echo request contains an Internet Protocol (IP) and ICMP header, followed by a ping PID and a **timeval** structure, and enough bytes to fill out the packet. The default is to continuously send echo requests until an Interrupt is received (Ctrl-C).

The **ping** command sends one datagram per second and prints one line of output for every response received. The **ping** command calculates round-trip times and packet loss statistics, and displays a brief summary on completion. The **ping** command completes when the program times out or on receipt of a **SIGINT** signal. The *Host* parameter is either a valid host name or Internet address.

By default, the **ping** command will continue to send echo requests to the display until an Interrupt is received (Ctrl-C). The Interrupt key can be changed by using the **stty** command.

Because of the load that continuous echo requests can place on the system, repeated requests should be used primarily for problem isolation.

Flags

Item	Description
-c *Count*	Specifies the number of echo requests, as indicated by the *Count* variable, to be sent (and received).
-w *timeout*	This option works only with the -c option. It causes ping to wait for a maximum of 'timeout' seconds for a reply (after sending the last packet).
-d	Starts socket-level debugging.
-D	This option causes a hex dump to standard output of ICMP ECHO_REPLY packets.
-f	Specifies flood-ping option. The **-f** flag "floods" or outputs packets as fast as they come back or one hundred times per second, whichever is more. For every ECHO_REQUEST sent, a . (period) is printed, while for every ECHO_REPLY received, a backspace is printed. This provides a rapid display of how many packets are being dropped. Only the root user may use this option. **Note:** This can be very hard on a network and should be used with caution. Flood pinging is only permitted by the root user. The **-f** flag is incompatible with the **-i** *Wait* flag.

Item	Description
-I *a.b.c.d*	Specifies that the interface specified by *a.b.c.d* is to be used for outgoing IPv4 multicasts. The **-I** flag is an uppercase i.
-o *interface*	Specifies that *interface* is to be used for outgoing IPv6 multicasts. The interface is specified in the form 'en0', 'tr0' etc.
-i *Wait*	Waits the number of seconds specified by the *Wait* variable between the sending of each packet. The default is to wait for one second between each packet. This option is incompatible with the **-f** flag.
-L	Disables local loopback for multicast pings.
-l *Preload*	Sends the number of packets specified by the *Preload* variable as fast as possible before falling into normal mode of behavior (one per second). The **-l** flag is a lowercase l.
-n	Specifies numeric output only. No attempt is made to look up symbolic names for host addresses.
-p *Pattern*	Specifies up to 16 'pad' bytes to fill out the packet you send. This is useful for diagnosing data-dependent problems in a network. For example, **-p ff** fills the packet with all 1's.
-q	Specifies quiet output. Nothing is displayed except the summary lines at startup time and when finished.
-r	Bypasses the routing tables and sends directly to a host on an attached network. If the *Host* is not on a directly connected network, the **ping** command generates an error message. This option can be used to ping a local host through an interface that no longer has a route through it.
-R	Specifies record route option. The **-R** flag includes the RECORD_ROUTE option in the ECHO_REQUEST packet and displays the route buffer on returned packets. **Note:** The IP header is only large enough for nine such routes. Also, many hosts and gateways ignore this option.
-a *addr_family*	Maps the destination address of the ICMP packets to IPv6 format if addr_family is equal to "inet6".
-s *PacketSize*	Specifies the number of data bytes to be sent. The default is 56, which translates into 64 ICMP data bytes when combined with the 8 bytes of ICMP header data.
-S *hostname/IP addr*	Uses the IP address as the source address in outgoing ping packets. On hosts with more than one IP address, the **-S** flag can be used to force the source address to be something other than the IP address of the interface on which the packet is sent. If the IP address is not one of the machine's interface addresses, an error is returned and nothing is sent.
-T *ttl*	Specifies that the time-to-live for a multicast packet is *ttl* seconds.
-v	Requests verbose output, which lists ICMP packets that are received in addition to echo responses.

Parameters

Item	Description
PacketSize	Specifies the number of data bytes to be sent. The default is 56, which translates into 64 ICMP data bytes when combined with the 8 bytes of ICMP header data. This parameter is included for compatibility with previous versions of the **ping** command.

Item	Description
Count	Specifies the number of echo requests to be sent (and received). This parameter is included for compatibility with previous versions of the **ping** command.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To check the network connection to host canopus and specify the number of echo requests to send, enter:

   ```
   ping  -c 5 canopus
   ```

   OR

   ```
   ping canopus  56  5
   ```

   Information similar to the following is displayed:

   ```
   PING canopus.austin.century.com: (128.116.1.5): 56 data bytes
   64 bytes from 128.116.1.5: icmp_seq=0 ttl=255 time=2 ms
   64 bytes from 128.116.1.5: icmp_seq=1 ttl=255 time=2 ms
   64 bytes from 128.116.1.5: icmp_seq=2 ttl=255 time=3 ms
   64 bytes from 128.116.1.5: icmp_seq=3 ttl=255 time=2 ms
   64 bytes from 128.116.1.5: icmp_seq=4 ttl=255 time=2 ms

   ----canopus.austin.century.com PING Statistics----
   5 packets transmitted, 5 packets received, 0% packet loss
   round-trip min/avg/max = 2/2/3 ms
   ```

2. To get information about host `lear` and start socket-level debugging, enter:

   ```
   ping  -d lear
   ```

   Information similar to the following is displayed:

   ```
   PING lear.austin.century.com: (128.114.4.18) 56 data bytes

   round-trip min/avg/max = 6/8/17 ms
   ```

   Note: The output is repeated until an Interrupt (Ctrl-C) is received.

3. To obtain information about host opus and specify the number of data bytes to be sent, enter:

   ```
   ping  -s 2000 opus
   ```

   OR

   ```
   ping opus  2000
   ```

   Information similar to the following is displayed:

   ```
   PING opus.austin.century.com: (129.35.34.234): 2000 data bytes
   2008 bytes from 129.35.34.234: icmp_seq=0 ttl=255 time=20 ms
   2008 bytes from 129.35.34.234: icmp_seq=1 ttl=255 time=19 ms
   2008 bytes from 129.35.34.234: icmp_seq=2 ttl=255 time=20 ms
   ```

```
2008 bytes from 129.35.34.234: icmp_seq=3 ttl=255 time=20 ms

2008 bytes from 129.35.34.234: icmp_seq=5 ttl=255 time=19 ms
2008 bytes from 129.35.34.234: icmp_seq=6 ttl=255 time=19 ms
^C
----opus.austin.century.com PING Statistics----
7 packets transmitted, 7 packets received, 0% packet loss
round-trip min/avg/max = 19/19/20 ms
```

Note: The output is repeated until an Interrupt (Ctrl-C) is received.

4. To invoke the flood-ping option to host `stlopnor`, enter:

   ```
   ping  -f stlopnor
   ```

   Information similar to the following is displayed:

   ```
   Ping stlopnor.austin.century.com: (129.35.34.234): 56 data bytes
   .^C
   ----stlopnor.austin.century.com PING Statistics ----
   1098 packets transmitted, 1097 packets received, 0% packet loss
   round-trip min/avg/max = 4/4/11
   ```

   Note: The flood-ping output continues until an Interrupt (Ctrl-C) is received.

5. To specify an interval of five seconds between packets sent to host `opus`, enter:

   ```
   ping  -i5 opus
   ```

   Information similar to the following is displayed:

   ```
   PING opus.austin.century.com: (129.35.34.234): 56 data bytes
   64 bytes from 129.35.34.234: icmp_seq=0 ttl=255 time=5 ms
   64 bytes from 129.35.34.234: icmp_seq=1 ttl=255 time=5 ms
   64 bytes from 129.35.34.234: icmp_seq=2 ttl=255 time=6 ms
   ^C
   ----opus.austin.century.com PING Statistics----
   3 packets transmitted, 3 packets received, 0% packet loss
   round-trip min/avg/max = 5/5/6 ms
   ```

   Note: The output is repeated until an Interrupt (Ctrl-C) is received.

6. To send the number of packets specified by the *Preload* variable as fast as possible before falling into normal mode of behavior to host `opus`, enter:

   ```
   ping  -l 10 opus
   ```

   Information similar to the following is displayed:

   ```
   PING opus.austin.century.com: (129.35.34.234): 56 data bytes
   64 bytes from 129.35.34.234: icmp_seq=0 ttl=255 time=9 ms
   64 bytes from 129.35.34.234: icmp_seq=1 ttl=255 time=11 ms
   64 bytes from 129.35.34.234: icmp_seq=2 ttl=255 time=16 ms
   64 bytes from 129.35.34.234: icmp_seq=3 ttl=255 time=22 ms
   64 bytes from 129.35.34.234: icmp_seq=4 ttl=255 time=26 ms
   64 bytes from 129.35.34.234: icmp_seq=5 ttl=255 time=27 ms
   64 bytes from 129.35.34.234: icmp_seq=6 ttl=255 time=30 ms
   64 bytes from 129.35.34.234: icmp_seq=7 ttl=255 time=31 ms
   64 bytes from 129.35.34.234: icmp_seq=8 ttl=255 time=33 ms
   64 bytes from 129.35.34.234: icmp_seq=9 ttl=255 time=35 ms
   64 bytes from 129.35.34.234: icmp_seq=10 ttl=255 time=36 ms
   64 bytes from 129.35.34.234: icmp_seq=11 ttl=255 time=6 ms
   64 bytes from 129.35.34.234: icmp_seq=12 ttl=255 time=6 ms
   64 bytes from 129.35.34.234: icmp_seq=13 ttl=255 time=6 ms
   64 bytes from 129.35.34.234: icmp_seq=14 ttl=255 time=7 ms
   64 bytes from 129.35.34.234: icmp_seq=15 ttl=255 time=6 ms
   ^C
   ----opus.austin.century.com PING Statistics----
   16 packets transmitted, 16 packets received, 0% packet loss
   round-trip min/avg/max = 6/19/36 ms
   ```

   Note: The output is repeated until an Interrupt (Ctrl-C) is received.

7. To diagnose data-dependent problems in a network, enter:

```
ping  -p ff opus
```

This command sends packets with a pad-pattern of all 1's to host opus. Information similar to the following is displayed:

```
PATTERN: 0xff
PING opus.austin.century.com: (129.35.34.234): 56 data bytes
64 bytes from 129.35.34.234: icmp_seq=0 ttl=255 time=5 ms
64 bytes from 129.35.34.234: icmp_seq=1 ttl=255 time=5 ms
64 bytes from 129.35.34.234: icmp_seq=2 ttl=255 time=5 ms
64 bytes from 129.35.34.234: icmp_seq=3 ttl=255 time=6 ms
64 bytes from 129.35.34.234: icmp_seq=4 ttl=255 time=5 ms
^C
----opus.austin.century.com PING Statistics----
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 5/5/6 ms
```

Note: The output is repeated until an Interrupt (Ctrl-C) is received.

8. To specify quiet output, enter:

```
ping  -q bach
```

Only summary information similar to the following is displayed:

```
PING bach.austin.century.com: (129.35.34.234): 56 data bytes
^C
----bach.austin.century.com PING Statistics----
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 5/5/8 ms
```

Note: Although not displayed, the output of packets continues until an Interrupt (Ctrl-C) is received.

pioattred Command

Purpose

Provides a way to format and edit attributes in a virtual printer.

Syntax

pioattred **-q** *PrintQueueName* **-d** *QueueDeviceName* [**-o** *Action*] [**-a** *Attribute*]

Description

The **pioattred** command provides a way to format virtual printer attributes and to edit the attributes. Specifically, attributes in the printer definition file can be formatted and/or edited according to the action specified with the **-o** flag. Formatted attributes are written to standard output **stdout**. Attributes are edited with the editor specified in the **VISUAL** environment variable. The virtual printer definition file is assumed to be in the **/var/spool/lpd/pio/@local/custom/*** directory.

Flags

Item	Description
-a *Attribute*	Specifies the name of the attribute in the virtual printer definition file to format or edit. This flag may be specified many times.
-d *QueueDeviceName*	Specifies the *QueueDeviceName* spooler of the virtual printer definition to format or edit.

Item	Description
-o *Action*	Specifies the action that the **pioattred** command should take on the virtual printer definition. If this flag is omitted, the **pioattred** command assumes a value of 0 (zero). **0** Format the attributes specified. The result goes to **stdout**. **1** Format and edit the attribute(s) specified; use the editor specified in the **VISUAL** environment variable. If no editor is specified in the **VISUAL** environment variable, use the vi editor. If an error is made in editing the attributes, save the erroneous attributes in a temporary file, and return a return code indicating an error. The following values are used in the event that an error return code was returned after editing the attributes. **2** Edit the attributes again. The virtual printer definition will be the state it was left in when the error occurred. **3** Ignore the error and save the edited attributes in the virtual printer definition. **4** Clean up and leave things in the state they were before the **pioattred** command was started.
-q *PrintQueueName*	Specifies the *PrintQueueName* spooler of the virtual printer definition to format or edit.

Examples

1. To format the **ci** and **sh** attributes in the queue: quedev virtual printer definition, enter:

   ```
   pioattred -q queue -d quedev -o 0 -a ci -a sh
   ```

   OR

   ```
   pioattred -q queue -d quedev -a ci -a sh
   ```

2. To format all attributes in the queue: quedev virtual printer definition, enter:

   ```
   pioattred -q queue -d quedev -o 0
   ```

   OR

   ```
   pioattred -q queue -d quedev
   ```

3. To edit the **st** attribute in the queue: quedev virtual printer definition, enter:

   ```
   pioattred -q queue -d quedev -o 1 -a st
   ```

Files

Item	Description
/usr/sbin/pioattred	Contains the **pioattred** command.

piobe Command

Purpose

Print job manager for the printer backend.

Syntax

/usr/lpd/piobe [**-a** *PreviewLevel*] [**-A** *DiagnosticLevel*] [**-d** *InputDataStream*] [**-f** *FilterName*] [*FormatterFlags*] [*File* ...]

Description

The **piobe** command is a spooler backend program called by the **qdaemon** program to process a print job. The **piobe** command serves as the print job manager.

Based on the argument of the **-d** flag (or its default value in the database), which specifies the data stream type of the print files, the **piobe** command retrieves a pipeline from the database and passes it to a shell. The pipeline contains a string of filters to convert the print files as necessary and send them to a printer. If requested, the **piobe** command also retrieves and runs pipelines from the database to generate header and trailer pages.

The *FormatterFlags* argument (flags other than the flags listed in this topic) is assumed to be referenced by the filter commands in the pipelines. If a flag is specified but not referenced by the pipelines, an error message is issued and the print job ended.

> **Note:** The **piobe** command should not be typed directly on the command line. This command is invoked by the **qdaemon** process and is dependent on the various services provided by the **qdaemon** process.

Flags

Item	Description
-a *PreviewOption*	Provides a way to preview parameter values that would be used for a print job without actually printing any files. Values that can be specified for the *PreviewOption* variable are: **0** Specifies normal print processing **1** Returns a list of flag values and the pipeline of filters that would be used to convert the input data type to the data type expected by the printer, but does not actually invoke the pipeline of filters or send the file to the printer. The list of flag values returned are the default command line flag values from the configuration database. These values are overridden by any flag arguments specified on the command line. Please note that: • Only flags that are valid for the *InputDataTyp*e variable specified (or defaulted) for the **-d** flag are shown. • Flag values related only to the spooling of your print job, instead of the actual printing, are not shown. The default values for the spooling flags are included with the descriptions of the flags for the **qprt** command. • The flag values may not have been checked to verify that they are valid. The pipeline of filters shows the filter commands (and the flag values passed to the filter commands) that would process the data from your print file before it is sent to the printer. You can review the description for each of the filter commands to determine the type of filtering that would be performed.
-A *Value*	Specifies the level of diagnostic output. Diagnostic output is useful for diagnosing errors encountered by a pipeline of filters that is processing a print file, a header page, or a trailer page. Diagnostic output is mailed to the user who submitted the print job. The *Value* variable can be one of the following: **0** Discards any standard error output that is produced by the header, trailer, or print file pipelines. **1** If any standard error output is produced, returns the standard error output and the pipeline that produced it and ends the print job. **2** Returns the flag values, standard error output (if any), and completes pipelines, regardless of whether an error is detected. If an error is detected, the print job is ended. **3** Similar to a value of **2**, except that the file is not printed. A value of **1** is recommended. A value of **0** is used if a filter in a pipeline produces output to standard error, even if no error is encountered, such as for status information. A value of **2** or **3** is used for diagnosing a problem even if the problem does not cause any output to standard error.

Item	Description
-d *InputDataType*	Specifies the type of data that is in the file to be printed. This flag is a one-character identifier. Based on the data type for the print file and the data type expected by the printer, the print files are passed through filters (if necessary) before being sent to the printer. Examples of data type identifiers are: **a** IBM extended ASCII **p** Pass-through (sent to the printer unmodified) **s** PostScript **c** PCL **d** Diablo 630 **k** Kanji. If the printer you select does not support the *InputDataType* variable and filters are not available to convert the data type of your print file to a data type supported by the printer, the print job will be ended with an error message.
-f *FilterType*	Specifies a type of filter through which your print file is passed before being sent to the printer. This flag is a one-character identifier. The identifiers are similar to the filter flags available with the html

pioburst Command

Purpose

Generates burst pages (header and trailer pages) for printer output.

Syntax

/usr/lpd/pio/etc/pioburst [**-H** *HostName*] *TextFile*

Description

The **pioburst** command retrieves prototype text for a burst page from the file specified by the *TextFile* variable, fills in the variable fields identified by **%** escape sequences in the prototype text, and writes the constructed text to standard output. It is invoked as a filter in a pipeline by the print job manager, the **piobe** command.

The **%** escape sequences, which are replaced by corresponding values, are:

Item	Description
%A	Specifies the formatting flag values.
%D	Specifies the user to whom the print output is to be delivered.
%H	Specifies the name of the host machine printing the job.
%P	Specifies the time the print job was printed.
%Q	Specifies the time the print job was queued.

Item	Description
%S	Specifies the user who submitted the print job.
%T	Specifies the title of the print job.
%%	Specifies the % (percent sign).

Labels (20 characters long) for each of the variable fields can be specified by using the same escape sequence as for the variable field, except using lowercase letters. For example, to generate a label for the variable field specifying the print job was queued (**%Q**), use **%q**. The **%e** variable represents the label `END OF OUTPUT FOR:`.

The **pioburst** command requires the following environment variables to be initialized:

Item	Description
PIOTITLE	Title of the print job (for **%T**)
PIOQDATE	Time the print job was queued (for **%Q**)
PIOFROM	User who submitted the print job (for **%S**)
PIOTO	User to whom the print output is to be delivered (for **%D**)
PIOFLAGS	Flag values (for **%A**).

Flags

Item	Description
-H *HostName*	Specifies that the host name designated by the *HostName* variable override the default host name (the name of the host machine printing the job).

Example

To generate a header page and send it to standard output, enter:

```
pioburst /usr/lpd/pio/burst/H.ascii
```

Files

Item	Description
/usr/lpd/pio/etc/pioburst	Contains the **pioburst** command.

piocnvt Command

Purpose

Expands or contracts a predefined printer definition or a virtual printer definition.

Syntax

piocnvt [**-s** *State*] **-i** *SourceFile* [**-o** *TargetFile*]

Description

The **piocnvt** command takes either a predefined printer definition or a virtual printer definition and expands or contracts the file. An expanded printer definition file contains all the attributes associated with

that printer definition. A contracted printer definition contains only the printer specific attributes for that printer definition.

Printer definition files are arranged in a hierarchical parent-child relationship. For example the predefined printer definition `4201-3.asc` has the parent `master`. An expanded printer definition for `4201-3.asc` would contain all the attributes from `4201-3.asc` as well as those from `master`. A contracted printer definition for `4201-3.asc` would contain only the attributes not found in `master`. The **piocnvt** command simply provides a way to move back and forth between the expanded and contracted states of a printer definition file.

Flags

Item	Description
-i *SourceFile*	Specifies the complete path and name of the input file.
-o *TargetFile*	Specifies the complete path and name of the output file. If the **-o** flag is omitted, the *SourceFile* will be used for output.
-s *State*	Specifies whether the state of the *TargetFile* parameter should be expanded or contracted. If the **-s** flag is omitted, the **piocnvt** command attempts to determine the state by examining the **zD** attribute in the *SourceFile*. If a determination cannot be made the *TargetFile* parameter will be left in an expanded state. **+** Indicates that the state of the *TargetFile* parameter should be expanded. **!** Indicates that the state of the *TargetFile* parameter should be contracted.

Examples

1. To expand the virtual printer definition `lp0:lp0` into the file `new:lp0`; enter:

```
piocnvt -s+ -i lp0:lp0 -o new:lp0
```

2. To contract the virtual printer definition `lp0:lp0` in place; enter:

```
piocnvt -s! -i lp0:lp0
```

Files

Item	Description
/usr/sbin/piocnvt	Contains the **piocnvt** command.

piodigest Command

Purpose

Digests attribute values for a virtual printer definition into a memory image and stores the memory image in a file.

Syntax

/usr/lpd/pio/etc/piodigest [**-s** *DataStreamType*] [**-n** *DeviceName*] [**-p** *DirectoryPath*] [**-q** *PrintQueueName*] [**-t** *PrinterType*] [**-d** *QueueDeviceName*] { *ColonFileName* | **-** }

Description

The **piodigest** command retrieves virtual printer attribute values from a colon file, builds a memory image of the attribute values and their lookup tables, and writes the constructed memory image to a file. The memory image in the file is then available for access by a print formatter and by the **piobe** command (the print job manager). The command also creates Object Data Manager (ODM) stanzas for the specified queue and queue devices. The ODM stanzas are used in System Management Interface Tool (SMIT) dialogs. If an attribute called **zV** is specified and the attribute contains a value of **+**, the **piodigest** command performs syntax, reference, and limits validation on all attributes specified in the colon file.

The **piodidgest** command should be invoked whenever a customized version of a virtual printer definition is initially generated or is later modified. Each invocation of the **piodigest** command digests the attribute values for one virtual printer definition.

The *ColonFileName* parameter is the name of the input file in colon format. A colon file contains the attribute values for one virtual printer. A value of **-** (dash) for the *ColonFileName* parameter indicates that the colon file should be read from standard input.

The name of the output file that is generated will be of the form:

```
PrinterType.DataStreamType.DeviceName.PrintQueueName:QueueDeviceName
```

Flags

Item	Description
-d *QueueDeviceName*	Specifies the name of the virtual printer (queue device). If this flag is not specified, the virtual printer name specified by the **mv** attribute from the input colon file is assumed.
-n *DeviceName*	Specifies the name of the printer device, such as `lp0` for line printer 0, or `lp1` for line printer 1. If this flag is not specified, the device name specified by the **mn** attribute from the input colon file is assumed.
-p *DirectoryPath*	Specifies the path name of the directory where the output file is to be generated. If this flag is not specified, the **/var/spool/lpd/pio/@local/ddi** directory is assumed.
-q *PrintQueueName*	Specifies the name of the print queue to which the virtual printer is assigned. If this flag is not specified, the print queue name specified by the **mq** attribute from the input colon file is assumed.
-s *DataStreamType*	Specifies the printer data stream type. Example data stream types are **asc** (IBM extended ASCII), **ps** (PostScript), **pcl** (HP PCL), and **630** (Diablo 630). If this flag is not specified, the data stream type specified by the **md** attribute from the input colon file is assumed.
-t *PrinterType*	Specifies the printer type. Examples are `4201-3` and `ti2115`. If this flag is not specified, the printer type specified by the **mt** attribute from the input colon file is assumed.

Example

To generate a digested virtual printer definition, enter:

```
piodigest -d mypro -n lp0 -q proq -s asc -t 4201-3
```

The attribute values for the virtual printer assigned to the `mypro` queue device on the `proq` print queue are digested and stored in the file named **4201-3.asc.lp0.proq:mypro** in the **/var/spool/lpd/pio/@local/ddi** directory.

Files

Item	Description
/var/spool/lpd/pio/@local/ddi/*	Contains the digested, virtual printer definitions.
/usr/lpd/pio/etc/piodigest	Contains the **piodigest** command.

piodmgr Command

Purpose

Compacts the Object Data Manager (ODM) database in the **/var/spool/lpd/pio/@local/smit** directory.

Syntax

piodmgr { **-c** | **-h** }

Description

The **piodmgr** command extracts existing printer definitions from the ODM database in the **/var/spool/lpd/pio/@local/smit** directory, recreates the ODM database, compacts the database, and reloads the compacted database.

The **-c** and **-h** flags are mutually exclusive. The **-h** flag only compacts the database when the host name has been changed. The **-c** flag always compacts the database.

Note: Root user authority is needed to run this command.

Flags

Item	Description
-c	Extracts existing printer definitions from the ODM database, recreates the database, compacts the information, and replaces the database.
-h	Performs exactly like the **-c** flag, but the **-h** flag compacts the information only if the host name has been changed. If the host name has been changed, the **-h** flag extracts the new name and updates the host name information in the database. If the host name has not been changed, the **-h** flag does not compact the information. This flag is an optional compactor rather than an automatic compactor as with the **-c** flag.

Examples

1. To compact and update the ODM printer definition database, enter:

```
piodmgr -c
```

2. To perform compaction of the information depending on whether the host name has been changed or not, enter:

```
piodmgr -h
```

Files

Item	Description
/usr/lib/lpd/pio/etc/piodmgr	Contains the **piodmgr** command.
/var/spool/lpd/pio/@local/smit/*	Contains predefined printer definitions used by the command.

piofontin Command

Purpose

Copies fonts from a multilingual font diskette.

Syntax

piofontin **-t** *PrinterType* **-c** *Codepage* [**-d** *Device*]

Description

The **piofontin** command copies font files from a multilingual font diskette to a directory one level beneath the **/usr/lib/lpd/pio/fonts** label. The directory to which the font files are copied has the name specified by the *PrinterType* parameter. The font files are named according to the naming convention for files. Names are of the form:

```
codepage.typeface.pitch*10.quality
```

Only the root user can use the **piofontin** command.

Flags

Item	Description
-c *Codepage*	Specifies the code page for the fonts. For Greek fonts the value is 851, and for Turkish fonts the value is 853.
-d *Device*	Specifies the diskette-drive device name. This defaults to the **-d/dev/fd0** label, the standard 3.5-inch diskette drive.
-t *PrinterType*	Specifies the type of printer for the fonts. Supported printer types are 4201-3, 4202-3, 4207-2, 4208-2, 2380, 2381, 2390, and 2391.

Example

To read a diskette containing 4201-3 fonts in code page 851 from diskette drive `/dev/fd1;` enter:

```
piofontin 4201-3 851 /dev/fd1
```

The font files are copied to the **/usr/lib/lpd/pio/fonts/4201-3** directory.

File

Item	Description
/usr/sbin/piofontin	Contains the **piofontin** command.

pioformat Command

Purpose

Drives a printer formatter.

Syntax

/usr/lpd/pio/etc/pioformat -@ *DataBaseFile* [**-!** *FormatterName*] [**-# +** *PassThroughOption*]

Description

The **pioformat** command initiates the printer formatter driver. The formatter driver establishes access to the database values, loads and links a printer formatter, and then drives the formatter by calling its **setup** function, **initialize** function, **lineout** function, **passthru** function, and **restore** function as appropriate. The formatter driver also provides the **piogetopt** subroutine, **piogetstr** subroutine, **pioexit** subroutine used by the formatter.

The flags listed below are processed by the formatter driver and are not passed on to the formatter. However, all flags NOT listed below are assumed to be formatting flags and are passed on to the formatter.

Flags

Item	Description
-@ *DataBaseFile*	Specifies either of the following: • The full path name of the (digested) database file to be accessed • The print queue and queue device names, separated by a colon If the argument string begins with a **/** (slash) character, it is assumed to be a full path name. The combination of the queue name and the queue device name results in a unique string that is a part of the database file name and is used to search for the database file name in the **/var/spool/lpd/pio/@local/ddi** directory. This short form alternative is provided as a convenience when the formatter driver and formatter are run as standalone devices, instead of by the spooler.
-! *FormatterName*	Specifies the full path name of the formatter to be loaded, linked, and driven. If the **-!** flag is not specified, the default formatter name defined by the **mf** attribute name in the database is used. A default formatter name is provided as a convenience when the formatter driver and formatter are run as standalone devices, instead of by the spooler.

Item	Description
-# + *PassThroughOption*	Specifies that the print file should be passed through unmodified. If the **-# +** flag is not specified, the print file will be formatted. The parameter that is passed to the formatter's **setup** routine contains a value of 1 instead of 0, indicating that the file should be passed through instead of being formatted.

Examples

1. To format the `myfile` file according to the database file (virtual printer description) for the queue device named `std` associated with the print queue named `pro`, overriding the page width to 132 characters, and using the **pioformat** command and a formatter as a standalone filter, enter:

   ```
   cat myfile | pioformat  -@ pro:std -w 132 >/dev/lp0
   ```

2. To use the **pioformat** command and a formatter in a pipeline running under the spooler, enter:

   ```
   %Ide/pioformat  -@ %Idd/%Imm  -! %Idf/piof420x %Fbb %Fee ...
   ```

   For this example, assume that:

   - The printer is a 4207 Model 2 Proprinter.
   - The print queue name is `pro`.
   - There is only one queue device (virtual printer) defined for the print queue and its name is `std` and its output data stream type is `asc` (extended ASCII).
   - The printer device name is `/dev/lp0`.
   - The print job submitter specified the flag and argument `-i 5`.

   Before the print job manager (the **piobe** command) passes the pipeline to a shell to format the file, it resolves the pipeline's embedded references to attribute values. Based on the assumptions listed above for this example, the attribute references would be resolved as:

Item	Description
`%Ide -> /usr/lpd/pio/etc`	Directory where the **pioformat** command resides
`%Idd -> /var/spool/lpd/pio/@local/ddi`	Directory for database files
`%Imm -> 4207-2.asc.lp0.pro:std`	Database file name
`%Idf -> /usr/lpd/pio/fmtrs`	Directory for formatters
`%Fbb ->`	Null string, since submitter did not specify the **-b** flag
`%Fee -> -i 5`	Submitter specified this flag and argument.

   The resulting pipeline shown below would be passed to a shell to format the file (shown on multiple lines for readability):

```
/usr/lpd/pio/etc/pioformat        # initiate the formatter driver
-@/usr/lpd/pio/ddi/4207-2.asc.lp0.pro:std
                                  # (digested) database file
-!/usr/lpd/pio/fmtrs/piof420x     # loadable formatter
-i5                               # formatting option
                                  # (indent 5 characters)
```

Files

Item	Description
/usr/lpd/pio/etc/pioformat	Contains the formatter driver.
/usr/lpd/pio/fmtrs/*	Contains the formatters.
/var/spool/lpd/pio/@local/ddi/*	Contains the digested database files.

piofquote Command

Purpose

Converts certain control characters destined for PostScript printers.

Syntax

/usr/lpd/pio/etc/piofquote

Description

The **piofquote** command is a filter that converts certain control characters destined for PostScript printers that can emulate other printers. The command reads data from standard input, checks for control characters, and modifies them as needed. It then writes the data to standard output.

If a least 1 byte of data appears on standard input, the **piofquote** command writes a hex 04 control character to standard output before the first input data byte is written to standard output. The command also writes a hex 04 to standard output when end-of-file is recognized on standard input.

If a hex 01, 03, 04, 05, 11, 13, 14, or 1c control character is found in the input data read from standard input, the hex 40 bit in the control character is turned on and a hex 01 character is prefixed to the control character before it is written to standard output.

Files

Item	Description
standard input	Input data stream to be processed.
standard output	Output data stream containing converted control characters.

piolsvp Command

Purpose

Lists virtual printers on a system.

Syntax

piolsvp { **-q** | **-v** | **-Q** | **-p** | **-A** } [**-n***AttachmentField*]

piolsvp -P *Queue* [**:** *QueueDevice*] **-n***AttachmentField*

piolsvp -P *Queue* **-d**

piolsvp -N *AttachmentType* **-n***AttachmentField*

Description

The **piolsvp** command lists the virtual printers and attachment types on the system. The **piolsvp** command displays either the queues or the queues plus the queue-device pairs for virtual printers.

The order of the list of queues and queue-device pairs is the same as the order used by the **/etc/qconfig** file.

Flags

Item	Description
-A	Displays all attachment types and descriptions for the attachment types. The **.attach** and **.config** files in the **/usr/lib/lpd/pio/etc** directory define all attachment types.
-d	Displays the queue devices associated with a given queue.
-n*AttachmentField*	Specifies a field name for an attachment. The field name is typically a SMIT selector name. Possible values for the *AttachmentField* variable are: **submit_job** **add_queue** **add_printer** **remove_queue** **printer_conn** **change_queue** **change_filters** When the **-n** and **-A** flags are specified, only the attachment types that have a value for the specified attachment field in their attachment files are displayed. Attachment definitions are kept in the files with the *AttachmentType***.attach** naming convention. The **.attach** files reside in the **/usr/lib/lpd/pio/etc** directory. When the **-n** flag is specified with either the **-q** or **-v** flags, only queues and queue-device pairs that belong to defined attachment types are displayed. A defined attachment type has an assigned field value in the definition files. When the **-n** flag is specified with the **-P** flag, the SMIT selector name is displayed. The **-n** and **-P** flag combination also displays the queue device name and attachment type. When the **-n** flag is specified with the **-N** flag, the SMIT selector name is displayed for the specified attachment field and attachment type.
-N	Specifies an attachment type. The SMIT selector name associated with a given attachment field is displayed.
-p	Displays all the queue and queue-device pairs on the system and provides a description of each queue and queue-device pair. Only the queue name for the first queue-queue is displayed if there are queues with multiple queue devices.
-P	Specifies the queue name or queue device name for which information is displayed. The information consists of queue device name, attachment type, and SMIT selector value name.
-q	Displays all queues on the system. The **-q** flag also displays the queue-device pairs for queues that have more than one device.

Item	Description
-Q	Displays all the queues on the system. The **-Q** flag does not list queue-device pairs. Use the **-q** flag to list queue-device pairs.
-v	Displays all queue-device pairs for the queues that have virtual printers.

Examples

1. To display all the print queues on the system, enter:

```
piolsvp -q
```

   The output of this command is:

```
e4019a                  4019 (IBM ASCII)
d3816                   IBM 3816 Page Printer
ena_asc                 4029 (IBM ASCII)
ena_gl                  4029 (Plotter Emulation)
ena_pcl                 4029 (HP LaserJet II Emulation)
ena_ps                  4029 (PostScript)
hplj2                   Hewlett-Packard LaserJet II
tstx                    4216-31 (Proprinter XL Emulation)
e4019ps                 4019 (PostScript)
4019lxxa                4029 (PostScript)
4019lxxa:lxx            4029 (PostScript)
40191xxa:rkmlxx         4019 (IBM ASCII)
4019lxxa:rkmlxxl        4019 (IBM ASCII)
```

2. To display all the virtual printers in the system, enter:

```
piolsvp -v
```

   The output of this command is:

```
#QUEUE           DEVICE         DESCRIPTION
e4019a           e4019          4019 (IBM ASCII)
d3816            ena3816        IBM 3816 Page Printer
ena_asc          ena            4029 (IBM ASCII)
ena_gl           ena            4029 (Plotter Emulation)
ena_pcl          ena            4029 (HP LaserJet II Emulation)
ena_ps           ena            4029 (PostScript)

40191xxa         rkmlxx         4019 (IBM ASCII)
```

3. To list all the queues on the system, enter:

```
piolsvp -Q
```

   The output of this command is:

```
e4019a          4019 (IBM ASCII)
d3816           IBM 3816 Page Printer
ena_asc         4029 (IBM ASCII)
ena_gl          4029 (Plotter Emulation)
ena_pcl         4029 (HP LaserJet II Emulation)
ena_ps          4019 (PostScript)
hplj2           Hewlett-Packard LaserJet II
tstx            4216-31 (Proprinter XL Emulation)
e4019ps         4019 (PostScript)
4019lxxa        4029 (PostScript)
```

4. To list all the attachment types that have a SMIT selector value specified for the add_queue SMIT selector, enter:

```
piolsvp -A -nadd_queue
```

The output from this command is:

```
#ATTACHMENT TYPE        DESCRIPTION
local                   Local Attached
remote                  Remote Attached
ascii                   ASCII Terminal Attached
other                   Generic Backend Attached
```

5. To list information for the 4019lxxa queue, enter:

```
piolsvp -P4019lxxa -n add_queue
```

The output from this command is:

```
lxx     xsta    sm_xsta_addq_sel
```

6. To list the SMIT selector value for the remote attachment, enter:

```
piolsvp -Axst -nadd_queue
```

The output from this command is:

```
sm_xsta_addq_sel
```

Files

Item	Description
/usr/lib/lpd/pio/etc/piolsvp	Contains the **piolsvp** command.
/etc/qconfig	Contains the configuration files.
/var/spool/lpd/pio/@local/custom/*	Contains the customized virtual printer attribute files.
/usr/lib/lpd/pio/etc/*.attach	Contains the attachment type files

piomgpdev Command

Purpose

Manages printer pseudo-devices.

Syntax

piomgpdev **-p** *PseudoDevice* **-t** *AttachmentType* { **-A** | **-C** | **-R** | **-D** } [**-a** *Clause* ...]

Description

The **piomgpdev** command changes and removes pseudo-devices for printer attachments. The **piomgpdev** command stores information about the pseudo-devices in files in the **/var/spool/lpd/pio/@local/dev** directory. The file contains stanzas in the following form:

```
key_word = value
```

The information stored in these files pertains to connection characteristics for a given attachment and a printer.

Flags

Item	Description
-a *Clause*	Specifies a clause to be added or changed in the file for a pseudo-device. The clause is in the following form: `key_word = value` If the **-D** flag is specified, the clause can contain only the keyword.
-A	Adds a pseudo-device.
-C	Changes a pseudo-device.
-D	Displays information for a specified clause of a pseudo-device definition.
-p *PseudoDevice*	Specifies the name of a pseudo-device for a printer attachment.
-R	Removes a pseudo-device.

Files

Item	Description
/usr/lib/lpd/pio/etc/piomgpdev	Contains the **piomgpdev** command.
/var/spool/lpd/pio/@local/dev/*	Contains the printer pseudo-device files.

piomkapqd Command

Purpose

Builds a SMIT dialog to create print queues and printers.

Syntax

To Create a Print Queue for an Existing Printer

piomkapqd **-A** *AttachmentType* **-p** *Printer* **-d** *DeviceName* **-h** *Header* [**-e**]

To Create a Printer and a Print Queue

piomkapqd **-A** *AttachmentType* **-p** *Printer* **-v** *Device* **-s** *Subclass* **-r** *Adapter* **-h** *Header* [**-e**]

To Create a Printer Attached to a TTY or to Assign Printer Output to a File and Create a New Queue

piomkapqd **-A** *AttachmentType* **-p** *Printer* { **-T** *TTYName* | **-f** *FileName* } **-h** *Header* [**-e**]

To Use a User-Defined Attachment for a New Printer and Print Queue

piomkapqd **-A** *AttachmentType* **-p** *Printer* [**-d** *DeviceName*] **-c** *CmdExec* **-i** *DiscCmd* **-o** *ObjectID* **-h** *Header* [**-e**]

Description

The **piomkapqd** command creates a System Management Interface Tool (SMIT) dialog that allows the user to create new printers and print queues. The **piomkapqd** command also allows users to add their user-defined attachment types to a SMIT printer or queue definition dialog.

Flags

Item	Description
-A *AttachmentType*	Specifies the type of attachment used to connect the printer to the data source. Common values for the *AttachmentType* variable are: **local** Specifies a local attachment type. **ascii** Specifies an ASCII attachment type. **file** Specifies a file where the data is stored.
-c *CmdExec*	Specifies the value for the **cmd_to_execute** SMIT command. This flag is used when creating a user-defined attachment dialog. If this flag is not included, the **piomkpq** command is used as the default.
-d *DeviceName*	Specifies the name of the device, pseudo-device, or file where the output is directed, for example `lp0` or `tty1`.
-e	Specifies that an existing print queue is to be used for printer output. The **-e** prevents the **piomkapqd** command from creating a new queue.
-f *FileName*	Indicates the name of the file where output is stored.
-h *Header*	Specifies the title or header of the SMIT dialog that is being created.
-i *DiscCmd*	Specifies the value of the **cmd_to_discover** SMIT command. This flag is used when creating a user-defined attachment dialog. If this flag is not included, the **piomkapqd** command default value is used to create the dialog.
-o *ObjectID*	Specifies the SMIT object whose ID matches the value of the *ObjectID* variable.
-p *Printer*	Specifies the printer type as defined in the **/usr/lib/lpd/pio/predef** directory, for example `ibm4019`.
-r *ParentAdapter*	Specifies the parent adapter for the printer.
-s *Subclass*	Specifies the subclass type to which the printer belongs. The possible values for the *Subclass* variable are: • **parallel** • **rs232** • **rs422**
-T *TTYName*	Specifies the name of the TTY attached to the new printer or queue.
-v *Device*	Specifies the device type as defined in the ODM database. The **-v** flag retrieves printer definitions that are not stored in the **/usr/lib/lpd/pio/predef** directory.

Examples

1. To create a SMIT dialog that adds a print queue to an existing local printer, enter:

```
piomkapqd -A local -p ibm4019 -d lp0 -h 'Add a New Queue'
```

2. To create a SMIT dialog that adds a new printer named `lp2` and new print queue attached locally, enter:

```
piomkapqd -A local -p ibm4019 -v ibm4019 -s rs232 -r sa0 -h 'Add New Printer'
```

3. To create a SMIT dialog that adds a printer attached to a TTY and create a new queue for the printer, enter:

```
piomkapqd -A tty -p ibm4039 -T tty12 -h 'Add TTY Printer'
```

4. To create a SMIT dialog that directs output to a file name `stuff` and to create a new queue, enter:

```
piomkapqd -A file -p ibm4039 -f stuff -h 'Add Output File' -e
```

5. To create a SMIT dialog that adds a user-defined printer attachment type and creates a new queue, enter:

```
piomkapqd -A hpJetDirect -p hplj-4 [-d lp0] -c /usr/sbin/mkjetd -i /usr/bin/lsjd -o
JetDirect -h
'Add New Attachment Type'
```

File

Item	Description
/usr/lib/lpd/pio/etc/piomkapqd	Contains the **piomkapqd** command.

piomkpq Command

Purpose

Creates a print queue.

Syntax

To add a new printer

piomkpq **-A** *AttachmentType* **-p** *PrinterType* **-Q** *QueueName* **-D** *DataStream* **-v** *DeviceType* **-s** *Subclass* **-r** *ParentAdapter* **-w** *PortNumber* [**-a** { *interface* | *ptop* | *autoconfig* | *speed* | *parity* | *bpc* | *stops* | *xon* | *dtr* | *tbc*=*DescValue* }] ...

To create a new print queue

piomkpq **-A** *AttachmentType* **-p** *PrinterType* { **-D** *DataStream* | **-q** *QueueName* } **-s** *Subclass* **-r** *ParentAdapter* **-w** *PortNumber* **-v** *DeviceType* [**-a** { *interface* | *ptop* | *autoconfig* | *speed* | *parity* | *bpc* | *stops* | *xon* | *dtr* | *tbc*=*DescValue* }] ...

To create print queues for an existing printer

piomkpq **-A** *AttachmentType* **-p** *PrinterType* **-d** *DeviceName* { **-D** *DataStream* | **-q** *QueueName* }

To add an existing printer to an existing print queue

piomkpq **-A** *AttachmentType* **-p** *PrinterType* **-d** *DeviceName* **-D** *DataStream* **-q** *QueueName*

Description

The **piomkpq** command creates print queues and printers. This command is used by SMIT dialogs created with the **piomkapqd** command. The **piomkpq** command performs the following functions:

- Creates printer devices with various attachment types.
- Creates print queues.
- Creates queue devices.
- Creates virtual printers.

- Creates pseudo-devices.

Flags

Item	Description
-a	Specifies a device attribute. This takes the form *Attribute=Value*, for example: `-a speed=9600`. The valid attributes are: **Interface** **ptop** **autoconfic** **speed** **parity** **bpc** **stops** **xon** **dtr** **tbc**
-A *AttachmentType*	Specifies the type of attachment used to connect the printer to the data source. Common values for the *AttachmentType* variable are: **local** Specifies a local attachment type. **ascii** Specifies an ASCII attachment type. **file** Specifies a file where the data is stored.
-d *DeviceName*	Specifies the name of the device, pseudo-device, or file where the output is directed, for example `lp0` or `tty1`.
-D *DataStream*	Specifies the datastream of a print queue to be created or an existing print queue.
-p *PrinterType*	Specifies the printer type as defined in the **/usr/lib/lpd/pio/predef** directory, for example `ibm4019`.
-q *QueueName*	Specifies a new queue name. The **-q** and **-Q** flags are exclusive.
-Q *QueueName*	Specifies an existing queue name. The **-q** and **-Q** flags are exclusive.
-s *Subclass*	Specifies the subclass type to which the printer belongs. The possible values for the *Subclass* variable are: • **parallel** • **rs232** • **rs422**
-r *ParentAdapter*	Specifies the parent adapter for the printer.
-w *PortNumber*	Specifies the port number for the printer attachment.
-v *DeviceType*	Specifies the device type as defined in the ODM database.

Examples

1. To create a local print queue named `castor` of datastream ASCII for an existing IBM 4019 printer named `lp0`, enter:

```
piomkpq -A local -p ibm4019 -d lp0 -D asc -q castor
```

2. To add an existing local printer to an existing local print queue called `pyrite` for the datastream PostScript, enter:

```
piomkpq -A local -p ibm4019 -d lp0 -Q pyrite -D ps
```

3. To create local print queue called `baker` for a new printer, enter:

```
piomkpq -A local -p ibm4019 -D asc -Q baker -s parallel -r ppa0
-w p -v ibm4019 [-a ptop=120]
```

4. To create the **clues** file print queue, enter:

```
piomkpq -A file -p ibm4019 -d clues -D asc -q baker
```

Files

Item	Description
/usr/lib/lpd/pio/etc/piomkpq	Contains the **piomkpq** command.
/usr/lib/lpd/pio/etc/piomgpdev	Creates a pseudo-device.
/usr/sbin/mkdev	Creates a device.
/usr/bin/mkque	Creates a queue.
/usr/bin/mkquedv	Creates a queue device.
/usr/sbin/mkvirprt	Creates a virtual printer.

piomsg Command

Purpose

Sends a printer backend message to the user.

Syntax

piomsg [**-u** *UserList*] [**-c** *MsgCatalog* [**-s** *MsgSet*] **-n** *MsgNumber*] [**-a** *MsgArg*] ... [*MsgText*]

Description

The **piomsg** command either retrieves a printer backend message from a message catalog or sends a specified message text to one or more users. The **piomsg** command runs when a print job is executed. Typically, the **piomsg** command is used in printer colon files to send a message to the user submitting a print job while the print job is processed by the **piobe** command.

When the **-c**, **-s**, or **-n** flags are specified, the **piomsg** command retrieves a message from a message catalog. The command searches for the message in the directory specified in the **NLSPATH** environment variable. If the **NLSPATH** environment variable does not contain a directory path, the **piomsg** command searches the **/usr/lib/lpd/pio/etc** default directory. If no message is found in the **/usr/lib/lpd/pio/etc** directory, the command supplies the text specified in the *MessageText* variable. When the **-c**, **-s**, or **-n** flags are not specified, the **piomsg** command returns the value (if any) of the *MessageText* variable.

Each message is parsed for the **%s** or **%n$s printf** subroutine conversion specifications. The **printf** conversion specifications are replaced with supplied message strings, if any, before the message is sent to the user. The **piomsg** command processes escape sequences, such as, linefeed **/n** or horizontal tab **/t**, that are embedded in the message.

Flags

Item	Description
-a *MsgArg*	Specifies the message argument string. The value of the *MsgArg* variable is substituted into the message, if it contains the **%s** or **%n$s printf** subroutine conversion specifications. The **-a** flag can be specified up to 10 times to specify multiple arguments. If there are any errors while parsing conversion specifications, the original message is sent.
-c *MsgCatalog*	Specifies the message catalog that contains the message to be retrieved. The **-c** flag must be specified with the **-n** flag.
-n *MsgNumber*	Specifies the message number. The **-n** flag must be specified with the **-c** flag.
-s *MsgSet*	Specifies an optional message set. The default value for the *MsgSet* variable is 1. The **-s** flag must be specified with both the **-c** and **-n** flags.
-u *UserList*	Specifies the list of users who receive the message. The names of users or nodes in the *UserList* variable are separated by commas. To include a node name in the user list specify the @ character followed by a node name or address. If the **-u** flag is omitted, the message returns to the user who initiated the print job.

Examples

1. To retrieve message number `100` in message set number 1 from the `piobe.cat` message catalog and send the message to user `joe` on the same node as the print server and `tom` on node `foobar`, enter:

   ```
   piomsg -u joe,tom@foobar -c piobe.cat -n 100
   ```

2. To send a message with a message argument string to the user who submitted the print job, enter:

   ```
   piomsg -a "/usr/bin/troff" "The specified filter %s is not found\n"
   ```

3. To retrieve message number 5 in set number2 from the `xyz.cat`, use a dummy message in the event of a failure, and send the message to the printer, enter:

   ```
   piomsg -cxyz.cat -s2 -n5 "xyz.cat is not installed.\n"
   ```

   Note: When the **piomsg** command cannot retrieve messages from the catalog specified with the **NLSPATH** environment variable or the default directory, the supplied message text is sent to the users.

File

Item	Description
/usr/lib/lpd/pio/etc/piomsg	Contains the **piomsg** command.

pioout Command

Purpose

Printer backend's device driver interface program.

Syntax

/usr/lpd/pio/etc/pioout [**-A** *BytesPrinted*] [**-B** *TotalBytes*] [**-C** *NumberCancelStrings*] [**-D** *CancelString*] [**-E** *Mask*] [**-F** *FormFeedString*] [**-I** *InterventionRequiredUser*] [**-K** *TextString*] [**-L** *TextString*] [**-N** *NumberFormFeedStrings*] [**-O** *OutFile*] [**-P** *PrefixFile*] [**-R** *ParseRoutine*] [**-S** *SuffixFile*] [**-W+**]

Description

The **pioout** command is at the end of pipelines invoked by the **piobe** command (the print job manager) to print a file or a burst page on a printer. It reads input data from standard input, the prefix file (if the **-P** flag is specified), and the suffix file (if the **-S** flag is specified), and then writes the data to the printer (or *OutFile*, if the **-O** flag is specified). Error conditions and situations where intervention is required (unless the **-I** flag is specified) are reported to the user who submitted the print job.

The values specified with the **-A** flag and the **-B** flag are used to periodically report to the **qdaemon** process the percentage of the print job that has completed. The **-C** flag and the **-D** flag specify the data string sent to the printer if the print job is canceled.

The **-O** flag is used to generate a header page and store it in a temporary file. The **-P** flag is then used to print the header page (that was saved in a temporary file) just prior to printing the print file.

The **pioout** command requires the following environment variables to be initialized:

Item	Description
PIOTITLE	Title of the print job
PIODEVNAME	Device name
PIOQNAME	Print queue name
PIOQDNAME	Queue device name
PIOFROM	User who submitted the print job
PIOMAILONLY	If nonzero, message to user should always be mailed, not displayed.
PIOTERM	Overrides the terminal type assumed from the tty definition. This variable is only used for print jobs submitted to terminal-attached terminals.

Flags

Item	Description
-A *BytesPrinted*	Specifies the number of bytes already printed for the print job.
-B *TotalBytes*	Specifies the total number of bytes to be printed for the print job.
-C *NumberCancelStrings*	Specifies the number of times the string specified by the **-D** flag is to be sent to the printer when a print job is canceled. If this flag is not specified, the value is assumed to be 3168.
-D *CancelString*	Specifies the string to be sent to the printer when a print job is canceled. If the **-D** flag is not specified, the string is assumed to consist of 1 null character.
-E *Mask*	Specifies, as *Mask*, one or more device-driver error-flag names, separated by commas. If the mask is one returned by the **ioctl** subroutine with an **LPQUERY** command, the error condition indicated by the mask is ignored. Flag names can include **LPST_ERROR, LPST_NOSLCT**, and **LPST_SOFT**, and are defined in the **/usr/include/sys/lpio.h** file.

Item	Description
-F *FormFeed String*	Specifies the string to be sent to the printer to cause a form feed. If the **-F** flag is not specified, the string is assumed to be `\014`.
-I *InterventionRequiredUser*	Specifies the user to whom a message is to be sent when the printer requires intervention. If this flag is not specified, the message is sent to the user who submitted the print job. The *InterventionRequiredUser* parameter can be one or more user names, separated by commas. A null string represents the print job submitter. For example, the string `,jim@server02` causes intervention required messages to be sent to both the print job submitter and to user `jim` at node `server02`.
-K *TextString*	Specifies that messages sent by a PostScript printer will be discarded if they contain the specified text string. For example, if the *TextString* variable is `warming up`, messages that include the text `warming up` will be discarded.
-L *TextString*	Specifies that if a message received from a PostScript printer includes the specified text string, the text following this text string in the message will be sent to the intervention-required user specified by the **-I** flag.
-N *NumberFormFeedStrings*	Specifies the number of form-feed strings to be sent to the printer at the end of the input data stream. If this flag is not specified, the value is assumed to be zero. This flag is normally used only to align continuous forms after the printer has been idle, or to feed forms when the printer goes idle.
-O *OutFile*	Specifies that the output is sent to the specified file instead of being sent to the printer.
-P *PrefixFile*	Specifies the file sent to the printer before the first byte of the print file is sent. If the print job terminates before the first byte of the print file arrives, the prefix file is not sent.
-R *ParseRoutine*	Specifies the full path name of a routine to parse data read from the printer. An example of a parse routine is contained in the **/usr/include/piostruct.h** file. If the **-R** flag is not specified, a default parse routine is used.
-S *SuffixFile*	Specifies the file sent to the printer after the print file has been sent. If the print job terminates before the first byte of the print file arrives, the suffix file is not sent.
-W +	Specifies that EOF (hex 04) must be received from the printer in order to exit.

piopredef Command

Purpose

Creates a predefined printer data-stream definition.

Syntax

piopredef [**-r**] **-d** *QueueDeviceName* **-q** *PrintQueueName* **-s** *DataStreamType* **-t** *PrinterType*

Description

The **piopredef** command creates a predefined printer data-stream definition from a virtual printer definition. It can be thought of as the inverse of the **mkvirprt** command, displayed with the **chvirprt** command, and then specified with the **piopredef** command to create a predefined definition for the unsupported printer.

The new predefined printer definition can then be specified with a **mkvirprt** command to generate additional virtual printers for the unsupported printer type on the same computer, or transported to other computers and used there.

Flags

Item	Description
-d *QueueDeviceName*	Specifies with the *QueueDeviceName* variable the spooler of the customized virtual printer definition to be used to create the predefined printer definition.
-q *PrintQueueName*	Specifies with the *PrintQueueName* variable the spooler of the virtual printer definition to be used to create the predefined printer definition.
-r	Specifies that if the **-s** flag and the **-t** flag specify a predefined printer definition that already exists, the existing one should be replaced.
-s *DataStreamType*	Specifies with the *DataStreamType* variable the printer for the predefined printer definition to be created. Example data stream types are: **asc** IBM extended ASCII **gl** Hewlett-Packard GL **pcl** Hewlett-Packard PCL **ps** PostScript **630** Diablo 630 **855** Texas Instruments 855.
-t *PrinterType*	Specifies the printer type for the predefined printer definition to be created. Examples of existing printer types are: 4201-3, hplj-2, ti2115, and so on.

Note: If no flags are specified, the command syntax is displayed.

Example

To create a new predefined printer definition from an existing virtual printer definition for the virtual printer, enter:

```
piopredef -d mypro -q proq -s asc -t 9234-2
```

The attributes for the virtual printer assigned to the `mypro` queue device on the `proq` print queue are copied to create a new predefined printer definition for the `9234-2` printer (`asc` data stream).

Files

Item	Description
/etc/piopredef	Contains the **piopredef** command.
/usr/lpd/pio/predef/*	Predefined printer data stream attribute files. File names are in the format: `PrinterType.DataStreamType`.
/var/spool/lpd/pio/@local/custom/*	Customized virtual printer attribute files. File names are in the format: `PrintQueueName:QueueDeviceName`.

pkgadd Command

Purpose

Transfers a software package or set to the system.

Syntax

To Install a Software Package

pkgadd [**-d** *Device*] [**-r** *Response*] [**-n**] [**-a** *Admin*] [-P *Path*] [*Pkginst1* [*Pkginst2* [. . .]]]

To Copy a Software Package to the Specified Spool Directory

pkgadd -s *Spool* [**-d** *Device*] [*Pkginst1* [*Pkginst2* [. . .]]]

Description

pkgadd transfers the contents of a software package or set from the distribution medium or directory to install it onto the system. A package is a collection of related files and executables that can be independently installed. A set is made up of a special-purpose package, referred to as a Set Installation Package (SIP), and a collection of one or more packages that are members of the set. The SIP controls the installation of the set.

pkgadd checks that all packages listed on the command line are on the installation medium. If any of the packages listed does not exist, no changes are made to the system, that is, none of the listed packages are installed.

Note: Nonroot users must meet the following conditions to run the pkgadd command successfully:

1. Users must have write permission to the paths specified in the pkgmap file.
2. The current *user:group* must match the *user:group* specified in the pkgmap file.
3. Users must have write permissions on the `/var/sadm/install` and `/var/sadm/pkg` directories.

Used without the **-d** flag, **pkgadd** looks in the default spool directory for the package (**/var/spool/pkg**). Used with the **-s** flag, it writes the package to a spool directory instead of installing it.

Error messages are always logged. In addition, when **pkgadd** terminates, it sends mail (by default, to "root") with all the error messages and a summary of which packages installed completely, partially, or not at all.

Flags

Item	Description
-d *Device*	Installs or copies a package/set from *Device*. *Device* can be the full pathname to a directory, file or named pipe, or "-" which specifies packages in datastream format read from standard input. The default device is the installation spool directory (**/var/spool/pkg**).
-r *Response*	Identifies a file or directory, *Response*, which contains the answers to questions posed by a "request script" during a previous **pkgask** session conducted in interactive mode [see the **pkgask** command]. When *Pkginst* is a package, *Response* can be a full pathname or a directory; when *Pkginst* is a SIP, *Response* must be a directory.
-n	Specifies that installation runs in non-interactive mode. The default mode is interactive.
-a *Admin*	Defines an installation administration file, *Admin*, to be used in place of the default administration file to specify whether installation checks (such as the check on the amount of space, the system state, and so on) are done. The token "none" overrides the use of any **admin** file, and thus forces interaction with the user. Unless a full pathname is given, **pkgadd** looks in the **/var/sadm/install/admin** directory for the file. By default, the file **default** in that directory is used. **default** specifies that no checking is done, except to see if there is enough room to install the package and if there are dependencies on other packages. The **-a** flag cannot be used if *Pkginst* is a SIP.
-P *Path*	Specifies an alternative root directory path for installation. Files will be installed under this location.
Pkginst	Defines a short string used to designate an abbreviation for the package/set name. (The term "package instance" is used loosely: it refers to all instantiations of *Pkginst*.) See the **pkginfo** command and the **pkginfo** file format. If *Pkginst* is a SIP, the SIP controls installation of the set by using request scripts and pre-install scripts. The SIP request script, not the package installation tools, is responsible for prompting the user for responses and taking the appropriate actions. If the request script fails, only the SIP is processed. To indicate all instances of a package, specify '*Pkginst***.***', enclosing the command line in single quotes, as shown, to prevent the shell from interpreting the "*" character. Use the token "all" to refer to all packages available on the source medium.
-s *Spool*	Reads the package into the directory *Spool* instead of installing it.

Special Notes

The **-r** flag can be used to indicate a directory name as well as a filename. The directory can contain numerous *Response* files, each sharing the name of the package with which it should be associated. This would be used, for example, when adding multiple interactive packages with one invocation of **pkgadd**. Each package that had a request script would need a *Response* file. If you create response files with the same name as the package (for example, *Package1* and *Package2*) then, after the **-r** flag, name the directory in which these files reside.

The **-n** flag causes the installation to halt if any interaction is needed to complete it.

When invoked with no *Pkginst* specified on the command line, **pkgadd** only displays the names of sets if at least one SIP exists on the media. Because of this, you shouldn't include packages on the same media if some are members of sets and some are not. If you do, the packages which are not members of sets can be installed only if their **pkginst** names are provided on the command line.

The **pkgadd** command checks to see if any of the files in *Pkginst* are already installed on the system and, if any are, saves this fact before continuing with installation. Later, **pkgadd** does not reinstall these files

on the system. If one of the packages installation scripts removes such a file, the result is that the file will no longer be on the system when package installation completes.

The **pkgadd** command does not uncompress any files that were already compressed (that is, only those in "**.Z**" form) before being processed by **pkgmk**.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion of script.
1	Fatal error. Installation process is terminated at this point.
2	Warning or possible error condition. Installation continues. A warning message is displayed at the time of completion.
3	Script was interrupted and possibly left unfinished. Installation terminates at this point.
4	Script was suspended (administration). Installation terminates at this point.
5	Script was suspended (interaction was required). Installation terminates at this point.
10	System should be rebooted when installation of all selected packages is completed. (This value should be added to one of the single-digit exit codes described above.)
20	The system should be rebooted immediately upon completing installation of the current package. (This value should be added to one of the single-digit exit codes described above.)
77	No package was selected for the set.
99	Internal error.

Files

Item	Description
/var/sadm/install/admin/default	default package administration file
/var/sadm/install/logs/*pkginst*.log	error message log
/var/spool/pkg	default spool directory

pkgask Command

Purpose

Stores answers to a request script.

Syntax

pkgask [**-d** *Device*] **-r** *Response* [*Pkginst* [*Pkginst* [. . .]]

Description

pkgask enables an administrator to store answers to an interactive package (one with a request script) or a set of packages. A set is made up of a special-purpose package, referred to as a Set Installation Package (SIP), and a collection of one or more packages that are members of the set. The SIP controls the installation of the set.

Invoking **pkgask** generates a *Response* file that is then used as input at installation time. The use of this *Response* file prevents any interaction from occurring during installation since the file already contains all of the information the package needs.

When **pkgask** runs, it creates the response file as well as the following directories:

Item	Description
/ptfvars	Contains variables pertaining to the package.
/fileinfo	Contains checksum information about the package.
/oldfiles	Contains backups of previous versions of the package.

To install the package on another system non-interactively, you must copy all of these files and directories to the target system.

Note: If you overwrite any of these directories, for example, to install another package non-interactively, you will not be able to successfully remove the first package unless you restore the original directory contents first.

You can use the **-r** flag to indicate a directory name as well as a filename. The directory name is used to create numerous *Response* files, each sharing the name of the package with which it should be associated. This is useful, for example, when you add multiple interactive packages with one invocation of **pkgadd**. Each package needs a *Response* file. To create multiple response files with the same name as the package instance, name the directory in which the files should be created and supply multiple instance names with the **pkgask** command. When installing the packages, you can identify this directory to the **pkgadd** command.

Flags

Item	Description
-d *Device*	Runs the request script for a package on *Device*. *Device* can be the full pathname to a directory (such as **/var/tmp**), or "-" which specifies packages in datastream format read from standard input. The default device is the installation spool directory (**/var/spool/pkg**).
-r *Response*	Identifies a file or directory, *Response*, which should be created to contain the responses to interactions with the packages request script. The file, or directory of files, can later be used as input to the **pkgadd** command [see the **pkgadd** command]. When *Pkginst* is a package, *Response* can be a full pathname or a directory; when *Pkginst* is a SIP, *Response* must be a directory.

Item	Description
Pkginst	Defines a short string used to designate an abbreviated package/set name. (The term "package instance" is used loosely: it refers to all instantiations of *Pkginst*, even those that do not include instance identifiers.) To create a package name abbreviation, assign it with the "PKG" parameter. For example, to assign the abbreviation "cmds" to the Advanced Commands package, enter **PKG=cmds**. If *Pkginst* specifies a SIP, all request scripts for packages which are members of that set are run (if any) and the resulting response files are placed in the directory provided to the **-r** flag. To indicate all instances of a package, specify '*Pkginst*.*', enclosing the command line in single quotes, as shown, to prevent the shell from interpreting the "*" character. Use the token "all" to refer to all packages available on the source medium. **Note:** When invoked with no *Pkginst* specified on the command line, **pkgask** only displays the names of sets if at least one SIP exists on the device. Thus, if you have packages which are not members of sets, they can be referenced only if their *Pkginst* names are provided on the command line.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion of script.
1	Fatal error. Installation process is terminated at this point.
2	Warning or possible error condition. Installation continues. A warning message is displayed at the time of completion.
3	Script was interrupted and possibly left unfinished. Installation terminates at this point.
4	Script was suspended (administration). Installation terminates at this point.
5	Script was suspended (interaction was required). Installation terminates at this point.
10	System should be rebooted when installation of all selected packages is completed. (This value should be added to one of the single-digit exit codes described above.)
20	The system should be rebooted immediately upon completing installation of the current package. (This value should be added to one of the single-digit exit codes described above.)
77	No package was selected for the set.
99	Internal error.

Files

Item	Description
/var/spool/pkg	default spool directory

pkgchk Command

Purpose

Checks the accuracy of an installation.

Syntax

To Check the Contents of Installed Objects

pkgchk [**-l** | **-a** **-c** **-f** **-q** **-v**] [**-n** **-x**] [-P *path*] [**-p** *Path1*[,*Path2* . . .] [**-i** *File*] [*Pkginst* . . .]

To Check the Contents of a Package Spooled on a Specified Device

pkgchk **-d** *Device* [**-l** | **-v**] [**-p** *Path1*[,*Path2* . . .] [**-i** *File*] [*Pkginst* . . .]

To Check the Contents of a Package Described in the Specified pkgmap

pkgchk **-m** *Pkgmap* [**-e** *Envfile*] [**-l** | **-a** **-c** **-f** **-q** **-v**] [**-n** **-x**] [**-i** *File*] [**-p** *Path1*[,*Path2* . . .]]

Description

pkgchk checks the accuracy of installed files or, by use of the **-l** flag, displays information about package files. The command checks the integrity of directory structures and the files. Discrepancies are reported on **stderr** along with a detailed explanation of the problem.

The first synopsis defined above is used to list or check the contents and/or attributes of objects that are currently installed on the system. Package names can be listed on the command line, or by default the entire contents of a machine is checked. If packages are installed in an alternative root directory path using the pkgadd command with the -P option, contents and attributes can be checked or listed using the same alternative root directory path specified with the -P option.

The second synopsis is used to list or check the contents of a package which has been spooled on the specified device, but not installed. Note that attributes cannot be checked for spooled packages.

The third synopsis is used to list or check the contents and/or attributes of objects which are described in the indicated *Pkgmap*.

Flags

Item	Description
-l	Lists information on the selected files that make up a package. It is not compatible with the **a**, **c**, **f**, **g**, and **v** flags.
-a	Audits the file attributes only, does not check file contents. Default is to check both.
-c	Audits the file contents only, does not check file attributes. Default is to check both.
-f	Corrects file attributes if possible. If used with the **-x** flag, it removes hidden files. When **pkgchk** is invoked with this flag it creates directories, named pipes, links, and special devices if they do not already exist.
-q	Enables quiet mode. Does not give messages about missing files.
-v	Enables verbose mode. Files are listed as processed.
-n	Ignores volatile or editable files. This should be used for most post-installation checking.

Item	Description
-x	Searches exclusive directories only, looking for files that exist that are not in the installation software database or the indicated *Pkgmap* file. (An exclusive directory is a directory created by and for a package; it should contain only files delivered with a package. If any non-package files are found in an exclusive directory, **pkgchk** reports an error.) If **-x** is used with the **-f** flag, hidden files are removed; no other checking is done. **Note:** To remove hidden files only, use the **-f** and **-x** flags together. To remove hidden files and check attributes and contents of files, use the **-f**, **-x**, **-c**, and **-a** flags together.
-p	Only checks the accuracy of the pathname or pathnames listed. "pathname" can be one or more pathnames separated by commas (or by white space, if the list is quoted).
-i	Reads a list of pathnames from *File* and compares this list against the installation software database or the indicated *Pkgmap* file. Pathnames that are not contained in "inputfile" are not checked.
-d	Specifies the device on which a spooled package resides. *Device* can be a directory pathname, or "-" which specifies packages in datastream format read from standard input.
-m	Requests that the package be checked against the pkgmap file *Pkgmap*.
-e	Requests that the pkginfo file named as *Envfile* be used to resolve parameters noted in the specified pkgmap file.
Pkginst	Defines a short string used to designate an abbreviation for the package name. (The term "package instance" is used loosely: it refers to all instantiations of *Pkginst*, even those that do not include instance identifiers.) To indicate all instances of a package, specify '*Pkginst*.*****', enclosing the command line in single quotes, as shown, to prevent the shell from interpreting the "*" character. Use the token "all" to refer to all packages available on the source medium.
-P *path*	Requests that the package in the alternate root directory path be checked.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion of script.
1	Fatal error. Installation process is terminated at this point.

Files

Item	Description
/usr/sbin/pkgchk	Contains the **pkgchk** command.

pkginfo Command

Purpose

Displays software package and/or set information.

Syntax

To Display Information on Installed Packages

pkginfo [**-q**] [**-x** | **-l**] [**-r**] [**-p** | **-i**] [**-a** *Arch*] [-P *Path*] [**-v** *Version*] [**-c** *Category1*,[*Category2*[, . . .]]] [*Pkginst* [, *Pkginst* [, . . .]]]

To Display Information on Packages Contained in the Specified Device

pkginfo [**-d** *Device*] [**-q**] [**-x** | **-l**] [**-a** *Arch*] [-P *Path*] [**-v** *Version*] [**-c** *Category1* [,*Category2*[, . . .]]] [*PkginstPkginst* [, *Pkginst* [, . . .]]]

Description

pkginfo displays information about software packages or sets that are installed on the system (as requested in the first synopsis) or that reside on a directory (as requested in the second synopsis). A package is a collection of related files and executable that can be independently installed. A set is made up of a special-purpose package, referred to as a Set Installation Package (SIP), and a collection of one or more packages that are members of the set. The SIP controls the installation of the set.

When run without flags, **pkginfo** displays one line of information about every installed package (whether installed completely or partially) whose category is not the value "set". The information displayed includes the primary category, package instance, and name of the package. For UNIX software packages produced before UNIX System V Release 4, **pkginfo** displays only the package name and abbreviation.

The **-p** and **-i** flags are meaningless if used in conjunction with the **-d** flag. The **-p** and **-i** flags are mutually exclusive. The **-x** and **-l** flags are mutually exclusive.

Flags

Item	Description
-q	Enables quite mode - no information is displayed. This flag overrides the **-x**, **-l**, **-p**, and **-i** flags. (Can be invoked by a program to query whether or not a package has been installed.)
-x	Extracts and displays the following information about the specified package: abbreviation, name, and, if available, architecture and version.
-l	Displays a "long format" report (that is, one that includes all available information) about the specified package(s).
-r	Lists the installation base for the specified package if the package is relocatable.
-p	Displays information only for partially installed packages.
-i	Displays information only for fully installed packages.
-a *Arch*	Specifies the architecture of the package as *Arch*.
-P *Path*	Displays information for packages installed in the alternative root directory path.
-v *Version*	Specifies the version of the package as *Version*. All compatible versions can be requested by preceding the version name with a tilde "~".

Item	Description
-c *Category . . .*	Displays information about packages that belong to category *Category*. (Categories are defined in the category field of the **pkginfo** file; see the **pkginfo** file format for details.) More than one category may be specified in a comma-separated list. A package is required to belong to only one category, even when multiple categories are specified. The package-to-category match is not case-sensitive. If the category specified is "set", **pkginfo** displays information about Set Installation Packages (SIPs).
Pkginst	Defines a short string used to designate an abbreviation for the package/set name. (The term "package instance" is used loosely: it refers to all instantiations of *Pkginst*, even those that do not include instance identifiers.) To indicate all instances of a package, specify '*Pkginst***.***', enclosing the command line in single quotes, as shown, to prevent the shell from interpreting the "*" character. Use the token "all" to refer to all packages available on the source medium. If *Pkginst* is a SIP, information about the packages with which the SIP is associated is displayed.
-d *Device*	Displays information from packages/sets that reside on *Device*. *Device* can be the full pathname to a directory (such as **/var/tmp**), or "**-**" which specifies packages in datastream format read from standard input. The default device is the installation spool directory (**/var/spool/pkg**).

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion of script.
1	Fatal error. Installation process is terminated at this point.

Files

Item	Description
/var/spool/pkg	Default spool directory

pkgmk Command

Purpose

Produces an installable package.

Syntax

pkgmk [**-c**] [**-o**] [**-a** *Arch*] [**-b** *BaseDir*] [**-d** *Directory*] [**-f** *Prototype*] [**-l** *Limit*] [**-p** *PStamp*] [**-r** *RootPath*] [**-v** *Version*] [*Variable*=*Value* ...] [*PkgInst*]

Description

pkgmk produces an installable package to be used as input to the **pkgadd** command. A package is a collection of related files and executables that can be independently installed. The package contents will be in directory structure format.

The **pkgmk** command uses the package prototype file as input and creates a **pkgmap** file. The contents for each entry in the prototype file is copied to the appropriate output location. Information concerning the contents (checksum, file size, modification date) is computed and stored in the **pkgmap** file, along with attribute information specified in the prototype file.

Flags

Item	Description
-a *Arch*	Overrides the architecture information provided in the **pkginfo** file with *Arch*.
-b *BaseDir*	Prepends the indicated *BaseDir* to locate relocatable objects on the source machine.
-c	Compresses non-information files. You must also specify the **-r** option when using **-c**. Entries in the *Prototype* file that reference relative paths above the *RootPath* specification will not be compressed. Any files that were already compressed (that is, only those in ".Z" form) before being processed by **pkgmk** will not be uncompressed by the **pkgadd** command.
-d *Directory*	Creates the package in *Directory*. The directory named must already exist.
-f *Prototype*	Uses the file *Prototype* as input to the command. The default name for this file is either **Prototype** or **prototype**. You can use **pkgproto** to create the *Prototype* file. In this case, you must manually add in the entries for any installation scripts and files you are using in the package. You only need entries for those files and scripts that you use. However, you must always add an entry for the **pkginfo** file for the package. See **pkgproto** for more information.
-l *Limit*	Specifies the maximum size in 512-byte blocks of the output device as *Limit*. By default, if the output file is a directory or a mountable device, **pkgmk** will employ the **df** command to dynamically calculate the amount of available space on the output device. Useful in conjunction with **pkgtrans** to create a package with datastream format.
-o	Overwrites the same instance. The package instance will be overwritten if it already exists.
-p *PStamp*	Overrides the production stamp definition in the **pkginfo** file with *PStamp*.
-r *RootPath*	Appends the source pathname in the *Prototype* file to the indicated *RootPath* to locate objects on the source machine.

Item	Description
-v *Version*	Overrides version information provided in the **pkginfo** file with *Version*.
Variable=*Value*	Places the indicated variable in the packaging environment.
PkgInst	A short string used to designate an abbreviation for the package name. **pkgmk** will automatically create a new instance if the version and/or architecture is different. A user should specify only a package abbreviation; a particular instance should not be specified unless the user is overwriting it.

Examples

1. If you want to create a package named mypkgA containing the **lsps** and **lsuser** commands, you must first create the contents of the package. For example:

```
mkdir -p /home/myuser/example/pkgmk/sbin
cp /usr/sbin/lsps /home/myuser/example/pkgmk/sbin
cp /usr/sbin/lsuser /home/myuser/example/pkgmk/sbin
```

   Then, create the **pkginfo** file. In this example the **pkginfo** file is /home/myuser/example/pkgmk/pkginfo, which contains the following:

```
PKG="mypkgA"
NAME="My Package A"
ARCH="PPC"
RELEASE="1.0"
VERSION="2"
CATEGORY="Application"
PSTAMP="AIX  2001/02/05"
```

   Then, create the *Prototype* file, /home/myuser/example/pkgmk/prototype file which contains the following:

```
!search /home/myuser/example/pkgmk/sbin
i pkginfo=/home/myuser/example/pkgmk/pkginfo
d example /example 1777 bin bin
d example /example/pkgmk 1777 bin bin
d example /example/pkgmk/sbin 1777 bin bin
f example /example/pkgmk/sbin/lsps 555 bin bin
f example /example/pkgmk/sbin/lsuser 555 bin bin
```

   Then, create the package with the above *Prototype* and **pkginfo** files using the **pkgmk** command:

```
pkgmk -d /tmp -f /home/myuser/example/pkgmk/prototype
```

   This produces the following output:

```
Building pkgmap from package prototype file
## Processing pkginfo file
    WARNING:parameter <CLASSES> set to "example"

## Attempting to volumize 5 entries in pkgmap
Part  1 -- 218 blocks, 10 entries
/tmp/mypkgA/pkgmap

/tmp/mypkgA/root/example/pkgmk/sbin/lsps
/tmp/mypkgA/root/example/pkgmk/sbin/lsuser
## Packaging complete
```

   The newly created package named mypkgA now exists in /tmp/mypkgA.

Exit Status

Item	Description
0	Successful completion of script.
1	Fatal error. Installation process is terminated at this point.
99	Internal error.

Files

Item	Description
/usr/sbin/pkgmk	Contains the **pkgmk** command.

pkgparam Command

Purpose

Displays package parameter values.

Syntax

To Display the Value of a Parameter Contained in pkginfo

pkgparam [**-v**] [**-d** *Device*] [-P *path*] *Pkginst* [*Param* **...**]

To Display the Value of a Parameter Contained in a Device

pkgparam -d *Device* [**-v**] [*Param* **...**]

To Display the Value of a Parameter Contained in a File

pkgparam -f *File* [**-v**] [*Param* **...**]

Description

pkgparam displays the value associated with the parameter or parameters requested on the command line. The values are located in one of the following places: in the **pkginfo** file for *Pkginst*, on the *Device* named with the **-d** flag, or on the specific file named with the **-f** flag. When a *Device* is given, but a *Pkginst* is not (as shown in the second synopsis), parameter information for all packages residing on *Device* is shown.

If packages are installed in an alternative root directory path using the pkgadd command with the -P option, package parameters can be requested using the same alternative root directory path specified with the -P option.

One parameter value is shown per line. Only the value of a parameter is given unless the **-v** flag is used. With this flag, the output of the command is in this format:

```
Parameter1='Value1'
Parameter2='Value2'
Parameter3='Value3'
```

If no parameters are specified on the command line, values for all parameters associated with the package are shown.

Flags

Item	Description
-v	Specifies verbose mode. Displays name of parameter and its value.

Item	Description
-d *Device*	Specifies the *Device* on which a *Pkginst* is stored. *Device* can be the full pathname to a directory (such as **/var/tmp**), or "**-**" which specifies packages in datastream format read from standard input.
-f	Requests that the command read *File* for parameter values. This file should be in the same format as a **pkginfo** file. As an example, such a file might be created during package development and used while testing software during this stage.
Pkginst	Defines a specific package for which parameter values should be displayed. The format *Pkginst*.* can be used to indicate all instances of a package. When using this format, enclose the command line in single quotes to prevent the shell from interpreting the "*" character.
Param	Defines a specific parameter whose value should be displayed.
-P *path*	Searches for the `pkginfo` file in the alternate root directory path.

Exit Status

If parameter information is not available for the indicated package, the command exits with a non-zero status.

Item	Description
0	Successful completion of script.
1	Fatal error. Installation process is terminated at this point.

Files

Item	Description
/var/spool/pkg	default spool directory
/usr/sbin/pkgparam	Contains the **pkgparam** command.

pkgproto Command

Purpose

Generates a prototype file.

Syntax

pkgproto [**-i**] [**-c** *Class*] [*Path1* [**=***Path2*] ...]

Description

The **pkgproto** commands scans the indicated paths and generates a prototype file that may be used as input to the **pkgmk** command. To do this, the standard output of this command must be redirected to a file. The file can then be used when invoking **pkgmk**.

If no *Paths* are specified on the command line, standard input is assumed to be a list of *Paths*. If the *Path* listed on the command line is a directory, the contents of the directory are searched. However, if input is read from stdin, a directory specified as a path is not searched.

The prototype file attributes *mac*, *fixed*, and *inherited*, cannot be determined by **pkgproto** and must be manually added to the file.

By default, **pkgproto** creates symbolic link entries for any symbolic link encountered (ftype=s). When you use the **-i** flag, **pkgproto** creates a file entry for symbolic links (ftype=f). The prototype file must be edited to assign file types such as v (volatile), e (editable), or x (exclusive directory). **pkgproto** detects linked files. If multiple files are linked together, the first path encountered is considered the source of the link.

The output from this command is sent to standard output. You must redirect standard output to a file if you wish to use the result as a prototype file when invoking **pkgmk**. Since **pkgmk** uses prototype as the default filename for the prototype file, we suggest you direct the output of **pkgproto** to the file name prototype.

You must add entries to the prototype file produced by this command for any installation scripts and files your package may need. At minimum, you will need an entry for the **pkginfo** file. You may also need entries for any of the following files you use in your package: **copyright**, **compver**, **depend**, **setinfo**, **space**, any installation or removal scripts you define for the package, and/or any classes you define.

Note:

1. By default, **pkgproto** creates symbolic link entries for any symbolic link encountered (ftype=s). When you use the `-i` option, **pkgproto** creates a file entry for symbolic links (ftype=f). The prototype file must be edited to assign file types such as v (volatile), e (editable), or x (exclusive directory). **pkgproto** detects linked files. If multiple files are linked together, the first path encountered is considered the source of the link.
2. The output from this command is sent to standard output. You must redirect standard output to a file if you wish to use the result as a prototype file when invoking **pkgmk**. Since **pkgmk** uses prototype as the default filename for the prototype file, we suggest you direct the output of **pkgproto** to the file name **prototype**.
3. Note that you must add entries to the **prototype** file produced by this command for any installation scripts and files your package may need. At minimum, you will need an entry for the **pkginfo** file; see **pkginfo** for more information. You may also need entries for any of the following files you use in your package: **copyright**, **compver**, **depend**, **setinfo**, **space**, any installation or removal scripts you define for the package, and/or any classes you define, (e.g., postinstall).

Flags

Item	Description
-i	Ignores symbolic links and records the paths as ftype=f (a file) versus ftype=s (symbolic link).
-c *Class*	Maps the class of all paths to *Class*.
Path1	Path of directory where objects are located.
Path2	Path that should be substituted on output for *Path1*.

Examples

The following examples show uses of **pkgproto** and a partial listing of the output produced.

1.
```
$ pkgproto /usr/bin=bin /usr/usr/bin=usrbin /etc=etc
f none bin/sed=/bin/sed 0775 bin bin
f none bin/sh=/bin/sh 0755 bin daemon
f none bin/sort=/bin/sort 0755 bin bin
d none etc/master.d 0755 root daemon
f none etc/master.d/kernel=/etc/master.d/kernel 0644 root daemon
f none etc/rc=/etc/rc 0744 root daemon
```

2.
```
   $ find / -type d -print | pkgproto
   d none / 755 root root
   d none /usr/bin 755 bin bin
   d none /usr 755 root root
   d none /usr/bin 775 bin bin
   d none /etc 755 root root
   d none /tmp 777 root root
```

3. Identical to the previous example, but with the output captured in a file for later processing with **pkgmk**. Entries added for the required **pkginfo** file, and, for instance, a postinstall script that might be executed after the files are copied into the correct locations.

```
$ find / -type d -print | pkgproto >prototype
$ (edit the file to add entries for pkginfo and postinstall)
$ cat prototype
i pkginfo
i postinstall
d none / 755 root root
d none /usr/bin 755 bin bin
d none /usr 755 root root
d none /usr/bin 775 bin bin
d none /etc 755 root root
d none /tmp 777 root root
```

Return Codes

Item	Description
0	Successful completion of script.
1	Fatal error. Installation process is terminated at this point.

Files

Item	Description
/usr/sbin/pkgproto	Contains the **pkgproto** command

pkgrm Command

Purpose

Removes a package or set from the system.

Syntax

To Remove an Installed Software Package

pkgrm [**-n**] [**-a** *Admin*] [-P *Path*] [*Pkginst1* [*Pkginst2* [. . .]]]

To Remove a Software Package from a Spool Device

pkgrm -s *Spool* [*Pkginst*]

Description

pkgrm removes a previously installed or partially installed package/set from the system. A package is a collection of related files and executables that can be independently installed. A set is made up of a special-purpose package, referred to as a Set Installation Package (SIP), and a collection of one or more packages that are members of the set.

pkgrm checks that all packages listed on the command line are on the system. If any of the packages listed does not exist, no changes are made to the system, that is, none of the listed packages are removed.

A check is also made to determine if any other packages depend on the one being removed. The action taken if a dependency exists is defined in the *Admin* file (see the **-a** flag, below).

The default state for the command is interactive mode, meaning that prompt messages are given during processing to allow the administrator to confirm the actions being taken. Non-interactive mode can be requested with the **-n** flag.

The **-s** flag can be used to specify the directory from which spooled packages should be removed.

Flags

Item	Description
-n	Enables non-interactive mode. If there is a need for interaction, the command exits. Use of this flag requires that at least one package instance be named upon invocation of the command.
-a *Admin*	Defines an installation administration file, *Admin*, to be used in place of the default administration file. [For a description of the format of an *Admin* file, see the **admin** file format.] The token "none" overrides the use of any *Admin* file, and thus forces interaction with the user. Unless a full pathname is given, **pkgrm** looks in the **/var/sadm/install/admin** directory for the file. By default, the file **default** in that directory is used.
-P *Path*	Removes the specified packages from the alternative root directory path.
-s *Spool*	Removes the specified package(s) from the directory *Spool*.
Pkginst	Defines a short string used to designate an abbreviation for the package/set name. (The term "package instance" is used loosely: it refers to all instantiations of *Pkginst*, even those that do not include instance identifiers.) If *Pkginst* specifies a SIP, all installed packages which are members of the set, and the SIP itself, are removed in reverse dependency order. To indicate all instances of a package, specify '*Pkginst*.*', enclosing the command line in single quotes, as shown, to prevent the shell from interpreting the "*" character. Use the token "all" to refer to all packages available on the source medium.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion of script.
1	Fatal error. Installation process is terminated at this point.
99	Internal error.

Files

Item	Description
/usr/sbin/pkgrm	Contains the **pkgrm** command

pkgtrans Command

Purpose

Translates package format.

Syntax

pkgtrans [**-i** **-o** **-n** **-s**] [**-z** *Blocksize*] *Device1* *Device2* [*Pkginst1* [*Pkginst2* [...]]]

Description

The **pkgtrans** command translates an installable package from one format to another. It translates the following:

- A file system format to a datastream
- A datastream to a file system format

You cannot run **pkgtrans** from **csh**.

Flags

Item	Description
-i	Copies the **pkginfo** and *Pkgmap* files. If the packages category is defined as "set" for Set Installation Packages (SIPs) (see **setinfo** file format), then that packages' **setinfo** file is also copied.
-o	Overwrites the same instance on the destination device. The package instance is overwritten if it already exists.
-n	Creates a new instance of the package on the destination device. If the package instance already exists on the destination device, it is left unchanged and a new instance is created. The new instance has a sequence number attached to distinguish it from the existing instance. For example, assume the destination device already contained an instance of package *X*. If you use **pkgtrans** with the **-n** flag to write a new instance of package *X* to the device, the existing instance of package *X* remains on the destination device, and a new instance, called *X.2*, would be created on the device. If you executed **pkgtrans** again with the **-n** flag, a third instance, called *X.3*, would be created.
-s	Indicates that the package should be written to *Device2* as a datastream rather than as a file system. The default behavior is to write to *Device2* in the file system format.
-z *Blocksize*	Indicates the blocksize to be used when transferring to cartridge tape. Packages that have been written to tape using the **-z** flag and a value not equal to 512 are always read using a blocksize of 32768. Thus, the **-z** flag is not applicable when reading from cartridge tape.
Device1	Indicates the source device. Can be - (hyphen) which specifies packages in datastream format read from standard input. The package or packages on this device are translated and placed on *Device2*. If *Device1* is a regular file or directory, you must use the absolute pathname, rather than a relative pathname.
Device2	Indicates the destination device. Can be - (hyphen) which specifies packages written to standard output in datastream format. Translated packages are placed on this device. If *Device2* is a regular file or directory, you must specify it as an absolute pathname, rather than a relative pathname.
Pkginst	Specifies which package on *Device1* should be translated. The token "all" may be used to indicate all packages. *Pkginst.** can be used to indicate all instances of a package. If no packages are defined, a prompt shows all packages on the device and asks which to translate. If a set is being transferred to datastream format, the *Pkginst* arguments should begin with the SIP and be followed by the packages listed in the SIP's **setinfo** file, in the order in which they appear in that file.

Note: By default, **pkgtrans** does not transfer any instance of a package if any instance of that package already exists on the destination device. Use of the **-n** flag creates a new instance if an instance of this package already exists. Use of the **-o** flag overwrites the same instance if it already exists. Neither of these flags are useful if the destination device is a datastream, because the entire datastream is overwritten anyway.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion of script.
1	Fatal error. Installation process is terminated at this point.

Files

Item	Description
/usr/sbin/pkgtrans	Contains the **pkgtrans** command.

Examples

1. To translate all packages located on drive *Device* and place the translations in **/tmp**, type:

```
pkgtrans Device /tmp all
```

2. To translate "pkg1" and "pkg2" in **tmp** and place them on *Device* in a datastream format, type:

```
pkgtrans -s /tmp Device pkg1 pkg2
```

platform_dump Command

Purpose

Perform platform (Hardware & Firmware) dump related actions.

Syntax

`platform_dump` { `-c` | `-d` | `-e` | `-f` *fstype* | `-F` *flag* | `-l` | `-q` | `-S` | `-s` *seq_no* } [`-L`]

Description

The `platform_dump` command was introduced in AIX to support hardware and firmware problem determination for POWER5 platforms. You can use this command to help the operating system save firmware-related and hardware-related dumps. This command is supported only on partitions which have service authority enabled, except for Hardware Management Console (HMC) managed systems. On an HMC managed system, the dumps go to the HMC. The `platform_dump` command is normally run by operating system functions such as base installation and dumpcheck. Platform dumps contain:

- The hardware state
- The hypervisor state
- The FSP (Flexible Service Processor) state information

The disk space for platform dump files is reserved using the `platform_dump` command. A dedicated logical volume, **/dev/fwdump**, is created in the rootvg volume group and mounted on the **/var/adm/ras/platform** directory. The **fwdump_dev** device and **fwdump_dir** mount point are both saved in ODM in the SWservAt object class. During installation, AIX utilizes the `platform_dump` command to reserve the necessary disk space. The disk space is reserved only if the partition is designated to be a service partition. The maximum possible size for the platform dumps is indicated to AIX so that enough space can be allocated beforehand for the platform dumps. Note that this size can change dynamically. The operating system detects this and informs you about the extra requirements and automatically expands the logical volume if possible.

Note: If you assign service partition authority to an AIX partition after the partition was installed, run the `platform_dump -f <fstype>` command to create the **/dev/fwdump** rootvg logical volume. The *fstype* argument can have the **jfs2** or **jfs** value.

The `-L` flag is provided to record command output to the error log.

Flags

Item	Description
`-c`	Performs a check on the estimated platform dump size (as indicated by the firmware) and the disk space allocated for the platform dumps. It will report the following: If estimated size is less than or equal to allocated space, will return 0. If estimated size is greater than allocated space, will return 1.
`-d`	Deletes the file system space reserved for platform dumps and free up the same for other uses. Any existing dump files on the reserved disk space will be lost.
`-e`	Provides an estimate of disk space required to save the platform dumps when they occur. This option will interact with the firmware to provide this estimate. It is expected that, based on this space information, the user will have enough disk space allocated for platform dumps to be saved. The value output will be the required size in bytes.
`-f` *fstype*	Reserves enough disk space on the system for platforming dumps. The `-f` option will create a file system (if one does not exist) exclusively for platform dumps. If a file system already exists and the size is not enough, the file system size will be increased. The *fstype* must be a valid file system type. If the file system already exists, `any` may be specified.
`-F` *flag*	Enables or disables platform dumps. If flag is 0, platform dumps are disabled, if 1, platform dumps are enabled.
`-l`	Lists the current configuration of platform dump.
`-L`	Tells `platform_dump` to log its output as well as displaying it. This does not apply to the size output by the `-e` option.
`-q`	Checks whether the platform supports platform dumps or not. Will return 0 if platform dump is supported.
`-s` *seq_no*	Saves the platform dump from the firmware as identified in the dump notification event. *seq_no* indicates the sequence number of the dump notification event as stored in the AIX error log file. This sequence number will be used by this command to parse the detailed data area and obtain dump tag and dump type information needed to obtain the dump data from firmware.
`-S`	Saves the scan dumps on systems which support scan data. When this option is specified, the command will check for the existence of a scan dump, and if so will read and save the `scandump` data from firmware using the existing scan dump interface.

Exit Status

0
On successful completion.

1
Returned if `-c` was specified, and there is insufficient space to save platform dumps.

255
Returned if platform dumps are not supported on the system.

3
Returned if platform dumps has been disabled.

2
Returned in an error is encountered.

Security

The `platform_dump` may only be executed by the root user.

Example

1. To get an estimate of the platform dumps size, type the following:

   ```
   platform_dump -e
   ```

   This will report the estimated platform dump size in bytes.

plotgbe Command

Purpose

Plots HP-GL files to a plotter device.

Syntax

/usr/lpd/plotgbe [**-fr=***X*] [**-noin**] *File*

Description

The **plotgbe** command is a backend program which plots HP-GL files to a plotter device. The plotter device must be attached to a 5085/5086 workstation via the 5080 Attachment Adapter. To use the **plotgbe** command, you must define a print queue for the **plotgbe** backend program. See **enq** command, use the **-o** flag to pass options to the **plotgbe** backend for processing.

The **plotgbe** backend command also generates the appropriate HP-GL commands for plotter initialization and plot scaling. This data is sent to the plotter before the user-specified HP-GL file is sent. Thus, any scaling or initialization commands included in the HP-GL file override those generated by the **plotgbe** backend command.

> **Note:** The user must have read access to the file sent to the **plotgbe** command with the print request command.

Flags

Item	Description
-fr=*X*	Provides for plotting multi-frame drawings. This option causes *X* number of frames to be plotted, where *X* is a number in the range 1 through 9. For example, plotting a 20' drawing on E-size role media may require 5 frames. Thus, the option `fr=5` would be passed to the **plotgbe** backend.
-noin	Allows plotter front panel settings to remain in effect for the current plot without being reset to default values. Normally, the P1 and P2 positions which define the plot page on the plotter are set by the **plotgbe** command to their default location. Use the **-noin** no-initialization option to override the default locations.

Examples

1. To send the file `longaxis.gl` to the `plt` plotter queue and specify to the backend that the file requires five frames to print, enter:

```
enq -Pplt -o -fr=5 longaxis.gl
```

2. To send the file `plotdata.gl` to the `plt` plotter queue, specifying that the plot page positions are not to be reset to default for this file, enter:

```
enq -Pplt -o -noin plotdata.gl
```

3. To send the file `twoplot.gl` to the `plt` plotter queue, specifying no plot page initialization and that the plotter print the drawing in two frames, enter:

```
enq -Pplt -o -noin -o fr=2 twoplot.gl
```

Files

Item	Description
/usr/lpd/plotgbe	Contains the **plotgbe** command.

plotlbe Command

Purpose

Plots HP-GL files to a plotter device.

Syntax

/usr/lpd/plotlbe [**-fr=***X*] [**-noin**] *File*

Description

The **plotlbe** command is a backend program which plots HP-GL files to a plotter attached to a serial port defined as a TTY device. To use the **plotlbe** command, you must define a TTY device for the serial port and define a print queue for the **plotlbe** backend program.

When configuring the TTY serial port, set the baud-rate, parity, and stop bits to the appropriate settings for your plotter. You must also set XON/XOFF to FALSE for your TTY port.

The **plotlbe** command is called by the **qdaemon** process. It should not be entered on the command line. Any options needed for a specific print request to a plotter should be passed to the **plotlbe** command with the command used to request a print job (usually the **enq** command). With the **enq** command, use the **-o** flag to pass options to the **plotlbe** backend for processing.

The **plotlbe** backend command supports the following plotters: 7731, 7372, 7374, 7375-1, 7375-2, 6180, 6182, 6184, 6186-1, and 6186-2.

The **plotlbe** command supports ENQ/ACK handshaking. Refer to your plotter programming manual for more information on handshaking.

The **plotlbe** backend command also generates the appropriate HP-GL commands for plotter initialization and plot scaling. This data is sent to the plotter before the user-specified HP-GL file is sent. Thus, any scaling or initialization commands included in the HP-GL file override those generated by the **plotlbe** backend command.

> **Note:** The user must have read access to the file sent to the **plotlbe** command with the print request command.

Flags

Item	Description
-fr=*X*	Provides for plotting multi-frame drawings. This option causes *X* number of frames to be plotted, where *X* is a number in the range 1 through 9. For example, plotting a 20' drawing on E-size roll media may require 5 frames. Thus, the option `-fr=5` would be passed to the **plotlbe** backend.
-noin	Allows plotter front panel settings to remain in effect for the current plot without being reset to default values. Normally, the P1 and P2 positions which define the plot page on the plotter are set by the **plotlbe** command to their default locations. Use the **-noin** no-initialization option to override the default locations.

Examples

1. To send the file `longaxis.gl` to the `plt` plotter queue and specify to the backend that the file requires five frames to plot, enter:

```
enq -Pplt -o -fr=5 longaxis.gl
```

2. To send the file `plotdata.gl` to the `plt` plotter queue, specifying that the plot page positions are not to be reset to default for this file, enter:

```
enq -Pplt -o -noin plotdata.gl
```

3. To send the file `twoplot.gl` to the `plt` plotter queue, specifying no plot page initialization and that the plotter print the drawing in two frames, enter:

```
enq -Pplt -o -noin -o fr=2 twoplot.gl
```

Files

Item	Description
/usr/lpd/plotlbe	Contains the **plotlbe** command.

pmctl Command

Purpose

Starts, resets, or stops generating Performance Monitor events.

Syntax

pmctl [{ [**-E** [*mode*]] [**-f** *interval*] {[**-y** *command*]} } | [**-h**] | [**-r**] | [**-S**]] [**-s**] [{ **-a** **-y** *command* [**-f** *interval*] }]

Description

The **pmctl** command starts, stops, or resets the generation of Performance Monitor events in the PMAPI subsystem to support manual offline mode with the **tprof -E** command. It also reports the current status of the PMAPI subsystem.

Flags

Item	Description
-a	Turns on large page analysis.

Item	Description
-E [*mode*]	Enables event-based profiling. You can specify one of the following modes: **PM_*event*** Specifies the hardware event to profile. If no mode is specified for the **-E** flag, the default event is processor cycles (**PM_CYC**). **EMULATION** Enables the emulation profiling mode. **ALIGNMENT** Enables the alignment profiling mode. **ISLBMISS** Enables the Instruction Segment Lookaside Buffer miss profiling mode. **DSLBMISS** Enables the Data Segment Lookaside Buffer miss profiling mode.
-f *interval*	Specifies the sampling interval to use. • For processor cycle, **EMULATION**, **ALIGNMENT**, **ISLBMISS**, and **DSLBMISS** events, specify 1 to 500 milliseconds (default = 10). • For other Performance Monitor events, specify 10000 up to MAXINT occurrences (default = 10000). If you use the **-f** flag with the **-y** flag, specify 1 up to MAXINT occurrences for other Performance Monitor events (default = 10000).
-h	Prints man page information.
-r	Releases and resets the PMAPI subsystem.
-S	Stops generating Performance Monitor events.
-s	Prints the current status of the PMAPI subsystem.
-y *command*	Turns on the event-based profiling only for the specified command and its descendents.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To stop generating Performance Monitoring events, enter the following command:

```
pmctl –S
```

2. To reset generating Performance Monitoring events, enter the following command:

```
pmctl –r
```

3. To report the current status of the PMAPI subsystem, enter the following command:

```
pmctl –s
```

4. To start generating Performance Monitoring events, enter the following command:

```
pmctl –E
```

5. To start generating Performance Monitoring events only for the specified **workload** command and its descendents, enter the following command:

```
pmctl –E –y workload
```

6. To support the **tprof -E** command in manual offline mode, enter the following command:

```
trace -adf -o mydata.trc
trcon
pmctl –E
sleep 10; trcstop
gensyms > mydata.syms
tprof –suker mydata
```

7. To support the **tprof -E** command in manual offline mode profiling for the specified **workload** command and its descendents, enter the following command:

```
trace -adf -o mydata.trc
trcon
pmctl –E –y workload
trcstop
gensyms > mydata.syms
tprof –suker mydata
```

pmcycles Command

Purpose

Measures processor clock speed.

Syntax

pmcycles [**-d**] [**-m**]

Description

The **pmcycles** command displays the *nominal processor speed* for the system in MHz. The nominal processor speed is the maximum frequency at which the system can run across all environments and workload conditions. Depending on system conditions, the nominal processor frequency might not represent the minimum or maximum achievable processor speed.

The **lparstat -E 1 1** and **mpstat -E 1 1** commands must be used to determine the current processor speed. The **pmcycles** command might be deprecated in the future.

Flags

Item	Description
-d	Displays the decrementer in MHz and nanoseconds per tick.
-m	Displays the speed of each of the processors.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To display the processor speed, type:

```
pmcycles
```

   Output similar to the following appears:

```
This machine runs at 133 MHz
```

2. To display each processor speed, type:

```
pmcycles -m
```

   Output similar to the following appears:

```
Cpu 0 runs at 200 MHz
CPU 1 runs at 200 MHz
```

pmlist Command

Purpose

Lists information about supported processors.

Syntax

pmlist [**-h**]

pmlist -l [**-o t** | **c** | **x**]

pmlist { **-s** | **-e** *ShortName* | **-c** *Counter* [,*event*] | **-g** *Group* | **-S** *Set* | **-D** *DerivedMetricID* | **-m** *MetricGroup* | **-V** *Variable* } [**-p** *ProcessorType*] [**-s**] [**-d**] [**-o t** | **c** | **x**] [**-f** *Filter*]

Description

The **pmlist** command performs the following functions:

- List the supported processors.
- List the information summary for a specified processor.
- List the event table for a specified processor.
- List any existing event groups for a specified processor.
- List any existing event sets for a specified processor.
- List the event set and formula for a specified derived metric.
- List the variables in the derived metric files.

Flags

Item	Description
-c -1	Lists all events for all counters.
-c *Counter*	Lists all events for the specified *Counter*.
-c *Counter*,*Event*	Lists the specified *Event* for the specified *Counter*.
-d	Displays event detailed description.
-D -1	Displays all the derived metrics supported.
-D *DerivedMetricID*	Displays the specified *DerivedMetricID*.

Item	Description
-e *ShortName*	Lists the description of the specified *ShortName* for all Counters.
-f v,**u**,**c**	Specifies the event filter as a comma-separated list of filters. The valid filters are: **v** (verified) , **u** (unverified) , and **c** (caveat). These filters represent the testing status of an event. The default filter is **v,u,c**.
-g -1	Lists all event groups.
-g *Group*	Lists the specified event *Group*.
-h	displays help information for the **pmlist** command.
-l	Lists all supported processor types.
-m -1	Lists all derived metrics by metric group.
-m *MetricGroup*	Displays all the derived metrics that pertain to the specified *MetricGroup*.
-o t | **c** | **x**	Specifies the output format for the **pmlist** command. The valid output formats are specified as one of: **t** (text format), **c** (CSV format) and **x** (XML format). The default output format is text.
-p *ProcessorType*	Specifies the processor type.
-s	Displays the processor information summary.
-S -1	Displays all the event sets supported.
-S *Set*	Displays the specified event *Set*.
-V -1	Displays all the variables that are used to calculate derived metrics.
-V *Variable*	Displays the specified variable.

Examples

1. To display the list of all supported processors, type:

```
pmlist -l
```

2. To display a summary information for the current processor, type:

```
pmlist -s
```

3. To display a summary information for the current processor in CSV format, type:

```
pmlist -s -o c
```

4. To display group number 62 for the current processor (if the current processor supports event groups), type:

```
pmlist  -g 62
```

5. To display detailed information for event 3 of counter 1 of POWER4 processor, type:

```
pmlist -p POWER4 -c 1,3 -d
```

6. To display set number 2 for the current processor (if the current processor supports event sets), type:

```
pmlist -S 2
```

pmtu Command

Purpose

Displays and deletes Path MTU discovery related information.

Syntax

pmtu [**-inet6**] **display**/[**delete** [**-dst** *destination*] [**-gw** *gateway*]]

Description

The **pmtu** command is provided to manage the Path MTU information. The command can be used to display the Path MTU table. By default the Ipv4 pmtu entries are displayed. Ipv6 pmtu entries can be displayed using the **–inet6** flag. This command also enables a root user to delete a pmtu entry with the **pmtu delete** command. The delete can be based on destination, gateway, or both.

A pmtu entry gets added into the PMTU table when a route add occurs with an MTU value.

A network option, **pmtu_expire**, is provided to expire unused pmtu entries. The default value of **pmtu_expire** is 10 minutes.

Flags

Item	Description
-dst	Specifies the destination of the pmtu entry to be deleted.
-gw	Specifies the gateway of the pmtu entry to be deleted.
-inet6	Specifies to display or delete Ipv6 pmtu entry.

Exit Status

Item	Description
0	The command completed successfully.
1	An error occurred.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To display Ipv4 pmtu entries, type:

   ```
   pmtu display
   ```

   The output will look similar to the following:

   ```
   dst           gw               If    pmtu     refcnt   redisc_t    exp
    ------------------------------------------------------------------------
   ```

```
192.168.5.5   192.168.10.33    en2    1500        1          0       0
```

The reference count signifies the number of current TCP and UDP applications using this pmtu entry.

The `redisc_t` entry signifies the amount of time that is elapsed since the last Path MTU discovery attempt. The PMTU is rediscovered after every *pmtu_rediscover_interval* minutes. Its default value is 30 minutes and can be changed using the **no** command.

The PMTU entry expiry is controlled by the network option *pmtu_expire*. Its default value is 10 minutes. This value can be changed using the **no** command. A value of 0 does not expire any entries. The `exp` entry signifies the expiry time. PMTU entries having more than zero `refcnt` have `exp` of 0. When the `refcnt` becomes zero, the `exp` time increases every minute and the entry gets deleted when the **exp** variable becomes equal to *pmtu_expire*.

2. To delete an entry based on destination, type:

```
pmtu delete -dst 192.168.5.5
```

3. To display Ipv6 , type:

```
pmtu -inet6 display
```

Output will look similar to the following:

```
dst                       gw      If    pmtu     refcnt   redisc_t   exp
 ------------------------------------------------------------------------
fe80::204:acff:fee4:ab3b  ::    lo0   16896        2          2        0
```

Location

/usr/sbin/pmtu

Files

Item	Description
/usr/sbin/pmtu	Contains the **pmtu** command.

pop3d Daemon

Purpose

Starts the Post Office Protocol Version 3 (POP3) server process.

Syntax

pop3d [**-c**]

Description

The **pop3d** command is a POP3 server. It supports the POP3 remote mail access protocol. Also, it accepts commands on its standard input and responds on its standard output. You normally invoke the **pop3d** command with the **inetd** daemon with those descriptors attached to a remote client connection.

The **pop3d** command works with the existing mail infrastructure consisting of **sendmail** and **bellmail.**

Flags

Item	Description
-c	Suppresses the reverse host name lookup.

Parameters

Item	Description
None	

Exit Status

All error and status information is written to a logfile if **syslogd** is configured for logging.

Security

The **pop3d** daemon is a PAM-enabled application with a service name of *imap*. System-wide configuration to use PAM for authentication is set by modifying the value of the **auth_type** attribute, in the **usw** stanza of **/etc/security/login.cfg**, to PAM_AUTH as the root user.

The authentication mechanisms used when PAM is enabled depend on the configuration for the **imap** service in **/etc/pam.conf**. The **pop3d** daemon requires **/etc/pam.conf** entries for the **auth** and **session** module types. Listed below is a recommended configuration in **/etc/pam.conf** for the **imap** service:

```
#
# AIX imap configuration
#
imap auth      required     /usr/lib/security/pam_aix

imap session   required     /usr/lib/security/pam_aix
```

Note: Because the **pop3d** daemon uses the **imap** library for authentication, the **imap** service is used for both the **imapd** and **pop3d** daemons.

Files

Item	Description
/usr/sbin/pop3d	Contains the **pop3d** command.
html	

pop3ds Daemon

Purpose

Starts the Post Office Protocol Version 3 (POP3) server process over TLS/SSL.

Syntax

pop3ds [**-c**]

Description

The **pop3ds** command is a POP3 server. It supports the POP3 remote mail access protocol. Also, it accepts commands on its standard input and responds on its standard output. You normally invoke the **pop3d3** command with the **inetd** daemon with those descriptors attached to a remote client connection.

The **pop3ds** command works with the existing mail infrastructure consisting of **sendmail** and **bellmail.**

Flags

Item	Description
-c	Suppresses the reverse host name lookup.

Parameters

Item	Description
None	

Exit Status

All error and status information is written to a logfile if **syslogd** is configured for logging.

Security

The **pop3ds** daemon is a PAM-enabled application with a service name of *imap*. System-wide configuration to use PAM for authentication is set by modifying the value of the **auth_type** attribute, in the **usw** stanza of **/etc/security/login.cfg**, to PAM_AUTH as the root user.

The authentication mechanisms used when PAM is enabled depend on the configuration for the **imap** service in **/etc/pam.conf**. The **pop3ds** daemon requires **/etc/pam.conf** entries for the **auth** and **session** module types. Listed below is a recommended configuration in **/etc/pam.conf** for the **imap** service:

```
#
# AIX imap configuration
#
imap auth      required     /usr/lib/security/pam_aix

imap session   required     /usr/lib/security/pam_aix
```

Note: Because the **pop3ds** daemon uses the **imap** library for authentication, the **imap** service is used for both the **imapds** and **pop3ds** daemons.

Files

Item	Description
/usr/sbin/pop3ds	Contains the **pop3ds** command.
html	

portmap Daemon

Purpose

Converts RPC program numbers into Internet port numbers.

Syntax

/usr/sbin/portmap

Description

The **portmap** daemon converts RPC program numbers into Internet port numbers.

When an RPC server starts up, it registers with the **portmap** daemon. The server tells the daemon which port number it is listening to and which RPC program numbers it serves. Thus, the **portmap** daemon

knows the location of every registered port on the host and which programs are available on each of these ports.

A client consults the **portmap** daemon only once for each program the client tries to call. The **portmap** daemon tells the client which port to send the call to. The client stores this information for future reference.

Since standard RPC servers are normally started by the **inetd** daemon, the **portmap** daemon must be started before the **inetd** daemon is invoked.

> **Note:** If the **portmap** daemon is stopped or comes to an abnormal end, all RPC servers on the host must be restarted.

Flags

None

Examples

1. To start the **portmap** daemon, enter the following command:

```
startsrc -s portmap
```

2. To stop the **portmap** daemon enter the following command:

```
stopsrc -s portmap
```

Files

Item	Description
inetd.conf	Starts RPC daemons and other TCP/IP daemons.
/etc/rpc	Contains a list of server names and their corresponding **rpc** program numbers and aliases.

portmir Command

Purpose

Allows one TTY stream (monitor) to attach to another TTY stream (target) and monitor the user session that is taking place on that stream.

Syntax

portmir { **-d** *mir_modem* **-t** *target* [**-m** *monitor*] | **-t** *target* [**-m** *monitor*] | { **-o** | **-c** *monitor* | **-q** }

Description

The **portmir** command allows one TTY stream (monitor) to attach to another TTY stream (target) and monitor the user session that is taking place on that stream. This is accomplished by pushing a special "mirror" module into both the target and monitor TTY streams.

Both the target and monitor TTYs receive a printed message on their respective displays when a monitoring session begins. The monitoring session can be terminated from either the target TTY, monitor TTY, or a third TTY not involved in the monitoring session. When the monitor is used in a non-service mode, both streams must be in the open state (that is, either a getty or active session must be taking place on each TTY) in order for the command to work. This is necessary to allow the pushing of the "mirror" streams module. The **portmir** command is supported for use with TTY devices only (PTS, TTY, LFT).

The terminal type, as defined in the TERM environment variable, must be the same for both the monitor and target TTY. The value of this environment variable must correspond to a valid entry in the **terminfo** database. An example terminal type would be ibm3151 or vt100. The LFT is similar to the vt100. Terminal emulators such as `aixterm` are usually similar in function to vt100.

Although the console can be used as either the target TTY or the monitor TTY, using the console as the monitor TTY is not recommended. However, if the console is used as the monitor TTY, note that the console is first automatically redirected to the target TTY for the duration of the monitoring session. When the monitoring session is terminated, the console is redirected back to the device specified in the CuAt ODM database attribute **syscons**. If the console had been previously redirected, the redirection is not preserved.

Async devices that provide offloading of character processing may have problems if they are mirroring devices that rely on the line discipline (**ldterm**) to provide this function. An example of this would be the 128-port async adapter. Use the **chdev** command to disable the fastcook attribute if a port of a dissimilar adapter is monitored. Run the command as follows:

```
chdev -l tty1 -a fastcook -disable
```

Flags

Item	Description
-c *monitor*	Configures port for service boot by creating CuAt ODM database attribute **portmir_monitor**, which contains the **device** parameter as the value field. This device is used later as the default monitoring device when the **portmir** command is invoked in service mode (**-s** flag). Mirroring must be configured by the system administrator to execute at service boot time using the **-c** option. The target defaults to the device defined in the **portmir_monitor** attribute.
-d *mir_modem*	Sets monitoring port for dial-in purposes. Only the root user can issue the command with this flag. Ensure that **/usr/share/mir_modem** is linked to the correct modem setup file. **/usr/share/mir_modem** contains example files; you may need to create your own, depending on your type of modem.
-m *monitor*	Specifies monitoring device. If neither the **-m** option nor the **-s** option are specified, then the monitoring device defaults to the port on which the **portmir** command was run.
-o	Turns off monitoring and terminates the command.
-q	Queries the value set with the **-c** option.
-t *target*	Specifies target device to be monitored.

Security

Only a single mirror session may be running at any one time.

To mirror a port in the nonservice mode, place a list of users who may monitor them in a **.mir** file in your home directory (not required for the root user). When the **mirror** daemon begins running, the daemon checks to see who is on that port. It then checks to see if the user of the monitoring port is authorized to monitor that port.

The **.mir** file must have the format of a single user ID per line.

Attention: Running the **su** command to change to root user during a mirror session gives root authority to *both* users.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges,

see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. After **user1** has placed **user2**'s login ID into **/u/user2/.mir** file, to mirror **user1** on target **tty1** from **user2** on monitor **tty2**, enter:

```
portmir -t tty1 -m tty2
```

2. To mirror target **tty1** to user on monitor **tty2** who is dialing in, enter:

```
portmir -t tty1 -m tty2 -d mir_modem
```

3. To set up mirroring for service boot, specifying the monitoring device during the service boot, enter:

```
portmir -c tty
```

4. To disable mirroring during the service boot, enter:

```
portmir -c off
```

5. To query the service boot mirroring device, enter:

```
portmir -q
```

Files

Item	Description
/usr/share/modems/mir_modem	Modem configuration file examples for setting up dial-in.
/usr/sbin/portmir	Contains the command file.

post Command

Purpose

Routes a message.

Syntax

post [**-alias** *File ...*] [**-format** | **-noformat**] [**-msgid** | **-nomsgid**] [**-filter** *File* | **-nofilter**] [**-width** *Number*] [**-verbose** | **-noverbose**] [**-watch** | **-nowatch**] *File*

Description

The **post** command routes messages to the correct destinations. The **post** command cannot be started by the user. The **post** command can be called only by other programs.

The **post** command searches a message for all components that specify a recipient's address and parses each address to check for the proper format. The **post** command then puts addresses into the standard format and calls the **sendmail**command. The **post** command also performs header operations, such as appending the `Date:` and `From:` components and processing the `Bcc:` component. The **post** command uses the *File* parameter to specify the name of the file to be posted.

> **Note:** The **post** command may report errors when parsing complex addresses (for example, `@A:harold@B.UUCP`). If you use complex addresses, use the **spost** command instead of the **post** command.

Flags

Item	Description
-alias *File*	Searches the specified mail alias file for addresses. This flag may be repeated to specify multiple mail alias files. The **post** command automatically searches the **/etc/mh/MailAliases** file.
-filter *File*	Uses the header components in the specified file to copy messages sent to `Bcc:` recipients.
-format	Puts all recipient addresses into a standard format for the delivery transport system. This flag is the default.
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For Message Handler (MH), the name of this flag must be fully spelled out.
-msgid	Adds a message-identification component (such as `Message-ID:`) to the message.
-nofilter	Strips the `Bcc:` header from the message for the `To:` and `cc:` recipients. Sends the message with minimal headers to the `Bcc:` recipients. This flag is the default.
-noformat	Does not alter the format of the recipient addresses.
-nomsgid	Does not add a message-identification component to the message. This flag is the default.
-noverbose	Does not display information during the delivery of the message to the **sendmail** command. This flag is the default.
-nowatch	Does not display information during delivery by the **sendmail** command. This flag is the default.
-verbose	Displays information during the delivery of the message to the **sendmail** command. This information allows you to monitor the steps involved.
-watch	Displays information during the delivery of the message by the **sendmail** command. This information allows you to monitor the steps involved.
-width *Number*	Sets the width of components that contain addresses. The default is 72 columns.

Files

Item	Description
/etc/mh/MailAliases	Contains the default mail aliases.
/etc/mh/mtstailor	Contains MH command definitions.

pppattachd Daemon

Purpose

Attaches an asynchronous device stream to the PPP (Point to Point Protocol) subsystem. Can be invoked as a daemon or a normal process.

Syntax

To Use a Specific tty Port as a Connection (Runs as a Daemon):

pppattachd /dev/tty*PortNumber* { **client** | **server** | **demand** } { **ip** | **ipv6** | **ip ipv6** } [**multilink**] [**connect** "*ConnectorProgram*"] [**inactive** *Seconds*] [**authenticate pap** | **chap**] [**peer pap** | **chap**] [**user** *Name*] [**remote** *HostName*] [**nodaemon**]

To Use Standard In and Standard Out as the tty Device (Runs as a Process):

pppattachd { **client** | **server** | **demand** } { **ip** | **ipv6** | **ip ipv6** } [**multilink**] [**inactive** *Seconds*] [**authenticate pap** | **chap**] [**peer pap** | **chap**] [**user** *Name*] [**remote** *HostName*] [**nodaemon**]

Description

The **pppattachd** daemon provides the mechanism to bind an asynchronous stream to the PPP subsystem. When placing an out going connection on a specific tty port, **pppattachd** becomes a daemon. When using stdin (standard in) and stdout (standard out) as the tty device for PPP communications **pppattachd** does not become a daemon. (It would be executed from the **$HOME/.profile** upon login on a tty device.)

You can activate PAP or CHAP authentication with the **authenticate** and **peer** options. Use the **smit** command to create entries in either the **/etc/ppp/pap-secrets** or **/etc/ppp/chap-secrets** file. The **pppattachd** daemon uses the passwords in these files to authenticate the connection. It searches only the **/etc/ppp/pap-secrets** file for PAP authentication and the **/etc/ppp/chap-secrets** file for CHAP authentication.

The multilink option is to used to identify the PPP link as having several attachments between the two PPP peers. PPP packets are fragmented at one peer, sent over the multiple attachments, and then reconnected on the remote peer that must also support multilink. The maximum receive reconstruction unit (MMRU) and endpoint descriptor are set through SMIT on the PPP Link Configuration menu. MRRU is the maximum data size before fragmentation. The endpoint discriminator uniquely identifies the local system.

Errors and messages are logged using the **syslog** facility.

Options

Item	Description
authenticate pap | **chap**	Defines the current system as the authenticator of either PAP or CHAP.
client | **server** | **demand**	Defines the type of subsystem connection to be bound to on the system running the daemon.
ip | **ipv6** | **ip ipv6**	Specifies protocol types.
connect "*ConnectorProgram*"	Specifies the program to use to place an outgoing connection. The tty device opened is passed as stdin and stdout to the program. The **/usr/sbin/pppdial** command is a connector program that can be used.
inactive *Seconds*	Specifies the number (unsigned integer) of seconds to wait for inactivity on the link before terminating the connection. The default value is 0 (no timeout).
multilink	Identifies the PPP link as having a group of attachments connecting to two PPP peers.
nodaemon	Specifies to the attachment process that it is not to become a daemon. You must use this option for attachment processes that are invoked with demand connections.
peer pap | **chap**	Defines the current system as the peer of either PAP or CHAP.

Item	Description
remote *HostName*	Defines the remote host name to be used for PAP authentication. An entry for *UserName RemoteHostName Password* must exist in **/etc/ppp/pap-secrets** file for a successful connection. This option only has meaning for PAP authentication on both the authenticator and peer.
user *Name*	Defines the user entry to use for PAP authentication. An entry for *UserName RemoteHostName Password* must exist in **/etc/ppp/pap-secrets** file for a successful connection. This option only has meaning for PAP authentication on the peer.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
!0	An error occurred.

Security

Access Control: Any User

Auditing Events: N/A

Examples

1. You want System A to act as a client to server System B. From System A enter:

   ```
   /usr/sbin/pppattachd /dev/tty0 client ip connect "sysbconnector"
   ```

   where `sysbconnector` is the connector program.

   On System B, the user that logged in would have invoked from **$HOME/.profile**:

   ```
   exec /usr/sbin/pppattachd server ip 2>/dev/null
   ```

2. You want server System B to contact client System A. From System B enter:

   ```
   /usr/sbin/pppattachd /dev/tty0 server ipv6 connect "sysaconnector"
   ```

   where `sysaconnector` is the connector program.

   On System A, the user that logged in would have invoked from **$HOME/.profile**:

   ```
   exec /usr/sbin/pppattachd client ipv6 2>/dev/null
   ```

3. You want System A to act as a client to server System B using PAP authentication. System B acts as the authenticator and System A is the peer to be authenticated. From System A enter:

   ```
   /usr/sbin/pppattachd /dev/tty0 client ip ipv6 peer pap user username \
   connect "sysbconnector"
   ```

   where `sysbconnector` is the connector program.

   On System A, the **/etc/ppp/pap-secrets** file contains: username * ppppassword. On System B, the user that logged in would have invoked from **$HOME/.profile**:

   ```
   exec /usr/sbin/pppattachd server ip ipv6 authenticate pap 2>/dev/null
   ```

On System B, the **/etc/ppp/pap-secrets** file contains: username * ppppassword.

Files

Item	Description
/usr/sbin/pppattachd	Contains the **pppattachd** daemon.
/etc/ppp/att*XXX*.pid	Contains the process id. *XXX* is the pid, the content of the file is the network layer ID to which the attachment was bound. The user must belong to uucp group for the pid file to be created.

pppcontrold Daemon

Purpose

Controls startup and management of the PPP (Point to Point Protocol) subsystem.

Syntax

To Start and Stop by Using the System Resource Controller:

startsrc -s pppcontrold

stopsrc -s pppcontrold

Description

The **pppcontrold** daemon reads in the **/etc/ppp/lcp_config** and **/etc/ppp/if_conf** files to install and configure the PPP subsystem. SMIT should be used to generate both /etc/ppp/lcp_config and /etc/ppp/if_conf. To modify these files the user must have root authority or be a member of the uucp group. The configuration files are read at initialization where the appropriate streams modules are configured and loaded, and the tcpip network interface layers are installed into the system. After configuring the subsystem, the **pppcontrold** daemon monitors the streams associated with the IP and IPv6 interfaces to perform operations such as setting IP addresses, and the flags of the IP and IPv6 interface. The **pppcontrold** daemon terminates upon reciept of SIGTERM or when the **stopsrc** command is invoked. The prefered method of starting and stopping the **pppcontrold** daemon is with SRC (System Resource Controller). You must have root authority to run the src commands.

Errors and messages are logged using the **syslog** facility.

The **pppcontrold** daemon creates the **/etc/ppp/pppcontrold.pid** file, which contains a single line with the command process ID used to terminate the **pppcontrold** daemon.

Flags

None

/etc/ppp/lcp_config File

This file provides the configuration information required for the subsystem. These values are used to ensure proper allocation of storage at the time the subsystem is configured. It is important to configure just what is needed since these values define storage that is allocated within the kernel. Blank lines and lines beginning with a # (pound sign) are ignored in the configuration file. Do not use blank lines or lines beginning with # (pound sign) within the interface definition. Only use these lines between interface definitions.

Required Keywords	
server_name *name*	Name of this system. This name should be unique to the system. Ensure that the first 20 bytes of the name are unique.

Required Keywords

lcp_server #	Number of server connections. Represents the number of server connections that the subsystem will allow. Storage for all specified connections is allocated at the time the subsystem is configured. The minimum value is 0 and the maximum value is gated by the amount of memory in the system.
lcp_demand #	Specify the maximum number of demand links that you want the PPP LCP multiplexor to support. Set this value to the number of demand interfaces that you expect to configure. The default value is 0.
lcp_client #	Number of client connections. The minimum value is 0 and the maximum value is gated by the amount of memory in the system. Client connections are IP and IPv6 interfaces configured without addresses.
num_if #	Number of IP and IPv6 interfaces to configure. Must be less than or equal to lcp_server + lcp_client.
num_if6 #	Maximum number of TCP/IPv6 interfaces to allow. The value is a decimal number. This number, along with "max ip interfaces" and "max ip & ipv6 interfaces", cannot be greater than total maximum number of server, client and demand links (max server links + max client links + max demand links = max ip interfaces + max ipv6 interfaces + max ip & ipv6 interfaces). When a machine is used solely as a client connecting up to one server, this field would be set to 1. On a server, this field would be set to the maximum number of IPv6 clients that can simultaneously connect to the server. In this case, make sure that you have enough IPv6 interfaces defined.
num_if_and_if6 #	Maximum number of TCP/IP and IPv6 interfaces to allow. The value is a decimal number. This number along with "max ip interfaces" and "max ipv6 interfaces" cannot be greater than total maximum number of server, client and demand links (max server links + max client links + max demand links = max ip interfaces + max ipv6 interfaces + max ip & ipv6 interfaces). When a machine is used solely as a client connecting up to one server, this field would be set to 1. On a server, this field would be set to the maximum number of IP and IPv6 clients that can simultaneously connect to the server. In this case, make sure that you have enough IP and IPv6 interfaces defined.
num_hdlc #	Maximum number of concurrent asynchronous PPP sessions (server, client and demand) that can be active. This field is a decimal number. The value can not be greater than the total maximum number of server, client and demand links ([max server connections + max client connections + max demand connections] = max async hdlc attachments = [max ip interfaces + max ipv6 interfaces + max ip & ipv6 interfaces]).

Optional Keywords

These keywords will override the global default LCP options.

Item	Description
txacm *0xXXXXXXXX*	Transmit Asynchronous Character Map.
-negacm	Do not negotiate async character mapping. Rejects the peers configuration information frames that contains this option.

Item	Description
-negmru	Do not negotiate MRU (Maximum Receive Unit). Rejects the peers configuration information frames that contains this option.
mru #	MRU desired. A default is 1500.
-negacf	Do not negotiate ACF (address control field) compression. ACF will not be compressed. Rejects the peers configuration information frames that contain this option.
-negprotocolcompress	Do not negotiate protocol compression. Normally, the PPP protocol field will be compressed by one byte for Network protocols. This disables negotiation of this option for both receiving and sending frames.

/etc/ppp/if_conf File

This file defines all the server TCP/IP interfaces. Blank lines and lines beginning with a # (pound sign) are ignored in the configuration file. Do not use blank lines or lines beginning with # (pound sign) within the interface definition . Only use these lines between interface definitions.

Keywords

interface Indicates that a new interface definition is being started.

`ip` and `ipv6` Specifies the protocol or protocols used for this interface and will coincide with the local_ip, local_ip6, remote_ip, and remote_ip6 keywords. These keywords can be used alone or in combination.

server Indicates that the interface is a server connection.

Requires the following keywords:

local_ip xxx.yyy.zzz.qqq

remote_ip xxx.yyy.zzz.qqq

local_ip6 ::XXXX:XXXX:XXXX:XXXX

remote_ip6 ::XXXX:XXXX:XXXX:XXXX

These addresses MUST be different on the pair basis, however the local IP and IPv6 address can be the same for all PPP interfaces. On a given server, the remote address must be unique. The "interface" "server" entry will contain only local_ip and remote_ip addresses if the smitty PPP IP Interfaces menu is used to configure the interface. remote_ip6 and local_ip6 will be seen in the entry if the smitty PPP IPv6 Interfaces menu is used. Finally, all four will be found if smitty PPP IP and IPv6 Interfaces is used.

client This is an IPv6 option only. A client interface is required for all IPv6 connections. The address will be randomly generated based on the system model and ID. You can elect to zero out the address, (::0:0:0:0 or simply ::) and have the server assign an IPv6 address to the client. An example **if_conf** file entry follows:

```
interface
client
ipv6
local_ip6 ::0000:0000:0000:0000

interface
client
ip
ipv6
local_ip6 ::0007:0000:0000:4445
```

Keywords

demand There is a local_XXX and remote_XXX that are dependant on the protocol type (IP, IPv6 or both). A quoted command string is also required to establish connection with the authenticating host (server). An example **if_conf** file entry follows:

```
interface
demand
ipv6
local_ip6 ::0007:0000:0000:4444
remote_ip6 ::0009:0000:0000:5555
dcmd "exec /usr/sbin/pppattachd /dev/tty3 demand ipv6 >/dev/tty3 nodaemon"

interface
demand
ip
ipv6
local_ip 44.44.44.46
remote_ip 66.66.66.66
netmask 255.255.255.0
local_ip6 ::0007:0000:0000:4446
remote_ip6 ::0009:0000:0000:6666
dcmd "exec /usr/sbin/pppattachd /dev/tty4 demand ip ipv6 >/dev/tty4 nodaemon"
```

Optional Keywords

netmask xxx.xxx.xxx.xxx Specifies a netmask for an IPv4 interface.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
!0	An error occurred.

Security

Access Control: You must have root authority to run this command.

Examples

Example **/ect/ppp/lcp_config** File:

```
# Comment line
server_name pppclient
lcp_server 0
lcp_client 3
lcp_demand 2
num_if 1
num_if6 2
num_if_and_if6 2
num_hdlc 5
```

Example **/ect/ppp/if_conf** File:

```
# Sample ip server configuration information.
# Note that the complete stanza does not contain
# comments or blank lines
interface
server
ip
local_ip 129.35.130.45
remote_ip 129.35.131.191
netmask 255.255.240.0

# Sample ipv6 server configuration information.
# Note that the complete stanza does not contain
```

```
# comments or blank lines
interface
server
ipv6
local_ip6 ::0009:2313:4C00:3193
remote_ip6 ::0009:2313:4C00:3194

#However between stanzas one can have blank or
# comment lines.

interface
server
ip
local_ip 129.35.130.45
remote_ip 129.35.131.196
netmask 255.255.240.0

interface
server
ip
local_ip 129.35.130.45
remote_ip 129.35.131.197
netmask 255.255.240.0

interface
server
ip
local_ip 129.35.130.45
remote_ip 129.35.131.201
netmask 255.255.240.0

interface
server
ip
local_ip 129.35.130.45
remote_ip 129.35.131.212
netmask 255.255.240.0
```

The above configuration files would result in a subsystem that installs the IP and IPv6 interfaces as follows:

```
pp0: flags=71<UP,POINTOPOINT,NOTRAILERS>
     inet 129.35.130.45 --> 129.35.131.191 netmask 0xfffff000
pp1: flags=31<UP,POINTOPOINT,NOTRAILERS>
     inet 129.35.130.45 --> 129.35.131.196 netmask 0xfffff000
pp2: flags=31<UP,POINTOPOINT,NOTRAILERS>
     inet 129.35.130.45 --> 129.35.131.197 netmask 0xfffff000
pp3: flags=31<UP,POINTOPOINT,NOTRAILERS>
     inet 129.35.130.45 --> 129.35.131.201 netmask 0xfffff000
pp4: flags=31<UP,POINTOPOINT,NOTRAILERS>
     inet 129.35.130.45 --> 129.35.131.212 netmask 0xfffff000
pp5: flags=30<POINTOPOINT,NOTRAILERS>
     inet netmask
```

Note: pp5 is the result of the lcp_client keyword in the /etc/ppp/lcp_config file (lcp_client 1). Both IP and IPv6 client interfaces will have no address associated with them until a connection" is established with the server and the IPs are negotiated through IPCP/IPV6CP. The only exception is with demand client interfaces. These interfaces will specify their own address and demand it during negotiation. As such, they will have their IP and IPv6 address associated with their interface as soon as the PPP subsystem is started.

Files

Item	Description
/usr/sbin/pppcontrold	Contains the **pppcontrold** daemon.
/etc/ppp/lcp_config	Configures the subsystem (**lcp_config** should be generated by SMIT).
/etc/ppp/if_conf	Configures the TCP/IP interfaces (**if_conf** should be generated by SMIT).
/etc/ppp/pppcontrold.pid	Contains the **pppcontrold** process id.
/etc/ppp/ppp.conf	Contains input to the **strload** command.

pppdial Command

Purpose

Establish an asynchronous connection with a remote system for use by the PPP (Point to Point Protocol) subsystem.

Syntax

pppdial [**-t** *TimeOut*] [**-v**] [**-d** *VerboseFile*] **-f** *ChatFile*

Description

The **pppdial** command provides the capability to establish a connection with a remote system over an asynchronous device. It is used with the **pppattachd** daemon as the means for carrying out the dialog with modems and remote systems to the point where PPP frames should be sent. The **pppdial** command uses standard input (stdin) and standard output (stdout) as the devices over which the dialog occurs.

Errors and messages are logged using the **syslog** facility.

Flags

Item	Description
-d *VerboseFile*	Logs the chat activity to *VerboseFile*. If *VerboseFile* does not exist, the **pppdial** command creates it. If *VerboseFile* does exists, the **pppdial** command appends the output to the existing file.
-f *ChatFile*	Specifies the file which contains the dialog that is to occur over the tty device. The content of *ChatFile* conforms to the syntax of the Basic Networking Utility (BNU)/UNIX to UNIX Copy Program (UUCP).
-t *TimeOut*	Specifies the number of seconds to wait before timing out during the **Expect** phase of the chat activity.
-v	Logs the chat activity using the syslog facility.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
!0	An error occurred.

Security

Access Control: Any User

Examples

To establish a connection with a remote system, enter on the command line in one line:

```
/usr/sbin/pppattachd client ip /dev/tty0 connect "/usr/sbin/pppdial
-v -f /home/pppuser/dialer.file"
```

The *ChatFile* named `/home/pppuser/dialer.file` contains:

```
''
atdt4311088
CONNECT
\\d\\n
ogin
pppuser
ssword
pppuserpwd
```

with the following meaning:

```
''            Expect a nul string
atdt4311088   Send the modem the dial command
              4311088 is the phone number to dial
CONNECT       Expect connect from the modem
\\d\\n        Delay for 1 second then send a new line
ogin          Expect the string ogin
pppuser       Send the string pppuser
              pppuser is the user id on the remote system
ssword        Expect the string ssword
pppuserpwd    Send the string pppuserpwd
              pppuserpwd is the password of the user pppuser on the
              remote system
```

The remote system must have a user `pppuser` defined with a password `pppuserpwd` and a **$HOME/.profile** containing:

```
exec pppattachd server ip ipv6 2>/dev/null
```

This is a very simplistic example. The example requires that the PPP subsystem is running on both the client and server (or remote) system. The example requires that the client system have a modem defined on `/dev/tty0`. The *ChatFile* contains the number 4311088 to dial. The remote system must also have a user defined with a password and a **.profile** which starts a PPP attachment on the remote system. The device (`/dev/tty0`), phone number, user, user password and mechanism starting the PPP attachment are variable and should reflect the current values on the server system.

Files

Item	Description
/usr/sbin/pppdial	Contains the **pppdial** command.

pppstat Command

Purpose

Extracts and displays the RAS (Reliability, Availability, and Serviceability) information of the PPP (Point to Point Protocol) subsystem.

Syntax

pppstat

Description

The **pppstat** command provides the capability to monitor particular characteristics of active links. The following information is displayed for all active links:

LCP Multiplexing Layer

Item	Description
Local MRU	Specifies the Maximum Receive Unit setting for this host. This is maximum length of a packet that the remote host can send to the local host.
Remote MRU	Specifies the Maximum Receive Unit setting for the remote host. This is the maximum length of a packet that we can send to the remote host.
Local To Peer ACCM	Specifies the ASYNC Character Map used in the transmission of packets to the remote host.
Peer To Local ACCM	Specifies the ASYNC Character Map used by the remote host in the transmission of packets to the local host.
Local To Remote Protocol Field Compression	Specifies whether Protocol Compression is used in the transmission of packets to the remote host.
Remote To Local Protocol Field Compression	Specifies whether Protocol Compression is used in the transmission of packets from the remote host to the local host.
Local To Remote Address/Control Field Compression	Specifies whether Address/Control field compression is being used in the transmission of packets to the remote host.
Remote To Local Address/Control Field Compression	Specifies whether Address/Control field compression is being used in the transmission of packets from the remote host to the local host.

LCP Multiplexing Layer prior to PPP negotiating

Item	Description
MRU	Specifies the Maximum Receive Unit for receiving packets. This is the value that this host attempted to negotiate with the remote host.
Receive ACCM	Specifies the initial remote-to-local ASYNC Character Map that was used in the negotiation.
Transmit ACCM	Specifies the initial local-to-remote ASYNC Character Map that was used in the negotiation.
Magic Number	Specifies the magic number attempted in negotiation.
Frame Check Size	Specifies the length of the Frame Check Sequence that this host attempted to negotiate. This is fixed at 16 bits.

HDLC Framing Layer

Item	Description
Bad Address Fields	Specifies the number of times a packet has been received with an incorrect address field.
Bad Controls Fields	Specifies the number of times a packet has been received with an incorrect control field.
Oversized Packets	Specifies the number of times a packet has been received that has a length that exceeds the Maximum Receive Unit length.
Bad Frame Check Sequence	Specifies the number of times a packet has been received with a bad Frame Check Sequence.

Item	Description
Incoming Good Octets	Specifies the number of octets received in valid packets.
Outgoing Good Octets	Specifies the number of octets sent successfully in packets.
Incoming Good Packets	Specifies the number of packets received successfully.
Outgoing Good Packets	Specifies the number of packets sent successfully.

The output is sent to **stdout**. Messages are sent to **stderr**.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Access Control: Any User

Auditing Events: N/A

Files

Item	Description
/usr/sbin/pppstat	Contains the **pppstat** command.

pprof Command

Purpose

Reports CPU usage of all kernel threads over a period of time.

Syntax

pprof { *time* | **-I** *pprof.flow* | **-i** *tracefile* | **-d** } [**-T** *bytes*] [**-v**] [**-s**] [**-n**] [**-f**] [**-p**] [**-w**] [**-r PURR**] [**-@** [*WparList* | **ALL**]

Description

The **pprof** command reports on all kernel threads running within an interval using the **trace** utility. The raw process information is saved to **pprof.flow**, and five reports are generated. The **pprof** command can also take previously generated **Pprof.flow** to regenerate reports. If no flags are specified, all reports are generated.

Types of Reports

Item	Description
pprof.cpu	Lists all kernel level threads sorted by actual cpu time. Contains: Process Name, Process ID, Parent Process ID, Process State at Beginning and End, Thread ID, Parent Thread ID, Actual CPU Time, Start Time, Stop Time, Stop - Start The WPAR name is also provided when the **-@** flag with no argument has been selected.
pprof.start	Lists all kernel threads sorted by start time. Contains: Process Name, Process ID, Parent Process ID, Process State Beginning and End, Thread ID, Parent Thread ID, Actual CPU Time, Start Time, Stop Time, Stop - Start The WPAR name is also provided when the **-@** flag with no argument has been selected.
pprof.namecpu	Lists information about each type of kernel thread (all executable with the same name). Contains: Process Name, Number of Threads, CPU Time, % of Total CPU Time The WPAR name is also provided when the **-@** flag with no argument has been selected.
pprof.famind	Lists all processes grouped by families (processes with a common ancestor). Child process names are indented with respect to the parent. Contains: Start Time, Stop Time, Actual CPU Time, Process ID, Parent Process ID, Thread ID, Parent Thread ID, Process State at Beginning and End, Level, Process Name. The WPAR name is also provided when the **-@** flag with no argument has been selected.
pprof.famcpu	Lists the information for all families (processes with a common ancestor). The Process Name and Process ID for the family is not necessarily the ancestor. Contains: Start Time, Process Name, Process ID, Number of Threads, Total CPU Time. The WPAR name is also provided when the **-@** flag with no argument has been selected.

Flags

Item	Description
-d	Waits for the user to execute **trcon** and **trcstop** from the command line.
-f	Specifies to only generate the **pprof.famcpu** and **pprof.famind** reports.
-i *tracefile*	Indicates to generate reports from a **tracefile**. The trace must contain the following hooks: 135,106,10C,134,139,465,467,00A
-I *pprof.flow*	Indicates to generate reports from a previously generated **pprof.flow**. Specifies to only generate the **pprof.namecpu** report.
-n	Specifies to only generate the **pprof.namecpu** report.
-p	Specifies to only generate the **pprof.cpu** report.
-r PURR	Uses PURR time instead of TimeBase in percent and CPU time calculation. Elapsed time calculations are unaffected.
-s	Specifies to only generate the **pprof.start** report.

Item	Description
-T	Sets the trace kernel buffer size in bytes. The default is 32000.
-v	Sets verbose mode (print extra details).
-w	Specifies to only generate **pprof.flow**.
-@ [*WparList* | **ALL**]	Displays WPAR information. **ALL** Lists all WPARs. ***WparList*** Specifies a comma-separated list of WPARs of interest.
time	Specifies the number of seconds to trace the system.

Note: Review the **/usr/lpp/perfagent/README.perfagent.tools** file for the latest on changes to the performance analysis tools.

pr Command

Purpose

Writes a file to standard output.

Syntax

pr [**+***Page*] [**-***Column* [**-a**] | **-m**] [**-d**] [**-F**] [**-r**] [**-t**] [**-e** [*Character*] [*Gap*]] [**-h** *Header*] [**-i** [*Character*] [*Gap*]] [**-l** *Lines*] [**-n** [*Character*] [*Width*]] [**-o** *Offset*] [**-s** [*Character*]] [**-w** *Width*] [**-x** [*Character*] [*Width*]] [**-f**] [**-p**] [*File* ... | **-**]

Description

The **pr** command writes the specified file or files to standard output. If you specify the **-** (minus sign) parameter instead of the *File* parameter, or if you specify neither, the **pr** command reads standard input. A heading that contains the page number, date, time, and name of the file separates the output into pages.

Unless specified, columns are of equal width and separated by at least one space. Lines that are too long for the page width are cut off. If standard output is a workstation, the **pr** command does not display error messages until it has ended.

Flags

Item	Description
-*Column*	Sets the number of columns to the value specified by the *Column* variable. The default value is 1. This option should not be used with the **-m** flag. The **-e** and **-i** flags are assumed for multicolumn output. A text column should never exceed the length of the page (see the **-l** flag). When the **-***Column* flag is used with the **-t** flag, use the minimum number of lines to write the output.
+*Page*	Begins the display with the page number specified by the *Page* variable. The default value is 1.
-a	Modifies the effect of the **-***Column* flag so that multiple columns are filled horizontally, from left to right. For example, if there are two columns, the first input line goes in column 1, the second goes in column 2, the third becomes line 2 of column 1, and so forth. If the **-a** flag is not specified, columns are created vertically.

Item	Description
-d	Produces double-spaced output.
-e[*Character*][*Gap*]	Expands tabs to character positions as follows: *Gap*+1, 2**Gap*+1, 3**Gap*+1, and so on. The default value of *Gap* is 8. Tab characters in the input expand to the appropriate number of spaces in order to line up with the next tab setting. If you specify a value for the *Character* variable (any character other than a digit), that character becomes the input tab character. The default value of the *Character* variable is the ASCII TAB character.
-F	Uses a form-feed character to advance to a new page. (Otherwise the **pr** command issues a sequence of line-feed characters.) Pauses before beginning the first page if the standard output is a workstation. This flag is equivalent to the **-f** flag.
-f	Uses a form-feed character to advance to a new page. (Otherwise the **pr** command issues a sequence of line-feed characters.) Pauses before beginning the first page if the standard output is a workstation. This flag is equivalent to the **-F** flag.
-h *Header*	Uses the specified header string as the page header. If the **-h** flag is not used, the page header defaults to the file name specified by the *File* parameter.
-i[*Character*][*Gap*]	Replaces white space wherever possible by inserting tabs to character positions, as follows: *Gap*+1, 2**Gap*+1, and 3**Gap*+1, and so forth. The default value of *Gap* is 8. If you specify a value for the *Character* variable (any character other than a digit), that character is used as the output tab character.
-l *Lines*	Overrides the 66-line default and resets the page length to the number of lines specified by the *Lines* variable. If the *Lines* value is smaller than the sum of both the header and trailer depths (in lines), the header and trailer are suppressed (as if the **-t** flag were in effect).
-m	Merges files. Standard output is formatted so the **pr** command writes one line from each file specified by the *File* parameter, side by side into text columns of equal fixed widths, based on the number of column positions. This flag should not be used with the **-** *Column* flag.
-n[*Character*][*Width*]	Provides line numbering based on the number of digits specified by the *Width* variable. The default is 5 digits. The line number occupies the first *Width*+1 column positions of each text column of default output, or of each line of output when the **-m** flag is set. If the *Character* variable is specified (any non-digit character), it is appended to the line number to separate it from what follows on the line. The default character separator is the tab character.
-o *Offset*	Indents each line by the number of character positions specified by the *Offset* variable. The total number of character positions per line is the sum of the width and offset. The default *Offset* value is 0.
-p	Pauses before beginning each page if the output is directed to a workstation. The **pr** command sounds the alarm at the workstation and waits for you to press the Enter key.
-r	Does not display diagnostic messages if the system cannot open files.
-s[*Character*]	Separates columns by the single character specified by the *Character* variable instead of by the appropriate number of spaces. The default value for the *Character* variable is an ASCII TAB character.

Item	Description
-t	Does not display the five-line identifying header and the five-line footer. Stops after the last line of each file without spacing to the end of the page.
-w *Width*	Sets the width of line to width column positions for multiple text-column output only. If the **-w** option is not specified and the **-s** option is not specified, the default width is 72. If the **-w** is not specified and the **-s** option is specified, the default width is 512. For single column output, input lines will not be truncated.
-x[*Character*][*Width*]	Provides the same line numbering functions as the **-n** flag.

Exit Status

This command returns the following exit values:

Item	Description
0	All files were successfully written.
>0	An error occurred.

Examples

1. To print a file with headings and page numbers on the printer, type:

   ```
   pr prog.c | qprt
   ```

   This adds page headings to the **prog.c** file and sends it to the **qprt** command. The heading consists of the date the file was last modified, the file name, and the page number.
2. To specify a title, type:

   ```
   pr  -h "MAIN PROGRAM" prog.c | qprt
   ```

   This prints the **prog.c** file with the title Main Program in place of the file name. The modification date and page number are still printed.
3. To print a file in multiple columns, type:

   ```
   pr -3 word.lst | qprt
   ```

   This prints the **word.lst** file in three vertical columns.
4. To print several files side by side on the paper:

   ```
   pr -m -h "Members and Visitors" member.lst visitor.lst | qprt
   ```

   This prints the **member.lst** and **visitor.lst** files side by side with the title Members and Visitors.
5. To modify a file for later use, type:

   ```
   pr -t -e prog.c > prog.notab.c
   ```

   This replaces tab characters in the **prog.c** file with spaces and puts the result in **prog.notab.c** file. Tab positions are at every eighth column (that is 9, 17, 25, 33, . . .). The **-e** flag tells the **pr** command to replace the tab characters; the **-t** flag suppresses the page headings.

Files

Item	Description
/usr/bin/pr	Contains the **pr** command.

Item	Description
/dev/tty*	Suspends messages.

praliases Command

Purpose

Displays mail aliases of the system.

Syntax

praliases [**-C** *file*] [**-f** *file*] [key]

Description

The **praliases** command displays current aliases of the system for each line, in no particular order. The special internal `@:@` alias is displayed, if present.

Flags

Item	Description
-C *file*	Reads the specified sendmail configuration file instead of the default sendmail configuration file.
-f *file*	Reads the specified file instead of the configured aliases files of the sendmail file.
key	Displays entries that match the keys, if one or more keys are specified on the command line.

Note: The **praliases** command exits with `0` on success and with `>0` if an error occurs.

Files

Item	Description
/etc/mail/ sendmail.cf	Contains the default sendmail configuration file.

prctmp Command

Purpose

Displays the session record files.

Syntax

/usr/sbin/acct/prctmp *File...*

Description

A user with administrative authority can enter the **prctmp** command to display the session record file created by the **acctcon1** command, normally the **/var/adm/acct/nite/ctmp** file. The session record file is converted into the connect-time total accounting record by the **acctcon2** command and then incorporated into the daily accounting report.

Security

Access Control: This command should grant execute (x) access only to members of the **adm** group.

Example

To display the session record file, enter:

```
prctmp /var/adm/acct/nite/ctmp
```

This command displays the session record file created by the **acctcon1** command.

Files

Item	Description
/usr/sbin/acct	The path to the accounting commands.
/var/adm/acct/nite	Contains accounting data files.

prdaily Command

Purpose

Creates an ASCII report of the previous day's accounting data.

Syntax

/usr/sbin/acct/prdaily [**-X**] [**-l**] [*mmdd*] [**-c**]

Description

The **prdaily** command is called by the **runacct** command to format an ASCII report of the previous day's accounting data. The report resides in the **/var/adm/acct/sum/rprt***mmdd* file, where *mmdd* specifies the month and day of the report.

Flags

Item	Description
-c	Reports exceptional resource usage by command. This flag may be used only on the current day's accounting data.
-l [*mmdd*]	Reports exceptional usage by login ID for the specified date. Use the *mmdd* variable to specify a date other than the current day.
-X	Processes all available characters for each user name instead of truncating to the first 8 characters. This flag will also cause the **prdaily** command to use the **/var/adm/acct/sumx** directory instead of the **/var/adm/acct/sum** directory.

Security

Access Control: This command should grant execute (x) access only to members of the **adm** group.

Files

Item	Description
/usr/sbin/acct	The path to the accounting commands.

Item	Description
/usr/sbin/acct/ptelus.awk	Calculates the limits for exceptional usage by login ID. This is a shell procedure.
/usr/sbin/acct/ptecms.awk	Calculates the limits of exceptional usage by command name. This is a shell procedure.
/var/adm/acct/sum	Cumulative directory for daily accounting records.
/var/adm/acct/sumx	Cumulative directory for daily accounting records when long user name processing is requested.

preparevsd Command

Purpose

Makes a virtual shared disk available.

Syntax

`preparevsd` {`-a` | *vsd_name*...}

Description

The **preparevsd** command brings the specified virtual shared disks from the stopped state to the suspended state. The virtual shared disks are made available. Open and close requests are honored, while read and write requests are held until the virtual shared disks are brought to the active state. If they are in the suspended state, this command leaves them in the suspended state.

You can use the System Management Interface Tool (SMIT) to run this command. To use SMIT, enter:

```
smit vsd_mgmt
```

and select the **Prepare a Virtual Shared Disk** option.

Under normal circumstances, you should not issue this command. The recoverable virtual shared disk subsystem uses this command to manage shared disks in a controlled manner. If you issue this command, the results may be unpredictable.

Flags

-a
Specifies that all the virtual shared disks in the stopped state are to be prepared.

Parameters

vsd_name
Specifies a virtual shared disk. If the virtual shared disk is not in the stopped state, you will get an error message.

Security

You must have `root` authority to run this command.

Restrictions

You must issue this command from a node that is online in the peer domain. To bring a peer domain online, use the **startrpdomain** command. To bring a particular node online in an existing peer domain, use

the **startrpnode** command. For more information on creating and administering an RSCT peer domain, refer to *RSCT Administration Guide* .

Under normal circumstances, you should not issue this command. The recoverable virtual shared disk subsystem uses this command to manage shared disks in a controlled manner. If you issue this command, the results may be unpredictable.

Examples

To bring the virtual shared disk **vsd1vg1n1** from the stopped state to the suspended state, enter:

```
preparevsd vsd1vg1n1
```

Location

/opt/rsct/vsd/bin/preparevsd

preprpnode Command

Purpose

Prepares a node to be defined to a peer domain.

Syntax

`preprpnode` [`-k`] [`-h`] [`-TV`] *node_name1* [*node_name2* ...]

`preprpnode -f` | `-F` { *file_name* | `"-"` } [`-k`] [`-h`] [`-TV`]

Description

The `preprpnode` command prepares security on the node on which the command is run so it can be defined in a peer domain. It allows for peer domain operations to be performed on this node and must be run before the node can join a peer domain using the `mkrpdomain` or `addrpnode` command.

Before the `mkrpdomain` command is issued on a node, the `preprpnode` command must be run on each node to be defined to the new peer domain, using the name of the node that is to run the `mkrpdomain` command as the parameter. This gives the `mkrpdomain` node the necessary authority to create the peer domain configuration on each new node and set up additional security.

Before the `addrpnode` command is issued on a node, the `preprpnode` command must be run on each node that is to be added, using the names of all online nodes as the parameters. This gives the online nodes the authority to perform the necessary operations on the new node.

The `preprpnode` command performs the following:

1. Establishes trust with the node names specified on the command by adding their public keys to the trusted host list.
2. Modifies the resource monitoring and control (RMC) access control list (ACL) file to enable access to peer domain resources on this node from the other nodes in the peer domain. This allows peer domain operations to occur on the node. The RMC subsystem is refreshed so that these access changes will take effect.
3. RMC remote connections are enabled.

If the nodes that are to be defined to a peer domain are already in a management domain, you do not need to exchange public keys. You can use the `-k` flag to omit this step.

Flags

-f | -F { *file_name* | "–" }
Reads a list of node names from *file_name*. Each line of the file is scanned for one node name. The pound sign (#) indicates that the remainder of the line (or the entire line if the # is in column 1) is a comment.

Use `-f "-"` or `-F "-"` to specify STDIN as the input file.

-k
Specifies that the command should not exchange public keys.

-h
Writes the command's usage statement to standard output.

-T
Writes the command's trace messages to standard error. For your software service organization's use only.

-V
Writes the command's verbose messages to standard output.

Parameters

***node_name1* [*node_name2 ...*]**
Specifies the node (or nodes) from which peer domain commands can be accepted. Typically, this is the name of the node that will be running the `mkrpdomain` command when forming the peer domain. When adding to the peer domain, it is a list of the nodes that are currently online in the peer domain. The node name is the IP address or the long or short version of the DNS host name. The node name must resolve to an IP address.

Security

The user of the `preprpnode` command needs write permission to the access control list (ACL) file. Permissions are specified in the ACL file. See the *RSCT: Administration Guide* for details on the ACL file and how to modify it.

Exit Status

0
The command ran successfully.

1
An error occurred with RMC.

2
An error occurred with a command-line interface script.

3
An incorrect flag was entered on the command line.

4
An incorrect parameter was entered on the command line.

5
An error occurred that was based on incorrect command-line input.

Restrictions

This command must run on a node that will be defined to the peer domain.

Implementation Specifics

This command is part of the Reliable Scalable Cluster Technology (RSCT) fileset for AIX.

Standard Input

When the `-f "-"` or `-F "-"` flag is specified, this command reads one or more node names from standard input.

Standard Output

When the `-h` flag is specified, this command's usage statement is written to standard output. All verbose messages are written to standard output.

Standard Error

All trace messages are written to standard error.

Examples

1. Suppose `mkrpdomain` will be issued from `nodeA`. To prepare `nodeB`, `nodeC`, and `nodeD` to be defined to a new peer domain, `ApplDomain`, run this command on `nodeB`, on `nodeC`, and then on `nodeD`:

   ```
   preprpnode nodeA
   ```

2. Suppose `nodeA` and `nodeB` are online in `ApplDomain`. To prepare `nodeC` to be added to the existing domain, run this command on `nodeC`:

   ```
   preprpnode nodeA nodeB
   ```

   Alternatively, create a file called `onlineNodes` with these contents:

   ```
   nodeA
   nodeB
   ```

   Then, run this command on `nodeC`:

   ```
   preprpnode -f onlineNodes
   ```

Location

/opt/rsct/bin/preprpnode

Files

The access control list (ACL) file — `/var/ct/cfg/ctrmc.acls` — is modified. If this file does not exist, it is created.

prev Command

Purpose

Shows the previous message.

Syntax

prev [**+***Folder*] [**-header** | **-noheader**] [**-showproc** *CommandString* | **-noshowproc**]

Description

The **prev** command displays the previous message in a folder. The **prev** command is similar to the **show** command with the **prev** value specified.

The **prev** command passes any flags that it does not recognize to the **showproc** program.

Flags

Item	Description
+*Folder*	Specifies the folder that contains the message you want to show.
-header	Displays a one-line description of the message being shown. The description includes the folder name and the message number. This flag is the default.
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For Message Handler (MH), the name of this flag must be fully spelled out.
-noheader	Prevents display of a one-line description of each message.
-noshowproc	Uses the **/usr/bin/cat** command to list the previous command.
-showproc *CommandString*	Uses the specified command string to perform the listing.

Profile Entries

The following entries are part of the *UserMhDirectory*/**.mh_profile** file:

Item	Description
`Current-Folder:`	Sets the default current folder.
`Path:`	Specifies the *UserMhDirectory*.
`showproc:`	Specifies the program used to show messages.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To display the previous message in the current folder, enter:

   ```
   prev
   ```

   The system responds with a message similar to the following:

   ```
   (Message schedule: 10)
   ```

   The text of the message is also displayed. In this example, message `10` in the current folder `schedule` is the previous message.
2. To show the previous message in the `meetings` folder, enter:

   ```
   prev  +meetings
   ```

   The system responds with a message similar to the following:

   ```
   (Message inbox: 5)
   ```

   In this example, message 5 in the `meetings` folder is the previous message.

Files

Item	Description
$HOME/.mh_profile	Contains the MH user profile.
/usr/bin/prev	Contains the **prev** command.

printenv Command

Purpose

Displays the values of environment variables.

Syntax

printenv [*Name*]

Description

The **printenv** command displays the values of environment variables. If you specify the *Name* parameter, the system only prints the value associated with the *Name* parameter. If you do not specify the *Name* parameter, the **printenv** command displays the current environment, showing one *Name* **=***Value* sequence per line.

If you specify a *Name* parameter that you have not defined in the environment, the **printenv** command returns an exit status of 1; otherwise it returns a status of 0 (zero).

Examples

1. To find the current setting of the **MAILMSG** environment variable, enter:

   ```
   printenv MAILMSG
   ```

2. The command returns the value of the **MAILMSG** environment variable. For example:

   ```
   YOU HAVE NEW MAIL
   ```

printf Command

Purpose

Writes formatted output.

Syntax

printf *Format* [*Argument* ...]

Description

The **printf** command converts, formats, and writes its *Argument* parameters to standard output. The *Argument* parameters are formatted under control of the *Format* parameter. The formatted output line cannot exceed **LINE_MAX** bytes in length.

The following environment variables affect the execution of the **printf** command:

Item	Description
LANG	Determines the locale to use for the locale categories when both **LC_ALL** and the corresponding environment variable (beginning with **LC_**) do not specify a locale.
LC_ALL	Determines the locale to be used to override any values for locale categories specified by the setting of **LANG** or any other **LC_** environment variable.
LC_CTYPE	Determines the locale for the interpretation of sequences of bytes of text data as characters; for example, single versus multibyte characters in parameters.
LC_MESSAGES	Determines the language in which messages should be written.
LC_NUMERIC	Determines the locale for numeric formatting. This environment variable affects the format of numbers written using the **e, E, f, g,** and **G** conversion characters.

The *Format* parameter is a character string that contains three types of objects:

- Plain characters copied to the output stream.
- Conversion specifications, each of which cause 0 or more items to be retrieved from the value parameter list.
- The following escape sequences. When copied to the output stream, these sequences cause their associated action to be displayed on devices capable of the action:

Item	Description
****	Backslash
\a	Alert
\b	Backspace
\f	Form feed
\n	New line
\r	Carriage return
\t	Tab
\v	Vertical tab
*****ddd*	Where *ddd* is a one-, two-, or three-digit octal number. These escape sequences are displayed as a byte with the numeric value specified by the octal number.

The *Argument* parameter is a list of one or more strings to be written to standard output under the control of the *Format* parameter.

The *Format* parameter is reused as often as necessary to satisfy the *Argument* parameters. Any extra **c** or **s** conversion specifications are evaluated as if a null string *Argument* were supplied; other extra conversion specifications are evaluated as if a 0 *Argument* were supplied. Where the *Format* parameter contains no conversion specifications and *Argument* parameters are present, the results are unspecified.

Each conversion specification in the *Format* parameter has the following syntax in this order:

1. A **%** (percent sign).
2. Zero or more options, which modify the meaning of the conversion specification. The option characters and their meanings are:

Item	Description
-	The result of the conversion is left-aligned within the field.
+	The result of a signed conversion always begins with a sign (+ or -).

Item	Description
blank	If the first character of a signed conversion is not a sign, a blank is prefixed to the result. If both the blank and + option characters are displayed, then the blank option character is ignored.
#	This option specifies that the value is to be converted to an alternate form. For **c**, **d**, **i**, **u**, and **s** conversions, the option has no effect. For **o** conversion, it increases the precision to force the first digit of the result to be a, 0 (zero). For **x** and **X** conversions, a nonzero result has 0x, or 0X prefixed to it, respectively. For **e**, **E**, **f**, **g**, and **G** conversions, the result always contains a radix character, even if no digits follow the radix character. For **g** and **G** conversions, trailing zeros are not removed from the result as they usually are.
0	For **d**, **i**, **o**, **u**, **x**, **e**, **E**, **f**, **g**, and **G** conversions, leading zeroes (following any indication of sign or base) are used to pad to the field width, no space padding is performed. If the **0** (zero) and the **-** (minus sign) options are displayed, the **0** (zero) option is ignored. For **d**, **i**, **o**, **u**, **x**, and **X** conversions, if a precision is specified, the **0** (zero) option is ignored.

Note: For other conversions, the behavior is undefined.

3. An optional decimal digit string that specifies the minimum field width. If the converted value has fewer characters than the field width, the field is padded on the left to the length specified by the field width. If the left-adjustment option is specified, the field is padded on the right. If the result of a conversion is wider than the field width, the field is expanded to contain the converted result. No truncation occurs. However, a small precision may cause truncation on the right.
4. An optional precision. The precision is a . (dot) followed by a decimal digit string. If no precision is given, it is treated as 0 (zero). The precision specifies:
   - The minimum number of digits to be displayed for the **d**, **o**, **i**, **u**, **x**, or **X** conversions.
   - The number of digits to be displayed after the radix character for the **e** and **f** conversions.
   - The maximum number of significant digits for the **g** conversion.
   - The maximum number of bytes to be printed from a string in the **s** conversion.
5. A character that indicates the type of conversion to be applied, such as:

Item	Description
%	Performs no conversion. Prints a % (percent sign).
a, **A**	Accepts a floating-point value and converts the value to a decimal notation that is in the format `[-]0x`*h*`.`*hhhh*`p±`*d*. The decimal notation contains one hexadecimal digit before the decimal point. This hexadecimal digit must be a non-zero value if the specified floating-point value is a normalized floating-point value or is unspecified. The number of hexadecimal digits after the decimal point indicates the precision value. If the precision value is not specified by using the *Format* parameter and the exponent value of the FLT_RADIX argument is 2, the precision value represents the floating-point value. If the precision value is not specified and the exponent value of the FLT_RADIX argument is not 2, the precision value can distinguish between the different floating-point values in the internal representation format that is used by the **a**, **A** conversion specifier. The trailing zeros in the decimal notation can be removed. If the precision value is zero and the **#** flag is not specified, the decimal point is not displayed. The letters `abcdef` are used for **a** conversion specifier and the letters ABCDEF are used for **A** conversion specifier. The **A** conversion specifier provides a number with the characters X and P instead of the characters x and p. To represent the decimal exponent of 2, the exponent of the FLT_RADIX argument must contain one digit to as many digits as needed. If the floating-point value is zero, the exponent value is also zero. The floating-point value that represents an infinity or NaN data type is converted to the format of the **f**, **F** conversion specifier.

Item	Description
d, **i**	Accepts an integer value and converts it to signed decimal notation. The precision specifies the minimum number of digits to be displayed. If the value being converted can be represented in fewer digits, it is expanded with leading zeros. The default precision is 1. The result of converting a zero value with a precision of zero is a null string. Specifying a field width with a zero as a leading character causes the field width value to be padded with leading zeros.
o	Accepts an integer value and converts it to signed octal notation. The precision specifies the minimum number of digits to be displayed. If the value being converted can be represented in fewer digits, it is expanded with leading zeros. The default precision is 1. The result of converting a zero value with a precision of zero is a null string. Specifying a field width with a zero as a leading character causes the field width value to be padded with leading zeros. An octal value for field width is not implied.
u	Accepts an integer value and converts it to unsigned decimal notation. The precision specifies the minimum number of digits to be displayed. If the value being converted can be represented in fewer digits, it is expanded with leading zeros. The default precision is 1. The result of converting a zero value with a precision of zero is a null string. Specifying a field width with a zero as a leading character causes the field width value to be padded with leading zeros.
x, **X**	Accepts an integer value and converts it to hexadecimal notation. The letters abcdef are used for the **x** conversion and the letters ABCDEF are used for the **X** conversion. The precision specifies the minimum number of digits to be displayed. If the value being converted can be represented in fewer digits, it is expanded with leading zeros. The default precision is 1. The result of converting a zero value with a precision of zero is a null string. Specifying a field width with a zero as a leading character causes the field width value to be padded with leading zeros.
f, **F**	Accepts a floating-point value and converts it to a decimal notation in the format **[-]***ddd . ddd*. The number of digits after the radix character or the decimal point is equal to the specified precision value. The **LC_NUMERIC** locale category determines the radix character that must be used in this format. If a precision value is removed from the floating-point value, six digits are added in the output after the radix character. If the precision value is 0 (zero), the radix character is not displayed. A floating-point value that represents an infinity data type is converted to the format `[-]inf` or `[-]infinity`. The format `[-]inf` or `[-]infinity` is implementation-dependent. A floating-point value that represents a NaN data type is converted to the format `[-]nan` (*n-char-sequence*) or `[-]nan`. The meaning of any *n-char-sequence* is implementation-dependent. The **F** conversion specifier provides the formats `INF`, `INFINITY`, or `NAN` instead of `inf`, `infinity`, or `nan`.
e, **E**	Accepts a float or double value and converts it to the exponential form [**-**] *d***.***dd***e**{**+**|**-**}*dd*. There is one digit before the radix character (shown here as the decimal point) and the number of digits after the radix character is equal to the precision specification. The **LC_NUMERIC** locale category determines the radix character to use tin this format. If no precision is specified, then six digits are output. If the precision is 0 (zero), then no radix character will be displayed. The **E** conversion character produces a number with E instead of e before the exponent. The exponent always contains at least two digits. However, if the value to be printed requires an exponent greater than two digits, additional exponent digits are printed as necessary.
g, **G**	Accepts a float or double value and converts it in the style of the **f** or **e** conversion characters (or **E** in the case of the **G** conversion), with the precision specifying the number of significant digits. Trailing zeros are removed from the result. A radix character is displayed only if it is followed by a digit. The style used depends on the value converted. Style **g** results only if the exponent resulting from the conversion is less than -4, or if it is greater than or equal to the precision.
c	Accepts a value as a string and prints the first character in the string.

Item	Description
s	Accepts a value as a string and prints characters from the string until the end of the string is encountered or the number of characters indicated by the precision is reached. If no precision is specified, all characters up to the first null character are printed.
b	Accepts a value as a string, that may contain backslash-escape sequences. Bytes from the converted string are printed until the end of the string or number of bytes indicated by the precision specification is reached. If the precision is omitted, all bytes until the first null character are printed.

The following backslash-escape sequences are supported:

- The escape sequences previously listed above under the description of the *Format* parameter. These are converted to the individual characters they represented.
- The \c (backslash c) sequence, which is not displayed and causes the **printf** command to ignore any remaining characters in the string parameter containing it, any remaining string parameters, and any additional characters in the *Format* parameter.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. Enter the following command:

   ```
   printf "%5d%4d\n" 1 21 321 4321 54321
   ```

   This produces the following output:

   ```
       1  21
     3214321
   54321   0
   ```

   The *Format* parameter is used three times to print all of the given strings. The 0 (zero) is supplied by the **printf** command to satisfy the last %4d conversion specification.
2. Enter the following command:

   ```
   printf "%c %c\n" 78 79
   ```

   This produces the following output:

   ```
   7 7
   ```

3. The following example demonstrates how the **%$** format specifier can be used to print the date in an order different from the order of the arguments:

   ```
   printf (""%1$s, %3$d. %2$s, %4$d:%5$.2d", weekday, month, day, hour, min);
   Sunday, 3. July, 10:02
   (weekday, day. month, hour:min)
   ```

Files

Item	Description
/usr/bin/printf	Contains the **printf** command.

probevctrl Command

Purpose

Changes and displays the ProbeVue dynamic tracing parameters and the ProbeVue sessions.

Syntax

probevctrl [**-c** *attribute = value*] [**-C**] [**-f** { *milli*|*micro* }] [**-d** *sessionID*] [**-l**] [**-n** *attribute = value*] [**-p**] [**-s** { *probevue_session_id* }] [**-t**] [**-u** *user-list*] [**-T** { *show*|*start*|*stop*|*reset* }]

Description

The **probevctrl** command changes and displays the ProbeVue dynamic tracing parameters, the per-processor trace buffer size, the consumed pinned memory, the user owning the session, the identifier of the process that started the session, and the information on whether the session has kernel probes for the ProbeVue sessions.

The following ProbeVue parameters are configurable:

- ProbeVue status (enabled/disabled).
- Maximum pinned memory (MB) allocated for all ProbeVue sessions.
- Maximum pinned memory (KB) allocated for a non-privileged user's ProbeVue session including the memory for the trace buffers.
- Number of concurrent ProbeVue sessions allowed for a regular user.
- Default size of the per-processor trace buffers (KB).
- The minimum period in milliseconds that a regular user can request the trace consumer to read from its trace buffers.
- The default period in milliseconds that the ProbeVue buffers will be read by the trace consumer.
- The size of the per-processor computation stack used by a ProbeVue session (KB).
- The minimum time interval allowed for global root user in interval probes.
- The percentage of memory that is allocated for the dynamic data structure.
- The size of the per-processor local table in KB.
- The number of page fault contexts for handling page faults.
- The maximum number of threads a ProbeVue session should support when it has thread local variables.
- The maximum size of per-CPU buffer, in bytes, used by a **net** probe action.
- The maximum time, in milliseconds, a **systrace** probe action can take when the action is started in interrupt context.
- The maximum time, in milliseconds, a **sysproc** probe action can take when the action is started in interrupt context.
- The maximum time, in milliseconds, an **io** probe action can take when the action is started in interrupt context.
- The maximum time, in milliseconds, a **net** probe action can take when the action is started in interrupt context.
- The maximum time, in milliseconds, a **CPU-bound interval** probe action can take when the action is started in the interrupt context.

Only the root user or the users having the **aix.ras.probevue.manage** authorization can update the ProbeVue parameters and view all the ProbeVue sessions. Otherwise, users can view only the sessions owned by themselves. Each session is displayed in the following format:

Sid	Pid	Uid	Buffer size in bytes	Consumed memory in bytes	Kernel probes	Profiling
sid	*pid*	*uid*	*bufsize*	*memory*	yes or no	yes or no

By default, the ProbeVue is enabled. Attempt to disable the ProbeVue when the ProbeVue sessions are active will fail.

Flags

-c

Specifies non-user ProbeVue parameters. Arguments to this flag must be separated by commas or enclosed in double quotation marks and separated by commas or spaces. If either the **-p** or the **-t** flag is not specified with this flag, new values will be made effective both in the present boot and next boot sessions. The valid *attribute-value* pairs are as follows:

trace= {on | off}
Specifies whether the ProbeVue must be enabled or disabled.

default_buffer_size=*default_buffer_size*
Specifies the default size of the per-processor trace buffers in KB. This is rounded to the next 4KB page.

max_total_mem_size=*max_total_mem_size*
Specifies the maximum pinned memory in MB consumable by the entire ProbeVue framework.

default_read_rate=*default_read_rate*
Specifies the default period in milliseconds that the ProbeVue buffers will be read by the trace consumer.

stack_size=*stack_size_in_4Kpages*
Specifies the size of the per-processor computation stack in KB. This will be rounded to the next 4KB page.

local_table_size=*number*
Specifies the size of the per-processor local table in KB. Half of the space allocated for the local table is used by temporary strings. The default value is set to 4 KB.

min_interval=*interval in ms*
Specifies the minimum time interval allowed for global root user in interval probes.

num_pagefaults=*number*
Specifies the number of page fault contexts for handling page faults. The specified number of page fault contexts are preallocated during ProbeVue framework initialization.

num_threads_traced=*number*
Specifies the maximum number of threads a ProbeVue session can support when it has thread local variables. The ProbeVue framework preallocates all the thread-local variables at the start of a session for the maximum number of threads that are specified with this attribute.

max_net_buf_size=*number*
Specifies the maximum size of per-CPU buffer, in bytes, used by a **net** probe action.

max_intr_systrcprb_time=*number*
Specifies the maximum amount of time, in milliseconds, that a probe action can take to run when the **systrace** probe action is started in interrupt context.

max_intr_sysprocprb_time=*number*
Specifies the maximum amount of time, in milliseconds, that a probe action can take to run when the **sysproc** probe action is started in interrupt context.

max_intr_ioprb_time=*number*
Specifies the maximum amount of time, in milliseconds, that a probe action can take to run when the **io** probe action is started in interrupt context.

max_intr_netprb_time=*number*
Specifies the maximum amount of time, in milliseconds, that a probe action can take to run when the **net** probe action is started in interrupt context.

async_stats_fetch_interval=*number*
Specifies the asynchronous fetch interval in milliseconds to fetch the system statistics. This attribute is a global value that is applicable for all ProbeVue sessions. ProbeVue sets the asynchronous fetch interval based on this value. The default value for the tunable is 1000 milliseconds. Changes in the tunable value does not affect the running sessions and the specified value is used only for the new sessions.

fetch_stats_async_only={yes | no}
Specifies that all system statistics must be fetched in the asynchronous mode even if the synchronous fetch is possible. The default value for this parameter is no. Changes in the tunable value does not affect the running sessions and the specified value will be used only for the new sessions.

max_intr_cpuboundprb_time=*number*
Specifies the maximum amount of time, in milliseconds, that a probe action can take to run when the **CPU-bound interval** probe action is started in interrupt context.

-C
Sets the ProbeVue session tunable to initial values. The **-C** option uses the current configuration of system to determine configuration initial values (High Config or Low Config) to be set and updates both current and next boot parameters. For more information about high and low configuration values of tunables, see the **ProbeVue dynamic tracing facility** topic.

Note: Before using the **-C** flag, ensure there is no active ProbeVue session.

-d *sessionId*
Displays the list of probes enabled for the specified session. When you specify all as the session ID, then the probes for all the ProbeVue sessions that can be viewed by the user is displayed. A list of ProbeVue sessions and the associated session ID can be obtained using the **probevctrl** command.

-f
Specifies the format in which time consumed data for probe actions needs to be displayed. The **-f** option can be used along with the **-T** option and it shows action on a specific session. The possible formats follow:

milli
Displays the time in milliseconds.

micro
Displays the time in microseconds.

The default format is **milli**.

-l
Lists the present value of the ProbeVue configuration parameters. If the **-p** or the **-t** flag is not specified, parameter values for the present boot session are displayed.

-n
Specifies the configurable parameters for regular users. Arguments to this option must be separated by commas or enclosed in double quotation marks and separated by commas or spaces. If either the **-p** or the **-t** flag is not specified with this flag, new values will be made effective both in the present boot and next boot sessions. The valid *attribute-value* pairs are as follows:

max_mem_size=*max_mem_size*
Specifies the maximum pinned memory in MB consumable by a ProbeVue session.

max_sessions=*max_sessn*
Specifies the maximum concurrent sessions allowed.

min_read_rate=*min_read_rate*
Specifies the minimum period in milliseconds that a regular user can request the trace consumer to read from its trace buffers.

pin_mem_dvar_pc=*pin_mem_dvar_pc*
Specifies the percentage of memory that can be allocated to the dynamic data structure for dynamic type variables. This memory can be used for stack trace and associative array type dynamic variables. The value of this parameter is set in the range 10-100. The default value is 50.

-p
Specifies that the default values for the next boot must be updated and displayed.

-s *probevue_session_id*
Specifies the session on which the action is to be performed. This flag must be used with the **-T** flag.

-u
Specifies comma-separated user list whose ProbeVue sessions must be listed. If the **-u** flag is not specified, all of the ProbeVue sessions that the user can view are displayed. A user with the **aix.ras.probevue.manage** authorization can view all of the ProbeVue sessions in the system. Users without this authorization can view only the ProbeVue sessions they own.

-t
Specifies that the default values for the present boot session must be updated and displayed.

-T show | start | stop | reset
Specifies whether to show, start, stop, or reset the probe action profiling for the session that is specified by the **-s** flag. The **-s** flag must be used along with this flag.

Examples

1. To modify the next boot default buffer size and to turn on the dynamic tracing, enter:

   ```
   probevctrl -c trace=on,default_buffer_size=8 -p
   ```

   or

   ```
   probevctrl -c "trace=on default_buffer_size=8" -p
   ```

2. To list the next boot ProbeVue configuration, enter:

   ```
   probevctrl -l -p
   ```

3. To list the present ProbeVue configuration, enter:

   ```
   probevctrl -l -t
   ```

4. To list all of the ProbeVue sessions, enter:

   ```
   probevctrl
   ```

5. To list all of the ProbeVue sessions owned by the user guest, enter:

   ```
   probevctrl -u guest
   ```

6. To increase the percentage of pinned memory that is allocated for the dynamic data structures (stack trace and associative array) for the next boot from a default 50 -75, enter:

   ```
   probevctrl -n  pin_mem_dvar_pc = 75
   ```

probevue Command

Purpose

Starts a dynamic trace session. The command can preprocess the header file and exit without starting the dynamic trace session.

Syntax

probevue [**-c** "{ **timestamp** = { **0** | **1**| **2**} **thread** = { **on** | **off** } **tid** = { *t1*, ... } **pid** = { *p1*, ... } abs_mem_for_dvars=*memory_in_KB* num_threads_traced=*number_of_thread_to_trace*}"] [**-d**] [**-i** *Async_Fetch_Interval*] [**-e** *Pinned_memory_dvar_percent*] [**-f** *to_print_time_profile_data_milli_or_micro*] [**-I** *Include_file1, ...*] [**-K**] [**-o** *Output_file*] [**-q** info={none|normal|detail}] [**-s** *Buffer_size*][**-t** *Interval*][**-T**] [**-u**] [**-X** *Program_name* [**-A** "*Arguments_to_program*"] [**-L** *"Lib path"*] [**-g**]] [*Script_name* [*Arguments_to_script*]]

probevue [**-P** *C ++_header_file*]

probevue [**-l** "{ **syscall** | **syscallx** | **syscallx32** | **syscallx64** | **interval** | **systrace** | **sysproc** | **io** | **net**}"]

Description

The **probevue** command analyzes the operating system and user programs by dynamically enabling the user-specified probes, starting the actions that are associated with the probes when they are triggered, and presenting the captured trace data.

When you specify the **probevue** command with a vue script, the command enables the tracing that was specified in the script, and produces the tracing output.

When the **-P** option is specified with the C++ header file, the command produces the preprocessed encrypted C header file. The encrypted C header file can be further used to probe C++ application by using the **-I** option of the **probevue** command.

The arguments to the **probevue** command and the vue script can be specified in a script instead of the command line. The script can be run repeatedly with same arguments by using this script. A vue language construct #VUE_CMD_ARGS can be used to specify the arguments to the **probevue** command in the file and the #VUE_SCRIPT_ARGS language construct can be used to specify the arguments to the vue script.

Notes:

- When the arguments are specified in the script, all the arguments for a vue construct must be on the same line.
- If arguments to the **probevue** command are specified by command line and in the script, only command line arguments are considered and all command arguments in the script are ignored. This process applies to the vue script arguments also.
- The #VUE_CMD_ARGS and #VUE_SCRIPT_ARGS constructs do not support standard input.
- The dynamic memory requirement of the `probevue` command is proportional to the product of number of CPUs and per-CPU trace buffer size (the value of the **`default_buffer_size`** tunable parameter of the `probevctrl` command). Hence, in a system that has large number of CPUs and higher value of per-CPU buffer can cause the `probevue` command to exceed the memory limit set by the `ulimit` parameter. In such scenarios, run the `probevue` command with the **`-u`** flag to cross that limit.

Flags

Item	Description
-A "*Arguments_to_program*"	Specifies the arguments to the program that you specified to using the **-X** flag. If there are multiple arguments to the application, enclose each argument in quotation marks.

Item	Description
-g	Turn on grouping of output from every clause of the probevue session i.e. all the output from a clause will appear together without getting interleaved by output from any other clause that is running simultaneously in another CPU. The **-g** flag overrides the `group_output_start()` or the `group_output_end()` statements present in the VUE script. Output of every clause is grouped from clause start to clause end irrespective of the `group_output_start()` or the `group_output_end()` statements present in the clauses.
-c	Specifies how the trace data needs to be formatted. You must enclose arguments to this option in quotation marks and separate each argument by spaces. The options are as follows: **timestamp={0|1|2}** Controls the reporting of the time stamp that is associated with an event in the trace report. Specify one of the following values: **0** Displays the timestamp, in seconds and microseconds, for each message relative to the beginning of the trace. The first line of the trace output shows the base time from which the individual time stamps are measured. **1** With each message, displays the actual time taken to create the message. **2** With each message, displays the actual time taken to create the message as per the *printf's %A* format. **Note:** If both options are desired then 0,1 must be entered. That is, there must be no spaces between 0,1. **thread={on|off}** Displays the thread ID which generated the message, with each message. The default value is **off**. **pid={*p1*,..}** Displays only the messages that were generated by the processes specified. **Note:** If the thread has died before the trace consumer tries to know the process to which the thread belongs, or if the process that you specified no longer exists, the consumer cannot display the messages that were generated by the threads in this process, when you filter the messages by the process ID. **tid={*t1*,..}** Displays only the messages that were generated by the threads that you specified. **abs_mem_for_dvars=*memory_in_KB*** Specifies the pinned memory, in kilo bytes (KB), that is allocated for dynamic type variables. This option is mutually exclusive to the **-e** option. **num_threads_traced=*number_of_thread_to_trace*** Specifies the maximum number of threads that the current ProbeVue session can support when the session has thread-local variables. This value overrides the corresponding global ProbeVue tunable value.
-d	Displays the list of probes enabled for the session.

Item	Description
-e *Pinned_memory_dvar_percent*	Specifies the percentage of the dynamic data structure memory allocated for dynamic type variables. A minimum of 10 and a maximum of 100 value can be specified as the percentage.
-f	Specifies the format in which the time taken by probe action must be displayed. The supported formats follow: **milli** Displays time in milliseconds. **micro** Display time in microseconds. The default format is **milli**.
-i *Async_Fetch_Interval*	Specifies how often the asynchronous statistics is fetched for the **probevue** command. This option overrides the global interval time for the **probevue** command. The minimum interval is 100 milliseconds.
-I *Include_file1*	Uses the file specified as a post-processed header file, that is one with no C-preprocessor operators. It can be passed through the command line to be included when compiling the vue script.
-K	Enables RAS events related functionality in a probeVue session.
-l	Lists all the probe points supported by the probe manager. When you specify the **-l** flag with the **probevue** command, no other flags must be used. You can specify more than one probe manager with the **-l** flag, such as `-l syscall -l syscallx -l interval`. The probe manager supports **interval**, **syscall**, **syscallx**, **systrace**, **io**, **sysproc**, and **net** probes for the **-l** flag. If you specify wrong arguments or an incorrect probe manager with the **-l** option, a usage error is displayed. • `probevue -l syscall`: Lists all the possible system call that can be traced on the system. • `probevue -l syscallx`: Displays all base system calls that can be traced on the system. This option lists the system call separately for the 32 and 64-bit systems. • `probevue -l syscallx32`: Displays the 32-bit base system calls that can be traced on the system. • `probevue -l syscallx64`: Displays the 64-bit base system calls that can be traced on the system. • `probevue -l interval`: Specifies the minimum and maximum interval duration supported for regular and root users with the **interval** probe. • `probevue -l systrace`: Displays a description about the systrace probe. **Note:** For syscallx probe manager, when the **-l syscallx** probe is used, it displays both 32-bit and 64-bit base-system calls. To view only 32-bit calls, use **syscallx32** probes, and to view only 64-bit calls, use **syscallx64** probes.

Item	Description
-L "*Lib path*"	Prioritizes library search in the specified path. If the libraries are not found in the specified path, searches libraries in the default library path that is saved in the header of the `loader` section in the eXtended COFF (XCOFF) file. The **-L** flag is applicable to the user function tracing (uft) and C++ probe managers that use the name of the executable file. The **-L** flag is ignored for other probe managers.
-o *Output_file*	Writes the report to a file rather than to the standard output.
-P C++ *header file*	Preprocesses the **C++** header file and creates an output preprocessed file for each input **C++** header file. The preprocessed output file has the same name as the input **C++** header file, with a .Vue suffix. **Note:** You cannot use other flags with the **-P** option. The **-P** flag accepts any file name, except the file name with a .Vue suffix.
-q *info=level*	Specifies reporting level of informational messages while parsing the vue script. The possible values follow: **none** No informational messages are displayed. **normal** Only important informational messages are displayed. **detail** All informational messages that can result in incorrect execution are reported.
-s *Buffer_size*	Specifies the size of the per-CPU trace buffers in KB. This is rounded to the next 4K page. You can use following levels:
-t *Interval*	Specifies how often the trace buffers are read. The minimum interval that you can specify is 10 milliseconds. The time interval specified by the regular user (that is a user without the **aix.ras.probevue.trace** privilege) is rounded to the next highest multiple of 10 milliseconds. The read rate is retrieved from the **probeVue** configuration. **Note:** A regular user can specify the minimum read rate and the **probevctrl** command can change the default read rate.
-T	Starts probe action profiling at the start of session. The **-T** flag ensures that probe actions are profiled when the session is started.
-u	Starts probeVue session and sets the data segment to unlimited value. The **-u** flag is used to print stack traces from multiple processes of large binaries.
-X *Program_name*	Starts a program and enables probes before the program starts. You can use the special environment variables **$__CPID** and **$__CTID** within a vue script to identify the process ID and the thread ID of the application that is launched.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To start a **probeVue** session with script **syscall.e**, enter:

```
probevue syscall.e
```

2. To send the trace report to the **/tmp/trace_report** file, enter:

```
probevue -o /tmp/trace_report syscall.e
```

3. To display the trace report of the thread IDs 12345,4567 and the timestamp relative to the beginning of trace, enter:

```
probevue -c "timestamp=0 tid=12345,4567" syscall.e
```

4. To include the header file **stat.i** and allocate 4K of per-CPU buffer, enter:

```
probevue –I stat.i –s 4 syscall.e
```

5. To preprocess the C++ header file **myheader.h** , enter:

```
  probevue –P myheader.h
```

   The **probevue** command generates the **myheader.Vue** file, which is an encrypted **C++** header file and is included in the trace session by using the **-I** option.

6. To increase the percentage of pinned memory for the current session of the dynamic data structures (stack trace and associative array), from a default of 50 -75 for the **ASO.e** script, enter:

```
probevue -e 75  ASO.e
```

7. The following script is an example of providing the arguments in the script:

```
!#/usr/bin/probevue
    #VUE_CMD_ARGS=-o /tmp/trace_out
    #VUE_SCRIPT_ARGS=read

    @@syscall:*:$1:entry
    {
        printf("%t\n", get_stktrace(4));
    }
```

   The script runs as: `./script.e`

Files

Item	Description
/usr/bin/ probevue	Contains the **probevue** command.

proccred Command

Purpose

Prints the credentials (effective, real, saved user IDs and group IDs) of processes.

Syntax

proccred *ProcessID* ...

Description

The **/proc** filesystem provides a mechanism to control processes. It also gives access to information about the current state of processes and threads, but in binary form. The proctools commands provide ascii reports based on some of the available information.

Most of the commands take a list of process IDs or **/proc/***ProcessID* strings as input. The shell expansion **/proc/*** can therefore be used to specify all processes in the system.

Each of the proctools commands gathers information from **/proc** for the specified processes and displays it to the user. The proctools commands like procrun and procstop start and stop a process using the **/proc** interface.

The information gathered by the commands from **/proc** is a snapshot of the current state of processes, and therefore can vary at any instant except for stopped processes.

The **proccred** command prints the credentials (effective, real, saved user IDs and group IDs) of processes.

Flags

Item	Description
ProcessID	Specifies the process id.

Examples

1. To display the credentials of process 5046, enter:

```
proccred  5046
```

Files

Item	Description
/proc	Contains the **/proc** filesystem.

procfiles Command

Purpose

Reports information about all file descriptors opened by processes.

Syntax

procfiles [**-F**] [**-n**] [**-c**] *ProcessID* ...

Description

The **/proc** filesystem provides a mechanism to control processes. It also gives access to information about the current state of processes and threads, but in binary form. The **proctools** commands provide ASCIIi reports based on some of the available information.

Most of the commands take a list of process IDs or **/proc/***ProcessID* strings as input. The shell expansion **/proc/*** can therefore be used to specify all processes in the system.

Each of the proctools commands gathers information from **/proc** for the specified processes and displays it to the user. The **proctools** commands like procrun and procstop start and stop a process using the **/proc** interface.

The information gathered by the commands from **/proc** is a snapshot of the current state of processes, and therefore can vary at any instant except for stopped processes.

Regular files have permission based on mode it was opened with. Any non-regular files have 0 access mode.

The **procfiles** command reports information on all file descriptors opened by processes. With the **-n** option it also displays the names of the corresponding files.

Flags

Item	Description
-c	Prints the output in column format.
-F	Forces procfiles to take control of the target process even if another process has control.
-n	Prints the names of the files referred to by file descriptors.
ProcessID	Specifies the process id.

Examples

1. To display status and control information on the file descriptors opened by process 11928, enter the following command:

   ```
   procfiles 11928
   ```

   The output of this command might look like this:

   ```
   11928 : -sh
     Current rlimit: 2000 file descriptors
      0: S_IFCHR mode:0622 dev:10,4  ino:2584 uid:100 gid:100 rdev:28,1
         O_RDONLY
      1: S_IFCHR mode:0622 dev:10,4  ino:2584 uid:100 gid:100 rdev:28,1
         O_RDONLY
      2: S_IFCHR mode:0622 dev:10,4  ino:2584 uid:100 gid:100 rdev:28,1
         O_RDONLY
      63: S_IFREG mode:0600 dev:10,8  ino:311 uid:100 gid:100 rdev:40960,10317
         O_RDONLY size:2574
   ```

2. To display name, status and control information on the file descriptors opened by process 15502, enter the following command:

   ```
   procfiles -n 15502
   ```

   The output of this command might look like this:

   ```
   15502 : /home/guest/test
     Current rlimit: 2000 file descriptors
      0: S_IFCHR mode:0622 dev:10,4  ino:2584 uid:100 gid:100 rdev:28,1
         O_RDONLY
      1: S_IFCHR mode:0622 dev:10,4  ino:2584 uid:100 gid:100 rdev:28,1
         O_RDONLY
      2: S_IFCHR mode:0622 dev:10,4  ino:2584 uid:100 gid:100 rdev:28,1
         O_RDONLY
      3: S_IFREG mode:0644 dev:10,7  ino:26 uid:100 gid:100 rdev:0,0
         O_RDONLY size:0  name:/tmp/foo
   ```

3. To display status and control information on the file descriptors opened by the 278684 process, enter the following command:

   ```
   procfiles -c 278684
   ```

   The output of this command might look like this:

```
278684 : -ksh
  Current rlimit: 2000 file descriptors
------------------------------------------------------------------------------
 FD   TYPE   MODE      DEV/RDEV     UID       GID          OPMOD           INODE
------------------------------------------------------------------------------
 0     c   ---------  10, 4(19, 0)  root      system        R-W            16385
 1     c   ---------  10, 4(19, 0)  root      system        R-W            16385
 2     c   ---------  10, 4(19, 0)  root      system        R-W            16385
 61    -   rw-r--r--  10, 7         root      system        R-W            32
 63    -   rw-------  10, 4         root      system        R-W | A        1051
```

Files

Item	Description
/proc	Contains the **/proc** filesystem.

procflags Command

Purpose

Prints the **/proc** tracing flags, the **pending** and **held** signals, and other **/proc** status information for each thread in the specified processes.

Syntax

procflags [**-r**] *ProcessID* ...

Description

The **/proc** filesystem provides a mechanism to control processes. It also gives access to information about the current state of processes and threads, but in binary form. The proctools commands provide ascii reports based on some of the available information.

Most of the commands take a list of process IDs or **/proc/***ProcessID* strings as input. The shell expansion **/proc/*** can therefore be used to specify all processes in the system.

Each of the proctools commands gathers information from **/proc** for the specified processes and displays it to the user. The proctools commands like procrun and procstop start and stop a process using the **/proc** interface.

The information gathered by the commands from **/proc** is a snapshot of the current state of processes, and therefore can vary at any instant except for stopped processes.

The **procflags** command prints the **/proc** tracing flags, the pending and held signals, and other **/proc** status information for each thread in the specified processes. The machine register contents are printed when option **-r** is used and the process is stopped on an event of interest. The events of interest are **PR_REQUESTED**, **PR_FAULTED**, **PR_SYSENTRY**, and **PR_SYSEXIT** as defined in **<sys/procfs.h>**.

Flags

Item	Description
-r	Displays the current machine registers state if a process is stopped in an event of interest.
ProcessID	Specifies the process id.

Examples

1. To display the tracing flags of process 5046, enter:

```
procflags  5046
```

The output of this command might look like this:

```
5046 : -sh
data model = _ILP32 flags = PR_FORK
/4289: flags = PR_ASLEEP | PR_NOREGS
```

2. To display the tracing flags and registers values of process 5040 which was stopped on an event of interest, enter:

```
procflags -r 5040
```

The output of this command might look like this:

```
5040 : ls
data model = _ILP32 flags = PR_FORK
/6999: flags = PR_STOPPED | PR_ISTOP
why = PR_FAULTED  what = FLTBPT what = kfork
gpr0  = 0x0               gpr1  = 0x2ff227b0        gpr2  = 0xf0083bec
gpr3  = 0x2ff22cb3        gpr4  = 0x11              gpr5  = 0x65
gpr6  = 0x50              gpr7  = 0x0               gpr8  = 0x41707a7c
gpr9  = 0x4c4f47          gpr10 = 0x80000000        gpr11 = 0x34e0
gpr12 = 0x0               gpr13 = 0xdeadbeef        gpr14 = 0x1
gpr15 = 0x2ff22c0c        gpr16 = 0x2ff22c14        gpr17 = 0x0
gpr18 = 0xdeadbeef        gpr19 = 0xdeadbeef        gpr20 = 0xdeadbeef
gpr21 = 0xdeadbeef        gpr22 = 0x10              gpr23 = 0xfd
gpr24 = 0x2f              gpr25 = 0x2ff227f0        gpr26 = 0x0
gpr27 = 0x2ff22d87        gpr28 = 0x2ff22cb3        gpr29 = 0x0
gpr30 = 0x0               gpr31 = 0xf0048260        iar = 0xd01be900
msr = 0x2d032             cr = 0x28222442           lr = 0xd01d9de0
ctr = 0xec                xer = 0x0                 fpscr = 0x0
fpscrx = 0x0
```

Files

Item	Description
/proc	Contains the **/proc** filesystem.

procldd Command

Purpose

Lists the objects loaded by processes, including shared objects explicitly attached using **dlopen()**.

Syntax

procldd [**-F**] *ProcessID* ...

Description

The **/proc** filesystem provides a mechanism to control processes. It also gives access to information about the current state of processes and threads, but in binary form. The **proctools** commands provide ASCII reports based on some of the available information.

Most of the commands take a list of process IDs or **/proc/***ProcessID* strings as input. The shell expansion **/proc/*** can therefore be used to specify all processes in the system.

Each of the proctools commands gathers information from **/proc** for the specified processes and displays it to the user. The **proctools** commands like procrun and procstop start and stop a process using the **/proc** interface.

The information gathered by the commands from **/proc** is a snapshot of the current state of processes, and therefore can vary at any instant except for stopped processes.

The **procldd** command lists the objects loaded by processes, including shared objects explicitly attached using **dlopen()**. All the information needed is gathered from the **/proc/***ProcessID***/map** files.

Flags

Item	Description
-F	Forces procldd to take control of the target process even if another process has control.
ProcessID	Specifies the process id.

Examples

1. To display the list of objects loaded by process 12644, enter:

```
procldd 12644
```

The output of this command might look like this:

```
12644 : -ksh
ksh
/usr/lib/libiconv.a[shr4.o]
/usr/lib/libi18n.a[shr.o]
/usr/lib/nls/loc/en_US
/usr/lib/libcrypt.a[shr.o]
/usr/lib/libc.a[shr.o]
```

Files

Item	Description
/proc	Contains the **/proc** filesystem.

procmap Command

Purpose

Prints the address space map of processes.

Syntax

procmap [**-F**] [**-S**] { **-X** [**-f**] [**-n**] [**-u**] [**-q**]}] *ProcessID* ...

Description

The **/proc** file system provides a mechanism to control processes. It also gives access to information about the current state of processes and threads, but in binary form. The proctools commands provide *ascii* reports based on some of the available information.

Most of the commands take a list of process IDs or **/proc/***ProcessID* strings as input. The shell expansion **/proc/*** can therefore be used to specify all processes in the system.

Each of the proctools commands gathers information from **/proc** for the specified processes and displays it to the user. The proctools commands like the **procrun** and **procstop**start and stop a process using the **/proc** interface.

The information gathered by the commands from **/proc** is a snapshot of the current state of processes, and therefore can vary at any instant except for stopped processes.

The **procmap** command prints the address space map of processes. It displays the starting address and size of each of the mapped segments in the process. It gets all the information necessary from the **/proc/***ProcessID***/map** files.

Flags

Item	Description
-F	Forces the **procmap** command to take control of the target process even if another process has control.
-S	Displays shared memory information of the target process. **Note:** The **-S** option is obsolete. You can use the **-X** option for similar functionality.
-X	Displays extended information about each address range and includes all mapped objects of the target process.
-n	Displays unsorted address ranges for the mapped segments of the target process.
-u	Displays the values in the most appropriate unit. The unit used in the report is specified for each metric.
-q	Suppresses the header information.
-f	Displays the filename instead of device number and inode number for the mapped file of the target process. The *MAPPED OBJECT* column for the mapped files displays one of the following values: • `dev:remote` for the remote files. • `dev:remote` from within a WPAR using global host storage. • `<full pathname>` from within a WPAR using direct storage. • `dev:<major#>, <minor#>, ino:<inode#>` outside a WPAR using direct storage. • For the non-WPAR local files, the file names is resolved, or the string `dev<major#>, <minor#>, ino:<inode#>` is displayed with the correct major, minor, and inode numbers for the file.
ProcessID	Specifies the process id.

The following are brief descriptions of the contents of the columns with -X flag:

Item	Description
`Start-ADD`	Start address of the memory region.
`End-ADD`	End address of the memory region.
`SIZE`	Size of the memory region.
`MODE`	Read, write and execute permission of the memory region.
`PSIZ`	Page size of the memory region. The following values are displayed:
`s`	4K page size
`m`	64K page size
`L`	16M page size
`H`	16GB page size
`TYPE`	Type of the memory region. The following values are displayed:

Item	Description
HEAP	Heap Region
KER/LDR	Other Kernel/Loader Segments
KERTXT	Kernel Text
MAINDATA	Main Data/BSS for the process
MAINTEXT	Main Executable for the process
MFILE	Map File
PLIBDATA	Private Library Data
PLIBTEXT	Private Library Text
PMMAP	Private Memory Map
PMMFILE	Private Memory Map file
PMMPSXRT	Private POSIX Real Time Shared Memory Map
REALMEM	Real Memory Mapped
SHM	Shared Memory
SHMEXT	Extended Shared Memory
SHMFILE	Shared Memory File
SLIBDATA	Shared Library Data
SLIBTEXT	Shared Library Text
SMMAP	Shared Memory Map
SMMFILE	Shared Memory Map file
SMMPSXRT	Shared POSIX Real Time Shared Memory
STACK	Stack Region
VSID	Virtual Segment ID of the memory region.
MAPPED OBJECT	Mapped object name.

Examples

1. To display the address space of process 12644, enter:

```
procmap 12644
```

   The output of this command might look like this:

```
12644 : -ksh
10000000         232K  read/exec         ksh
20000ef8          54K  read/write        ksh
d008b100          80K  read/exec         /usr/lib/libiconv.a[shr4.0]
f03e4c70          41K  read/write        /usr/lib/libiconv.a[shr4.o]
d0080100          40K  read/exec         /usr/lib/libi18n.a[shr.o]
f03f0b78           4K  read/write        /usr/lib/libi18n.a[shr.o]
d007a000          11K  read/exec         /usr/lib/nls/loc/en_US
d007d130           8K  read/write        /usr/lib/nls/loc/en_US
d00790f8           2K  read/exec         /usr/lib/libcrypt.a[shr.o]
f03e3508           0K  read/write        /usr/lib/libcrypt.a[shr.o]
d02156c0        2282K  read/exec         /usr/lib/libc.a[shr.o]
f03474e0         621K  read/write        /usr/lib/libc.a[shr.o]
   Total        3380K
```

2. To display the address ranges of process with PID 1573580, enter:

```
# procmap -X 1573580
```

```
1573580 : ./self_mod_32

Start-ADD       End-ADD            SIZE MODE  PSIZ  TYPE       VSID          MAPPED OBJECT

```

Files

Item	Description
/proc	Contains the **/proc** filesystem.

procrun Command

Purpose

Starts a process that has stopped on the **PR_REQUESTED** event.

Syntax

procrun *ProcessID* ...

Description

The **/proc** filesystem provides a mechanism to control processes. It also gives access to information about the current state of processes and threads, but in binary form. The proctools commands provide ascii reports based on some of the available information.

Most of the commands take a list of process IDs or **/proc/***ProcessID* strings as input. The shell expansion **/proc/*** can therefore be used to specify all processes in the system.

Each of the proctools commands gathers information from **/proc** for the specified processes and displays it to the user. The proctools commands like procrun and procstop start and stop a process using the **/proc** interface.

The information gathered by the commands from **/proc** is a snapshot of the current state of processes, and therefore can vary at any instant except for stopped processes.

The **procrun** command starts the process that has stopped on the **PR_REQUESTED** event.

Flags

Item	Description
ProcessID	Specifies the process id.

Examples

1. To restart process 30192 which was stopped on the **PR_REQUESTED** event, enter:

```
procrun 30192
```

Files

Item	Description
/proc	Contains the **/proc** filesystem.

procsig Command

Purpose

Lists the signal actions defined by processes.

Syntax

procsig *ProcessID* ...

Description

The **/proc** filesystem provides a mechanism to control processes. It also gives access to information about the current state of processes and threads, but in binary form. The proctools commands provide ASCII reports based on some of the available information.

Most of the commands take a list of process IDs or **/proc/***ProcessID* strings as input. The shell expansion **/proc/*** can therefore be used to specify all processes in the system.

Each of the proctools commands gathers information from **/proc** for the specified processes and displays it to the user. The proctools commands like procrun and procstop start and stop a process using the **/proc** interface.

The information gathered by the commands from **/proc** is a snapshot of the current state of processes, and therefore can vary at any instant except for stopped processes.

The **procsig** command lists the signal actions defined by processes.

Flags

Item	Description
ProcessID	Specifies the process id.

Examples

1. To list all the signal actions defined for process 11928, enter:

```
procsig 11928
```

The output of this command might look like this:

```
HUP         caught
INT         caught
QUIT        caught
ILL         caught
TRAP        caught
ABRT        caught

Files

Item	Description
/proc	Contains the **/proc** filesystem.

procstack Command

Purpose

Prints the hexadecimal addresses and symbolic names for all the threads in the process.

Syntax

procstack [**-F**] [**-g**] *ProcessID* ...

Description

The /proc filesystem provides a mechanism to control processes. It also gives access to information about the current state of processes and threads, but in binary form. The **proctools** commands provide ASCII reports based on some of the available information.

Most of the commands take a list of process IDs or **/proc/***ProcessID* strings as input. The shell expansion **/proc/*** can therefore be used to specify all processes in the system.

Each of the **proctools** commands gathers information from /proc for the specified processes and displays it to the user. The **proctools** commands like **procrun** and **procstop** start and stop a process using the **/proc** interface.

The information gathered by the commands from **/proc** is a snapshot of the current state of processes, and therefore can vary at any instant except for stopped processes.

The **procstack** command prints the hexadecimal addresses and symbolic names for all the threads in the process.

Flags

Item	Description
-F	Forces the **procstack** command to take control of the target process even if another process has control.
-g	Prevents the conversion of symbol names to human-readable names.
ProcessID	Specifies the process ID.

Examples

1. To display the current stack of process 11928, enter:

```
procstack 11928
```

   The output of this command might look like this:

```
11928 : -sh
d01d15c4  waitpid   (?, ?, ?) + e0
10007a1c  job_wait   (?) + 144
10020298  xec_switch   (?, ?, ?, ?, ?) + 9c0
10021db4  sh_exec   (?, ?, ?) + 304
10001370  exfile   () + 628
10000300  main   (?, ?) + a1c
10000100  __start   () + 8c
```

2. To display the current stack of all the threads of the multi-threaded process 28243 for application *appl*, enter:

```
procstack 28243
```

   The output of this command would look like this:

```
28243 : appl
---------- tid# 54321 -----------
d0059eb4  _p_nsleep   (?, ?) + 10
d01f1fc8  nsleep   (?, ?) + b4
d026a6c0  sleep   (?) + 34
100003a8  main   () + 98
10000128  __start   () + 8c
```

```
---------- tid# 43523 ----------
d0059eb4  _p_nsleep   (?, ?) + 10
d01f1fc8  nsleep   (?, ?) + b4
d026a6c0  sleep   (?) + 34
10000480  PrintHello   (d) + 30
d004b314  _pthread_body   (?) + ec
---------- tid# 36352 ----------
d0059eb4  _p_nsleep   (?, ?) + 10
d01f1fc8  nsleep   (?, ?) + b4
d026a6c0  sleep   (?) + 34
10000480  PrintHello   (c) + 30
d004b314  _pthread_body   (?) + ec
```

Files

Item	Description
/proc	Contains the **/proc** filesystem.

procstop Command

Purpose

Stops processes on the **PR_REQUESTED** event.

Syntax

procstop *ProcessID* ...

Description

The **/proc** filesystem provides a mechanism to control processes. It also gives access to information about the current state of processes and threads, but in binary form. The **proctools** commands provide ASCII reports based on some of the available information.

Most of the commands take a list of process IDs or **/proc/***ProcessID* strings as input. The shell expansion **/proc/*** can therefore be used to specify all processes in the system.

Each of the proctools commands gathers information from **/proc** for the specified processes and displays it to the user. The **proctools** commands like **procrun** and **procstop** start and stop a process using the **/proc** interface.

The information gathered by the commands from **/proc** is a snapshot of the current state of processes, and therefore can vary at any instant except for stopped processes.

The **procstop** command stops processes on the **PR_REQUESTED** event.

Flags

Item	Description
ProcessID	Specifies the process id.

Examples

1. To stop process 7500 on the **PR_REQUESTED** event, enter:

```
procstop 7500
```

Files

Item	Description
/proc	Contains the **/proc** filesystem.

proctree Command

Purpose

Prints the process tree containing the specified process IDs or users.

Syntax

proctree [**-a**] [{ *ProcessID* | *User* }]

proctree [**-a**] [**-T**] [**-t**] [{ *-p ProcessID* | *-u User* }] [**-@** [*WparName*]]

Description

The **/proc** filesystem provides a mechanism to control processes. It also gives access to information about the current state of processes and threads, but in binary form. The **proctools** commands provide ASCII reports based on some of the available information.

Most of the commands take a list of process IDs or **/proc/***ProcessID* strings as input. The shell expansion **/proc/*** can therefore be used to specify all processes in the system.

Each of the proctools commands gathers information from **/proc** for the specified processes and displays it to the user. The **proctools** commands like **procrun** and **procstop** start and stop a process using the **/proc** interface.

The information gathered by the commands from **/proc** is a snapshot of the current state of processes, and therefore can vary at any instant except for stopped processes.

The **proctree** command prints the process tree containing the specified process IDs or users. The child processes are indented from their respective parent processes. An argument of all digits is taken to be a process ID, otherwise it is assumed to be a user login name. The default action is to report on all processes, except children of process 0.

When you specify the -@ flag with no parameters, all WPAR names are displayed. If you specify the *WparName* parameter, only those WPAR names are displayed.

For displaying thread IDs and associated pthread IDs, specify the **-t** option. For a kernel process, the **proctree** command displays only the thread ID.

Note: If the information about the process cannot be retrieved, the **proctree** command displays only the process ID. The other information about the process is shown as blank. For example, the **proctree** command shows only the process ID for the zombie process.

Flags

Item	Description
-a	Includes children of process 0 in the display. The default is to exclude them.
ProcessID	Specifies the process ID.
-p ProcessID	Specifies the process ID.
-T	Displays the formatted output of the process tree.
-t	Displays thread IDs and associated pthread IDs for the process.

Item	Description
User	Specifies the user name.
-u User	Specifies the user name.
-@	Displays all WPAR names. **Note:** The **-@** flag is not supported when executed within a workload partition.
-@ WparName	Displays only the processes of the WPAR you specify using the *WparName* parameter. **Note:** The **-@** flag is not supported when executed within a workload partition.

Examples

1. To display the ancestors and all the children of the 12312 process, enter the following command:

   ```
   proctree 12312
   ```

   The output of this command might look like this:

   ```
   4954    /usr/sbin/srcmstr
      7224    /usr/sbin/inetd
         5958    telnetd -a
            13212    -sh
               14718    ./proctree 13212
   ```

2. To display the ancestors and children of the 12312 process, including children of process 0, enter the following command:

   ```
   proctree -a 12312
   ```

   The output of this command might look like this:

   ```
   1    /etc/init
      4954    /usr/sbin/srcmstr
         7224    /usr/sbin/inetd
            5958    telnetd -a
               13212    -sh
                  14724    ./proctree -a 13212
   ```

3. To display the process tree of WPAR corral2, enter the following command:

   ```
   proctree -@ corral2
   ```

   The output of this command might look like this:

   ```
   corral2       401496   /etc/init
   corral2       319680   /usr/sbin/srcmstr
   corral2       102636   /usr/sbin/inetd
   corral2       249954   /opt/rsct/bin/rmcd -a IBM.LPCommands -r
   corral2       254132   /opt/rsct/bin/IBM.AuditRMd
   corral2       295098   /opt/rsct/bin/IBM.ServiceRMd
   corral2       303218   /usr/dt/bin/dtlogin
   corral2       307370   /usr/sbin/writesrv
   corral2       323836   /usr/sbin/qdaemon
   corral2       331970   /usr/sbin/muxatmd
   corral2       348210   /usr/sbin/syslogd
   corral2       352472   sendmail: accepting connections H nnections
   corral2       364564   /opt/rsct/bin/IBM.ERrmd
   corral2       405522   /usr/sbin/portmap
   corral2       282800   /usr/bin/xmwlm -L
   corral2       311454   /usr/sbin/cron
   corral2       376920   /usr/lib/errdemon
   ```

4. To display the WPAR name of the processes, enter the following command:

```
proctree -@
```

The output of this command might look like this:

```
Global     114788   /usr/dt/bin/dtlogin -daemon
Global     86108   dtlogin <:0>        -daemon
Global     123022   dtgreet 8  :0
Global     77944   /usr/lib/errdemon
Global     94314   /usr/sbin/syncd 60
Global     168084   /usr/sbin/srcmstr
Global     110688   /opt/rsct/bin/IBM.ServiceRMd
corral2    401496   /etc/init
corral2    319680   /usr/sbin/srcmstr
corral2    102636   /usr/sbin/inetd
corral2    249954   /opt/rsct/bin/rmcd -a IBM.LPCommands -r
corral2    254132   /opt/rsct/bin/IBM.AuditRMd
corral2    331970   /usr/sbin/muxatmd
corral2    348210   /usr/sbin/syslogd
corral2    364564   /opt/rsct/bin/IBM.ERrmd
corral2    405522   /usr/sbin/portmap
corral2    282800   /usr/bin/xmwlm -L
corral2    311454   /usr/sbin/cron
corral2    376920   /usr/lib/errdemon
Global     151626   /usr/ccs/bin/shlap64
Global     274578   /usr/sbin/getty /dev/console
...
```

5. To display the ancestors, all of the children, and the WPAR name of the 102636 process, enter the following command:

```
proctree  -p 102636 -@
```

The output of this command might look like this:

```
Global     168084    /usr/sbin/srcmstr
corral2    401496    /etc/init
corral2    319680    /usr/sbin/srcmstr
corral2    102636    /usr/sbin/inetd
```

6. To display the formatted process-tree output of the 213246 process, enter the following command:

```
proctree -T -p 213246
```

The output of this command might look like this:

```
192652        \--/usr/sbin/srcmstr
200830              \--/usr/sbin/inetd
213246                    \--telnetd -a
229592                          \---ksh
```

7. To display thread IDs and associated pthread IDs for the 344172 process, enter the following command:

```
proctree -t -p 344172
```

The output of this command might look like this:

```
192652    /usr/sbin/srcmstr
     TID : 225535 (pTID :      1)
   200830    /usr/sbin/inetd
        TID : 360677 (pTID :      1)
      323642    telnetd -a
           TID : 770057 (pTID :      1)
         307428    -ksh
              TID : 1056861 (pTID :      1)
            344172    appthd
                 TID : 1065119 (pTID :      1)
                 TID : 1028171 (pTID :    258)
                 TID : 1011789 (pTID :   2057)
                 TID : 1024105 (pTID :   1800)
```

8. To display the formatted process-tree output for the 344172 process along with thread IDs and associated pthread IDs, enter the following command:

```
proctree -tT -p 344172
```

The output of this command might look like this:

```
192652   \--/usr/sbin/srcmstr
             ~~TID : 225535 (pTID :      1)
200830       \--/usr/sbin/inetd
                 ~~TID : 360677 (pTID :      1)
323642           \--telnetd -a
                      ~~TID : 770057 (pTID :      1)
307428                \---ksh
                         ~~TID : 1056861 (pTID :      1)
344172                        \--appthd
                                 |~~TID : 1065119 (pTID :      1)
                                 |~~TID : 1028171 (pTID :    258)
                                 |~~TID : 1011789 (pTID :   2057)
                                  ~~TID : 1024105 (pTID :   1800)
```

Files

Item	Description
/proc	Contains the **/proc** filesystem.

procwait Command

Purpose

Waits for all of the specified processes to terminate.

Syntax

procwait [**-v**] *ProcessID* ...

Description

The **/proc** filesystem provides a mechanism to control processes. It also gives access to information about the current state of processes and threads, but in binary form. The **proctools** commands provide ASCII reports based on some of the available information.

Most of the commands take a list of process IDs or **/proc/***ProcessID* strings as input. The shell expansion **/proc/*** can therefore be used to specify all processes in the system.

Each of the proctools commands gathers information from **/proc** for the specified processes and displays it to the user. The **proctools** commands like **procrun** and **procstop** start and stop a process using the **/proc** interface.

The information gathered by the commands from **/proc** is a snapshot of the current state of processes, and therefore can vary at any instant except for stopped processes.

The **procwait** command waits for all of the specified processes to terminate.

Flags

Item	Description
-v	Specifies verbose output. Reports terminations to standard output.
ProcessID	Specifies the process id.

Examples

1. To wait for process 12942 to exit and display the status, enter:

```
procwait -v 12942
```

   The output of this command might look like this:

```
12942 : terminated, exit status 0
```

Files

Item	Description
/proc	Contains the **/proc** filesystem.

procwdx Command

Purpose

Prints the current working directory of processes.

Syntax

procwdx [**-F**] *ProcessID* ...

Description

The **/proc** filesystem provides a mechanism to control processes. It also gives access to information about the current state of processes and threads, but in binary form. The **proctools** commands provide ASCII reports based on some of the available information.

Most of the commands take a list of process IDs or **/proc/***ProcessID* strings as input. The shell expansion **/proc/*** can therefore be used to specify all processes in the system.

Each of the proctools commands gathers information from **/proc** for the specified processes and displays it to the user. The **proctools** commands like **procrun** and **procstop** start and stop a process using the **/proc** interface.

The information gathered by the commands from **/proc** is a snapshot of the current state of processes, and therefore can vary at any instant except for stopped processes.

The **procwdx** command prints the current working directory of processes.

Flags

Item	Description
-F	Forces procfiles to take control of the target process even if another process has control.
ProcessID	Specifies the process id.

Examples

1. To display the current working directory of process 11928, enter:

```
procwdx 11928
```

   The output of this command might look like this:

```
11928 :  /home/guest
```

Files

Item	Description
/proc	Contains the **/proc** filesystem.

prof Command

Purpose

Displays object file profile data.

Syntax

prof [**-t** | **-c** | **-a** | **-n**] [**-o** | **-x**] [**-g**] [**-z**] [**-h**] [**-s**] [**-S**] [**-v**] [**-L** *PathName*] [*Program*] [**-m** *MonitorData* ...]

Description

The **prof** command interprets profile data collected by the **monitor** subroutine for the object file *Program* (**a.out** by default). It reads the symbol table in the object file *Program* and correlates it with the profile file (**mon.out** by default). The **prof** command displays, for each external text symbol, the percentage of execution time spent between the address of that symbol and the address of the next, the number of times that function was called, and the average number of milliseconds per call.

Note: Symbols from C++ object files have their names demangled before they are used.

To tally the number of calls to a function, you must have compiled the file using the **cc** command with the **-p** flag. The **-p** flag causes the compiler to insert a call to the **mcount** subroutine into the object code generated for each recompiled function of your program. While the program runs, each time a parent calls a child function the child calls the **mcount** subroutine to increment a distinct counter for that parent-child pair. Programs not recompiled with the **-p** flag do not have the **mcount** subroutine inserted and therefore keep no record of which function called them.

The **-p** flag also arranges for the object file to include a special profiling startup function that calls the **monitor** subroutine when the program begins and ends. The call to the **monitor** subroutine when the program ends actually writes the **mon.out** file. Therefore, only programs that explicitly exit or return from the main program cause the **mon.out** file to be produced.

Note: To change the name of the generated output file, use the PROF environment variable and set it as follows:

```
PROF=filename:<filename>
```

For example, if you set PROF=`myprof`, then the generated file will be named as `myprof.out`.

The location and names of the objects loaded are stored in the **mon.out** file. If you do not select any flags, **prof** will use these names. You must specify a program or use the **-L** option to access other objects.

Note: Imported external routine calls, such as a call to a shared library routine, have an intermediate call to local **glink** code that sets up the call to the actual routine. If the timer clock goes off while running this code, time is charged to a routine called *routine***.gl**, where *routine* is the routine being called. For example, if the timer goes off while in the **glink** code to call the **printf** subroutine, time is charged to the **printf.gl** routine.

Flags

The mutually exclusive flags **a**, **c**, **n**, and **t** determine how the **prof** command sorts the output lines:

Item	Description
-a	Sorts by increasing symbol address.
-c	Sorts by decreasing number of calls.
-n	Sorts lexically by symbol name.
-t	Sorts by decreasing percentage of total time (default).

Note: The **prof** command can still run successfully if you use more than one of flags **a**, **c**, **n**, and **t** in the same command. The **prof** command accepts the first of these flags it encounters on the command line and ignores the others.

The mutually exclusive flags **o** and **x** specify how to display the address of each symbol monitored.

Item	Description
-o	Displays each address in octal, along with the symbol name.
-x	Displays each address in hexadecimal, along with the symbol name.

Note: The **prof** command can still run successfully if you use both the **-o** and **-x** flags in the same command. The **prof** command accepts the first of these two flags it encounters on the command line and ignores the other flag.

Use the following flags in any combination:

Item	Description
-g	Includes non-global symbols (static functions).
-h	Suppresses the heading normally displayed on the report. This is useful if the report is to be processed further.
-L *PathName*	Uses alternate path name for locating shared objects.
-m *MonitorData*	Takes profiling data from *MonitorData* instead of **mon.out**.
-s	Produces a summary file in **mon.sum**. This is useful when more than one profile file is specified.
-S	Displays a summary of monitoring parameters and statistics on standard error.
-v	Suppresses all printing and sends a graphic version of the profile to standard output for display by the plot filters. When plotting, low and high numbers, by default 0 and 100, can be given to cause a selected percentage of the profile to be plotted with accordingly higher resolution.
-z	Includes all symbols in the profile range, even if associated with 0 (zero) calls and 0 (zero) time.

Examples

1. To display, without a header, the amount of time spent at each symbol address, sorted by time, enter:

```
prof -t -h
```

2. The following example obtains a local version of any shared libraries used to create the **runfile** file in the **/home/score/lib** directory. The data file used will be **runfile.mon** rather than **mon.out**.

```
prof -x -L/home/score/lib runfile -m runfile.mon
```

Files

Item	Description
mon.out	Default profile.
a.out	Default object file.
mon.sum	Summary profile.

proff Command

Purpose

Formats text for printers with personal printer data streams.

Syntax

proff [**-L***List*] [**-P***Printer*] [**-t**] [*nroffFlags*] [*File* ...]

Description

The **proff** command formats text by using the **nroff** command on the specified files for printers that support ppds (personal printer data streams), such as the Quietwriter III printer, the Quickwriter printer, and the Proprinter printer.

If no file is specified, standard input is read. A parameter value of **-** (minus) specifies standard input.

Parameters

Item	Description
nroffFlags	Specifies the **nroff** command flags used by the **proff** command to format the text file for a ppds-supported printer output.
File	Specifies the text file that the **proff** command formats for printers that support ppds.

Flags

Item	Description
-L*List*	Passes the specified list as flags for the **qprt** command. To pass a single flag to the **qprt** command, use the **-L** flag followed immediately by the **nroff** command flag being passed. For example: `-L-h.` To pass multiple flags or a string to the **lpr** command, use the **-L** flag followed immediately by the flags or string enclosed by " " (double quotes): `-L"-h -r -m".`
-P*Printer*	Sends output to a specified printer corresponding to an entry in the **/etc/qconfig** file. The default is taken from the **PRINTER** environment variable, if it exists; otherwise the system default queue name is used.
-t	Sends output to standard output.

Item	Description
-	Specifies that standard input is used as the source for the formatting process. All other flags are passed to the **nroff** command.

Example

The following is a typical command sequence to process output for the IBM Proprinter printer:

```
proff -t testfile
```

Environment Variable

Item	Description
PRINTER	Specifies the desired printer queue.

Files

Item	Description
/usr/share/lib/nterm/tab.ppds	Contains driving tables for printers with personal printer data streams.
/etc/qconfig	Describes the queues and devices.

projctl Command

Purpose

Supports project-based advanced accounting activities.

Syntax

projctl **add** *projname projnumber* [*comment*] [{ **-d** *projpath* | **-p** [*DN*] }]

projctl **merge** *sourceprojpath* [**-d** *targetprojfile*]

projctl **rm** *projname* [{ **-d** *projpath* | **-p** [*DN*] }]

projctl **chg** *projname* [**-p** *pid* [, *pid*]] [**-f**]

projctl **exec** *projname* <*cmd line*> [**-f**]

projctl **chattr agg** *projname* {**-s**|**-u**} [{ **-d** *projpath* | **-p** [*DN*] }]

projctl *qpolicy* [**-g** [*DN*]]

projctl **qprojs** [**-n**]

projctl **qproj** [*projectname*]

projctl **qapp** *appname*

projctl {**chkusr** | **chkgrp** | **chkprojs** | {{**chkadm** | **chkall**} [**-d** *admpath*]}}

projctl **ldusr** [**-r**] [**-a**]

projctl **unldusr** [**-a**]

projctl **ldgrp** [**-r**] [**-a**]

projctl **unldgrp** [**-a**]

projctl ldprojs -g [**-r**] [**-a**]

projctl ldprojs -g [*DN*] **-d** *projpath*

projctl ldprojs -p [*DN*] **-d** *projpath*

projctl unldprojs -g [*DN*] [**-f**] [**-a**]

projctl unldprojs -p [*DN*]

projctl ldadm -g [*name*] [**-r**] [**-a**]

projctl ldadm -g [*name:*]*DN* | *name*] **-d** *admpath*

projctl ldadm -p [[*name:*]*DN* | *name*] **-d** *admpath*

projctl unldadm -g [**-a**]

projctl unldadm -p [[*name:*]*DN* | *name*]

projctl ld [**-r**]

projctl ldall [**-d** *admpath*] [**-r**] [**-a**]

projctl unldall [**-f**] [**-a**]

Description

The various subcommands of **projctl** command perform project-based advanced accounting activities such as adding a new project, removing a new project, and loading a specific accounting policy. These various options of **projctl** command are as explained below.

Flags

Item	Description
-a	Automatically loads the policies during system reboot.
-d	Generally specifies the path from where the project definition file or the admin policy file should be referred. When used in the `merge` subcommand, it specifies the target project definition file where the merged project definitions are to be stored.
-f	Overrides the policy rules when specified with `chg` and `exec` subcommands. Clears the project assigned to the processes when called with `unldall` subcommand. Force unload all the project definitions when called with `unldprojs` subcommand.
-g	Specifies that the projects and policies are to be downloaded from the LDAP repository.
-n	Sorts the list of project definitions based on the name.
-p	When used in the `chg` subcommand, passes the list of process IDs that require a change in project assignment. When used in the `add`, `rm`, and `chattr` subcommands, specifies the LDAP DN where the project definition is to be updated. When used in the `ld` and `unld` subcommands, specifies that the projects and policies are to be uploaded to the LDAP repository. Its argument indicates the DN where the projects and policies are to be uploaded.
-r	Reloads the policies.
-s	Used in **projctl chattr agg** subcommand to enable the project aggregation property.
-u	Used in **projctl chattr agg** subcommand to disable the project aggregation property.

Parameters

Item	Description
admpath	Path from where to select the admin policy file.

Item	Description
appname	Absolute path of the application whose project assignment list is requested.
cmd line	Absolute path of the command to be executed through **projctl exec** command.
comment	Project comments.
DN	Distinguished Name that indicates the absolute path to the project and policy objects on the LDAP server.
name	Name of the alternate admin policy definitions on the LDAP server.
pid	Process IDs.
projname	Name of the project.
projnumber	Numeric value for the project.
projpath	Path from where to select the project definition file.
sourceprojpath	Path from where the project definition file to be merged is to be picked up.
targetprojfile	Target project definition file where the project definitions should be merged.

Subcommands

add Subcommand

The **add** subcommand adds the definition of the project to the project definition file. If the **–d** flag is specified then the project definition is added into the project definition file, under the named path. The default is to add to the **/etc/project/projdef** system project definition file. The project definition file under any other path should be named as **.projdef:**. If the new project is to be added to the system project definition file and the projects are already loaded in kernel, then the specified new project will be added into kernel project registry. Otherwise, the entry will be made only in the file. The **add** subcommand takes the project name, project number, and an option argument for project comments as parameters. By default, the aggregation property of the project will be set to no for all the projects created using this command.

If `-p` is specified, the new project definition is added to default project *DN* or the specified *DN* on the LDAP server. If `-p` is not specified, `.config` will provide source information. Running the `-p` option requires root authority.

Each entry created by **projctl add** in the Project Definition File has the following format:

```
ProjectName:ProjectNumber:AggregationStatus::Comment
```

Examples for Project Definitions that illustrate the file format are as follows:

```
:: Project Definition File
:: Dated: 23-JUN-2003
AIX:3542:yes::To Classify AIX Legacy Applications
Test_Project:0x10000:yes::To Classify Testing work
```

chattr agg Subcommand

The **chattr agg** subcommand enables and disables aggregation property for the given project. If **-s** flag is used the aggregation is enabled. If **-u** flag is used aggregation is disabled. If **–d** flag is specified then the project definition is updated in the project definition file under the specified path. The default is to update the system project definition file (**/etc/project/projdef**). If the update is to the system project definition file and it is already loaded in kernel, then the specified new project is updated in kernel project registry as well. Otherwise, the changes will be made only to the project definition file.

If `-p` is specified, the project definition is modified on default project *DN* or the specified DN on the LDAP server. If `-p` is not specified, `.config` will provide source information. Executing the `-p` option requires root authority.

chg Subcommand

The **chg** subcommand enables the user to change the list of projects that the user is permitted to use for his processes. The intended project name is given as input to this subcommand. If the process IDs are provided as input, those processes will be classified under the specified project. If there are no process IDs provided as input, the project change will happen to the process which started the **projctl** command.

By default, the **chg** subcommand changes the project assignment within the scope of available rules. To override the rules and assign a project directly to a process, the **-f** force option must be specified.

chk Subcommand

The **chk** subcommands check the validity of various project policies. The subcommands validate the projects and policies so that they can be loaded safely into the kernel. There are several **chk** subcommands to support various project policies. The subcommands include:

Item	Description
chkadm	Validates the admin policies. Each rule in the admin policy file usually has four attributes: user-id, group-id, application path name, and the project names. The **chkadm** subcommand checks whether these attributes are valid and reports any errors found in the policies. When the **-d** option is used, the **chkadm** subcommand uses the admin policy file from the specified path for checking the rules. It also uses the alias and the temporary project definition file (**.projdef**), if required. The projects used in the rule will be first searched in the system project definition file. If it is not found there, then the **.projdef** file under the specified path will be used.
chkall	Performs all the above validation activities, that is, it validates projects, user, group and admin policies. When the **–d** option is used, the **chkadll** subroutine uses the admin, alias, and project definition files from the specified path to validate the admin policies.
chkgrp	Validates the group policies. The validation involves checking whether the project list of the group contains valid projects.
chkprojs	Validates the system project definition file. Project Definitions are validated for uniqueness, project name and number validity, and attributes validity. The project name should be a POSIX alphanumeric string and the project number should be within the numeric range 0x00000001 - 0x00ffffff. The project numbers can be either decimal or hexadecimal numbers. All hexadecimal numbers should be shown with a prefix of `0x`. The aggregation property can be either a y or a n to indicate the status of aggregation. The **chkprojs** subcommand performs all these validity checks on the project definitions and reports any errors found with the project definitions.
chkusr	Validates the user policies. The validation involves checking whether the project list of the user contains valid projects.

Note: If wildcard characters are used in the admin policy rules then **chkadm** and **chkall** subcommands expand the wildcard characters and validate the output obtained.

exec Subcommand

The **exec** subcommand allows a user to launch arbitrary commands with any of the project names from the list of projects on which the command can work. Similar to **chg** option, used to override the rules and use any project to run the command line, the **-f** force option should be used. To get the list of projects that the command can be assigned to, use the **projctl qapp** subcommand.

ld Subcommand

The **ld** subcommands are used to load and reload projects and policies. There are specific load commands to perform the load operation on a specific policy. These various subcommands are as follows:

Item	Description
ld	Loads the policies, which should be loaded during the system startup. It refers the **/etc/project/.config** file to determine which policies to load. If the kernel is loaded already with any one policy or project definition, then this command simply returns.
ldadm	Loads the admin policies. Similar to **ldusr** and **ldgrp** subcommands, **ldadm** also checks and loads the projects first, if they are yet to be loaded. Then it loads the admin policy rules, after validating them. When the **-d** option is used, the admin policy file will be picked from the specified path. The alias and the temporary project definition file under the specified path will be used to check the existence of alias and project entries. After the policies are loaded, this subcommand also copies the admin policy file to **/etc/project/.admin**. Loading the admin policies related to LDAP is handled by the following `-p` and `-g` arguments: **projctl ldadm -g [*name*]** Specifies that an admin policy will be loaded into the kernel using the LDAP repository. If `-g` is not specified, the local admin policy (`/etc/project/admin`) will be downloaded into the kernel. **projctl ldadm -g [[*name*:]DN | *name*] -d *admpath*** Specifies that an LDAP admin policy will be downloaded to a local file without downloading the policy into the kernel. The source admin policy is located at the specified DN or is found using the accounting DNs in the `ldap.cfg` file. The `-d` parameter is used to specify where the policy files (projects, admin, and alias) are written. If the target location is below `/etc/project/`, the files are written according to the conventions used by the system. Files are written to: • `/etc/project/admin`, `/etc/project/alias`, `/etc/project/projdef` • `/etc/project/ldap/admin`, `/etc/project/ldap/alias`, `/etc/project/ldap/projdef` • `/etc/project/projdef`, `/etc/project/alter/policyname/admin`, `.../alias` • `/etc/project/ldap/projdef`, `/etc/project/ldap/alter/policyname/admin`, `.../alias` Otherwise, the three files are written to the specified directory. When an explicit DN is specified with the `-g` option, the projects are not downloaded because they could also be located on a different DN. In this case, the user has to download them separately. **projctl ldadm -p [[*name*:]DN | *name*] -d *admpath*** Specifies that an admin policy located at the directory *localpath* will be uploaded to the LDAP server. This command also uploads projects that it finds in the `localpath/.projdef` temporary project definition file. When an explicit DN is specified with the `-p` option, only the admin policy is uploaded to the LDAP server because the projects could be located on a different DN. In this case, the user must explicitly upload the respective `.projdef` file to the appropriate DN. The system does not know the identity of this DN. The `-d` argument must be specified when the `-g` or `-p` arguments are used. The `-r` and `-a` arguments cannot be specified with the `-p` argument. If the `-a` argument is specified and the `-g` argument is not specified, the admin policies in the `.config` file are loaded. If the `-r` option is used, the `.active` file is used to determine the identity of the policies to load. The `-r` and `-a` options cannot be used together.
ldall	Downloads user, group, and admin policies into the kernel. Similar to the `ldusr` and `ldgrp` commands, this option attempts to download LDAP projects if an accounting DN has been specified for projects, because the User and Group Policies are not associated with Local or LDAP Users individually. This command attempts to download the default Admin policy using the configured admin DN in addition to downloading the Local Admin Policy.

Item	Description
ldgrp	Loads the group project policies. If they are not yet loaded, the **ldgrp** subcommand checks and loads the projects first. It then verifies the validity of the project list for all the groups and loads the rules.
ldprojs	Loads the project definitions from the system project definition **/etc/project/projdef** file. Before loading the projects, it checks the validity of the rules. If the rules are found to valid, then it loads them. **projctl ldprojs -g** Specifies that the project definitions will be loaded into the kernel using the LDAP repository. **projctl ldprojs -p** Specifies that project definitions are to be uploaded to the LDAP server. If `-g` and the `-p` are not specified, the locally defined projects (`/etc/project/projdef`) are loaded into the kernel. **projctl ldprojs -g [*DN*] -d *localpdfpath*** Specifies that the project definition file from the LDAP repository will be downloaded to a local file without downloading the projects into the kernel. If the `-d` argument is not specified, the projects are downloaded to `/etc/project/ldap/projdef` and they are downloaded into the kernel. The `-d` argument directs you to create the file at the designated location, but not to download it into the kernel. In this case, the `projdef` file is created at the designated location rather than in the `.projdef` file. The source project definitions are located at the specified DN. Alternately, you can find them using the configured accounting DN in the `ldap.cfg` file. **projctl ldprojs -d *localpdfpath*** Loads the local project definition file into the kernel. **projctl ldprojs -p [*DN*] -d *localpdfpath*** Specifies that the project definitions located at the specified path will be uploaded to the LDAP server. The project definitions should be available in the `projdef` file at the specified directory. The `-d` argument must be specified when the `-g` or `-p` directs you to create the file at the designated location, but not to download it into the kernel. In this case, the `projdef` arguments are used. This way, the upload and download operations can be symmetric with respect to the specification of parameters. The `-r` and `-a` arguments cannot be specified with the `-p` argument. If the `-a` argument is specified and the `-g` argument is not specified, the project repositories in the `.config` file are loaded. If the `-r` option is used, the `.active` file is used to determine the project repositories to load. The `-r` and `-a` options cannot be used together.
ldusr	Loads the user project policies. If they are not yet loaded, the **lduser** subcommand checks and loads the projects first. It then verifies the validity of the project list for all the users and loads the rules.

Note:

- When **–r** option is used, all the above subcommands reload the respective policies. The **ld –r** subcommand queries the kernel to get the details of loaded policies and reloads them. The policy files to be reloaded will be referred from the **/etc/project/.active** file.
- When **ldadm** and **ldall** subcommands are issued with both the options **–d** and **–r**, **-r** will be ignored.
- All the **ld** subcommands update the **/etc/project/.active** file with the details of the policy that is loaded. When the **-a** option is passed, these subcommands also update the **/etc/project/.config** file in addition to updating the **.active** file. The **/etc/project/.config** file provides the details on the policies to be loaded automatically on system reboot.

merge Subcommand

The **merge** subcommand merges the projects defined in the project definition file under the specified path with the system project definition **/etc/project/projdef** file, by default. If a target project file name

is passed using the **-d** option, the project definitions under the specified path are merged with the target project definition file. The merge operation will fail if there are conflicting entries between the target project definition file and the project definition file under the specified path. The **merge** command skips any duplicate entries to maintain unique entries in the target project definition file.

qapp Subcommand

The **qapp** subcommand displays the list of projects that an application can switch to in the current environment. It displays the list of all projects with which the specified application can be started.

qpolicy Subcommand

The **qpolicy** subcommand displays the currently loaded policies. This command queries the kernel to get the information about the types of loaded policies and displays them. If `-g` is specified, this command lists the policies from the LDAP default admin DN or from the specified DN.

qproj Subcommand

The **qproj** subcommand displays the details of the project name passed as its argument. If no argument is passed, then this subcommand lists all the project definitions in the system to which the calling process can be assigned. The display format will be the same as that of **qprojs** subcommand.

qprojs Subcommand

The **qprojs** subcommand displays the list of all the project definitions that is currently loaded in the kernel registry. The **-n** option provides the list sorted based on the project name. The display contains the project name, project number, and its aggregation status.

rm Subcommand

The **rm** subcommand removes the definition of locally defined projects from the project definition file. If the **–d** flag is specified, then the project definition is removed from the project definition file under the specified path. The default is to remove it from the system project definition file (**/etc/project/projdef**). If the update is to the system project definition file and it is already loaded in kernel, then the specified project is removed from kernel project registry. Otherwise, the entry will be removed only from the file.

If `-p` is specified, the source will be the LDAP from where the project definitions are to be removed. If an explicit DN is specified, the project definition will be removed from that specific DN. If no DN is passed, the default DN configured in the `ldap.cfg` file will be used. If the LDAP projects are currently loaded, the project definition is removed from the kernel project registry and the local LDAP project file also. Otherwise, only the LDAP repository is updated.

Note: The `-p` and `-d` options cannot be used together. If neither of these options are specified, the `.config` file will be used to provide the source information. This command requires root authority to execute.

unld Subcommand

The **unld** subcommands are used to unload project policies. Similar to the **ld** subcommands, the **unld** subcommands are used to unload specific policies. These various subcommands are as follows:

Item	Description
unldadm	Unloads the admin policies.
unldall	Unloads all the loaded policies.
unldgrp	Unloads the group policies.
unldprojs	Unloads only the project definitions.
unldusr	Unloads the user policies.

Note:

- All these subcommands update the **.active** file after the respective policy is unloaded.

- When the **-a** option is used, the **/etc/project/.config** file is also updated with the unloaded status of the respective policy.
- The `-g` parameter specifies that the respective LDAP repository should be unloaded from the kernel. If `-g` is not specified, then the loaded repositories that are named in the `.active` file are unloaded.
- The `-p` option must be specified to remove the specified LDAP repository from the LDAP server.
- In the `unldadm` and `unsubcommand`, the *name* parameter indicates the admin policy name on the admin DN.

Exit Status

Item	Description
0	The command completed successfully.
>0	An error occurred. **1** Default error return code for read, write, and malloc failures. **2** EINVAL and ENOENT **3** EPERM and EACCES **4** EEXIST

Examples

1. To add a project `newproj` to the system project definition file, type:

   ```
   projctl add newproj 34 "Test Project"
   ```

2. To remove the project `test1` from the project definition file under the path `/tmp/myproj`, type:

   ```
   projctl rm test1 –d /tmp/myproj
   ```

3. To enable the aggregation status of the project `newproj`, type:

   ```
   projctl chattr agg newproj –s
   ```

4. To execute the **ps** command under the project `newproj`, overriding the existing rules, type:

   ```
   projctl exec newproj "/usr/bin/ps" –f
   ```

5. To retrieve the currently loaded policies, type:

   ```
   projctl qpolicy
   ```

   Output:

   ```
   Project definitions are loaded.
   Project definition file name:  /etc/project/projdef
   User policies are loaded.
   ```

6. To load the admin policies from the path `/tmp/myproj`, type:

   ```
   projctl ldadm –d /tmp/myproj
   ```

7. To unload all the project policies now and during system reboot, type:

   ```
   projctl unldall -a
   ```

8. To add a new project to the LDAP repository on a different DN, where DN is `ou=projects,ou=aacct,ou=cluster1,cn=aixdata`, type:

```
projctl add newproj 34 -p ou=projects,ou=aacct,ou=cluster1,cn=aixdata
```

9. To download the LDAP projects from the default DN to a local file under the `/etc/project/ldap` path, type:

```
projctl ldprojs -g -d /etc/project/ldap
```

10. To load the LDAP admin policies stored under the label `newdef` in the default DN to the kernel, type:

```
projctl ldadm -g newdef
```

Location

/usr/bin/projctl

Files

Item	Description
/usr/bin/projctl	Contains the **projctl** command.
/etc/project/projdef	Contains the system project definition file.
/etc/project/ldap/projdef	Contains the default LDAP project definition file.
/etc/project/.active	Contains the status of currently loaded policies.
/etc/project/.config	Contains the status of the policies to be loaded during system reboot.
/etc/security/ldap/ldap.cfg	Contains the LDAP client configuration details for handling advanced accounting data.

prompter Command

Purpose

Starts a prompting editor.

Syntax

prompter [**-erase** *Character*] [**-kill** *Character*] [**-prepend** | **-noprepend**] [**-rapid** | **-norapid**] *File*

Description

Part of the Message Handler (MH) package, the **prompter** command starts the prompting editor for message entry. The **prompter** command is not started by the user. The **prompter** command is called by other programs only.

The **prompter** command opens the file specified by the *File* parameter, scans it for empty components such as the `To:` component, and prompts you to fill in the blank fields. If you press the Enter key without filling in a required field, the **prompter** command deletes the component.

The **prompter** command accepts text for the body of the message after the first blank line or line of dashes in the file. If the body already contains text and the **-noprepend** flag is specified, the **prompter** command displays the text followed by the message:

```
--------Enter additional text
```

The **prompter** command appends any new text entered after the existing message. If you specify the **-prepend** flag, the **prompter** command displays the following message:

```
--------Enter initial text
```

Any new text precedes the body of the original message. When you press the Ctrl-D key sequence for End of File, the **prompter** command ends text entry and returns control to the calling program.

Flags

Item	Description
-erase *Character*	Sets the character to be used as the erase character. The value of the *Character* variable can be the octal representation of the character in the form \NNN where \NNN is a number or the character itself. For example, the character \e is \145 in octal representation.
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For MH, the name of this flag must be fully spelled out.
-kill *Character*	Sets the character to be used as the kill, or stop, character. The value of the *Character* variable can be the octal representation of the character in the form \NNN where \NNN is a number or the character itself. For example, the character \e is \145 in octal representation.
-noprepend	Appends additional text after text already in the message body.
-norapid	Displays text already in the message body. This is the default.
-prepend	Appends additional text before text already in the message body. This is the default.
-rapid	Does not display text already in the message body.

Profile Entries

Item	Description
`Msg-Protect:`	Sets the protection level for your new message files.
`prompter-next:`	Specifies the editor used after exiting the **prompter** command.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Item	Description
$HOME/ html	

proto Command

Purpose

Constructs a prototype file for a file system.

Syntax

proto *Directory* [*Prefix*]

Description

The **proto** command creates a prototype file for a file system or part of a file system. The **mkfs** command.

Specify the root directory from which the prototype file is made with the *Directory* parameter. The prototype file includes the complete subtree below the *Directory* parameter, and is contained on the same file system as the base directory specified by the *Directory* parameter.

The *Prefix* parameter is added to the names of all the initialization files, forcing the initialization files to be taken from a place other than the prototype. Before the output from the **proto** command can be used with the **LC_COLLATE** environment variables.

Example

To make a prototype file for an existing file system `/works`, enter:

```
proto /works
```

If the `/works` file system contains two directories called `dir1` and `dir2`, and the `dir1` directory contains the `file1` file, then the **proto** command displays:

```
#Prototype file for /works
d---  755  0 0
  dir1  d---  755  0 0
    file1         ----   644  0 0   /works/dir1/file1
          $
  dir2  d---  755  0 0
          $
    $
$
```

Files

Item	Description
/usr/sbin/proto	Contains the **proto** command.

proxymngr Command

Purpose

Proxy manager service.

Syntax

proxymngr [**-config** filename] [**-timeout** seconds] [**-retries** #] [**-verbose**]

Description

The **proxymngr** (proxy manager), is responsible for resolving requests from **xfindproxy** (and other similar clients), starting new proxies when appropriate, and keeping track of all of the available proxy services. The proxy manager strives to reuse existing proxies whenever possible.

There are two types of proxies that the proxy manager deals with, managed and unmanaged proxies.

A managed proxy is a proxy that is started on demand by the proxy manager.

An unmanaged proxy is started either at system boot time, or manually by a system administrator. The proxy manager is made aware of its existence, but no attempt is made by the proxy manager to start unmanaged proxies.

Flags

Item	Description
-config	Overrides the default **proxymngr** config file. See below for more details about the **proxymngr** config file.
-timeout	Sets the number of seconds between attempts made by the proxy manager to find an unmanaged proxy. The default is 10.
-retries	Sets the maximum number of retries made by the proxy manager to find an an unmanaged proxy. The default is 3.
-verbose	Causes various debugging and tracing records to be displayed as requests are received and proxies are started.

Proxy Manager Config File

The proxy manager maintains a local configuration file describing the proxy services available. This configuration file is installed in **/usr/X11R6.3/lib/X11/proxymngr/pmconfig** during the installation of **proxymngr**. The location of the configuration file can be overwritten using the **-config** command line flag.

Aside from lines starting with an exclamation point for comments, each line of the configuration file describes either an unmanaged or managed proxy service.

For unmanaged proxies, the format is:

<*service-name*> unmanaged <*proxy-address*>

service-name is the name of the unmanaged proxy service, and must not contain any spaces, for example XFWP. *service-name* is case insenstive.

proxy-address is the network address of the unmanaged proxy. The format of the address is specific to the *service-name*. For example, for the XFWP service, the *proxy-address* might be `firewall.x.org:100`.

If there is more than one entry in the config file with the same unmanaged *service-name*, the proxy manager will try to use the proxies in the order presented in the config file.

For managed proxies, the format is:

<*service-name*> managed <*command-to-start-proxy*>

service-name is the name of the managed proxy service, and must not contain any spaces, for example LBX. *service- name* is case insensitive.

command-to-start-proxy is the command executed by the proxy manager to start a new instance of the proxy. If *command- to-start-proxy* contains spaces, the complete command should be surrounded by single quotes. If desired, *command-to- start-proxy* can be used to start a proxy on a remote machine. The specifics of the remote execution method used to do this is not specified here.

Example: sample configuration file

```
! proxy manager config file
!
! Each line has the format:
!    <serviceName> managed <startCommand>
!        or
!    <serviceName> unmanaged <proxyAddress>
!
lbx managed /usr/X11R6.3/bin/lbxproxy
!
! substitute site-specific info
xfwp unmanaged firewall:4444
```

Proxy Manager Details

When the proxy manager gets a request from **xfindproxy** (or another similar client), its course of action will depend on the *service-name* in question.

For a managed proxy service, the proxy manager will find out if any of the already running proxies for this service can handle a new request. If not, the proxy manager will attempt to start up a new instance of the proxy (using the *command-to-start-proxy* found in the config file). If that fails, an error will be returned to the caller.

For an unmanaged proxy service, the proxy manager will look in the config file to find all unmanaged proxies for this service. If there is more than one entry in the config file with the same unmanaged *service-name*, the proxy manager will try to use the proxies in the order presented in the config file. If none of the unmanged proxies can satisfy the request, the proxy manager will timeout for a configurable amount of time (specified by **-timeout** or default of 10) and reattempt to find an unmanaged proxy willing to satisfy the request. The number of retries can be specified by the **-retries** argument, or a default of 3 will be used. If the retries fail, the proxy manager has no choice but to return an error to the caller (since the proxy manager can not start unmanaged proxy services).

prs Command (SCCS)

Purpose

Displays a Source Code Control System (SCCS) file.

Syntax

prs [**-a**] [**-d** *String*] [**-r** [*SID*] | [**-c** *Cutoff*]] [**-e** | **-l**] *File* ...

Description

The **prs** command first reads the specified files and then writes to standard output a part or all of a Source Code Control System (SCCS) file. If you specify a directory for the *File* parameter, the **prs** command performs the requested actions on all SCCS files (those with the **s.** prefix). If you specify a **-** (minus) for the *File* parameter, the **prs** command reads standard input and interprets each line as the name of an SCCS file. The **prs** command continues to read input until it reaches an end-of-file character.

Data Keywords

Data keywords specify the parts of an SCCS file to be retrieved and written to standard output. All parts of an SCCS file have an associated data keyword. There is no limit to the number of times a data keyword can be in a specified file.

The information that the **prs** command displays consists of user-supplied text and appropriate values (extracted from the SCCS file) substituted for the recognized data keywords in the order they are displayed in the specified file. The format of a data keyword value is either simple, in which the keyword substitution is direct, or multiline, in which the substitution is followed by a carriage return. Text consists of any characters other than recognized data keywords. Specify a tab character with **\t** (backslash, letter t) and a carriage return or new-line character with a **\n** (backslash, letter n). Remember to use the **\t** and

\n with an extra **** (backslash) to prevent the shell from interpreting the **** and passing only the letter **t** or **n** to the **prs** command as text.

The following table lists the keywords associated with information in the delta table of the SCCS file. All the keywords have a simple format unless otherwise indicated.

Delta Table Keywords

Keyword	Data Represented	Value
:R:	Release number	num
:L:	Level number	num
:B:	Branch number	num
:S:	Sequence number	num
:I:	SCCS ID string (SID)	:R::L::B::S:
:Dy:	Year delta created	YY
:Dm:	Month delta created	MM
:Dd:	Day delta created	DD
:D:	Date delta created	YY/MM/DD
:Th:	Hour delta created	HH
:Tm:	Minute delta created	MM
:Ts:	Second delta created	SS
:T:	Time delta created	HH/MM/SS
:DT:	Delta type	D or R

Item	Description	Value
:P:	User who created the delta	login name
:DS:	Delta sequence number	num
:DP:	Previous delta sequence number	num
:Dt:	Delta information	:DT::I::D::T::P::DS::DP:
:Dn:	Sequence numbers of deltas included	:DS: . . .
:Dx:	Sequence numbers of deltas excluded	:DS: . . .
:Dg:	Sequence numbers of deltas ignored	:DS: . . .
:DI:	Sequence numbers of deltas included,excluded, and ignored	:Dn:/:Dx:/:Dg:
:Li:	Lines inserted by delta	num

Item	Description	Value
:Ld:	Lines deleted by delta	num
:Lu:	Lines unchanged by delta	num
:DL:	Delta line statistics	:Li:/:Ld:/:Lu:
:MR: (multiline format)	MR numbers for delta	text
:C: (multiline format	Comments for delta	text

The following table lists the keywords associated with header flags in the SCCS file. All the keywords have a simple format unless otherwise indicated.

Header Flag Keywords

Keyword	Data Represented	Value
:Y:	Module type	text
:MF:	MR validation flag set	yes or no
:MP:	MR validation program name	text
:KF:	Keyword/error warning flag set	yes or no
:BF:	Branch flag set	yes or no
:J:	Joint edit flag set	yes or no
:LK:	Locked releases	:R: . . .
:Q:	User-defined keyword	text
:M:	Module name	text
:FB:	Floor boundary	:R:
:CB:	Ceiling boundary	:R:
:Ds:	Default SID	:I:
:ND:	Null Delta flag set	yes or no
:FL: (multiline format)	Header flag list	text

The following table lists the keywords associated with other parts of the SCCS file. All the keywords have a simple format unless otherwise indicated.

Other Keywords

Keyword	Data Represented	Value
:UN: (multiline format)	User names	text

Other Keywords *(continued)*

Keyword	Data Represented	Value
:FD: (multiline format)	Descriptive text	text
:BD: (multiline format)	Body of text	text
:GB: (multiline format)	Text in a g-file	text
:W:	A what string	:Z::M: \tab :I:
:A:	A what string	:Z::Y::M::I::Z:
:Z:	A what string delimiter	@(#)
:F:	SCCS file name	text
:PN:	SCCS file path name	text

Flags

Each flag or group of flags applies independently to each named file.

Item	Description
-a	Writes information for the specified deltas, whether or not they have been removed (see the **rmdel** command). If you do not specify the **-a** flag, the **prs** command supplies information only for the specified deltas that have not been removed.
-c *Cutoff*	Specifies a cutoff date and time for the **-e** and **-l** flags. Specify the *Cutoff* value in the following form: `YY[MM[DD[HH[MM[SS]]]]]` All omitted items default to their maximum values, so specifying -c8402 is the same as specifying -c840229235959. You can separate the fields with any non-numeric character. For example, you can specify `-c84/2/20,9:22:25` or `-c"84/2/20 9:22:25"` or `"-c84/2/20 9:22:25"`. The **-c** flag cannot be specified with the **-r** flag.
-d *String*	Specifies the data items to be displayed. The string consists of optional text and SCCS file-data keywords. The string may include MBCS (multibyte character set) characters. If the string contains spaces, you must enclose the string in quotation marks.
-e	Requests information for all deltas created earlier than and including the delta specified by the **-r** flag.
-l	Requests information for all deltas created later than and including the delta specified by the **-r** flag.
-r [*SID*]	Specifies the SCCS ID string (SID) of the delta for which the **prs** command will retrieve information. Do not enter a space between the **-r** flag and the optional SID parameter. If no SID is specified, the command retrieves the information for the SID of the highest numbered delta. The **-r** flag cannot be specified with the **-c** flag.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To display information on all deltas generated for SCCS file name **s.test.c** (including all deltas removed using the **rmdel** command), type:

```
prs -a s.test.c
```

2. To display user login name, the number of lines inserted by delta, and the number of lines deleted by delta for SID `1.2` of `s.test.c`, type:

```
prs -r1.2 -d":P:\n:Li:\n:Ld:" s.test.c
```

Files

Item	Description
/usr/bin/prs	Contains the **prs** command**.**

prtacct Command

Purpose

Formats and displays files in **tacct** format.

Syntax

/usr/sbin/acct/prtacct [**-X**] [**-W**] [**-f** *Fields*] [**-v**] *File* [**"***Heading***"**]

Description

The **prtacct** command formats and displays any total-accounting file; these files are in **tacct** format. You can enter this command to view any **tacct** file, such as the daily reports on connect time, process time, disk usage, and printer usage. To specify a title for the report with the *Heading* parameter, enclose the heading text in " " (quotation marks).

Flags

Item	Description
-f *Fields*	Selects fields to be displayed, using the field-selection mechanism of the **acctmerg** command.
-v	Produces verbose output in which more precise notation is used for floating-point numbers.
-W	Processes all available characters for each user name instead of truncating to the first 8 characters. This flag causes the **prtacct** command to expect to read in **tacctx** structures. It will then print out in the same column order, but it will allow long user names to misalign the columns. If the **-W** flag and the **-X** flag are used together, the **-X** takes precedence.

Item	Description
-X	Processes all available characters for each user name instead of truncating to the first 8 characters. This flag causes the **prtacct** command to expect to read in **tacctx** structures and print out the user name in the last column. If the **-W** flag and the **-X** flag are used together, the **-X** will take precedence.

Security

Access Control: This command should grant execute (x) access only to members of the **adm** group.

Examples

To format and display selected records from the total accounting file for connect-time accounting, you first must create a file upon which to execute the **prtacct** command. In this example, you create the **tacct** file using the **acctcon1** and **acctcon2** commands. Enter:

```
tail /var/adm/wtmp > wtmp.sav

acctcon1 -t < wtmp.sav | sort +1n +2 | acctcon2 > tacct
```

If you created this file previously to process connect-time accounting data, you do not need to create it again.

The next step uses the **prtacct** command with the **-f** flag to display the fields of data in the total-accounting file that you want to see. The text for a heading can be included in quotation marks. To view the login name, prime connect-time, and nonprime connect-time records, and include the heading, Connect-time Accounting, enter:

```
prtacct -f 2,11,12 tacct "Connect-time Accounting"
```

You can also use this command to format and display other total-accounting files, such as the daily reports on process time, disk usage, and printer usage.

Files

Item	Description
/usr/sbin/acct	The path to the accounting commands.
/var/adm/pacct	Current file for process accounting.
/var/adm/pacct*	Used if the **pacct** file gets too large.

prtconf Command

Purpose

Displays system configuration information.

Syntax

prtconf [**-c**] [**-k**] [**-L**] [**-m**] [**-s**] [**-v**]

Description

If you run the **prtconf** command without any flags, it displays the system model, machine serial, processor type, number of processors, processor clock speed, cpu type, total memory size, network information, filesystem information, paging space information, and devices information.

Flags

Item	Description
-c	Displays cpu type, for example, 32-bit or 64-bit.
-k	Display the kernel in use, for example, 32-bit or 64-bit.
-L	Displays LPAR partition number and partition name if this is an LPAR partition, otherwise returns "-1 NULL".
-m	Displays system memory.
-s	Displays processor clock speed in MegaHertz.
-v	Displays the VPD found in the Customized VPD object class for devices.

Exit Status

0
The command completed successfully.

>0
An error occurred.

Examples

1. To display the system configuration information, enter:

```
prtconf
```

The system displays a message similar to the following:

```
System Model: IBM,7025-F50
Machine Serial Number: 1025778
Processor Type: PowerPC_604
Number Of Processors: 2
Processor Clock Speed: 332 MHz
CPU Type: 32-bit
Kernel Type: 32-bit
LPAR Info: -1 NULL
Memory Size: 512 MB
Good Memory Size: 512 MB
Firmware Version: IBM,L02113
Console Login: enable
Auto Restart: false
Full Core: false

Network Information
Host Name: vd01.austin.ibm.com
IP Address: 9.3.207.112
Sub Netmask: 255.255.255.128
Gateway: 9.3.207.1

```
Memory Size: 512 MB
```

Files

Item	Description
/usr/sbin/prtconf	Contains the **prtconf** command.

prtgblconfig Command

Purpose

The **prtgblconfig** command configures the global settings for the AIX printing subsystem.

Syntax

prtgblconfig [**-s** *name* = *value*] [**-r** *name*]

Description

The **prtgblconfig** command either sets a printing subsystem setting or resets it to a default value. Currently, this command is used to set the ERRMSGCONTROL setting. This setting affects the global printer message. This setting can be used to select one of the following options:

- ALLON (All messages turned on).
- LOGALL (All messages turned on, but logged to a log file).
- CRITON (Only the most critical error messages turned on).
- ALLOFF (All messages turned off).

Currently, the LOGALL option and the CRITON option is same as the ALLON option.

Flags

Item	Description
-s *name* = *value*	Specifies that the printing subsystem setting specified in the *name* parameter is set with the value specified in the *value* parameter.
-r *name*	Resets the printing subsystem setting specified in the *name* parameter to a default value.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To set the printing subsystem to ignore all of the messages generated by the printing subsystem, enter:

   ```
   prtgblconfig -s ERRMSGCONTROL=ALLOFF
   ```

2. To reset the error message control of the printing subsystem to a default value, enter:

   ```
   prtgblconfig -r ERRMSGCONTROL
   ```

   Note: Some messages generated by the printing subsystem cannot be ignored and are logged in the console log file. For more information about starting a print job, see the **qprt** command.

Files

Item	Description
/etc/prtglobalconfig	Contains the global configuration file.
/usr/sbin/qdaemon	Contains the qdaemon daemon.
/etc/qconfig	Contains the configuration file.
/etc/qconfig.bin	Contains the digested, binary version of the /etc/qconfig file.

ps Command

Purpose

Shows status of processes. This document describes the standard AIX **ps** command as well as the System V version of the **ps** command.

Syntax

X/Open Standards

ps [**-A**] [-M] [**-N**] [**-Z**] [**-a**] [**-d**] [**-e**] [**-f**] [**-k**] [**-l**] [**-F** *format*] [**-o** *Format*] [**-c** *Clist*] [**-G** *Glist*] [**-g** *Glist*] [**-m**] [**-n** *NameList*] [**-p** *Plist*] [**-P**] [**-t** *Tlist*] [**-U** *Ulist*] [**-u** *Ulist*] [**-T** *pid*] [**-L** *pidlist*] [-X] [**-@** [*WparName*]]

Berkeley Standards

ps [**a**] [**c**] [**e**] [**ew**] [**eww**] [**ewww**] [**g**] [**n**] [**w**] [**x**] [**l** | **s** | **u** | **v**] [**t** *tty*] [X] [*ProcessNumber*]

Description

The **ps** command writes the status of active processes and if the **-m** flag is given, displays the associated kernel threads to standard output. While the **-m** flag displays threads associated with processes using extra lines, you must use the **-o** flag with the **THREAD** field specifier to display extra thread-related columns.

Without flags, the **ps** command displays information about the current terminal. The **-f**, **-o**, **l**, **-l**, **s**, **u**, and **v** flags only determine how much information is provided about a process; they do not determine which processes are listed. The **l**, **s**, **u**, and **v** flags are mutually exclusive.

With the **-o** flag, the **ps** command examines memory or the paging area and determines what the command name and parameters were when the process was created. If the **ps** command cannot find this information, the command name stored in the kernel is displayed in square brackets.

The **COLUMNS** environment variable overrides the system-selected, horizontal screen size.

The command-line flags that accept a list of parameters (the **-o**, **-G**, **-g**, **-p**, **-t**, **-U**, and **-u** flags) are limited to 128 items. For example, the **-u** *Ulist* flag can specify no more than 128 users.

For cases in which the output of the **ps** command does not include workload partition (WPAR) names but does include Project IDs (**PROJECT**), User IDs (**UID** or **USER**), or Group IDs (**GID**) associated with a process running within a workload partition under the current operating environment, the IDs are preceded by a plus sign (+) to indicate the association with a workload partition. Each workload partition contains its own definition of users, groups, and project IDs that may be different from the IDs defined for the global environment. The **-@** option may be specified to include workload partition names in the output.

Note: The **ps** command does not show the decrease in the memory usage count when the application releases the memory. When the memory is released from the application, the memory is assigned to the per process memory freelist. The **ps** command accounts the memory that is released as the allocated memory for the application.

Depending on the flags used with the **ps** command, column headings are displayed above the information displayed to standard output. The headings are defined in the following list and the flags that cause these headings to be displayed are shown in parentheses :

ADDR
(**-l** and **l** flags) Contains the segment number of the process stack, if normal; if a kernel process, the address of the preprocess data area.

BND
(**-o THREAD** flag) The logical processor number of the processor to which the kernel thread is bound if any. For a process, this field is displayed if all its threads are bound to the same processor.

C
(**-f**, **l**, and **-l** flags) CPU utilization of process or thread, incremented each time the system clock ticks and the process or thread is found to be running. The value is decayed by the scheduler by dividing it by 2 once per second. For the `sched_other` policy, CPU utilization is used in determining process scheduling priority. Large values indicate a CPU intensive process and result in lower process priority, whereas small values indicate an I/O intensive process and result in a more favorable priority.

CMD
(**-f**, **-l**, and **l** flags) Contains the command name. Under the **-f** flag, the **ps** command tries to determine the current command name and arguments, both of which may be changed asynchronously by the process. These are then displayed. If this fails, the command name is written as it would appear without the **-f** option in square brackets.

COMMAND
(**s**, **u**, and **v**) Contains the command name. The full command name and its parameters are displayed with the **-f** flag.

F Field Table

Flags	Hexadecimal Value	Definition
SLOAD	0x00000001	Indicates that the process is operating in core memory.
SNOSWAP	0x00000002	Indicates that the process cannot be swapped out.
STRC	0x00000008	Indicates that the process is being traced.
SWTED	0x00000010	Indicates that the process stopped while being traced.
SFWTED	0x00000020	Indicates that the process stopped after a call to the **fork** subroutine, while being traced.
SEWTED	0x00000040	Indicates that the process stopped after a call to the **exec** subroutine, while being traced.
SLWTED	0x00000080	Indicates that the process stopped after a call to the **load** or **unload** subroutine, while being traced.
SFIXPRI	0x00000100	Indicates that the process has a fixed priority, ignoring the **pcpu** field descriptor.
SKPROC	0x00000200	Indicates a Kernel process.
SOMASK	0x00000400	Indicates restoration of the old mask after a signal is received.

F Field Table *(continued)*		
Flags	**Hexadecimal Value**	**Definition**
SWAKEONSIG	0x00000800	Indicates that the signal will abort the **sleep** subroutine. The contents must *not* be equal to those of the **PCATCH** flag. The contents of both **PCATCH** and **SWAKEONSIG** must be greater than those of **PMASK**.
SUSER	0x00001000	Indicates that the process is in user mode.
SLKDONE	0x00002000	Indicates that the process has done locks.
STRACING	0x00004000	Indicates that the process is a debugging process.
SMPTRACE	0x00008000	Indicates multi-process debugging.
SEXIT	0x00010000	Indicates that the process is exiting.
SSEL	0x00020000	Indicates that the processor is selecting: wakeup/waiting danger.
SORPHANPGRP	0x00040000	Indicates an orphaned process group.
SNOCNTLPROC	0x00080000	Indicates that the session leader relinquished the controlling terminal.
SPPNOCLDSTOP	0x00100000	Indicates that the **SIGHLD** signal is *not* sent to the parent process when a child stops.
SEXECED	0x00200000	Indicates that process has been run.
SJOBSESS	0x00400000	Indicates that job control was used in the current session.
SJOBOFF	0x00800000	Indicates that the process is free from job control.
PSIGDELIVERY	0x01000000	Indicates that the process is used by the program-check handler.
SRMSHM	0x02000000	Indicates that the process removed shared memory during a call to the **exit** subroutine.
SSLOTFREE	0x04000000	Indicates that the process slot is free.
SNOMSG	0x08000000	Indicates that there are no more **uprintf** subroutine messages.

WPAR

(**-@** flag) Contains the workload partition name. Under the **-@** flag, the **ps** command displays the name of the workload partition in which the process is running. Specify the **-@** flag with the *wparname* parameter to display the process information.

DPGSZ

(**Z** flag) The data page size of the process.

F

(**-l** and **l** flags) Some of the more important F field flags (hexadecimal and additive) associated with processes and threads are listed in the following table:

F Field Table		
Flags	**Hexadecimal Value**	**Definition**
SLOAD	0x00000001	Indicates that the process is operating in core memory.
SNOSWAP	0x00000002	Indicates that the process cannot be swapped out.
STRC	0x00000008	Indicates that the process is being traced.
SKPROC	0x00000200	Indicates a kernel process.
SEXIT	0x00010000	Indicates that the process is exiting.
SLPDATA	0x00020000	Indicates that the process uses large pages.
SEXECED	0x00200000	Indicates that the process has been run.
SEXECING	0x01000000	Indicates that the process is execing (performing an exec).
SPSEARLYALLOC	0x04000000	Indicates that paging space for this process is allocated early.
TKTHREAD	0x00001000	Indicates that the thread is a kernel-only thread.

Note: You can see the definitions of all process and thread flags by consulting the **p_flags** and **t_flags** fields in the **/usr/include/sys/proc.h** and **/usr/include/sys/thread.h** files respectively.

LIM
(**v** flag) The soft limit on memory used, specified through a call to the **setrlimit** subroutine. If the limit has not been specified, then `xx` is displayed. If the limit is set to the system limit (unlimited), a value of `UNLIM` is displayed.

NI
(**-l** and **l** flags) The nice value; used in calculating priority for the `sched other` policy.

PID
(all flags) The process ID of the process.

PGIN
(**v** flag) The number of disk I/Os resulting from references by the process to pages not loaded in core.

PPID
(**-f**, **l**, and **-l** flags) The process ID of the parent process.

PRI
(**-l** and **l** flags) The priority of the process or kernel thread; higher numbers mean lower priority.

PROJECT
(**-P** flag) Project name assigned to the process. Under the current operating environment, the **PROJECT** and **USER** fields are not translated to names for processes running within a workload partition. The **-U** and **-u** flags only apply to the current operating environment, unless the **-@** flag is included with a specific workload partition name. If the **-@** flag is used to specify a workload partition other than the current operating environment, and the **-U** and **-u** flags are specified, the list of user IDs must be numeric.

RSS
(**v** flag) The real-memory (resident set) size of the process (in 1 KB units).

S
(**-l** and **l** flags) The state of the process or kernel thread :

For processes:

O
Nonexistent

A
Active

W
Swapped

I
Idle (waiting for startup)

Z
Canceled

T
Stopped

For kernel threads:

O
Nonexistent

R
Running

S
Sleeping

W
Swapped

Z
Canceled

T
Stopped

SC
(**-o THREAD** flag) The suspend count of the process or kernel thread. For a process, the suspend count is defined as the sum of the kernel threads suspend counts.

SCH
(**-o THREAD, sched** flag) The scheduling policy for a kernel thread. The policies `sched_other`, `sched_fifo`, and `sched_rr` are respectively displayed using: `0`, `1`, `2`. The scheduling policies is displayed only when a **sched** flag is specified.

SIZE
(**v** flag) The virtual size of the data section of the process (in 1 KB units).

SHMPGSZ
(**Z** flag) The shared memory page size of the process.

SPGSZ
(**Z** flag) The stack page size of the process.

SSIZ
(**s** flag) The size of the kernel stack. This value is always 0 (zero) for a multi-threaded process.

STAT
(**s**, **u**, and **v** flags) Contains the state of the process:

0
Nonexistent

A
Active

I
Intermediate

Z
Canceled

T
Stopped

K
Available kernel process

STIME
(**-f** and **u** flags) The starting time of the process. The **LANG** environment variables control the appearance of this field.

SUBPROJ
(**-P** flag) Subproject Identifier assigned to the process.

SZ
(**-l** and **l** flags) The size in 1 KB units of the core image of the process.

THCNT
(**-o thcount** flag) The number of kernel threads owned by the process.

TID
(**-o THREAD** flag) The thread ID of the kernel thread.

TIME
(all flags) The total runtime for the process. The time is displayed in the format of *mm:ss* or *mmmm:ss* if the runtime reaches 100 minutes, which is different from the displayed format if you use the **-o time** flag.

TPGSZ
(**Z** flag) The text page size of the process.

TRS
(**v** flag) The size of resident-set (real memory) of text.

TSIZ
(**v** flag) The size of text (shared-program) image.

TTY
(all flags) The controlling terminal for the process:

-
The process is not associated with a terminal.

?
Unknown.

Number
The TTY number. For example, the entry 2 indicates TTY2.

UID
(**-f**, **-l**, and **l** flags) The user ID of the process owner. The login name is printed under the **-f** flag.

USER
(**u** flag) The login name of the process owner. Under the current operating environment, the **PROJECT** and **USER** fields are not translated to names for processes running within a workload partition.

WCHAN
(**-l** flag) The event for which the process or kernel thread is waiting or sleeping. For a kernel thread, this field is blank if the kernel thread is running. For a process, the wait channel is defined as the wait channel of the sleeping kernel thread if only one kernel thread is sleeping; otherwise a star is displayed.

WCHAN
(**l** flag) The event on which the process is waiting (an address in the system). A symbol that classifies the address is selected, unless a numerical output is requested.

%CPU
(**u** and **v** flags) The percentage of time the process has used the CPU since the process started. This value is computed by dividing the time the process uses the CPU by the elapsed time of the

process. In a multi-processor environment, the value is further divided by the number of available CPUs because several threads in the same process can run on different CPUs at the same time. (Because the time base over which this data is computed varies, the sum of all **%CPU** fields can exceed 100%.)

%MEM
(**u** and **v** flags) The percentage of real memory used by this process. The %MEM value tends to exaggerate the cost of a process that is sharing program text with other processes. It does not account for times when multiple copies of a program are run and a copy of the program text is shared by all instances. The size of the text section is accounted for in every instance of the program. This means that if several copies of a program are run, the total %MEM value of all processes could exceed 100%.

A process that has exited and has a parent that has not yet waited for the process is marked <defunct>. A process that is blocked trying to exit is marked <exiting>. The **ps** command attempts to determine the file name and arguments given when the process was created by memory or by the swap area.

Notes:

1. The process can change while the **ps** command is running. Some data displayed for defunct processes is irrelevant.
2. The **ps** program examines the memory to retrieve the file name and arguments used when the process was created. However, a process can destroy information, making this method of retrieving file name and arguments unreliable.
3. The **ps** program searches the local resources for users and group information.

Flags

The following flags are preceded by a **-** (minus sign):

Item	Description
-A	Writes to standard output information about all processes.
-a	Writes to standard output information about all processes, except the session leaders and processes not associated with a terminal.
-c *Clist*	Displays only information about processes assigned to the workload management classes listed in the *Clist* variable. The *Clist* variable is either a comma-separated list of class names or a list of class names enclosed in double quotation marks (" "), which is separated from one another by a comma or by one or more spaces, or both.
-d	Writes information to standard output about all processes, except the session leaders.
-e	Writes information to standard output about all processes, except kernel processes.
-F *Format*	Same as the **-o** *Format*
-f	Generates a full listing.
-G *Glist*	Writes information to standard output only about processes that are in the effective groups listed for the *Glist* variable. The *Glist* variable is either a comma-separated list of effective group identifiers, or a list of effective group identifiers enclosed in double quotation marks (" ") and separated from one another by a comma or by one or more spaces.
-g *Glist*	Writes information to standard output only about processes that are in the process groups listed for the *Glist* variable. The *Glist* variable is either a comma-separated list of process group identifiers or a list of process group identifiers enclosed in double quotation marks (" ") and separated from one another by a comma or by one or more spaces.
-k	Lists kernel processes.
-l	Generates a long listing. Also see the **l** flag.
-L *pidlist*	Generates a list of descendants of each and every pid that has been passed to it in the *pidlist* variable. The *pidlist* variable is a list of comma-separated process IDs. The list of descendants from all the given pid is printed in the order in which they appear in the process table.
-M	Lists all 64 bit processes.
-m	Lists kernel threads as well as processes. Output lines for processes are followed by an additional output line for each kernel thread. This flag does not display thread-specific fields (**bnd**, **scount**, **sched**, **thcount**, and **tid**), unless the appropriate **-o** *Format* flag is specified.
-N	Gathers no thread statistics. With this flag, **ps** reports those statistics that can be obtained by not traversing through the threads chain for the process.

Item	Description
-n *NameList*	Specifies an alternative system name-list file in place of the default. The operating system does not use the **-n** flag because information is supplied directly to the kernel.
-o *Format*	Displays information in the format specified by the *Format* variable. Multiple field specifiers can be specified for the *Format* variable. The *Format* variable is either a comma-separated list of field specifiers or a list of field specifiers enclosed within a set of " " (double-quotation marks) and separated from one another by a comma or by one or more spaces, or both. Each field specifier has a default header. The default header can be overridden by appending an **=** (equal sign) followed by the user-defined text for the header. The fields are written in the order specified on the command-line in column format. The field widths are specified by the system to be at least as wide as the default or user-defined header text. If the header text is null (such as if **-o user=** is specified), the field width is at least as wide as the default header text. If all header fields are null, no header line is written. The following field specifiers are recognized by the system: **args** Indicates the full command name being executed. All command-line arguments are included, though truncation may occur. The default header for this field is **COMMAND**. **bnd** Indicates to which (if any) processor a process or kernel thread is bound. The default header for this field is **BND**. **class** Indicates the workload management class assigned to the process or thread. The default header for this field is **CLASS**. **comm** Indicates the short name of the command being executed. Command-line arguments are not included. The default header for this field is **COMMAND**. **cpu** Determines process scheduling priority. CPU utilization of a process or thread, incremented each time the system clock ticks and the process or thread is found to be running. The value is decayed by the scheduler by dividing it by 2 once per second. For the sched_other policy, Large values indicate a CPU intensive process and result in lower process priority whereas small values indicate an I/O intensive process and result in a more favorable priority. **dpgsz** Indicates the data page size of a process. **etime** Indicates the elapsed time since the process started. The elapsed time is displayed in the following format: [[*dd***-**]*hh***:**]*mm***:***ss* where *dd* specifies the number of days, *hh* specifies the number of hours, *mm* specifies the number of minutes, and *ss* specifies the number of seconds. The default header for this field is **ELAPSED**. **group** Indicates the effective group ID of the process. The textual group ID is displayed. If the textual group ID cannot be obtained, a decimal representation is used. The default header for this field is **GROUP**. **nice** Indicates the decimal value of the process nice value. The default header for this field is **NI**.

Item	Description
-o *Continued*	**pcpu** Indicates the ratio of CPU time used to CPU time available, expressed as a percentage. The default header for this field is **%CPU**. **pgid** Indicates the decimal value of the process group ID. The default header for this field is **PGID**. **pid** Indicates the decimal value of the process ID. The default header for this field is **PID**. **ppid** Indicates the decimal value of the parent process ID. The default header for this field is **PPID**. **rgroup** Indicates the real group ID of the process. The textual group ID is displayed. If the textual group ID cannot be obtained, a decimal representation is used. The default header for this field is **RGROUP**. **ruser** Indicates the real user ID of the process. The textual user ID is displayed. If the textual user ID cannot be obtained, a decimal representation is used. The default header for this field is **RUSER**. **scount** Indicates the suspend count for a kernel thread. The default header for this field is **SC**. **sched** Indicates the scheduling policy for a kernel thread. The default header for this field is **SCH**. **shmpgsz** Indicates the shared memory page size of a process. **spgsz** Indicates the stack page size of a process. **tag** Indicates the Workload Manager application tag. The default header for this field is **TAG**. The tag is a character string up to 30 characters long and may be truncated when displayed by **ps**. For processes that do not set their tag, this field displays as a **-** (hyphen). **tcpu** Total CPU time. Indicates the total accumulated CPU time for a single process. The command displays the information when WLM is running either in active or passive mode else, this field displays as a - (hyphen). The default header for this field is **TCPU**. **tctime** Total connect time. Indicates the total amount of time that a login session can be active. This is meaningful only in the case of session leader processes. The default header for this field is **TCTIME**. **tdiskio** Total disk I/O. Indicates the total accumulated blocks of disk I/O for a single process. The default header for this field is **TDISKIO**. **tpgsz** Indicates the text page size of a process. **vmsize** Indicates the WLM virtual memory limits. When this is used, a new header, VMSIZ is displayed. VMSIZ displays the virtual memory used by the process. This value is displayed in 1 MB units. **thcount** Indicates the number of kernel threads owned by the process. The default header for this field is **THCNT**.

Item	Description
-o *Continued*	**THREAD** Indicates the following fields: • User name (the **uname** field) • Process and parent process IDs for processes (the **pid** and **ppid** fields) • Kernel thread ID for threads (the **tid** field) • The state of the process or kernel thread (the **S** field) • The CPU utilization of the process or kernel thread (the **C** field) • The priority of the process or kernel thread (the **PRI** field) • The suspend count of the process or kernel thread (the **scount** field) • The wait channel of the process or kernel thread (the **WCHAN** field) • The flags of the process or kernel thread (the **F** field) • The controlling terminal of the process (the **tty** field) • The CPU to which the process or kernel thread is bound (the **bnd** field) • The command being executed by the process (the **comm** field). Threads are not displayed with the **-o THREAD** flag, unless the **-m** flag is also specified. **Note:** The `ps -o THREAD` flag does not print the scheduler policies. The scheduling policies are displayed only when a **sched** flag is specified. **tid** Indicates the thread ID of a kernel thread. The default header for this field is **TID**. **time** Indicates the cumulative CPU time since the process started. The time is displayed in the following format: [*dd***-**] *hh***:***mm***:***ss* where *dd* specifies the number of days, *hh* specifies the number of hours, *mm* specifies the number of minutes, and *ss* specifies the number of seconds. The default header for this field is **TIME**. **tty** Indicates the controlling terminal name of the process. The default header for this field is **TT**. **user** Indicates the effective user ID of the process. The textual user ID is displayed. If the textual user ID cannot be obtained, a decimal representation is used. The default header for this field is **USER**. **vsz** Indicates, as a decimal integer, the size in kilobytes of the process in virtual memory. The default header for this field is **VSZ**. Otherwise, multiple fields in a specified format can be displayed by the *Format* variable, including field descriptors. If field descriptors are used in the *Format* variable, it must be enclosed in double quotation marks (" "). The following table shows how field descriptors correspond to field specifiers: `Field Descriptors  Field Specifiers  Default Headers` `%a  args  COMMAND` `%c  comm  COMMAND` `%t  etime  ELAPSED` `%D  dpgsz  DPGSZ` `%G  group  GROUP` `%n  nice  NI` `%C  pcpu  %CPU` `%r  pgid  PGID` `%p  pid  PID` `%P  ppid  PPID` `%g  rgroup  RGROUP` `%u  ruser  RUSER` `%S  spgsz  SPGSZ` `%x  time  TIME` `%T  tpgsz  TPGSZ gd` `%y  tty  TTY` `%U  user  USER` `%z  vsz  VSZ` Each field specifier has a default header. The default header can be overridden by appending an equal sign (=) followed by the user-defined text for the header. The fields are written in the order specified on the command-line in column format. The field widths are specified by the system to be at least as wide as the default or user-defined header text. If the header text is null (for example, `-o user=` is specified), the field width is at least as wide as the default header text. If all header fields are null, no header line is written.

Item	Description
	Following is the mapping between the default headers and various field specifiers. Every entry in the Default Header column can be overridden by appending an equal sign (=) to the corresponding entry in the Field specifier followed by the user-defined text for the header.

```
Default Header                Field specifier

```

-p *Plist*	Displays only information about processes with the process numbers specified for the *Plist* variable. The *Plist* variable is either a comma-separated list of process ID numbers or a list of process ID numbers enclosed in double quotation marks (" ") and separated from one another by a comma or by one or more spaces, or both.
-P	Displays the Project name, Project origin, and subproject identifier for the project. If the stick bit is set for the process, the project name is preceded by an asterisk (*) character. The `Project origin` field designates the currently loaded project repository (LOCAL or LDAP).
-t *Tlist*	Displays only information about processes associated with the controlling ttys listed in the *Tlist* variable. The *Tlist* variable is either a comma-separated list of tty identifiers or a list of tty identifiers enclosed in double quotation marks (" ") and separated from one another by a comma or by one or more spaces, or both.
-T *pid*	Displays the process hierarchy rooted at a given pid in a tree format using ASCII art. This flag can be used in combination with the **-f**, **-F**, **-o**, and **-l** flags.
-u *Ulist*	This flag is equivalent to the **-U** *Ulist* flag. The **-u** flag only applies to the current operating environment unless the **-@** flag is also specified. If the **-@** flag is used to specify a workload partition other than the current operating environment and the **-u** flag is specified, the list of user IDs must be numeric.
-U *Ulist*	Displays only information about processes with the user ID numbers or login names specified for the *Ulist* variable. The *Ulist* variable is either a comma-separated list of user IDs or a list of user IDs enclosed in double quotation marks (" ") and separated from one another by a comma and one or more spaces. The **-U** flag only applies to the current operating environment unless the **-@** flag is also specified. If the **-@** flag is used to specify a workload partition other than the current operating environment and the **-U** flag is specified, the list of user IDs must be numeric. In the listing, the **ps** command displays the numerical user ID unless the **-f** flag is used; then the command displays the login name. This flag is equivalent to the **-u** *Ulist* flag. See also the **u** flag.

Item	Description
-X	Prints all available characters of each user/group name instead of truncating to the first eight characters.
-Z	Displays the page size settings of processes. **DPGSZ** Indicates the data page size of a process. **SHMPGSZ** Indicates the shared memory page size the process allocates. **SPGSZ** Indicates the stack page size of a process. **TPGSZ** Indicates the text page size of a process.
-@ [*WparName*]	Displays the process information that is associated with the workload partition *WparName*. If you do not specify the *WparName* parameter, the process information for all workload partitions is displayed. Workload partition information is displayed for all processes. You must specify other flags to the **ps** command to determine which process information to be displayed.

Options

The following options are not preceded by a minus sign (-):

Item	Description
a	Displays information about all processes with terminals (ordinarily only the own processes of the user are displayed).
c	Displays the command name, as stored internally in the system for purposes of accounting, rather than the command parameters, which are kept in the process address space.
e	Displays the environment as well as the parameters to the command, up to a limit of 80 characters.
ew	Wraps the display from the **e** flag one extra line.
eww	Wraps the display from the **e** flag and displays the **ENV** list until the flag reaches the **LINE_MAX** value.
ewww	Wraps the display from the **e** flag and displays the **ENV** list until the flag reaches the **INT_MAX** value.
g	Displays all processes.
l	Displays a long listing having the **F**, **S**, **UID**, **PID**, **PPID**, **C**, **PRI**, **NI**, **ADDR**, **SZ**, **PSS**, **WCHAN**, **TTY**, **TIME**, and **CMD** fields.
n	Displays numerical output. In a long listing, the **WCHAN** field is printed numerically rather than symbolically. In a user listing, the **USER** field is replaced by a **UID** field.
s	Displays the size (SSIZ) of the kernel stack of each process (for use by system maintainers) in the basic output format. This value is always 0 (zero) for a multi-threaded process.
t *tty*	Displays processes whose controlling tty is the value of the *tty* variable, which should be specified as printed by the **ps** command; that is, `0` for terminal **/dev/tty/0**, `lft0` for **/dev/lft0**, and `pts/2` for **/dev/pts/2**.
u	Displays user-oriented output. This includes the **USER**, **PID**, **%CPU**, **%MEM**, **SZ**, **RSS**, **TTY**, **STAT**, **STIME**, **TIME**, and **COMMAND** fields.
v	Displays the **PGIN**, **SIZE**, **RSS**, **LIM**, **TSIZ**, **TRS**, **%CPU**, **%MEM** fields.
w	Specifies a wide-column format for output (132 columns rather than 80). If repeated, (for example, `ww`), uses arbitrarily wide output. This information is used to decide how much of long commands to print.
x	Displays processes without a controlling terminal in addition to processes with a controlling terminal.
X	Prints the full user name or group name. The name is not truncated.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To display all processes, type:

```
ps -e -f
```

   To display all processes with expanded user name, type:

```
ps -X -e -f
```

2. To list processes owned by specific users, type:

```
ps -f -l -ujim,jane,su
```

3. To list processes that are associated with the **/dev/console** and **/dev/tty1** ttys, type:

```
ps -t console,tty/1
```

4. To list processes not associated with a terminal, type:

```
ps -t -
```

5. To display a specified format with field specifiers, type:

```
ps -o ruser,pid,ppid=parent,args
```

   The output is:

```
RUSER   PID     parent  COMMAND
helene  34      12      ps -o ruser,pid,ppid=parent,args
```

6. To display a specified format with field descriptors, type:

```
ps -o "< %u > %p %y : %a"
```

   The output is:

```
< RUSER  >      PID     TT :    COMMAND
< helene >      34      pts/3 : ps -o < %u > %p %y : %a
```

7. To display information about processes and kernel threads controlled by the current terminal, type:

```
ps -lm
```

   The output is like:

```
     F S UID  PID PPID  C PRI NI ADDR  SZ WCHAN   TTY  TIME  CMD
240003 A  26 8984 7190  1  60 20 2974 312       pts/1  0:00  -ksh
   400 S   -    -    -  1  60  -    -   -           -     -  -
200005 A  26 9256 8984 15  67 20 18ed 164       pts/1  0:00  ps
     0 R   -    -    - 15  67  -    -   -           -     -  -
```

8. To display information about all processes and kernel threads, type:

```
ps -emo THREAD
```

   The output is like:

```
USER   PID  PPID  TID S  C PRI SC   WCHAN   FLAG   TTY BND  CMD
jane  1716 19292    - A 10  60  1       * 260801 pts/7   -  biod
   -     -     - 4863 S  0  60  0 599e9d8   8400     -   -  -
   -     -     - 5537 R 10  60  1 5999e18   2420     -   3  -
luke 19292 18524    - A  0  60  0 586ad84 200001 pts/7   -  -ksh
   -     -     - 7617 S  0  60  0 586ad84    400     -   -  -
luke 25864 31168    - A 11  65  0       - 200001 pts/7   -  -
   -     -     - 8993 R 11  65  0       -      0     -   -  -
```

9. To list all the 64-bit processes, type:

```
ps -M
```

10. To display the project assignment details for the processes, type:

```
ps -P
```

11. To display the page size settings of the processes, type:

```
ps -Z
```

The output is like:

```
          PID    TTY TIME DPGSZ SPGSZ TPGSZ SHMPGSZ CMD
        41856 pts/15 0:00    4K    4K    4K    64K    ps
        84516 pts/15 0:00    4K    4K    4K    64K    ksh
```

Files

Item	Description
/**usr**/**bin**/**ps**	Contains the **ps** command.

Using the ps command in *Performance management*.

System V ps command

Syntax (System V)

/usr/sysv/bin/ps [**-a**] [**-A**] [**-c**] [**-d**] [**-e**] [**-f**] [**-j**] [**-l**] [**-L**] [**-P**] [**-y**] [**-g** *pgrplist*] [**-o** *format*] [**-p** *proclist*] [**-s** *sidlist*] [**-t** *termlist*] [{ **-u** | **-U** } *uidlist*] [**-G** *grplist*] [-X]

Description (System V)

The **ps** command prints information about active processes. Without flags, **ps** prints information about processes associated with the controlling terminal. The output contains the process ID, terminal identifier, cumulative runtime, and the command name. The information displayed with flags varies accordingly.

Output

Depending on the flags used with the **ps** command, column headings vary for the information displayed. The headings are defined in the following list (flags that cause these headings to appear are shown in parentheses):

F (-l)
Flags (hexadecimal and additive) associated with the process, or the thread if the **-L** option is specified. Some of the more important F field flags (hexadecimal and additive) associated with processes and threads are shown below:

F Field Table		
Flags	**Hexadecimal Value**	**Definition**
SLOAD	0x00000001	Indicates that the process is operating in core memory.
SNOSWAP	0x00000002	Indicates that the process cannot be swapped out.
STRC	0x00000008	Indicates that the process is being traced.
SKPROC	0x00000200	Indicates a Kernel process.
SEXIT	0x00010000	Indicates that the process is exiting.
SEXECED	0x00200000	Indicates that process has been run.
SEXECING	0x01000000	Indicates that the process is execing (performing an exec).
TKTHREAD	0x00001000	Indicates that the thread is a kernel only thread.

Note: You can see the definitions of all process and thread flags by referring to the **p_flags** and **t_flags** fields in the **/usr/include/sys/proc.h** and **/usr/include/sys/thread.h** files respectively.

S (-l)
The state of the process or kernel thread :

For processes:

O
Nonexistent

A
Active

W
Swapped

I
Idle

Z
Canceled

T
Stopped

For kernel threads:

O
Nonexistent

R
Running

S
Sleeping

W
Swapped

Z
Canceled

T
Stopped

UID (-f,- l)
The user ID number of the process (the login name is printed under the -f option).

PID (all)
The process ID of the process.

PPID (-f,-l)
The process ID of the parent process.

CLS (-c)
Scheduling class for the process. Printed only when the **-c** flag is used.

NI (-l)
The nice value of the process used in calculating priority for the **sched_other** policy.

PRI (-c, -l)
The priority of the process or kernel thread. Higher numbers mean lower priority.

ADDR (-l)
Contains the segment number of the process stack, if normal; if a kernel process, the address of the preprocess data area.

SZ (-l)
The size in pages of the core image of the process.

WCHAN(-l)
The event for which the process or kernel thread is waiting or sleeping. For a kernel thread, this field is blank if the kernel thread is running. For a process, the wait channel is defined as the wait channel of the sleeping kernel thread if only one kernel thread is sleeping; otherwise a star is displayed.

STIME (-f,-u)
The starting time of the process. The **LANG** environment variables control the appearance of this field.

TTY (all)
The controlling terminal for the process:

-
The process is not associated with a terminal.

?
Unknown

TIME (all)
The total runtime for the process. The time is displayed in the format of *mm:ss* or *mmmm:ss* if the runtime reaches 100 minutes, which is different from the displayed format if you use the **-o time** flag.

LTIME (-L)
The runtime for an individual LWP.

CMD (all)
Contains the command name. The full command name and its parameters are displayed with the **-f** flag.

LWP (-L)
The tid of the kernel thread.

NLWP(-Lf)
The number of kernel threads in the process.

PSR (-P)
The logical processor number of the processor to which the kernel thread is bound (if any). For a process, this field is shown if all its threads are bound to the same processor.

RSS (-ly)
The real memory (resident set) size of the process (in 1 KB units).

Format

The following list describes the field specifiers recognized by the system. These field specifiers can be used with the **-o** flag to specify the format for the output of the **ps** command.

The field specifiers recognized by the system are:

addr
Indicates the segment number of the process stack, if normal; if a kernel process, the address of the preprocess data area. The default header for this field is **ADDR**.

args
Indicates the full command name being executed. All command-line arguments are included, though truncation may occur. The default header for this field is **COMMAND**.

c
CPU utilization of process or thread, incremented each time the system clock ticks and the process or thread is found to be running. The value is decayed by the scheduler by dividing it by 2 once per second. For the **sched_other** policy, CPU utilization is used in determining process scheduling priority. Large values indicate a CPU intensive process and result in lower process priority whereas small values indicate an I/O intensive process and result in a more favorable priority. The default header for this field is **C**.

class
Indicates the scheduling policy for a kernel thread. The policies are sched_other, sched_fifo and sched_rr. The default header for this field is **CLS**.

comm
Indicates the short name of the command being executed. Command-line arguments are not included. The default header for this field is **COMMAND**.

etime
Indicates the elapsed time since the process started. The elapsed time is displayed in the format

```
[[ dd -] hh: ]mm :ss
```

where *dd* specifies the number of days, *hh* specifies the number of hours, *mm* specifies the number of minutes, and *ss* specifies the number of seconds.

The default header for this field is **ELAPSED**.

f
Indicates flags (hexadecimal and additive) associated with the process. The default header for this field is **COMMAND**.

fname
Indicates the first 8 bytes of the base name of the process's executable file. The default header for this field is **COMMAND**.

gid
Indicates the effective group ID number of the process as a decimal integer. The default header for this field is **GID**. The login name is printed under the **-f** option.

group
Indicates the effective group ID of the process. The textual group ID is displayed. If the textual group ID cannot be obtained, a decimal representation is used. The default header for this field is **GROUP**.

lwp
Indicates the thread ID of the kernel thread. The default header for this field is **TID**.

nice
Indicates the decimal value of the process nice value. The default header for this field is **NI**.

nlwp
Indicates the number of kernel threads owned by the process. The default header for this field is **THCNT**.

pcpu
Indicates the ratio of CPU time used to CPU time available, expressed as a percentage. The default header for this field is **%CPU**.

pgid
Indicates the decimal value of the process group ID. The default header for this field is **PGID**.

pid
Indicates the decimal value of the process ID. The default header for this field is **PID**.

pmem
Indicates the percentage of real memory used by this process. The default header for this field is **%MEM**.

ppid
Indicates the decimal value of the parent process ID. The default header for this field is **PPID**.

pri
Indicates the priority of the process or kernel thread ; higher numbers mean lower priority. The default header for this field is **PRI**.

psr
Indicates the logical processor number of the processor to which the kernel thread is bound (if any). The default header for this field is **PSR**.

rgid
Indicates the real group ID number of the process as a decimal integer. The default header for this field is **RGID**.

rgroup
Indicates the real group ID of the process. The textual group ID is displayed. If the textual group ID cannot be obtained, a decimal representation is used. The default header for this field is **RGROUP**.

rss
Indicates the real memory (resident set) size of the process (in 1 KB units). The default header for this field is **RSS**.

ruid
Indicates the real user ID number of the process as a decimal integer. The default header for this field is **RUID**.

ruser
Indicates the real user ID of the process. The textual user ID is displayed. If the textual user ID cannot be obtained, a decimal representation is used. The default header for this field is **RUSER**.

s
Indicates the state of the process. The default header for this field is **S**.

sid
Indicates the process ID of the session leader. The default header for this field is **SID**.

stime
Indicates the starting time of the process. The LANG environment variables control the appearance of this field. The default header for this field is **STIME**.

time
Indicates the cumulative CPU time since the process started. The time is displayed in the same format as in **etime**. The default header for this field is **TIME**.

tty
Indicates the controlling terminal name of the process. The default header for this field is **TT**.

uid
Indicates the effective user ID number of the process as a decimal integer. The default header for this field is **UID**.

user
Indicates the effective user ID of the process. The textual user ID is displayed. If the textual user ID cannot be obtained, a decimal representation is used. The default header for this field is **USER**.

vsz
Indicates, as a decimal integer, the size in kilobytes of the core image of the process. The default header for this field is **VSZ**.

wchan
Indicates the event for which the process or kernel thread is waiting or sleeping. For a kernel thread, this field is blank if the kernel thread is running. For a process, the wait channel is defined as the wait channel of the sleeping kernel thread if only one kernel thread is sleeping; otherwise a star is displayed.

The default header for this field is **WCHAN**.

Flags (System V)

Some flags accept lists as arguments. Items in a list can be either separated by commas or else enclosed in double quotes and separated by commas or spaces. Values for *proclist* and *pgrplist* must be numeric.

Item	Description
-a	Writes to standard output information about all processes, except the session leaders and processes not associated with a terminal.
-A	Writes to standard output information about all processes.
-c	Prints information in a format that reflects scheduler properties. The **-c** flag affects the output of the **-f** and **-l** flags, as described below.
-d	Writes to standard output information about all processes, except the session leaders.
-e	Writes to standard output information about all processes, except kernel processes.

Item	Description
-f	Generates a full listing.
-g *pgrplist*	Writes to standard output information only about processes that are in the process groups specified by *pgrplist*. Values for *pgrplist* must be numeric.
-G *grplist*	Writes to standard output information only about processes that are in the process groups specified by *grplist*. The **-G** flag accepts group names.
-j	Displays session ID and process group ID.
-l	Generates a long listing.
-L	Prints status of active threads within a process.
-o *format*	Displays information in the format specified by *format*. Multiple field specifiers can be specified for the format variable. The field specifiers that can be used with the **-o** flag are described above in the Format section.
-p *proclist*	Displays information only about processes with the process numbers specified by *proclist*. Values for *proclist* must be numeric.
-P	Displays the logical processor number of the processor to which the primary kernel thread of the process is bound (if any).
-s *sidlist*	Displays all processes whose session leader's IDs are specified by *sidlist*.
-t *termlist*	Displays information only about processes associated with the terminals specified by *termlist*.
-u *uidlist*	Displays information only about processes with the user ID numbers or login names specified by *uidlist*.
-U *uidlist*	Displays information only about processes with the user ID numbers or login names specified by *uidlist*.
-X	Prints all available characters of each user and group name instead of truncating to the first 8 characters.
-y	When combined with the **-l** option, changes the long listing so that it prints the "RSS'' and "SZ'' fields in kilobytes and does not print the "F'' and "ADDR'' fields.

Exit Status (System V)

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security (System V)

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples (System V)

1. To display all processes, enter:

```
ps -e -f
```

2. To list processes owned by the user 'guest', enter:

```
ps -f -l -u guest
```

3. To list processes that are associated with the **/dev/pts/0** and **/dev/pts/1** terminals, enter:

```
ps -t pts/0,pts/1
```

4. To list processes not associated with a terminal, enter:

```
ps -t -
```

5. To display a specified format with field specifiers, enter:

```
ps -o ruser,pid,ppid,args
```

6. To display information about all kernel threads in a process, enter:

```
ps -L
```

7. To display session ID and process group IDs of all the processes, enter:

```
ps -jA
```

8. To display the scheduling class and priority of processes, enter:

```
ps -c -l
```

9. To display information about kernel threads and the number of kernel threads in a process, enter:

```
ps -L -f
```

10. To display the processor to which the process or kernel thread is bound to, enter:

```
ps  -P
```

11. To print an ASCII art for a given process (`inetd` in the example below), enter :

```
ps -T 14220
```

Output will look like the following:

```
    PID    TTY  TIME CMD
  14220      -  0:00 inetd
  16948      -  0:00    |\--telnetd
  32542  pts/4  0:00    |    \--ksh
  26504      -  0:00    |\--telnetd
  41272  pts/5  0:00    |    \--ksh
  26908  pts/5  0:00    |        \--vi
  28602      -  0:00    |\--telnetd
  24830  pts/0  0:00    |    \--ksh
 676416  pts/0  0:00    |        \--ksh
  29984      -  0:00    |\--telnetd
  38546  pts/6  0:00    |    \--ksh
  32126      -  0:00    |\--telnetd
  11162  pts/7  0:00    |    \--ksh
  34466      -  0:00    |\--rpc.ttdbserver
  35750      -  0:00    |\--telnetd
  23612  pts/3  0:00    |    \--ksh
  36294      -  0:00    |\--telnetd
  38096  pts/8  0:00    |    \--ksh
  39740      -  0:00    |\--telnetd
  42226  pts/9  0:01    |    \--ksh
  40632      -  0:00    |\--telnetd
  40232  pts/2  0:00    |    \--ksh
  32910  pts/2  0:00    |        \--dbx
 987990  pts/2  0:00    |            \--a.out
  40722      -  0:00    |\--telnetd
  16792 pts/10  0:00    |    \--ksh
  37886 pts/10  0:00    |        \--ps
 105716      -  0:00     \--telnetd
  29508  pts/1  0:00         \--ksh
  39478  pts/1  0:00             \--ksh
  38392  pts/1  0:00                 \--vi
```

12. To print information about all processes rooted at a given pid, enter:

```
ps -fL 14220
```

Output will look like the following:

```
  UID   PID  PPID   C    STIME    TTY  TIME CMD
root 14220  8676   0   Apr 07      -  0:00 /usr/sbin/inetd
root 16948 14220   0   Apr 06      -  0:00 telnetd -a
root 23612 35750   0   Apr 10  pts/3  0:00 -ksh
root 24830 28602   1 18:30:56  pts/0  0:00 -ksh
root 28602 14220   0 18:30:55      -  0:00 telnetd -a
```

```
root 32542 16948   0   Apr 06  pts/4  0:00 -ksh
root 34466 14220   0   Apr 10      -  0:00 rpc.ttdbserver 100083 1
root 35750 14220   0   Apr 10      -  0:00 telnetd -a
root 40228 24830   8 18:36:01  pts/0  0:00 ps -fL 14220
```

13. To display all processes with expanded user name, type:

```
ps -X -e -f
```

14. To display the scheduling policies of a thread, enter the following command:

```
#ps -m -o THREAD,sched
 USER     PID    PPID      TID ST  CP PRI SC WCHAN   F     TT BND COMMAND     SCH
suresana 1609830 4227284        - A   16  68  1   - 200001 pts/144   - ps -m
                                                              -o THREAD sched 0
       -       -       -  6381739 R   16  68  1   -400000      -   - -         0
suresana 4227284 4239476        - A    1  60  1   -200801 pts/144   - bash    0
       -       -       -  4177981 S    1  60  1   -410400      -   - -         0
suresana 4239476  921694        - A    0  60  1   -240001 pts/144   - -ksh    0
       -       -       -  5554385 S    0  60  1   -10400       -   - -         0
```

Files (System V)

Item	Description
/usr/sysv/bin/ps	Contains the System V R4 **ps** command.
/etc/passwd	Contains the user ID information.
/dev/pty*	Indicates terminal (PTY) names.
/dev/tty*	Indicates terminal (TTY) names.

ps4014 Command

Purpose

Converts a Tektronix 4014 file to PostScript format.

Syntax

ps4014 [**-m**] [**-C**] [**-N**] [**-R**] [**-s***Width*,*Height*] [**-l***Left*,*Bottom*] [**-S***Width*] [**-p***OutFile*] [*File*]

Description

The **ps4014** command reads in a Tektronix 4014 format file and converts it to PostScript format for printing on a PostScript printer. If no file is specified, the standard input is used. The resulting PostScript file can be directed to standard output or to a named file.

> **Note:** By default, the 4014 image is scaled to occupy nearly the entire page in a landscape orientation.

Flags

> **Note:** The **-m**, **-C**, and **-N** flags specify values for 4014 hardware options that affect the interpretation of 4014 commands.

Item	Description
-C	Causes a carriage return to move the pen position to the left margin but not down to the next line. By default, a carriage return command moves the pen down to the next line and over to the left margin.

Item	Description
-l*Left*,*Bottom*	Specifies the location on the printed page of the bottom left corner of the converted raster image. The values specified by the *Left* and *Bottom* parameters are the distances (in inches) from the bottom left corner of the printed page to the bottom left corner of the image.
-m	Enables the "Margin 2" mode for the 4014.
-N	Causes line feed to move the pen position down to the next line but not to the left margin. By default, a line feed command moves the pen down to the next line and over to the left margin.
-p*OutFile*	Causes the PostScript file to be written to the file specified by the *OutFile* parameter rather than the standard output.
-R	Rotates the image 90 degrees on the page for portrait orientation. The default is landscape orientation.
-s*Width*,*Height*	Specifies the size of the converted raster image on the printed page. The *Width* and *Height* parameters specify the dimensions (in inches) of the resulting image on the printed page.
-S*Width*	Allows you to scale the image without distorting its shape. The *Width* parameter specifies the width, in inches, of the resulting image on the printed page. The height of the image is computed to maintain the same ratio of height to width on the output image as on the input raster-format file.

International Character Support

See the html

ps630 Command

Purpose

Converts Diablo 630 print files to PostScript format.

Syntax

ps630 [**-f***Bodyfont*] [**-p***File*] [**-s***Pitch*] [**-F***Boldfont*] [*File* ...]

Description

The **ps630** command converts Diablo 630 format print files to PostScript format for printing on a PostScript printer. If no *File* variable is specified, the **ps630** command reads from standard input. By default, the PostScript file is sent to the standard output.

The **ps630** command can convert **nroff** files generated with the **-Txerox** flag. Typewheel emulation information can be specified as options. Font specifications (for bold and regular) are PostScript font names (such as Times-Roman, Times-Bold, Courier-Bold, Courier-BoldOblique). You can select 10, 12, or 15 characters per inch.

Some applications produce bold type by double-striking a character. This type of bolding is not translated into PostScript format. Only the bold effect produced by issuing the proper Diablo command sequence (Esc-O) results in bold characters.

The output of the **ps630** command cannot be page-reversed. Times-Roman and Helvetica are narrow fonts that may look squeezed if no adjustment to the page width is made by the application.

The following Diablo 630 commands are not supported:

- Print suppression

- HY-Plot
- Extended character set
- Downloading print wheel information or program mode
- Page lengths other than 11 inches
- Paper feeder control
- Hammer energy control
- Remote diagnostic
- Backward printing control.

  Note: The Diablo 630 command for reverse printing is supported.

Flags

Item	Description
-f*Bodyfont*	Sets the font to be used for normal printing. The default is Courier.
-p*File*	Causes the PostScript file to be written to the file specified by the *File* parameter rather than to the standard output.
-s*Pitch*	Selects type size for printing (both the regular and bold fonts are scaled to this size). Pitch is in characters per inch and must be one of 10, 12, or 15. The default is 12.
-F*Boldfont*	Sets the font to be used for bold type. The default is Courier-Bold.

International Character Support

See the html

psc or psdit Command

Purpose

Converts **troff** intermediate format to PostScript format.

Syntax

{ **psc** | **psdit** } [**-f1** *CodeSet***:***Font*] [**-F***FontDirectory*] [**-M***MediaName*] [**-p***Prologue*] [**-o***List*] [*File*]

Description

The **psc** and **psdit** commands translate a file created by device-independent **troff** to PostScript format for printing with a PostScript printer. If no file is specified, the standard input is used. The PostScript file is sent to the standard output.

Note: The input for the **psc** and **psdit** commands should be prepared with the corresponding **-Tpsc** option, such as the **troff** or **pic** command.

The **psc** and **psdit** commands can handle extended characters created by modifying the printer code field in the font file (**/usr/lib/font/devpsc/R**). The modified field contains a string surrounded by double quotation marks. The string contains a **\b** (backslash b) followed by a sequence of characters from the standard font that is composed into a new character by overstriking.

The **psc** and **psdit** commands allow users to cause the **troff** command to include arbitrary PostScript code in the generated PostScript file. The **psc** and **psdit** commands recognize the undefined **%** (percent) command in the **troff** intermediate file format to signal the start of raw PostScript code to be placed as is in the output file. Everything between (but not including) the **%** (percent sign) and a line containing a **.** (period) will be placed in the generated PostScript output.

This PostScript output is not insulated from the **troff** command coordinate system or the state of the generated PostScript output. However, two functions are defined in the prologue so that users can insulate themselves if so desired. The **PB** (picture begin) function performs a PostScript save operation, translates the PostScript coordinate system to **troff**'s idea of the current position on the page, and changes the scale and orientation of the coordinate system axes to the standard PostScript 72 units per inch. The **PE** (picture end) macro ends this protected environment.

Several methods can be used to incorporate such included PostScript code into the **troff** intermediate file. For example, the **.sy**, **\!**, and **.cf** subcommands of the **troff** command use the following example to include the PostScript language description of a completely separate, printable document. In this example, the **showpage** operator is redefined to include `mypic.ps` as an illustration:

```
standard troff input
\&
.fl
\!%PB
\!/showpage{}def
.fl
.sy cat mypic.ps
\!PE
\!.
more standard troff input
```

Information containing various media sizes for the **psdit** command and the **enscript** command are contained in the file **/usr/lib/ps/MediaSizes**.

The information required for each entry in the **MediaSizes** file can be obtained from the **PostScript Printer Description**, or **PPD**, file that matches the PostScript printer used with TranScript. The **PPD** files are available from Adobe Systems Incorporated. The measurements extracted form the **PPD** files are in points. A printer's point is 1/72 of an inch.

Any line in the **MediaSizes** file beginning with an ASCII ***** (asterisk) is ignored when matching media size names provided on the command line to the **enscript** command and the **psdit** command.

Each entry in the **MediaSizes** file contains either eight or nine fields. The first eight fields are required for all entries. The ninth field is optional. Fields are separated by white space. The fields for each entry are as follows:

Field Name	Description
EntryName	Character string to match against a media name provided with the **-M** option with the **enscript** command or the **psdit** command.
MediaWidth	Media width in points.
MediaDepth	Media depth in points.
ImageableLLX	Imageable lower left-hand corner x coordinate in points.
ImageableLLY	Imageable lower left-hand corner y coordinate in points.
ImageableURX	Imageable upper right-hand corner x coordinate in points.
ImageableURY	Imageable upper right-hand corner y coordinate in points.
PageRegionName	PostScript sequence for the particular printer to identify the size of the imageable area.
PaperTrayName	PostScript sequence for the particular printer to select a particular paper/media tray. This field is optional.

Note: The sequence can be multiple PostScript operators or words for both the **PageRegionName** field and the **PaperTrayName** field. To specify such a sequence, use the ASCII " (double quotation mark character) to delimit the entire sequence.

The following are examples of field entries in the **MediaSizes** file:

Name	Entries
Letter	**Width** 612 **Depth** 792 **llx** 18 **lly** 17 **urx** 597 **ury** 776 **Page- Region- Name** Letter **Page- Tray- Name**
Legal	**Width** 612 **Depth** 1008 **llx** 18 **lly** 17 **urx** 597 **ury** 992 **Page- Region- Name** Legal **Page- Tray- Name**

Flags

-f1 *CodeSet*:*Font*

Item	Description
-F*FontDirectory*	Takes font information from *FontDirectory* instead of the default.
-M*MediaName*	Specifies a media name to use to determine the amount of imageable area on the paper. The name provided is matched against entries in the **MediaSizes** file. For instance, `-M legal` would request a legal size of paper as the imageable area. If this option is not used, the default size is letter size, which is 8.5 inches wide by 11.0 inches deep.
-p*Prologue*	Uses the contents of *Prologue* instead of the default PostScript prologue.

Item	Description
-o*List*	Prints pages whose numbers are given in the list separated by commas. The list contains single numbers and ranges in the format *N1*-*N2*, where *N1* and *N2* represent page numbers. A missing *N1* means the range begins with the lowest-numbered page; a missing *N2* means the range ends with the highest-numbered page.

Examples

The following statements are equivalent:

```
pic -Tpsc File | troff -Tpsc | psc
pic -Tpsc File | troff -Tpsc | psdit
```

Environment Variables

Item	Description
PSLIBDIR	Path name of a directory to use instead of the **/usr/lib/ps** file for the **psc** and **psdit** command prologue.
TRANSCRIPT	Absolute path name of a file to use instead of **/usr/lib/ps/transcript.conf** for the MBCS handling.

Files

Item	Description
/usr/lib/font/devpsc/*	Contains the **troff** default description files for a PostScript virtual device.
/usr/lib/ps/psdit.pro	Contains the default PostScript prologue.
/usr/lib/ps/MediaSizes	Contains the default file used for media sizes.
/usr/lib/ps/transcript.conf	Contains the default value used for PostScript codeset and font name.

pshare Command

Purpose

Enables or reports the availability of shared login ports.

Syntax

pshare [**-a**] [*Device*]

Description

The **pshare** command enables shared ports. Shared ports are bidirectional. If you do not specify a *Device* parameter, the **pshare** command reports the names of all currently enabled shared ports. To enable a shared port, the **getty** command attempts to create a **lock** file in the **/etc/locks** directory that contains the ASCII process ID of the process. If another process is already using the port, the **getty** command waits until the port is available and tries again. The system enables a port by updating an entry in the **/etc/inittab** file and then sending a signal to the **init** process. After receiving the signal and reading the updated status entry, the process takes the appropriate action.

Use the *Device* parameter to specify the ports to be enabled. Permitted values include:

- Full device name, such as the **/dev/tty1** device
- Simple device name, such as the **tty1** device
- A number (for example, 1 to indicate the **/dev/tty1** device)

Note: You must have root user authority to run this command.

Flags

Item	Description
-a	Enables all ports as shared.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

To enable the workstation attached to the **/dev/tty2** port as a shared port, enter:

```
pshare /dev/tty2
```

Item	Description
/etc/inittab	Controls system initialization.

Files

Item	Description
/etc/locks	Contains **lock** files for the **pshare** and **pdelay** commands.
/usr/sbin/pshare	Contains the **pshare** command.

psplot Command

Purpose

Converts files in plot format to PostScript format.

Syntax

psplot [**-g** *Prologue*] [*File...*]

Description

The **psplot** command reads files in plot format and converts them to PostScript format on the standard output. If no files are specified, the standard input is used. The conversion is almost one-to-one, with one PostScript function call for each plot primitive. You can modify the behavior of the file by changing the definitions of the PostScript functions in the prologue.

Flags

Item	Description
-g*Prologue*	Uses the contents of the *Prologue* file instead of the default PostScript prologue. If this flag is not specified, the default prologue file is used.

International Character Support

The html

psrasc Command

Purpose

Collects centralized RAS data.

Syntax

psrasc type [**-d**] [**-n** *number*] **-o** *outputFile* **logSpace/logStream**

Description

The **psrasc** command extracts the Reliability/Availability/Serviceability (RAS) data log records centralized on a PowerHA pureScale log stream and builds a file in the RAS data AIX format. The PowerHA pureScale service name is **CentralizedLogService**. Binding information for that service name must be setup before using the **psrasc** command.

RAS data types

When the specified type is **syslog**, the log records contain system log messages, including message initiator hostname. The format of the generated file is similar to the system log destination files. When the specified type is **errlog**, the log records contain error log entries. The generated file is an error log file that can be later exploited by the **errpt** command.

Flags

Item	Description
type	Specifies the type of RAS data contained in the log records. This must be the first parameter. Supported RAS data types are: **syslog** and **errlog**. From this type, depends the format of the output file.
-d	Specifies that the collected log record are deleted.
-n *number*	Specifies the number of log records to collect. Oldest log records are collected. When this parameter is not specified, all the log records are collected.
-o *outputFile*	Specifies the relative or absolute pathname of the output file. If the file already exists, it is overwritten.
log_space/ log_stream	Specifies the fullname of the log stream from which system log messages are collected. Fullname is made of the parent log space name and the log stream name separated by a **/** (slash).

Exit Status

This command returns the following exit values:

Item	Description
`0`	Successful completion.
`> 0`	An error occurred.

Examples

1. To collect log records of the log stream named **CentralizedRAS/Syslog** into the **syslog.out** file on the

   PowerHA pureScale server identified by the **CentralizedLogService** service name, enter:

   ```
   psrasc syslog -o syslog.out CentralizedRAS/Syslog
   ```
2. To collect the 100 oldest log records of the log stream named **CentralizedRAS/Syslog** into the **/var/adm/ras/cluster_syslog** file on the PowerHA pureScale server

   identified by the **CentralizedLogService** service name and delete them, enter:

   ```
   psrasc syslog -d -n 100 -o /var/adm/ras/cluster_syslog CentralizedRAS/Syslog
   ```
3. To collect log records of the log stream named **CentralizedRAS/Errlog** into the file **centralizedRAS_errlog** on the PowerHA pureScale server identified by the CentralizedLogService service name, enter:

   ```
   psrasc errlog -o centralizedRAS_errlog CentralizedRAS/Errlog
   ```
4. To collect and delete the 100 oldest log records of the log stream named **CentralizedRAS/Errlog** into the **/var/adm/ras/cluster_errlog** error log file on

   the PowerHA pureScaleserver identified by the **centralizedRAS_error** service, enter:

   ```
   psrasc errlog -d -n 100 -o /var/adm/ras/cluster_errlog CentralizedRAS/Errlog
   ```

psrev Command

Purpose

Reverses the page order of a PostScript file and selects a page range for printing.

Syntax

psrev [**-R**] [**-s***Pagespec*,...] [*File*]

Description

The **psrev** command reverses the page order of the file specified by the *File* variable and prints the pages specified by the *Pagespec* parameter. The file must conform to PostScript file structuring conventions. If no value for the *File* is specified, the **psrev** command reads from standard input. The **psrev** command writes the resulting file to the standard output.

Flags

Item	Description
-R	Does not reverse the page order (but subsets the pages if specified).
-s*Pagespec*	Specifies a range (or several ranges) of pages to be printed. The *Pagespec* parameter is a string with no spaces. The *Pagespec* parameter can be a single page number or a range of the form *N-M*, which prints pages *N* through *M*. *-N* prints from the beginning of the document to page *N*. *M-* prints from page *M* to the end of the document.

Examples

The following are examples of using the **psrev** command showing page ranges and an individual page in nonreversed order:

```
psrev -R -s2-4,6
```

```
psrev -R -s2-4,6-8
```

Files

Item	Description
/var/tmp/RV*	Contains the temporary file if the input is a pipe.

psroff Command

Purpose

Converts files from **troff** format to PostScript format.

Syntax

psroff [**-t**] [**-d***Queue*] [**-n***Number*] [**-t***Title*] [**-D***FontDirectory*] [**-F***FontFamily*] [**-P***Flag*] [*troffFlags*] [*File ...*]

Description

The **psroff** command is a shell script that runs the **troff** command in an environment to produce output on a PostScript printer. It uses the **psdit** command to convert **troff** intermediate output to PostScript format, and spools this output for printing. If no files are specified, the standard input is used.

To include arbitrary PostScript language commands or files in a **troff** document, see the **psdit** command.

PostScript Font Information

The PostScript Fonts for Transcript table shows the fonts available for the TranScript commands. The fonts are available by long name when using the **enscript** command, and by short name when using the **psroff** or **troff** commands. The following table shows the **psroff** commands (short names) used to declare a default set of fonts. The alphabetic characters are case-sensitive:

PostScript Fonts for Transcript	
Long Name (Short Name)	**Font Family**
AvantGarde-Book (ag)	AvantGarde
AvantGarde-Demi (Ag)	AvantGarde
AvantGarde-DemiOblique (AG)	AvantGarde
AvantGarde-BookOblique (aG)	AvantGarde
Bookman-Demi (Bo)	Bookman
Bookman-DemiItalic (BO)	Bookman
Bookman-Light (bo)	Bookman
Bookman-LightItalic (bO)	Bookman
Courier (C)	Courier

PostScript Fonts for Transcript *(continued)*	
Long Name (Short Name)	**Font Family**
Courier-Bold (CB)	Courier
Courier-BoldOblique (CO)	Courier
Courier-Oblique (CO)	Courier
Garamond-Bold (Ga)	Garamond
Garamond-BoldItalic (GA)	Garamond
Garamond-Light (ga)	Garamond
Garamond-LightItalic (gA)	Garamond
Helvetica (H)	Helvetica
Helvetica-Bold (HB)	Helvetica
Helvetica-Oblique (HO)	Helvetica
Helvetica-BoldOblique (HD)	Helvetica
Helvetica-Narrow (hn)	Helvetica
Helvetica-Narrow-Bold (Hn)	Helvetica
Helvetica-Narrow-BoldOblique (HN)	Helvetica
Helvetica-Narrow-Oblique (hN)	Helvetica
LubalinGraph-Book (lu)	Lubalin
LubalinGraph-BookOblique (lU)	Lubalin
LubalinGraph-Demi (Lu)	Lubalin
LubalinGraph-DemiOblique (LU)	Lubalin

Item	**Description**
NewCenturySchlbk (NC)	NewCentury
NewCenturySchlbk-Bold (Nc)	NewCentury
NewCenturySchlbk-Italic (nC)	NewCentury
NewCenturySchlbk-Roman (nc)	NewCentury
Optima (op)	Optima
Optima-Bold (Op)	Optima
Optima-BoldOblique (OP)	Optima
Optima-Oblique (oP)	Optima
Palatino-Bold (PB)	Palatino
Palatino-BoldItalic (PX)	Palatino
Palatino-Italic (PI)	Palatino
Palatino-Roman (PA)	Palatino
Souvenir-Demi (Sv)	Souvenir
Souvenir-DemiItalic (SV)	Souvenir

Item	Description
Souvenir-Light (sv)	Souvenir
Souvenir-LightItalic (sV)	Souvenir
Times-Bold (TB)	Times
Times-BoldItalic (TD)	Times
Times-Italic (TI)	Times
Times-Roman (TR)	Times
Symbol (S)	(none)
ZapfChancery-MediumItalic (ZC)	Zapf
ZapfDingbats	(none)

Flags

Item	Description
-D*FontDirectory*	Finds font family directories in the specified font directory, rather than the standard font directory, which was configured in the installation procedure. It may be necessary to use both this flag and the **-F** flag to imitate the **-F** flag in the **troff** command.
-d*Queue*	Causes the output to be queued to the queue specified by the *Queue* parameter. If the **-d** flag is not used, the **psroff** command queues output on the default queue, the first queue known to the **qdaemon**. This flag is recognized by the spooler print.
-F*FontFamily*	Uses the specified font family for the R/I/B/BI fonts, rather than the Times default family. The Times, Courier, and Helvetica font families are defined at your site, and others are available as well. Ensure that the printer you use contains the font family you pick. This flag overrides the **troff** command **-F** flag. If you want to use the **troff** command **-F** flag, you should run the **troff** command directly or use the **-D** flag instead.
-n*Number*	Causes the number of output copies specified by the *Number* parameter to be produced. The default is one. This flag is recognized by the spooler print.
-P*Flag*	Passes the *Flag* parameter to the spooler. This flag is useful when a conflict exists between a spooler flag and a flag with the **psroff** command.
-t	Sends the PostScript output to the standard output, rather than spooling it to a printer. This flag overrides the **troff** command **-t** flag. If you want the **troff** command **-t** flag, you should run the **troff** command directly.
-t*Title*	Sets the job name for use on the first banner page. The default is to use the name of the first input file. This flag is recognized by the spooler print.

Parameters

Item	Description
troffFlags	Specifies standard flags available with the **troff** command.
File	Specifies the **troff** intermediate output file. The default is the standard input.

Files

Item	Description
/usr/share/lib/tmac/tmac.*	Contains the standard macro files.
/usr/lib/font/devpsc/*	Contains the **troff** description files for PostScript virtual device.
/usr/lib/ps/*.afm	Contains Adobe Font Metrics (AFM) files for use with the **enscript** command.
/usr/lib/ps/font.map	Contains the list of font names with their abbreviations.
/usr/lib/ps/ditroff.font	Contains font family files for the **troff** command.

pstart Command

Purpose

Enables or reports the availability of login ports (normal, shared, and delayed).

Syntax

pstart [**-a**] [*Device*]

Description

The **pstart** command enables all ports (normal, shared, and delayed) listed in the **/etc/inittab** file. The system enables a port by updating an entry in the **/etc/inittab** file and then sending a signal to the **init** process. When the **init** process receives the signal and reads the updated status entry, it takes the appropriate action.

Use the *Device* parameter to specify the ports to be enabled. Permitted values include:

- A full device name, such as the **/dev/tty1** device
- A simple device name, such as the **tty1** device
- A number (for example, 1 to indicate the **/dev/tty1** device)

If you do not specify a *Device* parameter, the **pstart** command reports the names of all enabled ports and whether they are currently enabled as normal, shared, or delayed.

Note: You must have root user authority to run this command.

Flag

Item	Description
-a	Enables all ports (normal, shared, and delayed ports).

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To display the names of all ports (normal, shared, and delayed) currently enabled and how they are enabled, enter:

```
pstart
```

2. To enable all normal, shared, and delayed ports listed in the **/etc/inittab** file, enter:

```
pstart -a
```

Files

Item	Description
/etc/locks	Contains **lock** files for the **pshare** and **pdelay** commands.
/usr/sbin/pstart	Contains the **pstart** command file.

pstat Command

Purpose

Interprets the contents of the various system tables and writes it to standard output.

Syntax

pstat [**-a**] [**-A**] [**-f**] [**-i**] [**-p**] [**-P**] [**-s**] [**-S**] [**-t**] [**-u***ProcSlot*] [**-T**] [**-U** *ThreadSlot*] [[*KernelFile*] *CoreFile*]

Description

The **pstat** interprets the contents of the various system tables and writes it to standard output. You must have root user or **system** group authority to run the **pstat** command.

Flags

Item	Description
-a	Displays entries in the process table.
-A	Displays all entries in the kernel thread table.
-f	Displays the file table.
-i	Displays the i-node table and the i-node data block addresses.
-p	Displays the process table.
-P	Displays runnable kernel thread table entries only.
-s	Displays information about the swap or paging space usage.
-S	Displays the status of the processors.
-t	Displays the tty structures.
-u *ProcSlot*	Displays the user structure of the process in the designated slot of the process table. An error message is generated if you attempt to display a swapped out process.
-T	Displays the system variables. These variables are briefly described in var.h.
-U *ThreadSlot*	Displays the user structure of the kernel thread in the designated slot of the kernel thread table. An error message is generated if you attempt to display a swapped out kernel thread.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To display the i-nodes of the system dump saved in the **dumpfile** core file, enter:

   ```
   pstat -i dumpfile
   ```

   Symbols are retrieved from the **/usr/lib/boot/unix** file.
2. To display the file table and the user structure for the process in process table slot 0 (zero) of the system currently running, enter:

   ```
   pstat -f -u 0
   ```
3. To display the tty structures for a system dump, whose core file is **dumpfile** and whose kernel is the **/usr/lib/boot/unix.back** file, enter:

   ```
   pstat -t /usr/lib/boot/unix.back dumpfile
   ```
4. To display all threads in the kernel thread table and the user structure of the thread in thread table slot 2, enter:

   ```
   pstat -A -U 2
   ```

Files

Item	Description
/**usr**/**sbin**/**pstat**	Contains the **pstat** command.
/dev/mem	Default system-image file.
/usr/lib/boot/unix	Default kernel-image file.
/usr/include/sys/*.h	Contains header files for table and structure information.

ptpd Daemon

Purpose

Starts the Precision Time Protocol (1588-2008) daemon (**ptpd**).

Syntax

/usr/sbin/ptpd [**-?**] [**-h**] [**-H**] [**-e** *setting*] [**-k**] [**-v**] [**-O**] [**-L**] [**-A**] [**-s**] [**-m**] [**-M**] [**-y**] [**-E**] [**-P**] [**-a**] [**-n**] [**-C**] [**-V**] [**-c** *file*] [**-R** *dir*] [**-f** *file*] [**-S** *file*] [**-d** *domain_number*] [**-u** *IP_address*] [**-r** *number*] [**-l** *file*] [**-i** *dev*]

Description

The **ptpd** daemon implements the Precision Time Protocol (PTP) version 2 as defined by the IEEE 1588-2008 standard. PTP provides precise time coordination of LAN-connected computers. You must run this daemon with root authority to manipulate the system clock and use lower port numbers. The **ptpd** daemon supports IPv4 multicast, unicast, hybrid mode (mixed), and Ethernet mode operations. The

ptpd daemon can achieve and maintain submicrosecond level timing precision, even without hardware assistance.

Configure the **ptpd** daemon by using the `/etc/ptpd2.conf` configuration file (default file). The short (**-x**) and long (**--xxxxx**) flags provide basic control over the daemon operation, and provide only the basic PTP protocol settings. Other settings can be displayed by the **-h**, **-H**, and **-e** flags.

The **ptpd** daemon can be started either from System Resource Controller (SRC) or from the command line.

Use the following SRC commands to manipulate the **ptpd** daemon:

startsrc
Starts a subsystem, group of subsystems, or a subserver.

stopsrc
Stops a subsystem, group of subsystems, or a subserver.

refresh
Causes a subsystem or group of subsystems to read the appropriate configuration file again.

lssrc
Gets the status of a subsystem, group of subsystems, or a subserver.

Note: The **ptpd** daemon does not support Network Time Protocol (NTP) and Simple Network Management Protocol (SNMP) related functions.

The **ptpd** daemon uses the following terms:

slave device
A system running the **ptpd** daemon that accepts commands from a *master* device and synchronizes its system time to match the associated boundary clock time.

master device
A device bound to a boundary clock that synchronizes time with a set of one or more PTP *slave* devices on the same network.

grandmaster device
A *master* device that has the best clock provided by the Best Master Clock algorithm. It synchronizes all of the other *master* devices (also known as the boundary clocks), which in turn update and synchronize all of the associated *slave* devices. The grandmaster clock is also known as best master clock or best clock.

Flags

Short flag	Long flag	Description
-a	**--delay-override**	Overrides delay request interval announced by master in worker state. This flag sets the `ptpengine` attribute to the following setting: `ptpengine:log_delayreq_override`
-A	**--auto-lock**	Uses preset or port mode-specific lock-file names. This flag is useful when you run multiple instances of the **ptpd** daemon.
-c *file*	**--config-file** *file*	Specifies the path of the configuration file.
-C	**--foreground**	Specifies the command to run in foreground. This flag sets the `global` attribute as follows: `global:foreground=Y` **Note:** This option is ignored if the **ptpd** daemon is started from SRC.

Short flag	Long flag	Description
-d *domain_number*	**--domain** *domain_number*	Specifies the PTP domain number to become part of. This flag sets the `ptpengine` attribute as follows: `ptpengine:domain`
-D [DD]	**--debug**	Specifies the debug level. This flag sets the `global` attribute as follows: `global:debug_level` You can specify multiple instances to increase the debug level information. For example, the **-D** option specifies minimal debug information. The **-DD** option specifies detailed debug information. The **-DDD** option specifies maximum debug information.
-e *setting*	**--explain** *setting*	Shows help information for a single setting. This flag sets the `section` attribute as follows: `section:key`
-E	**--e2e**	Specifies end-to-end delay detection. This flag sets the `ptpengine` attribute as follows: `ptpengine:delay_mechanism=E2E`
-f *file*	**--log-file** *file*	Specifies the path of the log file. This flag sets the `global` attribute as follows: `global:logfile`
-h	**--help**	Shows help screen.
-H	**--long-help**	Shows detailed help for all settings and behaviors.
-i *dev*	**--interface** *dev*	Specifies the interface to be used for **ptpd** implementation. For example, `en0`. This flag sets the `ptpengine` attribute as follows: `ptpengine:interface`
-k	**--check-config**	Checks the PTP configuration and exits. Returns 0 if the configuration is correct.
-l *file*	**--lockfile** *file*	Specifies the path of lock-file. This flag sets the `global` attribute as follows: `global:lock_file`
-L	**--ignore-lock**	Skips checking and locking the lock-file. This flag sets the `global` attribute as follows: `global:ignore_lock`
-m	**--masterslave**	Specifies the full IEEE 1588 implementation: master, slave when not gandmaster (best master). This flag sets the `ptpengine` attribute as follows: `ptpengine:preset=masterslave`

Short flag	Long flag	Description
-M	**--masteronly**	Specifies master only mode: passive when not best GM. This flag sets the `ptpengine` attribute as follows: `ptpengine:preset=masteronly`
-n	**--clock:no_adjust**	Specifies not to adjust the clock. This flag sets the `clock` attribute as follows: `clock:no_adjust`
-O	**--default-config**	Shows default configuration and exits. The output can be used as a configuration file.
-p	**--print-lockfile**	Prints path of the lock-file and exits. This flag is useful for `init` scripts in combination with auto lock-files.
-P	**--p2p**	Specifies peer-to-peer delay detection. This flag sets the `ptpengine` attribute as follows `ptpengine:delay_mechanism=P2P`
-r *number*	**--delay-interval** *number*	Specifies the interval of delay request message (log 2). This flag sets the `ptpengine` attribute as follows: `ptpengine:log_delayreq_interval`
-R *dir*	**--lock-directory** *dir*	Specifies the directory to store lock-files. This flag sets the `global` attribute as follows: `global:lock_directory`
-S *file*	**--statistics-file** *file*	Specifies the path of statistics file. This flag sets the `global` attribute as follows: `global:statistics_file`
-s	**--slaveonly**	Turns on the slave-only mode. This flag sets the `ptpengine` attribute as follows: `ptpengine:preset=slaveonly`
-u	**--unicast**	Specifies unicast mode (no unicast negotiation) and sends all messages to IP. This flag sets the `ptpengine` attribute as follows: `ptpengine:ip_mode=unicast + ptpengine:unicast_address`
-v	**--version**	Prints the version string and exits.
-V	**--verbose**	Specifies the command to run in foreground and to log all the messages to the standard output. This flag sets the `global` attribute as follows: `global:verbose_foreground=Y` **Note:** This option is ignored if the **ptpd** daemon is started from SRC.

Short flag	Long flag	Description
-y	**--hybrid**	Specifies hybrid mode: mixed multicast and unicast operation. Multicast for sync and announce, unicast for delay request and response. This flag sets the `ptpengine` attribute as follows: `ptpengine:ip_mode=hybrid`

PTP daemon port states

The **ptpd** port can have the following states:

State	Description
`init`	Initializing
`flt`	Faulty
`lstn_init`	Listening (first time)
`lstn_reset`	Listening (subsequent reset)
`pass`	Passive (not best master, not announcing)
`uncl`	Uncalibrated
`slv`	Worker
`pmst`	Pre-master
`mst`	Master (active)
`dsbl`	Disabled
`? (unk)`	Unknown state

Statistics log file format

The following options are available when you enable the **ptpd** statistics log:

ptpengine:log_statistics
Updates the login information for each received PTP packet.

ptpengine:statistics_file
Specifies the location path of the statistics log file.

Note: This option enables statistics gathering.

When the statistics logging is enabled, a **ptpd** worker logs clock sync information when sync and delay response message are received. When the **ptpd** daemon starts up or flushes the log, a comment line (starting with #) is logged, containing the names of all columns. The log file is in the comma-separated values (CSV) format and can be easily imported into statistics tools and spreadsheet software packages for analysis and creating graphs. The size of the log files increases when you run the **ptpd** daemon for longer duration and with high message rates. Therefore, to reduce the number of messages logged, the `global:statistics_log_interval` setting can be used to limit the log output to one message per configured interval. The size and maximum number of the statistics log files can also be controlled.

The description of the columns in the statistics log file follows:

Timestamp
Time when the message was received. The date and time information are represented as text, UNIX time stamp (with fractional seconds), or both forms (in this case, an extra field is added), depending on the `global:statistics_timestamp_format` setting. When you import the log file to plotting software, if the software can understand UNIX time, set the time stamp format to `unix` or `both`, because some software do not interpret the fractional part of the second when it converts the date and time from text.

State
The state of the port. For more information about various port states, see "PTP daemon port states" on page 3261.

Clock ID
Port identity of the current best master, as defined by IEEE 1588 standard. This ID is the local clock's ID if the local clock is the best master. This parameter is displayed as `clock_id` or `port` (host). Port is the PTP clock port number, not the User Datagram Protocol (UDP) port numbers. The clock ID is an Extended Unique Identifier (EUI)-64 64-bit ID, converted from the 48-bit MAC address, by inserting `0xfffe` at the middle of the MAC address.

One-way delay
Current value of one-way delay (or mean-path delay) in seconds, calculated by the **ptpd** daemon that is in the worker state from the delay request and delay response message exchange.

Note: If this value remains at zero, it means that no delay response messages are being received, which might be because of a network issue.

Offset from master
Current offset value from master device in seconds. It is the main output of the PTP engine that is in the worker state. This value is the input for clock corrections in the clock servo algorithms. This value is typically measured when estimating the performance of the worker device.

Slave to master
Intermediate offset value (seconds) extracted from the delay request and delay response message exchange. This value is used for computing one-way delay. If the last value was rejected by a filter, the previous value is shown in the log file. This value is zero (0) if the delay response messages are not received.

Master to slave
Intermediate offset value (seconds) extracted from the sync messages. This value is used for computing the offset value from the master devices. If the last value was rejected by a filter, the previous value is shown in the log file.

Observed drift
The frequency difference between the worker clock and the master clock as measured by the integral accumulator of the clock control proportional integral (PI) servo model. This value stabilizes when the clock offset value is stabilized, and this value is used to detect clock stability.

Last packet received
This field shows which message was received last. It displays S for sync messages and D for delay response messages. If a worker device logs no D entries, it means that the worker device is not receiving delay response messages because of network issue.

One-way delay mean
One-way delay mean computed over the last sampling window.

One-way delay std dev
One-way delay standard deviation computed over the last sampling window.

Offset from master mean
Offset from master mean computed over the last sampling window.

Offset from master std dev
Offset from master standard deviation computed over the last sampling window.

Observed drift mean
Observed drift or local clock frequency adjustment mean computed over the last sampling window.

Observed drift std dev
Observed drift or local clock frequency adjustment standard deviation computed over the last sampling window. A lower value indicates that the clock is controlled less aggressively. Therefore, the value is more stable.

Note: All the statistical measures (mean and standard deviation) are computed and displayed only if the **ptpd** daemon was created by using the **--enable-statistics** flag. The duration of the sampling period is controlled with the `global:statistics_update_interval` setting.

Handling signals

The **ptpd** daemon handles the following signals:

Item	Description
SIGHUP	Reloads the configuration file (if used by the daemon) and reopens log files. The **refresh** subcommand of the SRC performs the same task.
SIGUSR1	When the subsystem is in the worker state, the **ptpd** daemon forces the clock to step to a current offset value from a master value.
SIGUSR2	Dumps all PTP protocol counters to current log target (and clears the counters if the `ptpengine:sigusr2_clears_counters` attribute is set).
SIGINT| SIGTERM	Closes log files and other open files. It also cleans up lock file and exits.
SIGKILL	Forces an unclean exit.

Exit status

Upon exit, the **ptpd** daemon returns 0 on success, either successfully started in daemon mode, or exited cleanly. The value of 0 is also returned when the **-k** (**--check-config**) option is used and the configuration was correct. A nonzero exit code is returned on errors. The value of 127 is returned if the **ptpd** daemon is started by a non-root user. The value of 3 is returned on lock-file errors and when the **ptpd** daemon cannot be started as daemon. The value of 2 is returned on memory allocation errors when the daemon is started. For all other error conditions such as configuration errors, running the **ptpd** daemon in help mode or without any parameters, self shutdown of subsystems, and network startup errors, the value of 1 is returned.

Examples

1. To start the **ptpd** daemon with the SRC, enter the following command:

   ```
   startsrc -s ptpd
   ```

2. To stop the **ptpd** daemon with the SRC, enter the following command:

   ```
   stopsrc -s ptpd
   ```

3. To refresh the **ptpd** daemon with the SRC, enter the following command:

   ```
   refresh -s ptpd
   ```

   The **ptpd** daemon reloads the configuration file (if used by the daemon) and reopens log files.

4. To check whether the configuration file in the `/etc/ptpd2.conf` path is configured correctly, enter the following command:

   ```
   ptpd -k
   ```

5. To view the meaning of a single setting, enter the following command:

   ```
   ptpd -e ptpengine:interface
   ```

   The output explains the meaning of the `ptpengine:interface` setting.

Files

Item	Description
`/etc/ptpd2.conf`	Default path of the **ptpd** daemon configuration file.

Item	Description
`/usr/samples/tcpip/ptpd2/ptpd2.conf`	Sample file of the `ptpd2.conf` configuration file.

ptsc Command

Purpose

Collects information from a trusted platform module (TPM) in preparation for an attestation request from an openpts verifier.

Syntax

ptsc [**options**] [**commands**]

Description

The **ptsc** command is the openpts collector. The command is used to gather measurements and events from the TPM (through the **tscd** interface), construct reference manifests (RMs) and convey them when requested to the openpts verifier. When a system is first configured for trusted boot, the collector must be initialized by using the **-i** option. This option generates a UUID and an associated RM stored in the /var/ptsc/<UUID>/rm0.xml file. If the system is changed and a new RM is required, the **-u** option is used and the verifier must be reinitialized.

Flags

Item	Description
Commands	
-i	Initializes the openpts collector.
-s	Specifies the startup (both self-test and the timestamp).
-t	Indicates the self-test.
-u	Updates the RM.
-U	Updates the RM automatically.
-D	Displays the configuration settings of the target or ALL the options. This is the default setting.
-m	If **-M** mode
Options	
-c *configfile*	Changes the location of the configuration file. The default is /etc/ptsc.conf.
-P *name=value*	Sets the properties.
-R	Removes the RM.
-Z	Uses an SRK secret of all zeros.
Miscellaneous	
-h	Displays the command usage information.
-V	Displays the information in verbose mode. Multiple **-V** options increase the verbosity and is used for debugging.

Files

Item	Description
/etc/ptsc.conf	The configuration file. This is the default location of the configuration file.
/var/ptsc/rm-uuid	The UUID of the current RM.
/var/ptsc/uuid	The UUID of the collector.
/var/ptsc/<UUID>/rm0.xml	The reference manifest.

ptsevt Command

Purpose

Manages the notifications of updates to the AIX system boot image.

Syntax

ptsevt [**-a**] [**-r**] [***host port***]

ptsevt -c

ptsevt [**-u uuid**] **-e**

Description

The **ptsevt** utility delivers events, by using the **-e** option about the boot image updates to which the attestation software known as listeners can subscribe. The optional **-u** argument can be used to specify the universally unique identifier (UUID) of the collector of the AIX system that is being updated. If the **-u** argument is not specified, the **ptsevt** command uses the default value found in the `/var/ptsc/uuid` file.

Subscribers can be added or removed by using the **-a** and **-r** options, respectively. The host can be a symbolic address or an IP or IPv6 number, and the TCP port must be a decimal number.

The **-c** option is used to clear the subscription list.

Flags

Item	Description
-a	Adds the listener specified by the host and port arguments to the destinations mentioned in the subscriber list.
-c	Clears the list of subscribers.
-e	Sends an event notification to all subscribers in the list.
-r	Removes the listener specified by the host and port arguments from the list of subscribers.
-u	Specifies the UUID that is sent as part of the notification. By default, the **ptsevt** command uses the value found in the **/var/ptsc/uuid** file.

Files

Item	Description
/var/ptsc/subscribers	The subscribers list.
/var/ptsc/subscribers.lo ck	The subscribers list lock file.
/var/ptsc/uuid	The default UUID sent as part of the notification.

ptsevtd Command

Purpose

Manages the notifications of updates to the AIX system boot image.

Syntax

ptsevtd [**-c** command] [**-d**] [**-f**] [**-p** ***port name***]

Description

The **ptsevtd** daemon listens to the events delivered by the **ptsevt** command when an attested system is being updated. By default, whenever an event is received, the **ptsevtd** command calls the **openpts** command with the universally unique identifier (UUID) of the system that is sending the event as the first argument. This process updates the corresponding reference manifest with the latest or the expected measurements. The -c option can be used to specify an alternative command that is called when a notification is received.

Use the -f option to run the daemon in the foreground. The -d option is specified multiple times to make the output more verbose. The -p argument specifies the port to be used to listen for event notifications.

Flags

Item	Description
-c	Specifies the command to call when a notification is received. If the option is not specified, the **openpts** command is used by default.
-d	Specifies the level to increase the verbosity of the output.
-f	Runs the listener in the foreground. The output is sent to the **stderr** console.
-p	Specifies the TCP port to use for event notifications. The default is 34185.

ptx Command

Purpose

Generates a permuted index.

Syntax

ptx [**-f**] [**-r**] [**-t**] [**-b** *Breakfile*] [**-g** *Number*] [**-w** *Number*] [**-i** *Ignore* | **-o** *Only*] [**—**] [*Infile* [*Outfile*]]

Description

The **ptx** command reads the specified English-language text (the *Infile* parameter), creates a rearranged index from it, and writes to the specified file (*Outfile*). Standard input and standard output are the defaults.

The **ptx** command searches the specified file (*Infile*) for keywords, sorts the lines, and generates the file *Outfile*. The *Outfile* file can then be processed with the **nroff** or **troff** command to produce a rearranged index.

The **ptx** command follows three steps:

1. Performs the permutation, generates one line for each keyword in an input line, and rotates the keyword to the front of the line.
2. Sorts the permuted file.

3. Rotates the sorted lines so that the keyword comes at the middle of each line.

The resulting lines in the *Outfile* file are in the following form:

```
.xx "" "before keyword" "keyword" "after keyword"
```

where `.xx` is an **nroff** or **troff** macro provided by the user or by the **ptx** command. The **mptx** macro package provides the `.xx` macro definition.

The `before keyword`, and `keyword`, and `after keyword` fields incorporate as much of the line as can fit around the keyword when it is printed. The first field and last field, at least one of which is always the empty string, are wrapped to fit in the unused space at the opposite end of the line.

Notes:

1. Line-length counts do not account for overstriking or proportional spacing.
2. Lines that contain a ~ (tilde) do not work, because the **ptx** command uses that character internally.
3. The **ptx** command does not discard non-alphanumeric characters.

Flags

Item	Description
-b *BreakFile*	Uses the characters in the specified break file to separate words. Tab characters, new-line characters, and spaces are always used as break characters.
-f	Folds uppercase and lowercase characters for sorting.
-g *Number*	Uses the specified number as the number of characters that the **ptx** command reserves for each gap among the four parts of the line as it is printed. The default *Number* variable value is 3.
-i *Ignore*	Does not use any words specified in the *Ignore* file as keywords. If the **-i** and **-o** flags are not used, the **/usr/lib/eign** file is the default *Ignore* file.
-o *Only*	Uses only the words specified in the *Only* file as keywords.
-r	Considers any leading non-blank characters of each input line as reference identifiers separate from the text of the line. Attaches the identifier as a fifth field on each output line.
-t	Prepares the output for the phototypesetter.
-w *Number*	Uses the specified number as the length of the output line. The default line length is 72 characters for the **nroff** command and 100 for the **troff** command.
—	(double dash) Indicates the end of flags.

Parameters

Item	Description
Infile	Specifies the English-language text. Standard input is the default file. The **ptx** command searches the specified file for keywords, sorts the lines, and generates the file *Outfile*.
Outfile	Specifies the file to which the **ptx** command writes the index created from the *Infile* file. Standard output is the default file. The *Outfile* file can be processed with the **nroff** or **troff** command to produce a rearranged index.

Files

Item	Description
/usr/lib/eign	Contains the default *Ignore* file.
/usr/share/lib/tmac/tmac.ptx	Contains the macro file.

pvcauth command

Purpose

The **pvcauth** command is used to authenticate with an IBM Power Virtualization Center (PowerVC) and get a token. This token is required to use the PowerVC services for the AIX Live Update operation. This token is valid only for a set time period. This command can also be used to invalidate a token.

Syntax

To authenticate with PowerVC and to get a token, use the following syntax:

```
pvcauth [ -u user_name ] [ -p password ] -a pvc [ -o project ][ -P port ]
```

To invalidate and remove a previously generated token, use the following syntax:

```
pvcauth -r -a pvc
```

To list all the known PowerVC authentication tokens, use the following syntax:

```
pvcauth -l
```

Description

You can use the **pvcauth** command if you have access to all types of object and if you have appropriate PowerVC administrative authority. The **pvcauth** command generates a token that can be used by an AIX partition administrator to perform the Live Update operation. If the command succeeds, a token is stored in the kernel. You can now use the **geninstall** command to perform the Live Update operation.

To use this command, you must have authority to perform the following tasks:

- Power on a managed partition.
- Shut down a managed partition.
- Create a managed partition.
- Remove a managed partition.
- Manage storage volumes.
- Manage network adapters.

Parameters

password
A string of up to 64 characters that specifies a password.

port
A string of up to 16 characters that specifies a port number to contact PowerVC. The default value of this parameter is 5000.

project
A string of up to 64 characters that specifies the PowerVC project name.

pvc
A string of up to 64 characters that specifies either the host name or the IP address of the PowerVC for authentication.

user_name
A string of up to 64 characters that specifies the PowerVC user name.

Flags

-a *pvc*
Specifies the host name or the IP address of PowerVC for authentication.

-o *project*
Specifies a PowerVC project name that is used to authenticate with PowerVC. If you do not specify the **-o** flag, the project name is set to the default name as **ibm-default**.

-l
Lists all the known PowerVC authentication tokens. The information that is listed includes the current Time To Live (TTL) value for the token.

-p *password*
Specifies the PowerVC password for authentication. If you do not specify the **-p** flag, you are prompted for the password after you run the **pvcauth** command.

-P *port*
Specifies a port number that can be used to contact PowerVC.

-r
Removes the token that is generated by PowerVC.

-u *user_name*
Specifies the PowerVC user name that can be used for authentication. You must have access to all types of objects and appropriate PowerVC administrative authority.

Examples

1. To authenticate with an HMC, called `apollo`, which has a firewall and in which the PowerVC port 5000 is not accessible, a rebound proxy node can be set up to use a different port that is open. To authenticate a logical partition called `mylpar` and to use the SSH client with port 14111 on a proxy node that is called `proxy1`, enter the following commands:

   ```
   root @ proxy1: /
   # ssh -R localhost:14111:apollo:5000 root@mylpar

   root @ mylpar: /
   # pvcauth -a localhost -u hscroot -P 14111
   Enter HMC password:
   ```

   You can specify the `management_console` attribute as `localhost` in the `pvc` stanza of the **lvupdate.data** file to initiate the Live Update operation.
2. To authenticate with PowerVC that has an IP address 5.5.55.121 with password prompt, enter the following command:

   ```
   # pvcauth -a 5.5.55.121 -u root
        Enter password for root:
   ```

3. To invalidate a previous authentication with PowerVC that has an IP address 5.5.55.121, enter the following command:

   ```
   # pvcauth -r -a 5.5.55.121
   ```

pvi Command

Purpose

Provides a privileged editor so that you can access privileged files.

Syntax

pvi [**-l**] [**-R**] [**-w** *Number*] [**-c** | **+** [*Subcommand*]] [*File*]

Description

The **pvi** command calls the **pvi** editor, a privileged version of the **vi** editor, to edit the file specified by the *File* parameter. Only one file can be opened at a time, and this file must have the security attributes that are defined in the privileged file database. You can display the file in the editor only when at least one of the authorizations matches at least one of the authorizations in the **readauths** or the **writeauths** attribute for the file. The contents of the buffer can then be modified. You can write to the file using the editor only when at least one of the authorizations matches at least one of the authorizations in the **writeauths** attribute for the file. Files opened by the **pvi** command can only be written to the same path they were opened from.

You enter and leave the **pvi** editor in command mode, but to add or change text, you must enter the text input mode. See the text input mode for information about the subcommands that initiate the text input mode. You can save the text to a file with one of the **:w** commands, and exit the **pvi** editor using the **:q** command.

The full-screen display editor, which is started by the **pvi** command, is based on the **ex** editor. You can use the **ex** subcommands within the **pvi** editor. Subcommands function at the cursor position on the display screen.

The **pvi** editor makes a copy of the file that you are editing in an edit buffer. The contents of the file are not changed until you save the changes.

Note: There are several functions of the **vi** editor that you cannot use with the **pvi** editor. If you refer to the information on the **vi** editor, be aware that the **-r** flag, the **-t** flag, shell escapes, user-defined macros, key mapping, and setting **vi** options permanently are not supported by the **pvi** editor. Only one buffer is opened at a time and a file can only be written to the same path from which it was opened.

Editor Limitations

The maximum limits of the **pvi** editor assume single-byte characters:

- 256 characters per a global command list
- 2048 characters in a shell escape command
- 128 characters in a string-valued option
- 30 characters in a tag name
- 524,230 lines silently enforced
- 128 map macros with 2048 characters total

Editing Modes

The **pvi** editor operates in the following modes:

Item	Description
command mode	The **pvi** editor starts in the command mode. Any subcommand can be called except those that only correct text during the text input mode. To see a description of the subcommands, refer to the topics in "Subcommands for the **pvi** editor". To identify the subcommands that cannot be called from the command mode, refer to "Changing Text While in Input Mode". The **pvi** editor returns to the command mode when the subcommands and other modes end. Press the **Esc** key to cancel a partial subcommand.
text input mode	The **pvi** editor enters the text input mode when you use a permitted command that adds or changes text. To see a list of subcommands that initiate text input mode, refer to "Adding Text to a File" and the subcommands that change text from the command mode, the **C** subcommand and the **cx** subcommands. After entering one of these subcommands, you can edit text with any of the subcommands that function in the text input mode. To see a list of the subcommands, refer to the topics in "Subcommands for the pvi Editor". To return to command mode from text input mode, press **Esc** for a typical exit or press the **Ctrl + C** keys to create an **INTERRUPT** signal.
last line mode	Some subcommands read input on a line displayed at the bottom of the screen. These subcommands include those with the prefix colon (:), slash (/), and question mark (?). When you enter the initial character, the **pvi** editor places the cursor at the bottom of the screen so you can enter the remaining command characters. To run the subcommand, press **Enter**. To cancel the subcommand, press **Ctrl** + **C** to create an **INTERRUPT** signal. When you use the colon (:) to enter the last line mode, the following characters have special meaning when used before the commands that specify counts: **%** All lines regardless of the cursor position **$** Last line . Current line

Customizing the pvi Editor

You can customize the **pvi** editor on a temporary basis by following the directions in "Setting vi Editor Options".

Subcommands for the pvi Editor

You can find information about the **vi** editor subcommands that are applicable to the **pvi** editor in the following list:

- **vi** General Subcommand Syntax.
- **vi** Subcommands for Adjusting the Screen.
- Editing Text with the **vi** Editor.
- Manipulating Files with the **vi** Editor.
- Subcommands for Interrupting and Ending the **vi** Editor.

Flags

Item	Description
-c [*Subcommand*]	Carries out the **ex** editor subcommand before the editing begins. This provides a line-oriented text editor. When you specify a null operand for the *Subcommand* parameter, for example, `-c ''`, the editor places the cursor on the last line of the file.
-l	Enters the editor in the list processing (LISP) mode. In this mode, the editor indents appropriately for LISP mode, and the **(,)**, **{, }**, **[[,** and **]]** subcommands are modified to act in LISP. These subcommands place the cursor at the specified LISP function. For more information on the LISP subcommands, refer to "Moving to Sentences, Paragraphs, and Sections".
-R	Sets the **readonly** option to protect the file against overwriting.
-w *Number*	Sets the default window size to the value specified by the *Number* parameter. This is useful when you use the editor over a low-speed line.
+ [*Subcommand*]	Same as the **-c** Subcommand.

Security

Access Control: This command grants the execute (x) access to all users.

Role-Based Access Control: The command grants read access to a file if the user has an authorization that matches one in the **readauths** or the **writeauths** authorization list in the privileged file database. The command only grants the write access to a file if the user has an authorization that matches one in the **writeauths** authorization list in the privileged file database.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To call a privileged editor to edit the **plans** file, enter:

   ```
   pvi plans
   ```

   This command puts the **pvi** editor into the command mode. To add or change text, you must enter the text input mode or use a command accepted in the command mode.
2. To save the text that you create with the **pvi** editor, leave the text input mode by pressing **Esc**, and then enter:

   ```
   :w
   ```
3. To exit the **pvi** editor from the text input mode, press **Esc** to enter the command mode, and then enter:

   ```
   :q!
   ```

   If the editor is already in the command mode, you do not need to press **Esc** before giving the quit (**q!**) command.

File

Item	Description
/usr/bin/pvi	Contains the **pvi** command.

Item	Description
/etc/security/privfiles	Contains the security attributes for the privileged files.

pwchange Command

Purpose

Change user authentication and privacy keys dynamically.

Syntax

pwchange [**-e**] [**-d** *DebugLevel*] [**-p** *Protocol*] [**-u** *KeyUsage*] [**-s**] [*OldPassword* *NewPassword*] [*IPAddress* | *HostName* | *EngineID*]

Description

The **pwchange** command is provided to facilitate dynamic changes of user authentication and privacy keys. Dynamic configuration of authentication and privacy keys is done by doing **set** commands to objects of syntax keyChange. The keyChange syntax provides a way of changing keys without requiring that the actual keys (either new or old) be flowed directly across the wire, which would not be secure. Instead, if an object,such as **usmUserAuthKeyChange** (for example) is to be set, the keyChange value must be derived from the old and new passwords and the engineID of the agent at which the key will be used. The **pwchange** command is used to generate the keyChange values.

The **pwchange** command generates different output, depending on which protocol and what key usage is selected. Keychange values are typically twice as long as the key to be changed.

Flags

Item	Description
-d *DebugLevel*	This flag indicates what level of debug information is desired. Debug tracing is either on or off: 1 causes debug tracing to be generated to the screen of the command issuer (sysout). Debug tracing is off (0) by default.
-e	This flag indicates that the agent for which the keychange value is being defined is identified by engineID rather than by IP address or host name.
-p *Protocol*	This flag indicates the protocols for which the keychange values should be generated. Valid values are: **HMAC-MD5** Generates keychange values for use with the HMAC-MD5 authentication protocol. **HMAC-SHA** Generates keychange values for use with the HMAC-SHA authentication protocol. **all** Generates both HMAC-MD5 and HMAC-SHA keychange values. The default is that keychange values for the HMAC-MD5 protocol are generated.

Item	Description
-s	This flag indicates that output should be displayed with additional spaces to improve readability. By default, data is displayed in a condensed format to facilitate cut-and-paste operations on the keychange values onto command lines in shell scripts.
-u *KeyUsage*	This flag indicates the usage intended for the keychange value. Valid values are: **auth** An authentication keychange value. **priv** A privacy keychange value. **all** Both authentication and privacy keychange values. **Note:** There is no difference between a keychange value generated for authentication and a keychange value generated for privacy. However, the length of privacy keychange values depends on whether the keychange value is localized.

Parameters

Item	Description
EngineID	Specifies the engineID (1-32 octets, 2-64 hex digits) of the destination host at which the key is to be used. The engineID must be a string of 1-32 octets (2-64 hex digits). The default is that the agent identification is not an engineID.
HostName	Specifies the destination host at which the key is to be used.
IPAddress	Specifies an IPv4 or an IPv6 address of the agent at the destination host at which the key is to be used.
NewPassword	Specifies the password that will be used in generating the new key. The password must be between eight and 255 characters long.
OldPassword	Specifies the password that was used in generating the key originally. The password must be between eight and 255 characters long.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

The **pwchange** command generates different output depending on which protocol and what key usage is selected. Key change values are typically twice as long as the key to be changed.

1. The following command demonstrates how the **pwchange** command can be used:

   ```
   pwchange oldpassword newpassword 9.67.113.79
   ```

   The output of this command looks similar to:

   ```
   Dump of 32 byte HMAC-MD5 authKey keyChange value:
     3eca6ff34b59010d262845210a401656
     78dd9646e31e9f890480a233dbe1114d
   ```

   The value to be set should be passed as a hex value with the **clsnmp** command (all on one line):

   ```
    clsnmp set usmUserAuthKeyChange.12.0.0.0.2.0.0.0.0.9.67.113.79.2.117.49
    \'3eca6ff34b59010d262845210a40165678dd9646e31e9f890480a233dbe1114d\'h
   ```

   Note: The backslash in the preceding example is required before the single quotation mark to enable AIX to correctly interpret the hexadecimal value.

   The index of the usmUserTable is made up of the EngineID and the ASCII representation of the user name. In this case it is 2 characters long and translates to 117.49.

   Note: pwchange incorporates a random component in generating keys and keyChange values. The output from multiple commands with the same input does not produce duplicate results.

2. The following command demonstrates how the **pwchange** command can be used with IPv6 address:

   ```
   pwchange oldpassword newpassword 2000:1:1:1:209:6bff:feae:6d67
   ```

   The output of this command looks similar to:

   ```
   Dump of 32 byte HMAC-MD5 authKey keyChange value:
     0000774adc53ba4b0427dc2f65568435
     721847d1b5cb597daa85d003033afba3
   ```

   The value to be set should be passed as a hex value with the **clsnmp** command (all on one line):

   ```
   clsnmp set usmUserAuthKeyChange.21.128.0.0.2.2.32.0.0.1.0.1.0.1.2.9.107.255.254.174.
   109.103.6.105.112.118.54.117.49
   \'36133c69415502662063761f835ef616de294f37f758c74ff1544ca3de279b8\'h
   ```

   Note: The backslash in the preceding example is required before the single quotation mark to enable AIX to correctly interpret the hexadecimal value.

   The index of the usmUserTable is made up of the EngineID, in this case 21 octets: 128.0.0.2.2.32.0.0.1.0.1.0.1.2.9.107.255.254.174.109.103; And the ASCII representation of the user name, in this case it is 6 characters long and translates to 105.112.118.54.117.49.

   Note: The **pwchange** command incorporates a random component in generating keys and keyChange values. The output from multiple commands with the same input does not produce duplicate results.

pwck Command

Purpose

Verifies the correctness of local authentication information.

Syntax

pwck

Description

The **pwck** command verifies the correctness of the password information in the user database files by checking the definitions for all users. The **pwck** command internally calls the **pwdck** command with **-n** and **ALL** options.

Exit Status

0
The command completed successfully.

>0
An error occurred.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To verify that all the users and administrators exist in the user database, and have any errors reported (but not fixed), enter:

```
pwck
```

Files

Item	Description
/usr/bin/pwck	Contains the **pwck** command.

pwd Command

Purpose

Displays the path name of the working directory.

Syntax

pwd [**-L** | **-P**]

Description

The **pwd** command writes to standard output the full path name of your current directory (from the root directory). All directories are separated by a / (slash). The root directory is represented by the first /, and the last directory named is your current directory.

Flags

-L
Displays the value of the PWD environment variable if the PWD environment variable contains an absolute path name of the current directory that does not contain the file names **.** (dot) or **..** (dot-dot). Otherwise, the **-L** flag behaves the same as the **-P** flag.

-P
Displays the absolute path name of the current directory. The absolute path name displayed with the **-P** flag does not contain file names that, in the context of the path name, refer to files of type symbolic link.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

Entering:

```
pwd
```

displays the current directory as:

```
/home/thomas
```

Files

Item	Description
/usr/bin/pwd	Contains the **pwd** command.

pwdadm Command

Purpose

Administers users' passwords.

Syntax

pwdadm [**-R** *load_module*] [**-f** *Flags* | **-q** | **-c**] *User*

Description

The **pwdadm** command administers users' passwords. The root user or a member of the security group can supply or change the password of the user specified by the *User* parameter. The invoker of the command must provide a password when queried before being allowed to change the other user's password. When the command executes, it sets the **ADMCHG** attribute. This forces the user to change the password the next time a **su** command is given for the user.

Note: The behavior described for this command is for a local user. For users defined in a remote domain, attributes will be retrieved and stored in the remote domain rather than in the local files.

Root users and members of the security group should not change their personal password with this command. The **ADMCHG** attribute would require them to change their password again the next time a **login** command or an **su** command is given for the user. Only the root user or a user with PasswdAdmin authorization can change password information for administrative users, who have the **admin** attribute set to true in the **/etc/security/user** file.

Only the root user, a member of the security group, or a user with PasswdManage authorization can supply or change the password of the user specified by the *User* parameter.

When this command is executed, the `password` field for the user in the **/etc/passwd** file is set to ! (exclamation point), indicating that an encrypted version of the password is in the **/etc/security/passwd** file. The **ADMCHG** attribute is set when the root user or a member of the security group changes a user's password with the **pwdadm** command.

A new password must be defined according to the rules in the **/etc/security/user** file, unless the **-f NOCHECK** flag is included. Only 7-bit characters are supported in passwords. By including the **-f** flag with the **pwdadm** command, the root user or a member of the security group can set attributes that change the password rules. If there is no password entry in the **/etc/security/passwd** file when the **-f** flag is used, the `password` field in the **/etc/passwd** file is set to ! (exclamation point) and an * (asterisk) appears in the `password=` field to indicate that no password has been set.

The **-q** flag permits the root user or members of the security group to query password information. Only the status of the **lastupdate** attribute and the **flags** attribute appear. The encrypted password remains hidden.

The **-c** flag clears all password flags for the user.

Flags

Item	Description
-c	Clears all password flags for the user.
-f *Flags*	Specifies the **flags** attribute of a password. The *Flags* variable must be from the following list of comma-separated attributes: **NOCHECK** Signifies that new passwords need not follow the guidelines established in the **/etc/security/user** file for password composition. **ADMIN** Specifies that password information may be changed only by the root user. Only the root user can enable or disable this attribute. **ADMCHG** Resets the **ADMCHG** attribute without changing the user's password. This forces the user to change passwords the next time a **login** command or an **su** command is given for the user. The attribute is cleared when the user specified by the *User* parameter resets the password.
-q	Queries the status of the password. The values of the **lastupdate** attribute and the **flags** attribute appear.
-R *load_module*	Specifies the loadable I&A module that is used to change the user's attributes.

Security

Access Control: Only the root user and members of the security group should have execute (x) access to this command. The command should have the **trusted computing base** attribute and be **setuid** to the root user to have write (w) access to the **/etc/passwd** file, the **/etc/security/passwd** file, and other user database files.

Files Accessed:

Mode	File
rw	**/etc/passwd**
rw	**/etc/security/passwd**
r	**/etc/security/user**

Auditing Events:

Event	Information
PASSWORD_Change	user
PASSWORD_Flags	user, flags

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To set a password for user susan, a member of the security group enters:

   ```
   pwdadm susan
   ```

   When prompted, the user who invoked the command is prompted for a password before Susan's password can be changed.
2. To query the password status for user susan, a member of the security group enters:

   ```
   pwdadm -q susan
   ```

   This command displays values for the **lastupdate** attribute and the **flags** attribute. The following example shows what appears when the **NOCHECK** and **ADMCHG flags** attributes are in effect:

   ```
   susan:
           lastupdate=
           flags= NOCHECK,ADMCHG
   ```

Files

Item	Description
/usr/bin/pwdadm	Contains the **pwdadm** command.
/etc/security/passwd	Contains password information.

html

pwdck Command

Purpose

Verifies the correctness of local authentication information.

Syntax

pwdck { **-p** | **-n** | **-t** | **-y** } [**-l**]{ **ALL** | *User ...* }

Description

The **pwdck** command verifies the correctness of the password information in the user database files by checking the definitions for **ALL** the users or for the users specified by the *User* parameter. If more than one user is specified, there must be a space between the names.

Note: This command writes its messages to **stderr**.

You must select a flag to indicate whether the system should try to fix erroneous attributes. The following attributes are checked for locally defined users in the **/etc/passwd** file:

Item	Description
entry	Ensures that each entry is readable and that it contains at least two : (colons). If you indicate that the system should fix errors, the entire entry is discarded.
passwd	Ensures that the password field is an ! (exclamation point). If you indicate that the system should fix errors, it transfers the information in the password field to the **/etc/security/passwd** file, updates the **lastupdate** attribute in the **/etc/security/passwd** file, and then replaces the password field in the **/etc/passwd** file with an !. In general, passwords are required if the **minalpha**, **minother**, or **minlen** password restriction is set to a nonzero value in the **/etc/security/user** file.
user	Ensures that the user name is a unique string of 8 bytes or less. It cannot begin with a + (plus sign), a : (colon), a - (minus sign), or a ~ (tilde). It cannot contain a : (colon) in the string and cannot be the **ALL**, **default**, or ***** keywords. If you indicate that the system should fix errors, it removes this user's entry line from the **/etc/passwd** file. If the user name starts with a + or a - symbol, the user is not locally defined, and checks are not performed.

Attributes checked in the **/etc/security/passwd** file are:

Item	Description
line	Ensures that each line is readable and is part of a stanza. Any invalid line is discarded.
password	Ensures that the **password** attribute exists and is not blank, if passwords are required on the system. If you indicate that the system should fix errors, the password is set to ***** (asterisk), and the **lastupdate** attribute is discarded. In general, passwords are required if either of the **minalpha** or **minother** password restrictions are set to nonzero values in the **/etc/security/user** file. If a user's **flags** attribute specifies the **NOCHECK** keyword, a password is not required for this user, and the check is ignored.
lastupdate	Ensures that the **lastupdate** attribute exists for a valid non-blank password, and that its time is prior to the current time. If you indicate that the system should fix errors, the **lastupdate** attribute is discarded or updated, depending on the **password** attribute. The **lastupdate** attribute is discarded if the **password** attribute doesn't exist, or equals a blank or an * (asterisk). Otherwise, the **lastupdate** time is set to the current time.
flags	Ensures that the **flags** attribute contains only the keywords **ADMIN**, **ADMCHG**, and **NOCHECK**. If you indicate that the system should fix errors, it deletes any undefined flags.

Attributes checked in the **/etc/security/user** file are:

Item	Description
auth1	Ensures that each SYSTEM;*username* entry defined for a local user has an *username* entry in the **/etc/security/passwd** file. If you indicate that the system should fix errors, a stanza is added to the **/etc/security/passwd** file for each missing entry, in the following format: `username:` `password = *` If a user's entry and a default entry both are missing from the **/etc/security/user** file, the system assumes the following values and the check on auth1 is performed: `auth1 = SYSTEM;user` **Note:** The **auth1** attribute is deprecated and should not be used.

Item	Description
auth2	Ensures that each authname;*username* entry defined for a local user has an *username* entry in the **/etc/security/passwd** file. If you indicate that the system should fix errors, an entry is added for each missing entry. If a user's entry and a default entry both are missing from the **/etc/security/user** file, the system assumes the following values and the check on **auth2** is performed: `auth2 = NONE` When ALL is specified, the **pwdck** command ensures that each stanza in the **/etc/security/passwd** file corresponds to an authentication name of a local user as a SYSTEM;*username* entry in the **/etc/security/user** file. If you indicate that the system should fix errors, a stanza which does not correspond to an username entry in the **/etc/security/user** file is discarded from the **/etc/security/passwd** file. The **pwdck** command locks the **/etc/passwd** file and the **/etc/security/passwd** file when it updates them. If either of these files are locked by another process, the **pwdck** command waits a few minutes for the files to be unlocked, and terminates if this does not happen. The **pwdck** command checks to see if the **/etc/passwd** file and the **/etc/security/passwd** file are modified by another process while the current **pwdck** process is running. If you indicate that the system should fix errors, the **pwdck** command updates the **/etc/passwd** file and the **/etc/security/passwd** file, and may overwrite any changes made by the other process. **Note:** The **pwdck** command disables any Extended Access Control Lists (ACLs) on the files when it fixes errors and reports them. The **pwdck** command also checks to see if the database management security files (**/etc/passwd.nm.idx**, **/etc/passwd.id.idx**, **/etc/security/passwd.idx**, and **/etc/security/lastlog.idx**) files are up-to-date or newer than the corresponding system security files. Please note, it is alright for the **/etc/security/lastlog.idx** to be not newer than **/etc/security/lastlog**. If the database management security files are out-of-date, a warning message appears indicating that the root user should run the **mkpasswd** command. Generally, the **sysck** command calls the **pwdck** command as part of the verification of a trusted-system installation. In addition, the root user or a member of the security group can enter the command. **Note:** The **auth2** attribute is deprecated and should not be used.

Flags

Item	Description
-l	Locks file during entire run.
-n	Reports errors but does not fix them.
-p	Fixes errors but does not report them.
-t	Reports errors and asks if they should be fixed.
-y	Fixes errors and reports them.

Security

Access Control: This command should grant execute (x) access to the root user and members of the security group. The command should be **setuid** to the root user, to read and write the authentication information, and have the **trusted computing base** attribute.

Files Accessed:

Mode	File
rw	/etc/passwd
r	/etc/security/user
rw	/etc/security/passwd
r	/etc/security/login.cfg

Auditing Events:

Event	Information
PASSWORD_Check	user, error/fix, status
PASSWORD_Ckerr	file/user, error, status

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To verify that all local users have valid passwords, enter:

   ```
   pwdck -y ALL
   ```

   This reports errors, and fixes them.
2. To ensure that user `ariel` has a valid stanza in the **/etc/security/passwd** file, enter:

   ```
   pwdck -y ariel
   ```

Files

Item	Description
/usr/bin/pwdck	Contains the **pwdck** command.
/etc/security/passwd	Contains actual passwords and security information.
/etc/security/login.cfg	Contains configuration information and password restrictions.

pwtokey Command

Purpose

Converts passwords into localized and non localized authentication and privacy keys.

Syntax

pwtokey [**-e**] [**-d** *DebugLevel*] [**-p** *Protocol*] [**-u** *KeyUsage*] [**-s**] *Password* [*EngineID* | *HostName* | *IPAddress*]

Description

AIX provides a facility called **pwtokey** that allows conversion of passwords into localized and nonlocalized authentication and privacy keys. The **pwtokey** procedure takes as input a password and an identifier of the agent and generates authentication and privacy keys. Since the procedure used by the pwtokey facility is the same algorithm used by the **clsnmp** command, the person configuring the SNMP agent can

generate appropriate authentication and privacy keys to put in the **snmpd.conf** file for a user, given a particular password and the IP address at which the agent will run.

If the IP address or the hostname is specified, the SNMP agent must be an AIX agent. The engineID will be created using a vendor-specific formula that incorporates the IP address of the agent and an enterprise ID representing AIX.

Flags

Item	Description
-d *DebugLevel*	This flag indicates what level of debug information is desired. Debug tracing is either on or off, so a value of 1 causes debug tracing to be generated to the screen of the command issuer (sysout), and a value of 0 specifies that no debug tracing be generated. Debug tracing is off (0) by default.
-e	This flag indicates that the agent for which the key is being defined is identified by engineID rather than by IP address or host name.
-p *Protocol*	This flag indicates the protocols for which the keys should be generated. Valid values are: **HMAC-MD5** Generates keys for use with the HMAC-MD5 authentication protocol. **HMAC-SHA** Generates keys for use with the HMAC-SHA authentication protocol **all** Generates both HMAC-MD5 and HMAC-SHA keys. The default is that keys for the HMAC-MD5 protocol are generated.
-s	This flag indicates that output data should be displayed with additional spaces to improve readability. By default, data is displayed in a condensed format to facilitate cut-and-paste operations on the keys into configuration files or command lines.
-u *KeyUsage*	This flag indicates the usage intended for the key. Valid values are: **auth** An authentication key. **priv** A privacy key. **all** Both authentication and privacy keys. **Note:** There is no difference between a key generated for authentication and a key generated for privacy. However, the length of privacy keys depends on whether the key is localized or not.

Parameters

Item	Description
EngineID	Specifies the engineID of the SNMP agent at which the key will be used. The engineID is determined at SNMP agent initialization from the snmpd.boots file. The engineID must be a string of 1-32 octets (2-64 hex digits). The default is that the agent identification is not an engineID.
HostName	Specifies the SNMP agent at which the key will be used on an SNMP request.
IPAddress	Specifies an IPv4 or an IPv6 address of the SNMP agent at which the key will be used on an SNMP request.
Password	Specifies the text string to be used in generating the keys. The password must be in the range of 8-255 characters long. In general, while any printable characters can be used in the passwords, the AIX shell may interpret some characters rather than passing them to the pwtokey command. Include passwords in single quotes to avoid interpretation of the characters by the AIX shell. **Note:** This password is not related to the community name (or "password") used with community-based security (SNMPv1 and SNMPv2c). This password is used only to generate keys for user-based security, an entirely different security scheme.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. This example shows a simple invocation of the **pwtokey** command:

   ```
   pwtokey testpassword 9.67.113.79
   ```

   The output from this command looks similar to the following:

   ```
   Display of 16 byte HMAC-MD5 authKey:
    775b109f79a6b71f94cca5d22451cc0e

   Display of 16 byte HMAC-MD5 localized authKey:
    de25243d5c2765f0ce273e4bcf941701
   ```

   As this example shows, **pwtokey** generates two keys—one that is localized (has been tailored to be usable only at the agent identified) and one that has not been localized. Typically, the localized key is used in the configuration for the SNMP agent. The nonlocalized key is used in the configuration for the clsnmp command.

2. The **pwtokey** can be invoked requesting HMAC-SHA keys for both authentication and privacy, as in the following example:

```
pwtokey -p HMAC-SHA -u all testpassword 9.67.113.79
```

The output of this command looks similar to the following:

```
Display of 20 byte HMAC-SHA authKey:
 b267809aee4b8ef450a7872d6e348713f04b9c50

Display of 20 byte HMAC-SHA localized authKey:
 e5438092d1098a43e27e507e50d32c0edaa39b7c

Display of 20 byte HMAC-SHA privKey:
 b267809aee4b8ef450a7872d6e348713f04b9c50

Display of 16 byte HMAC-SHA localized privKey:
 e5438092d1098a43e27e507e50d32c0e
```

The output for the privacy keys is the same as the output for the authentication keys, except that the localized privacy key has been truncated to 16 bytes, as is required for DES.

Note: If encryption is used, it is more secure to use different passwords for authentication and privacy.

3. The following example shows that the **pwtokey** command is using an IPv6 address:

```
pwtokey testpassword 2000:1:1:1:209:6bff:feae:6d67
```

The output from this command looks similar to the following:

```
Display of 16 byte HMAC-MD5 authKey:
 775b109f79a6b71f94cca5d22451cc0e

Display of 16 byte HMAC-MD5 localized authKey:
 2a30fe53690fa6b62dba3f9ea30e11fb
```

As this example shows, the **pwtokey** command generates two keys: one that is localized (has been tailored to be usable only at the agent identified) and one that has not been localized. Typically, the localized key is used in the configuration for the SNMP agent. The non-localized key is used in the configuration for the **clsnmp** command. SNMP agent at which the key will be used on an SNMP request is an IPv6 address.

pxed Command

Purpose

Implements a Preboot Execution Environment (PXE) Proxy Dynamic Host Configuration Protocol (DHCP) server.

Syntax

To start the **pxed** daemon using the system resource controller:

startsrc -s **pxed** [**-a**]

To start the **pxed** daemon without using the system resource controller:

pxed [**-f** *ConfigurationFile*]

Description

The Preboot Execution Environment defines a protocol and mechanism through which network-connected client systems can automatically download boot images from a network server to start their operating system. As an extension to the BOOTP and DHCP protocols, it provides the configuration ability for administrators that are not necessarily DHCP or network administrators to manage the operating systems installed on the PXE-capable client systems.

Like a DHCP server, the PXE Proxy DHCP server provides information needed by a PXE client to locate and download its appropriate boot files from a network server. However, the PXE Proxy DHCP server does not administer client IP addresses or other DHCP client options.

The PXE Proxy DHCP server is intended to be used when the management of the system boot images must be separated from the management of the DHCP addresses and DHCP client network configurations. The **pxed** daemon can be configured to run on a system that is the DHCP server or is not the DHCP server.

Flags

Item	Description
-a	The argument to be supplied.
-f *ConfigurationFile*	Specifies the path and name of the configuration file that is to be used by the server. If unspecified, the default is **/etc/pxed.cnf**.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Access Control: You must have root authority to run this command.

The PXE protocol allows for a nonprivileged user to be the administrator of the PXE client boot images because the **pxed** daemon listens to client messages on ports other than the well-known, protected DHCP server port. However, to configure such an environment, the DHCP server must be running on the same server system as the **pxed** daemon, and the file permissions on the **pxed** daemon must be changed for non-root execution.

Files

Item	Description
/usr/sbin/pxed	Contains the PXE Proxy DHCP server daemon.
/usr/sbin/db_file.dhcpo	Implements a database to be used by the PXE Proxy DHCP server and the DHCP server to store, retrieve, and manage configuration information.
/etc/pxed.cnf	The default configuration file for the **pxed** daemon.

q

The following AIX commands begin with the letter *q*.

qadm Command

Purpose

Performs system administration functions for the printer spooling system.

Syntax

qadm { **-G** } | { [**-D** *Printer*] [**-K** *Printer*] [**-U** *Printer*] [**-X** *Printer*] }

Description

The **qadm** command is a front-end command to the **enq** command. This command brings printers, queues, and the spooling system up or down and also cancels jobs. The **qadm** command translates the requested flags into a format that can be run by the **enq** command.

The **qadm** command works only on local print jobs. Remote print is not supported.

> **Note:** You must either have root user authority or belong to the printq group to run this command.

You could also use the System Management Interface Tool (SMIT) **smit qadm** fast path to run this command.

Flags

Item	Description
-D *Printer*	Brings down the printer you name in the *Printer* variable. The **qdaemon** process stops sending jobs to the device. Entering the **qchk -P** *Printer* command, where *Printer* matches the *Printer* variable in the **-D** flag, reports the device is *down*. The **qadm** command allows current jobs to finish before stopping the printer.
-G	Gracefully brings down the queuing system. This flag temporarily interrupts the **qdaemon** process after all currently running jobs on all queues are finished. Use of this flag is the only way to bring the system down without causing such problems as jobs hanging up in the queue.
-K *Printer*	Brings down the printer that you name in the *Printer* variable, ending all current jobs immediately. Jobs remain in the queue and run again when the printer is brought back
-U *Printer*	Brings up the printer that you name in the *Printer* variable. The **qdaemon** process sends jobs to the printer again. Entering the **qchk -P** *Printer* command, where *Printer* matches the *Printer* variable in the **-U** flag, reports the device is *ready*.
-X *Printer*	Cancels all the jobs of the user that executed the command. If you have root user privileges or are a member of the printq group, then all jobs on the queue system will be canceled.

> **Note:** When **-U** and **-D** flags are used together, the **-U** flag has higher priority.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To bring the queuing system down gracefully, enter:

   ```
   qadm  -G
   ```

2. To cancel all of a particular user's jobs on printer `lp0`, or all jobs on printer `lp0` if you are have root user authority, enter:

   ```
   qadm  -X lp0
   ```

3. To bring up the printer `lpd0` attached to queue `lp0`, enter:

   ```
   qadm  -U lp0:lpd0
   ```

Files

Item	Description
/usr/sbin/qdaemon	Contains the **qdaemon** daemon.
/var/spool/lpd/qdir/*	Contains the job description files.
/var/spool/lpd/stat/*	Contains information on the status of the devices.
/var/spool/qdaemon/*	Contains the temporary copies of enqueued files.
/etc/qconfig	Contains the configuration file.
/etc/qconfig.bin	Contains the digested, binary version of the **/etc/qconfig** file.

qcan Command

Purpose

Cancels a print job.

Syntax

qcan [**-X**] [**-x** *JobNumber*] [**-P** *Printer*]

Description

The **qcan** command cancels either a particular job number or all jobs in a print queue.

You could also use the System Management Interface Tool (SMIT) **smit qcan** fast path to run this command.

The **qstatus** was enhanced to improve the administration of local queues showing duplicate 3-digit job numbers. You can use the **-W** flag with the **enq**, **qchk**, **lpstat**, and **lpq** status commands to display more job number digits.

If your queue display shows duplicate 3-digit job numbers, use **qchk -W** to list job numbers with greater precision. You can then cancel a specific job.

For example, `qchk` might display job number 123 twice while, `qchk -W` would display job number 1123 and 2123. If you want to cancel job number 2123, specifying `qcan -x 123`, causes the **qdaemon**

to cancel the first matching job number it finds in its internal list, which may be 1123. By having the additional information that the **-W** flag provides, you can cancel a specific job number.

Flags

Item	Description
-P *Printer*	Specifies the *Printer* where either all jobs or the selected job number will be canceled.
-x *JobNumber*	Specifies that only the job number specified by the *JobNumber* variable be canceled.
-X	Cancels all jobs or all jobs for the specified printer. If you have root user authority, all jobs on that queue are deleted. If you do not have root user authority, only jobs you submitted will be canceled. This flag is only valid for local print jobs.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To cancel all jobs queued on printer `lp0`, enter:

   ```
   qcan  -X  -P lp0
   ```

2. To cancel job number 123 on whatever printer the job is on, enter:

   ```
   qcan  -x 123
   ```

Files

Item	Description
/usr/sbin/qdaemon	Contains the **qdaemon** daemon.
/var/spool/lpd/qdir/*	Contains the job description files.
/var/spool/lpd/stat/*	Contains information on the status of the devices.
/var/spool/qdaemon/*	Contains the temporary copies of enqueued files.
/etc/qconfig	Contains the configuration file.
/etc/qconfig.bin	Contains the digested, binary version of the **/etc/qconfig** file.

qchk Command

Purpose

Displays the status of a print queue.

Syntax

qchk [**-A**] [**-L**] [**-W**] [**-P** *Printer*] [**-#** *JobNumber*] [**-q**] [**-u** *UserName*] [**-w** *Delay*]

Description

The **qchk** command displays the current status information regarding specified print jobs, print queues, or users. Use the appropriate flag followed by the requested name or number to indicate specific status information. If you run the **qchk** command with no flags, the status of the default queue is returned.

You could also use the System Management Interface Tool (SMIT) **smit qchk** fast path to run this command.

Flags

Item	Description
-# *JobNumber*	Requests the status of the job number specified by the *JobNumber* variable. The **qchk** command looks for *JobNumber* on the default queue when the **-#***JobNumber* flag is used alone. To search for *JobNumber* on all queues **-#** flag must be used with the **-A** flag. The **-#** flag may also be used in conjunction with the **-P** *Queue* flag. **Notes:** 1. Specify the **-P** *Queue* to override the default destination printer. 2. If jobs 1, 2, and 3 are in the printer queue, and you specify that you want the status of job 3 while job 1 is running, the status information will show job 1 and job 3, not only job 3. 3. If you specify a job number that does not exist, the system displays the current job number on the queue instead of an error message.
-A	Requests the status of all queues.
-L	Displays information in a long-form mode. If the **-L** and **-W** flags are used simultaneously, the**-L** flag displays status of the print job in a semicolon-separated format.
-P *Printer*	Requests the status of the printer specified by the *Printer* variable.
-q	Requests the status of the default print queue.
-u *UserName*	Requests the status of all print jobs sent by the user specified by the *UserName* variable.
-W	Displays information in a wide-form mode with longer queue names, device names, and job numbers. Larger job number information is supported. If the **-W** and **-L** flags are used simultaneously, the **-W** flag displays the status of the print job in a semicolon-separated format.
-w *Delay*	Updates requested status information at intervals, in seconds, as specified by the *Delay* variable until all print jobs are finished.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To display the default print queue, enter:

   ```
   qchk -q
   ```

2. To display the long status of all queues until empty, while updating the screen every 5 seconds, enter:

```
qchk -A -L -w 5
```

3. To display the status for printer `lp0`, enter:

```
qchk -P lp0
```

4. To display the status for job number 123, enter:

```
qchk -# 123
```

5. To display the status of all print jobs while restricting the queue status to only printer lp0, enter:

```
qchk -A -P lp0
```

6. To display the wide status of the default print queue, enter:

```
qchk -W -q
```

Files

Item	Description
/usr/sbin/qdaemon	Contains the **qdaemon** daemon.
/var/spool/lpd/qdir/*	Contains the job description files.
/var/spool/lpd/stat/*	Contains information on the status of the devices.
/var/spool/qdaemon/*	Contains the temporary copies of enqueued files.
/etc/qconfig	Contains the configuration file.
/etc/qconfig.bin	Contains the digested, binary version of the **/etc/qconfig** file.

qdaemon Command

Purpose

Schedules jobs enqueued by the **enq** command.

Syntax

qdaemon

Description

The **qdaemon** command is a background process (usually started by the **startsrc** command) that schedules printing jobs enqueued by the **enq** command.

Recommendation: To edit the **/etc/qconfig** file, use the **chque**, **mkque**, **rmque**, **chquedev**, **mkquedev**, and **rmquedev** commands or SMIT. Further, it is recommended to run these commands during slow or off-peak time.

If manual editing of the **/etc/qconfig** file is necessary, you can first issue the **enq -G** command to bring the queuing system and the **qdaemon** to a halt after all jobs are processed. Then you can edit the **/etc/qconfig** file and restart the **qdaemon** with the new configuration.

Security

Privilege Control: Only the root user and members of the printq group should have execute (x) access to this command.

Auditing Event	Information
ENQUE_exec	Queue name, job name, host name, file name, user name

Files

Item	Description
/usr/sbin/qdaemon	Contains the **qdaemon** daemon.
/var/spool/lpd/qdir/*	Contains the job description files.
/var/spool/lpd/pio/@local/fullmsg	Contains a flag file whose existence activates **qdaemon** messages to contain complete information.
/var/spool/lpd/stat/*	Contains information on the status of the devices.
/var/spool/qdaemon/*	Contains the temporary copies of enqueued files.
/etc/qconfig	Contains the configuration file.
/etc/qconfig.bin	Contains the digested, binary version of the **/etc/qconfig** file.

qhld Command

Purpose

Holds and releases a spooled print job.

Syntax

qhld [**-r**] { **-#***JobNumber* [**-P***Queue*] | **-P***Queue* | **-u***User* [**-P***Queue*] }

Description

The **qhld** command holds print jobs in a spooled state. The job to be held is designated by job number, queue, or user name. The **-r** flag releases the hold on the print job.

The **qstatus** was enhanced to improve the administration of local queues showing duplicate 3-digit job numbers. You can use the **-W** flag with the **enq**, **qchk**, **lpstat**, and **lpq** status commands to display more job number digits.

If your queue display shows duplicate 3-digit job numbers, use **qchk -W** to list job numbers with greater precision. You can then hold a specific job.

For example, `qchk` might display job number 123 twice while, `qchk -W` would display job number 1123 and 2123. If you want to hold job number 2123, specifying `qhld -#` 123, causes the **qdaemon** to hold the first matching job number it finds in its internal list, which may be 1123. By having the additional information that the **qstatus -W** provides, you can hold a specific job number.

Flags

Item	Description
-#*JobNumber*	Specifies the print job number to be held.
-P*Queue*	Specifies the print queue to be held.
-r	Releases the print job by number, queue, or user name.
-u*User*	Specifies the name of user whose print jobs are to be held.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges,

see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To hold the print job number `300`, enter:

```
qhld -#300
```

2. To hold all print jobs on queue `lp0`, enter:

```
qhld -P lp0
```

3. To hold all jobs that belong to user `fred`, enter:

```
qhld -u fred
```

4. To release job number `300`, enter:

```
qhld -#300 -r
```

5. To release all the jobs on queue `lp0`, enter:

```
qhld -Plp0 -r
```

6. To release all jobs that belong to user `fred`, enter:

```
qhld -u fred -r
```

Files

Item	Description
/usr/sbin/qdaemon	Contains the **qdaemon** daemon.
/var/spool/lpd/qdir/*	Contains the job description files.
/var/spool/lpd/stat/*	Contains information on the status of the devices.
/var/spool/qdaemon/*	Contains the temporary copies of enqueued files.
/etc/qconfig	Contains the configuration file.
/etc/qconfig.bin	Contains the digested, binary version of the **/etc/qconfig** file.

qmov Command

Purpose

Moves spooled print jobs to another queue.

Syntax

qmov -m*NewQueue* { **-#***JobNumber* [**-P***Queue*] | **-P***Queue* | **-u***User* [**-P***Queue*] }

Description

The **qmov** command moves spooled print jobs to another print queue. The print job to be moved is identified by job number, queue, or user name. The format of the command requires the queue where the job is to be moved to as the first argument and the name of the job to move as the second argument.

The **qstatus** was enhanced to improve the administration of local queues showing duplicate 3-digit job numbers. You can use the **-W** flag with the **enq**, **qchk**, **lpstat**, and **lpq** status commands to display more job number digits.

If your queue display shows duplicate 3-digit job numbers, use **qchk -W** to list job numbers with greater precision. You can then move a specific job.

For example, `qchk` might display job number 123 twice while, `qchk -W` would display job number 1123 and 2123. If you want to move job number 2123, specifying `qmov -#` 123, causes the **qdaemon** to move the first matching job number it finds in its internal list, which may be 1123. By having the additional information that the **qstatus -W** provides, you can move a specific job number.

Flags

Item	Description
-#*JobNumber*	Specifies the job number of the print job to be moved.
-m*NewQueue*	Specifies the name of the destination print queue.
-P*Queue*	Specifies the present print queue of the job to be moved.
-u*User*	Specifies the name of the user whose print jobs are to be moved.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To move job number 280 to queue `lp0`, enter:

   ```
   qmov -mlp0 -#280
   ```

2. To move all print jobs on queue `lp1` to queue `lp0`, enter:

   ```
   qmov -mlp0 -Plp1
   ```

3. To move all of Mary's print jobs to queue `lp0`, enter:

   ```
   qmov -mlp0 -u mary
   ```

Files

Item	Description
/usr/sbin/qdaemon	Contains the **qdaemon** daemon.
/var/spool/lpd/qdir/*	Contains the job description files.
/var/spool/lpd/stat/*	Contains information on the status of the devices.
/var/spool/qdaemon/*	Contains the temporary copies of enqueued files.
/etc/qconfig	Contains the configuration file.
/etc/qconfig.bin	Contains the digested, binary version of the **/etc/qconfig** file.

qosadd Command

Purpose

Adds a QoS (Quality of Service) Service Category or Policy Rule.

Syntax

To add a Service Category:

qosadd [**-s** *ServiceCategory*] [**-t** *OutgoingTOS*] [**-b** *MaxTokenBucket*] [**-f** *FlowServiceType*] [**-m** *MaxRate*] **service**

To add a Policy Rule:

qosadd [**-s** *ServiceCategory*] [**-r** *ServicePolicyRules*] [**-l** *PolicyRulePriority*] [**-n** *ProtocolNumber*] [**-A** *SrcAddrRange*] [**-a** *DestAddrRange*] [**-P** *SrcPortRange*] [**-p** *DestPortRange*] **policy**

Description

The **qosadd** command adds the specified Service Category or Policy Rule entry in the **policyd.conf** file and installs the changes in the QoS Manager.

Flags

Flags with service add:

Item	Description
-s	The name of the **ServiceCategory** attribute, which is mandatory.
-t	The **OutgoingTOS** attribute, specified as an 8 bit binary number.
-b	The **MaxTokenBucket** attribute, specified in Kb (Kilobits).
-f	The **FlowServiceType** attribute, which is ControlledLoad or Guaranteed.
-m	The **MaxRate** attribute, which is specified in Kbps (Kilobits per second).

Flags with policy add:

Item	Description
-s	The name of the **ServiceCategory** attribute, which is mandatory.
-r	The name of the **ServicePolicyRules** attribute, which is mandatory.
-l	The **PolicyRulePriority** attribute, which is a positive integer.
-n	The **ProtocolNumber** attribute, which is defined in the **/etc/protocols** file.
-A	The **SrcAddrRange** attribute, which is the Source IP address range from a1 to a2 where a2 >= a1.
-a	The **DestAddrRange** attribute, which is the Destination IP address range from i1 to i2 where i2 >= i1.
-P	The **SrcPortRange** attribute, which is the Source Port range from a1 to a2 where a2 >= a1.
-p	The **DestPortRange** attribute, which is the Destination Port range from i1 to i2 where i2 >= i1.

Exit Status

Item	Description
0	Successful completion
Positive Integer	An error occurred.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To add the sc01 service, type:

```
qosadd -s sc01 -t 10000001 -b 81 -f ControlledLoad -m 41 service
```

2. To add the pr01 policy, type:

```
qosadd -s sc01 -r pr01 -l 2 -n 17 -A 9.3.25.1-9.3.25.10 -a  9.3.25.33-9.3.25.33
-p 9001-9010 -P 9000-9000 policy
```

3. To add the sc02 service, type:

```
qosadd -s sc02 -t 10000001 -b 81 service
```

4. To add the pr02 policy, type:

```
qosadd -s sc02 -r pr02 -l 2 -n 17 policy
```

qoslist Command

Purpose

Lists a specific QoS (Quality of Service) Service Category or Policy Rule or lists all of them.

Syntax

To list a Service Category:

qoslist [*ServiceCategory*] **service**

To list a Policy Rule:

qoslist [*ServicePolicyRule*] **policy**

Description

The **qoslist** command lists the specified Service Category or Policy Rule. The **qoslist** command lists all Service Categories or Policy Rules if no specific name is given.

Exit Status

Item	Description
0	Successful completion

Item	Description
Positive Integer	An error occurred.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To list the sc01 service, type:

```
qoslist sc01 service
```

2. To list the the pr01 policy, type:

```
qoslist pr01 policy
```

3. To list all of the QoS ServiceCategories, type:

```
qoslist service
```

4. To list all of the QoS PolicyRules, type:

```
qoslist policy
```

qosmod Command

Purpose

Modifies an existing QoS (Quality of Service) Service Category or Policy Rule.

Syntax

To modify an existing Service Category:

qosmod [**-s** *ServiceCategory*] [**-t** *OutgoingTOS*] [**-b** *MaxTokenBucket*] [**-f** *FlowServiceType*] [**-m** *MaxRate*] **service**

To modify an existing Policy Rule:

qosmod [**-s** *ServiceCategory*] [**-r** *ServicePolicyRules*] [**-l** *PolicyRulePriority*] [**-n** *ProtocolNumber*] [**-A** *SrcAddrRange*] [**-a** *DestAddrRange*] [**-P** *SrcPortRange*] [**-p** *DestPortRange*] **policy**

Description

The **qosmod** command modifies the specified Service Category or Policy Rule entry in the **policyd.conf** file and installs the changes in the QoS Manager.

The **qosmod** command clears out all the statistics of the old policy. When a **qosstat** command is executed immediately after **qosmod**, the user may not see all the data connections that were using the older rule shifted to the modified rule. This is because the reclassification of the data connection is delayed until a data packet arrives on that connection.

Note: Modifying the priority or filter spec of the rule only results in reclassification of the data connections which use that particular rule. Connections using other rules maintain their existing classification.

Flags

Flags with service modify:

Item	Description
-s	The name of the **ServiceCategory** attribute, which is mandatory.
-t	The **OutgoingTOS** attribute, specified as an 8-bit binary number.
-b	The **MaxTokenBucket** attribute, specified in Kb (Kilobits).
-f	The **FlowServiceType** attribute, which is ControlledLoad or Guaranteed.
-m	The **MaxRate** attribute, which is specified in Kbps (Kilobits per second).

Flags with policy modify:

Item	Description
-s	The name of the **ServiceCategory** attribute, which is mandatory.
-r	The name of the **ServicePolicyRules** attribute, which is mandatory.
-l	The **PolicyRulePriority** attribute, which is a positive integer.
-n	The **ProtocolNumber** attribute, which is defined in the **/etc/protocols** file.
-A	The **SrcAddrRange** attribute, which is the Source IP address range from a1 to a2, where a2 >= a1.
-a	The **DestAddrRange** attribute, which is the Destination IP address range from i1 to i2, where i2 >= i1.
-P	The **SrcPortRange** attribute, which is the Source Port range from a1 to a2, where a2 >= a1.
-p	The **DestPortRange** attribute, which is the Destination Port range from i1 to i2, where i2 >= i1.

Exit Status

Item	Description
0	Successful completion
Positive Integer	An error occurred.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To modify the sc01 service, type:

```
qosmod -s sc01 -t 10001100 -b 84 -f Guaranteed  service
```

2. To modify the pr01 policy, type:

```
qos -s sc01 -r pr01 -l 10 -n 6 -A 9.3.25.15-9.3.25.20 -a 9.3.25.39-9.3.25.39 -p 9015-9020
policy
```

3. To modify the sc02 service, type:

```
qosmod -s sc02 -t 10001111 service
```

4. To modify the pr02 policy, type:

```
qosmod -s sc02 -r pr02 -l 13 -n 6 policy
```

qosremove Command

Purpose

Removes a QoS (Quality of Service) Service Category or Policy Rule.

Syntax

To remove a Service Category:

qosremove [*ServiceCategory*] **service**

To remove a Policy Rule:

qosremove [*ServicePolicyRule*] **policy**

To remove all the Policies and Service categories installed in the kernel:

qosremove all

Description

The **qosremove** command removes the specified Service Category or Policy Rule entry in the **policyd.conf** file and the associated policy or service in the QoS Manager.

Exit Status

Item	Description
0	Successful completion
Positive Integer	An error occurred.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To remove the sc01 service, type:

```
qosremove sc01 service
```

2. To remove the pr01 policy, type:

```
qosremove pr01 policy
```

qosstat Command

Purpose

Show Quality of Service (QoS) status.

Syntax

qosstat [**-A**] [**-F**] [**-S**]

Description

The **qosstat** command displays information about the installed Qos policies. Using **qosstat** without any flags returns filter/flow specification and statistical information for each installed policy.

Flags

Item	Description
-A	Returns the policy rule handle for each installed policy. A unique handle is assigned by the qoS manager for each policy installed.
-F	Returns the flow and filter specification for each policy installed.
-S	Returns the statistical information for each policy installed.

Examples

1. **qosstat**

```
Policy Rule handle 1:

Filter specification for rule index 1:
        PolicyRulePriority:                     0
        protocol:                   TCP
        source IP addr:             INADDR_ANY
        destination IP addr:        INADDR_ANY
        source port:                80
        destination port:           ANY_PORT
Flow Class for rule index 1:
        service class:     Diff-Serv
        peak rate:         100000000 bytes/sec
        average rate:      128 bytes/sec
        bucket depth:      4096 bytes
        TOS (in profile):  0
        TOS (out profile): 0
Statistics for rule index 1:
        total number of connections:          0
        total bytes transmitted:              0
        total packets transmitted:            0
        total in-profile bytes transmitted:   0
        total in-profile packets transmitted: 0
Policy Rule Handle 2:

Filter specification for rule index 2:
        PolicyRulePriority:                      0
        protocol:                   TCP
        source IP addr:             INADDR_ANY
        destination IP addr:        INADDR_ANY
        source port:                100
        destination port:           ANY_PORT
Flow Class for rule index 2:
        service class:     Diff-Serv
        peak rate:         100000000 bytes/sec
        average rate:      128 bytes/sec
        bucket depth:      4096 bytes
        TOS (in profile):  0
        TOS (out profile): 0
Statistics for rule index 2:
        total number of connections:          0
```

```
        total bytes transmitted:              0
        total packets transmitted:            0
        total in-profile bytes transmitted:   0
        total in-profile packets transmitted: 0
```

2. **qosstat -A**

```
Policy Rule Handle 1:
        rule index:    1

Policy Rule Handle 2:
        rule index:    2
```

3. **qosstat -F**

```
Policy Rule Handle 1:
Filter specification for rule index 1:
        PolicyRulePriority:                    0
        protocol:                   TCP
        source IP addr:             INADDR_ANY
        destination IP addr:        INADDR_ANY
        source port:                80
        destination port:           ANY_PORT
Flow Class for rule index 1:
        service class:     Diff-Serv
        peak rate:         100000000 bytes/sec
        average rate:      128 bytes/sec
        bucket depth:      4096 bytes
        TOS (in profile):  0
        TOS (out profile): 0

Policy Rule Handle 2:
Filter specification for rule index 2:
        PolicyRulePriority:                    0
        protocol:                   TCP
        source IP addr:             INADDR_ANY
        destination IP addr:        INADDR_ANY
        source port:                100
        destination port:           ANY_PORT
Flow Class for rule index 2:
        service class:     Diff-Serv
        peak rate:         100000000 bytes/sec
        average rate:      128 bytes/sec
        bucket depth:      4096 bytes
        TOS (in profile):  0
        TOS (out profile): 0
```

4. **qosstat -S**

```
Statistics for rule index 1:
        total number of connections:          0
        total bytes transmitted:              0
        total packets transmitted:            0
        total in-profile bytes transmitted:   0
        total in-profile packets transmitted: 0

Policy Rule Handle 2:
Statistics for rule index 2:
        total number of connections:          0
        total bytes transmitted:              0
        total packets transmitted:            0
        total in-profile bytes transmitted:   0
        total in-profile packets transmitted: 0
```

qpri Command

Purpose

Prioritizes a job in the print queue.

Syntax

qpri -# *JobNumber* **-a** *PriorityNumber*

Description

The **qpri** command prioritizes a job in a print queue by specifying the job number and giving it a priority number.

The **qpri** command works only on local print jobs and the local side of remote queues. Remote print jobs are not supported. Also, you must have root user authority or belong to the printq group to run this command.

You could also use the System Management Interface Tool (SMIT) **smit qpri** fast path to run this command.

The **qstatus** was enhanced to improve the administration of local queues showing duplicate 3-digit job numbers. You can use the **-W** flag with the **enq**, **qchk**, **lpstat**, and **lpq** status commands to display more job number digits.

If your queue display shows duplicate 3-digit job numbers, use **qchk -W** to list job numbers with greater precision. You can then alter the priority of a specific job.

For example, `qchk` might display job number 123 twice while, `qchk -W` would display job number 1123 and 2123. If you want to alter the priority of job number 2123, specifying `qpri -#` 123, causes the **qdaemon** to alter the priority of the first matching job number it finds in its internal list, which may be 1123. By having the additional information that the **qstatus -W** provides, you can alter the priority of a specific job number.

Flags

Item	Description
-# *JobNumber*	Specifies the job number on which to change priority.
-a *PriorityNumber*	Specifies the new priority number for the print job specified by the *JobNumber* variable. The range of priority numbers is 1 through 20, except for the root user or a member of the printq group, who can select priority numbers from 1 through 30.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Example

To change job number 123 to priority number 18, enter:

```
qpri  -# 123  -a 18
```

Files

Item	Description
/usr/sbin/qdaemon	Contains the **qdaemon** daemon.
/var/spool/lpd/qdir	Contains the job description files.
/var/spool/lpd/stat	Contains information on the status of the devices.
/var/spool/qdaemon	Contains the temporary copies of enqueued files.
/etc/qconfig	Contains the configuration file.
/etc/qconfig.bin	Contains the digested, binary version of the **/etc/qconfig** file.

qprt Command

Purpose

Starts a print job.

Syntax

qprt [**-a** *PreviewOption*] [**-A** *Level*] [**-b** *BottomMargin*] [**-B** *Value*] [**-c**] [**-C**] [**-d** *InputDataType*] [**-D** "*User*"] [**-e** *EmphasizedOpt*] [**-E** *DblHigh*] [**-f** *Filter*] [**-F** *Name*] [**-g** *Begin*] [**-G** *Coord*] [**-h "***Header***"**] [**-H "***HostName***"**] [**-i** *Indent*] [**-I** *FontPath*] [**-j** *Init*] [**-J** *Restore*] [**-k** *Color*] [**-K** *Condense*] [**-l** *Length*] [**-L** *LineWrap*] [**-m** *Message*] [**-M** *MessageFile*] [**-n**] [**-N** *NumberCopies*] [**-O** *PaperHand*] [**-p** *Pitch*] [**-P** *Queue* [**:***QueueDevice*]] [**-Q** *Value*] [**-q** *Quality*] [**-r**] [**-R** *Priority*] [**-s** *NameType*] [**-S** *Speed*] [**-t** *TopMargin*] [**-T "***Title***"**] [**-u** *PaperSrc*] [**-U** *Directional*] [**-v** *LinesPerIn*] [**-V** *Vertical*] [**-w** *PageWidth*] [**-W** *DblWide*] [**-x** *LineFeed*] [**-X** *CodePage*] [**-y** *DblStrike*] [**-Y** *Duplex*] [**-z** *Rotate*] [**-Z** *FormFeed*] [**-#** { **j** | **h** | **v** }] [**-=** *OutputBin*]{ *File* | **-** } ...

Description

The **qprt** command creates and queues a print job to print the file specified by the *File* parameter. To print a file from standard input, specify a **-** (dash) instead of a file name. If you specify multiple files, then they all together make up one print job. The **qprt** command prints the files in the order you specify them.

To print a file, you must have read access to it. Using the **-r** flag you can remove a file after printing it. To remove a file, you must have write access to the directory that contains it. If you want the **qprt** command to notify you when a print job completes, specify the **-n** flag.

You can use the **-B** flag in conjunction with the **-D**, **-H**, and **-T** flags to customize burst pages. Burst pages mark the beginning, end, or both of a print job. To mark the beginning and end of a print job with burst pages, use the **-B aa** flag.

All flags are optional and you can specify them in any order. The **qprt** command ignores spaces between a flag and its argument. You can group flags without arguments after a single **-** (dash). All flags and their arguments must precede the *File* parameter.

You could also use the System Management Interface Tool (SMIT) **smit qprt** fast path to run this command.

Some of the flags and arguments listed in this command are invalid for particular printer types. If you experience problems using an option, you can use SMIT to preview a **qprt** command statement. See the System management interface tool (SMIT) in *General Programming Concepts: Writing and Debugging Programs*. Alternatively, consult your printer manual to find out what options your printer supports.

Flags

Item	Description
-#{j|h|v}	Specifies a special functionality. The possible values for the *Value* variable are: **j** Displays a job number for the specified print job. **h** Queues the print job but holds it in a HELD state. **v** Validates the specified printer backend flag values. As part of the validation process, the command performs legality checking for illegal flag values, type checking, range checking, list checking, and other types of validation. Typically, the validation of backend flag values is useful because illegal flags are identified when the print job is submitted rather than at a later stage when the print job is processed.
-= *OutputBin*	Specifies the output bin destination for a print job. If you do not specify this flag, it uses the default value from the printer driver. The possible values for *OutputBin* are: **0** Top printer bin. **1 - 49** High Capacity Output (HCO) bins 1 - 49. **>49** Printer specific output bins. **Note:** Valid output bins are printer dependent.
-a *PreviewOption*	Previews parameter values for a print job without actually printing any files. You can specify a **0** or a **1** for the *PreviewOption* variable. If you specify **0**, the **qprt** command preview displays normal print processing. If you specify a **1**, the command returns a list of the flag values and the filter pipeline that would be used to convert the input data type to the data type expected by the printer. These flag values are the default command line flag values from the configuration database, overridden by any flag parameters specified on the command line. Only flags that are valid for the *InputDataType* variable specified (or defaulted) for the **-d** flag are shown. Flag values related only to the spooling of your print job, instead of the actual printing, are not shown. The default values for the spooling flags are included with the flag descriptions. The flag values are not checked to verify that they are supported by the printer. The pipeline of filters shows the filter commands (and the flag values passed to the filter commands) that would process the data from your print files before it is sent to the printer. You can review the description for each of the filter commands to determine the type of filtering that is performed.

Item	Description
-A *Level*	Sets the level of diagnostic output. Diagnostic output is useful for diagnosing errors encountered by a filter pipeline that is processing a print file, a header page, or a trailer page. Diagnostic output is mailed to the user who submitted the print job. You can specify one of the following levels: **0** Discards any standard error output produced. **1** Returns flag values, the standard error output, and the complete pipeline that produced any standard error output. **2** Returns the flag values, standard error output (if any), and complete pipelines, regardless of whether an error is detected. If an error is detected, the print job is terminated. **3** Similar to a value of **2**, except that the file is not printed. A value of **1** is recommended. A value of **0** is useful if a filter in a pipeline produces output to standard error, even if no error is encountered (for example, status information). A value of **2** or **3** is useful for diagnosing a problem, even if the problem does not cause any output to standard error.
-b *BottomMargin*	Specifies the bottom margin, the number of blank lines to be left at the bottom of each page.
-B *Value*	Prints burst pages. The *Value* variable consists of a two-character string. The first character applies to header pages. The second character applies to trailer pages. The following values are valid: **a** Always print the (header or trailer) page for each file in each print job. **n** Never print the (header or trailer) page. **g** Print the (header or trailer) page once for each print job (group of files). For example, the **-B ga** flag prints a header page at the beginning of each print job and a trailer page after each file in each print job. **Note:** In a remote print environment, the default is determined by the remote queue on the server.
-c	Copies each print file and prints from the copy. Specify this flag if you plan to modify the print file or files after the **qprt** command is issued, but before the print job completes. If this flag is not specified and the print job is printed on the same node where it was submitted, copies of the print file or files are not made. Printing occurs directly from the file or files you specified with the *File* parameter.

Item	Description
-C	Mails messages generated by your print job to you, even if you are logged in. By default, the **qprt** command displays messages on the console. The **-C** flag only applies to local print jobs. If you want to be notified when a job sent to a remote printer is completed, use the **-n** flag to receive a mail message. **Note:** You cannot redirect certain messages from the **qdaemon** and the printer backend in any way. They are sent directly to the **/dev/console** file.
-d *InputDataType*	Identifies the input data type of the file or files to print. Based on the input data type and the data type expected by the printer, the print files are passed through filters (if necessary) before being sent to the printer. You can specify any of the following input data types: **a** Extended ASCII **c** PCL **d** Diablo 630 **g** Hewlett-Packard GL **p** Pass-through (sent to printer unmodified) **s** PostScript If the printer you select does not support the specified input data type, and if filters are not available to convert the data type of your print file or files to a data type supported by the printer, the print job terminates with an error message.
-D *"User"*	Labels the output for delivery to *User*. Normally the output is labeled for delivery to the user name of the person issuing the **qprt** command request. The value of *User* must be a single word meeting the same requirements of a regular user ID.
-e *EmphasizedOpt*	Sets emphasized print to one of the following: **+** Use emphasized print. **!** Do not use emphasized print.
-E *DblHigh*	Sets double-high print to one of the following: **+** Use double-high print. **!** Do not use double-high print.

Item	Description
-f *Filter*	Identifies the filter to pass your print files through before sending them to the printer. The identifiers are similar to the filter flags available with the **lpr** command. The available filter identifiers are **p**, which invokes the **pr** filter, **n**, which processes output from the **troff** command, and **l**, which allows control characters to be printed.
-F *Name*	Specifies the list of X font files containing the image of characters to be used for printing. Items in the list must be separated by commas. The *Name* parameter value can be full path names, font alias names, or XLFD names. The **-F** Name flag is effective only for MBCS printer queues.
-g *Begin*	Sets the page number to begin printing. This flag is recognized only if the print files are to be formatted (for example, with the **-d a** flag). It is not recognized for pass-through (the **-d p** flag), PostScript (the **-d s** flag), and other types of data that are already formatted.
-G *Coord*	Indicates how to print pages on laser printers that cannot print to the edge of the paper. Use one of the following for the *Coordinate* variable: **+** Whole page coordinate system **!** Print page coordinate system
-h "*Header***"**	Specifies the header text for use by the **pr** command when the **-f p** flag is also specified. If this flag is not specified, the **pr** command uses the print file name as the header. This flag is useful if you also specified the **-c** flag. With the **-c** flag, the print file name used by the **pr** command as the default header is the name of a temporary file generated by the spooler, instead of the file name you specified with the **qprt** command.
-H "*HostName***"**	Sets the host name on the header page.
-i *Indent*	Indents each line the specified number of spaces. You must include the *Indent* variable in the page width specified by the **-w** flag.
-I *FontID*	(uppercase i) Specifies a font identifier. Specifying a font identifier overrides the pitch (the **-p** flag) and type style (the **-s** flag). The **-I***FontID* command is effective for single byte code set print queues only.
-I*FontPath*	(uppercase i) Specifies the comma-separated list of font paths required for the **-F** flag when the font files are designated with a font alias name or an XLFD name. The *FontPath* flag is effective only for MBCS printer queues.
-j *Init*	Initializes the printer before each file is printed. You can specify any of the following: **0** No initialization **1** Full initialization **2** Emulator selection only

Item	Description
-J *Restore*	Restores the printer at the end of the print job. You can specify one of the following: **+** Restore at the end of the print job. **!** Do not restore at the end of the print job.
-k *Color*	Specifies the print color. Typical values are black, red, blue, green, and so on. Consult your printer manual for colors supported and the ribbon position assigned to a particular color.
-K *Condense*	Sets condensed print to one of the following: **+** Use condensed print. **!** Do not use condensed print.
-l *Length*	(lowercase L) Sets the page length. If the *Length* variable is 0, page length is ignored, and the output treated as one continuous page. The page length includes the top and bottom margins and indicates the printable length of the paper.
-L *LineWrap*	Sets line wrap for lines wider than the page width to one of the following: **+** Wrap long lines to the next line. **!** Truncate long lines at the right margin.

Item	Description
-m "*Message***"**	Displays the specified message on the console when the print job is assigned a printer and is ready to begin printing. The print job does not proceed until the message is acknowledged at the console.
-M *MessageFile*	Identifies a file containing message text. This text is displayed on the console when the print job is assigned a printer and is ready to begin printing. The print job does not proceed until the message is acknowledged at the console.
-n	Notifies you when the print job completes. If the **-D "***User***"** flag is also specified, the specified user is notified as well. By default, you are not notified when the print job completes.
-N *NumberCopies*	Specifies the number of copies to print. If this flag is not specified, one copy is printed.
-O *PaperHand*	Sets the type of input paper handling to one of the following: **1** Manual (insert one sheet at a time) **2** Continuous forms **3** Sheet feed

Item	Description
-p *Pitch*	Sets the number of characters per inch. Typical values for *Pitch* are 10 and 12. The actual pitch of the characters printed is also affected by the values for the **-K** (condensed) flag and the **-W** (double-wide) flag. If you are printing an ASCII file on a PostScript printer, this flag determines the character point size. You can specify positive numbers greater than or equal to 1.
-P *Queue*[:*QueueDevice*]	Specifies the print queue name and the optional queue device name. If this flag is not specified, the following conditions occur: • If the **LPDEST** environment variable is set, the **qprt** command uses the queue name specified by the **LPDEST** variable. If set, this value is always used, even if the **PRINTER** variable is also set. • If the **PRINTER** variable is set and no **LPDEST** variable is set, the **qprt** command uses the queue name specified by the **PRINTER** environment variable. Any destination command-line options override both the **LPDEST** and **PRINTER** environment variables. • If neither the **LPDEST** nor the **PRINTER** variable is set, the **qprt** command uses the system default queue name. (The system default queue name is the name of the first queue defined in the **/etc/qconfig** file.) If the *QueueDevice* variable is not specified, the first available printer configured for the queue is used. **Note:** If multiple printers are configured for the same print queue and one or more of the printers is not suitable for printing your files, you should use the *QueueDevice* variable. Otherwise, the spooler assigns the first available printer.
-q *Quality*	Sets the print quality to one of the following: **0** Fast font **1** Draft quality **2** Near letter quality **3** Enhanced quality **300** 300 dots per inch (dpi) **600** 600 dpi
-Q *Value*	Sets the paper size. The *Value* for paper size is printer-dependent. Typical values are: **1** for letter-size paper, **2** for legal, and so on. Consult your printer manual for the values assigned to specific paper sizes.
-r	Removes the print files after the print job completes. If this flag is not specified, the print files are not removed.

Item	Description
-R *Priority*	Sets the priority for the print job. Higher values for the *Priority* variable indicate a higher priority for the print job. The default priority value is **15**. The maximum priority value is **20** for most users and **30** for users with root user privilege and members of the system group (group 0). **Note:** You cannot use this flag when requesting remote print jobs.
-s *NameType*	Specifies a type style with the *NameType* variable. Examples are courier and prestige. The particular type style choices differ depending on the printer type.
-S *Speed*	Sets high-speed printing to one of the following: **+** Use high-speed printing. **!** Do not use high-speed printing.
-t *TopMargin*	Sets the top margin, the number of blank lines left at the top of each page.
-T "*Title***"**	Specifies a print job title with the *Text* variable. If this flag is not specified, the first file name on the **qprt** command line is used as the print job title. The print job title is displayed on the header page and on responses to inquiries about queue status.
-u *PaperSrc*	Sets the paper source to one of the following: **1** Primary **2** Alternate **3** Envelopes
-U *Directional*	Sets unidirectional printing to one of the following: **+** Use unidirectional printing. **!** Do not use unidirectional printing.
-v *LinesPerIn*	Sets the line density to a number of lines per inch. Typical values for the *LinesPerIn* variable are **6** and **8**.
-V *Vertical*	Sets vertical printing to one of the following: **+** Use vertical printing. **!** Do not use vertical printing.
-w *PageWidth*	Sets the page width in number of characters. The page width must include the number of indention spaces specified with the **-i** flag.

Item	Description
-W *DblWide*	Sets double-wide print to one of the following: **+** Use double-wide print. **!** Do not use double-wide print.
-x *LineFeed*	Specifies automatic line feed or automatic carriage return: **0** Do not change line feeds, vertical tabs, and carriage returns. **1** Add a line feed for each carriage return. **2** Add a carriage return for each line feed and each vertical tab.
-X *CodePage*	Provides the code page name. Valid values for the *CodePage* variable are ISO8859-1 through ISO8859-9, IBM-943, IBM-eucJP, IBM-eucKR, IBM-eucTW, and UTF-8. The code page in the user's locale definition is the default.
-y *DblStrike*	Sets double-strike print to one of the following: **+** Use double-strike print. **!** Do not use double-strike print.
-Y *Duplex*	Sets duplexed output. Duplexed output uses both the front and back of each sheet of paper for printing. You can set one of the following: **0** Simplex **1** Duplex, long edge binding **2** Duplex, short edge binding
-z *Rotate*	Rotates page printer output the number of quarter-turns clockwise as specified by the *Value* variable. The length (**-l**) and width (**-w**) values are automatically adjusted accordingly. **0** Portrait **1** Landscape right **2** Portrait upside-down **3** Landscape left

Item	Description
-Z *FormFeed*	Sends a form feed to the printer after each print file. You can specify either of the following: **+** Send a form feed command. **!** Do not send a form feed command to the printer. Use this option carefully since it can result in the next print job beginning on the last output page generated by this print job. Printers printing on continuous forms cannot determine the top of the form for subsequent pages.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To queue the `myfile` file to print on the first available printer configured for the default print queue using the default values, enter:

   ```
   qprt myfile
   ```

2. To queue a file on a specific queue, to print the file without using nondefault flag values, and to validate the flag values at the time of the print job submission, enter:

   ```
   qprt  -f p  -e +  -P fastest  -r  -n  -C  -#v somefile
   ```

   This command line passes the `somefile` file through the **pr** command (the **-f p** flag) and prints it using emphasized mode (the **-e +** flag) on the first available printer configured for the queue named **fastest** (the **-P fastest** flag). The **-#v** flag verifies that all flags associated with this command are valid before passing the print job to the printer backend. After the file is printed, it is removed (the **-r** flag), and the user who submitted the print job is notified (the **-n** flag) by mail (the **-C** flag) that the print job completed.

3. To print `myfile` on legal size paper, enter:

   ```
   qprt  -Q2 myfile
   ```

4. To enqueue the `myfile` file and return the job number, enter:

   ```
   qprt -#j myfile
   ```

5. To queue `MyFile` and hold it, enter:

   ```
   qprt -#h MyFile
   ```

Files

Item	Description
/etc/qconfig	Contains the queue and queue device configuration file.
/usr/bin/qprt	Contains the **qprt** command.

qstatus Command

Purpose

Provides printer status for the print spooling system.

Syntax

qstatus [**-#** *JobNumber*] [**-A**] [**-L**] [**-W**] [**-P** *Printer*] [**-e**] [**-q**] [**-u** *UserName*] [**-w** *DelaySeconds*]

Description

The **qstatus** command performs the actual status function for the print-spooling system. This command is never entered on the command line; it is called by the **enq** command. The **qstatus** command generates status information on specified jobs, printers, queues, or users.

The display generated by the **qstatus** command contains two entries for remote queues. The first entry contains the client's local queue and local device name and its status information. The second entry follows immediately; it contains the client's local queue name (again), followed by the remote queue name. Any jobs submitted to a remote queue are displayed first on the local side and are moved to the remote device as the job is processed on the remote machine.

Since the status commands communicate with remote machines, the status display may occasionally appear to hang while waiting for a response from the remote machine. The command will eventually time-out if a connection cannot be established between the two machines.

Flags

All flags are optional. If flags are not specified, the **qstatus** command returns the status of the following:

- The printer specified by the **LPDEST** variable, if the **LPDEST** environment variable is set. If set, this value is always used, even if the **PRINTER** variable is also set.
- The printer specified by the **PRINTER** environment variable, if the **PRINTER** variable is set and no **LPDEST** variable is set.
- The default printer, if neither the **LPDEST** nor the **PRINTER** variable is set.

  Note: Any destination command line options override both the **LPDEST** and the **PRINTER** environment variables.

Item	Description
-# *JobNumber*	Displays current status information for the job specified by the *JobNumber* variable. Normally, the status of all queued jobs is displayed. 1. Specify the **-P** *Queue* to override the default destination printer. 2. If jobs 1, 2, and 3 are in the printer queue, and you specify that you want the status of job 3 while job 1 is running, the status information will show job 1 and job 3, not only job 3. 3. If you specify a job number that does not exist, the system displays the current job number on the queue instead of an error message.
-A	Displays status information on all queues defined in the **/etc/qconfig** file.
-e	Excludes status information from queues that are not under the control of the **qdaemon** command. The status from such queues may appear in different formats. The **-e** flag can be used with any combination of flags.
-L	Displays status information in a long and detailed version. If the **-L** flag and the **-W** flag are used simultaneously, the **-L** flag displays the long status of the print job in a semicolon-separated format.

Item	Description
-P *Printer*	Displays current status information for the printer specified by the *Printer* variable. Normally, the default printer is used, or the value of either the **LPDEST** or **PRINTER** environment variable is used. The **LPDEST** variable always takes precedence over the **PRINTER** variable.
-q	Displays the current status of the default queue. The default queue is specified by the **LPDEST** variable, or if a **LPDEST** value does not exist, by the **PRINTER** environment variable. If neither variable exists, the **qstatus** command uses the first queue listed in the **/etc/qconfig** file.
-u *UserName*	Displays current status information for all jobs submitted by the user specified by the *UserName* variable. Normally, the status of all queued jobs is displayed.
-W	Displays a wide version of the status information with longer queue names, device names, and job numbers. Longer job number information is supported. If the **-L** flag and the **-W** flag are used simultaneously, the **-W** flag displays the long status of the print job in a semicolon-separated format.
-w *DelaySeconds*	Displays requested queue information at intervals specified by the *DelaySeconds* variable. When the queue is empty, the display ends.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To display the default print queue, enter:

   ```
   qstatus -q
   ```

2. To display the long status of all queues until empty, while updating the screen every 5 seconds, enter:

   ```
   qstatus -A -L -w 5
   ```

3. To display the status for printer `lp0`, enter:

   ```
   qstatus -P lp0
   ```

4. To display the status for job number 123, enter:

   ```
   qstatus -# 123 -P lp0
   ```

5. To display the status of all queues in wide format, enter:

   ```
   qstatus -A -W
   ```

Files

Item	Description
/var/spool/lpd/qdir/*	Contains the job description files.
/etc/qconfig	Contains the configuration file.
/etc/qconfig.bin	Contains the digested, binary version of the **/etc/qconfig** file.
/usr/lib/lpd/rembak	Contains the remote back end.
/usr/lib/lpd/qstatus	Contains the command file.

Item	Description
/var/spool/lpd/stat/*	Contains the status files for the **qstatus** command.

quiz Command

Purpose

Tests your knowledge.

Syntax

quiz { **-i** *File* | **-t** | *Category1 Category2* }

Description

The **quiz** command gives associative knowledge tests on various selectable subjects. It asks about items chosen from *Category1* and expects answers from *Category2*. If you do not specify the categories, the **quiz** command lists the available categories, provides instructions, and returns to the shell prompt.

The game provides the correct answer whenever you press the Enter key. When questions run out or when you press the Interrupt (Ctrl-C) or End Of File (Ctrl-D) key sequences, the game reports a score and ends.

Flags

Item	Description
-i *File*	Substitutes the named *File* for the standard index file. **Note:** In the following syntax description, brackets are normally used to indicate that an item is optional. However, a bold-faced bracket or brace should be entered as a literal part of the syntax. A vertical list of items indicates that one must be chosen. The lines in *File* must have the following syntax: **line = category [:category] . . .** **category = alternate [|alternate] . . .** **alternate = [primary]** **primary = character** **[category]** **option** **option = {category}** In an index file, the first category of each line must specify the name of an information file. The information file contains the names of files with quiz material. The remaining categories specify the order and contents of the data in each line of the information file. The quiz data in an information file follows the same syntax. A \ (backslash) is an escape character that allows you to quote syntactically significant characters or to insert a new-line character (\n) into a line. When either a question or its answer is blank, the **quiz** command does not ask the question. The construct **a|ab** does not work in an information file. Use **a{b}**.
-t	Provides a tutorial. Repeats missed questions and introduces new material gradually.

Examples

1. To start a Latin-to-English quiz, enter:

```
/usr/games/quiz latin english
```

The game displays Latin words and waits for you to enter what they mean in English.

2. To start an English-to-Latin quiz, enter:

```
/usr/games/quiz english latin
```

3. To set up a Latin-English quiz, add the following line to the index file:

```
/usr/games/lib/quiz/latin:latin:english
```

This line specifies that the **/usr/games/lib/quiz/latin** file contains information about the categories Latin and English.

You can add new categories to the standard index file, **/usr/games/lib/quiz/index**, or to an index file of your own. If you create your own index file, run the **quiz** command with the **-i***File* flag and enter your list of quiz topics.

4. The following is a sample information file:

```
cor:heart
sacerdos:priest{ess}
quando:when|since|because
optat:{{s}he |it }[desires|wishes]\|
desire|wish
alb[us|a|um]:white
```

This information file contains Latin and English words. The : (colon) separates each Latin word from its English equivalent. Items enclosed in { } (braces) are optional. A | (vertical bar) separates two items when entering either is correct. The [ ] (brackets) group items separated by vertical bars.

The first line accepts only the answer `heart` in response to the Latin word `cor`. The second accepts either `priest` or `priestess` in response to `sacerdos`. The third line accepts `when`, `since`, or `because` for `quando`.

The \ (backslash) at the end of the fourth line indicates that this entry continues on the next line. In other words, the fourth and fifth lines together form one entry. This entry accepts any of the following in response to `optat`:

```
she desires it desires desire
she wishes it wishes wish
he desires desires
he wishes wishes
```

If you start a Latin-to-English quiz, the last line of the sample information file instructs the **quiz** command to ask you the meaning of the Latin word `albus`. If you start an English-to-Latin quiz, the **quiz** command displays `white` and accepts `albus`, `alba`, or `album` for the answer.

If any of the characters { (left brace), } (right brace),[(left bracket) ,], (right bracket) or | (vertical bar) appear in a question item, the **quiz** command gives the first alternative of every | group and displays every optional group. Thus, the English-to-Latin question for the fourth definition in this sample is `she desires`.

Files

Item	Description
/usr/games/lib/quiz/index	Default index file for quiz categories.
/usr/games/lib/quiz/*	Used to specify the contents of a given file.
/usr/games	Location of the system's games.

quot Command

Purpose

Summarizes file system ownership.

Syntax

quot [**-c**] [**-f**] [**-h**] [**-n**][**-v**] [*FileSystem ...*]

quot -a [**-c**] [**-f**] [**-h**] [**-n**] [**-v**]

Description

The **quot** command summarizes file system ownership for JFS file systems by displaying the number of 512-byte blocks currently owned by each user in the specified file system (*FileSystem*). If no file system is specified, the **quot** command displays the same information for each of the JFS file systems in the `/etc/filesystems` file.

Flags

Item	Description
-a	Generate a report on all mounted systems.
-c	Displays a three-column report. The first column specifies the file size in 512-byte blocks. The second column specifies the number of files of that size. Finally, the third column specifies the cumulative total of 512-byte blocks in all files of that size or smaller. **Note:** Files greater than or equal to 500 blocks are grouped under a block size of 499. However, their exact block count contributes to the cumulative total of blocks.
-f	Displays the total number of blocks, the total number of files, and the user name associated with these totals.
-h	Estimates the number of blocks used by the file. This estimation is based on the file size and may return greater than actual block usage when used on files with holes.
-n	Produces a list of all files and their owners by running the following pipeline: `ncheck filesystem | sort +On | quot -n filesystem`
-v	Displays output in three columns containing the number of blocks not accessed in the last 30, 60, and 90 days.

Security

Access Control: This command is owned by the bin user and bin group.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To display the number of files and bytes owned by each user in the **/usr** file system, enter:

```
quot -f /usr
```

The system displays the following information:

```
/usr:
63056    3217    bin
20832     390    root
 1184      42    uucp
   56       5    adm
    8       1    guest
    8       1    sys
```

2. To display file size statistics, the number of files of each size, and a cumulative total, enter:

```
quot -c /usr
```

The system displays the following information:

```
/usr:
8       103      824
16      2        856
499     0        856
```

3. To generate a report of all mounted file systems, type:

```
quot -a
```

4. To generate a report of the **/var** file system, type:

```
#quot -v /var
/var:
45695   root            12852   11878   11774
 2569   guest            2567    1280     960
 2121   adm                92      91      91
 1343   bin               465     233     193
   14   uucp                0       0       0
    5   daemon              0       0       0
    1   invscout            1       1       1
    1   nuucp               1       1       1
    1   sys                 0       0       0
```

Files

Item	Description
/etc/passwd	Contains user names.
/etc/filesystems	Contains file system names and locations.

quota Command

Purpose

Displays disk usage and quotas.

Syntax

quota [**-u** [*User*]] [**-g** [*Group*]] [**-v** | **-q**]

Description

The `quota` command displays disk usage and quotas. By default, or with the `-u` flag, only user quotas are displayed. The `quota` command reports the quotas of all file systems listed in the `/etc/filesystems` file. If the `quota` command exits with a non-zero status, one or more file systems are over quota.

A root user may use the `-u` flag with the optional User parameter to view the limits of other users. Users without root user authority can view the limits of groups of which they are members by using the `-g` flag with the optional Group parameter.

Note:

1. In a JFS file system, if a particular user has no files in a file system on which that user has a quota, this command displays `quota: none` for that user. The user's actual quota is displayed when the user has files in the file system, or when the `-v` flag is specified. For JFS2, a user's actual quota is displayed in all cases.
2. In JFS2 systems, because the root user is not limited by quotas, limits for the root user are always displayed as zero (unlimited).
3. The rpc.rquotad protocol does not support the group quota for NFS. Thus, it does not return group quota information for NFS.

Flags

Item	Description
-g	Displays the quotas of the user's group.
-u	Displays user quotas. This flag is the default option.
-v	Displays quotas on file systems with no allocated storage.
-q	Prints a terse message, containing only information about file systems with usage over quota. **Note:** The **-q** flag takes precedence over the **-v** flag.

Security

Access Control: This command is owned by the root user and the bin group.

Privilege Control: This program is **setuid** in order to allow non-privileged users to view personal quotas.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To display your quotas as user `keith`, type:

   ```
   quota
   ```

   The system displays the following information:

   ```
   User quotas for user keith (uid 502):
   Filesystem  blocks  quota  limit  grace  Files  quota limit grace
           /u      20     55     60            20     60    65
   ```

2. To display quotas as the root user for user `davec`, type:

   ```
   quota -u davec
   ```

   The system displays the following information:

   ```
   User quotas for user davec (uid 2702):
   Filesystem  blocks  quota  limit  grace  files  quota limit grace
           /u      48     50     60             7     60    60
   ```

Files

Item	Description
quota.user	Specifies user quotas.
quota.group	Specifies group quotas.
/etc/filesystems	Contains file system names and locations.

quotacheck Command

Purpose

Checks file system quota consistency.

Syntax

quotacheck [-d] [**-g**] [**-u**] [**-v**] { **-a** | *Filesystem ...* }

Description

The `quotacheck` command examines a file system specified by the *FileSystem* parameter, builds a table of current disk usage, and compares the information in the table to that recorded in the file system's disk quota files. If any inconsistencies are detected, the quota files are updated. By default, both user and group quotas are checked.

The optional `-g` flag specifies that only group quotas are checked. The optional `-u` flag specifies that only user quotas are checked. Specifying both `-g` and `-u` flags is equivalent to the default behavior which checks both user and group quotas. The `-a` flag specifies that all file systems in the `/etc/filesystem` file with disk quotas enabled are checked.

For both JFS and JFS2 file systems, the optional `-d` flag deletes Usage statistics for any user or group ID that does not exist in `/etc/passwd` or `/etc/group`, and which has no allocation in the file system. The affected users or groups will no longer have statistics displayed by the `repquota` command.

The `quotacheck` command normally operates silently. If the `-v` flag is specified, the `quotacheck` command reports discrepancies between the calculated and recorded disk quotas.

For JFS, the `quotacheck` command determines the quota file names from the `/etc/filesystems` file (by default, the files are named `quota.user` and `quota.group` and are located at the root of the file system); for JFS2, the names and location of these files are predetermined and cannot be changed. If these files do not exist, the `quotacheck` command creates them.

Note: Do not run the `quotacheck` command against an active file system. If the file system has any current activity, running `quotacheck` may result in incorrect disk usage information.

Flags

Item	Description
-a	Checks all file systems with disk quotas enabled in **/etc/filesystems**.
-d	Deletes Usage statistics for undefined IDs with no allocation (both JFS and JFS2).
-g	Checks group quotas only.
-u	Checks user quotas only.
-v	Reports discrepancies between the calculated and recorded disk quotas.

Security

Access Control: Only a user with root user authority can execute this command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To check the user and group quotas in the `/usr` file system, type:

```
quotacheck /usr
```

2. To check only the group quotas in the `/usr` file system, type:

```
quotacheck -g /usr
```

Files

Item	Description
quota.usr	Specifies user quotas.
quota.group	Specifies group quotas.
/etc/filesystems	Contains file system names and locations.
/etc/group	Contains basic group attributes.
/etc/passwd	Contains user names.

quotaon or quotaoff Command

Purpose

Turns on and off file system quotas.

Syntax

quotaon [**-g**] [**-u**] [**-v**] { **-a** | *FileSystem ...* }

quotaoff [**-g**] [**-u**] [**-v**] { **-a** | *FileSystem ...* }

Description

The `quotaon` command enables disk quotas for one or more file systems specified by the *FileSystem* parameter. The specified file system must be defined with quotas in the `/etc/filesystems` file, and must be mounted. The `quotaon` command looks for the `quota.user` and `quota.group` files in the root directory of the associated file system, and will return an error if not found.

Note: For JFS only, the default quota file names (`quota.user` and `quota.group`) may be overridden in the `/etc/filesystems` file. The quota files can be external to the quota enabled file system by specifying full paths in the `/etc/filesystems` file. For JFS2 file systems, the file names may not be overridden and must reside in the root directory of the file system.

By default, both user and group quotas are enabled. The `-u` flag enables only user quotas; the `-g` flag enables only group quotas. Specifying both `-g` and `-u` flags is equivalent to the default (no option specified). The `-a` flag specifies that all file systems with disk quotas, as indicated by the `/etc/filesystems` file, are enabled.

The `quotaoff` command disables disk quotas for one or more file systems. By default, both user and group quotas are disabled. The `-a`, `-g`, and `-u` flags operate as with the `quotaon` command. The `-v` flag prints a message for each quota type (user or group) in every file system in which quotas are turned on or off with the `quotaon` and `quotaoff` commands, respectively.

An error (**EPERM**) will be returned if the `quota.user` and `quota.group` files are not owned by user **root** and group **system**. Ownership changes on these files are not permitted while quotas are active.

Flags

Item	Description
-a	Enables or disables all file systems that are read-write and have disk quotas, as indicated by the **/etc/filesystems** file. When used with the **-g** flag, only group quotas in the **/etc/filesystems** file are enabled or disabled; when used with the **-u** flag, only user quotas in the **/etc/filesystems** file are enabled or disabled.
-g	Specifies that only group quotas are enabled or disabled.
-u	Specifies that only user quotas are enabled or disabled.
-v	Prints a message for each file system in which quotas are turned on or off.

Security

Access Control: Only the root user can execute this command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To enable user quotas for the `/usr` file system, enter:

```
quotaon -u /usr
```

2. To disable user and group quotas for all file systems in the **/etc/filesystems** file and print a message, enter:

```
quotaoff -v -a
```

Files

Item	Description
quota.user	Specifies user quotas.
quota.group	Specifies group quotas.
/etc/filesystems	Contains file system names and locations.

r

The following AIX commands begin with the letter *r*.

raddbm Command

Purpose

Modifies entries in the local database of RADIUS user-authentication information.

Syntax

`raddbm` [`-a` *Command*] [`-d` *Database_filename*] [`-e` *EAP_type*] [`-i` *Config_filename*] [`-l` *Load_filename*] [`-n`] [`-p`] [`-t` *pwd_expire_wks*] [`-u` *User_ID*] [`-w`]

Description

The `raddbm` command is used to create and modify a local database of user-authentication information. The RADIUS server can be configured to use this database as the source of information it uses to authenticate users.

The local database is stored in a file. Data in the file is in a binary tree format to make searches faster. The database file name is specified in the RADIUS `/etc/radius/radiusd.conf` configuration file and has the default value of `dbdata.bin`. You can modify the file name by editing `radiusd.conf` through SMIT.

Each entry has the following fields:

Item	Description
USERID	Specifies the user's ID.
PASSWORD	Specifies the user's password.
PASSWORD_EXPIRATION	Specifies the password expiration time in number of weeks.
EAP_TYPE	Specifies the EAP type allowed for authentication.

Passwords in the database file are not stored in clear text in order to prevent simple password compromise, but the algorithm used to hide the passwords is not considered to be cryptographically secure. The file, `dbdata.bin`, is protected by `root:` security as the owner and group.

Several operations on the local database are supported by the `raddbm` command, including the following:

- Add a user to the database.

  To add a user, the command form is:

  ```
  raddbm -a ADD -u User_ID -e EAP_type -t pwd_expire_wks
  ```

  The user's password is prompted from standard input.

  The `-e` and `-t` flags are optional. If no value for the `-e` flag is entered, the default value of none is used for EAP_TYPE, meaning EAP packets are ignored for this user. If no value for the `-t` flag is entered, the default value of `0` is used for PASSWORD_EXPIRATION, meaning that password expiration is never checked. The `-p` flag is optional since the `raddbm` command always prompts for a new password when adding a new user.
- Change a user in the database.

  To change the user's information in the local database, type the following:

```
raddbm -a CHANGE -u User_ID -p -e EAP_type -t pwd_expire_wks
```

The `-e`, `-p`, and `-t` flags are optional, but at least one must be specified. If the `-p` flag is used, the `raddbm` command will prompt for the password.

- Delete a user from the database.

  To delete a user's entry from the database, type the following:

  ```
  raddbm -a DELETE -u User_ID
  ```

- List users in the database.

  To list a user's entries in the database, type the following:

  ```
  raddbm -a LIST
  raddbm -a LIST -u User_ID
  raddbm -a LIST -u User_ID -w
  ```

  The `-w` and `-u` flags are optional. If the `-w` flag is specified, all fields in the user's entry are displayed (except the password, which for security reasons is never displayed).

  If the `-u` flag is specified, the user's information is displayed in colon-separated format. If the `-u` flag is not specified, all entries in the database are displayed in column format.

- Create a new database.

  The RADIUS server ships an empty database in `/etc/radius/dbdata.bin`. If a user wants to create a new database, at least one user must be added at the time of creation. The form of the command is the following:

  ```
  raddbm -a ADD -u User_ID -e EAP_type -t pwd_expire_wks -n
  ```

  The user's password is prompted from standard input.

  The `-e` and `-t` flags are optional. They default to `EAP_type=NONE` and no password expiration checking.

- Load a list of users into the database.

  A list of users can be loaded directly into the database using the `-l` flag. A file must be created for each user that has records in it of the form:

  ```
  "userid" "password"
  ```

  The double quotes must be present.

  The file can then be used with the `-l` flag in the following way:

  ```
  raddbm -l filename
  ```

  Placing user passwords in plain text format in a file is strongly discouraged. This option is provided mainly for testing purposes.

Flags

Item	Description
?	Displays the help screen.
-a *Command*	Specifies the action to perform. Values are `ADD`, `LIST`, `DELETE`, or `CHANGE`.
-d *Database_filename*	Specifies the database file name. Used to override the default database file specified in the `radiusd.conf` RADIUS configuration file.
-e *EAP_type*	Specifies the EAP type the user is allowed to use for authentication. Currently, only `EAP-TLS`, `MD5-challenge`, or `none` is supported. The default is **none**.

Item	Description
`-i` *Config_filename*	Specifies the RADIUS configuration file name. Used to override the default `/etc/radius/radiusd.conf` configuration file .
`-l` *Load_filename*	Specifies the file name of the user name and password file to load.
`-n`	Creates a new database file. Valid only with the ADD command option. If this option is used, all previous information in the database is lost.
`-p`	Indicates that the user's password is to be changed. For security reasons, the password is prompted from standard input instead of read from the command line.
`-t` *pwd_expire_wks*	Specifies the number of weeks the user's password is valid. This flag is valid with the ADD and CHANGE commands. The default is 0, indicating no password expiration. Valid values are from 0 to 52.
`-u` *User_ID*	Specifies the user's ID. A valid user ID must be less than 253 characters in length, and can contain letters, numbers, and some special characters. It cannot contain blanks. Duplicate user IDs are not allowed.
`-w`	Generates a long listing of user information.

Exit Status

This command has the following exit values:

Item	Description
0	The command completed successfully.
>0	An error occurred.

Security

Only the root user or a member of the security group can execute this command.

Examples

1. To create a new local RADIUS database, you must add at least one user. To create the database, type the following:

   ```
   raddbm -a ADD -u user01 -n
   ```

   Note: The `-n` option will overwrite the existing database, destroying the previous contents. The database file created will be named the default name as specified in the `/etc/radius/radiusd.conf` RADIUS configuration file.
2. To add a user to the database, type the following:

   ```
   raddbm -a ADD -u user01
   ```

   The default values of EAP_TYPE = "none" and PASSWORD_EXPIRATION = "0" are used.
3. To delete a user from the database, type the following:

   ```
   raddbm -a DELETE -u user01
   ```
4. To change a user's password, type the following:

   ```
   raddbm -a CHANGE -u user01 -p
   ```

   The command prompts for the new password.
5. To display a long listing of all entries in the default database, type the following:

```
raddbm -a LIST -w
```

Passwords are not displayed.

6. To display a particular user's database entry, type the following:

```
raddbm -a LIST -u user01 -w
```

7. To add a list of users from a file, first create the file of users and passwords that has one entry per line and has the form:

```
"userid"  "password"
```

Then type the following:

```
raddbm -l Load_filename
```

Restrictions

The RADIUS daemon must be stopped before the `raddbm` command is run. Use the `radiusctl stop` command to stop the daemon. After you have modified the database, restart the daemon with the `radiusctl start` command.

Implementation Specifics

This command is part of the `radius.base` fileset.

Location

/usr/radius/bin/raddbm

Standard Input

For security reasons, when a user is added to the database, the user's password is read from standard input instead of from the command line.

Standard Error

If the call to the `raddbm` command fails, an information message is written to standard error.

Files

Item	Description
`/usr/radius/bin/raddbm`	Location of the `raddbm` command.
`/etc/radius/raddbm.bin`	The default database file as specified in the `radiusd.conf` file.
`/etc/radius/radiusd.conf`	Specifies the RADIUS configuration values, including the default database file name.

radiusctl Command

Purpose

Starts, stops, or restarts the RADIUS authentication, authorization, and accounting daemons.

Syntax

radiusctl start

radiusctl stop

radiusctl restart

Description

The **radiusctl** command starts, stops, or restarts the RADIUS server daemons used for controlling network authentication, authorization, and accounting.

This command enables full EAP-TLS support in the AIX RADIUS server in conjunction with the OpenSSL package shipped on the AIX Expansion Pack media.

The local user database of the AIX RADIUS server can be updated while the server is running, however, new changes take effect only after you restart the system. The **radiusctl** command also makes this possible.

Note: This command deprecates the old method of starting and stopping the AIX RADIUS server (for example, **startsrc -s radiusd**, **stopsrc -s radiusd**, and so on).

Flags

Item	Description
start	Starts running the RADIUS server. **Note:** If EAP-TLS is enabled through OpenSSL, you are prompted to enter the private key password when you attempt to start or restart the server.
stop	Stops the RADIUS server.
restart	Restarts the RADIUS server whether or not it is currently running. If the server is not running, this flag behaves the same as the **start** flag.

Examples

1. To start running the AIX RADIUS server, enter the following command:

   ```
   radiusctl start
   ```

2. To restart an already running AIX RADIUS server, enter the following command:

   ```
   radiusctl restart
   ```

3. To stop the AIX RADIUS server from running, enter the following command:

   ```
   radiusctl stop
   ```

ranlib Command

Purpose

Converts archive libraries to random libraries.

Syntax

ranlib [**-t**] [**-X** {**32**|**64**|**32_64**}] *Archive ...*

Description

The **ranlib** command converts each *Archive* library to a random library. A random library is an archive library that contains a symbol table.

If given the **-t** option, the **ranlib** command only touches the archives and does not modify them. This is useful after copying an archive or using the **-t** option of the **make** command in order to avoid having the **ld** command display an error message about an out-of-date symbol table.

Flags

Item	Description
-t	Touches the named archives without modifying them.
-X *mode*	Specifies the type of object file **ranlib** should examine. The *mode* must be one of the following: **32** Processes only 32-bit object files **64** Processes only 64-bit object files **32_64** Processes both 32-bit and 64-bit object files The default is to process 32-bit object files (ignore 64-bit objects). The *mode* can also be set with the **OBJECT_MODE** environment variable. For example, **OBJECT_MODE=64** causes **ranlib** to process any 64-bit objects and ignore 32-bit objects. The **-X** flag overrides the **OBJECT_MODE** variable.

Examples

To randomize the archive file `genlib.a`, enter:

```
ranlib genlib.a
```

Files

Item	Description
/usr/ccs/bin/ranlib	Contains the **ranlib** command.

raso Command

Purpose

Manages Reliability, Availability, Serviceability parameters.

Syntax

`raso` [`-p` | `-r`] [**-y**] [`-o` *Tunable* [= *Newvalue*]]

`raso` [`-p` | `-r`] [**-y**] [`-d` *Tunable*]

`raso` [`-p`] [`-r`] [**-y**] `-D`

`raso` [`-p`] [`-r`] [**-F**] `-a`

`raso` `-h` [*Tunable*]

`raso` [**-F**] `-L` [*Tunable*]

`raso` [**-F**] `-x` [*Tunable*]

Note: Multiple `-o`, `-d`, `-x`, and `-L` flags can be specified.

Description

Note: The `raso` command requires root authority.

The `raso` command is used to configure Reliability, Availability, Serviceability tuning parameters. The `raso` command sets or displays the current or next-boot values for all RAS tuning parameters. The `raso` command can also be used to make permanent changes or to defer changes until the next reboot. The specified flag determines whether the `raso` command sets or displays a parameter. The `-o` flag can be used to display the current value of a parameter or to set a new value for a parameter.

Understanding the Effect of Changing Tunable Parameters

Misuse of the `raso` command can cause performance degradation or operating system failure. Before modifying any tunable parameter, you should first carefully read about all of the parameter's characteristics in the Tunable Parameters section in order to fully understand the parameter's purpose. You should then ensure that the Diagnosis and Tuning sections for this parameter actually apply to your situation and that changing the value of this parameter could help improve the performance of your system. If the Diagnosis and Tuning sections both contain only "N/A", it is recommended that you do not change the parameter unless you are specifically directed to do so by AIX development.

Flags

Item	Description
-a	Displays the current, reboot (when used in conjunction with the `-r` flag), or permanent (when used in conjunction with the `-p` flag) values for all tunable parameters, with one tunable parameter per line displayed in pairs as *Tunable* = *Value*. For the permanent option, a value is only displayed for a parameter if its reboot and current values are equal. Otherwise `NONE` is displayed as the value.
-d *Tunable*	Resets *Tunable* to the default value. If *Tunable* needs to be changed (that is, it is currently not set to its default value) and is of type Bosboot or Reboot, or if it is of type Incremental and has been changed from its default value, and the `-r` flag is not used in combination, *Tunable* is not changed and a warning displays.
-D	Resets all tunables to their default values. If any tunables that need to be changed are of type Bosboot or Reboot, or if any tunables that need to be changed are of type Incremental and have been changed from their default value, and `-r` is not used in combination, these tunables are not changed and a warning displays.
-F	Forces restricted tunable parameters to be displayed when the options **-a**, **-L** or **-x** are specified alone on the command line. If you do not specify the **-F** flag, restricted tunables are not included, unless they are specifically named in association with a display option.
-h *Tunable*	Displays help about the `raso` command if no *Tunable* parameter is specified. Displays help about the *Tunable* parameter if a *Tunable* parameter is specified.
-L *Tunable*	Lists the characteristics of one or all tunables, with one tunable displayed per line using the following format: `NAME CUR DEF BOOT MIN MAX UNIT TYPE DEPENDENCIES` `mtrc_commonbufsize 3974 3974 3974 1 5067 4KBpages D mtrc_enabled` `mtrc_enabled 1 1 1 0 1 boolean B` `mtrc_rarebufsize 2649 2649 2649 1 3378 4KB pages D` `...` `where:` `CUR = current value` `DEF = default value` `BOOT = boot value` `MIN = minimal value` `MAX = maximum value` `UNIT = tunable unit of measure` `TYPE = parameter type: D (for Dynamic), S (for Static), R (for Reboot),B (for Bosboot), M (for Mount), I (for Incremental), C (for Connect), and d (for Deprecated)` `DEPENDENCIES = list of dependent tunable parameters, one per line`
-o *Tunable* [=*Newvalue*]	Displays the value or sets *Tunable* to *Newvalue*. If *Tunable* needs to be changed (the specified value is different than current value) and is of type Bosboot or Reboot, or if *Tunable* if it is of type Incremental and its current value is larger than the specified value, and if the `-r` flag is not used in combination, *Tunable* is not changed and a warning displays. If the `-r` flag is used in combination without a new value, the nextboot value for *Tunable* is displayed. If the `-p` flag is used in combination without a new value, a value is displayed only if the current and next boot values for *Tunable* are the same. Otherwise, `NONE` is displayed as the value.
-p	When the `-p` flag is used in combination with the `-o`, `-d`, or `-D` flag, changes apply to both the current and reboot values (in addition to the current value being updated, the `/etc/tunables/nextboot` file is updated). These combinations cannot be used on Reboot and Bosboot type parameters because the current values for these parameters cannot be changed. When the `-p` flag is used with the `-a` or `-o` flag without specifying a new value, values are displayed only if the current and next boot values for a parameter are the same. Otherwise, `NONE` is displayed as the value.

Item	Description
-r	When the `-r` flag is used in combination with the `-o`, `-d`, or `-D` flag, changes apply to reboot values (the `/etc/tunables/nextboot` file is updated). If any parameter of type Bosboot is changed, you are prompted to run the `bosboot` command. When the `-r` flag is used with the `-a` or `-o` flag and a new value is not specified, the next boot values for tunables are displayed instead of the current values.
-x *Tunable*	Lists the characteristics of one or all tunables, with one tunable displayed per line using the following format (spreadsheet format): `Tunable Current Default Reboot Minimum Maximum Unit Type Dependencies` where *Tunable* is the tunable parameter, *Current* is the current value of the tunable parameter, *Default* is the default value of the tunable parameter, *Reboot* is the reboot value of the tunable parameter, *Minimum* is the minimum value of the tunable parameter, *Maximum* is the maximum value of the tunable parameter, *Unit* is the tunable unit of measure, *Type* is the parameter type, and *Dependencies* is the list of dependent tunable parameters. If you make any change (with **-o**, **-d**, or **-D**) to a parameter of type Mount, it results in a warning message that the change is only effective for future mountings. If you make any change (with **-o**, **-d** or **-D**) to a parameter of type Connect, it results in **inetd** being restarted, and a warning message that the change is only effective for future socket connections. If you make any change (with **-o**, **-d**, or **-D**) to a parameter of type Bosboot or Reboot without **-r**, it results in an error message. If you make any change (with **-o**, **-d**, or **-D** but without **-r**) to the current value of a parameter of type Incremental with a new value smaller than the current value, it results in an error message.
-y	Suppresses the confirmation prompt before running the **bosboot** command.

If you make any change (with **-o**, **-d** or **-D**) to a restricted tunable parameter, it results in a warning message that a tunable parameter of the restricted-use type has been modified. If you also specify the **-r** or **-p** options on the command line, you are prompted for confirmation of the change. In addition, at system reboot, the presence of restricted tunables in the **/etc/tunables/nextboot** file, which were modified to a value that is different from their default value (using a command line specifying the **-r** or **-p** options), results in an error log entry that identifies the list of these modified tunables.

You can specify a modified tunable value using the abbreviations K, M, G, T, P and E to indicate units. The following table shows the prefixes and values that are associated with the number abbreviations.

Item	Description	
Abbreviation	**Prefix**	**Power of 2**
K	kilo	2^{10}
M	mega	2^{20}
G	giga	2^{30}
T	tera	2^{40}
P	peta	2^{50}
E	exa	2^{60}

Thus, a tunable value of 1024 might be specified as 1K.

Tunable Parameters Type

All the tunable parameters manipulated by the tuning commands (**no**, **nfso**, **vmo**, **ioo**, **schedo**, and **raso**) have been classified into these categories:

Item	Description
Dynamic	If the parameter can be changed at any time
Static	If the parameter can never be changed
Reboot	If the parameter can only be changed during reboot
Bosboot	If the parameter can only be changed by running bosboot and rebooting the machine

Item	Description
Mount	If changes to the parameter are only effective for future file systems or directory mounts
Incremental	If the parameter can only be incremented, except at boot time
Connect	If changes to the parameter are only effective for future socket connections. The parameters must be of type Bosboot.

For parameters of type Bosboot, whenever a change is performed, the tuning commands automatically prompt the user to ask if they want to execute the **bosboot** command. For parameters of type Connect, the tuning commands automatically restart the **inetd** daemon.

Note that the current set of parameters managed by the **schedo** command only includes Dynamic and Reboot types.

Compatibility Mode

When running the **raso** command in the pre 5.2 compatibility mode that is controlled by the **pre520tune** attribute of **sys** 0, the reboot values for parameters, except for those of type Bosboot, are not considered because in this mode they are not applied at the boot time. See NFS tuning on the client in the *Performance management* guide for detailed information.

In pre 5.2 compatibility mode, setting reboot values to tuning parameters continues to be achieved by imbedding calls to tuning commands in scripts called during the boot sequence. Parameters of type **Reboot** can therefore be set without the **-r** flag, so that existing scripts continue to work.

This mode is automatically turned ON when a machine is MIGRATED to AIX 5.2. For complete installations, it is turned OFF and the reboot values for parameters are set by applying the content of the **/etc/tunables/nextboot** file during the reboot sequence. Only in that mode are the **-r** and **-p** flags fully functional. See Kernel Tuning in the *Performance Tools Guide and Reference* for more information.

Tunable Parameters

For default values and range of values for tunables, refer the **raso** command help (**-h** <*tunable_parameter_name*>).

Item	Description
kern_heap_noexec	**Purpose:** Specifies whether no-execute protection should be enabled for the kernel heap. **Tuning:** With protection enabled, any attempt to execute code in the protected heap will result in a kernel exception.
kernel_noexec	**Purpose:** Specifies whether no-execute protection should be enabled for kernel data regions. **Tuning:** With protection enabled, any attempt to execute code in the protected regions will result in a kernel exception.

Item	Description
mbuf_heap_noexec	**Purpose:** Specifies whether no-execute protection should be enabled for the mbuf heap. **Tuning:** With protection enabled, any attempt to execute code in the protected heap will result in a kernel exception.
mtrc_commonbufsize	**Purpose:** Specifies the memory trace buffer size for common events of Lightweight Memory Trace (LMT) which provides system trace information for First Failure Data Capture (FFDC). **Tuning:** The default value is based on data generation under a reference system-wide activity, hardware, and system characteristics. The range upper limit is based on the hardware and system characteristics and depends on the current value of **mtrc_rarebufsize** because they share the LMT resource. Recorded events are saved in system dump and/or reported through user commands.
mtrc_enabled	**Purpose:** Defines the Lightweight Memory Trace (LMT) state. **Tuning:** Value of 1 means LMT is enabled. To be effective, any change of state requires a subsequent bosboot and system reboot.
mtrc_rarebufsize	**Purpose:** Specifies the memory trace buffer size for rare events of Lightweight Memory Trace (LMT) which provides system trace information for First Failure Data Capture (FFDC). **Tuning:** The default value is based on data generation under a reference system-wide activity, hardware, and system characteristics. The range upper limit is based on the hardware and system characteristics and depends on the current value of **mtrace_commonbufsize** because they share the LMT resource. Recorded events are saved in system dump and/or reported through user commands.
tprof_cyc_mult	**Purpose:** Specifies the Performance Monitor PM_CYC and software event sampling frequency multiplier as a means to control the trace sampling frequency.
tprof_evt_mult	**Purpose:** Specifies the Performance Monitor PM_* event sampling frequency multiplier as a means to control the trace sampling frequency.

Item	Description
tprof_inst_threshold	**Purpose:** Specifies the minimum number of completed instructions between Performance Monitor event samples as a means to control the trace sampling frequency. **Values:** • Default: 1000 • Range: 1 to 2G-1 • Type: Dynamic **Diagnosis:** Not applicable **Tuning:** Not applicable
tprof_evt_system	**Purpose:** Allows or restricts the non-privileged users from using the system-wide Performance Monitor event-sampling. **Values:** • Default: 0 • Range: 0, 1 • Type: Dynamic • Unit: Boolean **Tuning:** With **tprof_evt_system** enabled (value 1), the non-privileged users can use tprof and pmctl commands to perform system-wide Performance Monitor event-sampling. When disabled (value 0), non-privileged users can perform event-sampling for processes started with -y option of tprof and pmctl commands. In the disabled mode, non-privileged users cannot perform event-sampling of kernel and kernel extensions.

Examples

1. To list the current and reboot value, range, unit, type, and dependencies of all tunable parameters managed by the `raso` command, type the following:

```
raso -L
```

2. To turn off the Lightweight Memory Trace, type the following:

```
raso -r -o mtrc_enabled=0
```

3. To display help for mtrc_commonbufsize, type the following:

```
raso -h mtrc_commonbufsize
```

4. To set tprof_inst_threshold to 10000 after the next reboot, type the following:

```
raso -r -o tprof_inst_threshold=10000
```

5. To permanently reset all `raso` tunable parameters to their default values, type the following:

```
raso -p -D
```

6. To list the reboot level for all Virtual Memory Manager tuning parameters, type the following:

```
raso -r -a
```

ras_logger Command

Purpose

Log an error using the errors template.

Syntax

/usr/lib/ras/ras_logger [**-y** *template-file*]

Description

The **ras_logger** command logs one error, provided in standard input, using the error's template to determine how to log the data. The format of the input is the following:

```
error_label
resource_name
64_bit_flag
detail_data_item1
detail_data_item2
...
```

The **error_label** field is the error's label defined in the template. The **resource_name** field is up to 16 characters in length. The **64_bit_flag** field's values are 0 for a 32-bit error and 1 for a 64-bit error. The **detail_data** fields correspond to the **Detail_Data** items in the template.

Flags

Item	Description
-y *template-file*	Specifies a template file other than the **/var/adm/ras/errtmplt** default file.

Examples

1. Log an error. The template is the following:

```
 + FOO:
        Catname = "foo.cat"
        Err_Type = TEMP
        Class = O
        Report = TRUE
        Log    = TRUE
        Alert  = FALSE
        Err_Desc = {1, 1, "Error FOO"}
        Prob_Causes = {1, 2, "Just a test"}
        User_Causes = {1, 2, "Just a test"}
        User_Actions = {1, 3, "Do nothing"}
        Detail_Data = 4, {2, 1, "decimal"} ,DEC
        Detail_Data = W, {2, 1, "hex data"} ,HEX
        Detail_Data = 100, {2, 1, "long string"} ,ALPHA
```

   The ras_logger input in the **tfile** file appears as follows:

```
FOO
resource
0
15
A0
hello world
```

Run the **/usr/lib/ras/ras_logger <tfile** command. This will log the FOO error with **resource** as the resource name. The detail data will consist of 4 bytes set to decimal 15, 4 bytes of hex data set to 0xa0, and the string "hello world". Note that if the value of the 64-bit flag was 1, the hexidecimal data would be 8 bytes set to 0xa0.

2. Multi-item decimal values. The template is the following:

```
+ FOO:
        Catname = "foo.cat"
        Err_Type = TEMP
        Class = O
        Report = TRUE
        Log    = TRUE
        Alert  = FALSE
        Err_Desc = {1, 1, "Error FOO"}
        Prob_Causes = {1, 2, "Just a test"}
        User_Causes = {1, 2, "Just a test"}
        User_Actions = {1, 3, "Do nothing"}
        Detail_Data = 8, {2, 1, "decimal"} ,DEC
        Detail_Data = W, {2, 1, "hex data"} ,HEX
        Detail_Data = 100, {2, 1, "long string"} ,ALPHA
```

The **ras_logger** command enters the following into the **tfile**file:

```
FOO
resource
0
15 -15
A0
hello world
```

Note: The decimal data is normally shown by the **errpt** command as two separate values using 4 bytes each. The input therefore contains 15 and -15. This is how it is shown by the **errpt** command.

rbacqry Command

Purpose

Reports a set of used privileges and authorizations for a process.

Syntax

`/usr/sbin/rbacqry` [`-T` |`-C`] `-n` *programname* [`-i` *auditfile*] `-u` *username* [`-t` *timeperiod*]

`/usr/sbin/rbacqry -c` [`-s`]`-u` *username* `-S`

Description

The **rbacqry** command is used as a monitor utility to enable role based access control (RBAC) for applications. The **rbacqry** command reports the privileges and authorizations used by a program after the program is run. It uses the audit subsystem to log the privileges and authorizations of all processes that are created by the program and its spawning process.

The **rbacqry** command operates when the system is operating in the enhanced RBAC mode. The privileges obtained from this report can be assigned to the `innateprivs` and `inheritprivs` attributes for the application by using the **setsecattr** command, which enables the command for RBAC. You can consolidate the privileges for the children of a process and provide it under `inheritprivs` attribute or have separate entries for the children in the `/etc/security/privcmds` file for RBAC enablement.

Notes:

- The **rbacqry** command depends on the audit report that is generated by the AIX auditing subsystem.
- The `rbac` audit class is added to the`/etc/security/audit/config` file when the `rbacqry –c` command is run. The audit class can be configured manually.

- When you are tracing privileges and authorizations by using this utility, assign the `rbac` audit class to a specific user in the `/etc/security/audit/config` file to avoid creating large audit logs.
- The **rbacqry** command does not suggest or provide any RBAC roles as part of the output. The command provides only the privileges and authorizations used by the specified program.
- When you are tracing shell scripts by using the `rbacqry` tool, the shell interpreter (for example: `#!/usr/bin/ksh`) must be mentioned in the first line of the script that is being traced.

Flags

Item	Description
`-c`	Configures the `/etc/security/audit/config` file with the `rbac` class for the specified user.
`-C`	Provides a set of used privileges and authorization for the process tree in a comma-separated list of the set. This option is mutually exclusive with the –T option.
`-i` *auditfile*	Specifies the audit trail file to be processed by the **rbacqry** command. If not specified, the flag uses the `/audit/trail` file by default.
`-n` *programname*	Specifies the target program name that must be traced for used privileges.
`-s`	Starts the auditing subsystem if it is turned off. Restarts the audit subsystem if it is already on.
`-S`	Prints the output in stanza format.
`-T`	Provides a set of used privileges and authorizations for the processes in a tree format.
`-t` *timeperiod*	Accepts a value that is equal to the number of days from when the used privilege report must be generated from the current system date.
`-u` *username*	Specifies the user name. This option is required to configure the audit events for the user, and to query the process run by the user.

Exit status

Error Value	Descriptor
= 0	Successful completion
> 0	An error

Security

On Trusted AIX systems, only authorized users can run the **restore** command.

Item	Descriptor
`aix.fs.manage.restore`	Required to run this command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To determine the privileges and authorizations that are used by a program, use one of the following methods:

   a. When a program or application is run by a non-root user for which the **rbacqry** command must be run, complete the following steps:

      i) Enable the program for RBAC temporarily under a root or an authorized user's shell, by running the **setsecattr** command:

      ```
      setsecattr -c accessauths=ALLOW_ALL innateprivs=PV_ROOT secflags=FSF_EPS progpath
      ```

      Note: The program path must be a full pathname of the program for which the **rbacqry** command is run.

      ii) Run `setkst -t cmd` (as root or authorized user) to make the above changes effective.

      iii) Run the **rbacqry** command under a root or authorized user's shell to configure the user for auditing:

      ```
      rbacqry -c -s -u username
      ```

      iv) Run the specified program or application as non-root user.

      v) When the program execution completes, run the **rbacqry** command under a root or authorized user's shell to collect used privileges and authorizations:

      ```
      rbacqry -n program -u username (additional options can also be used)
      ```

      vi) Remove the program entry from the `/etc/security/privcmds` file that was added from step (i) by running the following commands as a root or authorized user:

      ```
      rmsecattr -c progpath; setkst -t cmd
      ```

   b. When a program or application is executed by a root user (as root login or switching to a root by using the **su** command) and for which the **rbacqry** command must be run, complete these steps:

      i) Run the **rbacqry** command under a root or authorized user's shell to configure the user for auditing:

      ```
      rbacqry -c -s -u root
      ```

      ii) Run the specified program or application as a root user.

      iii) When the program execution completes, run the **rbacqry** command under a root or authorized user's shell to collect used privileges and authorizations:

      ```
      rbacqry -n program -u root (additional options can also be used)
      ```

      Note: When tracing a program or application that was executed by switching to a root user by using the **su** command after following steps i and ii, run the **rbacqry** command as follows:

      ```
      rbacqry -n program -u user_name (additional options can also be used)
      ```

2. To determine the privileges and authorizations that are used by the **chfs** command (which was executed by user Scooby with aix authorization) and its spawning processes in a tree-formatted output, run the following command:

```
# rbacqry -n chfs -u scooby -T
CMD                     AUTHORIZATIONS                  USED_PRIVS
------------------------------------------------------------------------------
chfs                    aix.fs.manage.change
|                                                       PV_FS_RESIZE
|
|\extendlv              aix.lvm.manage.extend
|  |                                                    PV_AU_ADMIN            PV_KER_ACCT
|  |
|  |\putlvcb            aix.lvm.manage
```

```
|   |   |                                                    PV_FS_MKNOD             PV_PROC_PRIV
|   |   |                                                    PV_KER_LVM              PV_DEV_QUERY
|   |   |
|   |\lextendlv          aix.lvm.manage.extend
|   |   |                                                    PV_AU_ADD               PV_AU_PROC
|   |   |                                                    PV_FS_MKNOD             PV_PROC_PRIV
|   |   |                                                    PV_KER_ACCT             PV_KER_LVM
|   |   |                                                    PV_DEV_QUERY            PV_SU_UID
|   |   |
|   |   |\savebase        aix.system.boot.create
|   |   |   |                                                PV_AU_PROC              PV_FS_MKNOD
|   |   |   |                                                PV_PROC_PRIV            PV_KER_ACCT
|   |   |   |                                                PV_KER_LVM              PV_DEV_QUERY
|   |   |   |                                                PV_SU_UID
|   |   |   |
|   |   |   |\compress     aix.fs.manage.backup
|   |   |   |  |                                             PV_KER_ACCT             PV_SU_UID
|   |   |   |  |
.....
```

3. To display the privileges and authorizations that are used by the **chfs** command (which was executed by user Scooby with aix authorization) from a different audit trail file, run the following command:

```
# rbacqry -u scooby -n chfs -i /audit/trail_example
CMD           AUTHORIZATIONS               USED_PRIVS
-------------------------------------------------------------------------------
chfs          Used_Auth:                   PV_DAC_O              PV_FS_CHOWN
              aix.fs.manage.change         PV_FS_RESIZE
              Checked_Auths:
```

4. To obtain a comma-separated list of privileges that are used by the **chfs** command (which was executed by user Scooby with aix authorization), run the following command:

```
# rbacqry -n chfs -u scooby -C
CMD                     AUTHORIZATIONS          USED_PRIVS
-------------------------------------------------------------------------------
chfs                    aix.fs.manage.change
                                                PV_FS_RESIZE
extendlv                aix.lvm.manage.extend
                                                PV_AU_ADMIN,PV_KER_ACCT
putlvcb                 aix.lvm.manage

PV_FS_MKNOD,PV_PROC_PRIV,PV_KER_LVM,PV_DEV_QUERY
lextendlv               aix.lvm.manage.extend

PV_AU_ADD,PV_AU_PROC,PV_FS_MKNOD,PV_PROC_PRIV,
                                                PV_KER_ACCT,PV_KER_LVM,PV_DEV_QUERY,PV_SU_UID
savebase                aix.system.boot.create

PV_AU_PROC,PV_FS_MKNOD,PV_PROC_PRIV,PV_KER_ACCT,
                                                PV_KER_LVM,PV_DEV_QUERY,PV_SU_UID
compress                aix.fs.manage.backup
                                                PV_KER_ACCT,PV_SU_UID
.......
```

This output format is useful when the USED PRIVS set is added to the privileged command in the `/etc/security/privcmds` database.

Note: The system authorization and custom authorizations can be traced. If the system authorizations must be displayed in the output, a higher authorization (example aix authorization) must be assigned to the user.

5. To configure the user scooby for auditing, run the following command:
   a. To configure the user and to start the auditing for that user, run the following command:

```
#/usr/sbin/rbacqry -c -s -u scooby
```

   Audit subsystem started.

   b. To configure the user for auditing without restarting the auditing, run the following command:

```
#/usr/sbin/rbacqry -c -u scooby
```

Note: The user scooby is not traced by the auditing subsystem because the auditing is not restarted. An entry for scooby is made in the `/etc/security/audit/config` file. You must restart the auditing subsystem manually to allow the auditing to trace the user, or you must run the **rbacqry** command as follows:

```
#/usr/sbin/rbacqry -c -s -u scooby
```

User scooby already configured for audit. Audit subsystem started

6. To show the following stanza for the **-S** format, run the following command:

```
# rbacqry -u scooby -n chfs -S chfs:
                Used_Auth=aix.fs.manage.change
        Checked_Auths=
        Used_Privs=PV_DAC_O,PV_FS_CHOWN,PV_FS_RESIZE
```

7. To execute the **rbacqry** command without any format options, run the following command:

```
# rbacqry -u scooby -n chfs
CMD           AUTHORIZATIONS                USED_PRIVS
------------------------------------------------------------------------------
chfs          Used_Auth:                    PV_DAC_O              PV_FS_CHOWN
              aix.fs.manage.change          PV_FS_RESIZE
              Checked_Auths:
```

Note: The *checked_Auths* parameter are blank when no *checked Auths* parameters are present. If not the **rbacqry** command displays the *checked_auths* parameters as below:

```
# rbacqry -u scooby -n lsuser
CMD             AUTHORIZATIONS                  USED_PRIVS
------------------------------------------------------------------------------
lsuser          Used_Auth:                      PV_AZ_CHECK          PV_DAC_R
                ALLOW_ALL                       PV_DAC_X
                Checked_Auths:
                aix.security.user.list
                aix.security.user.audit
                aix.security.efs
```

Files

File path	Description
`/audit/trail`	Specifies the audit file to capture the audit logs.

rbactoldif Command

Purpose

Prints certain role-based access control (RBAC) and Domain role-based access control tables that are defined locally to standard output (**stdout**) in the LDIF format.

Syntax

rbactoldif -d *baseDN* [**-s** *tables*]

Description

The **rbactoldif** command reads data from locally defined RBAC tables and prints the result to **stdout** in LDIF format. If redirected to a file, the result can be added to an LDAP server with the **ldapadd** command or the **ldif2db** command.

The **rbactoldif** command reads the **/etc/security/ldap/sectoldif.cfg** file to determine what to name the authorization, role, privileged command, privileged device, and privileged file sub-trees that the data will

be exported to. The **rbactoldif** command only exports data to the AUTHORIZATION, ROLE, PRIVCMD, PRIVDEV, and PRIVFILE types defined in the file. The names specified in the file will be used to create sub-trees under the base distinguished name (DN) specified with the **-d** flag. For more information, see the **/etc/security/ldap/sectoldif.cfg** file in *Files Reference* .

Flags

Item	Description
-d *baseDN*	Specifies the base DN under which the RBAC data is placed.
-s *tables*	Specifies a set of tables to be read. If you do not specify the **-s** flag, all of the RBAC and Domain RBAC tables are read. Specify at least one of the following letters, each representing a table name: **a** Specifies the authorization table. **c** Specifies the privileged command table. **d** Specifies the privileged device table. **e** Specifies the domain table. **f** Specifies the privileged file table. **o** Specifies the domain object table. **r** Specifies the role table. **t** Specifies the trvi table.

Security

The **rbactoldif** command is owned by root and security group, with mode bits 500.

File Accessed

File	Mode
/etc/security/authorizations	r
/etc/security/roles	r
/etc/security/privcmds	r
/etc/security/privdevs	r
/etc/security/privfiles	r
/etc/security/.rbac_ids	r
/etc/security/domains	r
/etc/security/domobjs	r

Examples

1. To export all of the RBAC and Domain RBAC tables to LDIF format with base DN of `cn=aixdata`, use the following command:

```
rbactoldif -d cn=aixdata
```

2. To export only the authorization and role tables with base DN of `cn=aixdata`, use the following command:

```
rbactoldif -d cn=aixdata -s ar
```

3. To export only the `domobjs` tables with base DN of `cn=aixdata`, use the following command:

```
rbactoldif -d cn=aixdata -s o
```

rc Command

Purpose

Performs normal startup initialization.

Syntax

rc

Description

The **rc** command has an entry in the **/etc/inittab** file. The **init** command creates a process for the **rc** command entry in the **/etc/inittab** file. The **rc** command performs normal startup initialization for the system. The contents of **/etc/rc** are installation specific. If all of the necessary operations complete successfully, the file exits with a zero return code that allows the **init** command to start loggers to complete normal initialization and startup.

Note:

1. Many bringup functions such as activating page spaces and mounting filesystems are done by the **rc** command.
2. The root file system is implicitly mounted.

rc.mobip6 Command

Purpose

Enables the system to function as a mobile IPv6 home agent or correspondent node.

Syntax

rc.mobip6 { **start** [**-H**] [**-S**] | **stop** [**-N**] [**-F**] }

Description

The **/etc/rc.mobip6** file is a shell script that, when executed, enables the system to function as a mobile IPv6 home agent or correspondent node. If mobile IPv6 has been configured using system management to start at each system restart, the script will be executed automatically at restart.

Flags

Item	Description
-F	Disables IPv6 forwarding.
-H	Enables the system as a Mobile IPv6 home agent and correspondent node. If this flag is not used, the system will be enabled as a correspondent node only.
-N	Stops the **ndpd-router** daemon.
-S	Enables checking of IP security authentication.

Exit Status

0
The command completed successfully.

>0
An error occurred.

Security

You must have root authority or be a member of the system group to execute this command.

Examples

1. The following example enables the system as a mobile IPv6 home agent and correspondent node:

```
/etc/rc.mobip6 start -H
```

2. The following example enables the system as a mobile IPv6 correspondent node and enables IP security checking:

```
/etc/rc.mobip6 start -S
```

3. The following example disables all mobile IPv6 and IPv6 gateway functionality on the system:

```
/etc/rc.mobip6 stop -N -F
```

4. The following example disables all mobile IPv6 functionality but allows the system to continue functioning as an IPv6 gateway:

```
/etc/rc.mobip6 stop
```

Files

Item	Description
/etc/rc.mobip6	Contains the **rc.mobip6** command.

rc.powerfail Command

Purpose

Handles RPA (RS/6000 Platform Architecture) specific EPOW (Environmental and POwer Warning) events and shuts down the system if needed, as part of EPOW event handling.

Syntax

rc.powerfail [**-h**] | [[**-s**] [**-t** [*mm*]][-c [ss]]]

Description

The `rc.powerfail` command is started by the `/etc/inittab` file when `init` receives a SIGPWR signal from the kernel. The `rc.powerfail` command uses `ioctl()` to determine the state of the system. The `rc.powerfail` command should be called only when an EPOW event has occurred.

The various EPOW events handled by `rc.powerfail` and the corresponding event handling done by `rc.powerfail` are listed in the following table:

EPOW class	Event handling done by rc.powerfail	Example
1 These types of errors are considered non-critical cooling problems by the Operating System.	`rc.powerfail` warns the users currently logged onto the system through a `cron` entry which will be walled every 12 hours until the situation disappears.	Redundant Fan Faults. Internal Thermal Problems.
2 These types of errors are considered non-critical power problems by the Operating System.	`rc.powerfail` warns the users currently logged onto the system through a `cron` entry which will be walled every 12 hours until the situation disappears.	Redundant AC input fault.
3 These events are critical in nature and the system should be powered down as soon as possible.	`rc.powerfail` initiates the system shutdown in 10 minutes unless the user has specified some other wait time through the `-t` option.	Ambient temperature approaching specification limit.
4 These kinds of errors are extreme in nature and need an immediate halting of the system.	`rc.powerfail` is expected to process this event in 20 seconds. In these cases, `rc.powerfail` warns the users currently logged onto the system and then immediately halts the system.	Loss of AC input: All the power sources have lost power.
5, 7 These kinds of errors are extreme in nature and should be handled in terms of micro seconds.	Since they should be handled in micro seconds, `rc.powerfail` will not be handling these events. If `rc.powerfail` gets control in these conditions, it will continue to wait out the wait time period.	All the fan systems have failed, non redundant power fault.

As previously mentioned, in case of EPOW class 3 events, the `rc.powerfail` command is given approximately 10 minutes prior to shut down of the system. The user can alter this time by using the `-t` option on the `/etc/inittab` file's powerfail entry. Prior to the last 60 seconds, any users still logged-on are sent a message telling them how much time remains until shutdown. If, at any time in the last 60 seconds, the event clears, the system shutdown halts and the users are notified that all errors have cleared. If a shutdown is not desired, the user may add the `-s` option to the command in the `/etc/inittab` file.

Also in case of EPOW class 3 events, `rc.powerfail` will allow executing environment-specific scripts (if any) to be executed before system shutdown. These scripts will be located under `/usr/lib/scripts/epow`, and `rc.powerfail` will wait for 10 seconds, by default, for their completion. This wait time can be altered using the `-c` option. The value provided through the `-c` option will be taken as the wait time for these scripts, in seconds.

Flags

Item	Description
-h	Gives an information message containing the power status codes and the resulting action. The **rc.powerfail -h** command shuts down the system if needed, as part of EPOW event handling.
-s	Does not do a system shutdown if there is a power failure in systems with either a battery backup or fan fault. The logged-on users still receive all the appropriate messages, but the actual system shutdown is left up to the system administrator. This flag has no effect if a critical power failure is detected.
-t *mm*	Gives the number of whole minutes until system shutdown in the case of a primary power loss with battery backup or fan fault. This number should be equal to half the length of time guaranteed by the battery backup. This flag has no effect if a critical power failure is detected.
-c *ss*	Gives the number of seconds to wait for the completion of any environment specify third party scripts to be executed by rc.powerfail, at EPOW 3 situations.

Exit Status

If the system shuts down, no exit value is returned. Otherwise, the **rc.powerfail** command returns the following exit values:

Item	Description
0	Normal condition.
1	Syntax error.
2	**halt -q** failed
3	**shutdown -F** failed.
4	An error has occurred. Shut your system down immediately using **shutdown -F**.
5	An undefined state. Call your Service Representative.

Security

Access Control: root only.

Examples

1. To look at the cause of a power status equal to 3, enter:

   ```
   rc.powerfail -h
   ```

2. To block system shutdown when non-critical power failures or fan faults occur, enter:

   ```
   chitab "powerfail::powerfail:/etc/rc.powerfail -s >dev/console 2>&1"
   ```

   The next SIGPWR received by **init** will not cause a system shutdown if a non-critical power failure occurs.

3. To change the time until shutdown to 30 minutes, enter:

   ```
   chitab "powerfail::powerfail:/etc/rc.powerfail -t 30 >/dev/console 2>&1"
   ```

   Assuming the condition is not critical, the next SIGPWR received by `init` will have a 30 minute delay until system shutdown.

html	

rc.wpars Command

Purpose

Automatically starts a workload partition.

Syntax

/etc/rc.wpars

Description

The **/etc/rc.wpars** command invokes the **startwpar** command on all workload partitions with the **autostart** option (**mkwpar/chwpar -A**) enabled. The **/etc/rc.wpars** command runs automatically each time the system starts.

rcp Command

Purpose

Transfers files between a local and a remote host or between two remote hosts.

Syntax

rcp [**-p**] [**-F**] [**-k** *realm*] [**-m**] { { *User***@***Host***:***File* | *Host***:***File* | *File* } { *User***@***Host***:***File* | *Host***:***File* | *File* | *User***@***Host***:***Directory* | *Host***:***Directory* | *Directory* } | [**-r**] { *User***@***Host***:***Directory* | *Host***:***Directory* |*Directory* } { *User***@***Host***:***Directory* | *Host***:***Directory* | *Directory* } }

Description

The **/usr/bin/rcp** command is used to copy one or more files between the local host and a remote host, between two remote hosts, or between files at the same remote host.

Remote destination files and directories require a specified *Host***:** parameter. If a remote host name is not specified for either the source or the destination, the **rcp** command is equivalent to the **cp** command. Local file and directory names do not require a *Host***:** parameter.

Note: The **rcp** command assumes that a : (colon) terminates a host name. When you want to use a : in a filename, use a / (slash) in front of the filename or use the full path name, including the /.

If a *Host* is not prefixed by a *User***@** parameter, the local user name is used at the remote host. If a *User***@** parameter is entered, that name is used.

If the path for a file or directory on a remote host is not specified or is not fully qualified, the path is interpreted as beginning at the home directory for the remote user account. Additionally, any metacharacters that must be interpreted at a remote host must be quoted using a \ (backslash), a " (double quotation mark), or a ' (single quotation mark).

File Permissions and Ownership

By default, the permissions mode and ownership of an existing destination file are preserved. Usually, if a destination file does not exist, the permissions mode of the destination file is equal to the permissions

mode of the source file as modified by the **umask** command (a special command in the Korn shell) at the destination host. If the **rcp** command **-p** flag is set, the modification time and mode of source files are preserved at the destination host.

The user name entered for the remote host determines the file access privileges the **rcp** command uses at that host. Additionally, the user name given to a destination host determines the ownership and access modes of the resulting destination file or files.

Using Standard Authentication

The remote host allows access if one of the following conditions is satisfied:

- The local host is included in the remote host **/etc/hosts.equiv** file and the remote user is not the root user.
- The local host and user name is included in a **$HOME/.rhosts** file on the remote user account.

Although you can set any permissions for the **$HOME/.rhosts** file, it is recommended that the permissions of the .rhosts file be set to 600 (read and write by owner only).

In addition to the preceding conditions, the **rcp** command also allows access to the remote host if the remote user account does not have a password defined. However, for security reasons, the use of a password on all user accounts is recommended.

For Kerberos 5 Authentication

The remote host allows access only if all of the following conditions are satisfied:

- The local user has current DCE credentials.
- The local and remote systems are configured for Kerberos 5 authentication (On some remote systems, this may not be necessary. It is necessary that a daemon is listening to the klogin port).
- The remote system accepts the DCE credentials as sufficient for access to the remote account. See the **kvalid_user** function for additional information.

rcp and Named Pipelines

Do not use the **rcp** command to copy named pipelines, or FIFOs, (special files created with the **mknod -p** command). The **rcp** command uses the **open** subroutine on the files that it copies, and this subroutine blocks on blocking devices like a FIFO pipe.

Restrictions

The SP Kerberos V4 rcp execution path does not support remote-to-remote copy as Kerberos does not support forwarding credentials. The message you would receive under these circumstances is the message indicating you do not have tickets and must use **kinit** to login. The message would be issued from the remote source machine. Please see the example below for using Kerberos to perform a remote-to-remote copy.

Flags

Item	Description
-p	Preserves the modification times and modes of the source files in the copies sent to the destination only if the user has root authority or is the owner of the destination. Without this flag, the **umask** command at the destination modifies the mode of the destination file, and the modification time of the destination file is set to the time the file is received. When this flag is not used, the umask being honored is the value stored in the appropriate database. It is not the value that is set by issuing the **umask** command. The permission and ownership values that result from the **umask** command do not affect those stored in the database.
-r	Recursively copies, for directories only, each file and subdirectory in the source directory into the destination directory.

Item	Description
-F	Causes the credentials to be forwarded. In addition, the credentials on the remote system will be marked forwardable (allowing them to be passed to another remote system). This flag will be ignored if Kerberos 5 is not the current authentication method. Authentication will fail if the current DCE credentials are not marked forwardable.
-k *realm*	Allows the user to specify the realm of the remote station if it is different from the local systems realm. For these purposes, a realm is synonymous with a DCE cell. This flag will be ignored if Kerberos 5 is not the current authentication method.
-m	Support for metacharacters in filenames.

Parameters

Item	Description
*Host***:***File*	Specifies the host name (*Host*) and file name (*File*) of the remote destination file, separated by a : (colon). **Note:** Because the **rcp** command assumes that a : (colon) terminates a host name, you must insert a \ (backslash) before any colons that are embedded in the local file and directory names.
*User***@***Host***:***File*	Specifies the user name (*User***@**) that the **rcp** command uses to set ownership of the transferred file, the host name (*Host*), and file name (*File*) of the remote destination file. The user name entered for the remote host determines the file access privileges the **rcp** command uses at that host.
File	Specifies the file name of the local destination file.
*Host***:***Directory*	Specifies the host name (*Host*) and directory name (*Directory*) of the remote destination directory. **Note:** Because the **rcp** command assumes that a : (colon) terminates a host name, you must insert a \ (backslash) before any colons that are embedded in the local file and directory names.
*User***@***Host***:***Directory*	Specifies the user name (*User***@**) the **rcp** command uses to set ownership of the transferred file, the host name (*Host*), and directory name (*Directory*) of the remote destination directory. The user name entered for the remote host determines the file access privileges the **rcp** command uses at that host.
Directory	The directory name of the local destination directory.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

The remote host allows access only if at least one of the following conditions is satisfied:

- The local user ID is listed as a principal in the authentication database and had performed a **kinit** to obtain an authentication ticket.

- If a **$HOME/.klogin** file exists, it must be located in the local user's **$HOME** directory on the target system. The local user must be listed as well as any users or services allowed to **rsh** into this account. This file performs a similar function to a local .**rhosts** file. Each line in this file should contain a principal in the form of "principal.instance@realm." If the originating user is authenticated as one of the principals named in .**klogin**, access is granted to the account. The owner of the account is granted access if there is no .**klogin** file.

For security reasons, any **$HOME/.klogin** file must be owned by the remote user and only the AIX owner ID should have read and write access (permissions = 600) to .**klogin**.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

In the following examples, the local host is listed in the **/etc/hosts.equiv** file at the remote host.

1. To copy a local file to a remote host, enter:

   ```
   rcp localfile host2:/home/eng/jane
   ```

   The file `localfile` from the local host is copied to the remote host `host2`.
2. To copy a remote file from one remote host to another remote host, enter:

   ```
   rcp host1:/home/eng/jane/newplan host2:/home/eng/mary
   ```

   The file `/home/eng/jane/newplan` is copied from remote host `host1` to remote host `host2`.
3. To send the directory subtree from the local host to a remote host and preserve the modification times and modes, enter:

   ```
   rcp  -p  -r report jane@host2:report
   ```

   The directory subtree `report` is copied from the local host to the home directory of user `jane` at remote host `host2` and all modes and modification times are preserved. The remote file **/home/jane/.rhosts** includes an entry specifying the local host and user name.
4. This example shows how the root user can issue an **rcp** on a remote host when the authentication is Kerberos 4 on both the target and server. The root user must be in the authentication database and must have already issued **kinit** on the local host. The command is issued at the local host to copy the file, stuff, from node r05n07 to node r05n05 on an SP.

   ```
   /usr/lpp/ssp/rcmd/bin/rsh r05n07 'export KRBTKTFILE=/tmp/rcmdtkt$$; \
   /usr/lpp/ssp/rcmd/bin/rcmdtgt; \
   /usr/lpp/ssp/rcmd/bin/rcp /tmp/stuff r05n05:/tmp/stuff;'
   ```

   The root user sets the KRBTKTFILE environment variable to the name of a temporary ticket-cache file and then obtains a service ticket by issuing the **rcmdtgt** command. The **rcp** uses the service ticket to authenticate from host r05n07 to host r05n05.

Files

Item	Description
$HOME/.klogin	Specifies remote users that can use a local user account.
/usr/lpp/ssp/rcmd/bin/rcp	Link to AIX Secure **/usr/bin/rsh** that calls the SP Kerberos 4 **rcp** routine if applicable.

Prerequisite Information

Refer to the chapter on security in IBM *Parallel System Support Programs for AIX*: Administration Guide for an overview. You can access this publication at the following Web site: *http://www.rs6000.ibm.com/resource/aix_resource*

Refer to the "RS/6000 SP Files and Other Technical Information" section of IBM Parallel System Support Programs for AIX: Command and Technical Reference for additional Kerberos information. You can access this publication at the following Web site: *http://www.rs6000.ibm.com/resource/aix_resource*

rcvdist Command

Purpose

Sends a copy of incoming messages to additional recipients.

Syntax

rcvdist [**-form** *File*] *User ...*

Description

The **rcvdist** command forwards copies of incoming messages to users in addition to the original recipient. The **rcvdist** command is not started by a user. The **rcvdist** command is placed in the **.maildelivery** file called by the **/usr/lib/mh/slocal** command.

The **rcvdist** command sends a copy of an incoming message to the user or users specified by the *User* parameter. The default string is located in the **rcvdistcomps** file. This file formats the output from the command and sends it through the **send** command to the ID or alias specified.

You can copy the **rcvdistcomps** file into your local mail directory and change the string to suit your needs. The Message Handler (MH) package uses the **rcvdistcomps** file in your local mail directory first. Otherwise, you can use the **-form** flag to specify a file name that contains the string you want.

Flags

Item	Description
-form *File*	Specifies the file that formats the command output. The default is the **rcvdistcomps** file.
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For MH, the name of this flag must be fully spelled out.

Files

Item	Description
$HOME/.maildelivery	Provides the user with MH instructions for local mail delivery.
$HOME/.forward	Provides the user with the default message filter.

rcvpack Command

Purpose

Saves incoming messages in a packed file.

Syntax

rcvpack [*File*]

Description

The **rcvpack** command places incoming messages in the packed file specified by the *File* parameter. The **rcvpack** command is not started by the user. The **rcvpack** command is placed in the **$HOME/ .maildelivery** file runs the **rcvpack** command on all incoming messages.

Flags

Item	Description
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For MH, the name of this flag must be fully spelled out.

Files

Item	Description
$HOME/html	

rcvstore Command

Purpose

Incorporates new mail from standard input into a folder.

Syntax

rcvstore [**+***Folder*] [**-create** | **-nocreate**] [**-sequence** *Name*] [**-public** | **-nopublic**] [**-zero** | **-nozero**]

Description

The **rcvstore** command adds incoming messages to a specified message directory (a folder). The **rcvstore** command is not started by the user. The **rcvstore** command is placed in the **$HOME/**.maildelivery file.

You can specify **rcvstore** command flags in the **$HOME/** .mh_profile file.

Flags

Item	Description
-create	Creates the specified folder in your mail directory if the folder does not exist. This flag is the default.
+*Folder*	Places the incorporated messages in the specified folder. The default is +inbox.
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For MH, the name of this flag must be fully spelled out.
-nocreate	Does not create the specified folder if the folder does not exist.
-nopublic	Restricts the specified sequence of messages to your usage. The **-nopublic** flag does not restrict the messages in the sequence, only the sequence. This flag is the default if the folder is write-protected against other users.

Item	Description
-nozero	Appends the messages incorporated by the **rcvstore** command to the specified sequence of messages. This flag is the default.
-public	Makes the specified sequence of messages available to other users. The **-public** flag does not make protected messages available, only the sequence. This flag is the default if the folder is not write-protected against other users.
-sequence *Name*	Adds the incorporated messages to the sequence of messages specified by the *Name* parameter.
-zero	Clears the specified sequence of messages before placing the incorporated messages into the sequence. This flag is the default.

Profile Entries

Item	Description
`Folder-Protect:`	Sets the protection level for your new folder directories.
`Msg-Protect:`	Sets the protection level for your new message files.
`Path:`	Specifies the *UserMHDirectory* (the user's MH directory) variable.
`Unseen-Sequence:`	Specifies the sequences of commands used to keep track of your unseen messages.
`Rcvstore:`	Specifies flags for the **rcvstore** program.

Files

Item	Description
$HOME/.maildelivery	Provides the user with MH instructions for local mail delivery.
$HOME/.forward	Provides the user with the default message filter.

rcvtty Command

Purpose

Notifies the user of incoming messages.

Syntax

rcvtty [*Command*]

Description

The **rcvtty** command sends the user a message that incoming mail has arrived. The **rcvtty** command is not started by the user. The **rcvtty** command is placed in the **.maildelivery** file.

Flags

Item	Description
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For MH, the name of this flag must be fully spelled out.

Files

Item	Description
$HOME/$HOME/.mh_profile	Contains the MH user profile.

rdist Command

This document describes the old AIX **rdist** command located in the **/usr/bin/rdist** file as well as the new **/usr/sbin/rdist** command which is used with the new **rdistd** daemon.

/usr/bin/rdist Command

Purpose

Remote file distribution client program.

Syntax

To Use a Distribution File

rdist [**-n**] [**-q**] [**-b**] [**-D**] [**-R**] [**-h**] [**-i**] [**-v**] [**-w**] [**-y**] [**-f** *FileName*] [**-d** *Argument*=*Value*] [**-m** *Host*] ... [*Name*] ...

To Interpret Arguments as a Small Distribution File

rdist [**-n**] [**-q**] [**-b**] [**-D**] [**-R**] [**-h**] [**-i**] [**-v**] [**-w**] [**-y**] **-c** *Name ...* [*Login***@**] *Host* [**:***Destination*]

Description

Attention: Do not attempt to use the **rdist** command to send a file larger than 2 Gigabytes in size to a non-AIX machine. Doing so results in undefined behaviors and, in rare cases, the loss of data.

The **rdist** command maintains identical copies of files on multiple hosts. The **rdist** command preserves the owner, group, mode, and modified time of files, if possible, and can update programs that are running. The **rdist** command can receive direction from the following sources:

- The default distribution file, **distfile** file in your **$HOME** directory.
- A different distribution file, specified by the **-f** flag.
- Command-line arguments that augment or override variable definitions in the distribution file.
- Command-line arguments that serve as a small distribution file.

If you do not use the **-f** flag, the **rdist** command looks for the **distfile** file in your **$HOME** directory. If it doesn't find a **distfile** file, it looks for **Distfile** file.

The value specified by the *Name* parameter is read as the name of a file to be updated or a subcommand to execute. If you do not specify a value for the *Name* parameter on the command line, the **rdist** command updates all the files and directories listed in the distribution file. If you specify **-** (minus sign) for the *Name* parameter, the **rdist** command uses standard input. If the name of a file specified by the *Name* parameter is the same as the name of a subcommand, the **rdist** command interprets the *Name* parameter as a subcommand.

The **rdist** command requires that a **.rhosts** file be configured on each host. See File Format for TCP/IP in *Files Reference* for details.

Note:

1. If the **rdist** command is not present in the **/usr/bin/rdist** directory on a remote machine, create a link from the **/usr/bin/rdist** directory to the actual location of the **rdist** command. This location is usually the **/usr/ucb/rdist** directory.
2. Currently, the **rdist** command can handle only 7-bit ASCII file names.

Flags

Item	Description
-b	Performs a binary comparison and updates files if they differ.
-c	Directs the **rdist** command to interpret the remaining arguments as a small distribution file. Available arguments are: ***Name*** Specifies single name or list of names separated by blanks. The value can be either a file or a subcommand. **[*Login*@]*Host*** Specifies the machine to be updated and, optionally, the login name to be notified of the update. ***Destination*** Specifies a file on the remote machine if a single name is specified in the *Name* argument; specifies a directory if more than one name is specified. **Note:** Do not use the **-c** flag with the **-f**, **-d**, or **-m** flag.
-d *Argument*=*Value*	Defines the *Argument* variable as having the value specified by the *Value* variable. The **-d** flag defines or overrides variable definitions in the **distfile** file. The *Value* variable can be specified as an empty string, one name, or a list of names surrounded by parentheses and separated by tabs or spaces.
-D	Turns on the debugging output.
-f *FileName*	Specifies the name of the distribution file. If you do not use the **-f** flag, the default value is the **distfile** or **Distfile** file in your **$HOME** directory.
-h	Copies the file that the link points to rather than the link itself.
-i	Ignores unresolved links. The **rdist** command maintains the link structure of files being transferred and warns users if it cannot find all the links.
-m *Host*	Limits which machines are to be updated. You can use the **-m** *Host* option multiple times to limit updates to a subset of the hosts listed in the **distfile** file.
-n	Prints the subcommands without executing them. Use the **-n** flag to debug the **distfile** file.
-q	Operates in quiet mode. The **-q** option suppresses printing of modified files on standard output.
-R	Removes extraneous files. If a directory is being updated, any files that exist on the remote host but not in the master directory are removed. Use the **-R** flag to maintain identical copies of directories.
-v	Verifies that the files are up-to-date on all hosts; files that are out-of-date are then displayed. However, the **rdist -v** command neither changes files nor sends mail. This flag overrides the **-b** flag when they are used together.
-y	Prevents recent copies of files from being replaced by files that are not as recent. Files are normally updated when their time stamp and size differ. The **-y** flag prevents the **rdist** command from updating files more recent than the master file.
-w	Appends the entire path name of the file to the destination directory name. Normally, the **rdist** command uses only the last component of a name for renaming files, preserving the directory structure of the copied files. When the **-w** flag is used with a file name that begins with a ~ (tilde), everything except the home directory is appended to the destination name. File names that do not begin with a / (slash) or a ~ (tilde) use the destination user's home directory as the root directory for the rest of the file name.

Distribution File (distfile File)

The distribution file specifies the files to copy, destination hosts for distribution, and operations to perform when updating files to be distributed with the **rdist** command. Normally, the **rdist** command uses the **distfile** file in your **$HOME** directory. You can specify a different file If you use the **-f** flag.

Entry Formats

Each entry in the distribution file has one of the following formats:

Item	Description
VariableName **=** *NameList*	Defines variables used in other entries of the distribution file (*SourceList*, *DestinationList*, or *SubcommandList*).
[*Label***:**] *SourceList* **->** *DestinationList SubcommandList*	Directs the **rdist** command to distribute files named in the *SourceList* variable to hosts named in the *DestinationList* variable. Distribution file commands perform additional functions.
[*Label***:**] *SourceList* **::** *TimeStampFile SubcommandList*	Directs the **rdist** command to update files that have changed since a given date. Distribution file subcommands perform additional functions. Each file specified with the *SourceList* variable is updated if the file is newer than the time-stamp file. This format is useful for restoring files.

Labels are optional and used to identify a subcommand for partial updates.

Entries

Item	Description
VariableName	Identifies the variable used in the distribution file.
NameList	Specifies a list of files and directories, hosts, or subcommands.

Item	Description
SourceList	Specifies files and directories on the local host for the **rdist** command to use as the master copy for distribution.
DestinationList	Indicates hosts to receive copies of the files.
SubcommandList	Lists distribution file subcommands to be executed.

The **rdist** command treats new-line characters, tabs, and blanks as separators. Distribution file variables for expansion begin with a $ (dollar sign) followed by a single character or a name enclosed in {} (braces). Comments begin with a # (pound sign) and end with a new-line character.

Source and Destination List Format

The distribution file source and destination lists comprise zero or more names separated by blanks, as shown in the following format:

[*Name1*] [*Name2*] [*Name3*] ...

The **rdist** command recognizes and expands the following shell metacharacters on the local host in the same way as for the **csh** command.

- [(left bracket)
-] (right bracket)
- { (left brace)
- } (right brace)
- ((left parenthesis)
-) (right parenthesis)
- * (asterisk)
- ? (question mark)

To prevent these characters from being expanded, precede them with a \ (backslash). The **rdist** command also expands the ~ (tilde) in the same way as for the **csh** command, but does so separately on the local and destination hosts.

Distribution File Subcommands

Multiple commands to the shell must be separated by a ; (semicolon). Commands are executed in the user's home directory on the host being updated. The **special** subcommand can be used to rebuild private databases after a program has been updated.

The distribution file subcommand list may contain zero or more of the following subcommands:

Item	Description
install *Options* [*OptionalDestName*]**;**	Copies out-of-date files and directories. The **rdist** command copies each source file or directory to each host in the destination list. The available options as specified by the *Options* variable are the **rdist** command flags **-b**, **-h**, **-i**, **-R**, **-v**, **-w**, and **-y**. These options only apply to the files specified by the *SourceList* variable. When you use the **-R** flag, nonempty directories are removed if the corresponding file name is absent on the master host. The *OptionalDestName* parameter renames files. If no **install** subcommand appears in the subcommand list or the destination name is not specified, the source file name is used. Directories in the path name are created if they do not exist on the remote host. The login name used on the destination host is the same as the local host unless the destination name is of the format *login***@***host*.
notify *NameList***;**	Mails the list of updated files and any errors that may have occurred to the listed names (the *NameList* parameter). If no **@** (at sign) appears in the name, the destination host is appended to the name (*name***@***host*).
except *NameList***;**	Causes the **rdist** command to update all the files specified by the *SourceList* entry except for those files specified by the *NameList* variable.
except_pat *NameList***;**	Prevents the **rdist** command from updating any files that contain a string that matches a member of the list specified by the *NameList* variable.
special *NameList* **"***String***";**	Specifies shell commands (the **"***String***"** variable) to be executed on the remote host after the file specified by the *NameList* variable is updated or installed. If the *NameList* variable is omitted, the shell commands are executed for every file updated or installed. The shell variable **FILE** is set to the current file name before the **rdist** command executes the **"***String***"** variable. The **"***String***"** value must be enclosed in **" "** (double quotation marks) and can cross multiple lines in the distribution file.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	Specifies that an error occurred.

Examples

Examples of the Format: VariableName = NameList

1. To indicate which hosts' files to update, enter a line similar to the following:

```
HOSTS =( matisse root@arpa )
```

   where the HOSTS variable is defined to be `matisse` and `root@arpa`. The **rdist** command updates files on the hosts `matisse` and `root@arpa`. You could use this variable as a destination list.

2. To indicate a name to use as a value for a *SourceList* entry, enter a line similar to the following:

```
FILES = ( /bin /lib/usr/bin /usr/games
    /usr/include/{*.h,{stand,sys,vax*,pascal,machine}/*.h}
       /usr/lib /usr/man/man? /usr/ucb /usr/local/rdist )
```

   where the FILES value is defined to be the files to be used for the *SourceList* entry.

3. To indicate which files to exclude from the updating process, enter a line similar to the following:

```
EXLIB = ( Mail.rc aliases aliases.dir aliases.pag crontab dshrc
    sendmail.cf sendmail.fc sendmail.hf sendmail.st uucp vfont)
```

   where the EXLIB value is defined as a list of files to exclude from the updating process.

4. To copy all files from **/usr/src/bin** to **arpa** expanding the *namelist* variable so that all files except those present in the *namelist* variable and having `.o` as an extension are copied:

```
/usr/src/bin ->arpa
except_pat(\e\e.o\e ${<namelist> /SCCS\e ${<namelist>}
```

   or

```
/usr/src/bin ->arpa
except_pat(\\.o\e ${<namelist> /SCCS\e ${<namelist>}
```

5. To copy all files from **/usr/src/bin** to **arpa** except those with an `.o` extension:

```
/usr/src/bin ->arpa
except_pat(\\.o\$ /SCCS\$
```

Examples of the Format: [label:] SourceList - DestinationList SubcommandList

1. To copy a source list of files to a destination list of hosts, enter a line similar to the following:

```
${FILES} ->${HOSTS}
    install -R
    except /usr/lib/${EXLIB}  ;
    except /usr/games/lib  ;
    special /usr/sbin/sendmail "/usr/sbin/sendmail.bz"  ;
```

   The [*Label***:**] entry of the line is optional and not shown here. The $ (dollar sign) and the {} (braces) cause the file names FILES, HOSTS, and EXLIB to be expanded into the lists designated for them in the previous examples. The rest of the example comprises the subcommand list.

2. To use the [*Label***:**] entry, enter the line as follows:

```
srcsL:
/usr/src/bin -> arpa
    except_pat (\e\e.o\e$ /SCCS\e$ ) ;
```

The label is `srcsL:` and can be used to identify this entry for updating. The `/usr/src/bin` file is the source to be copied and host `arpa` is the destination of the copy. The third line contains a subcommand from the subcommand list.

3. To use a time-stamp file, enter a line similar to the following:

```
${FILES} :: stamp.cory
    notify root@cory
```

The $ (dollar sign) and {} (braces) cause the name specified by `FILES` to be expanded into the list designated for it. The time-stamp file is `stamp.cory`. The last line is a subcommand from the subcommand list.

Files

Item	Description
/usr/bin/rdist	Contains the **rdist** command.
$HOME/distfile	Contains a list of subcommands to be read by the **rdist** command.
/tmp/rdist	Contains an update list. This is a temporary file.

/usr/sbin/rdist Command

This document describes the old AIX **rdist** command located in the **/usr/bin/rdist** file as well as the new **/usr/sbin/rdist** command which is used with the new **rdistd** daemon.

Purpose (/usr/sbin/rdist)

Client program for distributing files remotely.

Syntax (/usr/sbin/rdist)

To Use a Distribution File

/usr/sbin/rdist [**-F n**] [**-A** *num*] [**-a** *num*] [**-d** *var=value*] [**-l** < *local logopts*>] [**-L** <*remote logopts*>] [**-f** *distfile*] [**-M** *maxproc* **-m** *host*] [**-o** *distops*] [**-t** *timeout*] [**-p** <*rdist-path*>] [**-P** <*transport-path*>] [*name* ...]

To Interpret Arguments as a Small Distribution File

/usr/sbin/rdist -Fn -c *name* ... [*login@*] *host* [*:dest*]

To Invoke the Old rdist as a Server

/usr/sbin/rdist -Server

For Version Information

/usr/sbin/rdist -V

Description (/usr/sbin/rdist)

rdist is a program to maintain identical copies of files over multiple hosts. It preserves the owner, group, mode, and modification time of files if possible and can update programs that are running. The **rdist** command can receive direction from the following sources:

- The distribution file **distfile** in the current directory.
- The standard input if **distfile** is specified as -.
- If the **-f** flag is not used, **rdist** looks for the file named *distfile* and *Distfile*.

- If the **-c** flag is used, the trailing arguments are interpreted as a small **distfile**. The equivalent **distfile** is as follows.

```
( filename ... ) -> [user@]host
     install       [dest name] ;
```

If no **name** arguments are specified, **rdist** will update all of the files and directories listed in **distfile**. Otherwise, the argument is taken to be the name of a file to be updated or the label of a command to execute. If the label and file names conflict, it is assumed to be a label. These may be used together to update specific files using specific commands.

The **-Server** option provides backward compatibility for older versions of **rdist** which used this option to put **rdist** into server mode. If **rdist** is started with the **-Server** command line option, it will attempt to run the old version of **rdist**. This option will only work if the old **rdist** is located at **/usr/bin/rdist**.

rdist uses an arbitrary transport program to access each target host. The transport program can be specified on the command line with the **-P** flag. If the **-P** flag is not used, **rsh** is taken as the transport program. If the **rsh** method is used and the target host is the string **localhost** and the remote user name is the same as the local user name, **rdist** will attempt to run the following command:

```
/bin/sh -c rdistd -S
```

Otherwise **rdist** will run the following command:

```
rsh host -l remuser rdistd -S
```

In the example above, the *host* parameter is the name of the target host, *remuser* is the name of the user to make the connection as and, **rdistd** is the **rdist** server command on the target host.

The transport program must be compatible with the above syntax for **rsh**. If not, the transport program should be wrapped in a shell script which understands this command line syntax.

On each target host **rdist** will run the following command:

```
rdistd -S
```

or

```
<rdistd path> -S
```

In the example above, the **-p** flag was specified. If **-p** flag is not included, or the <rdistd path> is a simple filename, **rdistd** or <rdistd path> must be somewhere in the **PATH** of the user running **rdist** on the remote (target) host.

The **rdist** command uses the following environment variables:

Item	Description
TMPDIR	Name of temporary directory to use. Default is **/tmp**.

Flags (/usr/sbin/rdist)

Item	Description
-A *num*	Update or install files only if a minimum number of free files (inodes) exists on a filesystem.
-a *num*	Update or install files only if a minimum amount of free space exists on a filesystem.
-d *var = value*	Assign *value* to variable *var*. This option is used to define or override variable definitions in the **distfile**. *Value* can be the empty string, one name, or a list of names surrounded by parentheses and separated by tabs and/or spaces.
-F	Update all clients sequentially without forking child processes.
-f *distfile*	Use **distfile** as the distribution file. If **distfile** is specified as **-**, read from standard input.
-l *logopts*	Sets local logging options. See the **Message Logging** section for more information on the syntax for *logopts*.
-L *logopts*	Sets remote logging options. *logopts* is the same as for local logging except the values are passed to the remote server (**rdistd**). See the **Message Logging** section for more information on the syntax of *logopts*.
-M *num*	Limit the maximum number of simultaneously running child **rdist** processes to *num*. The default is 4.

Item	Description
-m *machine*	Limits the updating of files to the given machine. Multiple **-m** arguments can be given to limit updates to a subset of the hosts listed in the **distfile**.
-n	Display but do not execute commands. Use the **-n** flag to debug **distfile**.
-o *distopts*	Specifies the dist options to enable. *distopts* is a comma separated list of options listed below. The valid values for *distopts* are: **chknfs** If the target filesystem is NFS, do not check or update files. **chkreadonly** If a file on the target host resides on a read only filesystem, no checking or updating of the file is attempted. **chksym** If the target on the remote host is a symbolic link, but is not on the master host, the remote target will be left a symbolic link. **compare** Perform a binary comparison and update files if they differ. **follow** Copy the file that the symbolic link points to rather than the link itself. **ignlnks** Ignore links which do not resolve. The normal behavior of **rdist** is to warn the user about unresolved links. **nochkowner** If the file already exists, do not check user ownership. The file ownership is only set when the file is updated. **nochkgroup** If the file already exists, do not check group ownership. The file ownership is only set when the file is updated. **nochkmode** Avoid checking file and directory permission modes. The permission mode is only set when the file is updated. **nodescend** Do not descend recursively into a directory. Only the existence, ownership, and mode of the directory are checked. **noexec** Do not check or update executable files that are in **a.out** format. **numchkgroup** Use the numeric group id (gid) to check group ownership instead of the group name. **numchkowner** Use the numeric user id (uid) to check user ownership instead of the user name. **quiet** Supress printing files that are being modified on the standard output. **remove** Remove any files in directories that exist on the remote host that do not exist in the master directory on the local host. **savetargets** Save files that are updated instead of removing them. Target files that are updated are first renamed from **filename** to **filename.OLD**. **sparse** Enable checking for sparse files. This option adds some additional processing overhead so it should only be enabled for targets likely to contain sparse files.
-o *distopts*	*(dist options, continued)*: **verify** Any file on any host that is out of date will be displayed but no file will be changed nor any mail sent. **whole** The whole file name is appended to the destination directory name. Normally, only the last component of a name is used when renaming files. This will preserve the directory structure of the files being copied instead of flattening the directory structure. For example, rdisting a list of files such as **/path/dir1/f1** and **/path/dir2/f2** to **/tmp/dir** would create files **/tmp/dir/path/dir1/f1** and **/tmp/dir/path/dir2/f2** instead of **/tmp/dir/dir1/f1** and **/tmp/dir/dir2/f2**. **younger** Files are normally updated if their *mtime* and *size* disagree. This option causes **rdist** not to update files that are younger than the master copy. This can be used to prevent newer copies on other hosts from being replaced. A warning message is printed for files which are newer than the master copy.
-p <*rdist-path*>	Search for the **rdistd** server in the given path on the target host.
-P <*rdist-path*>	Use the transport program as given in *transport-path*. The *transport-path* may be a colon seperated list of possible pathnames. In this case, the first component of the path to exist is used.
-t *timeout*	Sets the *timeout* period (in seconds) for waiting for responses from the remote **rdist** server. The default is 900 seconds.
-V	Prints the version information and exits.

Message Logging

The **rdist** command provides a set of message facilities, each of which contains a list of message types specifying which types of messages to send to that facility. The local client (**rdist**) and the remote server (**rdistd**) each maintain separate copies of what types of messages to log to what facilities.

The **-l** *logopts* flag specifies what logging options to use locally on the client. The **-L** *logopts* flag specifies what logging options to pass to the remote **rdistd** server.

The form of *logopts* should be the following:

```
facility=types:facility= types...
```

The valid facility names are as follows:

stdout
Messages to standard output.

file
Messages are sent to a file. The file name can be specified by the format **file** = *filename* = *types*.

syslog
Messages are sent to the **syslogd** facility.

notify
Messages are sent to the internal **rdistnotify** facility. This facility is used in conjunction with the **notify** ph in a **distfile** to specify what messages are mailed to the **notify** address.

types should be a comma separated list of message types. Each message type specified enables that message level. This is unlike the **syslog** system facility which uses an ascending order scheme. The following are the valid types:

change
Log messages for things that change.

info
Log general information.

notice
Log messages for general info about things that change. This includes things like making directories which are needed in order to install a specific target, but which are not explicitly specified in the **distfile**.

nerror
Log messages for normal errors that are not fatal.

ferror
Log messages for fatal errors.

warning
Log warnings about errors which are not as serious as **nerror** type messages.

verbose
Log messages for more information than normal, but less than debugging level.

debug
Log debugging information.

all
Log all but debug messages.

Distribution File (/usr/sbin/rdist)

The distribution file specifies the files to copy, destination hosts for distribution, and operations to perform when updating files to be distributed with the **rdist** command.

Entry Formats

Each entry in the distribution file has one of the following formats:

VariableName = NameList
Defines variables used in other entries of the distribution file (*SourceList*, *DestinationList*, or *SubcommandList*).

[Label:] SourceList -> DestinationList SubcommandList
Directs the **rdist** command to distribute files named in the *SourceList* variable to hosts named in the *DestinationList* variable.

Distribution file commands perform additional functions.

[Label:] SourceList :: TimeStampFile SubcommandList

Directs the **rdist** command to update files that have changed since a given date. Distribution file subcommands perform additional functions.

Each file specified with the *SourceList* variable is updated if the file is newer than the time-stamp file.

Labels are optional. They are used to identify a command for partial updates.

Entries

Item	Description
VariableName	Identifies the variable used in the distribution file.
NameList	Specifies a list of files and directories, hosts, or subcommands.
SourceList	Specifies files and directories on the local host for the **rdist** command to use as the master copy for distribution.
DestinationList	Indicates hosts to receive copies of the files.
SubcommandList	Lists distribution file subcommands to be executed.

The **rdist** command treats newline characters, tabs, and blanks as separators. Distribution file variables for expansion begin with a dollar sign followed by a single character or a name enclosed in braces.

Comments begin with a pound sign and end with a newline character.

Source and Destination List Format

The distribution file source and destination lists comprise zero or more names separated by blanks, as shown in the following format:

```
[Name1] [Name2] [Name3] ...
```

The **rdist** command recognizes and expands the following shell metacharacters on the local host in the same way as for the **csh** command.

- [left bracket
-] right bracket
- { left brace
- } right brace
- (left parenthesis
-) right parenthesis
- * asterisk
- ? question mark

To prevent these characters from being expanded, precede them with a backslash. The **rdist** command also expands the tilde in the same way as for the **csh** command, but does so separately on the local and destination hosts. When the **-o** *whole* option is used with a file name that begins with a tilde, everything except the home directory is appended to the destination name. File names which do not begin with a forward slash or a tilde use the destination user's home directory as the root directory for the rest of the file name.

Distribution File Subcommands

Multiple commands to the shell must be separated by a semicolon. Commands are executed in the user's home directory on the host being updated. The special subcommand can be used to rebuild private databases after a program has been updated.

The distribution file subcommand list may contain zero or more of the following subcommands:

install Options[OptionalDestName];

Copies out-of-date files and directories. The **rdist** command copies each source file or directory to each host in the destination list.

The available options as specified by the *Options* variable are the **rdist** command flags **-b**, **-h**, **-i**, **-R**, **-v**, **-w**, and **-y**.

These options only apply to the files specified by the *SourceList* variable.

When you use the **-R** flag, nonempty directories are removed if the corresponding file name is absent on the master host. The *OptionalDestName* parameter renames files.

If no install subcommand appears in the subcommand list or the destination name is not specified, the source file name is used. Directories in the path name are created if they do not exist on the remote host.

The login name used on the destination host is the same as the local host unless the destination name is of the format login@host.

notify NameList;
Mails the list of updated files and any errors that may have occurred to the listed names (the *NameList* parameter).

If no @ (at sign) appears in the name, the destination host is appended to the name (name@host).

except NameList;
Causes the **rdist** command to update all the files specified by the *SourceList* entry except for those files specified by the *NameList* variable.

except_pat NameList;
Prevents the **rdist** command from updating any files that contain a string that matches a member of the list specified by the *NameList* variable.

special NameList "String";
Specifies shell commands (the "String" variable) to be executed on the remote host after the file specified by the *NameList* variable is updated or installed.

If the *NameList* variable is omitted, the shell commands are executed for every file updated or installed.

The shell variable FILE is set to the current file name before the **rdist** command executes the "String" variable.

The variable REMFILE will contain the full pathname of the remote file that was just updated and the variable BASEFILE will contain the basename of the remote file that was just updated.

The "String" value must be enclosed in double quotation marks and can cross multiple lines in the distribution file.

cmdspecial NameList "String";
The **cmdspecial** command is similar to the **special** command, except it is executed only when the entire command is completed instead of after each file is updated.

The shell variable FILES will contain the list of files. Each file name in the FILES shell variable is separated by a colon.

NFS checks are disabled if a hostname ends in a plus sign. This is equivalent to disabling the **-o** *chknfs* option just for this one host.

Exit Status (/usr/sbin/rdist)

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples (/usr/sbin/rdist)

1. To indicate which hosts' files to update, enter a line similar to the following:

```
HOSTS =( matisse root@arpa )
```

In the above example, the HOSTS variable is defined to be matisse and root@arpa. The **rdist** command updates files on the hosts matisse and root@arpa.

You could use this variable as a destination list.

2. To indicate a name to use as a value for a SourceList entry, enter a line similar to the following:

```
FILES = ( /bin /lib/usr/bin /usr/games
    /usr/include/{*.h,{stand,sys,vax*,pascal,machine}/*.h}
       /usr/lib /usr/man/man? /usr/ucb /usr/local/rdist )
```

In the above example, the FILES value is defined to be the files to be used for the *SourceList* entry.

3. To indicate which files to exclude from the updating process, enter a line similar to the following:

```
EXLIB = ( Mail.rc aliases aliases.dir aliases.pag crontab dshrc
    sendmail.cf sendmail.fc sendmail.hf sendmail.st uucp vfont)
```

In the above example, the EXLIB value is defined as a list of files to exclude from the updating process.

4. To copy all files from /usr/src/bin to arpa expanding the namelist variable so that all files except those present in the namelist variable and having .o as an extension are copied:

```
/usr/src/bin ->arpa
except_pat(\e\e.o\e ${<namelist> /SCCS\e ${<namelist>}
```

or

```
/usr/src/bin ->arpa
except_pat(\\.o\e ${<namelist> /SCCS\e ${<namelist>}
```

5. To copy all files from /usr/src/bin to arpa except those with an .o extension:

```
/usr/src/bin ->arpa
except_pat(\\.o\$ /SCCS\$
```

Examples of the Format: [label:] SourceList - DestinationList SubcommandList

1. To copy a source list of files to a destination list of hosts, enter a line similar to the following:

```
${FILES} ->${HOSTS}
    install -R
    except /usr/lib/${EXLIB}  ;
    except /usr/games/lib  ;
    special /usr/sbin/sendmail "/usr/sbin/sendmail.bz"  ;
```

The [Label:] entry of the line is optional and not shown here. Thedollar sign and the braces cause the file names FILES, HOSTS, and EXLIB to be expanded into the lists designated for them in the previous examples.

The rest of the example comprises the subcommand list.

2. To use the [Label:] entry, enter the line as follows:

```
srcsL:
/usr/src/bin -> arpa
    except_pat (\e\e.o\e$ /SCCS\e$ ) ;
```

The label is srcsL: and can be used to identify this entry for updating. The **/usr/src/bin** file is the source to be copied and host arpa is the destination of the copy.

The third line contains a subcommand from the subcommand list.

3. To use a time-stamp file, enter a line similar to the following:

```
${FILES} :: stamp.cory
    notify root@cory
```

The dollar sign and braces cause the name specified by FILES to be expanded into the list designated for it. The time-stamp file is **stamp.cory**.

The last line is a subcommand from the subcommand list.

Files (/usr/sbin/rdist)

Item	Description
/usr/sbin/rdist	Contains the **rdist** command at version 6.1.5.
distfile	Contains the input commands.
$ TMPDIR/rdist*	The temporary file for update lists.

rdistd Command

Purpose

Server program for distributing files remotely.

Syntax

```
rdistd -S
rdistd -V
```

Description

rdistd is the server program for the **rdist** command. It is normally run by **rdist** through **rsh**.

The **-S** flag ensures that **rdistd** is not accidentally started since it normally resides in a normal user's PATH environment variable.

Flags

Item	Description
-V	Print version information and exit.

Exit Status

This command returns the following exit values:

0
Successful completion.

>0
An error occurred.

Files

Item	Description
/usr/sbin/rdistd	Containsthe **rdistd** server
/usr/bin/rdistd	Symbolic link to **/usr/sbin/rdistd**

rdump Command

Purpose

Backs up files onto a remote machine's device.

Note: User must have root authority to run this command.

Syntax

rdump [**-b** *Blocks*] [**-B**] [**-c**] [**-d** *Density*] [**-L** *Length*] [**-s** *Size*] [**-u**] [**-w**] [**-W**] [**-***Level*] **-f** *Machine***:***Device* [*FileSystem* | *DeviceName*]

Description

The **rdump** command copies file systems by i-node from your local machine to a remote machine. The files are copied, using the **backup** command format, to a device on the remote machine. The device is accessed by using a remote server on the remote machine. You must have root authority to execute the **rdump** command. You must also define a local machine running the **rdump** command in the **/.rhosts** file of the target remote machine.

To back up a file system, specify the **-***Level* and *FileSystem* parameters to indicate the files you want to back up. You can use the **-***Level* parameter to back up either all files on the system (a full backup) or only the files that have been modified since a specific full backup (an incremental backup). The possible levels are 0 to 9. If you do not supply a level, the default level is 9. A level 0 backup includes all files on the file system. A level *n* backup includes all files modified since the last level *n* - 1 (*n* minus 1) backup. The levels, in conjunction with the **-u** flag, provide a method of maintaining a hierarchy of incremental backups for each file system.

Note:

1. Use the **-u** flag when you perform an incremental backup (the **-***Level* parameter) to ensure that information regarding the last date, time, and level of each incremental backup is written to the **/etc/dumpdates** file.
2. If the **rmt** command on the remote machine is not in **/usr/sbin/rmt**, then a link will need to be created on the remote machine from **/usr/sbin/rmt** to its actual location (usually **/etc/rmt**).

Flags

Item	Description
-b *Blocks*	Specifies the number of blocks to write in a single output operation. If you do not specify the *Blocks* variable, the **rdump** command uses a default value appropriate for the physical device selected. Larger values of the *Blocks* variable result in larger physical transfers to tape devices.
-B	Terminates the command without querying the user when an error occurs. If you specify the **-B** flag, the **rdump** command returns a nonzero value.
-c	Specifies that the tape is a cartridge format, not a 9-track format.
-d *Density*	Specifies the density of the tape in bits-per-inch (bpi). This value is used in calculating the amount of tape used per volume. If you do not specify a value for the *Density* variable, the default density is 1600 bpi. When using the **-c** flag without specifying a tape density, the default density is 8000 bpi.
-f *Machine***:***Device*	Specifies the *Machine* variable as the hostname of the remote machine. To send output to the named device, specify the *Device* variable as a file name (such as the **/dev/rmt0** file). The *Device* variable should specify only tape devices.

Item	Description
-L *Length*	Specifies the length of the tape in bytes. This flag overrides the **-c**, **-d**, and **-s** flags. You can specify the size with a suffix of b, k, m, or g to represent Blocks (512 bytes), Kilo (1024 bytes), Mega (1024 Kilobytes), or Giga (1024 Megabytes), respectively. To represent a tape length of 2 Gigabytes, type the following: `-L 2g`.
-s *Size*	Specifies the size of the tape in feet using the *Size* variable. If you do not specify a tape size, the default size is 2300 feet. When using the **-c** flag without specifying a tape size, the default size is 1700 feet. When the tape drive reaches the specified size, the **rdump** command waits for the tape to be changed.
-u	Updates the time, date, and level of the remote backup in the **/etc/dumpdates** file. This file provides the information needed for maintaining incremental backups.
-w	Currently disabled.
-W	Displays the file systems found in the **/etc/dumpdates** files.
-*Level*	Specifies the remote backup level (0 to 9). The default value of the *Level* variable is 9.
-?	Displays the usage message.

Parameters

Item	Description
DeviceName	Specifies the physical device name (the block or raw name).
FileSystem	Specifies the name of the directory on which the file system is usually mounted. The **rdump** command reads the **/etc/filesystems** file for the physical device name. If you do not specify a file system, the default is the root (**/**) file system.

Exit Status

This command returns the following exit values:

Item	Description
0	Indicates that the command completed successfully.
>0	Indicates that an error occurred.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To back up files in the **/usr** directory on your local machine to a remote machine, type:

```
rdump -u -0 -fcanine:/dev/rmt0 /usr
```

The **-u** flag tells the system to update the current backup level records in the **/etc/dumpdates** file. The **-***Level* flag set to backup level 0 specifies that all the files in the **/usr** directory are to be backed up. The ID of the remote machine is `canine` and the device is the **/dev/rmt0** device.

2. To back up files in the **/usr** directory on your local machine to a remote machine using an 8mm, 2.3GB tape, type:

```
rdump -fcanine:/dev/rmt0 -L 2200m /usr
```

Note: 2.2GB is used here instead of 2.3GB to avoid hitting the actual end of the tape.

3. To back up files in the **/usr** directory on your local machine to a remote machine using 0.25-inch tape, type:

```
rdump -fcanine:/dev/rmt0 -c /usr
```

When using the **-c** flag, the **rdump** command defaults to the correct size and density values for 0.25-inch tape.

Files

Item	Description
/etc/dumpdates	Contains logs of the most recent remote dump dates.
/etc/filesystems	Contains information on file systems.
/dev/rhd4	Contains the device where the default file system (root) is located.
/usr/sbin/rdump	Contains the **rdump** command.

read Command

Purpose

Reads one line from standard input.

Syntax

read [**-p**][**-r**][**-s**][**-u**[*n*]] [*VariableName?Prompt*]

[*VariableName ...*]

Description

The **read** command reads one line from standard input and assigns the values of each field in the input line to a shell variable using the characters in the IFS (Internal Field Separator) variable as separators. The *VariableName* parameter specifies the name of a shell variable that takes the value of one field from the line of input. The first shell variable specified by the *VariableName* parameter is assigned the value of the first field, the second shell variable specified by the *VariableName* parameter is assigned the value of the second field, and so on, until the last field is reached. If the line of standard input has more fields than there are corresponding shell variables specified by the *VariableName* parameter, the last shell variable specified is given the value of all the remaining fields. If there are fewer fields than shell variables, the remaining shell variables are set to empty strings.

> **Note:** If you omit the *VariableName* parameter, the variable REPLY is used as the default variable name.

The setting of shell variables by the **read** command affects the current shell execution environment.

Flags

Item	Description
-p	Reads input from the output of a process run by the Korn Shell using |& (pipe, ampersand). **Note:** An end-of-file character with the **-p** flag causes cleanup for this process so that another can be spawned.
-r	Specifies that the read command treat a \ (backslash) character as part of the input line, not as a control character.
-s	Saves the input as a command in the Korn Shell history file.
-u [*n*]	Reads input from the one-digit file descriptor number, *n*. The file descriptor can be opened with the ksh exec built-in command. The default value of the *n* is 0, which refers to the keyboard. A value of 2 refers to standard error.

Parameters

Item	Description
VariableName?Prompt	specifies the name of one variable, and a prompt to be used. When the Korn Shell is interactive, it will write the prompt to standard error, and then perform the input. If *Prompt* contains more than one word, you must enclose it in single or double quotes.
VariableName...	specfies one or more variable names separated by white space.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	Detected end-of-file character or an error occurred.

Examples

1. The following script prints a file with the first field of each line moved to the end of the line:

```
while read -r xx yy
do
         print printf "%s %s/n" $yy $xx
done < InputFile
```

2. To read a line and split it into fields, and use "Please enter: " as a prompt, type:

```
read word1?"Please enter:  " word2
```

   The system displays:

```
Please enter:
You enter:
hello world
```

   The value of the *word1* variable should have "hello" and *word2* should have "world."

3. To create a co-process, then use print **-p** to write to the co-process, and use read **-p** to read the input from the co-process, type:

```
(read; print "hello $REPLY")
print -p "world"
read -p line
```

The value of the *line* variable should have "hello world."

4. To save a copy of the input line as a command in the history file, type:

```
read -s line < input_file
```

If input_file contains "echo hello world," then "echo hello world" will be saved as a command in the history file.

readlvcopy Command

Purpose

Reads a specific mirror copy of a logical volume.

Syntax

readlvcopy **-d** *device* [**-c** *copy* | **-C** *copy* | **-b**] [**-n** *number_of_blocks*] [**-o** *outfile*] [**-s** *skip*] [**-S** *seek*]

Description

Flags

Item	Description
-d *device*	logical volume special device file to be read from
-c *copy*	Requested mirror copy to read from. Valid values are 1, 2, or 3 for the first, second, or third copy of the data. Data is read even if the logical partition has been marked stale. The default is the first copy of the data.
-C *copy*	Requested mirror copy to read from. Valid values are 1, 2, or 3 for the first, second, or third copy of the data. Stale logical partitions are not read.
-b	Read mirror copy marked as online backup.
-n *number_of_blocks*	Number of 128K blocks to read
-o *outfile*	Destination file. The default is *stdout*
-s *skip*	Number of 128K blocks to skip into *device*.
-S *seek*	Number of 128K blocks to seek into *outfile*

reboot or fastboot Command

Purpose

Restarts the system.

Syntax

{ **reboot** | **fastboot** } [**-l**] [**-n**] [**-q**] [**-t** *mmddHHMM* [*yy*]]

Description

The **reboot** command can be used to perform a reboot operation if no other users are logged into the system. The **lsattr** command and enter `lsattr -D -l sys0`. The default value is **true**. To reset the autorestart attribute value to **false**, use the **/var/adm/wtmp**, the login accounting file. These actions are inhibited if the **-l**, **-n**, or **-q** flags are present.

The **fastboot** command restarts the system by calling the **reboot** command. The **fsck** command runs during system startup to check file systems. This command provides BSD compatibility.

Flags

Item	Description
-l	Does not log the reboot or place a shutdown record in the accounting file. The **-l** flag does not suppress accounting file update. The **-n** and **-q** flags imply **-l**.
-n	Does not perform the **sync** command. Use of this flag can cause file system damage.
-q	Restarts without first shutting down running processes. **Note:** A file system synchronization will not occur if the **-q** flag is used. If you want the file system to be synchronized, manually run the **sync** command or use the **shutdown -r** command.
-t	Shuts down the system immediately and then restarts the system on the specified date. A valid date has the following format: *mmddHHMM* [*yy*] where: ***mm*** Specifies the month. ***dd*** Specifies the day. ***HH*** Specifies the hour. ***MM*** Specifies the minute. ***yy*** Specifies the year (optional). The two digit value represents the value of the year in the current century (based on the system time). For example, if the current year based on the systems time is 1985, 99 means 1999 and if the current year is 2005 then 99 means 2099 and 04 means 2004.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

To shut down the system without logging the reboot, enter:

```
reboot  -l
```

Files

Item	Description
/etc/rc	Specifies the system startup script.
/var/adm/wtmp	Specifies login accounting file.

rebootwpar Command

Purpose

Stops and restarts a system workload partition.

Restriction: You cannot run the **rebootwpar** command on an application workload partition.

Syntax

rebootwpar [**-F** | **-h**] [**-N** | **-t** *seconds*] [**-v**] *WparName*

Description

The **rebootwpar** command stops and restarts the workload partition.

Flags

Item	Description
-F	Specifies a forced stop.
-h	Specifies a hard stop.
-N	Specifies there is no timeout for halt.
-t *seconds*	Specifies the halt timeout in seconds.
-v	Verbose mode.
WparName	Specifies the workload partition name.

Security

Access Control: Only the root user can run this command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

To reboot the workload partition called "MyWpar", enter:

```
rebootwpar MyWpar
```

recfgct Command

Purpose

Reconfigures the Reliable Scalable Cluster Technology (RSCT) subsystems.

Syntax

```
/opt/rsct/install/bin/recfgct [ -i Node_ID | -n | -s | -h ]
```

Description

Attention: Use this command with extreme caution.

The `recfgct` command is used to remove all RSCT data under the `/var/ct` directory, generate a new node ID, and make it appear as if the RSCT components are just installed. Because of the destructive nature of this command, it is not normally started by the system administrator. You must use this command *only* if you need to remove a duplicate node ID or if an IBM service representative instructs you to use it.

When RSCT is first installed, a node ID is automatically generated. The node ID is a true random 64-bit number. Each system where RSCT is installed must have a unique node ID. If a copy of an operating system image (OSI) that has RSCT installed on it is installed on another system, the other system has the same node ID as the system from which the copy is made. This is referred to as *cloning*. For AIX platform, cloning is typically performed using such AIX-supported commands and procedures as `mksysb`. These commands and procedures call `recfgct` automatically. For other platforms, the `recfgct` command must be run immediately after a cloned OSI is installed.

If the `-s` flag is specified, after all data under the `/var/ct` directory is removed, the node ID contained in the `/etc/ct_node_id` file is used to re-create the `/var/ct/cfg/ct_node_id` file.

Flags

-i *Node_ID*
Specifies the node ID that must be used. The node ID must contain 9 - 16 hexadecimal characters.

-n
Generates a new node ID. It is the default behavior if no option is specified.

-s
Saves the node ID.

-h
Writes the command usage statement to standard output and then exits.

Restrictions

The `-h` flag is supported on the following RSCT levels:

- RSCT 2.4.9.1 (or later) for AIX 5.3
- RSCT 2.5.1.1 (or later) for AIX 6.1 and all Linux platforms
- RSCT 3.1.0.0 (or later) for AIX 7.1 and later

If you try to run the `recfgct -h` command on a prior version of RSCT, the `-h` flag is ignored and all RSCT data is removed.

Files

/etc/ct_node_id
Contains a copy of the RSCT node ID

/var/ct/cfg/ct_node_id
Contains the RSCT node ID

Standard output

When the `-h` flag is specified, this command usage statement is written to standard output and then the command exits.

Exit status

0
The command ran successfully.

1
The command did not run successfully.

Security

Privilege control: only the `root` user must have execute (x) access to this command.

Implementation specifics

This command is part of the `rsct.core` fileset for the AIX operating system and `rsct.core-3.1.0.0-0.`*platform*`.rpm` package for Linux, Solaris, and Windows operating system, where *platform* is `i386`, `ppc`, `ppc64`, `s390`, or `x86_64`.

Location

`/opt/rsct/install/bin/recfgct`

Examples

1. After installing a cloned operating system image, enter:

```
/opt/rsct/install/bin/recfgct
```

recreatevg Command

Purpose

Re-creates a volume group that exists on a specified set of disks. Imports and varies on the volume group.

Syntax

recreatevg [-y *VGname*] [-p] [-f] [-Y*Lv_Prefix* | -l *LvNameFile*] [-L *Label_Prefix*] [-n] [-V *MajorNumber*] [-d] [-O] *PVname*...

Description

The **recreatevg** command re-creates a volume group on a set of disks that are duplicated from another set of disks that belong to a specific volume group. This command overcomes the problem of duplicated Logical Volume Manager (LVM) data structures and identifiers that are caused by a disk duplication process. This command allocates new physical volume identifiers (PVID) for the member disks, as the PVIDs are also duplicated by the disk duplication. Similarly, duplicated logical volume members are given new names with the user-specified prefixes.

1. The **recreatevg** command removes all logical volumes that fully or partially exist on the physical volumes that are not specified on the command line. Mirrored logical volumes can be an exception (see the -f flag).
2. The **recreatevg** command warns, if the log for the logical volume of a file system does not exist on the disks that are specified on the command line.
3. The **recreatevg** command fails, if the input list does not match the list that is compiled from the Volume Group Descriptor Area (VGDA).
4. The set of disks in the list must have consistent VGDA data. The **recreatevg** command does not fix VGDA problems.

5. When re-creating a concurrent-capable volume group, the volume group is not varied on when the **recreatevg** command completes. The new volume group must be varied on manually.

Flags

Item	Description
-d	Instead of completely re-creating the VG, the d flag causes the **recreatevg** command to create only new PVIDs for the specified disks and update the LVM metadata with the new PVIDs. Logical volumes (LVs) names and labels is not changed and the VG is not imported. This flag is incompatible with other flags except the -0 flag.
-f	Re-creates a volume group (VG) from a subset of disks. Only those disks and the logical volumes (LVs) that is present entirely on this subset of disks is present in the re-created VG. All other disks and LVs from the original VG is deleted in the re-created VG. For mirrored LVs, only LV mirror copies with physical partitions allocated on the deleted disks are removed. Therefore, a mirrored LV can be re-created with fewer mirror copies when one of copies is present on the subset of disks.
-l*LvNameFile*	Changes logical volume names to the name specified by *LvNameFile*. Entries must be in the format LV:NEWLV1. All logical volumes that are not included in *LvNameFile* are re-created with default system generated names. NEWLV1 name can be the same as LV name in the *LvNameFile* stanza (LV:NEWLV1) to leave the logical volume with the same name.
-L*Label_Prefix*	Changes the labels of logical volumes on the VG being re-created to this prefix. You must modify the /etc/filesystems filepath manually if a simple modification of the mount point is not enough to define the stanza uniquely. Specifying / (slash) as the *Label_Prefix*, leaves the label in the logical volume unchanged.
-n	Specifies that after **recreatevg** the volume group is imported but varied off. Default is imported and varies on.
-p	Disables the automatic generation of the new PVIDs. If the -p flag is used, you must ensure that there are no duplicated PVIDs on the system. All the disks that are hardware that is mirrored must have their PVIDs changed to a unique value.
-0	Forces the volume group to be re-created and varied on even if the metadata on the disk indicates that this volume group is varied on in another node. See the varyonvg command for detailed information.
-V*MajorNumber*	Allows the major number of the volume group to be specified rather than having the major number generated automatically.
-y *VGname*	Allows the volume group name to be specified rather than having the name generated automatically. Volume group names must be unique system wide and can range from 1 to 15 characters. The name cannot begin with a prefix already defined in the PdDv class in the Device Configuration database for other devices. The new volume group name is sent to standard output.

Item	Description
-Y *Lv_Prefix*	Causes the logical volumes on the volume group that is being re-created to be renamed with this prefix. The total length of the prefix and the logical volume name must be less than or equal to 15 characters. If the length exceeds 15 characters, the logical volume is renamed with a default name. The default name must comply to the following conditions: • Cannot begin with a prefix that is already defined in the PdDv class of the Device Configuration database. • Cannot use a name that is already used by another system. Specifying NA as the *Lv_Prefix*, leaves all the logical volume names unchanged.

Security

Access Control: You must have root authority to run this command.

Examples

1. To re-create a volume group that contains three physical volumes, enter the command:

   ```
   recreatevg hdisk1 hdisk2 hdisk3
   ```

   The volume group on hdisk1, hdisk2, and hdisk3 is re-created with an automatically generated name, which is displayed.
2. To re-create a volume group on hdisk1 with the new name testvg, enter the command:

   ```
   recreatevg -y testvg hdisk1
   ```
3. To re-create a volume group on hdisk14, re-create all logical volumes in that volume group, and rename them with the prefix newlv, enter the command:

   ```
   recreatevg -Y newlv hdisk14
   ```

Files

Item	Description
`/usr/sbin`	Directory where the **recreatevg** command is present.

recsh Command

Purpose

Invokes the recovery shell.

Syntax

recsh

Description

When the **libc.a** library is moved or renamed, an error message `Killed` will be displayed from the shell as there is no **libc.a** library available for the system to load and run the utilities. The **recsh** command

invokes recovery shell, which provides the ability to rename **libc.a** library if it is accidently moved. It uses an alternative **libc.a** library that is shipped with the system.

Note: This is a recovery shell and users should not use **recsh** as default shell.

Examples

1. If libc.a is renamed accidentally then the system will be in an unstable state where in execution of any utility will not be possible. To recover at this point, type:

```
recsh; cp -p  libc.a.new /usr/lib/libc.a; exit
```

Location

/usr/bin/recsh

Files

Item	Description
/usr/bin/recsh	Specifies the path name to the recovery shell.

redefinevg Command

Purpose

Redefines the set of physical volumes of the given volume group in the device configuration database.

Syntax

redefinevg { **-d** *Device* | **-i** *Vgid* } *VolumeGroup*

Description

During normal operations the device configuration database remains consistent with the Logical Volume Manager (LVM) information in the reserved area on the physical volumes. If inconsistencies occur between the device configuration database and the LVM, the **redefinevg** command determines which physical volumes belong to the specified volume group and re-enters this information in the device configuration database. The **redefinevg** command checks for inconsistencies by reading the reserved areas of all the configured physical volumes attached to the system.

> **Note:** To use this command, you must either have root user authority or be a member of the **system** group.

Flags

Item	Description
-d *Device*	The volume group ID, *Vgid*, is read from the specified physical volume device. You can specify the *Vgid* of any physical volume belonging to the volume group that you are redefining.
-i *Vgid*	The volume group identification number of the volume group to be redefined.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Example

To redefine rootvg physical volumes in the Device Configuration Database, enter a command similar to the following:

```
redefinevg -d hdisk0 rootvg
```

Files

Item	Description
/usr/sbin/synclvodm	Contains the **synclvodm** command.

reducevg Command

Purpose

Removes physical volumes from a volume group. When all physical volumes are removed from the volume group, the volume group is deleted.

Syntax

reducevg [**-d**] [**-f**] *VolumeGroup PhysicalVolume ...*

Description

> **Attention:** You can use the **reducevg** command while the volume group is in concurrent mode. However, if you run this command while the volume group is in concurrent mode and the end result is the deletion of the volume group, then the **reducevg** command will fail.

The **reducevg** command removes one or more physical volumes represented by the *PhysicalVolume* parameter from the *VolumeGroup*. When you remove all physical volumes in a volume group, the volume group is also removed. The volume group must be varied on before it can be reduced.

All logical volumes residing on the physical volumes represented by the *PhysicalVolume* parameter must be removed with the **rmlv** command or the **-d** flag before starting the **reducevg** command.

Note:

1. To use this command, you must either have root user authority or be a member of the **system** group.
2. Sometimes a disk is removed from the system without first running **reducevg** *VolumeGroup PhysicalVolume*. The VGDA still has this removed disk in it's memory, but the *PhysicalVolume* name no longer exists or has been reassigned. To remove references to this missing disk you can still use **reducevg**, but with the Physical Volume ID (PVID) instead of the disk name: **reducevg** *VolumeGroup PVID*.
3. You cannot use the **reducevg** command on a snapshot volume group.
4. You cannot use the **reducevg** command on a volume group that has an active firmware assisted dump logical volume.
5. The `reducevg` command discards any background space reclamation process that is running for the physical volumes that are removed from the volume group. To identify whether a space reclamation is running, you can use the `lvmstat` command with **`-r`** option.

For volume groups created on AIX 5.3 and varied on without the **varyonvg -M** flag, reducevg will dynamically raise the logical track group size for the volume group if necessary to match the common max transfer size of the remaining physical volumes.

You could also use the System Management Interface Tool (SMIT) **smit reducevg** fast path to run this command.

Flags

Item	Description
-d	Deallocates the existing logical volume partitions and then deletes resultant empty logical volumes from the specified physical volumes. User confirmation is required unless the **-f** flag is added. **Attention:** The **reducevg** command with the **-d** flag automatically deletes all logical volume data on the physical volume before removing the physical volume from the volume group. If a logical volume spans multiple physical volumes, the removal of any of those physical volumes may jeopardize the integrity of the entire logical volume.
-f	Removes the requirement for user confirmation when the **-d** flag is used.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To remove physical volume `hdisk1` from volume group `vg01`, enter:

   ```
   reducevg vg01 hdisk1
   ```

2. To remove physical volume `hdisk1` and all residing logical volumes from volume group `vg01` without user confirmation, enter the following command. **Attention:** The **reducevg** command with the **-d** flag automatically deletes all logical volume data before removing the physical volume.

   ```
   reducevg  -d  -f vg01 hdisk1
   ```

   The physical volume `hdisk1` and all residing logical volumes are removed.

Files

Item	Description
/usr/sbin/reducevg	Directory where the **reducevg** command resides.
/tmp	Directory where the temporary files are stored and while the command is running.

refer Command

Purpose

Finds and inserts literature references in documents.

Syntax

refer [**-b**] [**-e**] [**-P**] [**-S**] [**-a** [*Number*]] [**-B** *Label***.***Macro*] [**-c** *Keys*] [**-f** *Number* | **-k** *Label* | **-l** *Letter***,** *Digit*] [**-n**] [**-p** *Reference*] [**-s** *Keys*] [*File ...*]

Description

The **refer** command is a preprocessor for the **nroff** or the **troff** command. The **refer** command finds and formats references for footnotes or endnotes. It is also the basis for a series of programs designed to index, search, sort, and print standalone bibliographies or other data entered in the appropriate form.

Given an incomplete citation with sufficiently precise phs, the **refer** command searches a bibliographic database for references containing these phs anywhere in the title, author, journal, and so on. The input file (or else standard input) is copied to standard output, except for lines enclosed by the .[(period, left bracket) and .] (period, right bracket) delimiters. Lines enclosed by the delimiters are assumed to contain phs and are replaced by information from the bibliographic database. The user can search different databases, override particular fields, or add new fields. The reference data, from whatever source, is assigned to a set of **troff** command strings. Macro packages, such as the **ms** macro package, print the finished reference text from these strings. By default, references are flagged by footnote numbers.

To use your own references, put them in the format described in the Example section. These references can be accessed either by using the **-p** flag or by setting the **REFER** environment variable to those reference files. The references can be searched more rapidly by running the **indxbib** command on them before using the **refer** command. If you do not index, a linear search is made. When the **refer** command is used with any of the preprocessor commands (**eqn**, **neqn**, or **tbl** command), the **refer** command should be issued first, to minimize the volume of data passed through pipes.

> **Note:** Anytime you edit a reference file, you must reissue the **indxbib** command on that file. If you do not use the **indxbib** command, remove any **.ia**, **.ib**, **.ic**, and **.ig** files associated with that reference file; otherwise, you will get a `too many hits` error message from the **refer** command.

The **refer** command and associated programs expect input from a file of references composed of records separated by blank lines. A record is a set of fields (lines), each containing one kind of information. Fields start on a line beginning with the **%** (percent sign), followed by a key letter, a space character, and finally the contents of the field, and continue until the next line, starting with a **%** (percent sign). The output ordering and formatting of fields is controlled by the macros specified for the **nroff** and **troff** commands (for footnotes and endnotes), or the **roffbib** command (for standalone bibliographies). For a list of the most common key letters and their corresponding fields, see the **addbib** command.

Flags

Item	Description
-b	Bare mode: do not put any flags in text (either numbers or labels).
-e	Instead of leaving the references where encountered, accumulates them until a sequence of the following form is encountered: `.[` `$LIST$` `.]` then writes out all references collected so far.
-P	Places punctuation marks after the reference signal, rather than before. The punctuation marks are locale-specific and are defined in the **refer message catalog**.
-S	Produces references in the natural or social science format.
-a *Number*	Reverses the first specified number of author names (Jones, J. A. instead of J. A. Jones). If the *Number* variable is omitted, all author names are reversed.

Item	Description
-B *Label***.***Macro*	Specifies bibliography mode. Takes a file composed of records separated by blank lines and turns that file into **troff** command input. The specified label is turned into the specified macro, with the *Label* variable value defaulting to **%X** and the *.Macro* variable value defaulting to **.AP** (annotation paragraph).
-c *Keys*	Capitalizes, with SMALL CAPS, the fields whose key letters are in the *Keys* variable. For example, Jack becomes JACK .
-f *Number*	Sets the footnote number to the specified number instead of the default of 1. With labels rather than numbers, this flag has no effect. See the **-k** flag and the **-l** flag.
-k *Label*	Instead of numbering references, uses labels as specified in a reference data line beginning with **%***Label*. By default, the *Label* variable value is **L.**
-l *Letter***,***Digit*	Instead of numbering references, uses labels made from the senior author's last name and the year of publication. Only the first specified letters of the last name and the last specified digits of the date are used. If either the *Letter* variable or the *Digit* variable is omitted, the entire name or date, respectively, is used.
-n	Does not search the default **/usr/share/dict/papers/Ind** file .If the **REFER** environment variable is set, the specified file is searched instead of the default file. In this case, the **-n** flag has no effect.
-p *Reference*	Takes the *Reference* variable as a file of references to be searched. The default file is searched last.
-s *Keys*	Sorts references by fields whose key letters are specified by the *Keys* variable string. Renames reference numbers in text accordingly. Implies the **-e** flag. The key letters specified by the *Keys* variable can be followed by a number to indicate how many such fields are used, with q + (plus sign) indicating a very large number. The default value is **AD**, which sorts first by senior author and then by date. For example, to sort on all authors and then title, enter `-sA+T`**.** It is important to note that blank spaces at the end of lines in bibliography fields cause the records to sort and reverse incorrectly. Sorting large numbers of references can cause a core dump.

Example

Following is an example of a **refer** command entry:

```
%A M.E. Lesk

%T Some Applications of Inverted Indexes on the UNIXSystem

%B UNIXProgrammer's Manual

%V 2b

%I Bell Laboratories
%C Murray Hill, NJ

%D 1978
```

Files

Item	Description
/usr/share/dict/papers/Ind	Contains the default reference file.
/usr/lbin/refer	Contains companion programs.

refile Command

Purpose

Moves files between folders.

Syntax

refile [**-src** **+***Folder*] [**-draft**] [**-file** *File*] [*Messages*] [**-nolink** | **-link**] [**-nopreserve** | **-preserve**] **+***Folder* ...

Description

The **refile** command moves messages between folders. If you do not specify a source folder, the **refile** command uses the current folder as the source. If you specify a destination folder that does not exist, the system requests permission to create it.

The **refile** command also copies messages from one folder to another. When moving a message, by default, the system does not keep a copy of the message in the original folder. To leave a copy behind, use the **-preserve** flag.

Flags

Item	Description
-draft	Copies the current draft message from your mail directory.
-file *File*	Copies the specified file. The file must be in valid message format. Use the **inc** command to format and file new messages correctly.
+*Folder*	Copies the messages to the specified folder. Any number of folders can be specified.
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For MH, the name of this flag must be fully spelled out.
-link	Leaves the messages in the source folder or file after they are copied.

Item	Description
Messages	Specifies the messages to be copied. You can specify several messages, a range of messages, or a single message. Use the following references to specify messages: ***Number*** Number of the message. ***Sequence*** A group of messages specified by the user. Recognized values include: **all** All the messages in a folder. **cur or . (period)** Current message. This is the default. **first** First message in a folder. **last** Last message in a folder. **next** Message following the current message. **prev** Message preceding the current message. **/DT>** If the **-link** and **all** flags are used together, the current message in the current folder does not change. Otherwise, if a message is specified, the refiled message becomes the current message.
-nolink	Removes the messages from the source folder or file after they are copied. This flag is the default.
-nopreserve	Renumbers the messages that are copied. Renumbering begins with a number one higher than the last message in the destination folder. This flag is the default.
-preserve	Preserves the message numbers of copied messages. If messages with these numbers already exist, the **refile** command issues an error message and does not alter the contents of the folders.
-src +*Folder*	Identifies the source folder. By default, the system uses the current folder.

Profile Entries

The following entries are part of the *UserMHDirectory*/**.mh_profile** file:

Item	Description
`Current-Folder:`	Sets the default current folder.
`Folder-Protect:`	Sets the protection level for your new folder directories.
`Path:`	Specifies the *UserMhDirectory*.
`rmmproc:`	Specifies the program used to remove messages from a folder.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To refile the current message from the current folder and place it in a new folder called `meetings`, enter:

   ```
   refile  +meetings
   ```

   The system responds with a message similar to the following:

   ```
   Create folder "/home/jeanne/Mail/meetings"?
   ```

   Enter y to create the folder. A copy of the original message is not retained in the current folder.
2. To copy the current message from the current folder and to the `meetings` folder, enter:

   ```
   refile  -link +meetings
   ```

   The original message remains in the current folder.
3. To refile the current message draft into the `test` folder, enter:

   ```
   refile  -draft +test
   ```

   A copy of the message draft is not retained in the current folder.
4. To refile the current message from the current folder and into several folders, enter:

   ```
   refile  +tom +pat +jay
   ```

   A copy of the message is not retained in the current folder.

Files

Item	Description
$HOME/.mh_profile	Sets the MH user profile.
/usr/bin/refile	Contains the **refile** command.

refresh Command

Purpose

Requests a refresh of a subsystem or group of subsystems.

Syntax

refresh [**-h** *Host*] { **-g** *Group*| **-p** *SubsystemPID*| **-s** *Subsystem*}

Description

The **refresh** command sends the System Resource Controller a subsystem refresh request that is forwarded to the subsystem. The refresh action is subsystem-dependent.

> **Note:** The **refresh** command is unsuccessful if the communication method for the subsystems is signals.

Flags

Item	Description
-g *Group*	Specifies a group of subsystems to refresh. The **refresh** command is unsuccessful if the *Group* name is not contained in the subsystem object class.
-h *Host*	Specifies the foreign *Host* machine on which this refresh action is requested. The local user must be running as "root". The remote system must be configured to accept remote System Resource Controller requests. That is, the **srcmstr** daemon (see **/etc/inittab**) must be started with the **-r** flag and the **/etc/hosts.equiv** or **.rhosts** file must be configured to allow remote requests.
-p *SubsystemPID*	Specifies a particular instance of the subsystem to refresh.
-s *Subsystem*	Specifies a subsystem to refresh. The *Subsystem* name can be the actual subsystem name or the synonym name for the subsystem. The **refresh** command is unsuccessful if *Subsystem* name is not contained in the subsystem object class.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To refresh the a group, like `tcpip`, enter:

   ```
   refresh  -g tcpip
   ```

2. To refresh a subsystem, like `xntpd`, enter:

   ```
   refresh  -s xntpd
   ```

Files

Item	Description
/etc/objrepos/SRCsubsys	Specifies the SRC Subsystem Configuration Object Class.
/etc/services	Defines the sockets and protocols used for Internet services.
/dev/SRC	Specifies the **AF_UNIX** socket file.
/dev/.SRC-unix	Specifies the location for temporary socket files.

refrsrc Command

Purpose

Refreshes the resources within the specified resource class.

Syntax

`refrsrc` [`-h`] [`-TV`] *resource_class*

Description

The `refrsrc` command refreshes the resources within the specified resource class. Use this command to force the Resource Monitoring and Control (RMC) subsystem to detect new instances of resources in cases where the configuration could be altered by operating system commands (`mkfs`, for example).

This command makes a request to the RMC subsystem to refresh the configuration of the resources within a resource class. The request is actually performed by the linked resource manager.

Any application that is monitoring resources in the specified resource class may receive events as the configuration is refreshed.

Flags

-h
Writes the command's usage statement to standard output.

-T
Writes the command's trace messages to standard error. For your software-service organization's use only.

-V
Writes the command's verbose messages to standard output.

Parameters

resource_class
Specifies the resource class name.

Security

The user needs read permission for the *Resource_class* specified in `refrsrc` to run `refrsrc`. Permissions are specified in the access control list (ACL) file on the contacted system. See the *RSCT: Administration Guide* for information about the ACL file and how to modify it.

Exit Status

0
The command has run successfully.

1
An error occurred with RMC.

2
An error occurred with the command-line interface (CLI) script.

3
An incorrect flag was specified on the command line.

4
An incorrect parameter was specified on the command line.

5
An error occurred with RMC that was based on incorrect command-line input.

Environment Variables

CT_CONTACT
When the CT_CONTACT environment variable is set to a host name or IP address, the command contacts the Resource Monitoring and Control (RMC) daemon on the specified host. If the environment variable is not set, the command contacts the RMC daemon on the local system where the command is being run. The resource class or resources that are displayed or modified by the command are located on the system to which the connection is established.

CT_IP_AUTHENT
When the CT_IP_AUTHENT environment variable exists, the RMC daemon uses IP-based network authentication to contact the RMC daemon on the system that is specified by the IP address to which the CT_CONTACT environment variable is set. CT_IP_AUTHENT only has meaning if CT_CONTACT is set to an IP address; it does not rely on the domain name system (DNS) service.

CT_MANAGEMENT_SCOPE
Determines the management scope that is used for the session with the RMC daemon to monitor and control the resources and resource classes. The management scope determines the set of possible target nodes where the resources and resource classes can be monitored and controlled. The valid values are:

0
Specifies *local* scope.

1
Specifies *local* scope.

2
Specifies *peer domain* scope.

3
Specifies *management domain* scope.

If this environment variable is *not* set, *local* scope is used.

Implementation Specifics

This command is part of the Reliable Scalable Cluster Technology (RSCT) fileset for AIX.

Standard Output

When the `-h` flag is specified, this command's usage statement is written to standard output.

The command output and all verbose messages are written to standard output.

Standard Error

All trace messages are written to standard error.

Examples

1. To refresh the configuration of the resources in class IBM.FileSystem, enter:

```
refrsrc IBM.FileSystem
```

Location

/opt/rsct/bin/refrsrc

refsensor Command

Purpose

Refreshes a sensor or a microsensor defined to the resource monitoring and control (RMC) subsystem.

Syntax

To refresh a sensor:

`refsensor` [–a | –n *host1*[,*host2*...] | –N { *node_file* | "–" }] [–h] [–v | –V] *sensor_name*

To refresh a microsensor:

`refsensor –m [–a | –n host1[,host2...] | –N { node_file | "–" } ] [–h ] [ –v | –V ] sensor_name`

Description

The `refsensor` command refreshes a sensor or microsensor resource that is defined to the RMC subsystem. *Sensors* and *microsensors* are RMC resources with attributes that can be monitored. Sensors and microsensors must be monitored for `refsensor` to run successfully.

A sensor can be refreshed using `refsensor` in one of two ways: either by running the sensor command that is defined for the sensor resource or by specifying values for specific sensor attributes. A microsensor can be refreshed using `refsensor` to query the values of the microsensor's load module. Use the `-m` flag to refresh a microsensor.

When the `refsensor` command runs, it does not affect the interval, if any, that is defined (using `mksensor`) for running the sensor command or for querying the microsensor load module . That is, if a monitored sensor or microsensor is being updated every 60 seconds, running `refsensor` does not cause the interval timer to be reset to 60 seconds.

The `refsensor` command runs on any node. If you want `refsensor` to run on all of the nodes in a domain, use the `-a` flag. If you want `refsensor` to run on a subset of nodes in a domain, use the `-n` flag. Instead of specifying multiple node names using the `-n` flag, you can use the `-N` *node_file* flag to indicate that the node names are in a file. Use `-N "–"` to read the node names from standard input.

If Cluster Systems Management (CSM) is installed on your system, you can use CSM defined node groups as node name values to refer to more than one node. For information about working with CSM node groups and using the CSM `nodegrp` command, see the *CSM: Administration Guide* and the *CSM: Command and Technical Reference*.

To have `refsensor` update specific sensor attributes, specify one or more *attr=value* parameters. Only the attributes specified will be updated. No other sensor attributes will be updated. The sensor attributes that can be specified as parameters are:

Float32
The type `float32` attribute for this sensor resource

Float64
The type `float64` attribute for this sensor resource

Int32
The type `int32` attribute for this sensor resource

Int64
The type `int64` attribute for this sensor resource

Quantum
The type `quantum` attribute for this sensor resource

String
The type `string` attribute for this sensor resource

Uint32
The type `uint32` attribute for this sensor resource

Uint64
The type `uint64` attribute for this sensor resource

For example, to update the `Int32` and `Float32` sensor attributes for the sensor named `Sensor1`, enter:

```
refsensor Sensor1 Int32=45 Float32=7.8
```

Microsensor attributes cannot be updated separately.

Flags

–a
Refreshes sensors that match the specified name on all nodes in the domain.
The CT_MANAGEMENT_SCOPE environment variable determines the cluster scope. If CT_MANAGEMENT_SCOPE is not set, first the management domain scope is chosen if it exists, then the peer domain scope is chosen if it exists, and then local scope is chosen, until the scope is valid for the command. The command will run once for the first valid scope found. For example, if both a management domain and a peer domain exist, `refsensor -a` with CT_MANAGEMENT_SCOPE not set will run in the management domain. In this case, to run in the peer domain, set CT_MANAGEMENT_SCOPE to 2.

–m
Specifies that the resource to be refreshed is a microsensor resource.

–n *host1*[,*host2*...]
Specifies one or more nodes on which the sensor should be refreshed. By default, the sensor is refreshed on the local node. This flag is only appropriate in a management domain or a peer domain.

–N { *node_file* | "–" }
Specifies that node names are read from a file or from standard input.

Use `-N` *node_file* to indicate that the node names are in a file.

- There is one node name per line in *node_file*
- A number sign (#) in column 1 indicates that the line is a comment
- Any blank characters to the left of a node name are ignored
- Any characters to the right of a node name are ignored

Use `-N "–"` in a management domain or a peer domain to read the node names from standard input.

–h
Writes the command's usage statement to standard output.

–v | –V
Writes the command's verbose messages to standard output.

Parameters

sensor_name
Specifies the name of the sensor to be refreshed.

attr=value
Specifies which sensor attributes will be refreshed and the values to which they will be set.

Security

To refresh sensors using this command, you need write permission for the `IBM.Sensor` resource class.

To refresh microsensors using this command, you need write permission for the `IBM.MicroSensor` resource class.

Permissions are specified in the access control list (ACL) file on the contacted system. See the *RSCT: Administration Guide* for details on the ACL file and how to modify it.

Exit Status

0
The command has run successfully.

1
An incorrect combination of flags and parameters has been entered.

4
The sensor is not monitored and cannot be refreshed.

6
No sensor resources were found.

n
Based on other errors that can be returned by the RMC subsystem.

Environment Variables

CT_CONTACT
When the CT_CONTACT environment variable is set to a host name or IP address, the command contacts the resource monitoring and control (RMC) daemon on the specified host. If this environment variable is not set, the command contacts the RMC daemon on the local system where the command is being run. The resource class or resources that are displayed or modified by the command are located on the system to which the connection is established.

CT_IP_AUTHENT
When the CT_IP_AUTHENT environment variable exists, the RMC daemon uses IP-based network authentication to contact the RMC daemon on the system that is specified by the IP address to which the CT_CONTACT environment variable is set. CT_IP_AUTHENT only has meaning if CT_CONTACT is set to an IP address; it does not rely on the domain name system (DNS) service.

CT_MANAGEMENT_SCOPE
Determines the management scope that is used for the session with the RMC daemon to monitor and control the resources and resource classes. The management scope determines the set of possible target nodes where the resources and resource classes can be monitored and controlled.

The valid values are:

0
Specifies *local* scope.

1
Specifies *local* scope.

2
Specifies *peer domain* scope.

3
Specifies *management domain* scope.

If this environment variable is *not* set, *local* scope is used.

Implementation Specifics

This command is part of the `rsct.core` fileset for AIX and `rsct.core-3.1.0.0-0.`*platform*`.rpm` package for Linux, Solaris, and Windows, where *platform* is `i386`, `ppc`, `ppc64`, `s390`, or `x86_64`.

Examples

1. To refresh the sensor called `Sensor1` so that its defined sensor command is run, enter:

```
refsensor Sensor1
```

2. To refresh the sensor called `Sensor1` so that `Int32` is set to `50`, `Float32` is set to `123.45`, and `String` is set to `"test input"`, enter:

```
refsensor Sensor1 Int32=50 Float32=123.45 String="test input"
```

3. To refresh the sensor called `Sensor1` on the nodes that are listed in the `/u/joe/common_nodes` file so that `Sensor1`'s defined sensor command is run, enter:

```
refsensor -N /u/joe/common_nodes Sensor1
```

where /u/joe/common_nodes contains:

```
# common node file
#
node1.myhost.com    main node
node2.myhost.com    backup node
```

4. To refresh the microsensor called IBM.Sensor1 so that the attribute values are queried using the defined microsensor load module, enter:

```
refsensor -m IBM.Sensor1
```

Location

/opt/rsct/bin/refsensor

regcmp Command

Purpose

Compiles patterns into C language **char** declarations.

Syntax

regcmp [**-**] *File* [*File* ...]

Description

The **regcmp** command compiles the patterns in *File* and places output in a *File***.i** file, or a *File***.c** file when the **-** option is specified. The resulting compiled patterns are initialized **char** declarations. Each entry in *File* must be a C variable name followed by one or more blanks, followed by a pattern enclosed in **"** **"** (double quotation marks).

The output of the **regcmp** command is C source code. A resulting *File***.i** file can be included in C programs, and a resulting *File***.c** file can be a file parameter to the **cc** command.

A C language program that uses the output of the **regcmp** command should use the **regex** subroutine to apply it to a string.

In most cases, the **regcmp** command makes unnecessary the use of the **regcmp** subroutine in a C language program, saving execution time and program size.

Flag

Item	Description
-	Places the output in a *File***.c** file. The default is to put the output in *File.***i**.

Examples

1. To compile the patterns in stdin1 and the patterns in stdin2, enter:

```
regcmp stdin1 stdin2
```

This creates the stdin1.i and stdin2.i files.

2. To creates stdin1.c and stdin2.c files, enter:

```
regcmp - stdin1 stdin2
```

Note: Assuming that the same `stdin1` and `stdin2` files are used in both examples, the resulting `stdin1.i` and `stdin1.c` files are identical, and the resulting `stdin2.i` and `stdin2.c` files are identical.

File

Item	Description
/usr/ccs/bin/regcmp	Contains the **regcmp** command.

rembak Command

Purpose

Sends a print job to a queue on a remote server.

Syntax

rembak **-S** *Server* **-P** *Queue* [**-R**] [**-N** *Filter*] [**-L**] [**-p**] [**-q**] [**-x**] [**-#** *JobNumber*] [**-u** *UserName*] [**-X**] [**-o** *Option*] [**-T** *Timeout*] [**-C**] [**-D** *DebugOutputFile*] [*File* ...]

Description

The **rembak** command sends a job to be queued on a remote server. The request can either be a print job, a status request, a job cancel request, or a request to kill the remote queuing system. The server and the queue flags are required. All the other flags are optional, depending on what needs to be done.

This command should only be called by the **qdaemon** command. It is not intended to be entered on the command line by a user. See the **enq** command for details on how to issue a print job request, or use the System Manager Interface Tool (SMIT) to request a print job.

Flags

Item	Description
-# *JobNumber*	Specifies the *JobNumber* to cancel.
-C	Sends control file first. The **lpd** protocol allows two handshaking sequences for processing a print job. The default consists of sending the data files(s) first followed by the control file. The other sequence is to send the control file first followed by the data file(s). If **-C** is specified, **rembak** will send the control file first followed by the data file(s).
-D *DebugOutputfile*	Turns on the debugging option for **rembak**. If no output file name is specified, or if there are any problems creating or writing to the output file, the debugging option is ignored. If the output file specified already exists, new debugging output is appended to the end of it.
-L	Indicates a long (verbose) status request from the remote queue.

Item	Description
-N *Filter*	Indicates the machine type of the remote server. The filter name is specified by the **s_statfilter** attribute in the **/etc/qconfig** file. Values for the *filter* variable include the following: **/usr/lib/lpd/aixshort** Indicates the server is another AIX machine. **/usr/lib/lpd/aixv2short** Indicates the server is an RT with an AIX Version 2 operating system. **/usr/lib/lpd/bsdshort** Indicates the server is a bsd machine **/usr/lib/lpd/attshort** Indicates the server is an AT&T machine
-o *Option*	Specifies an *Option* to be sent to the backend on the remote server. (These *Options* are passed through the **rembak** command.)
-p	Indicates that the port range used by **rembak** is restricted to ports below 1023.
-P *Queue*	Specifies the name of the *Queue* on the remote server where the print job is sent.
-q	Indicates a short (abbreviated) status request from the remote queue.
-R	Restarts the remote queuing system. **Note:** The **-R** flag is not supported when sending a request to an operating system. The **lpd** daemon does not support such a request. The **-R** flag is supported only for compatibility with other systems.
-S *Server*	Specifies the name of the remote print *Server* where the print request is sent.
-T *Timeout*	Sets a timeout period, in minutes, for **rembak** to wait for acknowledgements from the remote server. If no value is specified, a default timeout of 90 seconds is used. This default is also used if Timeout is 0 or a negative value.
-u *UserName@HostName*	Cancels a print job for *UserName* that was submitted from the *HostName* machine. **Note:** The queuing system does not support multibyte host names.
-X	Specifies that the **rembak** command send the **-o** *Option* to the remote server, even if the remote server is a non-AIX machine. If the remote is a non-AIX machine, then the *Option* is sent without the **-o** flag. Thus, **-o -abc** is sent as **-abc**. To use the **-X** flag on a remote queue, the following line for the specific queue must be included in the **/etc/qconfig** file: `backend = /usr/lib/lpd/rembak -X` The **qprt**, **lpr** and other queuing commands are not guaranteed to work when -X is specified on a queue. Use the **enq** command.
-x	Cancels a job request. Use the **-#** *JobNumber* flag or the **-u** *UserName* flag to cancel a request.

Examples

1. To print the files `spinach`, `asparagus`, and `broccoli` on the queue `popeye` on the remote server `olive`, which is an RT with an AIX Version 2 operating system, enter:

```
rembak -S olive -P popeye -N /usr/lib/lpd/aixv2short spinach asparagus broccoli
```

2. To issue a verbose status request to `olive` for the queue `popeye`, enter:

```
rembak -S olive -P popeye -N /usr/lib/lpd/aixv2short -L
```

3. To cancel job number 23 on a remote server submitted by user `sweetpea` from machine `bluto`, which is a Version 3 machine, enter:

```
rembak -S olive -P popeye -N /usr/lib/lpd/aixv2short -x -#23 -u sweetpea@bluto
```

Files

Item	Description
/usr/lib/lpd/rembak	Contains the **rembak** command.
/etc/hosts.lpd	Contains host names that are allowed to do print requests.
/etc/hosts.equiv	Contains host names that are allowed to do print requests.

remove Command

Purpose

Deletes files from **var/adm/acct/sum** and **var/adm/acct/nite** subdirectories.

Syntax

/usr/sbin/acct/remove

Description

The **remove** command deletes all **/var/adm/acct/sum(x)/wtmp***, **/var/adm/acct/sum(x)/pacct***, and **/var/adm/acct/nite(x)/lock*** files. The **remove** command must be scheduled with the **cron** daemon. Also, the **remove** command should be run at the end of every accounting period, rather than every night.

Security

Access Control: This command should grant execute (x) access only to members of the **adm** group.

Files

Item	Description
/usr/sbin/acct	The path to the accounting commands.
/var/adm/acct/nite	Contains accounting data files.
/var/adm/acct/nitex	Contains accounting data files when user names greater than 8 characters are used.
/var/adm/acct/sum	Cumulative directory for daily accounting records.
/var/adm/acct/sumx	Cumulative directory for daily accounting records when user names greater than 8 character are used.

removevsd Command

Purpose

Removes a set of virtual shared disks.

Syntax

removevsd
{**-v** *vsd_names* | **-a**} [**-f**]

Description

Use this command to remove the logical volumes associated with the virtual shared disks. Volume groups are not removed with this command.

If the virtual shared disk is configured on any of the nodes on the system partition, this command is unsuccessful, unless the **-f** flag is specified.

You can use the System Management Interface Tool (SMIT) to run this command. To use SMIT, enter:

```
smit delete_vsd
```

and select the **Remove a Virtual Shared Disk** option.

Flags

-v
Specifies the virtual shared disk name or names that are to be removed by this command.

-a
Specifies that the command should remove all virtual shared disks in the RSCT peer domain.

-f
Forces the system to unconfigure the virtual shared disks and remove them. If **-f** is not specified and any of the virtual shared disks that are to be removed are configured, the command is unsuccessful.

Parameters

vsd_name
Specifies a virtual shared disk. If the virtual shared disk is not in the stopped state, you will get an error message.

Security

You must have `root` authority to run this command.

Restrictions

You must issue this command from a node that is online in the peer domain. To bring a peer domain online, use the **startrpdomain** command. To bring a particular node online in an existing peer domain, use the **startrpnode** command. For more information on creating and administering an RSCT peer domain, refer to *RSCT Administration Guide* .

Examples

To unconfigure and remove all defined virtual shared disks in a system or system partition, enter:

```
removevsd -a -f
```

Location

`/opt/rsct/vsd/bin/removevsd`

rendev Command

Purpose

Renames a device.

Syntax

```
rendev -l Name  -n NewName [-u]
```

Description

The **rendev** command enables devices to be renamed. The device to be renamed, is specified with the **-l** flag, and the new desired name is specified with the **-n** flag.

The new desired name must not exceed 15 characters in length. If the name has already been used or is present in the `/dev` directory, the operation fails. If the name formed by appending the new name after the character r is already used as a device name, or appears in the `/dev` directory, the operation fails.

If the device is in the Available state, the **rendev** command must unconfigure the device before renaming it. This is similar to the operation performed by the **rmdev –l Name** command. If the unconfigure operation fails, the renaming will also fail. If the unconfigure succeeds, the **rendev** command will configure the device, after renaming it, to restore it to the Available state. The **–u** flag may be used to prevent the device from being configured again after it is renamed.

Note: Disk drive devices that are members of the root volume group, or that will become members of the root volume group (by means of LVM or install procedures), must not be renamed. Renaming such disk drives may interfere with the ability to recover from certain scenarios, including boot failures.

Some devices may have special requirements on their names in order for other devices or applications to use them. Using the **rendev** command to rename such a device may result in the device being unusable.

Note: To protect the configuration database, the **rendev** command cannot be interrupted once it has started. Trying to stop this command before completion, could result in a corrupted database.

Flags

Item	Description
-l *Name*	Specifies the device, indicated by the *Name* parameter, to be renamed in the customized devices object.
-n *NewName*	Specifies the new name, indicated by the *NewName* parameter, to be assigned to the device.
-u	Optional flag, which indicates that the device is not to be configured after it is renamed.

Examples

1. To rename disk hdisk5 to hdisk2, enter:

   ```
   rendev -l hdisk5 -n hdisk2
   ```

2. To rename disk hdisk3 to ootvg, enter:

   ```
   rendev -l hdisk3 -n ootvg
   ```

The second command fails because **ootvg** appended to **r** results in the name **rootvg**, which conflicts with the rootvg volume group name.

renice Command

Purpose

Alters the nice value of running processes.

Syntax

renice [**-n** *Increment*] [**-g** | **-p** | **-u**] *ID ...*

Description

The **renice** command alters the nice value of one or more running processes. The *nice value* is the decimal value of the system scheduling priority of a process. By default, the processes affected are specified by their process IDs. When you specify a process group, the request applies to all processes in the process group.

The nice value is determined in an implementation-dependent manner. If the requested increment raises or lowers the nice value of the executed utility beyond implementation-dependent limits, the limit whose value was exceed is used.

If you do not have root user authority, you can only reset the priority of processes you own and can only increase their priority within the range of 0 to 20, with 20 being the lowest priority. If you have root user authority, you can alter the priority of any process and set the priority to any value in the range -20 to 20. The specified *Increment* changes the priority of a process in the following ways:

Item	Description
1 to **20**	Runs the specified processes slower than the base priority.
0	Sets priority of the specified processes to the base scheduling priority.
-20 to **-1**	Runs the specified processes quicker than the base priority.

The **renice** command maps these values to those actually used by the kernel.

Notes:

1. If you do not have root user authority, you cannot increase the nice value of processes (even if you had originally decreased their priorities).
2. You cannot use the **renice** command to change a process to run at a constant priority. To do this, use the **setpriority** system call.

Flags

Item	Description
-g	Interprets all IDs as unsigned decimal integer process group IDs.
-n *Increment*	Specifies the number to add to the nice value of the process. The value of *Increment* can only be a decimal integer from -20 to 20. Positive increment values cause a lower nice value. Negative increment values require appropriate privileges and cause a higher nice value.
-p	Interprets all IDs as unsigned integer process IDs. The -p flag is the default if you specify no other flags.
-u	Interprets all IDs as user name or numerical user IDs.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion
>0	An error occurred.

Examples

1. To alter the system scheduling priority so that process IDs 987 and 32 have lower scheduling priorities, enter:

   ```
   renice -n 5 -p 987 32
   ```

2. To alter the system scheduling priority so that group IDs 324 and 76 have higher scheduling priorities (if the user has the appropriate privileges to do so), enter:

   ```
   renice -n -4 -g 324 76
   ```

3. To alter the system scheduling priority so that numeric user ID 8 and user `sas` have lower scheduling priorities, enter:

   ```
   renice -n 4 -u 8 sas
   ```

Files

Item	Description
/usr/sbin/renice	Contains the **renice** command.
/etc/passwd	Maps user names to user IDs.

reorgvg Command

Purpose

Reorganizes the physical partition allocation for a volume group.

Syntax

reorgvg [**-i**] *VolumeGroup* [*LogicalVolume ...*]

Description

The **reorgvg** command reorganizes the placement of allocated physical partitions within the *VolumeGroup*, according to the allocation characteristics of each logical volume. Use the *LogicalVolume* parameter to reorganize specific logical volumes; highest priority is given to the first logical volume name in the *LogicalVolume* parameter list and lowest priority is given to the last logical volume in the parameter list. The volume group must be varied on and must have free partitions before you can use the **reorgvg** command.

The relocatable flag of each logical volume must be set to **y** with the **chlv -r** command for the reorganization to take effect; otherwise, the logical volume is ignored.

Note:

1. The **reorgvg** command does not reorganize the placement of allocated physical partitions for any striped logical volumes.
2. At least one free physical partition (PP) must exist on the specified volume group for the **reorgvg** command to run successfully. For mirrored logical volumes, one free PP per physical volume (PV) is required in order for the **reorgvg** command to maintain logical volume strictness during execution; otherwise the **reorgvg** command still runs, but moves both copies of a logical partition to the same disk during its execution.
3. To use this command, you must either have root user authority or be a member of the **system** group.
4. If you enter the **reorgvg** command with the volume group name and no other arguments, the entire volume group is reorganized.
5. You cannot use the **reorgvg** command on a snapshot volume group or a volume group that has a snapshot volume group.
6. You cannot use the **reorgvg** command on a volume group that has an active firmware assisted dump logical volume.

You could also use the System Management Interface Tool (SMIT)**smit reorgvg** fast path to run this command.

Flags

Item	Description
-i	Specifies physical volume names read from standard input. Only the partitions on these physical volumes are organized.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To reorganize logical volumes `lv03`, `lv04`, and `lv07` on volume group `vg02`, enter:

   ```
   reorgvg vg02 lv03 lv04 lv07
   ```

   Only the listed logical volumes are reorganized on `vg02`.
2. To reorganize only the partitions located on physical volumes `hdisk4` and `hdisk6` that belong to logical volumes `lv203` and `lv205`, enter:

   ```
   echo "hdisk4 hdisk6" | reorgvg -i vg02 lv203 lv205
   ```

   The partitions located on physical volumes `hdisk4` and `hdisk6` of volume group `vg02`, that belong to logical volumes `lv203` and `lv205`, are reorganized.

Files

Item	Description
/usr/sbin/reorgvg	Directory where the **reorgvg** command resides.
/tmp	Directory where the temporary files are stored while the command is running.

repl Command

Purpose

Replies to a message.

Syntax

repl [**+***Folder*] [**-draftfolder +***Folder* | **-nodraftfolder**] [*Message*] [**-draftmessage***Message*] [**-annotate** [**-noinplace** | **-inplace**] | **-noannotate**] [**-cc** *Names...*] [**-nocc** *Names...*] [**-query** | **-noquery**] [**-fcc +***Folder*] [**-form** *FormFile*] [**-editor** *Editor* | **-noedit**] [**-format** | **-noformat**] [**-filter** *File*] [**-width** *Number*] [**-whatnowproc** *Program* | **-nowhatnowproc**]

Description

The **repl** command starts an interface enabling you to compose a reply to a message. By default, the command drafts a reply to the current message in the current folder. If you do not specify the **-draftfolder** flag, or if the `Draft-Folder:` entry in the **$HOME/.mh_profile** file is undefined, the **repl** command searches your MH directory for a **draft** file. If you specify a folder, that folder becomes the current folder.

When you enter the **repl** command, the system places the `To:`, `cc:`, and `In-Reply-To:` fields in the draft and prompts you to enter the text of the reply. To exit the editor, press Ctrl-D. After exiting the editor, the **repl** command starts the MH **whatnow** command. You can see a list of available **whatnow** subcommands by pressing the Enter key at the `What now?` prompt. With these subcommands, you can re-edit, list, and send a reply, or end the processing of the **repl** command.

> **Note:** A line of dashes or a blank line must be left between the header and the body of the message for the message to be identified when it is sent.

The **repl** command uses the definitions in the **/etc/mh/replcomps** file to format the reply message. You can create a **replcomps** file in your MH directory or use the **-form** flag to define an alternate reply format. To leave a copy of the original message in the reply message, use the **-filter** flag.

To annotate the original message with redistribution information, use the **-annotate** flag. This flag annotates the original message with the `Resent:` field and the current date and time. A message is annotated only if you send the reply before you exit **repl** command processing.

Flags

Item	Description
-annotate	Annotates the message being replied to with the time and date of the reply. You can use the **-inplace** flag to preserve links to an annotated message.
-cc *Names*	Specifies the users who will be listed in the `cc:` field of the reply. You can specify the following variables for *Names*: **all**, **to**, **cc**, and **me**. The default is **-cc all**.
-draftfolder +*Folder*	Places the draft message in the specified folder. If **+***Folder* is not specified, then `Current-Folder` is assumed.
-draftmessage *Message*	Specifies the draft message. If you specify **-draftfolder** without the **-draftmessage** flag, the default message is new. If you specify this flag without the **-draftfolder** flag, the system creates the draft in the default file, *UserMHdirectory*/**draft**.
-editor *Editor*	Identifies the initial editor for composing the reply. If you do not specify the **-editor** flag, the **comp** command selects the default editor specified by the `Editor:` entry in your **$HOME/.mh_profile** file.

Item	Description
-fcc +*Folder*	Places a file copy of the reply in the specified folder. If you do not specify this flag, the **repl** command will not produce a file copy.
-filter *File*	Reformats the message being replied to and places the reformatted message in the body of the reply. You must specify a *File* variable with this flag. The **-filter** flag uses the format file acceptable to the **mhl** command.
+*Folder*	Identifies the folder that contains the message to reply to. If a folder is not specified, then `Current-Folder` is used.
-form *FormFile*	Specifies a reply format. The **repl** command treats each line in the specified format file as a format string.
-format	Removes duplicate addresses from the `To:`, `cc:`, and `Bcc:` fields and standardizes these fields using the columns specified by the **-width** flag. The **-format** flag indicates if Internet style is to be used, which serves as the default.
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For MH, the name of this flag must be fully spelled out.
-inplace	Forces annotation to be done in place in order to preserve links to the annotated message.
Message	Specifies a message. If you specify both a message to reply to and a message draft, you must use the **-draftmessge** flag. Use the following to define a message: ***Number*** Number of the message. **cur or . (period)** Current message. The default reply message. **first** First message in a folder. **last** Last message in a folder. **new** New message that is created. The default draft message is **new**. **next** Message following the current message. **prev** Message preceding the current message.
-noannotate	Prevents annotation. This flag is the default.
-nocc *Names*	Allows you to specify the users who will not be listed in the `cc:` field of the reply. You can specify the following for *Names*: **all**, **to**, **cc**, and **me**.
-nodraftfolder	Places the draft in the file *UserMhDirectory***/draft**.
-noedit	Suppresses the initial edit.
-noformat	Suppresses both removal of duplicate addresses from the `To:`, `cc:`, and `Bcc:` fields, and standardization of these fields.
-noinplace	Prevents annotation in place. This flag is the default.
-noquery	Automatically builds the `To:` and `cc:` fields. This flag is the default.

Item	Description
-nowhatnowproc	Prevents interactive processing for the **repl** command. This flag prevents editing.
-query	Queries you for permission to include each address in the `To:` and `cc:` fields.
-whatnowproc *Program*	Starts the specified command string as the program to guide you through the reply tasks. The default is the **whatnow** program.
-width *Number*	Sets the width of the address fields. The default is 72 columns.

Profile Entries

The following entries are entered in the *UserMhDirectory***/.mh_profile** file:

Item	Description
`Alternate-Mailboxes:`	Specifies the mailboxes.
`Current-Folder:`	Sets the default current folder.
`Draft-Folder:`	Sets the default folder for drafts.
`Editor:`	Sets the default editor.
`fileproc:`	Specifies the program used to refile messages.
`mhlproc:`	Specifies the program used to filter the message for which you are creating a reply.
`Msg-Protect:`	Sets the protection level for the new message files.
`Path:`	Specifies the user's MH directory.
`whatnowproc:`	Specifies the program used to prompt `What now?` questions.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To reply to the current message in the current folder, enter:

   ```
   repl
   ```

   The system responds with text similar to the following:

   ```
   To: patrick@venus
   cc: tom@thomas
   Subject: Re: Meeting on Monday
   In-reply-to: (Your message of Thu, 21 Jul 88 13:39:34 CST.)
                <8807211839.AA01868>
   --------------
   ```

   You can now enter your reply. When you finish entering the body of your reply, press the Ctrl-D key sequence to exit the editor. The system responds with the following:

   ```
   What now?
   ```

Enter send to send the reply. If you want to see a list of subcommands, press the Enter key. In this example, you are sending a reply to the current message in the current folder.

2. To send a reply to message 4 in the inbox folder, enter:

   ```
   repl  +inbox 4
   ```

   The system responds with a message similar to the following:

   ```
   To: dawn@chaucer
   cc: jay@venus
   Subject: Re: Status Report
   In-reply-to: (Your message of Thu, 21 Jul 88 13:39:34 CST.)
                <8807211839.AA01868>
   --------------
   ```

   You can now enter your reply. When you finish entering the body of your reply, press the Ctrl-D key sequence to exit the editor. The system responds with the following:

   ```
   What now?
   ```

   Enter send to send the reply. If you want to see a list of subcommands, press the Enter key.

3. To keep track of your reply to the current message in the current folder, use the **-annotate** flag to place a copy of the date and time in the message you are replying to, as follows:

   ```
   repl  -annotate
   ```

   The system responds with a message similar to the following:

   ```
   To: patrick@venus
   cc: tom@thomas
   Subject: Re: Meeting on Friday
   In-reply-to: (Your message of Mon, 17 Apr 89 13:39:34 CST.)
                <8904171839.AA01868>
   --------------
   ```

   You can now enter your reply. When you finish entering the body of your reply, press the Ctrl-D key sequence to exit the editor. The system responds with the following:

   ```
   What now?
   ```

   Enter send to send the reply. If you quit the editor without sending the reply, the annotation does not occur.

Files

Item	Description
$HOME/.mh_profile	Specifies the user's MH profile.
/etc/mh/replcomps	Contains the MH default reply template.
UserMhDirectory/**replcomps**	Contains the user's default reply form.
/usr/bin/repl	Contains the **repl** command.
UserMhDirectory/**draft**	Contains the current message draft.

replacepv Command

Purpose

Replaces a physical volume in a volume group with another physical volume.

Syntax

replacepv [**-f**] {*SourcePhysicalVolume* | *SourcePhysicalVolumeID* } *DestinationPhysicalVolume*

replacepv [**-R**] *dir_name* [*DestinationPhysicalVolume*]

Description

The **replacepv** command replaces allocated physical partitions and the data they contain from the *SourcePhysicalVolume* to *DestinationPhysicalVolume*. The specified source physical volume cannot be the same as *DestinationPhysicalVolume*.

Note:

1. The *DestinationPhysicalVolume* must not belong to a volume group.
2. The *DestinationPhysicalVolume* size must be at least the size of the *SourcePhysicalVolume*.
3. The **replacepv** command cannot replace a *SourcePhysicalVolume* with stale logical volume unless this logical volume has a non-stale mirror.
4. You cannot use the **replacepv** command on a snapshot volume group or a volume group that has a snapshot volume group.
5. Running this command on a physical volume that has an active firmware assisted dump logical volume temporarily changes the dump device to **/dev/sysdumpnull**. After the migration of logical volume is successful, this command calls the **sysdumpdev -P** command to set the firmware assisted dump logical volume to the original logical volume.
6. The VG corresponding to the SourcePhysicalVolume is examined to determine if a PV type restriction exists. If a restriction exists, the DestinationPhysicalVolume is examined to ensure that it meets the restriction. If it does not meet the PV type restriction, the command will fail.

The allocation of the new physical partitions follows the policies defined for the logical volumes that contain the physical partitions being replaced.

Flags

Item	Description
-f	Forces to replace a *SourcePhysicalVolume* with the specified *DestinationPhysicalVolume* unless the *DestinationPhysicalVolume* is part of another volume group in the Device Configuration Database or a volume group that is active.
-R *dir_name*	Recovers **replacepv** if it is interrupted by <ctrl-c>, a system crash, or a loss of quorum. When using the **-R** flag, you must specify the directory name given during the initial run of **replacepv**. This flag also allows you to change the *DestinationPhysicalVolume.*

Security

Access Control: You must have root authority to run this command.

Examples

1. To replace physical partitions from `hdisk1` to `hdisk6`, enter:

```
replacepv hdisk1 hdisk6
```

Files

Item	Description
/usr/sbin	Directory where the **replacepv** command resides.

Item	Description
/tmp	Directory where the temporary files are stored while the command is running.

repquota Command

Purpose

Summarizes quotas for a file system.

Syntax

repquota [**-v**] [**-c**] [**-g**] [**-u**] [**-l**] { -a | *FileSystem ...* }

Description

The **repquota** command prints a summary of quotas and disk usage for a file system specified by the *FileSystem* parameter. If the **-a** flag is specified instead of a file system, the **repquota** command prints the summary for all file systems enabled with quotas in the **/etc/filesystems** file. By default, both user and group quotas are printed.

For each user or group, the **repquota** command prints:

- Number of existing user or group files
- Amount of disk space being used by the user or group
- User or group quotas

Flags

Item	Description
-a	Specifies that quotas are printed for all file systems enabled with quotas in the **/etc/filesystems** file.
-c	Changes the output of the command to a colon-delineated format.
-g	Specifies that only group quotas are printed.
-l	Enables long user names to be printed on the repquota report. The default behavior of the report will be to truncate the name at 9 characters. If the **-l** option is specified, the full user name will be used.
-u	Specifies that only user quotas are printed.
-v	Prints a header line before the summary of quotas for each file system.

Security

Access Control: Only the root user can execute this command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

To print a summary of user quotas in the /u file system, enter:

```
repquota -u /u
```

The system prints the following information:

```
                  Block  limits                 File limits
User      used    soft    hard   grace   used   soft  hard  grace
root  --  3920     0       0             734     0     0
davec +-    28     8      30     3 days    3     0     0
keith --    48     0       0               7     0     0
```

The + printed in the first column next to davec indicates that the user has exceeded established block limits. If there were a + in the second column, it would indicate that the user had exceeded established file limits.

Files

Item	Description
quota.user	Specifies user quotas.
quota.group	Specifies group quotas.
/etc/filesystems	Contains file system names and locations.
/etc/group	Contains basic group attributes.
/etc/passwd	Contains user names and locations.

reset Command

Purpose

Initializes terminals.

Syntax

reset [**-e** *C*] [**-k** *C*] [**-i** *C*] [**-**] [**-s**] [**-n**] [**-I**] [**-Q**] [**-m** [*Identifier*] [*TestBaudRate*] **:***Type*] ... [*Type*]

Description

The **reset** command is a link to the **tset** command. If the **tset** command is run as the **reset** command, it performs the following actions before any terminal-dependent processing is done:

- Set Cooked and Echo modes to on
- Turn off cbreak and Raw modes
- Turn on new-line translation
- Restore special characters to a sensible state.

Any special character that is found to be NULL or -1 is reset to its default value. All flags to the **tset** command can be used with the **reset** command.

The **reset** command is most useful when a program dies and leaves a terminal in an undesirable state. The sequence <LF>reset<LF> (where <LF> is Ctrl-J, the line feed) may be required to get the **reset** command to run successfully since carriage-return might not work in this state. The <LF>reset<LF> sequence frequently will not be echoed.

Flags

Item	Description
-	The name of the terminal decided upon is output to standard output. This is intended to be captured by the shell and placed in the **TERM** environment variable.

Item	Description
-e *C*	Set the erase character to the character specified by the C variable on all terminals. The default is the backspace character on the terminal, usually ^ (cedilla). The character C can either be typed directly or entered using the ^ (cedilla).
-I	Suppresses transmission of terminal initialization strings.
-i *C*	Is similar to the **-e** flag, but uses the interrupt character rather than the erase character. The C variable defaults to ^C. The ^ character can also be used for this option.
-k *C*	Is similar to the **-e** flag, except uses the line-kill character rather than the erase character. The C variable defaults to ^X. The kill character is left alone if **-k** is not specified. The ^ character can also be used for this option.
-m*IdentifierTestbaudRate***:***Type*	Specifies which terminal type (in the *Type* parameter) is usually used on the port identified in the *Identifier* parameter. A missing identifier matches all identifiers. You can optionally specify the baud rate in the *TestBaudRate* parameter.
-n	On systems with the Berkeley 4.3 tty driver, specifies that the new tty driver modes should be initialized for this terminal. For a CRT, the CRTERASE and CRTKILL modes are set only if the baud rate is 1200 bps or greater. See the **tty** file for more information.
-Q	Suppresses printing of the `Erase set to` and `Kill set to` messages.
-s	Prints the sequence of **csh** commands that initialize the **TERM** environment variable, based on the name of the terminal decided upon.

Files

Item	Description
/usr/share/lib/terminfo/?/*	Contains the terminal capability database.

resetrsrc Command

Purpose

Resets a resource that is, forces the resource to move to the offline state.

Syntax

To reset one or more resources, using data entered on the command line:

`resetrsrc -s "`*selection_string*`"`` [-N { `*node_file* | `"-" }] [-h] [-TV] `*resource_class* [*arg*=*value...*]

`resetrsrc -r [-h] [-TV] `*resource_handle* [*arg*=*value...*]

To reset one or more resources using command arguments that are predefined in an input file:

`resetrsrc -f `*resource_data_input_file*` -s "`*selection_string*`" [ -N { `*node_file* | `"-" } ] [-h] [-TV] `*resource_class*

`resetrsrc -f `*resource_data_input_file*` -r [-h] [-TV] `*resource_handle*

To display the names and data types of the command arguments:

`resetrsrc -l [-h] `*resource_class*

Description

The `resetrsrc` command requests that the resource monitoring and control (RMC) subsystem force one or more resources offline. The request is performed by the appropriate resource manager.

To reset one or more resources, use the `-s` flag to force offline all of the resources that match the specified selection string. To reset one specific resource, use the `-r` flag to specify the resource handle that represents that specific resource.

Instead of specifying multiple node names in *selection_string*, you can use the `-N` *node_file* flag to indicate that the node names are in a file. Use `-N "-"` to read the node names from standard input.

Use the `-l` flag to determine whether the specified resource class accepts any additional command arguments.

The successful completion of this command does not guarantee that the resource is offline, only that the resource manager successfully received the request to force this resource offline. Monitor the resource dynamic attribute `OpState` to determine when the resource is forced offline. Register an event for the resource, specifying the `OpState` attribute, to know when the resource is offline. Or, intermittently run the `lsrsrc` command until you see that the resource is offline (the value of `OpState` is 2). For example:

```
lsrsrc -s 'Name == "/filesys1"' -t IBM.FileSystem Name OpState
```

If Cluster Systems Management (CSM) is installed on your system, you can use CSM defined node groups as node name values to refer to more than one node. For information about working with CSM node groups and using the CSM `nodegrp` command, see the *CSM: Administration Guide* and the *CSM: Command and Technical Reference*.

Parameters

resource_class
Specifies the name of the resource class that contains the resources that you want to force offline.

resource_handle
Specifies the resource handle that corresponds to the resource you want to force offline. Use the `lsrsrc` command to obtain a list of valid resource handles. The resource handle must be enclosed within double quotation marks, for example:

```
"0x4017 0x0001 0x00000000 0x0069684c 0x0d4715b0 0xe9635f69"
```

arg=value...
Specifies one or more pairs of command argument names and values.

arg
Specifies the argument name.

value
Specifies the value for this argument. The value data type must match the definition of the argument data type.

Command arguments are optional. If any *arg=value* pairs are entered, there must be one *arg=value* pair for each command argument defined for the offline function for the specified resource class.

Use `resetrsrc -l` to get a list of the command argument names and data types for the specific resource class.

Flags

-f *resource_data_input_file*
Specifies the name of the file that contains resource argument information. The following contents of the file is displayed:

```
PersistentResourceArguments::
argument1 = value1
argument2 = value2
```

-l
Lists the command arguments and data types. Some resource managers accept additional arguments that are passed to the offline request. Use this flag to list any defined command arguments and the data types of the command argument values.

-N { *node_file* | "-" }
Specifies that node names are read from a file or from standard input. Use `-N` *node_file* to indicate that the node names are in a file.

- There is one node name per line in *node_file*
- A number sign (#) in column 1 indicates that the line is a comment
- Any blank characters to the left of a node name are ignored
- Any characters to the right of a node name are ignored

Use `-N "-"` to read the node names from standard input.

The CT_MANAGEMENT_SCOPE environment variable determines the scope of the cluster. If CT_MANAGEMENT_SCOPE is not set, management domain scope is chosen first (if a management domain exists), peer domain scope is chosen next (if a peer domain exists), and then local scope is chosen, until the scope is valid for the command. The command runs once for the first valid scope it finds. For example, if a management domain and a peer domain both exist and CT_MANAGEMENT_SCOPE is not set, this command applies to the management domain. If you want this command to apply to the peer domain, set CT_MANAGEMENT_SCOPE to 2.

-r
Forces offline the specific resource that matches the specified resource handle.

-s "*selection_string*"
Specifies the selection string. All selection strings must be enclosed within either double or single quotation marks. If the selection string contains double quotation marks, enclose the entire selection string in single quotation marks. For example:

```
-s 'Name == "testing"'
-s 'Name ?= "test"'
```

Only persistent attributes can be listed in a selection string.

-h
Writes the command usage statement to standard output.

-T
Writes the command trace messages to standard error. For your software service organization use only.

-V
Writes the command verbose messages (if there are any available) to standard output.

Environment variables

CT_CONTACT
When the CT_CONTACT environment variable is set to a host name or IP address, the command contacts the resource monitoring and control (RMC) daemon on the specified host. If the environment variable is not set, the command contacts the RMC daemon on the local system where the command

is being run. The resource class or resources that are displayed or modified by the command are on the system to which the connection is established.

CT_IP_AUTHENT
When the CT_IP_AUTHENT environment variable exists, the RMC daemon uses IP-based network authentication to contact the RMC daemon on the system that is specified by the IP address to which the CT_CONTACT environment variable is set. CT_IP_AUTHENT has meaning only if CT_CONTACT is set to an IP address; it does not rely on the domain name system (DNS) service.

CT_MANAGEMENT_SCOPE
Determines the management scope that is used for the session with the RMC daemon to monitor and control the resources and resource classes. The management scope determines the set of possible target nodes where the resources and resource classes can be monitored and controlled. The valid values are:

0
Specifies *local* scope.

1
Specifies *local* scope.

2
Specifies *peer domain* scope.

3
Specifies *management domain* scope.

If this environment variable is *not* set, *local* scope is used.

Standard output

When the `-h` flag is specified, this command usage statement is written to standard output. When the `-V` flag is specified, this command verbose messages (if there are any available) are written to standard output.

Standard error

All trace messages are written to standard error.

Exit status

0
The command ran successfully.

1
An error occurred with RMC.

2
An error occurred with the command-line interface (CLI) script.

3
An incorrect flag was specified on the command line.

4
An incorrect parameter was specified on the command line.

5
An error occurred with RMC that was based on incorrect command-line input.

6
No resources were found that match the specified selection string.

Security

You need write permission for the *resource_class* specified in `resetrsrc` to run `resetrsrc`. Permissions are specified in the access control list (ACL) file on the contacted system. See the *Administering RSCT* guide for information about the ACL file and how to modify it.

Implementation specifics

This command is part of the `rsct.core.rmc` fileset for AIX and `rsct.core-3.1.0.0-0.`*platform*`.rpm` package for Linux, Solaris, and Windows, where *platform* is `i386`, `ppc`, `ppc64`, `s390`, or `x86_64`.

Location

/opt/rsct/bin/resetrsrc

Examples

Suppose that you have a peer domain called `foo` with three defined nodes: nodeA, nodeB, and nodeC. nodeA has two Ethernet cards: `ent0` and `ent1`.

1. Suppose nodeA is online and `ent0` (on nodeA) is also online. To force `ent0` offline on nodeA, run this command on nodeA:

   ```
   resetrsrc -s 'Name == "ent0"' IBM.EthernetDevice
   ```

2. Suppose nodeA and nodeB are online, `ent0` (on nodeA) is also online, and you are currently logged on to nodeB. To force `ent0` offline on nodeA, run this command on nodeB:

   ```
   resetrsrc -s 'NodeName == "nodeA" AND Name == "ent0"' IBM.EthernetDevice
   ```

3. Suppose nodeA and nodeB are online and file system `/filesys1` is defined and mounted on nodeB. To force `/filesys1` offline on nodeB, run this command on nodeA:

   ```
   resetrsrc -s 'NodeName == "nodeB" AND Name == "/filesys1"' IBM.FileSystem
   ```

4. Suppose the resource handle for `ent0` on nodeA is:

   ```
   0x406b 0x0001 0x00000000 0x0069564c 0x0dc1f272 0xb9de145e
   ```

   To force `ent0` offline on nodeA, run this command on nodeA:

   ```
   resetrsrc -r "0x406b 0x0001 0x00000000 0x0069564c 0x0dc1f272 0xb9de145e"
   ```

5. To reset `ent0` on nodeA and nodeB, using the `/tmp/common/node_file` file:

   ```
   # common node file
   #
   nodeA
   nodeB
   #
   ```

   as input, enter:

   ```
   resetrsrc -s 'Name == "ent0"' -N /tmp/common/node_file \
   IBM.EthernetDevice
   ```

resize Command

Purpose

Sets the **TERMCAP** environment variable and terminal settings to the current window size.

Syntax

resize [**-c** | **-u**] [**-s** [*Rows Columns*]]

Description

The **resize** command utility prints a shell command for setting the **TERM** and **TERMCAP** environment variables to indicate the current size of the xterm window from which the command is run. For this output to take effect, the **resize** command must either be evaluated as part of the command line (usually done with a shell alias or function) or else be redirected to a file that can then be read in. From the C shell (usually known as **/bin/csh**), the following alias could be defined in the user's **.cshrc** file:

```
%  alias rs 'set noglob; `eval resize`'
```

After resizing the window, the user would enter:

```
%  rs
```

Users of versions of the Bourne shell (usually known as **/bin/sh**) that do not have command functions will need to send the output to a temporary file and then read it back in with the . (dot) command:

```
$  resize >/tmp/out
$  . /tmp/out
```

Flags

Item	Description
-c	Indicates that C shell commands should be generated even if the user's current shell is not **/bin/csh**.
-u	Indicates that Bourne shell commands should be generated even if the user's current shell is not a Bourne shell.
-s [*Rows Columns*]	Indicates that Sun console escape sequences will be used instead of the special xterm escape code. If the *Rows* and *Columns* parameters are given, the **resize** command will ask the xterm window to resize itself. However, the window manager may choose to disallow the change.

Note: The -**c** or -**u** must appear to the left of -**s** if both are specified.

File

Item	Description
/etc/termcap	Provides modification for the base termcap entry.

resource_data_input Information File

Purpose

Describes how to use an input file for passing resource class information, such as resource attribute names and values, to the resource monitoring and control (RMC) command-line interface (CLI).

Description

You can use the `-f` flag with most RMC commands to specify the name of a resource data input file when you want to pass resource persistent attribute values and other information to the RMC CLI. This is useful when typing information about the command line would be too cumbersome or prone to typographical

errors. The data in this file is used for defining resources or for changing the persistent attribute values of a resource or resource class. The resource data input file, which must be in POSIX format, has no set location. It can be a temporary file or a permanent file, depending on your requirements.

The **chrsrc**, **mkrsrc**, **resetrsrc**, **rmrsrc**, **runact**, **startrsrc**, and **stoprsrc** commands read this file when they are issued with the `-f` flag. The **lsactdef**, **lsrsrc**, and **lsrsrcdef** commands generate a file with this format when they are issued with the `-i` flag.

Keywords are used in the input file to indicate which type of data is listed in the related stanza:

ResourceAction
Resource action element names and values for the resource action when starting an action. The **runact** command reads in the resource action elements. These elements are ignored if the input file is read by `runact -c`.

ResourceClassAction
Resource class action element names and values for the resource class action when starting a class action. The **runact** command reads in the resource action elements.

PersistentResourceArguments
Resource command argument names and values for those commands that accept them: **mkrsrc**, **resetrsrc**, **rmrsrc**, **startrsrc**, and **stoprsrc**. Command arguments are optional and are defined by the resource class. Specify the `-l` option with these commands to see the command arguments for a resource class.

PersistentResourceAttributes
Persistent attribute names and values for one or more resources for a specific resource class used to define a new resource or change attribute values for an existing resource. The persistent resource attributes are read in by the commands **mkrsrc** and **chrsrc**. These attributes are ignored if the input file is read by the **chrsrc** command that is specified with the `-c` flag.

PersistentResourceClassAttributes
Persistent attribute names and values for a resource class used to change the attribute values of an existing resource class. The persistent resource class attributes are read in by the **chrsrc** command only when the `-c` flag is specified.

In general, a *resource_data_input* file is a flat text file with the following format. **Bold** words are literal. Text that precedes a single colon (:) is an arbitrary label and can be any alphanumeric text.

```
PersistentResourceAttributes::
# This is a comment
    label:
      AttrName1  = value
      AttrName2  = value
      AttrName3  = value
    another label:
        Name        = name
        NodeNumber  = 1
    ⋮
    ::

PersistentResourceClassAttributes::
# This is a comment
    label:
      SomeSettableAttrName         = value
      SomeOtherSettableAttrName     = value
    ::
⋮

PersistentResourceArguments::
# This is a comment
    label:
      ArgName1  = value
      ArgName2  = value
      ArgName3  = value
    ::
⋮
```

See the Examples section for more details.

Some notes about formatting follow:

- The keywords PersistentResourceAttributes, PersistentResourceClassAttributes, and PersistentResourceArguments are followed by two colons (::).
- The order of the keyword stanzas is not significant in the file. For example, PersistentResourceClassAttributes can precede PersistentResourceClass. It does not affect the portion of the data that is read in by the calling CLI.
- Individual stanza headings (beneath the keywords) are followed by one colon (:), for example: `c175n05 resource info:`.
- White space at the beginning of lines is not significant. Tabs or spaces are suggested for readability.
- Any line with a pound sign (#) as the first printable character is a comment.
- Each entry on an individual line is separated by white space (spaces or tabs).
- Blank lines in the file are not significant and are suggested for readability.
- There is no limit to the number of resource attribute stanzas included in a particular PersistentResourceAttributes section.
- There is no limit to the number of resource class attribute stanzas included in a particular PersistentResourceClassAttributes section. Typically, there is only one instance of a resource class. In this case, only one stanza is expected.
- If only one resource attribute stanza is included in a particular PersistentResourceAttributes section, the *label:* line can be omitted. This also applies to the ResourceAction section.
- If only one resource class attribute stanza is included in a particular PersistentResourceClassAttributes section, the *label:* line can be omitted. This also applies to the ResourceClassAction section.
- Values that contain spaces must be enclosed in quotation marks.
- A double colon (::) indicates the end of a section. If a terminating double colon is not found, the next Reserved Keyword or end of file signals the end of a section.
- Double quotation marks included within a string that is surrounded by double quotation marks must be escaped. (\").

  Note: Double quotation marks can be nested within single quotation marks.

  Examples:

  - `"Name == \"testing\""`
  - `'Name == "testing"'`

    This syntax is preferred if your string is a selection string and you are going to cut and paste to the command line.
- Single quotation marks included within a string that is surrounded by single quotation marks must be escaped. (\').

  Note: Single quotation marks can be nested within double quotation marks.

  Here are some examples:

  - `'Isn\'t that true'`
  - `"Isn't that true"`

    This syntax is preferred if you are going to cut and paste to the command line.
- The format you use to enter data in a *resource_data_input* file might not be the same format used on the command line. The shell you choose to run the commands in has its own rules regarding quotation marks. Refer to the documentation for your shell for these rules, which determine how to enter data on the command line.

Implementation specifics

This information is part of the `rsct.core.rmc` fileset for AIX and `rsct.core-3.1.0.0-0.`*platform*`.rpm` package for Linux, Solaris, and Windows, where *platform* is i386, ppc, ppc64, s390, or x86_64.

Location

/opt/rsct/man/resource_data_input.7

Examples

1. This sample **mkrsrc** command:

```
mkrsrc -f /tmp/my_resource_data_input_file IBM.Example
```

uses the sample input file /tmp/my_resource_data_input_file for the IBM.Example resource class. The contents of the input file look like this:

```
PersistentResourceAttributes::
# Resource 1 - only set required attributes
resource 1:
    Name="c175n04"
    NodeList = {1}
# Resource 2 - setting both required and optional attributes
# mkrsrc -e2 IBM.Example displays required and optional
# persistent attributes
resource 2:
    Name="c175n05"
    NodeList = {1}
    Int32 = -99
    Uint32 = 99
    Int64 = -123456789123456789
    Uint64 = 123456789123456789
    Float32 = -9.89
    Float64 = 123456789.123456789
    String = "testing 123"
    Binary = 0xaabbccddeeff
    RH = "0x0000 0x0000 0x00000000 0x00000000 0x00000000 0x00000000"
    SD = [hello,1,{2,4,6,8}]
    Int32Array = {-4, -3, -2, -1, 0, 1, 2, 3, 4}
    Int64Array = {-4,-3,-2,-1,0,1,2,3,4}
    Uint32Array = {0,1,2,3,4,5,6}
    Uint64Array = {0,1,2,3,4,5,6}
    Float32Array = {-3.3, -2.2, -1.2, 0, 1, 2.2, 3.3}
    Float64Array = {-3.3, -2.2, -1.2, 0, 1, 2.2, 3.3}
    StringArray = {abc,"do re mi", 123}
    BinaryArray = {"0x01", "0x02", "0x0304"}
    RHArray     = {"0x0000 0x0000 0x00000000 0x00000000 0x00000000 0x00000000",
                   "0xaaaa 0xaaaa 0xbbbbbbbb 0xcccccccc 0xdddddddd 0xeeeeeeee"}
    SDArray     = {[hello,1,{0,1,2,3}],[hello2,2,{2,4,6,8}]}
```

2. This sample **chrsrc** command:

```
chrsrc -f  /tmp/Example/ch_resources -s 'Name == "c175n05"' IBM.Example
```

uses the sample input file /tmp/Example/ch_resources to change the attribute values of existing IBM.Example resources. The contents of the input file look like this:

```
PersistentResourceAttributes::
# Changing resources that match the selection string entered
# when running chrsrc command.
    resource 1:
        String            = "this is a string test"
        Int32Array        = {10,-20,30,-40,50,-60}
```

3. This sample **rmrsrc** command:

```
rmrsrc -l IBM.Examplebar
```

shows the optional command arguments:

```
rmrsrc IBM.Examplebar ExampleInt32=int32 ExampleUint32=uint32
```

4. This sample **rmrsrc** command:

```
rmrsrc -f /tmp/Examplebar/rm_resources -s 'Name == "c175n05"' IBM.Examplebar
```

uses the sample input `/tmp/Examplebar/rm_resources` file to specify the optional command arguments for **rmrsrc** command. The contents of the input file look like this:

```
PersistentResourceArguments::
# Specifying command arguments when running rmrsrc command.
resource 1:
    ExampleInt32      =   1
        ExampleUint32     =   0
```

restart-secldapclntd Command

Purpose

The **restart-secldapclntd** script is used to stop the currently running **secldapclntd** daemon process and then restart it.

Syntax

/usr/sbin/restart-secldapclntd [**-C** *CacheSize*] [**-p** *NumOfThread*] [**-t** *CacheTimeOut*] [**-T** *HeartBeatIntv*] [**-o** *ldapTimeOut*]

Description

The **restart-secldapclntd** script stops the **secldapclntd** daemon if it is running, and then restarts it. If the **secldapclntd** daemon is not running, it simply starts it.

Flags

By default, the **secldapclntd** daemon reads the configuration information specified in the **/etc/security/ldap/ldap.cfg** file at startup. If the following options are given in command line when starting **secldapclntd** process, the options from the command line will overwrite the values in the **/etc/security/ldap/ldap.cfg** file.

Item	Description
-C *CacheSize*	Sets the maximum cache entries used by the **secldapclntd** daemon to CacheSize number of entries. Valid range is 100-10,000 entries for user cache. The default is 1000. The group cache entries will be 10% of the user cache entries.
-o *ldapTimeOut*	Timeout period in seconds for LDAP client requests to the server. This value determines how long the client will wait for a response from the LDAP server. Valid range is 0 - 3600 (1 hour). Default is 60 seconds. Set this value to 0 to disable the timeout and force the client to wait indefinitely.
-p *NumOfThread*	Sets the number of thread used by the **secldapclntd** daemon to **NumOfThread** threads. Valid range is 1-1000. The default is 10.
-t *CacheTimeout*	Sets the cache to expire in CacheTimeout seconds. Valid range is 60- 3600 seconds. The default is 300 seconds.
-T *HeartBeatIntv*	Sets the time interval of heartbeat between this client and the LDAP server. Valid values are 60-3,600 seconds. Default is 300.

Security

A user with the **aix.security.ldap** authorization is authorized to use this command.

Examples

1. To restart the **secldapclntd** daemon, type:

```
/usr/sbin/restart-secldapclntd
```

2. To restart the **secldapclntd** with using 30 threads and cache timeout value of 500 seconds, type:

```
/usr/sbin/restart-secldapclntd -p 30 -t 500
```

Files

Item	Description
/etc/security/ldap/ldap.cfg	Contains information needed by the **secldapclntd** daemon to connect to the server.

restbase Command

Purpose

Reads the base-customized information from the boot image, and restores it into the Device Configuration database used during system boot phase 1.

Syntax

restbase [**-o** *File*] [**-d** *Path*] [**-v**]

Description

The **restbase** command reads the base-customized information from the boot disk and puts it in the specified Device Configuration database directory. By default, the base information is read from the boot disk. If no Device Configuration database directory is specified, then the **restbase** command restores this information into the **/etc/objrepos** directory. You can use the **-o** flag to specify a file, other than the boot disk, from which to read the base-customized information.

> **Attention:** The **restbase** command is intended to be executed only during phase 1 of system boot. Do not execute it in a run-time environment or you could destroy the Device Configuration database.

Flags

Item	Description
-o *File*	Specifies a file that contains base-customized data.
-d *Path*	Specifies a directory containing the base Device Configuration database.
-v	Causes verbose output to be written to standard output.

Examples

1. To restore base-customized information and see verbose output, enter:

```
restbase -v
```

2. To restore base information into an alternate device database, enter:

```
restbase -d /tmp/objrepos
```

Files

Item	Description
/usr/lib/objrepos/PdDv	Contains entries for all known device types supported by the system.
/etc/objrepos/CuDv	Contains entries for all device instances defined in the system.
/etc/objrepos/CuAt	Contains customized device-specific attribute information.
/etc/objrepos/CuDep	Describes device instances that depend on other device instances.
/etc/objrepos/CuDvDr	Stores information about critical resources that need concurrency management through the use of the Device Configuration Library routines.

restore Command

Purpose

Extracts files from archives that are created with the **backup** command.

Syntax

To restore files archived by file name

restore -x [d M n O Q v q e] [-b *Number*] [-L *Label*] [-I *Label*] [-f *Device*] [-s *SeekBackup*] [-E { force | ignore | warn }] [*File* ...]

To list files archived by file name

restore -T | -t [a l n q v Q] [-b*Number*] [-f*Device*] [-s*SeekBackup*]

To restore files archived by file system

restore -r [B O n q v y] [-b*Number*] [-f*Device*] [-s*SeekBackup*]

To restore files archived by file system

restore -R [B O n v y] [-b *Number*] [-f *Device*] [-s *SeekBackup*]

To restore files archived by file system

restore -i [O h m n q v y] [-b*Number*] [-f *Device*] [-s *SeekBackup*]

To restore files archived by file system

restore -x [B O h n m q v y] [-b*Number*] [-f*Device*] [-s*SeekBackup*] [*File* ...]

To restore files beginning at a specified volume number

restore -X *Number* [-MdnqveOQ] [-b *Number*] [-f *Device*] [-s *Number*] [-E { force | ignore | warn }] [*File* ...]

To list files archived by file system

restore -t | -T [B a l n h q v y] [-b *Number*] [-f *Device*] [-s *SeekBackup*] [*File* ...]

To restore file attributes archived by file name

restore -Pstring [B d qv Q] [b*Number*] [s *SeekNumber*] [-L *Label*] [-I *Label*] [-f *Device*] [*File* ...]

To restore file attributes archived by file system

restore -Pstring [hqv] [b *Number*] [s *SeekNumber*] [-f *Device*] [*File* ...]

Description

The **restore** command reads archives created by the **backup** command and extracts the files that are stored on them. These archives can be in either file name or file system format. An archive can be stored on disk, diskette, or tape. Files must be restored by using the same method that was used to archive the files. This operation requires that you know the format of the archive. The archive format can be determined by examining the archive volume header information that is displayed when you use the `-T` flag. When the `-x`, `-r`, `-T`, or `-t` flags are used, the **restore** command automatically determines the archive format.

Individual files can be restored from either file name or file system archives by using the `-x` flag and specifying the file name. The file name must be specified as it exists on the archive. Files can be restored interactively from file system archives by using the `-i` flag. The names of the files on an archive can be written to standard output by using the `-T` flag.

Users must have write access to the file system device or have Restore authorization to extract the contents of the archive.

The diskette device, `/dev/rfd0`, is the default media for the **restore** command. To restore from standard input, specify a `-` (dash) with the `-f` flag. You can also specify a range of devices, such as `/dev/rfd0`.

Notes:

1. If you are restoring from a multiple-volume archive, the **restore** command reads the volume that mounted, prompts you for the next volume, and waits for your response. After the next volume is inserted, press the Enter key to continue restoring files.
2. If an archive, created by using the **backup** command, is made to a tape device with the device block size set to 0, it is necessary for you to have explicit knowledge of the block size that was used when the tape was created to restore from the tape.
3. Multiple archives can exist on a single tape. When multiple archives are restored from the tape, the **restore** command expects the input device to be a no-retension-on-open, no-rewind-on-close tape device. Do not use a no-rewind tape device for restoring unless either the `-B`, `-s`, or `-X` flag is specified. For more information on using tape devices, see the **rmt** special file.

File system archives

File system archives are also known as i-node archives because the method used to archive the files. A file system name is specified with the **backup** command, and the files within that file system are archived based on their structure and layout within the file system. The **restore** command restores the files on a file system archive without any special understanding of the underlying structure of the file system.

When you restore the file system archives, the **restore** command creates and uses a file named `restoresymtable`. This file is created in the current directory. The file is necessary for the **restore** command to do incremental file system restores.

Note: Do not remove the `restoresymtable` file if you run incremental file system backups and restores.

The *File* parameter is ignored when you use either the `-r` or the `-R` flag.

File name Archives

File name archives are created by specifying a list of file names to archive to the **backup** command. The **restore** command restores the files from a file name archive without any special understanding of the underlying structure of the file system. The **restore** command allows for metacharacter to be used when you specify files for archive extraction. This process provides the capability to extract files from an archive that is based on pattern matching. A pattern file name must be enclosed in single quotations, and patterns must be enclosed in brackets (...).

About sparse files

Files in the operating system file system that contain long strings of Nulls can be stored efficiently when compared to the other files. If a string of Nulls spans an entire allocation block, that whole block is not stored on disk at all. Files where one or more blocks are omitted in this way are called sparse files. The missing blocks are also known as holes.

Note: Restores the non-sparse files as nonsparse because they were archived by the name format of the **backup** command for both packed and unpacked files. It is necessary to know the sparseness and nonsparseness of the file being restored before you archive the files. This check is required because by enabling the `-e` flag, the flag restores the sparse files as nonsparse. This flag must be enabled only if the files to be restored are non-sparse consisting of more than 4 KB Nulls. If the `-e` flag is specified during the restore operation, it successfully restores all normal files normally and nonsparse database files as nonsparse.

Flags

Item	Descriptor
`-a`	Specified with the `t` and T option, the `-a` option displays the list of files in the archive, along with their permissions.
`-B`	Specifies that the archive must be read from standard input. Normally, the **restore** command examines the actual medium to determine the backup format. When you use a | (pipe), this examination cannot occur. As a result, the archive is assumed to be in file system format, and the device is assumed to be standard input (`-f`).
`-b`*Number*	Specifies the number of 512-byte blocks for backups done by name. For backups that are done by i-node, the flag specifies the number of 1024-byte blocks to read in a single output. When the **restore** command reads from tape devices, the default is 100 for backups by name and 32 for backups by i-node. The read size is the number of blocks that are multiplied by the block size. The default read size for the **restore** command reading from tape devices is 51200 (100 * 512) for backups by name and 32768 (32 * 1024) for backups by i-node. The read size must be an even multiple of the tapes physical block size. If the read size is not an even multiple of the tapes physical block size and it is in fixed block mode (nonzero), the **restore** command tries to determine a valid value for *Number*. If successful, the **restore** command changes *Number* to the new value, write a message about the change to standard output, and continues. If unsuccessful in finding a valid value for *Number*, the **restore** command writes an error message to standard error and exits with a nonzero return code. Larger values for the *Number* parameter result in larger physical transfers from the tape device. The value of the `-b` flag is always ignored when the **restore** command reads from diskette. In this case, the command always reads in clusters that occupy a complete track.
`-d`	Indicates that, if the *File* parameter is a directory, all files in that directory must be restored. This flag can be used when the archive is in file name format.

Item	Descriptor
`-e`	Specifies to not restore sparse files actively. If a file has a block that is aligned and sized areas that are Null populated, then the restore operation creates physical space for those file system blocks to be allocated and filled with Nulls. The file size that is specified in bytes corresponds to the space taken within the file system. This flag must be enabled only if files are to be restored are nonsparse consisting of more than 4 KB Nulls. If the `-e` flag is specified during **restore**, it successfully restores all normal files normally and nonsparse database files as nonsparse.
`-E`	The `-E` option extracts beginning at a specified volume number and requires one of the following arguments. If you omit the `-E` option, `warn` is the default behavior. **force** Fails the restore operation on a file if the fixed extent size or space reservation of the file cannot be preserved. **ignore** Ignores any errors in preserving extent attributes. **warn** Issues a warning if the space reservation or the fixed size of the file cannot be preserved.
`-f`*Device*	Specifies the input device. To receive input from a named device, specify the *Device* variable as a path name such as `/dev/rmt0`. To receive input from the standard output device, specify a - (minus sign). The - (minus) feature allows to pipe the input of the**restore** command from the **dd** command. You can also specify a range of archive devices. The range specification must be in the following format: `/dev/deviceXXX-YYY` where *XXX* and *YYY* are whole numbers, and *XXX* must always be less than *YYY*; for example, `/dev/rfd0-3`. All devices in the specified range must be of the same type. For example, you can use a set of 8 mm, 2.3GB tapes or a set of 1.44MB diskettes. All tape devices must be set to the same physical tape block size. If the *Device* variable specifies a range, the**restore** command automatically goes from one device in the range to the next. After all the specified devices are exhausted , the**restore** command halts and requests that new volumes be mounted on the range of devices.
`-h`	Restores only the actual directory, not the files that are contained in it. This flag can be used when the archive is in file system format. This flag is ignored when used with the `-r` or `-R` flags.
`-I` *Label*	The **restore** command applies this integrity label for files without security labels in the archive. The label that is supplied must exist on the system. This option is valid only for restoring files by name on Trusted AIX.

Item	Descriptor
`-i`	Restores the selected files interactively from a file system archive. The following are the subcommand for the `-i` flag: **cd*Directory*** Changes the current directory to the specified directory. **add [*File*]** Specifies that the *File* parameter is added to the list of files to extract. If *File* is a directory, that directory and all the files that are contained in it are added to the extraction list (unless the `-h` flag is used). If *File* is not specified, the current directory is added to the extraction list. **delete [*File*]** Specifies that the *File* parameter is to be removed from the list of files to be extracted. If *File* is a directory, that directory and all the files that are contained in it are removed from the extraction list (unless the `-h` flag is used). **ls [*Directory*]** Displays the directories and files that are contained within the *Directory* parameter. Directory names are displayed with a / (slash) after the name. Files and directories, within the specified directory, that are on the extraction list are displayed with an * (asterisk) before the name. If verbose mode is on, the i-node number of the files and directories is also displayed. If the *Directory* parameter is not specified, the current directory is used. **extract** Restores all the directories and files on the extraction list. **pwd** Displays the full path name of the current directory. **verbose** Causes the **`ls`** subcommand to display the i-node number of files and directories. More information about each file is also displayed as it is extracted from the archive. **setmodes** Sets the owner, mode, and time for all directories added to the extraction list. **quit** Causes **`restore`** to exit immediately. Any files on the extraction list are not restored. **help** Displays a summary of the subcommand.
`-l`	Specified with the `-t` and `-T` option. When specified, displays a detailed list of files, which includes the timestamp, file permissions, file size, owner, and group. The `-l` option overrides the `-a` option.
`-L`*Label*	The **`restore`** command applies this sensitivity label for files without security labels in the archive. The label that is supplied must exist on the system. This option is valid only for restoring files by name on Trusted AIX.

Item	Descriptor
-M	Sets the access and modification times of restored files to the time of restoration. If a restored file is an archive that is created by the **ar** command, the modification times in all the member headers are also set to the time of restoration. You can specify the -M flag only when you are restoring individually named files and only if the -x or -X flags are also specified. When the -M flag is not specified, the **restore** command maintains the access and modification times as displayed on the backup medium. The-M flag is used when the data is in the AIX 4.2 backup by-i-node or by-name format.
-m	Renames restored files to the file's i-node number as it exists on the archive. This function is useful if a few files are being restored and you want these files that are restored under a different file name. Since any restored archive members are renamed to their i-node numbers, directory hierarchies and links are not preserved. Directories and hard links are restored as regular files. The -m flag is used when the archive is in file system format.
-n	By default the restore command restores any ACLs, PCLs, or named extended attributes in the archive. The -n flag causes the **restore** command to ignore any ACLs, PCLs, or named extended attributes in the archive and not restore them.When the archived files contain Encrypted file system (EFS) information, the EFS extended attributes are restored even if the -n flag is specified. On Trusted AIX systems, the -n option causes the **restore** command to ignore Trusted AIX security attributes. For more information about EFS restoration, see Backup and restore in *Security*.
-O	Causes the **restore** command to ignore Trusted AIX security attributes.
-Pstring	Restore only the file attributes. Does not restore the file contents. If the file specified does not exist in the target directory path, the files are not created. This flag restores file attributes selectively depending on the flags that are specified in the string parameter. String parameter can be a combination of the following characters: **A** restore all attributes. **a** restore only the permissions of the files. **o** restore only the ownership of the files. **t** restore only the timestamp of the files. **c** restore only the ACL attributes of the files. **Note:** Among the existing options for the **restore** command, options v, h, b, s, f, B, d, and q are valid with the P option. The P option can be used with both file name and file system archives. If the File argument is a symbolic link, then the metadata of the target file is modified and not that of the symbolic link. **Warning:** Usage of the -P flag overwrites the attributes of files that are owned by another user when run by the superuser.

Item	Descriptor
`-Q`	Specifies that the command must exit when an error is encountered, for backups done by name. This process does not attempt to recover and continue processing the archive, when an error occurs.
`-q`	Specifies that the first volume is ready to use and that the **restore** command cannot prompt you to `mount the volume and hit Enter`. If the archive spans multiple volumes, the **restore** command prompts you for the subsequent volumes.
`-r`	Restores all files in a file system archive. The `-r` flag is only used to restore complete level 0 backups or to restore incremental backups after a level 0 backup is restored. The `restoresymtable` file is used by **restore** to pass information between incremental restores. This file must be removed when the last incremental backup is restored. The *File* parameter is ignored when use the `-r` flag.
`-R`	Requests a specific volume of a multiple-volume, file system archive. The `-R` flag allows a previously interrupted restore to be restarted. The *File* parameter is ignored when you use the `-R` flag. When the **restore** command is restarted, it functions similar to the `-r` flag.
`-s`*SeekBackup*	Specifies the backup to seek and restore on a multiple-backup tape archive. The `-s` flag is only applicable when the archive is written to a tape device. To use the `-s` flag properly, a no-rewind-on-close and no-retension-on-open tape device, such as `/dev/rmt0.1` or `/dev/rmt0.5`, must be specified. If the `-s` flag is specified with a rewind tape device, the **restore** command displays an error message and exits with a nonzero return code. If a no-rewind tape device is used and the `-s` flag is not specified, a default value of `-s1` is used. The value of the *SeekBackup* parameter must be in the range of 1 to 100 inclusive. It is necessary to use a no-rewind-on-close, no-retension-on-open tape device because of the behavior of the `-s` flag. The value that is specified with `-s` is relative to the position of the tapes read/write head and not to an archives position on the tape. For example, to restore the first, second, and fourth backups from a multiple-backup tape archive, the respective values for the `-s` flag would be `-s1`, and `-s2`.
`-t`	Displays information about the backup archive. If the archive is in file system format, a list of files that are found on the archive is written to standard output. The name of each file is preceded by the i-node number of the file as it exists on the archive. The file names that are displayed are relative to the root (/) directory of the file system that was backed up. If the *File* parameter is not specified, all the files on the archive are listed. If the *File* parameter is used, then just that file is listed. If the *File* parameter refers to a directory, all the files that are contained in that directory are listed. If the archive is in file name format, information that is contained in the volume header is written to standard error. This flag can be used to determine whether the archive is in the file name or the file system format.
`-T`	Displays information about the backup archive. If the archive is in file name format, the information that is contained in the volume header is written to standard error, and a list of files that are found on the archive is written to standard output. The *File* parameter is ignored for file name archives. If the archive is in file system format, the behavior is identical to the `-t` flag.

Item	Descriptor
-v	Displays information when the file name is restored . If the archive is in file name format and either the -x or -T flag is specified, the size of the file as it exists on the archive is displayed in bytes. Directory, block, or character device files are archived with a size of 0. Symbolic links are listed with the size of the symbolic link. Hard links are listed with the size of the file, which is how they are archived. Once the archive is read, a total of these sizes is displayed. If the archive is in file system format, directory and nondirectory archive members are distinguished.
-x	Restores individually named files that are specified by the *File* parameter. If the *File* parameter is not specified, all the archive members are restored. If the *File* parameter is a directory and the archive is in file name format, only the directory is restored. If the *File* parameter is a directory and the archive is in file system format, all the files that are contained in the directory are restored. The file names that are specified by the *File* parameter must be the same as the names shown by the **restore**-T command. Files are restored with the same name they were archived with. If the file name was archived by using a relative path name (`./filename`), the file is restored relative to the current directory. If the archive is in file system format, files are restored relative to the current directory. The **restore** command automatically creates any needed directories. When you use this flag to restore file system backups, you are prompted to enter the beginning volume number. The **restore** command allows for shell-style pattern matching metacharacters to be used when files for archive extraction is specified . The rules for matching metacharacters are the same as used in shell pathname "globbing," namely: *** (asterisk)** Matches zero or more characters, but not a '.' (period) or '/' (slash). **? (question mark)** Matches any single character, but not a '.' (period) or '/' (slash). **[ ] (brackets)** Matches any one of the characters that are enclosed within the brackets. If a pair of characters that are separated by a dash is contained within the brackets, the pattern matches any character that lexically falls between the two characters in the current local. Additionally, a '.' (period) or a '/' (slash) within the brackets does not match a '.' (period) or a '/' (slash) in a file name. **\ (backslash)** Matches the immediately following character, preventing its possible interpretation as a metacharacter.
-X*VolumeNumber*	Begins restoring from the specified volume of a multiple-volume, file name backup. When the **restore** command is started, the command behaves similar to the -x flag. The -X flag applies to file name archives only.
-y	Continues restoring when tape errors are encountered. Normally, the **restore** command request input to continue. In either case, all data in the read buffer is replaced with zeros. The -y flag applies only when the archive is in file system format.
-?	Displays a usage message.

Exit Status

This command returns the following exit values:

Item	Descriptor
0	Successful completion.
>0	An error occurred.

Security

On Trusted AIX systems, only authorized users can run the **restore** command.

Item	Descriptor
aix.fs.manage.restore	Required to run this command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To list the names of files in either a file name or file system archive on the diskette device /dev/rfd0, type:

   ```
   restore -Tq
   ```

   The archive is read from the /dev/rfd0 default restore device. The names of all the files and directories that are contained in the archive are displayed. For file system archives, the file name is preceded by the i-node number of the file as it exists on the archive. The -q flag tells the **restore** command that the first volume is available and is ready to be read. As a result, you are not prompted to mount the first volume.

2. To restore a specific file, type:

   ```
   restore -xvqf myhome.bkup system.data
   ```

   This command extracts the file system.data into the current directory from the archive myhome.bkup. The archive in this example is in the current directory. File and directory names must be specified as they are displayed when the -T flag is used. The -v flag displays information during the extraction. This example applies to both file name and file system archives.

3. To restore a specific directory and the contents of that directory from a file name archive, type:

   ```
   restore -xdvqf /dev/rmt0 /home/mike/tools
   ```

   The -x flag tells **restore** to extract files by their file name. The -d tells **restore** to extract all the files and subdirectories in the /home/mike/tools directory. File and directory names must be specified as they are displayed when you use the -T flag. If the directories do not exist, they are created.

4. To restore a specific directory and the contents of that directory from a file system archive, type:

   ```
   restore -xvqf /dev/rmt0 /home/mike/tools
   ```

   This command extracts files by file name. File and directory names must be specified as they are displayed when you use the -T flag. If the directories do not exist, they are created.

5. To restore an entire file system archive, type:

   ```
   restore -rvqf /dev/rmt0
   ```

This command restores the entire file system that is archived on the tape device, `/dev/rmt0`, into the current directory. This example assumes you are in the root directory of the file system to be restored. If the archive is part of a set of incremental file system archives, the archives must be restored in increasing backup-level order beginning with level 0 (for example, `0`, `1`, and `2`).

6. To restore the fifth and ninth backups from a single-volume, multiple-backup tape, type:

```
restore -xvqs 5 -f/dev/rmt0.1
restore -xvqs 4 -f/dev/rmt0.1
```

The first command extracts all files from the fifth archive on the multiple-backup tape that is specified by `/dev/rmt0.1`. The `.1` designator specifies the tape device that is not retensioned when it is opened and rewound when it is closed. It is necessary to use a no-rewind-on-close, no-retension-on-open tape device because of the behavior of the `-s` flag. The second command extracts all the files from the fourth archive (relative to the current location of the tape head on the tape). After the fifth archive is restored, the tape read/write head is in a position to read the archive. To extract the ninth archive on the tape, you must specify a value of 4 with the `-s` flag. This is because the `-s` flag is relative to your position on the tape and not to an archives position on the tape. The ninth archive is the fourth archive from your current position on the tape.

7. To restore the fourth backup, which begins on the sixth tape on a 10-tape multiple-backup archive, put the sixth tape into the tape drive and type:

```
restore -xcs 2 -f /dev/rmt0.1 /home/mike/manual/chap3
```

Assuming the fourth backup is the second backup on the sixth tape, specifying `-s 2` advances the tape head to the beginning of the second backup on this tape. The **restore** command then restores the specified file from the archive. If the backup continues onto subsequent volumes and the file is not restored, the **restore** command instructs you to insert the next volume until the end of the backup is reached. The `-f` flag specifies the no-rewind, no-retension tape device name.

Note: The `-s` flag specifies the backup number relative to the tape inserted in the tape drive, not to the overall 10-tape archive.

8. To improve the performance on streaming tape devices, pipe the dd command to the **restore** command by typing:

```
dd if=/dev/rmt0 bs=64b | restore -xf- -b64
```

The dd command reads the archive from the tape by using a block size of 64 512-byte blocks and writes the archive to standard output. The **restore** command reads the standard input by using a block size of 64 512-byte blocks. The value of the block size that is used by the dd command to read the archive from the tape must be an even multiple of the block size that was used to create the tape with the **backup** command. For example, the following **backup** command cannot be used to create the archive that this example extracts:

```
find /home -print | backup -ivqf/dev/rmt0 -b64
```

This example applies to archives in file name format only. If the archive was in file system format, the **restore** command must include the `-B` flag.

9. To improve the performance of the **restore** command on the 9348 Magnetic Tape Unit Model 12, you can change the block size by typing:

```
chdev -l DeviceName -a BlockSize=32k
```

10. To restore non-sparse database files, type:

```
restore  -xef  /dev/rmt0
```

11. To restore files that were sparse before archive as sparse, type:

```
restore  -xf  /dev/rmt0
```

12. To restore only the permissions of the files from the archive, type:

```
restore -Pa -vf /dev/rmt0
```

13. To restore only the ACL attributes of the files from the archive, type:

```
 restore -Pc -vf /dev/rmt0
```

14. To view the table of contents along with the file permissions, type:

```
restore -Ta -vf /dev/rmt0
```

15. To view the table of contents of file name archive along with the timestamps and file permissions, type:

```
restore -Tl -vf /dev/rmt0
```

16. To view the table of contents of file system archive along with the timestamps and file permissions, type:

```
restore -tl -vf /dev/rmt0
```

Files

Item	Descriptor
/dev/rfd0	Specifies the default restore device.
/usr/sbin/restore	Contains the **restore** command.

restorevgfiles Command

Purpose

Restores files from a backup source.

Syntax

restorevgfiles [**-b** *blocks*] [**-f** *device*] [**-a**] [**-n**] [**-s**] [**-d** *path*] [**-D**] [*file_list*]

Description

The **restorevgfiles** command restores files from tape, file, CD-ROM, or their volume group backup source. The **restorevgfiles** command also works for multi-volume backups such as multiple CDs, DVDs, USB disks, or tapes.

The **restorevgfiles** and **listvgbackup -r** commands perform identical operations and should be considered interchangeable. The **restorevgfiles** command automatically applies the **-r** flag. The **-r** flag, while redundant, is retained for compatibility purposes and will cause no unusual behavior if specified. For a complete description of the **-r** flag, see the **listvgbackup** command.

Flags

Item	Description
-b *blocks*	Specifies the number of 512-byte blocks to read in a single input operation, as defined by the *blocks* parameter. If the *blocks* parameter is not specified, the number of blocks read will default to 100.
-f *device*	Specifies the type of device containing the backup (file, tape, CD-ROM, or other source) as defined by the *device* parameter. When **-f** is not specified, *device* will default to **/dev/rmt0**.

Item	Description
-a	Verifies the physical block size of the tape backup, as specified by the **-b** *block* flag. You may need to alter the block size if necessary to read the backup. The **-a** flag is valid only when a tape backup is used.
-n	Does not restore ACLs, PCLs, or extended attributes.
-s	Specifies that the backup source is a user volume group and not **rootvg**.
-d *path*	Specifies the directory path to which the files will be restored, as defined by the *path* parameter. If the **-d** parameter is not used, the current working directory is used. This can be a problem if the current working directory is root. We recommend writing to a temporary folder instead of to root.
-D	Produces debug output.

Parameters

Item	Description
file_list	Identifies the list of files to be restored. The full path of the files relative to the current directory should be specified in the space-separated list. All files in the specified directory will be restored unless otherwise directed. If you are restoring all files in a directory, we recommend writing to a temporary folder instead of to root.

Examples

1. To read the backup stored at **/dev/cd1** and restore all files to the **/data/myfiles** directory, enter:

   ```
   restorevgfiles -f /dev/cd1 -s -d /data/myfiles
   ```

2. To read the user vg backup from the default device at 20 512-byte blocks at a time and restore the **/myapp/app.h** file to the current directory, enter:

   ```
   restorevgfiles -b 20 -s ./myapp/app.h
   ```

3. To read the backup stored at **/dev/cd1** and restore the **/myapp/app.c** file to the **/data/testcode** directory, enter:

   ```
   restorevgfiles -f /dev/cd1 -s -d /data/testcode ./myapp/app.c
   ```

4. To read the backup stored at **/dev/usbms0** and restore all files to the **/data/myfiles** directory, enter the following command:

   ```
   restorevgfiles –f /dev/usbms0 –s –d /data/myfiles
   ```

Files

Item	Description
/usr/bin/restorevgfiles	Contains the **restorevgfiles** command

restvg Command

Purpose

Restores the user volume group and all its containers and files.

Syntax

restvg [**-b** *Blocks*] [**-d** *FileName*][**-f** *Device*] [**-l**] [**-q**] [**-r**] [**-s**] [**-n**] [**-P** *PPsize*] [*DiskName ...*]

Description

The **restvg** command restores the user volume group and all its containers and files, as specified in the **/tmp/vgdata/***vgname***/***vgname***.data** file (where *vgname* is the name of the volume group) contained within the backup image created by the **savevg** command.

The **restvg** command restores a user volume group. The **bosinstall** routine reinstalls the root volume group (**rootvg**). If the **restvg** command encounters a **rootvg** volume group in the backup image, the **restvg** command exits with an error.

If a **yes** value has been specified in the EXACT_FIT field of the **logical_volume_policy** stanza of the **/tmp/vgdata/***vgname***/***vgname***.data** file, the **restvg** command uses the map files to preserve the placement of the physical partitions for each logical volume. The target disks must be of the same size or larger then the source disks specified in the **source_disk_data** stanzas of the *vgname***.data** file.

Note:

- To view the files in the backup image or to restore individual files from the backup image, the user must use the **restore** command with the **-T** or **-x** flag, respectively. (Refer to the **restore** command for more information.)
- When you run the **varyonvg** command on the volume group, the logical track group (LTG) size will be set to the common max transfer size of the disks.

Flags

Item	Description
-b *Blocks*	Specifies the number of 512-byte blocks to read in a single input operation. If this parameter is not specified the default of 100 is used by the **restore** command. Larger values result in larger physical transfers to tape devices.
DiskName...	Specifies the names of disk devices to be used instead of the disk devices listed in the *vgname***.data** file. Target disk devices must be defined as empty physical volumes; that is, they must contain a physical volume identifier and must not belong to a volume group. If the target disk devices are new, they must be added to the system using the **mkdev** command. If the target disk devices belong to a volume group, they must be removed from the volume group using the **reducevg** command.
-d *FileName*	The -d flag is an optional flag, which, if specified, must be followed by a filename. This file will be used as the **vgname.data** file instead of the one contained within the backup image being restored. The filename can be specified by either a relative or an absolute pathname.
-f *Device*	Specifies the device name of the backup media. The default is **/dev/rmt0**.

Item	Description
-l	Displays useful information about a volume group backup. This flag requires the **-f** *device* flag. This flag causes **restvg** to display information such as volume group, date and time backup was made, uname output from backed up system, oslevel, recommended maintenance and technology level, backup size in megabytes, and backup shrink size in megabytes. The shrink size is the size of the data on all filesystems. The full size is the total size of each filesystem (unused + data). The **-l** flag also displays the logical volume and filesystem information of the backed up volume group, equivalent to running "**lsvg -l** *vgname*".
`-n`	Specifies that the existing MAP files are ignored. The `-n` flag overrides the value of the `EXACT_FIT` field in the logical_volume_policy stanza of the *vgname*`.data` file.
-P *PPsize*	Specifies the number of megabytes in each physical partition. If not specified, **restvg** uses the best value for the *PPsize*, dependent upon the largest disk being restored to. If this is not the same as the size specified in the *vgname***.data** file, the number of partitions in each logical volume will be appropriately altered with respect to the new *PPsize*. If a *PPsize* is specified that is smaller than appropriate for the disk sizes, the larger *PPsize* will be used. If a *PPsize* is specified that is larger than appropriate for the disk sizes, the specified larger *PPsize* will be used.
-q	Specifies that the usual prompt not be displayed before the restoration of the volume group image. If this flag is not specified, the prompt displays the volume group name and the target disk-device names.
-r	Recreates a volume groups structure only. This allows restvg to create (for the specified backup *FileName* or *Device*) the volume group, logical volumes, and filesystems, from the backup, without restoring any files or data. This is useful for users who use third party software for restoring data and just need all the AIX logical volume structure in place. **Note:** be used with either the **-f** *Device* flag or the **-d** *FileName* flag. This is because **restvg** requires a backup image or *vgname***.data** file to get all the information it needs to recreate the logical volume structure of the volume group desired.
-s	Specifies that the logical volumes be created at the minimum size possible to accommodate the file systems. This size is specified by the value of `LV_MIN_LPS` field of the **lv_data** stanza of the *vgname***.data** file (where *vgname* is the name of the volume group). The **-s** flag overrides the values of the `SHRINK` and `EXACT_FIT` fields in the **logical_volume_policy** stanza of the *vgname***.data** file. The **-s** flag causes the same effect as values of `SHRINK=yes` and `EXACT_FIT=no` would cause.

Examples

1. To restore the volume group image from the **/dev/rmt1** device, onto the **hdisk2** and **hdisk3** disks, enter:

```
restvg -f/dev/rmt1 hdisk2 hdisk3
```

2. To restore the volume group image saved in **/mydata/myvg** file onto the disks specified in the *vgname***.data** file contained within the backup image, enter:

```
restvg -f/mydata/myvg
```

3. To recreate the volume group logical volume structure without restoring any files using only the *vgname***.data** file **/home/my_dir/my_vg.data**, enter:

```
restvg -r -d /home/my_dir/my_vg.data
```

   Note: *vgname***.data** files can be created for a volume group by using the **mkvgdata** command.

4. To recreate the volume group logical volume structure without restoring any files using the *vgname***.data** file inside of the volume group backup located on the tape in **/dev/rmt0**, enter the following:

```
restvg -r -f /dev/rmt0
```

5. To display volume group information about the volume group backed up on the tape in **/dev/rmt0**, enter:

```
restvg -l -f /dev/rmt0
```

6. To restore the volume group image from the **/dev/usbms0** device, onto the disks specified in the **vgname.data** file contained within the backup image, enter the following command:

```
restvg –f /dev/usbms0
```

   Note: For information about backing up a volume group, see the **listvgbackup** command. To restore individual files from a volume group backup, see the **restorevgfiles** command.

restwpar Command

Purpose

Restores a workload partition.

Syntax

`restwpar` [`-a`] [`-A`] [`-b` *Blocks*] [`-B` *devexportsFile*] [`-C`] [`-d` *Directory*] [`-f` *Device*] [`-F`] [`-h` *hostName*] [`-i` *imagedataFileName*] [`-k`] [`-K`] [`-M` *mkwparFlags*] [`-n` *WparName* [`-r`] [`-s`] [`-S` { `a` | `A` | `f` | `F` | `n` }] [`-U`] [`-w` *wparSpecificationFile*]

Description

The **restwpar** command creates a workload partition from a workload partition backup image that was created by the **savewpar**, **mkcd**, or **mkdvd** command.

Warning: The **restwpar** command should not be run while an AIX Live Update operation is in progress.

A workload partition backup image contains an `image.data` file and a workload partition specification file that is used to establish the characteristics of workload partition *WparName*. You can use the `-i` and `-w` flags to override these default files.

If you do not specify the `-f` flag, the `/dev/rmt0` device is used as the input device.

If you specify a value of Yes in the EXACT_FIT field of the `logical_volume_policy` stanza of the `/tmp/wpardata/`*WparName*`/image.data` file, the **restwpar** command uses the map files to preserve the placement of the physical partitions for each logical volume.

If user volume groups are configured with a rootvg WPAR, then they are not automatically imported after restoring a rootvg WPAR.

Notes:

- To view the files in the backup image or to restore individual files from the backup image, use the **lssavewpar**, **restwparfiles**, or **restore** command with the `-T` or the `-x` flag.
- For shared workload partitions (WPARs), if the installation history of the source system is different from the installation history of the target system, the **restwpar** command and the **syncroot** command might fail for few filesets. You might see a failure message that is similar to the following example for the **syncroot** command, at the end of the `restwpar` operation:

  ```
  syncroot: Error synchronizing installp software
  syncroot: Returns Status = FAILURE
  ```

  You must restore or migrate the shared WPAR to a logical partition (LPAR) that has the installation history similar to the installation history of the source LPAR.

Flags

Item	Description
`-a`	Automatically resolves conflicting static settings if required. Resolvable settings are name, host name, base directory, and network configuration.
`-A`	Starts the workload partition each time when the `/etc/rc.wpars` command is run, which is added to the global `/etc/inittab` to run on each system start. The default is not to start the workload partition automatically.
`-b` *Blocks*	Specifies the number of 512-byte blocks to read in a single input operation. If you do not specify the *Blocks* parameter, the default value of 100 is used by the `restore` command. Larger values result in larger physical transfers to tape devices.
`-B` *devexportsFile*	Specifies a substitute file that can be used as the master device exports file. This file must match the format of a Device exports File. If you do not specify a file name, the `/etc/wpars/devexports` file is used.
`-C`	Forces the creation of the named workload partition, even when a compatibility check fails between the system from the backup image and the system where the backup is being restored. If the workload partition is not compatible with the target system. It might not be operable. If the operating system of the global system is at a later technology level or service pack level than the WPAR that has different modification or fix levels in the VRMF (version, release, modification and fix level), the workload partition (WPAR) can be synchronized with the new global system. Different factors affect the success of the synchronization. Review the logs after the synchronization operation is complete. Any updates that are applied to the new global system must be committed, and the updates to the WPAR must be committed before you back up the WPAR. If the new global system is installed on a system that is running AIX 6100-08 or 7100-02 technology levels, or earlier, you must run the **cp_bos_updates** command before you restore the workload partition for the synchronization to work.

Item	Description
-d *Directory*	Specifies a base directory for the workload partition. If you do not specify a directory name, the directory name from the WPAR specification file is used.
-f *Device*	Specifies the device name of the backup media. The default value is /dev/rmt0.
-F	Forces the creation of the named workload partition. If the named workload partition exists, it is stopped if active, and then removed, before the new workload partition is created.
-h *hostname*	Specifies a host name for theworkload partition. If not specified, the **mkwpar** command uses the workload partition name for the host name.
-i *imagedataFileName*	An optional flag that specifies a file name. The file is used as theimage.data file instead of the one contained within the backup image that is being restored.
-k	Creates logical volumes with minimum sizes from the backup.
-K	Creates the post-installation customization script.
-M *mkwparFlags*	Specifies the flags to pass directly to the **mkwpar** command to create the workload partition. The -M flag is used to pass other flags to the **mkwpar** command. If a flag is passed through its own option and through the -M flag, both flags are passed to the **mkwpar** command. **Note:** The *mkwparFlags* value cannot include the -iand -f flags as these flags are reserved for use by the **restwpar** command. Specifying the -i or -f flag as the *mkwparFlags* value causes an error.
-n *WparName*	Specifies the name for the workload partition to be created. If you do not specify the -n flag, the *WparName* is taken from the WPAR specification file.
-r	Duplicates the network name resolution configuration from the global system. The following files, if they exist, are copied into the workload partition: • /etc/resolv.conf • /etc/hosts • /etc/netsvc.conf • /etc/irs.conf • /etc/networks If the NSORDER environment variable is defined in the calling environment, it is added to the /etc/environment file of the workload partition.
-s	Starts the workload partition after it is created.

Item	Description
-S { a | A | f | F | n }	Specifies the type of synchronization to use after files are restored from the backup to synchronize the levels of software in the workload partition with the levels of the software in the global environment. **a** Causes additional installations with no removal of software. This option is the default. **A** Causes additional installations with no removal of software, and ignores any errors in synchronization. **Important:** If you specify -S A, the workload partition might be in an unusable state. **f** Causes additional installations, software rejection, and deinstallation. **F** Causes additional installations, software rejection, and deinstallation. This option ignores any errors in synchronization. **Important:** If you specify -S F, the workload partition might be in an unusable state. **n** Prevents the synchronization processing after the files are restored. **Important:** If you specify -S n, the workload partition might be in an unusable state.
-U	Specifies that the existing MAP files are ignored. The -U flag overrides the value of the EXACT_FIT field in the logical_volume_policy stanza of the *WparName*.data file.
-w *wparSpecificationFile*	An optional flag that specifies a file name. The file is used as the WPAR specification file rather than the version in the WPAR backup image by the **mkwpar** command.

Examples

1. To restore the workload partition image from the /dev/rmt1 device, enter the following command:

```
restwpar -f/dev/rmt1
```

2. To restore the workload partition image that is saved in the /mydata/wpar.img file with name mywpar and base directory /wpars/mywpar, enter the following command:

```
restwpar -f/mydata/wpar.img -n mywpar -d /wpars/mywpar
```

3. To restore the workload partition image from the /dev/usbms0 device, enter the following command:

```
restwparfiles -f/dev/usbms0
```

restwparfiles Command

Purpose

Restores files from a workload partition backup source.

Syntax

restwparfiles [**-b** *blocks*] [**-f** *device*] [**-a**] [**-m**] [**-n**] [**-d** *path*] [**-D**] [**-V**] [*file_list*]

Description

The **restwparfiles** command restores files from tape, file, CD-ROM, or other workload partition backup source. The **restwparfiles** command also works for multivolume backups such as multiple CDs, DVDs, USB disks, or tapes.

Flags

Item	Description
-a	Verifies the physical block size of the tape backup, as specified by the **-b** *blocks* flag. You might need to alter the block size to read the backup. The **-a** flag is valid only when you specify the device in the **-f** flag as tape.
-b *blocks*	Specifies the number of 512-byte blocks to read in a single input operation, as defined by the *blocks* parameter. If you do not specify the *blocks* parameter, the default number of blocks to read is 100.
-d *path*	Specifies the directory path where the files are restored, as defined by the *path* parameter. If you do not specify the **-d** flag, the current working directory is used. **Restriction:** The directory path where the files are restored must not be root (**/**) in the global environment, either through the use of **-d /** or if the current working directory is **/** and the **-d** flag is not specified.
-D	Produces debug output.
-f *device*	Specifies the device containing the backup (file, tape, CD-ROM, or other source) as defined by the *device* parameter. When you do not specify the **-f** flag, the default device is **/dev/rmt0**.
-m	Restores only informational and control files from the image. Use the flag to restore the **image.data** and **wpar.spec** files from the backup image. Files are restored under the **./.savewpar_dir/** directory.
-n	Specifies that ACLs, PCLs, or extended attributes are not to be restored.
-V	Verifies a tape backup. The **-V** flag requires the **-f** *device* flag and can be used to specify only tape devices. The **-V** flag causes the **restwparfiles** command to verify the readability of each file header on the volume group backup and print any errors that occur to the standard error log (**stderr**) file.

Parameters

Item	Description
file_list	Identifies the list of files to be restored. Specify the full path of the files relative to the current directory in the space-separated list. All files in the specified directory are restored unless directed. If you are restoring all files in a directory, write to a temporary folder instead of the **root** directory.

Examples

1. To read the backup stored on the **/dev/cd1** device and restore all files to the **/data/myfiles** directory, enter the following command:

```
restwparfiles -f /dev/cd1 -d /data/myfiles
```

2. To read the backup from the default device at twenty 512-byte blocks at a time and restore the **/myapp/app.c** file to the current directory, enter the following command:

```
restwparfiles -b 20 ./myapp/app.h
```

3. To read the backup stored on the **/dev/cd1** device and restore the **/myapp/app.c** file to the **/data/testcode** directory, enter the following command:

```
restwparfiles -f /dev/cd1 -d /data/testcode ./myapp/app.c
```

4. To read the backup stored at **/dev/usbms0** and restore all files to the **/data/myfiles** directory, enter the following command:

```
restwparfiles –f /dev/usbms0 –d /data/myfiles
```

resumevsd Command

Purpose

Activates an available virtual shared disk.

Syntax

`resumevsd` [`-p` | `-b` | `-l` *server_list*] {`-a` | *vsd_name* ...}

Description

The **resumevsd** command brings the specified virtual shared disks from the suspended state to the active state. The virtual shared disks remains available. Read and write requests which had been held while the virtual shared disk was in the suspended state are resumed.

You can use the System Management Interface Tool (SMIT) to run this command. To use SMIT, enter:

```
smit vsd_mgmt
```

and select the **Resume a Virtual Shared Disk** option.

Under normal circumstances, you should not issue this command. The recoverable virtual shared disk subsystem uses this command to manage shared disks in a controlled manner. If you issue this command, the results may be unpredictable.

Flags

-p
Specifies that the primary server node defined for the global volume group is to be the active server. The `-p` flag is not valid for CVSD.

-b
Specifies that the secondary server node defined for the global volume group is to be the active server. The `-b` flag is not valid for CVSD.

-a
Specifies that all the virtual shared disks that have been defined are to be resumed.

-l
Passes the `server_list` to the driver.

Parameters

vsd_name
Specifies a virtual shared disk.

Security

You must have `root` authority to run this command.

Restrictions

You must issue this command from a node that is online in the peer domain. To bring a peer domain online, use the **startrpdomain** command. To bring a particular node online in an existing peer domain, use the **startrpnode** command. For more information on creating and administering an RSCT peer domain, refer to *RSCT Administration Guide* .

Under normal circumstances, you should not issue this command. The recoverable virtual shared disk subsystem uses this command to manage shared disks in a controlled manner. If you issue this command, the results may be unpredictable.

Examples

To bring the virtual shared disk **vsd1vg1n1** from the suspended state to the active state, enter:

```
resumevsd vsd1vg1n1
```

Location

`/opt/rsct/vsd/bin/resumevsd`

rev Command

Purpose

Reverses characters in each line of a file.

Syntax

rev [*File ...*]

Description

The **rev** command copies the named files to standard output, reversing the order of characters in every line. If you do not specify a file, the **rev** command reads standard input.

Examples

To reverse characters in each line of a file, type:

```
rev file
```

If the `file` file contains the text:

```
abcdefghi
123456789
```

then the **rev** command displays:

```
ihgfedcba
987654321
```

Files

Item	Description
/usr/bin/rev	Contains the **rev** command.

revnetgroup Command

Purpose

Reverses the listing of users and hosts in network group files in NIS maps.

Syntax

/usr/sbin/revnetgroup { **-h** | **-u** } [*File*]

Description

The **revnetgroup** command reverses the order in which hosts and users are listed in the **/etc/netgroup** file. The **revnetgroup** command is called from the **/var/yp/Makefile** file to produce output for creating either the **netgroup.byuser** or **netgroup.byhost** NIS map. Each line in the output file begins with a key formed by concatenating the host or user name with the domain name. Following the key is a list of groups to which the host or user belongs. The list is preceded by a tab, and each group is separated by a comma.

> **Note:** The list of groups does not use the names of universal groups (groups that include all users in the network). Universal groups are listed under * (asterisk).

The **revnetgroup** command takes an optional file name if the default **/etc/netgroup** file is not desired. This feature provides users with flexibility to create custom network group maps.

Flags

Item	Description
-h	Produces output for creating the **netgroup.byhost** map.
-u	Produces output for creating the **netgroup.byuser** map.

Examples

1. To cause the **/etc/netgroup** file to list user names before host names, modify the appropriate stanza in the **/var/yp/Makefile** to read:

   ```
   revnetgroup -u
   ```

2. To create a new network group file, called newgroup, in the **/etc** directory, modify the appropriate stanza in the **/var/yp/Makefile** to read:

   ```
   revnetgroup -h newgroup
   ```

   The **-h** flag used in this example causes the new **/etc/newgroup** file to list host names before user names.

Files

Item	Description
/etc/netgroup	Contains lists of users and hosts in network groups.
/var/yp/Makefile	Contains rules for making NIS maps.

rexd Daemon

Purpose

Executes programs for remote machines.

Syntax

/usr/sbin/rpc.rexd

Description

The **rexd** daemon executes programs for remote machines when a client issues a request to execute a program on a remote machine. The **inetd**daemon starts the **rexd** daemon from the **/etc/inetd.conf** file.

Noninteractive programs use standard file descriptors connected directly to TCP connections. Interactive programs use pseudo-terminals, similar to the login sessions provided by the **rlogin** command. The **rexd** daemon can use the network file system (NFS) to mount the file systems specified in the remote execution request. Diagnostic messages are normally printed on the console and returned to the requester.

> **Note:** A root user cannot execute commands using **rexd** client programs such as the **on** command.

Files

Item	Description
/tmp_rex/rexd	Contains temporary mount points for remote file systems.
/etc/exports	Lists the directories that the server can export.
inetd.conf	Starts RPC daemons and other TCP/IP daemons.
/etc/passwd	Contains an entry for each user that has permission to log in to the machine.

rexec Command

Purpose

Executes commands one at a time on a remote host.

Syntax

rexec [**-a**][**-d** | **-n**] [**-i**] *Host Command*

Description

The **/usr/bin/rexec** command executes a command on the specified remote host.

The **rexec** command provides an automatic login feature by checking for a **$HOME/.netrc** file that contains the user name and password to use at the remote host. If such an entry is not found or if your

system is operating in secure mode (see the **securetcpip** command), the **rexec** command prompts for a valid user name and password for the remote host. In both cases, **rexec** causes **rexecd** on the remote system to use the default `compat` login authentication method for the user. **rexecd** does not look at the **/etc/security/user** file on the remote system for alternative authentication methods. You can also override the automatic login feature by specifying the **-n** flag on the **rexec** command line.

Restriction: Any user with a user ID less than or equal to 128 cannot log in to the remote Trusted AIX system.

Flags

Item	Description
-a	Indicates the standard error of the remote command is the same as standard output. No provision is made for sending arbitrary signals to the remote process.
-d	Enables socket-level debugging.
-i	Prevents reading the stdin.
-n	Prevents automatic login. With the **-n** flag specified, the **rexec** command prompts for a user name and password to use at the remote host, rather than searching for a **$HOME/.netrc** file.

Parameters

Item	Description
Command	Specifies the command, including any flags or parameters, to be executed on the remote host.
Host	Specifies in alphanumeric form the name of the host where the command is to be executed.

Examples

1. To execute the **date** command on a remote host, enter:

   ```
   rexec host1 date
   ```

   The output from the date command is now displayed on the local system. In this example, the **$HOME/.netrc** file on the local host contains a user name and password valid at the remote host.

   If you do not have a valid entry in the **$HOME/.netrc** file for the remote host, you will be prompted for your login ID and password. After you have entered the requested login information, the output from the date command is displayed on the local system.

2. To override the automatic login feature and execute the **date** command on a remote host, enter:

   ```
   rexec -nhost1 date
   ```

   Enter your name and password when prompted.

   The output from the date command is now displayed on the local system.

3. To list the directory of another user on a remote host, enter:

   ```
   rexec host1 ls -l /home/karen
   ```

   The directory listing of user `karen` on remote host `host1` is displayed on the local system.

   If you do not have a valid entry in the **$HOME/.netrc** file for the remote host, you will be prompted for your login ID and password. After you have entered the requested login information, the directory listing of user `karen` on remote host `host1` is displayed on the local system.

rexecd Daemon

Purpose

Provides the server function for the **rexec** command.

Syntax

> **Note:** The **rexecd** daemon is normally started by the **/etc/inetd.conf** or **kill -1** *InetdPID* command to inform the **inetd** daemon of the changes to its configuration file.

Note: The **rexecd** daemon ignores invalid options and if the **syslog** facility is enabled, the information will be logged to the system log.

Flags

Item	Description
-s	Enables socket-level debugging.
-c	Prevents reverse name resolution. When the **-c** flag is not specified, the **rexecd** daemon will fail if the reverse name resolution of the client fails.

Service Request Protocol

When the **rexecd** daemon receives a request, it initiates the following protocol:

1. The server reads characters from the socket up to a null (\0) byte and interprets the resulting string as an ASCII number (decimal).
2. If the number received is nonzero, the **rexecd** daemon interprets it as the port number of a secondary stream to be used for standard error output. The **rexecd** daemon then creates a second connection to the specified port on the client machine.
3. The **rexecd** daemon retrieves a null-terminated user name of up to 16 characters on the initial socket.

Security

The **rexecd** daemon is a PAM-enabled application with a service name of *rexec*. System-wide configuration to use PAM for authentication is set by modifying the value of the **auth_type** attribute, in the **usw** stanza of **/etc/security/login.cfg**, to PAM_AUTH as the root user.

The authentication mechanisms used when PAM is enabled depend on the configuration for the **rexec** service in **/etc/pam.conf**. The **rexecd** daemon requires **/etc/pam.conf** entries for the **auth**, **account**, and **session** module types. Listed below is a recommended configuration in **/etc/pam.conf** for the **rexec** service:

```
#
# AIX rexec configuration
#
rexec auth      required     /usr/lib/security/pam_aix

rexec account   required     /usr/lib/security/pam_aix

rexec session   required     /usr/lib/security/pam_aix
```

rgb Command

Purpose

Creates the database used by the X-Window system server for colors.

Syntax

rgb [*DatabaseName*] [*<InputfileName*]

Description

The **rgb** command reads lines from standard input and inserts them into its database to associate color names with specific red, green, and blue (RGB) values.

The **rgb** command produces two output files: *DatabaseName*.dir and *DatabaseName*.pag. If you do not specify a database file name, the default names **rgb.dir** and **rgb.pag** are used.

Each color entry is in the form:

```
Red Green Blue Colorname
```

where the *Red*, *Green*, and *Blue* elements are integer values ranging from 0-255. The actual color is determined by how the elements are combined. Each element can range from no intensity (0) to full intensity (255). The *Colorname* parameter can be descriptive or fanciful. For example, the sequence `250 250 250` could be named `white` or `snow`. Two or more entries can share the same element numbers or names.

Parameters

Item	Description
DatabaseName	Specifies the database to create for the output data.
<InputFileName	Specifies the name of the input file.

Examples

1. The following example shows a portion of an input file:

```
248 248 255     ghost white
245 245 245     white smoke
255 250 240     floral white
253 245 230     old lace
250 240 230     linen
255 218 185     peach puff
255 248 220     cornsilk
255 250 205     lemon chiffon
245 255 250     mint cream
240 255 255     azure
```

2. The following example generates the output files **Newcolor.dir** and **Newcolor.pag**.

```
rgb Newcolor < rgb.txt
```

   where **Newcolor** is the *DatabaseName* and **rgb.txt** is the *InputFileName*.

Files

Item	Description
/usr/lib/X11/rgb.txt	The default rgb database input file.

ripquery Command

Purpose

Queries the RIP gateways.

Syntax

ripquery [**-1**] [**-2**] [**-**[**a5**] *authkey*] [**-n**] [**-N** *dest***[/***mask***]** [**-p**] [**-r**] [**-v**] [**-w** *time*] *gateway*...

Description

The **ripquery** command is used to request all routes known by a RIP *gateway* by sending a RIP **REQUEST** or **POLL** command. The routing information in any routing packets returned is displayed numerically and symbolically. The **ripquery** command is intended to be used as a tool for debugging *gateway*s, not for network management. SNMP is the preferred protocol for network management.

Flags

Item	Description
-1	Send the query as a version 1 packet.
-2	Send the query as a version 2 packet (default).
-[**a5**] *authkey*	Specifies the authentication password to use for queries. If **-a** is specified, an authentication type of SIMPLE will be used, if **-5** is specified, an authentication type of MD5 will be used, otherwise the default is an authentication type of NONE. Authentication fields in incoming packets will be displayed, but not validated.
-n	Prevents the address of the responding host from being looked up to determine the symbolic name.
-N *dest***[/***mask***]**	Specifies that the query should be for the specified *dest/mask* instead of complete routing table. The specification of the optional mask implies a version 2 query. Up to 23 requests about specific destinations may be included in one packet.
-p	Uses the RIP **POLL** command to request information from the routing table. This is the default. If there is no response to the RIP **POLL** command, the RIP **REQUEST** command is tried. **gated** responds to a **POLL** command with all the routes learned via RIP.
-r	Uses the RIP **REQUEST** command to request information from the *gateway*'s routing table. Unlike the RIP **POLL** command, all *gateway*s should support the RIP **REQUEST**. If there is no response to the RIP **REQUEST** command, the RIP **POLL** command is tried. **gated** responds to a **REQUEST** command with all the routes he anounces out the specified interface.
-v	Version information about **ripquery** is displayed before querying the *gateway*s.
-w *time*	Specifies the time in seconds to wait for the initial response from a *gateway*. The default value is 5 seconds.

rksh Command

Purpose

Invokes the restricted version of the Korn shell.

Syntax

rksh [-i] [{ + | - }{ a e f h k m n p t u v x }] [-o *Option ...*] [-c *String* | -s | *File* [*Parameter*]]

Note: Preceding a flag with + (plus) rather than - (minus) turns off the flag.

Description

The `rksh` command invokes a restricted version of the Korn shell. It allows administrators to provide a controlled shell environment to the users. There is also a restricted version of `rksh` available for the enhanced Korn shell, called `rksh93`.

With a restricted shell a user cannot:

- Change the current working directory.
- Set the value of the SHELL, ENV, or PATH variable.
- Specify the pathname of a command that contains a / (slash).
- Redirect output of a command with > (right caret), >| (right caret, pipe symbol), <> (left caret, right caret), or >> (two right carets).

Flags

Item	Description
`-a`	Exports automatically all subsequent parameters that are defined.
`-c` *String*	Causes the Korn shell to read commands from the *String* variable. This flag cannot be used with the **-s** flag or with the *File*[*Parameter*] parameter.
`-e`	Executes the **ERR** trap, if set, and exits if a command has a nonzero exit status. This mode is disabled while reading profiles.
`-f`	Disables file name substitution.
`-h`	Designates each command as a tracked alias when first encountered.
`-i`	Indicates that the shell is interactive. An interactive shell is also indicated if shell input and output are attached to a terminal (as determined by the **ioctl** subroutine). In this case, the **TERM** environment variable is ignored (so that the **kill 0** command does not kill an interactive shell) and the **INTR** signal is caught and ignored (so that a wait state can be interrupted). In all cases, the **QUIT** signal is ignored by the shell.
`-k`	Places all parameter assignment arguments in the environment for a command, not just those arguments that precede the command name.
`-m`	Runs background jobs in a separate process and prints a line upon completion. The exit status of background jobs is reported in a completion message. On systems with job control, this flag is turned on automatically for interactive shells.
`-n`	Reads commands and checks them for syntax errors, but does not execute them. This flag is ignored for interactive shells.

Item	Description
-o *Option*	Prints the current option settings and an error message if you do not specify an argument. You can use this flag to enable any of the following options: **allexport** Same as the **-a** flag. **errexit** Same as the **-e** flag. **bgnice** Runs all background jobs at a lower priority. This is the default mode. **emacs** Enters an emacs-style inline editor for command entry. **gmacs** Enters a gmacs-style inline editor for command entry. **ignoreeof** Does not exit the shell when it encounters an end-of-file character. You must use the **exit** command, or override the flag and exit the shell by pressing the Ctrl-D key sequence more than 11 times. **keyword** Same as the **-k** flag. **markdirs** Appends a **/** (slash) to all directory names that are a result of filename substitution. **monitor** Same as the **-m** flag. **noclobber** Prevents redirection from truncating existing files. When you specify this option, use the redirection symbol **>|** (right caret, pipe symbol) to truncate a file. **noexec** Same as the **-n** flag. **noglob** Same as the **-f** flag. **nolog** Prevents function definitions from being saved in the history file. **nounset** Same as the **-u** flag. **privileged** Same as the **-p** flag. **verbose** Same as the **-v** flag. **trackall** Same as the **-h** flag. **vi** Enters the insert mode of a vi-style inline editor for command entry. Entering escape character 033 puts the editor into the move mode. A return sends the line. **viraw** Processes each character as it is typed in vi mode. **xtrace** Same as the **-x** flag. You can set more than one option on a single **rksh** command line.

Item	Description
-p	Disables the processing of the **$HOME/.profile** file when you use the shell as a login shell.
-s	Causes the **rksh** command to read commands from the standard input. Shell output, except for the output of the special commands, is written to file descriptor 2. This parameter cannot be used with the **-c** flag or with the *File*[*Parameter*] parameter.
-t	Exits after reading and executing one command.
-u	Treats unset parameters as errors when substituting.
-v	Prints shell input lines as they are read.
-x	Prints executed commands and their arguments.

Files

Item	Description
/usr/bin/rksh	Contains the path name to the restricted Korn shell.
/tmp/sh*	Contains temporary files that are created when a shell is opened.

rlogin Command

Purpose

Connects a local host with a remote host.

Syntax

rlogin *RemoteHost* [**-e** *Character*] [**-8**] [**-l** *User*] [**-f** | **-F**] [**-k** *realm*]

Description

The **/usr/bin/rlogin** command logs into a specified remote host and connects your local terminal to the remote host.

The remote terminal type is the same as that given in the **TERM** local environment variable. The terminal or window size is also the same, if the remote host supports them, and any changes in size are transferred. All echoing takes place at the remote host, so except for delays, the terminal connection is transparent. The Ctrl-S and Ctrl-Q key sequences stop and start the flow of information, and the input and output buffers are flushed on interrupts.

Remote Command Execution

When using the **rlogin** command, you can create a link to your path using a host name as the link name. For example:

```
ln -s /usr/bin/rsh HostName
```

Entering the host name specified by the *HostName* parameter with an argument (command) at the prompt, automatically uses the **rsh** command to remotely execute the command specified on the command line of the remote host specified by the *HostName* parameter.

Entering the host name specified by the *HostName* parameter without an argument (command) at the prompt, automatically uses the **rlogin** command to log in to the remote host specified by the *HostName* parameter.

In addition to the preceding conditions, the **rlogin** command also allows access to the remote host if the remote user account does not have a password defined. However, for security reasons, the use of a password on all user accounts is recommended.

The **rlogin** command execs (using the **exec** command) the **/usr/sbin/login** file to validate a user. This 1) allows all user and device attributes to take effect on telnet connections and 2) causes remote logins to count against the maximum number of login sessions allowable at a time (determined by the `maxlogins` attribute). Attributes are defined in the **/etc/security/user** and **/etc/security/login.cfg** files.

POSIX Line Discipline

The **rlogind** and **telnetd** daemons use POSIX line discipline to change the line discipline on the local TTY. If POSIX line discipline is not used on the local TTY, echoing other line disciplines may result in improper behavior. TCP/IP must have POSIX line discipline to function properly.

Flags

Item	Description
-8	Allows an 8-bit data path at all times. Otherwise, unless the start and stop characters on the remote host are not Ctrl-S and Ctrl-Q, the **rlogin** command uses a 7-bit data path and parity bits are stripped.
-e *Character*	Changes the escape character. Substitute the character you choose for *Character*.
-f	Causes the credentials to be forwarded. This flag will be ignored if Kerberos 5 is not the current authentication method. Authentication will fail if the current DCE credentials are not marked forwardable.
-F	Causes the credentials to be forwarded. In addition, the credentials on the remote system will be marked forwardable (allowing them to be passed to another remote system). This flag will be ignored if Kerberos 5 is not the current authentication method. Authentication will fail if the current DCE credentials are not marked forwardable.
-k *realm*	Allows the user to specify the realm of the remote station if it is different from the local systems realm. For these purposes, a realm is synonymous with a DCE cell. This flag will be ignored if Kerberos 5 is not the current authentication method.
-l *User*	Changes the remote user name to the one you specify. Otherwise, your local user name is used at the remote host.

Security

There are multiple authentication methods, each requiring different things to be set in order to allow the connection.

For Standard Authentication

The remote host allows access only if one or both of the following conditions is satisfied:

- The local host is included in the remote **$HOME/.rhosts** file in the remote user account.

Although you can set any permissions for the **$HOME/.rhosts** file, it is recommended that the permissions of the .rhosts file be set to 600 (read and write by owner only).

Note: The **AUTHSTATE** environment variable indicates the registry to which the user authenticates. For example, an LDAP user that is defined on the LDAP server has the **AUTHSTATE** set to LDAP if the user logs in to the remote system with a password. But if a user is authenticated through an entry in the **$HOME/.rhosts and /etc/hosts.equiv** files, the **AUTHSTATE** environment variable for that user is set to compat regardless of where the user ID is defined.

For Kerberos 5 Authentication

The remote host allows access only if all of the following conditions are satisfied:

- The local user has current DCE credentials.
- The local and remote systems are configured for Kerberos 5 authentication (On some remote systems, this may not be necessary. It is necessary that a daemon is listening to the klogin port).
- The remote system accepts the DCE credentials as sufficient for access to the remote account. See the html

rlogind Daemon

Purpose

Provides the server function for the **rlogin** command.

Syntax

> **Note:** The **rlogind** daemon is normally started by the **inetd** daemon. It can also be controlled from the command line, using SRC commands.

/usr/sbin/rlogind [**-a**] [**-c**] [**-l**] [**-n**] [**-s**]

Description

The **/usr/sbin/rlogind** daemon is the server for the **rlogin** remote login command. The server provides a remote login facility.

Changes to the **rlogind** daemon can be made using the System Management Interface Tool (SMIT) or System Resource Controller (SRC), by editing the **/etc/inetd.conf** or **/etc/services** file. Entering `rlogind` at the command line is not recommended. The **rlogind** daemon is started by default when it is uncommented in the **/etc/inetd.conf** file.

The **rlogind** daemon ignores unrecognized options and log this information through the **syslog** service if the **syslog** service is enabled in the system.

The **inetd** daemon get its information the /**etc**/**inetd.conf** file and the /**etc**/**services** file.

After changing the **/etc/inetd.conf** or /**etc**/**services** file, run the **refresh -s inetd** or **kill -1** *InetdPID* command to inform the **inetd** daemon of the changes to its configuration file.

Service Request Protocol

When the **rlogind** daemon receives a service request, the daemon initiates the following protocol:

1. The **rlogind** daemon checks the source port number for the request. If the port number is not in the range 512-1023, the **rlogind** daemon terminates the connection.
2. The **rlogind** daemon uses the source address of the initial connection request to determine the name of the client host. If the name cannot be determined, the **rlogind** daemon uses the dotted-decimal representation of the client host address.

Error Messages

The following error messages are associated with the **rlogind** daemon:

Item	Description
Try again.	A **fork** command made by the server has failed.
/usr/bin/shell:	No shell. The shell specified for the shell variable cannot be started. The shell variable may also be a program.

Flags

Item	Description
-a	Disables **pty** speed enhancement feature.
-c	Suppresses the sanity check of a host name lookup.
-l	Prevents any authentication based on the user's **$HOME/.rhosts** file. However, a root user is automatically logged in when there is a **.rhosts** file in root's home directory as specified by the **/etc/passwd** file.
-n	Disables transport-level keep-alive messages. The messages are enabled by default.
-s	Turns on socket level debugging.

Security

The **rlogind** daemon is a PAM-enabled application with a service name of *rlogin*. System-wide configuration to use PAM for authentication is set by modifying the value of the **auth_type** attribute, in the **usw** stanza of **/etc/security/login.cfg**, to PAM_AUTH as the root user.

The authentication mechanisms used when PAM is enabled depend on the configuration for the **rlogin** service in **/etc/pam.conf**. The **rlogind** daemon requires **/etc/pam.conf** entries for the **auth**, **account**, **password**, and **session** module types. Listed below is a recommended configuration in **/etc/pam.conf** for the **rlogin** service:

```
#
# AIX rlogin configuration
#
rlogin auth      sufficient   /usr/lib/security/pam_rhosts_auth
rlogin auth      required     /usr/lib/security/pam_aix

rlogin account   required     /usr/lib/security/pam_aix

rlogin password  required     /usr/lib/security/pam_aix

rlogin session   required     /usr/lib/security/pam_aix
```

Examples

> **Note:** The arguments for the **rlogind** daemon can be specified by using SMIT or by editing the **/etc/inetd.conf** file.

1. To start the **rlogind** daemon, enter the following:

   ```
   startsrc -t rlogin
   ```

   This command starts the **rlogind** subserver.
2. To stop the **rlogind** daemon normally, enter the following:

   ```
   stopsrc -t rlogin
   ```

   This command allows all pending connections to start and existing connections to complete but prevents new connections from starting.
3. To force stop the **rlogind** daemon and all **rlogind** connections, enter the following:

   ```
   stopsrc -f -t rlogin
   ```

   This command terminates all pending connections and existing connections immediately.
4. To display a short status report about the **rlogind** daemon, enter the following:

   ```
   lssrc -t rlogin
   ```

   This command returns the daemon's name, process ID, and state (active or inactive).

rm Command

Purpose

Removes (unlinks) files or directories.

Syntax

rm [**-f**] [**-r**] [**-R**] [**-i**] [**-e**] *File ...*

Description

The **rm** command removes the entries for the specified *File* parameter from a directory. If an entry is the last link to a file, the file is then deleted. If you do not have write permission for a file and the standard input is a terminal, you are prompted with the file name and ask to confirm that you want to delete the file. If you type a y (for yes), the file is deleted, type any other character and the file is not deleted. You do not need read or write permission for the file you want to remove. However, you must have write permission for the directory containing the file.

If the file is a symbolic link, the link is removed, but the file or directory that the symbolic link refers to remains. You do not need write permission to delete a symbolic link, if you have write permission in the directory.

If either of the files **.** (dot) or **..** (dot, dot) are specified as the base name portion of the *File* parameter, the **rm** command writes a diagnostic message to standard error and does nothing more with such parameters.

The **rm** command writes a prompt to standard error and reads a line from standard input if the **-f** flag is not specified, and either the *File* parameter does not have write permission and the standard input is a workstation, or the **-i** flag is specified. If the response is not affirmative, the **rm** command does nothing more with the current file and proceeds to the next file.

The files owned by other users cannot be removed if the sticky bit of the directory is set and the directory is not owned by the user.

> **Note:** The **rm** command supports the **—** (dash, dash) parameter as a delimiter that indicates the end of the flags.

An attempt to remove a file or directory that has been exported for use by the NFS version 4 server will fail with a message saying that the resource is busy. The file or directory must be unexported for NFS version 4 use before it can be removed.

Flags

Item	Description
-e	Displays a message after each file is deleted.
-f	Does not prompt before removing a write-protected file. Does not display an error message or return error status if a specified file does not exist. If both the **-f** and **-i** flags are specified, the last one specified takes affect.
-i	Prompts you before deleting each file. When you use the **-i** and **-r** flags together, the **rm** command also prompts before deleting directories. If both the **-i** and **-f** flags are specified, the last one specified takes affect.

Item	Description
-r	Permits recursive removal of directories and their contents when the *File* parameter is a directory. This flag is equivalent to the **-R** flag.
-R	Permits recursive removal of directories and their contents when the *File* parameter is a directory. This flag is equivalent to the **-r** flag.

Exit Status

This command returns the following exit values:

Item	Description
0	If the **-f** flag was not specified, all the named directory entries were removed; otherwise, all the existing named directory entries were removed.
>0	An error occurred.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To delete a file, enter:

   ```
   rm myfile
   ```

   If there is another link to this file, then the file remains under that name, but the name `myfile` is removed. If `myfile` is the only link, the file itself is deleted.

2. To delete a file without first receiving a confirmation prompt, enter:

   ```
   rm -f core
   ```

   No confirmation prompt is issued before the **rm -f** command attempts to remove the file named `core`. However, an error message displays if the `core` file is write-protected and you are not the owner of the file or you do not have root authority. No error message displays when the **rm -f** command attempts to remove nonexistent files.

3. To delete files one by one, enter:

   ```
   rm -i mydir/*
   ```

   After each file name is displayed, enter y to delete the file, or press the Enter key to keep it.

4. To delete a directory tree, enter:

   ```
   rm -ir manual
   ```

   This command recursively removes the contents of all subdirectories of the `manual` directory, prompting you regarding the removal of each file, and then removes the `manual` directory itself, for example:

   ```
   You:  rm -ir manual
   System: rm: Select files in directory manual? Enter y for yes.
   You:  y
   System: rm: Select files in directory manual/draft1? Enter y for yes.
   You:  y
   ```

```
System: rm: Remove manual/draft1?
You:  y
System: rm: Remove manual/draft1/chapter1?
You:  y
System: rm: Remove manual/draft1/chapter2?
You:  y
System: rm: Select files in directory manual/draft2? Enter y for yes.
You:  y
System: rm: Remove manual/draft2?
You:  y
System: rm: Remove manual?
You:  y
```

Here, the **rm** command first asks if you want it to search the `manual` directory. Because the `manual` directory contains directories, the **rm** command next asks for permission to search `manual/draft1` for files to delete, and then asks if you want it to delete the `manual/draft1/chapter1` and `manual/draft1/chapter2` files. The **rm** command next asks for permission to search the `manual/draft2` directory. Then asks for permission to delete the `manual/draft1`, `manual/draft2`, and `manual` directories.

If you deny permission to remove a subdirectory (for example, `manual/draft2`), the **rm** command does not remove the `manual` directory. Instead, you see the message: `rm: Directory manual not empty`.

Files

Item	Description
/usr/bin/rm	Contains the **rm** command.

rmail Command

Purpose

Handles remote mail received through Basic Networking Utilities (BNU).

Syntax

rmail *User*

Description

The **rmail** command interprets incoming mail received through the **uucp** command. It collapses `From` header lines in the form generated by the **bellmail** command into a single line of the form:

```
return-path!sender
```

The **rmail** command passes the processed mail on to the **sendmail** command. The *User* parameter must specify a user recognized by the **sendmail** command.

rmauth Command

Purpose

Removes one or more user-defined authorizations.

Syntax

rmauth [**-R** *load_module*] [**-h**] *Name*

Description

The **rmauth** command removes the user-defined authorization identified by the *Name* parameter. The command only removes existing user-defined authorizations in the authorization database. You cannot remove system-defined authorizations with this command. If an authorization is being referenced in the privileged command database, it cannot be removed until the authorization is no longer referenced by the database.

By default, the **rmauth** command only attempts to remove the specified authorization from the authorization database. You must remove authorizations from the lowest level of a hierarchy before the higher level can be removed. If you specify a higher level authorization and lower-level authorizations still exist, the command fails. To remove a hierarchy of authorizations, specify the **-h** flag. With the **-h** flag, any lower-level authorization beneath the specified authorization is also removed. If any of the lower level authorizations is being referenced in the privileged command database, no authorizations are removed and the entire operation fails.

If the system is configured to use databases from multiple domains, the **rmauth** command finds the first match from the database domains in the order that was specified by the **secorder** attribute of the authorizations stanza in the **/etc/nscontrol.conf** file. Meanwhile, the **rmauth** command removes that authorization entry from the domain. If any matching authorizations from the rest of the domains exist, they are not affected. Use the **-R** flag to remove an authorization from a specific domain.

When the system is operating in enhanced role based access control (RBAC) mode, modifications made to the authorization database are not used for security considerations until the database is sent to the kernel security tables using the **setkst** command.

Flags

Item	Description
-h	Allows removal of a hierarchy of authorizations.
-R *load_module*	Specifies the loadable module to use for the authorization deletion.

Parameters

Item	Description
Name	Specifies the authorization to remove.

Security

The **rmauth** command is a privileged command. You must have the **aix.security.role.remove** authorization to run the command:

Item	Description
aix.security.auth.remove	Required to run the command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Files Accessed

File	Mode
/etc/security/authorizations	rw

Examples

1. To remove the `custom.test` authorization, use the following command:

```
rmauth custom.test
```

2. To remove the `custom` authorization and all of its children authorizations, use the following command:

```
rmauth -h custom
```

3. To remove the `custom.test` authorization from LDAP, use the following command:

```
rmauth -h custom.test
```

rmaudrec Command

Purpose

Removes records from the audit log.

Syntax

`rmaudrec` [`-a` | `-n` *node_name1*[`,`*node_name2*]...] [`-S` *subsystem_name*]
`-s` *selection_string* [`-h`] [`-V`]

Description

The `rmaudrec` command is used to delete records in the audit log. The audit log is a facility for recording information about the system's operation. It can include information about the normal operation of the system as well as failures and other errors. It augments the error log functionality by conveying the relationship of the error relative to other system activities. All detailed information about failures is still written to the AIX error log.

Records are created in the audit log by subsystems that have been instrumented to do that. For example, the event response subsystem runs in the background to monitor administrator-defined conditions and then invokes one or more actions when a condition becomes true. Because this subsystem runs in the background, it is difficult for the operator or administrator to understand the total set of events that occurred and the results of any actions that were taken in response to an event. Because the event response subsystem records its activity in the audit log, the administrator can easily view its activity as well as that of other subsystems. In addition, records may sometimes need to be removed explicitly, which can be done using this command.

Each record in the audit log contains named fields. Each field contains a value that provides information about the situation corresponding to the record. For example, the field named `Time` indicates the time at which the situation occurred. Each record has a set of common fields and a set of subsystem-specific fields. The common fields are present in every record in the audit log. The subsystem-specific fields vary from record to record. Their names are only significant when used with a subsystem name because they may not be unique across all subsystems. Each record is derived from a template that defines which subsystem-specific fields are present in the record and defines a format string that is used to generate a message describing the situation. The format string may use record fields as inserts. A subsystem typically has many templates.

The field names can be used as variables in a *selection string* to choose which records are deleted. The selection string is matched against each record using the referenced fields of each record to perform the match. Any records that match will be removed. The selection string is specified with the `-s` flag.

A selection string is an expression composed of field names, constants, and operators. The syntax of a selection string is very similar to an expression in the C programming language. For information on how to specify selection strings, see the *Administering RSCT* guide.

The common field names are:

Field	Description
Time	Specifies the time when the situation occurred that the record corresponds to. The value is a 64-bit integer and represents the number of microseconds since UNIX Epoch (00:00:00 GMT January 1, 1970). See the constants below for specifying the time in more user-friendly formats.
Subsystem	Specifies the subsystem that generated the record. This is a string.
Category	Indicates the importance of the situation corresponding to the audit record, as determined by the subsystem that generated the record. The valid values are: `0` (informational) and 1 (error).
SequenceNumber	Specifies the unique 64-bit integer that is assigned to the record. No other record in the audit log will have the same sequence number.
TemplateId	Specifies the subsystem-dependent identifier that is assigned to records that have the same content and format string. This value is a 32-bit unsigned integer.
NodeName	Specifies the name of the node from which the record was obtained. This field name cannot be used in a selection string.

In addition to the constants in expressions, you can use the following syntax for dates and times with this command:

#mmddhhmmyyyy
: This format consists of a sequence of decimal characters that are interpreted according to the pattern shown. The fields in the pattern are, from left to right: *mm* = month, *dd* = day, *hh* = hour, *mm* = minutes, *yyyy* = year. For example, `#010523042002` corresponds to January 5, 11:04 PM, 2002. The fields can be omitted from right to left. If not present, the following defaults are used: year = the current year, minutes = 0, hour = 0, day = 1, and month = the current month.

#-mmddhhmmyyyy
: This format is similar to the previous one, but is relative to the current time and date. For example, the value `#-0001` corresponds to one day ago and the value `#-010001` corresponds to one month and one hour ago. Fields can be omitted starting from the right and are replaced by 0.

The audit records considered for deletion and matched against the selection string can be restricted to a specific subsystem by using the `-S` flag. If this flag is specified, the subsystem-specific field names can be used in the selection string in addition to the common field names.

The nodes from which audit log records are considered for deletion can be restricted to a set of specific nodes by using the `-n` flag. If this flag is specified, the search will be limited to the set of nodes listed. Otherwise, the search will be performed for all nodes defined within the current management scope as determined by the CT_MANAGEMENT_SCOPE environment variable.

It is advisable to first use the `lsaudrec` command with the same `-s` and `-n` flag values to list the records that will be deleted. This minimizes the possibility of the selection string matching more records than intended.

Flags

-a
: Specifies that records from all nodes in the domain are to be removed. If both the `-n` and the `-a` flags are omitted, records from the local node only are removed.

-n *node_name1*[,*node_name2*]...
: Specifies the list of nodes containing audit log records that will be examined and considered for deletion if they meet the other criteria, such as matching the specified selection string. Node group names can also be specified, which are expanded into a list of node names. If both the `-n` and the `-a` flags are omitted, records from the local node only will be deleted.

-S *subsystem_name*
Specifies a subsystem name. If this flag is present, only records identified by *subsystem_name* are considered for deletion. The records to be deleted can be further restricted by the `-s` flag. If the subsystem name contains any spaces, it must be enclosed in single or double quotation marks.

For backward compatibility, the subsystem name can be specified using the `-n` flag *only* if the `-a` and the `-S` flags are *not* specified.

-s *selection string*
Specifies a selection string. This string is evaluated against each record in the audit log. If the evaluation results in a non-zero result (TRUE), the record is removed from the audit log. If the selection string contains any spaces, it must be enclosed within single or double quotation marks. For information on how to specify selection strings, see the *RSCT: Administration Guide* .

The names of fields within the record can be used in the expression. If the `-S` flag is not specified, only the names of common fields can be used. See the **Description** for a list of the common field names and their data types. If the `-S` flag is specified, the name of any field for the specified subsystem as well as the common field names can be used.

If this flag is not specified, no records will be removed from the audit log.

-h
Writes the command's usage statement to standard output.

-V
Writes the command's verbose messages to standard error.

Parameters

***field_name1* [*field_name2*...]**
Specifies one or more fields in the audit log records to be displayed. The order of the field names on the command line corresponds to the order in which they are displayed. If no field names are specified, `Time`, `Subsystem`, `Severity`, and `Message` are displayed by default. If the management scope is not local, `NodeName` is displayed as the first column by default. See the **Description** for information about these and other fields.

Security

In order to remove records from an audit log when the `-S` flag is omitted, a user must have write access to the target resource class on each node from which records are to be removed. When the `-S` flag is specified, the user must have write access to the audit log resource corresponding to the subsystem identified by the `-S` flag on each node from which records are to be removed.

Authorization is controlled by the RMC access control list (ACL) file that exists on each node.

Exit Status

0
The command ran successfully.
