See Displaying and Modifying Variables in *General Programming Concepts: Writing and Debugging Programs*.

edit Subcommand

edit [*Procedure* | *File*]

The **edit** subcommand starts an editor on the specified file. The file might be specified through the *File* parameter or by specifying the *Procedure* parameter, where the editor is started on the file containing that procedure. If no file is specified, the editor is started on the current source file. The default is the **vi** editor. Override the default by resetting the **EDITOR** environment variable to the name of the required editor.

Examples

1. To start an editor on the current source file, enter:

```
edit
```

2. To start an editor on the `main.c` file, enter:

```
edit main.c
```

3. To start an editor on the file containing the `do_count()` procedure, enter:

```
edit do_count
```

See the **list** subcommand, the **vi** or **vedit** command.

enable Subcommand

enable { *Number* ... **all** }

The **enable** subcommand enables traces and stops associated with debug events. The traces and stops to be enabled can be specified through the *Number* parameters, or all traces and stops can be enabled by using the **all** flag. Use the **status** subcommand to display the event numbers associated by the **dbx** debug program with a trace or stop.

Flags

Item	Description
all	Removes all traces and stops.

Examples

1. To enable all traces and stops from the application program, type:

```
enable all
```

2. To enable traces and stops for event number 4, type:

```
enable 4
```

For more information, see **disable subcommand**, **delete subcommand**, **status subcommand**.

Also, see Setting and Deleting Breakpoints in *General Programming Concepts: Writing and Debugging Programs*.

fd Subcommand

fd [**raw**] [*start* [*end*]]

The **fd** subcommand displays file descriptor information. Using the **raw** option causes output to be displayed in raw hex format. Other optional arguments include *start* and *end* indices. If no index is given, then information about all available file descriptors is displayed. Use of one index displays a single file descriptor; two an inclusive range.

Examples

1. To view information about all file descriptors in hex, type:

```
fd raw
```

2. To view information about file descriptors in the range of 3 to 5, type:

```
fd 3 5
```

file Subcommand

file [*File*]

The **file** subcommand changes the current source file to the file specified by the *File* parameter; it does not write to that file. The *File* parameter can specify a full path name to the file. If the *File* parameter does not specify a path, the **dbx** program tries to find the file by searching the use path. If the *File* parameter is not specified, the **file** subcommand displays the name of the current source file. The **file** subcommand also displays the full or relative path name of the file if the path is known.

Examples

1. To change the current source file to the `main.c` file, enter:

```
file main.c
```

2. To display the name of the current source file, enter:

```
file
```

See the **func** subcommand. Also, see Changing the Current File or Procedure and Displaying the Current File in *General Programming Concepts: Writing and Debugging Programs*.

frame Subcommand

frame [*num*]

The **frame** subcommand changes the current function to the function corresponding to the specified stack frame number *num*. The current function is used for resolving names. The numbering of the stack frames starts from the currently active function stack frame (the function frame that is currently active is always numbered `0`). If there are *n* frames, the frame of the `main` function is numbered `n-1`. When no frame number is specified, information about the function associated with the current frame is displayed.

Examples

1. To move to frame number 2, enter:

```
frame 2
```

2. To display the current function on the stack, enter:

```
frame
```

See the **up** and **down** subcommands. Also, see Changing the Current File or Procedure and Displaying a Stack Trace in *General Programming Concepts: Writing and Debugging Programs*.

func Subcommand

func [*Procedure*]

The **func** subcommand changes the current function to the procedure or function specified by the *Procedure* parameter. If the *Procedure* parameter is not specified, the default current function is displayed. Changing the current function implicitly changes the current source file to the file containing the new function; the current scope used for name resolution is also changed.

Examples

1. To change the current function to the `do_count` procedure, enter:

```
func do_count
```

2. To display the name of the current function, enter:

```
func
```

See the **file** subcommand. Also, see Changing the Current File or Procedure in *General Programming Concepts: Writing and Debugging Programs*.

goto Subcommand

goto *SourceLine*

The **goto** subcommand causes the specified source line to be run next. Normally, the source line must be in the same function as the current source line. To override this restriction, use the **set** subcommand with the **$unsafegoto** flag.

Example

To change the next line to be executed to line 6, enter:

```
goto 6
```

See the **cont** subcommand, the **gotoi** subcommand, and the **set** subcommand.

gotoi Subcommand

gotoi *Address*

The **gotoi** subcommand changes the program counter address to the address specified by the *Address* parameter.

Example

To change the program counter address to address `0x100002b4`, enter:

```
gotoi 0x100002b4
```

See the **goto** subcommand.

handler Subcommand

handler { **atfork** | **cancel_cleanup** [**all** | *pthread id*] }

The **handler** subcommand displays information about atfork or cancelation cleanup handlers registered using **pthread_atfork**, and **pthread_cleanup_push**, respectively. Using the *atfork* option, the names of routines registered as `pre`, `parent` and `child` atfork handlers are displayed (with their respective arguments in the case of non-posix compliant atfork handlers). The **cancel_cleanup** option causes display of all registered cancelation cleanup handlers, with an optional *pthread id* parameter specifying a particular pthread, or **all** specifying all pthreads. If none is given, then the cancelation cleanup handlers for the current pthread are displayed, if there are any.

Examples

1. To view information about all registered atfork handlers, type:

   ```
   handler atfork
   ```

2. To view information about any registered cancelation cleanup handlers for the current pthread, type:

   ```
   handler cancel_cleanup
   ```

3. To view information about any registered cancelation cleanup handlers for the pthread object referred to as `$t2`, type:

   ```
   handler cancel_cleanup 2
   ```

help Subcommand

help [*Subcommand* | *Topic*]

The **help** subcommand displays help information for **dbx** subcommands or topics, depending upon the parameter you specify. Entering the **help** subcommand with the *Subcommand* parameter displays the syntax statement and description of the specified subcommand. Entering the **help** subcommand with the *Topic* parameter displays a detailed description of the specified topic. You do not need to provide the entire topic string with the **help** subcommand. The **dbx** program can recognize the topic if you provide a substring starting from the beginning of the topic. The following topics are available:

Item	Description
startup	Lists **dbx** startup options.
execution	Lists **dbx** subcommands related to program execution.
breakpoints	Lists **dbx** subcommands related to breakpoints and traces.
files	Lists **dbx** subcommands for accessing source files.
data	Lists **dbx** subcommands for accessing program variables and data.
machine	Lists descriptions of **dbx** subcommands for machine-level debugging.
environment	Lists **dbx** subcommands for setting **dbx** configuration and environment.
threads	Lists **dbx** subcommands for accessing thread-related objects.
expressions	Describes **dbx** expression syntax and operators.
scope	Describes how **dbx** resolves names from different scopes.
set_variables	Lists **dbx** debug variables with a usage description.
usage	Lists common **dbx** subcommands with brief descriptions.

Examples

1. To list all available **dbx** subcommands and topics, enter:

```
help
```

2. To display the description of the **dbx** subcommand **list**, enter:

```
help list
```

3. To display the description of the **dbx** topic **set_variables**, enter:

```
help set_variables
```

ignore Subcommand

ignore [*SignalNumber* | *SignalName*]

The **ignore** subcommand stops the trapping of a specified signal before that signal is sent to the application program. This subcommand is useful when the application program being debugged handles signals such as interrupts.

The signal to be trapped can be specified by:

- Number, with the *SignalNumber* parameter
- Name, with the *SignalName* parameter

Signal names are not case-sensitive. The **SIG** prefix is optional.

If the *SignalNumber* and the *SignalName* parameters are specified, all signals except the **SIGHUP**, **SIGCLD**, **SIGALRM**, and **SIGKILL** signals are trapped by default. The **dbx** debug program cannot ignore the **SIGTRAP** signal if it comes from a process outside of the debugger. If no arguments are specified, the list of currently ignored signals are displayed.

Example

To cause **dbx** to ignore alarm clock time-out signals sent to the application program, enter:

```
ignore alrm
```

See the **catch** subcommand. Also, see Handling Signals in *General Programming Concepts: Writing and Debugging Programs*.

kthread Subcommand

kthread [**raw**] [**info** | **ru**] [*tid*]

The **kthread** subcommand displays information about kernel threads. Using the **raw** option causes all output to be displayed in hex, regardless of whether it can be displayed in a more human-readable format. Using no arguments, summary information about all kernel threads is printed. Supplying a numeric thread ID causes the **dbx** command to show information about a single thread. The **info** option produces more detailed output about a thread, from the user thread structure. Use of the **ru** option displays the `ti_ru` data member, which contains resource usage information.

For more information about user threads, see **thread subcommand**.

Examples

1. To find information about the thread that is currently running, you must first obtain information about all threads by typing the following on the command line:

   ```
   kthread
   ```

   Threads that were running (or runnable) just before the **dbx** command stopped the process are marked with an asterisk. Choose the correct thread ID based on the output and type:

   ```
   kthread info tid
   ```

2. To view resource information in hex about all threads, type:

   ```
   kthread raw ru
   ```

limitbp Subcommand

limitbp (*bp1*, *Limit*) [(*bp2*, [**+**] *Limit*) ...]

The **limitbp** subcommand instructs the **dbx** command to stop running the debug program only when the breakpoint is executed a specified number of times. If the '**+**' character precedes the limit, the limit of that event is changed to the sum of the limit that is specified in the subcommand and the count of the number of times that the event is already executed. That is, the **dbx** command stops running the debug program when the breakpoint is about to be executed for the specified *Limit* after the **limitbp** subcommand is already run.

Examples

1. To instruct the **dbx** command to stop execution of the debug program when breakpoint 1 is about to be executed the 10th time, enter:

   ```
   limitbp (1, 10)
   ```

2. To instruct the **dbx** command to stop execution of the debug program when either breakpoint 1 is about to be executed the 15th time or breakpoint 2 is about to be executed the 20th time or both, enter:

   ```
   limitbp (1, 15) (2, 20)
   ```

3. To instruct the **dbx** command to stop execution of the debug program when breakpoint 1 is about to be executed the 20th time after the **limitbp** subcommand was run, enter:

   ```
   limitbp (1, +20)
   ```

list Subcommand

list [*Procedure* | *SourceLine-Expression* [**,***SourceLine-Expression*] | **at** *Address*]

The **list** subcommand displays a specified number of lines of the source file. The number of lines displayed are specified in one of following ways:

- By specifying a procedure using the *Procedure* parameter.

In this case, the **list** subcommand displays lines starting a few lines before the beginning of the specified procedure and until the list window is filled.

- By specifying a starting and ending source line number using the *SourceLine-Expression* parameter.

  The *SourceLine-Expression* parameter must consist of a valid line number followed by an optional + (plus sign), or - (minus sign), and an integer. In addition, a *SourceLine* of $ (dollar sign) might be used to denote the current line number; a *SourceLine* of @ (at sign) might be used to denote the next line number to be listed.

- By specifying the *$listwindow* internal **dbx** variable.

  If the **list** subcommand is used without parameters, the number of lines specified by the *$listwindow* variable are printed, beginning with the current source line. To change the default number of lines, set the *$listwindow* variable to the required number of lines. The *$listwindow* variable is a special debug program variable. Initially, the *$listwindow* variable is set to 10.

If the second source line is omitted, only the first line is printed.

All lines from the first line number specified to the second line number specified, inclusive, are then displayed.

When you specify an address after the **at** parameter in the **list** subcommand, the **list** subcommand displays the source lines that correspond to the specified address. Address can be specified as a decimal or hexadecimal unsigned integer, or a mnemonic that corresponds to registers, such as *$iar*, *$tfiar*, and *$tfhar* or debug variables.

Examples

1. To list the lines 1 through 10 in the current file, enter:

   ```
   list 1,10
   ```

2. To list 10, or `$listwindow`, lines around the `main` procedure, enter:

   ```
   list main
   ```

3. To list 11 lines around the current line, enter:

   ```
   list $-5,$+5
   ```

4. You can use simple integer expressions involving addition and subtraction in *SourceLineExpression* expressions. For example:

   ```
   (dbx) list $
   4 {

   (dbx) list 5
   5 char i = '4';

   (dbx) list sub
   23 char *sub(s,a,k)
   24 int a;
   25 enum status k;  .  .  .

   (dbx) move
   25
   (dbx) list @ -2
   23 char *sub(s,a,k)
   ```

5. You can display the source lines that correspond to a specific address. For example:

   ```
   (dbx) r
   [1] stopped in main at line 5
       5 int i, sum = 0;

   (dbx) list at $iar
   source file: "tt.c"
       5 int i, sum = 0;
       6 int last = 0;
       7
   ```

```
    8 scanf("%d", &last);
    9
    10 for ( i = 1; i &lt;=last; i++ ) {
    11 sum += i;
    12 }
    13 printf("sum = %d\n", sum);
    14

(dbx) list at ($iar+16)
source file: "tt.c"
    8 scanf("%d", &last);
    9
    10 for ( i = 1; i <= last; i++ ) {
    11 sum += i;
    12 }
    13 printf("sum = %d\n", sum);
    14
    15 return 0;
    16 }
```

See the **edit** subcommand, the **listi** subcommand, and the **move** subcommand. Also, see Displaying the current file in *General Programming Concepts: Writing and Debugging Programs*.

listi Subcommand

listi [*Procedure* | **at** *SourceLine* | *Address* [**,** *Address*]]

The **listi** subcommand displays a specified set of instructions from the source file. The instructions displayed are specified by:

- Providing the *Procedure* parameter, where the **listi** subcommand lists instructions from the beginning of the specified procedure until the list window is filled.
- Using the **at** *SourceLine* flag, where the **listi** subcommand displays instructions beginning at the specified source line and continuing until the list window is filled. The *SourceLine* variable can be specified as an integer or as a filename string followed by a : (colon) and an integer.
- Specifying a beginning and ending address using the *Address* parameters, where all instructions between the two addresses, inclusive, are displayed.

If the **listi** subcommand is used without flags or parameters, the next **$listwindow** instructions are displayed. To change the current size of the list window, use the **set $listwindow=***Value* subcommand.

Disassembly Modes

The **dbx** program can disassemble instructions for either the POWER family or PowerPC architecture. In the default mode, the **dbx** program displays the instructions for the architecture on which it is running.

The **$instructionset** and **$mnemonics** variables of the **set** subcommand for the **dbx** command allow you to override the default disassembly mode. For more information, see the **set** subcommand for the **dbx** command.

Flag

Item	Description
at *SourceLine*	Specifies a starting source line for the listing.

Examples

1. To list the next 10, or `$listwindow`, instructions, enter:

   ```
   listi
   ```

2. To list the machine instructions beginning at source line `10`, enter:

   ```
   listi at 10
   ```

3. To list the machine instructions beginning at source line 5 in file `sample.c`, enter:

   ```
   listi at "sample.c":5
   ```

4. To list the instructions between addresses `0x10000400` and `0x10000420`, enter:

```
listi 0x10000400, 0x10000420
```

See the **list** subcommand and the **set** subcommand. Also, see Debugging at the Machine Level with dbx in *General Programming Concepts: Writing and Debugging Programs*.

malloc Subcommand

malloc [> *File*]

The **malloc** subcommand with no options prints out a list of enabled options and allocation policies as well as a statistical summary of malloc usage since process startup.

malloc [**allocation** [{ *address* | *size* | *heap* | *pid* | *tid* | *time* } { "<" | "==" | ">" "!=" | “~=”]} *Value*]] [> *File*]

The **allocation** option to the **malloc** subcommand displays a sorted list of all the allocations currently held by the process. Using an optional `attribute RELOP value` argument allows for a more narrow selection of active allocations.

malloc [**freespace** [{ *address* | *size* | *heap* } { "<" | "==" | ">" | "!=" | “~=”]} *Value*]] [> *File*]

The **freespace** option to the **malloc** subcommand displays a sorted list of all the free space available in the process heap. Using an optional `attribute RELOP value` argument allows for a more narrow selection of free space nodes.

Note: ~= operator can be used only with address option. This operator is used to fetch the free space or allocation node to which the specified address belongs to.

malloc *address*

The **malloc** subcommand with address displays the nodes details of the address, the address need not be a starting address of an allocated or free node.

Flags

Item	Description
> *File*	Redirects output to the specified file.

For more information, see System Memory Allocation Using the malloc Subsystem in *General Programming Concepts: Writing and Debugging Programs*.

map Subcommand

map { [*Format*] [**entry** *ModuleNumber* [, *ModuleNumber*] | *Address* | *SymbolName*] [**for $t***threadnumber*] [**>** *File*] }

The **map** subcommand displays characteristics for loaded portions of the application. This information can include the module name, member name, text origin, text end, text length, data origin, data end, data length, TLS data origin, TLS data end, TLS data length, and file descriptor for each loaded module. The entries to be displayed can be specified in the following ways:

- By specifying a single entry using the *ModuleNumber* parameter.
- By specifying a range of entries using two comma-separated *ModuleNumber* parameters.
- By specifying an address to be resolved to a loaded module using the *Address* parameter.
- By specifying a symbol name to be resolved to a loaded module using the *SymbolName* parameter.

When called without one of the above specifications, the map subcommand displays information for all loaded portions of the application.

The *Format* argument specifies the output mode for the loaded module descriptions. The following list contains possible values for the *Format* argument:

Item	Description
abbr	Specifies the abbreviated output mode, which consists of a single line for each loaded module containing the entry number, module name, and optional member name for that module.
normal	Specifies the normal output mode, which consists of the entry number, module name, member name, text origin, text length, data origin, data length, and file descriptor for each loaded module. If the loaded module has TLS data, the TLS data origin and TLS data length are also displayed.
raw	Specifies the raw output mode, which consists of a single unformatted line for each module containing the following space-separated fields: entry number, module name with optional member name, text origin, text end, text length, data origin, data end, data length, and file descriptor. If the loaded module has TLS data, the TLS data origin, TLS data end, and TLS data length are also displayed.
verbose	Specifies the verbose output mode, which consists of the entry number, module name, member name, text origin, text end, text length, data origin, data end, data length, and file descriptor for each loaded module. If the loaded module has TLS data, the TLS data origin, TLS data end, and TLS data length are also displayed.

If no *Format* parameter is specified, the **dbx** command uses the value of the **$mapformat** internal variable. If no *Format* parameter is specified and **$mapformat** is unset, the **dbx** command displays loaded module information in normal mode.

The TLS data information of the specified thread is displayed if the loaded module has TLS data. If no thread is specified, the current thread is used.

Flags

Item	Description
> *File*	Redirects output to the specified file.
entry *ModuleNumber* [, *ModuleNumber*]	Specifies the module or range of modules to be displayed.
for $t *threadnumber*	Specifies the thread number.

Examples

1. To list all loaded modules in abbreviated mode, type:

```
map abbr
```

2. To list loaded modules 3 through 5 in verbose mode, type:

```
map verbose entry 3,5
```

3. To list the loaded module that contains address `0x20001000`, type:

```
map 0x20001000
```

4. To list the loaded module that contains variable `example`, type:

```
map example
```

5. To list the loaded modules in normal mode with TLS data information of the modules for the thread 2, type:

```
map normal for $t2
```

For more information, see the **$mapformat** internal variable. See also, Debugging at the Machine Level with dbx in *General Programming Concepts: Writing and Debugging Programs*.

move Subcommand

move *SourceLine*

The **move** subcommand changes the next line to be displayed to the line specified by the *SourceLine* parameter. This subcommand changes the value of the @ (at sign) variable.

The *SourceLine* variable can be specified as an integer or as a file name string followed by a : (colon) and an integer.

Examples

1. To change the next line to be listed to line 12, enter:

```
move 12
```

2. To change the next line to be listed to line 5 in file `sample.c`, enter:

```
move "sample.c":5
```

See the **list** subcommand. Also, see Displaying the Current File in *General Programming Concepts: Writing and Debugging Programs*.

multproc Subcommand

multproc [**on** | **parent** | **child** | **off**]

The **multproc** subcommand specifies the behavior of the **dbx** debug program when forked and exceed processes are created. The **on** flag is used to specify that a new **dbx** session is created to debug the child path of a fork. The original **dbx** continues to debug the parent path. The **parent** and **child** flags are used to specify a single path of a fork to follow. All flags except **off** enable **dbx** to follow an exceed process. The **off** flag disables multiprocess debugging. If no flags are specified, the **multproc** subcommand returns the status of multiprocess debugging.

The **dbx** program uses the X Window System for multiprocess debugging. The **dbx** program opens as many windows as needed for multiprocessing. The title for each child window is the process ID (pid) of the child process. To switch between processes, use the X Window System handling techniques to activate the window where the **dbx** command session is displayed. If the system does not have the X Window System support, a warning message is issued when the debugger forks, and the **dbx** program continues debugging only the parent process. Multiprocess debugging can also be unsuccessful for the following reasons:

- The **dbx** program is not running in the X Window System environment.
- The X Window System is running but the **dbx** global **$xdisplay** variable is not set to a valid display name. The **$xdisplay** variable is initialized to the shell **DISPLAY** environment variable. The **set** *Name=Expression* **dbx** subcommand can be used to change the value of the display name.
- The **/tmp** directory does not allow read or write access to the debugging program. The **dbx** program requires a small amount of space in this directory when controlling an Xwindow environment.
- The system does not have enough resources to accommodate a new Xwindow.

If **$xdisplay** is set to a remote display, the user might not be able to see the newly created Xwindow. If the **$xdisplay** setting is not correct, the X Window System or other system resources report the cause of the failure.

The **dbx** program does not distinguish between different types of failures, but the following message is sent when the subcommand is not successful:

```
Warning: dbx subcommand multiproc fails. dbx
continued with multproc disabled.
```

The user-defined configuration of the newly created window can be defined under the **dbx_term** application name in the **.Xdefaults** file.

Flags

Item	Description
on	Enables multiprocess debugging.
off	Disables multiprocess debugging.

Examples

1. To check the status of multiprocess debugging, enter:

```
multproc
```

2. To enable multiprocess debugging, enter:

```
multproc on
```

3. To disable multiprocess debugging, enter:

```
multproc off
```

See the **screen** subcommand and the **fork** subroutine. Also, see Debugging Programs Involving Multiple Processes in *General Programming Concepts: Writing and Debugging Programs*.

mutex Subcommand

mutex [**lock** | **unlock** | **thnum** | **utid** | *MutexNumber* ...]

The **mutex** subcommand displays information about mutexes. If the *MutexNumber* parameter is given, the **mutex** subcommand displays information about the specified mutexes. If no flags or parameters are specified, the **mutex** subcommand displays information about all mutexes.

The information listed for each mutex is as follows:

Item	Description
`mutex`	Indicates the symbolic name of the mutex, in the form $m*MutexNumber*.
`type`	Indicates the type of the mutex: `non-rec` (non recursive), `recursi` (recursive) or `fast`.
`obj_addr`	Indicates the memory address of the mutex.
`lock`	Indicates the lock state of the mutex: `yes` if the mutex is locked, `no` if not.
`owner`	If the mutex is locked, indicates the symbolic name of the user thread which holds the mutex.
`blockers`	List the user threads which are blocked on this mutex variable.

Note: The **print** subcommand of the **dbx** debug program recognizes symbolic mutex names, and can be used to display the status of the corresponding object.

Flags

Item	Description
lock	Displays information about locked mutexes.
unlock	Displays information about unlocked mutexes.
thnum	Displays information about all the mutexes held by a particular thread.
utid	Displays information about all the mutexes held by a user thread whose user thread id matches the user thread id.

Examples

1. To display information about all mutexes, enter:

```
mutex
```

2. To display information about all locked mutexes, enter:

   ```
   mutex  lock
   ```

3. To display information about mutexes number four, five and six enter:

   ```
   mutex 4 5 6
   ```

   The output is similar to:

   ```
   mutex   obj_addr         type     lock owner  blockers
   $m4    0x20003274        non-rec   no
   $m5    0x20003280        recursi   no
   $m6    0x2000328a        fast      no
   ```

4. To display information about all the mutexes held by thread 1, enter:

   ```
   mutex thnum 1
   ```

5. To display information about all the mutexes held by a thread whose user thread id is 0x0001, enter:

   ```
   mutex utid 0x0001
   ```

See the **attribute** subcommand, the **condition** subcommand, the **print** subcommand, and the **thread** subcommand.

Also, see. Using Mutexes *General Programming Concepts: Writing and Debugging Programs*.

next Subcommand

next [*Number*]

The **next** subcommand runs the application program up to the next source line. The *Number* parameter specifies the number of times the **next** subcommand runs. If the *Number* parameter is not specified, **next** runs once only.

If you use the **next** subcommand in a multithreaded application program, all the user threads run during the operation, but the program continues execution until the running thread reaches the specified source line. If you want to step the running thread only, use the **set** subcommand to set the variable **$hold_next**. Setting this variable might result in deadlock since the running thread might wait for a lock held by one of the blocked threads.

Examples

1. To continue execution up to the next source line, enter:

   ```
   next
   ```

2. To continue execution up to the third source line following the current source line, enter:

   ```
   next 3
   ```

See the **cont** subcommand, **goto** subcommand, **nexti** subcommand, **set** subcommand, and the **step** subcommand.

nexti Subcommand

nexti [*Number*]

The **nexti** subcommand runs the application program up to the next instruction. The *Number* parameter specifies the number of times the **nexti** subcommand runs. If the *Number* parameter is not specified, **nexti** runs once only.

If you use the **nexti** subcommand in a multithreaded application program, all the user threads run during the operation, but the program continues execution until the running thread reaches the specified machine instruction. If you want to step the running thread only, use the **set** subcommand to set the variable **$hold_next**. Setting this variable might result in deadlock since the running thread might wait for a lock held by one of the blocked threads.

Examples

1. To continue execution up to the next machine instruction, enter:

```
nexti
```

2. To continue execution up to the third machine instruction following the current machine instruction, enter:

```
nexti 3
```

See the **gotoi** subcommand, **next** subcommand, **set** subcommand, and **stepi** subcommand. Also, see Running a Program at the Machine Level in *General Programming Concepts: Writing and Debugging Programs*.

onceblock Subcommand

onceblock [**uninit** | **done**]

The **onceblock** subcommand displays information about blocks of initialization code registered using the **pthread_once** routine. With no arguments, information about all registered once blocks are shown. The optional **uninit** and **done** flags display only the once blocks that either have not, or have already executed, respectively, while supplying a numeric once ID displays information for a single once block.

Note: For the **onceblock** subcommand to work while debugging a live process, the environment variable AIXTHREAD_ONCE_DEBUG must be set equal to ON. Likewise, if debugging a core file, if the variable was not on when the process ran, the **onceblock** subcommand is not able to obtain any information.

Examples

1. To find out if any once blocks are not yet executed, type:

```
onceblock uninit
```

plugin Subcommand

plugin [*Name* [*Command*]]

The **plugin** subcommand passes the command specified by the *Command* parameter to the plug-in specified by the *Name* parameter. If no parameters are specified, the names of all available plug-ins are displayed.

Examples

1. To list all available plug-ins, type:

```
plugin
```

2. To start the subcommand "help" of a plug-in named "sample", type:

```
plugin sample help
```

3. To start the subcommand "`interpret 0x20000688`" of a plug-in named "`xyz`", type:

```
plugin xyz interpret 0x20000688
```

See the **pluginload** subcommand and **pluginunload** subcommand. Also see Developing for the dbx Plug-in Framework in *General Programming Concepts*.

pluginload Subcommand

pluginload *File*

The **pluginload** subcommand loads the plug-in specified by the *File* parameter. The *File* parameter must specify a path to the plug-in.

Note: Because the default **dbx** command is a 64-bit process, you must use the 32-bit version of the **dbx** command, named **dbx32**, to load 32-bit plug-ins.

Examples

To load the plug-in named "`sample`" at "`/home/user/dbx_plugins/libdbx_sample.so`", type:

```
pluginload /home/user/dbx_plugins/libdbx_sample.so
```

See the **plugin** subcommand and **pluginunload** subcommand. Also see Developing for the dbx Plug-in Framework in *General Programming Concepts*.

pluginunload Subcommand

pluginunload *Name*

The **pluginunload** subcommand unloads the plug-in specified by the *Name* parameter.

Examples

To unload the plug-in named "`sample`", type:

```
pluginunload sample
```

See the **plugin** subcommand and **pluginload** subcommand. Also see Developing for the dbx Plug-in Framework in *General Programming Concepts*.

print Subcommand

print *Expression* ...

print *Procedure* ([*Parameters*])

The **print** subcommand does either of the following operations:

- Prints the value of a list of expressions, specified by the *Expression* parameters.
- Executes a procedure, specified by the *Procedure* parameter and prints the return value of that procedure. Parameters that are included are passed to the procedure.

Examples

1. To display the value of x and the value of y shifted left two bits, enter:

   ```
   print x, y << 2
   ```

2. To display the value returned by calling the `sbrk` routine with an argument of 0, enter:

   ```
   print sbrk(0)
   ```

See the **assign** subcommand, the **call** subcommand, and the **set** subcommand.

printbp Subcommand

printbp [*bp1*] [*bp2*] ... | **all**

The **printbp** subcommand instructs the **dbx** command to print the number of times that each of the breakpoints or all the subcommands were run and the details of the limit on the breakpoint, if a limit was set on it.

Examples

1. To instruct the **dbx** command to print the number of times that breakpoint 1 is run and the details of the limit set, enter:

```
printbp 1
```

2. To instruct the **dbx** command to print the number of times that breakpoints 1 and 2 are run and to limit the number of times that breakpoints 1 and 2 can be allowed to run if a limit is set on them, enter:

```
printbp 1, 2
```

3. To instruct the **dbx** command to print the number of times that all breakpoints are run and the details of a limit on any breakpoint, if applicable, enter:

```
printbp all
```

proc Subcommand

proc [**raw**] [**cred** | **cru** | **ru** | **sigflags** | **signal**]

The **proc** subcommand displays information about the process. Usage of the **raw** option causes output to be displayed in raw hex, rather than interpreting values in a more human-readable fashion. Using the **proc** subcommand with no additional arguments outputs general information about the process, as is stored in the user process data structure. The **cred** option displays contents of the `pi_cred` data member, which describes the credentials of the process. The **cru** and **ru** options display data members `pi_cru` and `pi_ru` respectively, which contain resource usage information. The **sigflags** and **signal** options display information relating to the current signal status and registered signal handlers, as contained within the `pi_sigflags` and `pi_signal` data members.

Examples

1. To view resource usage information for the current process (or core file) in raw hex, type:

```
proc raw ru
```

2. To view signal handler information, type:

```
proc signal
```

prompt Subcommand

prompt [**"***String***"**]

The **prompt** subcommand changes the **dbx** command prompt to the string specified by the *String* parameter.

Example

To change the prompt to dbx>, enter:

```
prompt "dbx>"
```

See Defining a New dbx Prompt in *General Programming Concepts: Writing and Debugging Programs*.

quit Subcommand

quit

The **quit** subcommand terminates all processes running in the **dbx** debugging session.

See the **detach** subcommand.

registers Subcommand

registers [ALL | *$t*threadnumber ...] [**>***File*]

The **registers** subcommand displays the values of general-purpose registers, system control registers, floating-point registers, vector registers, and the current instruction register.

- General-purpose registers are denoted by the **$r***Number* variable, where the *Number* parameter indicates the number of the register.

  Note: The register value might be set to the **0xdeadbeef** hexadecimal value. The **0xdeadbeef** hexadecimal value is an initialization value assigned to general-purpose registers at process initialization.
- Floating point registers are denoted by the **$fr***Number* variable. By default, the floating-point registers are not displayed. To display the floating-point registers, use the **unset $noflregs dbx** subcommand.
- Vector registers are denoted by the **$vr*Number*** variable. The `$novregs` internal variable controls whether vector registers are displayed. The `$novregs` variable is set by default, and vector registers are not displayed. When `$novregs` is not set, and vector registers are valid (either debugging a program on a vector capable processor, or analyzing a core file containing vector registers state), then all the vector registers are displayed (vr0–vr31, vrsave, vscr). Vector registers can also be referenced by type. For example, the `$vrNf` (float), `$vrNs` (short), and `$vrNc` (char) vector register variables can be used with the `print` and `assign` subcommands to display and set vector registers by type.
- Vector scalar registers are denoted by the **$vsr*Number*** variable. By default, the vector scalar registers are not displayed. Unset **$novsregs** variable to display the vector scalar registers whenever vector scalar registers are valid (either debugging a program on a vector scalar capable processor, or analyzing a core file containing vector scalar registers state). As vector scalar registers are a superset of legacy floating point registers and vector registers, the debug variable **$novsregs** , when unset, takes precedence over **$noflregs** and **$novsregs** , whenever vector scalar registers state is valid. The **registers** subcommand will then display the vector scalar registers with the legacy register aliases along with it in braces. The floating point register aliases correspond to the low 64-bits only. Vector scalar registers can also be referenced by type as similar to vector registers. For example, the **$vsrNf** (float), **$vsrNs** (short), **$vsrNc** (char), **$vsrNg** (double) and **$vsrNll** (long long) vector scalar register variables can be used with the print and assign subcommands to display and set vector scalar registers by type.
- In the multithreaded environment option ALL displays the register details for all available threads. The register details of individual threads are displayed by specifying the thread number along with registers subcommand. Using the registers subcommand with no options display the registers for the current thread.

Note: The **registers** subcommand cannot display registers if the current thread is in kernel mode.

Flag

Item	Description
>*File*	Redirects output to the specified file.

See the **set** subcommand and the **unset** subcommand. Also, see Using Machine Registers in *General Programming Concepts: Writing and Debugging Programs*.

Example

To display the register details of threads $t1, $t2 and $t3, enter:

```
registers $t1 $t2 $t3
```

See the **set** subcommand and the **unset** subcommand. Also, see Using Machine Registers in *General Programming Concepts: Writing and Debugging Programs*.

rerun Subcommand

rerun [*Arguments*] [**<** *File*] [**>** *File*] [**> >** *File*] [**2>** *File*] [**2> >** *File*] [**>&** *File*] [**> >&** *File*]

The **rerun** subcommand begins execution of the object file. The *Arguments* are passed as command-line arguments. If the *Arguments* parameter is not specified, the arguments from the last **run** or **rerun** subcommand are reused.

Flags

Item	Description
<*File*	Redirects input so that input is received from *File*.
>*File*	Redirects output to *File*.
> >*File*	Appends redirected output to *File*.
2>*File*	Redirects standard error to *File*.
2> >*File*	Appends redirected standard error to *File*.
>&*File*	Redirects output and standard error to *File*.
> >&*File*	Appends output and standard error to *File*.

See the **run** subcommand.

resource Subcommand

resource { **owner** | **waiter** } [**all** | *pthread id*]

The **resource** subcommand displays information about which resources pthreads currently hold or are waiting on. The first argument, which is required, indicates whether you are interested in viewing pthreads that own resources or are waiting for them. The second argument can be used to indicate all pthreads, or a specific one. If none is given, then only information relevant to the current pthread is displayed, if applicable.

Note: The **resource** subcommand is only useful for debugging processes that run with several debugging environmental variables set to ON. These include AIXTHREAD_MUTEX_DEBUG, AIXTHREAD_COND_DEBUG, AIXTHREAD_RWLOCK_DEBUG, AIXTHREAD_READ_OWNER and AIXTHREAD_WAITLIST_DEBUG. If these variables are not turned on while debugging a live process, or were not on when a debugger core file was generated, the **resource** subcommand will be able to retrieve less information or none at all. Because use of these features can degrade performance, it is recommended that they be activated only for debugging purposes.

Examples

1. To ascertain whether the current pthread holds any resources, type:

```
resource owner
```

2. To view which resources any pthreads are waiting on, type:

```
resource waiter all
```

return Subcommand

return [*Procedure*]

The **return** subcommand causes the application program to execute until a return to the procedure specified by the *Procedure* parameter is reached. If the *Procedure* parameter is not specified, execution ceases when the current procedure returns.

Examples

1. To continue execution to the calling routine, enter:

```
return
```

2. To continue execution to the `main` procedure, enter:

```
return main
```

rwlock Subcommand

rwlock [read | write | *RwlockNumber*....]

The **rwlock** subcommand displays information about rwlocks. If the *RwlockNumber* parameter is given, the **rwlock** subcommand displays information about the specified rwlocks. If no flags or parameters are specified, the **rwlock** subcommand displays information about all rwlocks.

The information for each **rwlock** is as follows:

Item	Description
rwl	Indicates the symbolic name of the rwlock, in the form $rw *RwlockNumber*.
flag_value	Indicates the flag value.
owner	Indicates the owner of the rwlock
status	Indicates who is holding the rwlock. The values are read (if held by reader), write (if held by writer), free (if free).
wsleep[#]	Indicates threads blocking in write. # indicates the total number of threads blocking in write.
rsleep[#]	Indicates threads blocking in read. # indicates the total number of threads blocking in read.

Note: The **print** subcommand of the **dbx** debug program recognizes symbolic rwlock names, and can be used to display the status of the corresponding object.

Flags

Item	Description
read	Displays information about all rwlocks whose status is in read mode.
write	Displays information about all rwlocks whose status is in write mode.

Examples

1. To display information about all rwlocks, enter:

   ```
   rwlock
   ```

   The output is similar to:

   ```
   rwl     flag_value    owner status
   $rwl        1         $t1    write
           rsleeps[     0]:
           wsleeps[     0]:
   ```

2. To display information about all rwlocks in write mode:

   ```
   rwlock write
   ```

   The output is similar to:

   ```
   rwl     flag_value    owner status
   $rwl        1         $t1    write
           rsleeps[     0]:
           wsleeps[     0]:
   ```

See the **attribute** subcommand, the **condition** subcommand, **mutex** subcommand, the **print** subcommand, and the **thread** subcommand

run Subcommand

run [*Arguments*] [**<***File*] [**>***File*] [**> >***File*] [**2>***File*] [**2> >***File*] [**>&***File*] [**> >&***File*]

The **run** subcommand starts the object file. The *Arguments* are passed as command-line arguments.

Flags

Item	Description
<*File*	Redirects input so that input is received from *File*.
>*File*	Redirects output to *File*.
2>*File*	Redirects standard error to *File*.
> >*File*	Appends redirected output to *File*.
2> >*File*	Appends redirected standard error to *File*.
>&*File*	Redirects output and standard error to *File*.
> >&*File*	Appends output and standard error to *File*.

Example

To run the application with the arguments `blue` and 12, enter:

```
run blue 12
```

See the **rerun** subcommand.

screen Subcommand

screen

The **screen** subcommand opens an Xwindow for the **dbx** command interaction. You continue to operate in the window in which the process originated.

The **screen** subcommand must be run while the **dbx** debug program is running in the X Window System environment. If the **screen** subcommand is issued in a non-Xwindow environment, the **dbx** program displays a warning message and resumes debugging as if the **screen** subcommand was not given. The **screen** subcommand can also be unsuccessful in the following situations:

- The **dbx** program is not running in the X Window System environment.
- The X Window System is running but the **dbx** global **$xdisplay** variable is not set to a valid display name. The **$xdisplay** variable is initialized to the **DISPLAY** environment variable. The **dbx** subcommand **set** *Name=Expression* changes the value of the display name.
- The X Window System is running, but the **TERM** environment variable is not set to a valid command name to start a new window.
- The **/tmp** directory does not allow read or write access to the program. The **dbx** program requires a small amount of space in this directory when the screen command is executed.
- System does not have enough resources to accommodate a new Xwindow.

The **dbx** program does not distinguish between different types of failures, but the program does send the following message:

```
Warning: dbx subcommand screen fails. dbx
continues.
```

If **$xdisplay** is set to a remote display, you might not be able to see the newly created Xwindow. If the **$xdisplay** setting is not correct, the X Window System or other system resources report the problem.

The user-defined configuration of the newly created window can be defined under the **dbx_term** application name in the **.Xdefaults** file.

Example

To open an Xwindow for **dbx** command interaction, enter:

```
screen
```

set Subcommand

set [*Variable*=*Expression*]

The **set** subcommand defines a value for the **dbx** debug program variable. The value is specified by the *Expression* parameter; the program variable is specified by the *Variable* parameter. The name of the variable must not conflict with names in the program being debugged. A variable is expanded to the corresponding expression within other commands. If the **set** subcommand is used without arguments, the variables currently set are displayed.

Variable	Description
$catchbp	Catches breakpoints during the execution of the next command.
$codepage	Specifies the code set to use for interpreting characters within the program. When specified with a valid code page, all characters are read from the specified code set and converted to the code set in use by the current environment.
$compact_bt_ident	Specifies the limit on the number of characters in the identifier names that can be printed in a stack trace. The specified limit must be positive integers in the range 4 - 128. If this variable is set without specifying any limit value, the default number of characters that can be printed is 8. If the variable is set and the identifier name is four or more characters longer than the specified limit, the **dbx** command prints the specified number of characters of the original identifier name in the stack trace followed by three periods (...). For example, if the identifier name is *variable_example*, which is 16 characters long, and the specified limit is 7, the identifier name is printed as `variabl...`. However, if the identifier name is *variable_1*, which is 10 characters long, and the specified limit is 7, the **dbx** command does not shorten the identifier name to seven characters followed by three periods. It is printed as `variable_1`.
$compact_bt_string	Specifies the limit on the number of characters in the function argument strings that can be printed in a stack trace. The specified limit must be positive integers in the range 4 - 128. If this variable is set without specifying any limit value, the default number of characters that can be printed is 8. If the variable is set and the length of the string is four or more characters longer than the specified limit, the **dbx** command prints the specified number of characters of the original string in the stack trace followed by three periods (...). For example, if the string is *string_example*, which is 14 characters long, and the specified limit is 5, the string is printed as `strin...`. However, if the string is *string_1*, which is 8 characters long, and the specified limit is 5, the **dbx** command does not shorten the string to five characters followed by three periods. It is printed as `string_1`.
$deferevents	Turns on the deferred events feature.
$display_address_name	Displays the member variable identifiers and the memory address that the identifier occupies when examining a set of memory addresses that are using the **dbx** command.
$expandunions	Displays values for each part of variant records or unions.
$frame	Uses the stack frame pointed to by the address designated by the value of **$frame** for doing stack traces and accessing local variables.
$hexchars	Prints characters as hexadecimal values.
$hexin	Interprets addresses in hexadecimal.
$hexints	Prints integers as hexadecimal values.
$hexstrings	Prints character pointers in hexadecimal.
$hold_next	Holds all threads except the running thread during the **cont**, **next**, **nexti**, and **step** subcommands. Setting this variable might result in deadlock since the running thread might wait for a lock held by one of the blocked threads.
$ignoreifhandler	Does not stop when your program receives a signal which has a registered handler.
$ignoreload	Does not stop when your program performs the **load**, **unload**, or **loadbind** subroutine.
$ignorenonbptrap	Does not stop when your program encounters a non-breakpoint trap instruction and has a registered **SIGTRAP** handler.

Variable	Description
$instructionset	Overrides the default disassembly mode. The following list contains possible values for the *Expression* parameter: **"default"** Specifies the architecture on which the **dbx** program is running. **"com"** Specifies the instruction set for the common intersection mode of the PowerPC and POWER family architectures. The **dbx** program defaults to POWER processor-based mnemonics. **"pwr"** Specifies the instruction set and mnemonics for the POWER family architecture. **"pwrx"** Specifies the instruction set and mnemonics for the POWER2 implementation of the POWER family architecture for AIX 5.1 and earlier. **"pwr6"** Specifies the instruction set and mnemonics for the POWER6 implementation of the PowerPC architecture. **"pwr7"** Specifies the instruction set and mnemonics for the POWER7 implementation of the PowerPC architecture. **"pwr8"** Specifies the instruction set and mnemonics for the POWER8 implementation of the PowerPC architecture. **"pwr9"** Specifies the instruction set and mnemonics for the POWER9 implementation of the PowerPC architecture. **"601"** Specifies the instruction set and mnemonics for the PowerPC 601 RISC Microprocessor for AIX 5.1 and earlier. **"603"** Specifies the instruction set and mnemonics for the PowerPC 603 RISC Microprocessor for AIX 5.1 and earlier. **"604"** Specifies the instruction set and mnemonics for the PowerPC 604 RISC Microprocessor. **"970"** Specifies the instruction set and mnemonics for the PowerPC 970 microprocessor. **"ppc"** Specifies the instruction set and mnemonics defined in the POWER processor-based architecture, excluding the optional instructions. These instructions are available in all POWER processor-based implementations except the PowerPC 601 RISC Microprocessor in AIX 5.1 and earlier. **"any"** Specifies any valid POWER processor-based or POWER family instruction. For instruction sets that overlap, the default is the POWER processor-based mnemonics. If no value is set for the *Expression* parameter, the **dbx** program uses the default disassembly mode.
$java	When set, also sets the following variables, placing the **dbx** command in a mode to debug Java applications. When unset, also unsets the following variables: **$ignorenonbptrap** Suppresses notification of trap instructions generated by the Java Just-In-Time (JIT) compiler.
$listwindow	Specifies the number of lines to list around a function and the number to list when the **list** subcommand is used without parameters. The default is 10 lines.
$mapaddrs	Starts mapping addresses. Unsetting **$mapaddrs** stops address mapping.

Variable	Description
$mapformat	Specifies the default output mode for the **map** subcommand. **"abbr"** Specifies the abbreviated output mode, which consists of a single line for each loaded module containing the entry number, module name, and optional member name for that module. **"normal"** Specifies the normal output mode, which consists of the entry number, module name, member name, text origin, text length, data origin, data length, and file descriptor for each loaded module. If the loaded module has TLS data, the TLS data origin and TLS data length are also displayed. **"raw"** Specifies the raw output mode, which consists of a single unformatted line for each module containing the following space-separated fields: entry number, module name with optional member name, text origin, text end, text length, data origin, data end, data length, and file descriptor. If the loaded module has TLS data, the TLS data origin, TLS data end, and TLS data length are also displayed. **"verbose"** Specifies the verbose output mode, which consists of the entry number, module name, member name, text origin, text end, text length, data origin, data end, data length, and file descriptor for each loaded module. If the loaded module has TLS data, the TLS data origin, TLS data end, and TLS data length are also displayed. If no value is set for the *Expression* parameter, the **dbx** program uses the normal output mode.
$mnemonics	Changes the set of mnemonics to be used by the **dbx** program when disassembling. **"default"** Specifies the mnemonics that most closely match the specified instruction set. **"pwr"** Specifies the mnemonics for the POWER family architecture. **"ppc"** Specifies the mnemonics defined in the POWER processor-based architecture book, excluding the optional instructions. If no value is set for the *Expression* parameter, the **dbx** program uses the mnemonics that most closely match the specified instruction set.
$noargs	Omits arguments from subcommands, such as *where*, *up*, *down*, and *dump*.
$noflregs	Omits the display of floating-point registers from the **registers** subcommand.
$novregs	Omits the display of vector registers from the **registers** subcommand.
$novsregs	Omits the display of vector scalar registers from the **registers** subcommand
$octint	Interprets addresses in octal.
$octints	Prints integers in octal.
$pretty	Displays complex C and C++ data structure (struts, unions, arrays) values in a *pretty printed* format with the **print** subcommand. **"on"** Specifies pretty printing with each value on its own line and with indentation to represent the static scope of each value. **"verbose"** Specifies pretty printing with each value on its own line and with qualified names to represent the static scope of each value. A qualified name consists of a dot-separated list of the outer blocks with which the value is associated. **"off"** Specifies pretty printing off. This value is the default.
$print_dynamic	Displays the dynamic type of the C++ objects with print / dump command. By default this variable is not set.
$repeat	Repeats the previous command if no command was entered.
$sigblock	Blocks signals to your program.
$show_vft	Displays Virtual Function Table while printing C++ objects with print / dump command. By default it is not set.
$stack_details	Displays the frame number and the register set for each active function or procedure displayed by the where subcommand.

Variable	Description
$stepignore	Controls how the **dbx** command behaves when the **step**/tstep subcommand runs on a source line that calls another routine for which no debugging information is available. This variable enables the **step**/tstep subcommand to step over large routines for which no debugging information is available. The following list contains possible values for the *Expression* parameter: **"function"** Performs the function of the **next**/tnext subcommand for the **dbx** command. This value is the default value. **"module"** Performs the function of the **next**/tnext subcommand if the function is in a load module for which no debug information is available (such as a system library). **"none"** Performs the function of the **stepi**/tstepi subcommand for the **dbx** command in the background until it reaches an instruction for which source information is available. At that point **dbx** displays where execution stopped.
$trace_good_transaction	Instructs the **dbx** command to display the following message every time a transactional memory (TM) transaction is completed successfully. `Process {PID} may have performed a transaction - $texasr, $tfiar, $tfhar are valid and may be inspected` Successful transactions are not reported because this variable is disabled by default.
$thcomp	When **$thcomp** is set, the information displayed by the thread command **th-** is shown in a compressed format.
$unsafeassign	Turns off strict type checking between the two sides of an **assign** statement. Even if the **$unsafeassign** variable is set, the two sides of an **assign** statement might not contain storage types of different sizes.
$unsafebounds	Turns off subscript checking on arrays.
$unsafecall	Turns off strict type checking for arguments to subroutines or function calls.
$unsafegoto	Turns off the **goto** subcommand destination checking.
$vardim	Specifies the dimension length to use when printing arrays with unknown bounds. The default value is 10.
$xdisplay	Specifies the display name for the X Window System, for use with the **multproc** subcommand or the **screen** subcommand. The default is the value of the shell **DISPLAY** variable.

The **$unsafe** variables limit the usefulness of the **dbx** debug program in detecting errors.

Examples

1. To change the default number of lines to be listed to 20, enter:

```
set $listwindow=20
```

2. To disable type checking on the assign subcommand, enter:

```
set $unsafeassign
```

3. To disassemble machine instructions for the POWER7 processor, enter:

```
set $instructionset="pwr7"
```

4. To display strings encoded in the IBM-eucCN code set, enter:

```
set $codepage="IBM-eucCN"
```

5. To specify a limit of four characters in the identifiers and a limit of twelve characters in the strings that are displayed in a stack trace, enter the following command:

```
set $compact_bt_ident=6
set $compact_bt_string=12
```

The stack trace that uses identifiers such as long_identifier, long_variable_name_str, and recursive_fun, and string such as this_is_a_really_long_string looks similar to the following output:

```
long_i...(a = 11, long_v... = "this_is_a_re..."), line 3 in "example.c"
recurs...(), line 13 in "example.c"
```

See the **unset** subcommand. Also, see Changing Print Output with Special Debug Program Variables in *General Programming Concepts: Writing and Debugging Programs*.

set edit [vi, emacs] or set -o [vi, emacs] Subcommand

The **set** subcommand with the **-o** or **edit** option might be used to turn on one of the line edit modes. If the **set-o vi** or **set edit vi** command is given, you are placed in the input mode of the *vi* line editor. If the **set -o emacs** or **set edit emacs** command is given, you are placed in the input mode of the *emacs* line editor.

Example

1. To turn on the vi line editor, enter:

   ```
   set-o vi
   ```

   or

   ```
   set edit vi
   ```

sh Subcommand

sh [*Command*]

The **sh** subcommand passes the command specified by the *Command* parameter to the shell for execution. The **SHELL** environment variable determines which shell is used. The default is the **sh** shell. If no argument is specified, control is transferred to the shell.

Examples

1. To run the `ls` command, enter:

   ```
   sh ls
   ```

2. To escape to a shell, enter:

   ```
   sh
   ```

3. To use the SHELL environment variable, enter:

   ```
   sh echo $SHELL
   ```

See Running Shell Commands from dbx in *General Programming Concepts: Writing and Debugging Programs*.

skip Subcommand

skip [*Number*]

The **skip** subcommand continues execution of the application program from the current stopping point. A number of breakpoints equal to the value of the *Number* parameter are skipped and execution then ceases when the next breakpoint is reached or when the program finishes. If the *Number* parameter is not specified, it defaults to a value of one.

Example

To continue execution until the second breakpoint is encountered, enter:

```
skip 1
```

Also see the **cont** subcommand.

source Subcommand

source *File*

The **source** subcommand reads **dbx** subcommands from the file specified by the *File* parameter.

Example

To read the **dbx** subcommands in the `cmdfile` file, enter:

```
source cmdfile
```

See Reading dbx Subcommands from a File in *General Programming Concepts: Writing and Debugging Programs*.

status Subcommand

status [more] [**>***File*]

The **status** subcommand displays all user-defined breakpoints, tracepoints, and watchpoints, in addition to the remaining thread `tskip` counts (set by using the `tskip` subcommand). If the more parameter is specified, the **status** subcommand also displays the **dbx** subcommands associated with the breakpoints, tracepoints, and watchpoints. The **status** subcommand lists enabled events with square brackets ([]) surrounding the event number, disabled events with periods (..) surrounding the event number, and deferred events with angle brackets (<>) surrounding the event number.

The > flag sends the output of the **status** subcommand to a file specified in the *File* parameter.

Flag

Item	Description
>*File*	Redirects output to *File*.

Examples

1. To display all user-defined breakpoints, tracepoints, and watchpoints, as well as the remaining thread `tskip` counts, type:

   ```
   status
   ```

   The output is similar to:

   ```
   [1] stop at 13
   [2] stop at 14
   .3. stop at 15
   .4. stop at 16
   [5] stop at 17 ( count = 0, limit = 3 )
   <6> stop at 18 if g > 10
   <7> stop in func

   Remaining tskip counts:
   tskip 2 for $t1
   tskip 1 for $t5
   ```

   In the example output, events 3 and 4 are disabled, and events 6 and 7 are deferred.

2. To display all user-defined breakpoints, tracepoints, and watchpoints with associated **dbx** subcommands, enter:

   ```
   status more
   ```

   The output is similar to:

   ```
          [1] stop at 13
              [1] where
          .2. stop at 14
              [1] where
              [2] registers
   ```

```
        <3> stop at 15 if g > 10
            [1] where; registers
```

See the addcmd subcommand, the **clear** subcommand, the **delete** subcommand, the delcmd subcommand, the tskip subcommand, the **stop** subcommand, and the **trace** subcommand for the **dbx** command.

Also, see Setting and Deleting Breakpoints in *General Programming Concepts: Writing and Debugging Programs*.

step Subcommand

step [*Number*]

The **step** subcommand runs source lines of the application program. Specify the number of lines to be executed with the *Number* parameter. If the *Number* parameter is omitted, it defaults to a value of 1.

If you use the **step** subcommand on a multithreaded application program, all the user threads run during the operation, but the program continues execution until the running thread reaches the specified source line. If you want to step the running thread only, use the **set** subcommand to set the variable **$hold_next**. Setting this variable might result in deadlock since the running thread might wait for a lock held by one of the blocked threads.

Note: Use the **$stepignore** variable of the **set** subcommand to control the behavior of the **step** subcommand. The **$stepignore** variable enables the **step** subcommand to step over large routines for which no debugging information is available.

Examples

1. To continue execution for one source line, enter:

   ```
   step
   ```

2. To continue execution for five source lines, enter:

   ```
   step 5
   ```

3. To prevent the **dbx** program from single-stepping the **printf** function, as illustrated in the following example code:

   ```
   60 printf ("hello world \n");
   ```

   enter:

   ```
   set $stepignore="function"; step
   ```

See the **cont** subcommand, the **goto** subcommand, the **next** subcommand, the **set** subcommand, and the **stepi** subcommand.

stepi Subcommand

stepi [*Number*]

The **stepi** subcommand runs instructions of the application program. Specify the number of instructions to be executed in the *Number* parameter. If the *Number* parameter is omitted, it defaults to one.

If used on a multithreaded application program, the **stepi** subcommand steps the running thread only. All other user threads remain stopped.

Examples

1. To continue execution for one machine instruction, enter:

```
stepi
```

2. To continue execution for 5 machine instructions, enter:

```
stepi 5
```

See the **gotoi** subcommand, the **nexti** subcommand, and the **step** subcommand.

stop Subcommand

stop { [*Variable*] [**at** *SourceLine* | **in** *Procedure* | **on load** ["*ModuleName*"]] [**if** *Condition*]} ["{ "*Limit*" }"]

The **stop** subcommand halts the application program when certain conditions are fulfilled. The program is stopped when:

- The *Condition* is true when the **if** *Condition* flag is used.
- The *Procedure* is called if the **in** *Procedure* flag is used.
- The *Variable* is changed if the *Variable* parameter is specified.
- The *SourceLine* line number is reached if the **at** *SourceLine* flag is used.

  The *SourceLine* variable can be specified as an integer or as a file name string followed by a : (colon) and an integer.
- The *ModuleName* loaded module is loaded or unloaded if the **on load** flag is used and the *ModuleName* parameter is specified.

  The optional *ModuleName* variable can be specified as a single module name, or as a module name paired with a member name in the format:

  ```
  ModuleName(MemberName)
  ```
- Any loaded module is loaded or unloaded if the **on load** flag is used and the *ModuleName* parameter is not specified.

You can set the *Limit* parameter to instruct the **dbx** command to ignore a condition for a specified number of times. In other words, the *Limit* parameter specifies the number of times that the specified condition must be fulfilled before the debug program execution is stopped.

After any of these commands, the **dbx** debug program responds with a message reporting the event it built as a result of your command. The message includes the event ID associated with your breakpoint along with an interpretation of your command. The syntax of the interpretation might not be the same as your command. For example:

```
stop in main
[1] stop in main
stop at 19 if x == 3
[2] stop at "hello.c":19 if x = 3
stop in func
<3> stop in func
stop g
<4> stop g
stop in getdata {3}
[5] stop in getdata ( count = 0, limit = 3 )
```

The numbers in square brackets ([]) are the event identifiers associated with the breakpoints. The **dbx** debug program associates event numbers with each **stop** subcommand. When the program is halted as the result of one of the events, the event identifier is displayed along with the current line to show which event caused the program to stop. The numbers in angle brackets (<>) are the event identifiers for the deferred events. A deferred event is an event without having any breakpoint, tracepoint, or watchpoint associated with it, and is created whenever the input command involves the symbols that are not currently loaded in the memory. A normal event displayed in square brackets ([]) is also converted into a deferred event whenever the corresponding module is unloaded. Whenever the module corresponding to the deferred event is loaded into the memory, the deferred event is converted into the normal event, and

the corresponding breakpoint, tracepoint, or watchpoint is created. The events that you create coexist with internal events that are created by the **dbx** command, so the event numbers might not always be sequential.

A limit can be associated with an event after its creation by using the **limitbp** subcommand. To view the limit associated with an event, the **printbp** subcommand can be used.

Use the **status** subcommand to view these numbers. You can redirect output from **status** to a file. Use the **delete** or **clear** subcommand to turn the **stop** subcommand off, or use the **enable** or **disable** subcommands. Use the **addcmd** subcommand to add **dbx** subcommands to the specified event number and the **delcmd** subcommand to delete the associated **dbx** subcommands from the specified event number.

In a multithreaded application program, all user threads are halted when any user thread hits a breakpoint. A breakpoint set on a source line or function is hit by any user thread which executes the line or function, unless you specify conditions (as in example 9). The following aliases specify the conditions automatically:

- **bfth**(*Function*, *ThreadNumber*)
- **blth**(*SourceLine*, *ThreadNumber*)

ThreadNumber is the number part of the symbolic thread name as reported by the **thread** subcommand (for example, 5 is the *ThreadNumber* for the thread name $t5). These aliases are actually macros which produce the expanded subcommands shown in the following example:

```
stopi at &Function if ($running_thread == ThreadNumber)
stop at SourceLine if ($running_thread == ThreadNumber)
```

Flags

Item	Description
at *SourceLine*	Specifies the line number.
if *Condition*	Specifies the condition, such as true.
in *Procedure*	Specifies the procedure to be called.
on load *ModuleName*	Specifies the loaded module to be monitored.

Examples

1. To stop execution at the first statement in the `main` procedure, enter:

   ```
   stop in main
   ```

2. To stop execution when the value of the x variable is changed on line 12 of the execution, enter:

   ```
   stop x at 12
   ```

3. To stop execution at line 5 in file `sample.c`, enter:

   ```
   stop at "sample.c":5
   ```

4. To check the value of x each time that the **dbx** command runs a subroutine within `func1`, enter:

   ```
   stop in func1 if x = 22
   ```

5. To check the value of x each time that the **dbx** command begins to run `func1`, enter:

   ```
   stopi at &func1 if x = 22
   ```

6. To stop the program when the value of *Variable* changes, enter:

   ```
   stop Variable
   ```

7. To stop the program whenever *Condition* evaluates to true, enter:

```
stop if (x > y) and (x < 2000)
```

8. The following example shows how to display active events and remove them:

```
status
[1] stop in main
[2] stop at "hello.c":19 if x = 3
delete 1
status
[2] stop at "hello.c":19 if x = 3
clear 19
status
(dbx)
```

   The **delete** command eliminates events by event identifier. The **clear** command deletes breakpoints by line number.

9. To place a breakpoint at the start of `func1` only when executed by thread `$t5`, enter one of the following equivalent commands:

```
stopi at &func1 if ($running_thread == 5)
```

   or

```
bfth(func1, 5)
```

10. To stop the program when any module is loaded or unloaded, enter:

```
stop on load
```

11. To stop the program whenever module `Module` is loaded or unloaded, enter:

```
stop on load "Module"
```

12. To stop the program whenever member `Member` of module `Module` is loaded or unloaded, enter:

```
stop on load "Module(Member)"
```

13. To stop the program in a function `getdata` when it is called the third time, enter:

```
stop in getdata {3}
```

See the addcmd subcommand, the **clear** subcommand, the **delete** subcommand, the delcmd subcommand, **disable** subcommand, **enable** subcommand, the **limitbp** subcommand, the **printbp** subcommand, the **status** subcommand, the **stopi** subcommand, and the **trace** subcommand. Also, see Setting and Deleting Breakpoints in *General Programming Concepts: Writing and Debugging Programs*.

stophwp Subcommand

stophwp *Address Size*

The **stophwp** subcommand sets a hardware watchpoint stop for the specified memory region. The program stops when the contents of the region change.

Notes:

1. The success of the **stophwp** subcommand is hardware dependent. This feature is available only on POWER630 and POWER4 onwards.
2. As a result of the hardware limitation of being able to set only a single watchpoint, an active watchpoint event acts as a conflict when attempting to create another hardware watchpoint event with **stophwp** and **tracehwp**. As such, the previous event must be deleted before creating a new one. Also, since the existence of an active software watchpoint (created by some invocations of the **stop** and **trace** subcommands) negate the performance gains of hardware watchpoints, these types of events also act as conflicts which must be deleted before creating a hardware watchpoint.

Example

1. To stop the program when the contents of the 4 byte memory region starting at address 0x200004e8 change, enter:

```
stophwp 0x200004e8 4
```

See the **tracehwp** subcommand.

stopi Subcommand

stopi { [*Address*] [**at** *Address* | **in** *Procedure*] [**if** *Condition*]}

The **stopi** subcommand sets a stop at the specified location:

- With the **if** *Condition* flag, the program stops when the condition true is specified.
- With the *Address* parameter, the program stops when the contents of *Address* change.
- With the **at** *Address* flag, a stop is set at the specified address.
- With the **in** *Procedure* flag, the program stops when the *Procedure* is called.

Flags

Item	Description
if *Condition*	Specifies the condition, such as true.
in *Procedure*	Specifies the procedure to be called.
at *Address*	Specifies the machine instruction address.

Examples

1. To stop execution at address `0x100020f0`, enter:

```
stopi at 0x100020f0
```

2. To stop execution when the contents of address `0x100020f0` change, enter:

```
stopi 0x100020f0
```

3. To stop execution when the contents of address 0x100020f0 are changed by thread `$t1`, enter:

```
stopi 0x200020f0 if ($running_thread == 1)
```

See the **stop** subcommand. Also, see Debugging at the Machine Level with dbx in *General Programming Concepts: Writing and Debugging Programs*.

thdata Subcommand

thdata [*$tthreadnumber* [all | *key1* ...] ...] | [all]

The **thdata** subcommand prints the thread-specific data that is associated with different keys, which are created by using the **pthread_key_create()** function. You can use the **thdata** subcommand in the following ways.

Command	Action
thdata [all]	Prints the thread-specific data that is associated with all the keys for all the available threads.
thdata $t1 [all]	Prints the thread-specific data that is associated with all the keys for the *$t1* thread.

Command	Action
thdata $t1 key1 key2	Prints the thread-specific data that is associated with the keys *key1* and *key2* for the *$t1* thread.
thdata $t1 key1 key2 $t2 key1	Prints the thread-specific data that is associated with the keys *key1* and *key2* for the *$t1* thread, and the thread-specific data that is associated with the key *key1* for the *$t2* thread.

Examples

1. To print the data associated to the current thread with all the available keys, enter:

```
(dbx) thdata $t1
Thread  :  1
    Key : 1 Data pointer : 0x200f7a28
    Key : 2  Data pointer : 0x200f7aa8
    Key : 3 Data pointer : 0x200f7ac4
(dbx)
```

2. To print the data associated to multiple threads and multiple keys, enter:

```
(dbx) thdata $t1 2 3 $t2
Thread  :  1
    Key : 2  Data pointer : 0x200f7aa8
    Key : 3 Data pointer : 0x200f7ac4
Thread : 2
    Key : 2  Data pointer : 0x200f7b24
    Key : 3 Data pointer : 0x200f7ba4
(dbx)
```

See Thread-Specific Data in General Programming Concepts: Writing and Debugging Programs

thread Subcommand

Display Selected Threads

thread { [**info**] [**-**] [*ThreadNumber* ...] } | **current** | **run** | **susp** | **term** | **wait**

Select an Individual Thread

thread current [-] *ThreadNumber*

Hold or Release Threads

thread { **hold** | **unhold** } [-] [*ThreadNumber* ...]

Help for the options displayed

thread { **help**}

The **thread** subcommand displays and controls user threads.

The first form of the **thread** subcommand can display information in two formats. If the **thread** subcommand is **th**, then the information displayed is in the first format. If the **thread** subcommand is **th -**, then the information displayed is in the second format. If no parameters are given, information about all user threads is displayed. If one or more *ThreadNumber* parameters are given, information about the corresponding user threads is displayed. When the **thread** subcommand displays threads, the current thread line is preceded by a **>**. If the running thread is not the same as the current thread, its line is preceded by a *****. The information displayed by the **thread** subcommand in both the formats is described below.

The information displayed by the **thread** subcommand in the first format is as follows:

Item	Description
`thread`	Indicates the symbolic name of the user thread, in the form `$t`*ThreadNumber*.

Item	Description
state-k	Indicates the state of the kernel thread (if the user thread is attached to a kernel thread). This can be run, wait, susp, or term, for running, waiting, suspended, or terminated.
wchan	Indicates the event on which the kernel thread is waiting or sleeping (if the user thread is attached to a kernel thread).
state-u	Indicates the state of the user thread. Possible states are running, blocked, or terminated.
k-tid	Indicates the kernel thread identifier (if the user thread is attached to a kernel thread).
mode	Indicates the mode (kernel or user) in which the user thread is stopped (if the user thread is attached to a kernel thread).
held	Indicates whether the user thread has been held.
scope	Indicates the contention scope of the user thread; this can be sys or pro for system or process contention scope.
function	Indicates the name of the user thread function.

The information displayed by the **thread** subcommand in the second format is given below. By default, for the **thread** subcommand **th -**, the information is displayed in the long form.

Item	Description
thread	Indicates the symbolic name of the user thread, in the form $t*ThreadNumber*.

Kernel thread-related information

Item	Description
tid	Indicates the user thread identifier (if the user thread is attached to a kernel thread).
pri	Indicates the priority of the kernel thread.
sched	Indicates the scheduling policy of the kernel thread. This value can be fif, oth, rr, for fifo, other, or round robin scheduling policies.
state	Indicates the state of the kernel thread (if the user thread is attached to a kernel thread). This value can be run, wait, susp, or zomb, for running, waiting, suspended, or zombie.

User thread-related information

Item	Description
tid	Indicates the user thread identifier.
pri	Indicates the priority of the userl thread.
sched	Indicates the scheduling policy of the user thread. This value can be fif, oth, rr, for fifo, other, or round-robin scheduling policies.
state	Indicates the state of the user thread. This value can be running, creating, suspended, blocked, runnable, or terminated.
state	Indicates the user state in hex.
flags	Indicates the values for pthread flags in hex.
wchan	Indicates the event on which the kernel thread is waiting or sleeping (if the user thread is attached to a kernel thread).
mode	Indicates the mode (kernel or user) in which the user thread is stopped (if the user thread is attached to a kernel thread).
held	Indicates whether the user thread is held.

Item	Description
scope	Indicates the contention scope of the user thread; this value can be sys or pro for system or process contention scope.
cancelation	**pending** Indicates whether cancelation is pending or not. **state** Indicates the mode and state of cancelation. If the cancelation is not pending and the state and mode are enabled and deferred respectively, then it is represented by **ed**, if cancelation state and mode is enabled and asynchronous, then it is represented by **ea**, and if mode is not enabled, then it is represented by **d**. If the cancelation is pending and the cancelation state and mode is enabled and deferred respectively, then it is represented by **ED**, if cancelation state and mode is enabled and asynchronous, then it is represented by **EA**, and if mode is not enabled, then it is represented by **D**.

Item	Description
joinable	Indicates whether the thread can be joined or not.
boosted	Indicates the boosted value of the thread.
function	Indicates the name of the user thread function.
cursig	Indicates the current signal value.

If the option set $thcomp is set, then the information is displayed in the compressed form as shown in the following example.

```
m           mode           (k)ernel (u)ser
k           k-state        (r)unning (w)aiting (s)uspended (z)ombie
u           u-state        (r)unning (R)unnable (s)uspended (t)erminated

                           (b)locked (c)reating
h           held           (yes) (n)o
s           scope          (s)ystem (p)rocess
c           cancellation   not pending:  (e)nabled & (d)eferred,
                                         (e)nabled & (a)sync, (d)isabled
                           pending    :  (E)nabled & (D)eferred,
                                         (E)nabled & (A)sync, (D)isabled
j           joinable       (yes) (n)o
b           boosted        value of boosted field in pthread structure
plk         kernel thread  (oth)er  (fif)o  (rr)-> round-robin
            policy
plu         user thread    (oth)er  (fif)o  (rr)-> round-robin
            policy
prk         kernel thread  hex number
            policy
pru         user thread    hex number
            policy
k-tid                      kernel thread id in hex
u-tid                      pthread id in hex
fl                         value of flags field in pthread structure in hex
sta                        value of state field in pthread structure in hex
cs                         value of the current signal
wchan                      event for which thread is waiting
function                   function name
```

The second form of the **thread** subcommand is used to select the current thread. The **print**, **registers**, and **where** subcommands of the **dbx** debug program all work in the context of the current thread. The **registers** subcommand cannot display registers if the current thread is in kernel mode.

The third form of the **thread** subcommand is used to control thread execution. Threads can be held using the **hold** flag, or released using the **unhold** flag. A held thread is not resumed until it is released.

Note: The **print** subcommand of the **dbx** debug program recognizes symbolic thread names, and can be used to display the status of the corresponding object.

Flags

Item	Description
current	If the *ThreadNumber* parameter is not given, displays the current thread. If the *ThreadNumber* parameter is given, selects the specified user thread as the current thread.
help	Displays all the information about the thread options that are shown when **th -** command is used.
hold	If the *ThreadNumber* parameter is not given, holds and displays all user threads. If one or more *ThreadNumber* parameters are given, holds and displays the specified user threads.
unhold	If the *ThreadNumber* parameter is not given, releases and displays all previously held user threads. If one or more *ThreadNumber* parameters are given, releases and displays the specified user threads.
info	If the *ThreadNumber* parameter is not given, displays a long format listing of all user threads. If one or more *ThreadNumber* parameters are given, displays a long format listing the specified user threads. All the previous flags take [-] option. If this option is given, then the thread information displayed is in the second format and in the long form unless the `set $thcomp` option is set.
run	Displays threads which are in the `run` state.
susp	Displays threads which are in the `susp` state.
term	Displays threads which are in the `term` state.
wait	Displays threads which are in the `wait` state.

Examples

1. To display information about threads that are in the wait state, enter:

   ```
   thread  wait
   ```

   The output is similar to:

   ```
   thread  state-k   wchan state-u   k-tid mode held scope function
    $t1     wait            running   17381   u   no   pro  main
    $t3     wait            running    8169   u   no   pro  iothread
   ```

2. To display information about several given threads, enter:

   ```
   thread 1 3 4
   ```

   The output is similar to:

   ```
   thread  state-k   wchan state-u   k-tid mode held scope function
    $t1     wait            running   17381   u   no   pro  main
    $t3     wait            running    8169   u   no   pro  iothread
   >$t4     run             running    9669   u   no   pro  save_thr
   ```

3. To make thread 4 the current thread, enter:

   ```
   thread  current 4
   ```

4. To hold thread number 2, enter:

   ```
   thread  hold 2
   ```

5. To display information about threads that are in the wait state, in the second format, enter:

```
thread wait -
```

The output is similar to:

```
thread m k u h s c  j b  kpl  upl  kpr upr k_tid   u_tid   fl  sta wchan  function
*$t1   u r w n p ed y 0  oth  oth  61   1  0043e5  000001  51  004        main
 $t3   u r w n p ed y 0  oth  oth  61   1  001fe9  000102  51  004        iothread
>$t4   u r r n p ed y 0  oth  oth  61   1  0025c5  000203  50  064        save_thr
```

6. To display information about several given threads in the second format, enter:

```
thread - 1 2 3
```

The output is similar to:

```
thread m k u h s c  j b  kpl  upl  kpr upr k_tid   u_tid   fl  sta wchan function
*$t1   u r w n p ed y 0  oth  oth  61   1  0043e5  000001  51  004       main
 $t3   u r w n p ed y 0  oth  oth  61   1  00fe9   000102  51  004       iothread
>$t4   u r r n p ed y 0  oth  oth  61   1  0025c5  000203  50  064       save_thr
```

See the **attribute** subcommand, the **condition** subcommand, the **mutex** subcommand, the **print** subcommand, the **registers** subcommand, and the **where** subcommand.

Also, see Creating Threads in *General Programming Concepts: Writing and Debugging Programs*.

tls Subcommand

tls map

The **tls** subcommand takes only one flag that it uses to display the TLS initialization template origin and length for each loaded TLS module.

tm_status Subcommand

```
tm_status
```

The **tm_status** subcommand displays the contents of the *$texasr* variable (transaction exception and summary register) and interprets the contents to determine the cause and nature of a transaction failure.

Example

To display and interpret the values that are stored in the *$texasr* variable, enter the following command:

```
(dbx) tm_status
```

An output that is similar to the following example is displayed:

```
REGISTER : TEXASR = 0x100000018C000001
Bit(s)   |Field                    |Meaning
_____________________________________________________________________________
0-7      Failure Code               TM_SIG_DELIVERED | Failed due to signal delivery
7        Failure Persistent         Failure is transient
31       Abort                      Execution of TM instruction caused Abort
32       Suspended                  Failure while in Suspended State
34-35    Privilege                  During Failure process-thread privilege state was 0
36       Failure                    Summary Failure recording has been performed
37       TFIAR (in)exact            TFIAR is exact
38       Rollback Only Transaction  non-ROT tbegin. initiated
52-63    Transaction Level          1
```

tnext Subcommand

tnext [*Number*]

The **tnext** subcommand runs the running thread up to the next source line. The *Number* parameter specifies the number of times the `tnext` subcommand runs. If the *Number* parameter is not specified, `tnext` runs once only. This subcommand can be started only on system-scope threads.

All the threads are run during this operation. To catch breakpoints during this operation, set the `$catchbp` **dbx** variable. If the `$catchbp` variable is set and a breakpoint is reached for another thread, the `tnext` subcommand is not repeated for the remaining number of times.

Examples

1. To continue execution of the running thread up to the next source line, enter:

```
tnext
```

2. To continue execution of the running thread up to the third source line following the current source line, enter:

```
tnext 3
```

See the **tnexti** subcommand. Also, see Debugging Programs Involving Multiple Threads in *General Programming Concepts: Writing and Debugging Programs*.

tnexti Subcommand

tnexti [*Number*]

The **tnexti** subcommand runs the running thread up to the next instruction. The *Number* parameter specifies the number of times the `tnexti` subcommand runs. If the *Number* parameter is not specified, `tnexti` runs once only. This subcommand can be started only on system-scope threads.

All the threads are run during this operation. To catch breakpoints during this operation, set the `$catchbp` **dbx** variable. If the `$catchbp` variable is set and a breakpoint is reached for another thread, the `tnexti` subcommand is not repeated for the remaining number of times.

Examples

1. To continue execution of the running thread up to the next machine instruction, enter:

```
tnexti
```

2. To continue execution of the running thread up to the third machine instruction following the current machine instruction, enter:

```
tnexti 3
```

See the **tnext** subcommand. Also, see Debugging Programs Involving Multiple Threads in *General Programming Concepts: Writing and Debugging Programs*.

trace Subcommand

trace [*SourceLine* | *Expression* **at** *SourceLine* | *Procedure* | [*Variable*] [**at** *SourceLine* | **in** *Procedure*] | **on load** *ModuleName*] [**if** *Condition*]

The **trace** subcommand prints tracing information for the specified procedure, function, source line, expression, or variable when the program runs. The *SourceLine* variable can be specified as an integer or as a file name string followed by a : (colon) and an integer. A condition can be specified. The **dbx** debug program associates a number with each **trace** subcommand. Use the **status** subcommand to view these numbers. Use the **delete** subcommand to turn tracing off. You can enable and disable traces using the **enable** and **disable** subcommands, respectively.

The **trace** subcommand can display tracing information when modules are loaded or unloaded by the debugged process. The optional *ModuleName* parameter can be specified as a single module name, or as a module name paired with a member name in the format:

```
ModuleName(MemberName)
```

If the **on load** flag is used without the *ModuleName* parameter, the **dbx** command traces the load and unload of all modules.

By default, tracing is process-based. To make a thread-based trace, specify the thread in a condition (as in example 8).

Flags

Item	Description
at *SourceLine*	Specifies the source line where the expression being traced is found.
if *Condition*	Specifies a condition for the beginning of the trace. The trace begins only **if** *Condition* is true.
in *Procedure*	Specifies the procedure to use to find the procedure or variable being traced.
on load *ModuleName*	Specifies the load module to be monitored.

Examples

1. To trace each call to the `printf` procedure, enter:

   ```
   trace printf
   ```

2. To trace each execution of line 22 in the `hello.c` file, enter:

   ```
   trace "hello.c":22
   ```

3. To trace changes to the *x* variable within the `main` procedure, enter:

   ```
   trace x in main
   ```

4. To trace the data address `0x2004000`, enter:

   ```
   set $A=0x2004000
   trace $A
   ```

   Note: The **tracei** subcommand is designed to trace addresses.

5. You can restrict the printing of source lines to when the specified *Procedure* is active. You can also specify an optional *Condition* to control when trace information must be produced. For example:

   ```
   (dbx) trace in sub2
   [1] trace in sub2
   (dbx) run
   trace in hellosub.c:  8  printf("%s",s);
   trace in hellosub.c:  9  i = '5';
   trace in hellosub.c:  10  }
   ```

6. You can display a message each time a procedure is called or returned. When a procedure is called, the information includes passed parameters and the name of the calling routine. On a return, the information includes the return value from *Procedure*. For example:

   ```
   (dbx) trace sub
   [1] trace sub
   (dbx) run
   calling sub(s = "hello", a = -1, k = delete) from function main
   returning "hello" from sub
   ```

7. You can print the value of *Expression* when the program reaches the specified source line. The lines number and file are printed, but the source line is not. For example:

```
(dbx) trace x*17 at "hellosub.c":8 if (x > 0)
[1] trace x*17 at "hellosub.c":8 if x > 0
(dbx) run
at line 8 in file "hellosub.c": x*17 = 51

(dbx) trace x
[1] trace x
initially (at line 4 in "hello.c"):  x = 0
after line 17 in "hello.c":  x = 3
```

8. To trace changes to the *x* variable that are made by thread `$t1`, enter the following command:

```
(dbx) trace x if ($running_thread == 1)
```

9. To trace the load or unload of all modules, enter the following command:

```
trace on load
```

10. To trace the load or unload of module `Module`, enter the following command:

```
trace on load "Module"
```

11. To trace the load or unload of member `Member` in module `Module`, enter the following command:

```
trace on load "Module(Member)"
```

Also, see the **tracei** subcommand.

tracehwp Subcommand

tracehwp *Address Size*

The **tracehwp** subcommand sets a hardware watchpoint stop for the specified memory region. The **dbx** debug program prints tracing information when the contents of the region change.

Notes:

1. The success of the **tracehwp** subcommand is hardware dependent. This feature is available only on POWER630 and POWER4 onwards.
2. As a result of the hardware limitation of being able to set only a single watchpoint, an active watchpoint event acts as a conflict when attempting to create another hardware watchpoint event with **stophwp** and **tracehwp**. As such, the previous event must be deleted before creating a new one. Also, since the existence of an active software watchpoint (created by some invocations of the **stop** and **trace** subcommands) negate the performance gains of hardware watchpoints, these types of events also act as conflicts which must be deleted before creating a hardware watchpoint.

Examples

1. To trace each time the contents of the 4 byte memory region starting at address `0x200004e8` change, enter the following command:

```
tracehwp 0x200004e8 4
```

See the **stophwp** subcommand.

tracei Subcommand

tracei [[*Address*] [**at** *Address* | **in** *Procedure*] | *Expression* **at** *Address*] [**if** *Condition*]

The **tracei** subcommand turns on tracing when:

- The contents of the address specified by the *Address* parameter change if the *Address* flag is included.
- The instruction at *Address* is run if the **at** *Address* parameter is specified.

- The procedure specified by *Procedure* is active if the **in** *Procedure* flag is included.
- The condition specified by the *Condition* parameter is true if the **if** *Condition* flag is included.

Flags

Item	Description
at *Address*	Specifies an address. Tracing is enabled when the instruction at this address is run.
if *Condition*	Specifies a condition. Tracing is enabled when this condition is met.
in *Procedure*	Specifies a procedure. Tracing is enabled when this procedure is active.

Examples

1. To trace each instruction executed, enter the following command:

```
tracei
```

2. To trace each time the instruction at address `0x100020f0` is executed, enter the following command:

```
tracei at 0x100020f0
```

3. To trace each time the contents of memory location `0x20004020` change while the `main` procedure is active, enter the following command:

```
tracei 0x20004020 in main
```

4. To trace each time the instruction at address `0x100020f0` is executed by thread `$t4`, enter the following command:

```
tracei at 0x100020f0 if ($running_thread == 4)
```

See the **trace** subcommand. Also, see Debugging at the Machine Level with **dbx** in *General Programming Concepts: Writing and Debugging Programs*.

tskip Subcommand

tskip [*Number*]

The **tskip** subcommand continues the execution of the running thread from the current stopping point. The number of thread-level breakpoints specified by the *Number* parameter is skipped for the running thread. This subcommand can be started for system-scope threads only.

All the other threads are run during this operation, and all breakpoints and watchpoints specified by the user are caught. The execution can cease when any thread hits a breakpoint or watchpoint. Even though the execution started by **tskip** subcommand can stop because of an event for another thread, the **tskip** count specified for the previous thread is still active and the number of thread-level breakpoints specified by the **tskip** count is ignored for that thread when the process continues. When the thread ends, the **tskip** count associated with it is deleted.

Use the **status** subcommand to view the remaining **tskip** count for the threads. Use the **delete** subcommand to delete the remaining **tskip** count for the threads.

Example

To continue execution until the second thread-level breakpoint is encountered starting from the current stopping point for the running thread, enter:

```
tskip 1
```

See the cont subcommand. Also, see Debugging Programs Involving Multiple Threads in *General Programming Concepts: Writing and Debugging Programs*.

tstep Subcommand

tstep [*Number*]

The **tstep** subcommand runs the specified number of source lines from the current source line for the running thread. The *Number* parameter specifies the number of times the `tstep` subcommand runs. If the *Number* parameter is not specified, `tstep` runs once only. This subcommand can be started only on system-scope threads.

All the threads are run during this operation. If `$hold_next` is set, all the threads except the running thread is held.

Note: Use the `$stepignore` variable of the `set` subcommand to control the behavior of the `tstep` subcommand. The `$stepignore` variable enables the `tstep` subcommand to step over large routines for which no debugging information is available.

Examples

1. To continue execution of the running thread up for one source line, enter:

   ```
   tstep
   ```

2. To continue execution of the running thread for five source lines, enter:

   ```
   tstep 5
   ```

3. To prevent the **dbx** program from single-stepping the `printf` function, as illustrated in the example code:

   ```
   60 printf ("hello world /n");
   ```

   enter:

   ```
   set $stepignore="function"; step
   ```

See the cont subcommand, the goto subcommand, **tnext** subcommand, the set subcommand, and the **tstepi** subcommand. Also, see Debugging Programs Involving Multiple Threads in *General Programming Concepts: Writing and Debugging Programs*.

tstepi Subcommand

tstepi [*Number*]

The **tstepi** subcommand runs the specified number of instructions from the current instruction for the running thread. The *Number* parameter specifies the number of times the `tstepi` subcommand runs. If the *Number* parameter is not specified, `tstepi` runs once only. This subcommand can be started only on system-scope threads.

All the threads are run during this operation. If `$hold_next` is set, all the threads except the running thread is held.

Examples

1. To continue execution of the running thread up for one machine instruction, enter:

   ```
   tstepi
   ```

2. To continue execution of the running thread for five machine instructions, enter:

   ```
   tstepi 5
   ```

See the gotoi subcommand, **tnexti** subcommand, and the **tstep** subcommand. Also, see Debugging Programs Involving Multiple Threads in *General Programming Concepts: Writing and Debugging Programs*.

tstop Subcommand

tstop { in *Procedure* | [*Variable*] at *SourceLine* [if *Condition*] } [**for $t***threadnumber*]

The **tstop** subcommand sets a source-level breakpoint stop for a thread and halts the application program when the specified thread reaches the breakpoint. The thread specified must exist at the same time as the creation of the event. The current thread is used if no thread is specified. The specified thread is stopped when any of the following occurs:

- The `if` *Condition* flag is used, and the *Condition* is true.
- The `in` *Procedure* flag is used, and the *Procedure* is called.
- The `at` *SourceLine* flag is used, and the *SourceLine* line number is reached. The *SourceLine* variable can be specified as an integer or as a file name string followed by a colon (:) and an integer.

Thread-level breakpoints can be set on system scope threads only. When a thread-level and a process-level breakpoint are hit at the same time, both the breakpoints are processed and the thread-level breakpoint is ported. When the thread terminates, the events associated with it are deleted.

Flags

Item	Description
at *SourceLine*	Specifies the line number.
for $t *threadnumber*	Specifies the thread number.
if *Condition*	Specifies the condition (for example, `true`).
in *Procedure*	Specifies the procedure to be called.

Examples

1. To stop execution at the first statement in the `func` procedure while running thread 2, enter:

```
tstop in func for $t2
```

2. To stop execution of the current thread when the value of the x variable is changed on line 12 of the execution, enter:

```
tstop x at 12
```

See the **ttrace** subcommand. Also, see Debugging Programs Involving Multiple Threads in *General Programming Concepts: Writing and Debugging Programs*.

tstophwp Subcommand

tstophwp *address size* [**for $t***threadnumber*]

The **tstophwp** subcommand sets a thread-level hardware watchpoint stop for the specified memory region. The program stops when the contents of the region changes while running the specified thread. The thread specified must exist at the same time as the creation of the event. The current thread is used if no thread is specified. The thread-level watchpoint events can be set only for system-scope threads. When the thread terminates, the events associated with it are deleted.

Notes:

1. The success of the `tstophwp` subcommand is hardware-dependent. This feature is available only on POWER630 and POWER4 onwards.
2. As a result of the hardware limitation allowing only a single watchpoint to be set, an active thread watchpoint event acts as a conflict when attempting to create another hardware watchpoint event for the same thread using `tstophwp` and `ttracehwp`. To avoid this, the previous event must be deleted

before creating a new one. Because the existence of an active software watchpoint (created by some invocations of the `stop` and `trace` subcommands) can negate the performance gains of hardware watchpoints, these types of events must also be deleted before creating a hardware watchpoint to avoid conflicts.

3. When a process-level watchpoint exists, a thread having no thread-level watchpoint watches the process watchpoint location. If a thread has a thread-level watchpoint, the thread watches the thread watchpoint location.
4. A thread-level hardware watchpoint and a process-level hardware watchpoint can coexist and do not conflict with each other.
5. If a process-level and a thread-level watchpoint exist for the same address, the process-level watchpoint event is reported.

Flags

Item	Description
for $t *threadnumber*	Specifies the thread number.

Example

To stop the program when thread 2 is running and the contents of the 4-byte memory region starting at address `0x200004e8` change, enter:

```
tstophwp 0x200004e8 4 for $t2
```

See the **ttracehwp** subcommand. Also, see Debugging Programs Involving Multiple Threads in *General Programming Concepts: Writing and Debugging Programs*.

tstopi Subcommand

tstopi { `in` *Procedure* | [*Address*] `at` *Address* [`if` *Condition*] } [**for $t***threadnumber*]

The **tstopi** subcommand sets an instruction-level breakpoint stop for a thread. The thread specified must exist at the same time as the creation of the event. The current thread is used if no thread is specified. The specified thread is stopped when any of the following occurs:

- The `if` *Condition* flag is used, and the *Condition* is true.
- The `in` *Procedure* flag is used, and the *Procedure* is called.
- The `at` *Address* flag is used, and the *Address* is reached.

Thread-level breakpoints can be set on system scope threads only. When a thread-level and a process-level breakpoint are hit at the same time, both the breakpoints are processed and the thread-level breakpoint is reported. When the thread terminates, the events associated with it are deleted.

Flags

Item	Description
at *Address*	Specifies the machine instruction address.
for $t *threadnumber*	Specifies the thread number.
if *Condition*	Specifies the condition.
in *Procedure*	Specifies the procedure to be called.

Example

1. To stop execution at address `0x100020f0` while running thread 2, enter:

```
tstopi at 0x100020f0 for $t2
```

2. To stop execution when the `func` procedure is entered while running the current thread, enter:

```
tstopi in func
```

See the **ttracei** subcommand. Also, see Debugging Programs Involving Multiple Threads in *General Programming Concepts: Writing and Debugging Programs*.

ttrace Subcommand

ttrace { [*Variable*] `at` *SourceLine* | *Procedure* } [`if` *Condition*] [**for $t***threadnumber*]

The **ttrace** subcommand prints tracing information when the specified thread runs for the specified procedure, function, source line, and variable. The *SourceLine* variable can be specified as an integer or as a file name string followed by a colon (:) and an integer. The **dbx** debug program associates a number with each **ttrace** subcommand. Use the `status` subcommand to view these numbers. Use the **delete** subcommand to turn tracing off. You can enable and disable traces using the **enable** and **disable** subcommands, respectively.

The current thread is used if no thread is specified. Thread-level trace can be set only for system-scope threads. The thread specified must exist at the same time as the creation of the event. When the thread ends, the events associated with it are deleted.

Flags

Item	Description
at *SourceLine*	Specifies the source line where the expression being traced is found.
for $t *threadnumber*	Specifies the thread number.
if *Condition*	Specifies a condition for the beginning of the trace. The trace begins only if *Condition* is true.
in *Procedure*	Specifies the procedure to find the procedure or variable being traced.

Examples

1. To trace each call to the `printf` procedure while running thread 2, enter:

```
ttrace printf for $t2
```

2. To trace each execution of line 22 in the `hello.c`/ file while the current thread is running, enter:

```
ttrace "hello.c":22
```

See the **ttracei** subcommand. Also, see Debugging Programs Involving Multiple Threads in *General Programming Concepts: Writing and Debugging Programs*.

ttracei Subcommand

ttracei [*Address*] `at` *Address* [`if` *Condition*] } [**for $t***threadnumber*]

The **ttracei** subcommand turns on tracing for the specified thread when any of the following occurs:

- The `if` *Condition* flag is included, and the *Condition* is true.
- The `at` *Address* flag is specified, and the instruction at *Address* is run.

The current thread is used if no thread is specified. Thread-level trace can be set only for system-scope threads. The thread specified must exist at the time as the creation of the event. When the thread ends, the events associated with it are deleted.

Flags

Item	Description
at *Address*	Specifies an address. Tracing is enabled when the instruction at this address is run.
for $t *threadnumber*	Specifies the thread number.
if *Condition*	Specifies a condition. Tracing is enabled when this condition is met.

Example

1. To trace each time the instruction at address `0x100020f0` is executed while thread 3 is running, enter:

```
tracei at 0x100020f0 for $t3
```

2. To trace each time the instruction at address `0x100020f0` is executed by the current thread, enter:

```
tracei at 0x100020f0
```

See the **ttrace** subcommand. Also, see Debugging Programs Involving Multiple Threads in *General Programming Concepts: Writing and Debugging Programs*.

ttracehwp Subcommand

ttracehwp *address size* [**for $t***threadnumber*]

The**ttracehwp** subcommand sets a thread-level hardware watchpoint trace for the specified memory region. The **dbx** debug program prints tracing information when the contents of the region change while running the specified thread. The thread specified must exist at the same time as the creation of the event. The current thread is used if no thread is specified. The thread-level watchpoint events can be set only for system-scope threads. When the thread terminates, the events associated with it are deleted.

Note:

1. The success of the `ttracehwp` subcommand is hardware dependent. This feature is available only on POWER630 and POWER4 onwards.
2. As a result of the hardware limitation allowing only a single watchpoint to be set, an active thread watchpoint event acts as a conflict when attempting to create another hardware watchpoint event for the same thread using `tstophwp` and `ttracehwp`. To avoid this, the previous event must be deleted before creating a new one. Because the existence of an active software watchpoint (created by some invocations of the `stop` and `trace` subcommands) can negate the performance gains of hardware watchpoints, these types of events must also be deleted before creating a hardware watchpoint to avoid conflicts.
3. When a process-level watchpoint exists, a thread having no thread-level watchpoint watches the process watchpoint location. If a thread has a thread-level watchpoint, the thread watches the thread watchpoint location.
4. A thread-level hardware watchpoint and a process-level hardware watchpoint can coexist and do not conflict with each other.
5. If a process-level and a thread-level watchpoint exist for the same address, the process-level watchpoint event is reported.

Flags

Item	Description
for $t *threadnumber*	Specifies the thread number.

Example

To trace each time the contents of the 4-byte memory region starting at address `0x200004e8` change while running thread 2, enter:

```
ttracehwp 0x200004e8 4 for $t2
```

See the **tstophwp** subcommand. Also, see Debugging Programs Involving Multiple Threads in *General Programming Concepts: Writing and Debugging Programs*.

unalias Subcommand

unalias *Name*

The **unalias** subcommand removes the alias specified by the *Name* parameter.

Example

To remove an alias named `printx`, enter:

```
unalias printx
```

See the **alias** subcommand. Also, see Creating Subcommand Aliases in *General Programming Concepts: Writing and Debugging Programs*.

unset Subcommand

unset *Name*

The **unset** subcommand deletes the **dbx** debug program variable associated with the name specified by the *Name* parameter.

Example

To delete the variable inhibiting the display of floating-point registers, enter:

```
unset $noflregs
```

See the **set** subcommand. Also, see Changing Print Output With Special Debugging Variables in *General Programming Concepts: Writing and Debugging Programs*.

up Subcommand

up [*Count*]

The **up** subcommand moves the current function up the stack *Count* number of levels. The current function is used for resolving names. The default for the *Count* parameter is one.

Examples

1. To move the current function up the stack 2 levels, enter:

   ```
   up 2
   ```

2. To display the current function on the stack, enter:

   ```
   up 0
   ```

See the **down** subcommand. Also, see Changing the Current File or Procedure, Displaying a Stack Trace in *General Programming Concepts: Writing and Debugging Programs*.

use Subcommand

use [{ + | *Directory* | '['*RegularExpression* = *NewPath*']' } ...]

The **use** subcommand sets the list of directories to be searched and path mappings to be applied when the **dbx** debug program looks for source files. If the **use** subcommand is specified without arguments, the current list of directories to be searched and path mappings to be applied are displayed.

The **@** (at-sign) is a special directory that directs the **dbx** program to look at the full-path name information in the object file, if it exists. If you have a relative directory called @ to search, you must use `./@` in the search path.

The **use** subcommand uses the + (plus-sign) to add more directories or mappings to the list of directories to be searched. The + represents the current list of directories and mappings when specified as input to the **use** subcommand. To append a directory or mapping to the end of the current list, the + must be specified before the new directory or mapping. To add a directory to the beginning of the current list, the + must be specified after the new directory or mapping. If you have a directory named +, specify the full-path name for the directory (for example, `./+` or `/tmp/+`).

The **use** subcommand interprets strings enclosed in `[` and `]` (square brackets) which contain an = (equal-sign) as path mappings. These path mappings are used with the special @ directory. They make it easier for the user to express source file locations in the case that entire directory structures of source files are relocated after compilation.

The following rules apply when attempting to locate a source file during debugging:

- Directories in the list are evaluated in the order specified.
- Upon evaluation of a directory in the list, the directory is searched for the specified file. If the file exists in the directory and is readable, this file is used.
- Upon evaluation of the special @ directory, when one or more path mappings are specified, if the *RegularExpression* portion of a path mapping matches the first *n* characters of the full-path name information in the object file and the substitution of the *NewPath* portion of the path mapping yields a readable file, this file is used.
- Upon evaluation of the special @ directory, when either no path mappings are specified or none match, the directory corresponding to the full-path name information is searched. If the file exists in the directory and is readable, this file is used.
- If more than one path mapping yields a readable file, the path mapping whose *RegularExpression* matches the most characters (1 ... n) of the full-path name information (that is, the most specific) is applied and the resulting file is used.
- If more than one path mapping yields a readable file and each path mapping has equal specificity, the path mapping nearest to the beginning of the list is applied and the resulting file is used.

Note: If the special @ directory is not a member of the list, any path mappings that might be specified are ignored.

Examples

1. To change the list of directories to be searched to the current directory (.), the parent directory (..), and the `/tmp` directory, enter:

   ```
   use . .. /tmp
   ```

2. To change the list of directories to be searched to the current directory (.), the directory the source file was located in at compilation time (@), and the `../source` directory, enter:

   ```
   use . @ ../source
   ```

3. To add the `/tmp2` directory to the list of directories to be searched, enter:

```
use + /tmp2
```

4. To add the /tmp3 directory to the beginning of the list of directories to be searched, enter:

```
use /tmp3 +
```

5. To express that source files whose full-path name information begins with /home/developer are now located under /mnt, enter:

```
use + [/home/developer=/mnt]
```

6. To direct the **dbx** program to first look under /latest and then, if the file does not exist there, to look under /stable for files with full-path name information beginning with /home/developer, enter:

```
use + [/home/developer=/latest] [/home/developer=/stable]
```

Also, see the **edit** subcommand and the **list** subcommand.

whatis Subcommand

whatis *Name*

The **whatis** subcommand displays the declaration of *Name*, where the *Name* parameter designates a variable, procedure, or function name, optionally qualified with a block name.

Note: Use the **whatis** subcommand only while running the **dbx** debug program.

Examples

1. To display the declaration of the x variable, enter:

```
whatis x
```

2. To display the declaration of the main procedure, enter:

```
whatis main
```

3. To display the declaration of the x variable within the main function, enter:

```
whatis main.x
```

4. To print the declaration of an enumeration, structure, or union tag, use $$TagName:

```
(dbx) whatis $$status
enum $$status { run, create, delete, suspend };
```

where Subcommand

where [all | *$tthreadumber* [(*startframe endframe*)] ...] [*startframe endframe*] [**>***File*]

The **where** subcommand displays a list of active procedures and functions associated with the frame numbers *startframe* to *endframe*. The numbering of the stack frame starts from the currently active function stack frame (which is always numbered 0). If there are *n* frames, the frame of the main function is numbered n-1. By using the >*File* flag, the output of this subcommand can be redirected to the specified file.

In the multithreaded environment option all displays the stack details for all available threads. The stack details of individual threads are displayed by specifying the thread number along with where subcommand. If start and end frames for individual threads are not specified, stack frames are displayed by the global start and end frame numbers. Command with no options displays the stack frames of current thread.

Flag

Item	Description
>*File*	Redirects output to the specified file.

See the `frame` subcommand, **up** subcommand, and **down** subcommand. Also, see Displaying a Stack Trace in *General Programming Concepts: Writing and Debugging Programs*.

Example

1. To display the stack details of all the threads, enter:

```
where all
```

2. To display the stack details of threads $t1, $t2 and $t3, enter:

```
where $t1 $t2 $t3
```

3. To display the stack details of threads $t2 with stack frames 2 -3, $t1 and $t3 both with stack frames 1-4, enter:

```
where $t1 $t2(2 3) $t3 1 4
```

See the `frame` subcommand, **up** subcommand, and **down** subcommand. Also, see Displaying a Stack Trace in *General Programming Concepts: Writing and Debugging Programs*.

whereis Subcommand

whereis *Identifier*

The **whereis** subcommand displays the full qualifications of all the symbols whose names match the specified identifier. The order in which the symbols print is not significant.

Examples

To display the qualified names of all symbols named x, enter:

```
whereis x
```

Also, see the **which** subcommand.

which Subcommand

which *Identifier*

The **which** subcommand displays the full qualification of the identifier. The full qualification consists of a list of the outer blocks with which the identifier is associated.

Examples

To display the full qualification of the x symbol, enter:

```
which x
```

See the **whereis** subcommand. Also. see Scoping of Names in in *General Programming Concepts: Writing and Debugging Programs*.

Files

Item	Description
`a.out`	Object file; contains object code.
`core`	Contains core dump.

Item	Description
`.dbxinit`	Contains initial commands.

Debugging applications that use transactional memory

For applications that use transactional memory (TM), the most reliable debugging aids are the transaction exception and summary register (*$texasr*), transaction failure handler address register (*$tfhar*), and transaction failure instruction address register (*$tfiar*) variables.

The *$texasr*, *$tfhar*, and *$tfiar* variables can be displayed by using the **print** subcommand, which is similar to displaying the *$iar* variable. However, you cannot manipulate the values in these registers by using the **assign** subcommand.

The *$tfhar* and *$tfiar* variables contain addresses of instructions from the debugged text segment in a transaction failure. Similar to the *$iar* variable, the two most significant bits of the *$tfhar* and *$tfiar* register variables are reserved and cannot be considered for reading the address from these register variables.

Note: When you use the `$tfiar` and `$tfhar` register variables with the **list** subcommand, the **dbx** command fetches the address after excluding the two most significant bits from the contents of these register variables.

```
(dbx) list at $tfiar
```

or

```
(dbx) list at $tfhar
```

The cause of a transaction failure can be determined by using the *$texasr* variable. The **tm_status** subcommand interprets the cause and nature of a transaction failure.

The **dbx** command monitors the occurrence of a transaction and displays the cause of the transaction failure through the following series of messages. These following messages are displayed after you run the **run** subcommand, the **rerun** subcommand, or the **continue** subcommand.

- `Process {PID} may have failed a transaction - $texasr, $tfiar, $tfhar are valid and may be inspected`
- `Process {PID} may have performed a transaction - $texasr, $tfiar, $tfhar, are valid and may be inspected`

  This message is displayed only when the *$trace_good_transaction* internal variable is set.
- `Process {PID} is in Transactional State – debugging efforts through dbx may result in repeated transaction failure or undefined behavior`
- `Process {PID} is in Suspended State – debugging efforts through dbx may result in repeated transaction failure or undefined behavior`

Where `PID` is the process ID of the process that is debugged.

dc Command

Purpose

Provides an interactive desk calculator for doing arbitrary-precision integer arithmetic.

Syntax

dc [*File*]

Description

The **dc** command is an arbitrary-precision arithmetic calculator. The **dc** command takes its input from the *File* parameter or standard input until it reads an end-of-file character. After the **dc** command receives the input, it evaluates the value and writes the evaluation to standard output. It operates on decimal integers, but you can specify an input base, an output base, and a number of fractional digits to be maintained. The **dc** command is structured as a stacking, reverse Polish notation calculation.

The **bc** command is a preprocessor for the **dc** command. It provides infix notation and a syntax similar to the C language, which implements functions and control structures for programs.

Subcommands

Item	Description
c	Cleans the stack: the **dc** command pops all values on the stack.
d	Duplicates the top value on the stack.
f	Displays all values on the stack.
i	Pops the top value on the stack and uses that value as the number radix for further input.
I	Pushes the input base on the top of the stack.
k	Pops the top of the stack and uses that value as a nonnegative scale factor. The appropriate number of places is displayed on output and is maintained during multiplication, division, and exponentiation. The interaction of scale factor, input base, and output base is reasonable if all are changed together.
l*x*	Pushes the value in the register that is represented by the *x* variable on the stack. The register that is represented by the *x* variable is not changed. All registers start with a value of 0.
L*x*	Treats the *x* variable as a stack and pops its top value onto the main stack.
o	Pops the top value on the stack and uses that value as the number radix for further output.
O	Pushes the output base on the top of the stack.
p	Displays the top value on the stack. The top value remains unchanged.
P	Interprets the top of the stack as a string, removes it, and displays it.
q	Exits the program. If the **dc** command is running a string, it pops the recursion level by two.
Q	Pops the top value on the stack and on the string execution level by that value.
s*x*	Pops the top of the stack and stores it in a register named *x*, where the *x* variable can be any character.
S*x*	Treats the *x* variable as a stack. It pops the top of the main stack and pushes that value onto the stack that is represented by the *x* variable.
v	Replaces the top element on the stack by its square root. Any existing fractional part of the option is taken into account, but otherwise, the scale factor is ignored.
x	Treats the top element of the stack as a character string and runs it as a string of **dc** commands.
X	Replaces the number on the top of the stack with its scale factor.

Item	Description
z	Pushes the number of elements in the stack onto the stack.
Z	Replaces the top number in the stack with the number of digits in that number.
Number	Pushes the specified value onto the stack. A *Number* is an unbroken string of the digits 0 through 9. To specify a negative number, precede it with _ (underscore). A number can contain a decimal point.
+ - / * % ^	Adds (+), subtracts (-), multiplies (*), divides (/), remainders (%), or exponentiates (^) the top two values on the stack. The **dc** command pops the top two entries off the stack and pushes the result on the stack in their place. The **dc** command ignores fractional parts of an exponent.
[*String*]	Puts the bracketed *String* parameter onto the top of the stack.
[**=** | **>** | **<**] *x*	Pops the top two elements of the stack and compares them. Evaluates the register that is represented by the *x* variable as if it obeys the stated relation.
!	Interprets the rest of the line as an operating system command.
?	Gets and runs a line of input.
;:	The **bc** command uses these characters for array operations.

Examples

1. To use the **dc** command as a calculator, enter the following command:

```
You:    1 4 / p
System: 0
You:    1 k   [ Keep 1 decimal place ]s.
        1 4 / p
System: 0.2
You:    3 k   [ Keep 3 decimal places ]s.
        1 4 / p
System: 0.250
You:    16 63 5 / + p
System: 28.600
You:    16 63 5 + / p
System: 0.235
```

   Comments can be used in the **dc** command as in the example. Comments are enclosed in brackets and can be followed the `s.` character. The comments in the format `[Comment]s.` are ignored by the **dc** command. Only those comments that are enclosed in brackets are stored on the top of the stack.

   When you enter the **dc** command expressions directly from the keyboard, press Ctrl-D to end the **bc** command session and return to the shell command line.

2. To load and run a **dc** program file, enter the following command:

```
You:    dc prog.dc
        5 lf x p [ 5 factorial ]s.
System: 120
You:    10 lf x p [ 10 factorial ]s.
System: 3628800
```

   This entry interprets the **dc** program saved in the `prog.c` program file, then reads from the workstation keyboard. The `lf x` evaluates the function that is stored in register `f`, which can be defined in the `prog.c` program file as:

```
[ f: compute the factorial of n ]s.
[ (n = the top of the stack) ]s.
[ If 1>n do b; If 1<n do r ]s.
 [d 1 >b d 1 <r] sf
[ Return f(n) = 1 ]s.
 [d - 1 +] sb
```

```
[ Return f(n) = n * f(n-1) ]s.
 [d 1 - lf x *] sr
```

You can create **dc** program files with any text editor or with the **-c** (compile) flag of the **bc** command. When you enter the **dc** command expressions directly from the keyboard, press Ctrl-D to end the **bc** command session and return to the shell command line.

Files

Item	Description
/usr/bin/dc	Contains the **dc** command.

dcp Command

Purpose

Runs commands concurrently on multiple nodes and hardware devices.

Syntax

dcp [**-h**] [**-V**] [**-q**] [**-a**] [**--all-nodes** *context_list*] [**-A**] [**--all-devices** *context_list*] [**-n** *node_list*] [**-N** *nodegroups*] [**-d** *device_list*] [**-D** *devicegroups*] [**-C** *context*] [**-f** *fanout*] [**-l** *user_ID*] [**-o** *node_options*] [**-O** *device_options*] [**-p**] [**-P**] [**-Q**] [**-r** *node_remote_copy*] [**--device-rcp** *device_remote_copy*] [**-R**] [**-t** *timeout*] [**-X** *env_list*] [**-T**] [**-v**] *source_file... target_path*

Description

The **dcp** command concurrently copies files to or from remote target nodes, hardware devices, or both. Targets can be selected from multiple contexts. A context is a target database that contains definitions of nodes and devices, such as NIM. The **dcp** command issues a remote copy command for each node or device specified. When files are pulled from a target, they are placed into the *target_path* with the name of the remote node or device that is appended to the copied *source_file* name. The **/usr/bin/rcp** command is the model for syntax and security. The **dcp** command is a DSM Distributed Shell Utility. The configuration and environmental settings for **dsh** impact the behavior of **dcp**. See the **dsh** command for more details.

Parameters

Item	Description
TARGET CONTEXT	Target context specification is identical for the **dcp** and **dsh** commands. See target context in the **dsh** man page for details on specifying contexts for the **dcp** command.
TARGET SPECIFICATION	Target specification is identical for the **dcp** and **dsh** commands. See the **dsh** man page for details on specifying targets for the **dcp** command.
TARGET LISTS	Target list syntax is identical for the **dcp** and **dsh** commands.
REMOTE USER	A *user_ID* can be specified for the remote copy command. Remote user specification is identical for the **dcp** and **dsh** commands.

Item	Description
REMOTE COPY COMMAND	The **dcp** command uses a configurable remote copy command to run remote commands on remote targets. Support is explicitly provided for AIX Remote Shell **rcp** command, the **OpenSSH scp** command and the **rsync** command. For node targets, the remote copy command is determined by using the parameters in the order of precedence: 1. The **-r** flag. 2. The **DCP_NODE_RCP** environment variable. 3. The **/usr/bin/rcp** command. For device targets, the remote shell is determined by the following order of precedence: 1. The **--device-rcp** flag. 2. The **DCP_DEVICE_RCP** environment variable. 3. The default device remote copy command as defined by the target context. 4. The **RemoteCopyCmd** attribute that is defined for the device target. The remote copy command is specified with a command-line flag or environment variable by using the following syntax: `[context:]path[,[context:]path]...` where *path* is the path to the remote copy command, and *context:* identifies the remote copy command context to use for copying files. A remote copy command path that is specified without a context applies to all other contexts where an explicit remote copy command path is not specified in the list. The remote copy command options can be configured by using command-line flags or environment variables. For node targets, the remote copy command options are determined by the following order of precedence: 1. The **-o** flag. 2. The **DCP_NODE_OPTS** environment variable. For device targets, the remote copy command options are determined by the following order of precedence: 1. The **-O** flag. 2. The **DCP_DEVICE_OPTS** environment variable. The remote copy command options are specified by using the following syntax: `[context:]"options"[, [context:]"options"]...` where *options* are the remote copy command options, and *context:* identifies the remote shell options context to use for copying files. Options that are specified without a context apply to all other contexts where explicit options have not been specified in the list. The options must be specified within double quotation marks ("") to distinguish them from the **dcp** options.
COMMAND EXECUTION	Specifies concurrent remote copy command processes (fanout) that can be specified with the **-f** flag or the **DSH_FANOUT** environment variable. The fanout is only restricted by the number of remote shell commands that can be run in parallel. You can experiment with the **DSH_FANOUT** value on your management server to see whether higher values are appropriate. A timeout value for remote copy command execution can be specified with the **-t** flag or **DSH_TIMEOUT** environment variable. If any remote target does not respond within the timeout value, the **dcp** command displays an error message and exits. The **-T** flag provides diagnostic trace information for **dcp** command execution. Default settings and the actual remote copy commands that are run to the remote targets are displayed. The **dcp** command can be run silently by using the **-Q** flag; no target standard output or standard error is displayed. The parameters for this variable follow: ***source_file...*** Specifies the complete path for the file to be copied to or from the target. Multiple files can be specified. When used with the **-R** flag, only a single directory can be specified. When used with the **-P** flag, only a single file can be specified. ***target_path*** Specifies the complete path to copy one or more *source_file* files to on the target. If the **-P** flag is specified, the *target_path* is the local host location for the copied files. The remote file directory structure is re-created under *target_path* and the remote target name is appended to the copied *source_file* name in the *target_path* directory.

Keywords

Item	Description
-a	Includes in the target list all nodes that are defined in the default context. The default context can be set by using the **-C** flag or the **DSH_CONTEXT** environment variable.
-A	Includes in the target list all devices that are defined in the default context. The default context can be set by using the **-C** flag or the **DSH_CONTEXT** environment variable. This flag is disabled on HMCs.
--all-devices *context_list*	Includes in the target list all devices that are defined in the contexts that are listed in *context_list*. The default context is not implicitly included in this list. This flag is disabled on HMC.
--all-nodes *context_list*	Includes in the target list all nodes that are defined in the contexts that are listed in *context_list*. The default context is not implicitly included in this list.
-C	Specifies the full path of the remote copy command that is used to copy files to or from device targets. A remote copy command for a specific context can be defined by including `context:` before the path.

Item	Description
--context*context*	Specifies the default context to use when the **dcp** command resolves target names. The context value must correspond to a valid context extension module in the `/opt/ibm/sysmgt/dsm/pm/Context` directory.
--device-rcp *device_remote_copy*	Starts the audit subsystem. The *device_remote_copy* syntax follows: `[context:]path[,[context:]path]...` This flag is disabled on HMCs. This keyword reads the instructions in the configuration files and determines the remote shell for device targets.
-d | **--devices** *device_list*	Specifies a list of device targets to include in the target list. The *device_list* syntax is: `[context:] [user_ID@] device_name[,\` `[context:][user_ID@]device_name]...` This flag is disabled on HMCs.
-D | **--devicegroups** *devicegroups*	Includes in the target list all devices that are defined in the device groups that are specified in the *devicegroups* list. The *devicegroups* syntax follow: `[context:] [user_ID@]devicegroup[,\` `[context:] [user_ID@]devicegroup]...` This flag is disabled on HMCs.
-f | **--fanout** *fanout*	Specifies a fanout value for the maximum number of concurrently running remote shell processes. Sequential execution can be specified by indicating a fanout value of 1. If this flag is omitted, the default fanout value of 64 is used.
-l | **--user** *user_ID*	Specifies a remote user name to use for remote copy execution.
-h | **--help**	Displays command usage information.
-n | **--nodes** *node_list*	Specifies a list of node targets to include in the target list. The *node_list* syntax follows: `[context:] [user_ID@]node_name[,\` `[context:] [user_ID@]node_name]...`
-o | **--node-options** *node_options*	Specifies options to pass to the remote copy command for node targets. The options must be specified within double quotation marks to distinguish them from the **dcp** command flags. Options for nodes in a specific context can be defined by including `context:` before the option list. The syntax of *node_options* follows: `[context:]"options"[, [context:]"options"]...`
-N | **--nodegroups** *nodegroups*	Includes all nodes in the target list that are defined in the node groups that are specified in the *nodegroups* list. The syntax of *nodegroups* follows: `[context:] [user_ID@]nodegroup[,\` `[context:] [user_ID@]nodegroup]...`
-O --device-options *device_options*	Specifies options to pass to the remote copy command for device targets. The options must be specified within double quotation marks to distinguish them from the **dcp** command flags. Options for devices in a specific context can be defined by including `context:` before the option list. The syntax of *device_options* follows: `[context:]"options"[,[context:]"options"]...` This flag is disabled on HMCs.
-p | --preserve	Preserves the source file characteristics as implemented by the configured remote copy command.
-P | --pull	Pulls (copies) the files from the targets and places them in the *target_path* directory on the local host. The *target_path* must be a directory. Files that are pulled from remote machines have `_target` appended to the file name to distinguish between them. When the **-P** flag is used with the **-R** flag, `_target` is appended to the directory. Only one file per invocation of the **dcp -P | --pull** command can be pulled from the specified targets.
-Q	Runs the **dcp** command silently such that no target standard output or standard error is displayed.
-q | --show-config	Displays the current environment settings relevant to all **dsh** utility commands. This flag includes the values of all environment variables and settings for all currently installed and valid contexts. Each setting is prefixed with `context:` to identify the source context of the setting.

Item	Description
-r | --node-rcp *node_remote_copy*	Specifies the full path of the remote copy command that is used to copy files to or from node targets. A remote copy command for a specific context can be defined by including `context:` before the path. The *node_remote_copy* syntax follows: `[context:]path[,[context:]path]...` If *path* contains **rsync**, it is assumed that the **rsync** command performs the remote copy.
-R | --recursive	Recursively copies files from a local directory to the remote targets, or when specified with the **-P** flag. It recursively pulls (copies) files from a remote directory to the local host. A single source directory can be specified by using the *source_file* parameter.
-t | --timeout *timeout*	Specifies the time, in seconds, to wait for the remote copy command to finish each remote target. If a target does not respond within the timeout value, the **dcp** command displays an error message and stops the remote copy process for the remote target. If not specified, the **dcp** command waits indefinitely for the remote copy process to finish each target.
-T | --trace	Activates the trace mode. Sends the **dcp** command diagnostic messages to standard output.
-v | --verify	Verifies each target before it runs any remote commands on the target. If a target is not responding, remote command execution for the target is canceled.
-X *env_list*	Ignores the **dcp** command environment variables. This option accepts an argument, which is a comma-separated list of environment variable names, that must not be ignored. If there is no argument to this option, or the argument is an empty string, all the **dcp** environment variables are not accepted.
-V | **--version**	Displays version information for the **dcp** command environment variables. **DSH_CONTEXT** Specifies the default context to use when it resolves targets. This variable is overridden by the **-C** flag. **DSH_DEVICE_LIST** Specifies a file that contains a list of device targets. This variable is overridden by the **-d** flag. This environment variable is ignored on HMCs. **DCP_DEVICE_OPTS** Specifies the options to use for the remote shell command with device targets only. This variable is overridden by the **-0** flag. This environment variable is ignored on HMCs. **DCP_DEVICE_RCP** Specifies the full path of the remote copy command that is used to copy files to or from device targets. This variable is overridden by the **--device-rcp** flag. This environment variable is ignored on HMCs. **DSH_FANOUT** Specifies the fanout value. This variable is overridden by the **-f** flag. **DCP_NODE_OPTS** Specifies the options to use for the remote copy command with node targets only. This variable is overridden by the **-o** flag. **DCP_NODE_RCP** Specifies the full path of the remote command that is used to copy files to and from node targets. This variable is overridden by the **-r** flag. **DSH_NODE_LIST** Specifies a file that contains a list of node targets. This variable is overridden by the **-n** flag. This variable has replaced the **WCOLL. DSH_NODEGROUP_PATH** variable. The **DSH_NODE_LIST** variable also specifies a colon-separated list of directories that contain node group files for the **dsh** context. When the **-a** flag is specified in the **dsh** context, a list of unique node names is collected from all node group files in the path. **DSH_TIMEOUT** Specifies the time, in seconds, to wait for output from each remote target. This variable is overridden by the **-t** flag. **RSYNC_RSH** This **rsync** environment variable specifies the remote shell to be used as the transport for the **rsync** command. Exit status and exit values for each remote copy command execution are displayed in messages from the **dcp** command, if the remote copy command exit value is non-zero. A non-zero return code from a remote copy command indicates that an error was encountered during the remote copy. If a remote copy command encounters an error, execution of the remote copy on that target is bypassed. The **dcp** command exit code is 0 if the **dcp** command ran without errors and all remote copy commands finished with exit codes of 0. If internal **dcp** command errors occur or the remote copy commands do not complete successfully, the **dcp** command exit value is greater than 0. The exit value is increased by 1 for each successive instance of an unsuccessful remote copy command execution. Security: The **dcp** command has no security configuration requirements. All remote command security requirements (configuration, authentication, and authorization) are imposed by the underlying remote command that is configured for the **dcp** command. Authentication and authorization are assumed to be configured between the local host and remote targets. Interactive password prompting is not supported; execution is bypassed and an error is displayed for a remote target if password prompting occurs. The security configurations as they pertain to the remote environment and remote shell command are user-defined. When `/usr/bin/rcp` is configured as your remote command by using Kerberos Version 5, you must first run the Kerberos **kinit** command to obtain a ticket-granting ticket. You must also ensure that your Kerberos principal is in the `.k5login` file in the remote `user&csqg;s` home directory on the targets.

Examples

1. To copy the /tmp/etc/hosts file from the local host to the /etc directory on node3, node4, node5, and to user gregb on device16 in the NIM context, enter the following command:

```
dcp -n node3-node5 -d NIM:gregb@device16 /tmp/etc/hosts /etc:
```

2. To copy the /etc/hosts file from all managed nodes in the cluster to the /tmp/hosts.dir directory on the local host, enter the following command:

```
dcp -aP /etc/hosts /tmp/hosts.dir
```

   A suffix that specifies the name of the target is appended to each file name. The contents of the /tmp/hosts.dir directory are like:

hosts._node1	hosts._node4	hosts._node7
hosts._node2	hosts._node5	hosts._node8
hosts._node3	hosts._node6	

3. To copy the /var/log/testlogdir directory from all targets in NodeGroup1 in the NIM context and DeviceGroup4 in the **dsh** context, with a fanout of 12, and save each directory on the local host as /var/log._target, enter the following command:

```
dcp -C DSH -N NIM:NodeGroup1 -D DeviceGroup 4 -f 12 \ -RP /var/log/testlogdir /var/log
```

4. To copy /localnode/smallfile and /tmp/bigfile to /tmp on node1 by using the **rsync** command, enter the following command:

```
RSYNC_RSH=/usr/bin/ssh; dcp -r /usr/bin/rsync -o "-z" \ -n node1 /localnode/smallfile /tmp/
bigfile /tmp
```

   This command uses **rsync** with the **RSYNC_RSH** environment variable and the **-z** flag on **rsync**.

5. To copy the /etc/hosts file from the local host to all the nodes in the cluster, and ignore all the **dcp** environment variable, enter the following command:

```
dcp -X -a /etc/hosts /etc/hosts
```

6. To copy the /etc/hosts file from node1 and node2 to the /tmp/hosts.dir directory on the local host and ignore all the **dcp** environment variables except the **DCP_NODE_OPTS**, enter the following command:

```
dcp -n node1,node2 -P -X 'DCP_NODE_OPTS' /etc/hosts /tmp/hosts.dir
```

dd Command

Purpose

Converts and copies a file.

Syntax

dd [**bs=***BlockSize*][**cbs=***BlockSize*]

[**conv=** [ascii |block|ebcdic | ibm | unblock]

[lcase | ucase] [iblock]

[noerror] [swab] [sync]

[oblock] [notrunc]][**count=**

InputBlocks] [**files=***InputFiles*] [**fskip=**

SkipEOFs] [**ibs=***InputBlockSize*] [**if=**

InFile] [**obs=***OutputBlockSize*] [**of=**

OutFile] [**seek=***RecordNumber*] [**skip=**

SkipInputBlocks][**span=***yes*|*no*]

dd [*Option*=*Value*]

Description

The **dd** command reads the *InFile* parameter or standard input, does the specified conversions, then copies the converted data to the *OutFile* parameter or standard output. The input and output block size can be specified to take advantage of raw physical I/O.

Note: The term *Block* refers to the quantity of data read or written by the **dd** command in one operation and is not necessarily the same size as a disk block.

Where sizes are specified, a number of bytes is expected. A number ending with **w**, **b**, or **k** specifies multiplication by 2, 512, or 1024 respectively; a pair of numbers separated by an **x** or an ***** (asterisk) indicates a product. The count parameter expects the number of blocks, *not* the number of bytes, to be copied.

The character-set mappings associated with the **conv=ascii** and **conv=ebcdic** flags are complementary operations. These flags map between ASCII characters and the subset of EBCDIC characters found on most workstations and keypunches.

Use the **cbs** parameter value if specifying any of the **block**, **unblock**, **ascii**, **ebcdic**, or **ibm** conversions. If **unblock** or **ascii** parameters are specified, then the **dd** command performs a fixed-length to variable-length conversion. Otherwise it performs a conversion from variable-length to fixed-length. The **cbs** parameter determines the fixed-length.

Attention: If the **cbs** parameter value is specified smaller than the smallest input block, the converted block is truncated.

After it finishes, the **dd** command reports the number of whole and partial input and output blocks.

Note:

1. Usually, you need only write access to the output file. However, when the output file is not on a direct-access device and you use the **seek** flag, you also need read access to the file.
2. The **dd** command inserts new-line characters only when converting with the **conv=ascii** or **conv=unblock** flags set; it pads only when converting with the **conv=ebcdic**, **conv=ibm**, or **conv=block** flags set.
3. Use the **backup**, **tar**, or **cpio** command instead of the **dd** command whenever possible to copy files to tape. These commands are designed for use with tape devices. For more information on using tape devices, see the **rmt** special file.
4. The block size values specified with the **bs**, **ibs** and **obs** flags must always be a multiple of the physical block size for the media being used.
5. When the **conv=sync** flag is specified, the **dd** command pads any partial input blocks with nulls. Thus, the **dd** command inserts nulls into the middle of the data stream if any of the reads do not receive a full block of data (as specified by the **ibs** flag). This is a common occurrence when reading from pipes.
6. If the **bs** flag is specified by itself and no conversions other than **sync**, **noerror** or **notrunc** are specified, then the data from each input block will be written as a separate output block; if the read returns less than a full block and **sync** is not specified, then the resulting output block will be the same size as the input block. If the **bs** flag is not specified, or a conversion other than **sync**, **noerror** or **notrunc** is specified, then the input will be processed and collected into fullsized output blocks until the end of input is reached.

Spanning across devices

The **dd** can be made to span across devices if the input file is larger than the output device physical size.

Note: Care has to be taken when specifying the block size *bs* as exact multiple of the physical size of the device because improper block size will result in data inconsistency, or overlap.

The spanning of **dd** across devices will not occur if either one of the InFile or the OutFile parameter is stdin or stdout.

Spanning will occur in such a way that **dd** will prompt for next device during write if the output device is full. During read from the input device, **dd** will prompt for next device if the data is completely read from the input device even when the device has not reached the end. In this case it would be required to press 'n' to quit.

Flags

Item	Description
bs=*BlockSize*	Specifies both the input and output block size, superseding the **ibs** and **obs** flags. The block size values specified with the **bs** flag must always be a multiple of the physical block size for the media being used.
cbs=*BlockSize*	Specifies the conversion block size for variable-length to fixed-length and fixed-length to variable-length conversions, such as **conv=block**.
count=*InputBlocks*	Copies only the number of input blocks specified by the *InputBlocks* variable.

Item	Description
conv= *Conversion*,....	Specifies one or more conversion options. Multiple conversions should be separated by commas. The following list describes the possible options: **ascii** Converts EBCDIC to ASCII. This option is incompatible with the **ebcdic**, **ibm**, **block**, and **unblock** options. **block** Converts variable-length records to fixed-length. The length is determined by the conversion block size (cbs). This option is incompatible with the **ascii**, **ebcdic**, **ibm**, and **unblock** options. **ebcdic** Converts ASCII to standard EBCDIC. This option is incompatible with the **ascii**, **ibm**, **block**, and **unblock** options. **ibm** Converts ASCII to an IBM version of EBCDIC. This option is incompatible with the **ascii**, **ebcdic**, **block**, and **unblock** options. **iblock, oblock** Minimize data loss resulting from a read or write error on direct access devices. If you specify the **iblock** variable and an error occurs during a block read (where the block size is 512 or the size specified by the **ibs=***InputBlockSize* variable), the **dd** command attempts to reread the data block in smaller size units. If the **dd** command can determine the sector size of the input device, it reads the damaged block one sector at a time. Otherwise, it reads it 512 bytes at a time. The input block size (**ibs**) must be a multiple of this retry size. This option contains data loss associated with a read error to a single sector. The **oblock** conversion works similarly on output. **lcase** Makes all alphabetic characters lowercase. **noerror** Does not stop processing on an error. **notrunc** Does not truncate the output file. Instead, blocks not explicitly written to output are preserved. **ucase** Makes all alphabetic characters uppercase. **swab** Swaps every pair of bytes. **sync** Pads every input block to the **ibs** value. **unblock** Converts fixed-length blocks to variable-length. The length is determined by the conversion block size (cbs). This option is incompatible with the **ascii**, **ebcdic**, **ibm**, and **block** options.
files=*InputFiles*	Copies the number of files specified by the *InputFiles* variable value of input files before ending (makes sense only where input is a magnetic tape or similar device).
fskip=*SkipEOFs*	Skips past the number of end-of-file characters specified by the *SkipEOFs* variable before starting to copy; this *SkipEOFs* variable is useful for positioning on multifile magnetic tapes.

Item	Description
ibs=*InputBlockSize*	Specifies the input-block size; the default is 512 bytes or one block. The block-size values specified with the **ibs** flag must always be a multiple of the physical block size for the media being used.
if=*InFile*	Specifies the input file name; standard input is the default.
obs=*OutputBlockSize*	Specifies the output-block size; the default is 512 bytes or one block. The block size values specified with the **obs** flag must always be a multiple of the physical block size for the media being used.
of=*OutFile*	Specifies the output file name; standard output is the default.
seek=*RecordNumber*	Seeks the record specified by the *RecordNumber* variable from the beginning of output file before copying.
skip=*SkipInputBlocks*	Skips the specified *SkipInputBlocks* value of input blocks before starting to copy.
span=*yes*/*no*	Allows spanning across devices if specified `yes` and works as default if specified as no. See Spanning Across Devices, for more information..

Exit Status

This command returns the following exit values:

Item	Description
0	The input file was copied successfully.
>0	An error occurred.

Examples

1. To convert an ASCII text file to EBCDIC, type:

   ```
   dd  if=text.ascii  of=text.ebcdic  conv=ebcdic
   ```

   This command converts the `text.ascii` file to EBCDIC representation, storing the EBCDIC version in the `text.ebcdic` file.

   Note: When you specify the **conv=ebcdic** parameter, the **dd** command converts the ASCII ^ (circumflex) character to an unused EBCDIC character (9A hexadecimal), and the ASCII ~ (tilde) to the EBCDIC ^ (NOT symbol).
2. To convert the variable-length record ASCII file **/etc/passwd** to a file of 132-byte fixed-length EBCDIC records, type:

   ```
   dd  if=/etc/passwd  cbs=132  conv=ebcdic  of=/tmp/passwd.ebcdic
   ```
3. To convert the 132-byte-per-record EBCDIC file to variable-length ASCII lines in lowercase, type:

   ```
   dd  if=/tmp/passwd.ebcdic  cbs=132  conv=ascii  of=/tmp/passwd.ascii
   ```
4. To convert the variable-length record ASCII file **/etc/passwd** to a file of 132-byte fixed-length records in the IBM version of EBCDIC, type:

   ```
   dd  if=/etc/passwd  cbs=132  conv=ibm  of=/tmp/passwd.ibm
   ```
5. To copy blocks from a tape with 1KB blocks to another tape using 2KB blocks, type:

   ```
   dd  if=/dev/rmt0  ibs=1024  obs=2048  of=/dev/rmt1
   ```
6. To use the **dd** command as a filter, type:

   ```
   ls -l | dd  conv=ucase
   ```

This command displays a long listing of the current directory in uppercase.

Note: The performance of the **dd** command and **cpio** command to the 9348 Magnetic Tape Unit Model 12 can be improved by changing the default block size. To change the block size, use the **chdev** command in the following way:

```
chdev -l Device_name -a block_size=32k
```

7. To perform efficient transfers to 3.5-inch 1.4MB diskette using 36 blocks of 512 bytes, type:

   dd if=Filename of=/dev/rfd0 bs=36b conv=sync

   This command writes the value of the *Filename* parameter to the diskette device a cylinder at a time. The conv=sync is required when reading from disk and when the file size is not a multiple of the diskette block size. Do not try this if the input to the **dd** command is a pipe instead of a file, it will pad most of the input with nulls instead of just the last block.
8. To copy blocks from a input file with block size set to 720b blocks into a 1.44MB size diskette type:

   ```
   dd if=testfile of=/dev/fd0 bs=720b conv=sync
   ```

   Note: If the input file is larger than the physical size of the output device then dd will prompt you for another device.
9. To copy blocks from a input file with block size set to 32k blocks to a tape type:

   ```
   dd if=inputfile of=/dev/rmt0 bs=32k conv=sync
   ```
10. To copy blocks of data from tape to a file in the current directory with block size set to 32k blocks type as follows:

    ```
    dd if=/dev/rmt0 of=outfile bs=32k conv=sync
    ```
11. To copy blocks from an input file with block size set to 720b, onto a 1.44MB size diskette, enter:

    ```
    dd if=testfile of=/dev/fd0 bs=720b conv=sync span=yes
    ```

    Note: If the input file is larger than the physical size of the output device, then **dd** will prompt you for another device.
12. To copy blocks from an input file with block size set to 32k, to a tape, enter:

    ```
    dd if=inputfile of=/dev/rmt0 bs=32k conv=sync span=yes
    ```
13. To copy blocks of data from tape with block size set to 32k, to a file in the current directory, enter:

    ```
    dd if=dev/rmt0 of=outfile bs=32k conv=sync span=yes
    ```

Files

Item	Description
/usr/bin/dd	Contains the **dd** command.

defif Method

Purpose

Defines a network interface in the configuration database.

Syntax

defif [**-c** *Class* **-s** *Subclass*] **-t** *Type*

Description

The **defif** method defines the specified instance of a network interface. It only defines interfaces for currently configured adapters. To define the specified instance, the **defif** method does the following:

1. Creates a customized interface instance in the configuration database.
2. Derives the logical name of the interface instance.
3. Retrieves the predefined attributes.
4. Updates the Customized Dependency object class to reflect dependencies of the defined interface instance.
5. Sets the status flag of the interface instance to **defined**.

Flags

Item	Description
-c *Class*	Specifies the interface class to be defined. The valid value is **if**.
-s *Subclass*	Specifies the subclass of interface to be defined. Valid values are: **TR** Token-ring **EN** Ethernet **SL** Slip **XT** X.25 **LO** Loopback
-t *Type*	Specifies the type of interface to be defined. Valid values are: **tr** Token-ring **en** Ethernet **sl** Slip **ie3** IEEE 802.3 Ethernet **lo** Loopback **xt** X.25

Examples

To define a token-ring network interface instance, enter the method in the following format:

```
defif -t tr
```

definet Method

Purpose

Defines an inet instance in the system configuration database.

Syntax

definet [**-c** *Class*]

Description

The **definet** method creates an object in the ODM configuration database specifying the customized attributes of the inet instance. It performs the following operations:

1. Creates a customized inet instance.
2. Sets the status flag of the inet instance to defined.

This method is called by the **mkdev** high-level command and is not meant to be issued on the command line.

Note: The **definet** method is a programming tool and should not be executed from the command line.

Flags

Item	Description
-c *Class*	Specifies the inet instance to be defined. The only valid value for the *Class* variable is **tcpip**.

Examples

To define the inet0 instance, issue the following method:

```
definet
```

defragfs Command

Purpose

Increases a file system's contiguous free space.

Syntax

defragfs [**-q** | **-r** | **-s**] [**-f** [**-v**] [**-y**]] { *Device* | *FileSystem* }

Description

The **defragfs** command increases a file system's contiguous free space by reorganizing allocations to be contiguous rather than scattered across the disk. The file system to be defragmented can be specified with the *Device* variable, which is the path name of the logical volume (for example, **/dev/hd4**). It can also be specified with the *FileSystem* variable, which is the mount point in the **/etc/filesystems** file.

The **defragfs** command is intended for fragmented and compressed file systems. However, you can use the **defragfs** command to increase contiguous free space in nonfragmented file systems.

You must mount the file system read-write for this command to run successfully. Using the **-q** flag, the **-r** flag or the **-s** flag generates a fragmentation report. These flags do not alter the file system.

The **defragfs** command is slow against a Enhanced Journaled File System (JFS2) file system with a snapshot due to the amount of data that must be copied into snapshot storage object. The **defragfs** command issues a warning message if there are snapshots. The **snapshot** command can be used to delete the snapshots and then used again to create a new snapshot after the **defragfs** command completes.

On a JFS2 file system, you can specify the **-f** flag with the **defragfs** command to defragment the file system by relocating data extents to be adjacent, and then combining them. Additionally, if you specify the **-v** flag, the **defragfs** command also displays the fragmentation of the file system before and after running the **defragfs** command. The **-f** , **-v**, and **-y** flags can only be used on a JFS2 file system. The **-v** flag is compatible only with the **-f** flag.

The **defragfs** command takes more time to run if you use with the **-f** flag. It is recommended the **defragfs** command be run during a maintenance window.

Any file system activity might decrease the performance of the defragmentation process.

The **defragfs** command might not significantly improve performance of a file system in which the logical volume is located in part or completely on Solid-State Drives (SSDs).

The **defragfs** command cannot run if internal snapshots exist in the system. The **defragfs** command issues a warning message if external snapshots exist in the system unless the **defragfs** command is run with the **-f** flag. If the **defragfs** command is run with the **-f** flag, the **defragfs** command cannot be run with external snapshots. The **defragfs** command takes time to run on a JFS2 file system with a snapshot because of the amount of data that must be copied into the snapshot storage object. The **snapshot** command can be used to delete the snapshots and then the **snapshot** command can be used again to create a new snapshot after the **defragfs** command completes.

The **defragfs** command shows better performance if run on a file system that does not share a log volume with other file systems. If the **defragfs** command is run on a file system that shares a log volume with other file systems, the **defragfs** command displays a warning and asks for confirmation. If you run the **defragfs** command with the **-y** flag, it suppresses the warning. The **-y** flag is only compatible with the **-f** flag.

Flags

Item	Description
-f	Relocates and combines data extents for each file in the file system. This process prioritizes file organization over file system free space contiguity.
-q	Reports the current state of the file system.
-r	Reports the current state of the file system and the state that would result if the **defragfs** command is run without either the **-q**, **-r** or **-s** flag.
-s	Reports the fragmentation in the file system. This option causes **defragfs** to pass through meta data in the file system which may result in degraded performance.
-v	Displays the fragmentation percentage of file system at the start and at the end of the defragmentation operation.
-y	Suppresses warning message that is displayed by the **defragfs** command when multiple file systems are currently mounted by using the same log volume. When the warning messages are suppressed, the **defragfs** command operation continues without any interruption.

Note: The **-v** and the **-y** flag can only be used with the **-f** flag.

Output

On a JFS file system, the definitions for the messages reported by the **defragfs** command are as follows:

Number of free fragments
The number of free fragments in the file system.

Number of allocated fragments
The number of allocated fragments in the file system.

Number of free spaces shorter than a block
The number of free spaces within the file system that are shorter than a block. A free space is a set of contiguous fragments that are not allocated.

Number of free fragments in short free spaces
The total number of fragments in all the short free spaces. A short free space is one that is shorter than a block.

Number of fragments moved
The total number of fragments moved.

Number of logical blocks moved
The total number of logical blocks moved.

Number of allocation attempts
The number of times free fragments were reallocated.

Number of exact matches
The number of times the fragments that are moved would fit exactly in some free space.

Total number of fragments
The total number of fragments in the file system.

Number of fragments that may be migrated
The number of fragments that may be moved during defragmentation.

File system is in percent fragmented
Shows to what extent the file system is fragmented in percentage.

On a JFS2 file system the definitions for the messages reported by the **defragfs** command are as follows:

Total allocation groups
The number of allocation groups in the file system. Allocation groups divide the space on a file system into chunks. Allocation groups allow JFS2 resource allocation policies to use well known methods for achieving good I/O performance.

Allocation groups defragmented
The number of allocation groups that were defragmented.

Allocation groups skipped - entirely free
The number of allocation groups that were skipped because they were entirely free.

Allocation groups skipped - too few free blocks
The number of allocation groups that were skipped because there were too few free blocks in them for reallocation.

Allocation groups skipped - contains a large contiguous free space
The number of allocation groups that were skipped because they contained a large contiguous free space which is not worth defragmenting.

Allocation groups are candidates for defragmenting
The number of allocation groups that are fit for defragmenting.

Average number of free runs in candidate allocation groups
The average number of free runs per allocation group, for allocation groups that are found fit for defragmentation. A free run is a contiguous set of blocks which are not allocated.

Total number of blocks
The total number of blocks in the file system.

Number of blocks that may be migrated
The number of blocks that may be moved during defragmentation.

File system is in percent fragmented
Shows to what extent the file system is fragmented in percentage.

Percentage of fragmentation in the file system: *percentage*
The percentage of fragmentation in the file system before and after running the **defragfs** command. The following example shows the percentage of fragmentation in the file system:

```
# defragfs -fv /exampleFS
File fragmentation before defrag: 100.00%
File fragmentation after defrag: 0.00%
```

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To defragment the **/data1** file system located on the **/dev/lv00** logical volume, enter:

   ```
   defragfs /dev/lv00
   ```

2. To defragment the **/data1** file system by specifying its mount point, enter:

   ```
   defragfs /data1
   ```

3. To generate a report on the **/data1** file system that indicates its current status as well as its status after being defragmented, enter:

   ```
   defragfs  -r /data1
   ```

4. To generate a report on the fragmentation in the **/data1** file system, enter:

   ```
   defragfs -s /data1
   ```

Files

Item	Description
/etc/filesystems	Lists the known file systems and defines their characteristics.

defvsd Command

Purpose

Designates a node as either having or using a virtual shared disk.

Syntax

defvsd *logical_volume_name global_group_name vsd_name*

Description

This command is run to specify logical volumes residing on globally accessible volume groups to be used as virtual shared disks.

You can use the System Management Interface Tool (SMIT) to run the **defvsd** command. To use SMIT, enter:

```
smit vsd_data
```

and select the **Define a Virtual Shared Disk** option.

Flags

-r
Resets the outgoing and expected sequence numbers for the nodes specified on the node on which the command is run. Use this flag when another node has either been rebooted, cast out, or all virtual shared disks have been reconfigured on that node. The specified nodes are also cast in.

Note: This option should be used only under direct guidance from IBM Service. It should never be used under normal circumstances.

-R
Resets the outgoing and expected sequence number for all nodes on the node on which the command is run. Use this flag after rebooting the node. All nodes in the virtual shared disk network will be cast in.

Note: This option should be used only under direct guidance from IBM Service. It should never be used under normal circumstances.

-p
Sets the level of virtual shared disk parallelism to the number specified. The valid range is 1 to 9. The default is 9. A larger value can potentially give better response time to large requests. (See *RSCT for AIX 5L: Managing Shared Disks* for more information regarding tuning virtual shared disk performance.)

This value is the *buf_cnt* parameter on the `uphysio` call that the virtual shared disk IP device driver makes in the kernel. Use `statvsd` to display the current value on the node on which the command is run.

-k
Casts out the node numbers specified on the local node. The local node ignores requests from cast out nodes. Use `-r` to cast nodes back in.

Note:

1. Before using this flag, refer to the “Restrictions” section that follows.
2. This option should be used only under direct guidance from IBM Service. It should never be used under normal circumstances.

-t
Lists the current routing table and mbuf headers cached by the virtual shared disk driver.

-T
Clears or releases all cached routes.

-v *vsd_name ...*
Resets the statistics in the number of read and write requests on the specified virtual shared disks.

-V
Resets all the configured virtual shared disk's statistics in the number of read and write requests.

-C
Resets the virtual shared disk device driver counters displayed by the `statvsd` command. Exceptions are the outgoing and expected request sequence numbers among the client and server nodes.

-K
Casts out all nodes on the local node. Local requests are still honored.

Note:

1. Before using this flag, refer to the “Restrictions” section that follows.
2. This option should be used only under direct guidance from IBM Service. It should never be used under normal circumstances.

-M
Sets the virtual shared disk maximum IP message size. This is the largest sized block of data the virtual shared disk sends over the network for an I/O request. This limit also affects local virtual shared disk I/O block size. The value is in bytes and must not be greater than the maximum transmission unit (MTU) size of the network. All nodes should use the same value. The recommended values are:

- 61440 (60KB) for a switch
- 8192 (8KB) for jumbo frame Ethernet
- 1024 (1KB) for 1500-byte MTU Ethernet

Parameters

logical_volume_name
Is the name of the logical volume you want to specify as a virtual shared disk. This logical volume must reside on the global volume group indicated. The length of the name must be less than or equal to 15 characters.

global_group_name
Is the name of the globally-accessible volume group previously defined by the **vsdvg** command where you want to specify a virtual shared disk. The length of the name must be less than or equal to 31 characters.

vsd_name
Specifies a unique name for the new virtual shared disk. This name must be unique within the RSCT peer domain, and, in order to avoid possible future naming conflicts, should also be unique across the overall cluster. The suggested naming convention is **vsdnn***gvg_name*. The length of the name must be less than or equal to 31 characters.

Note: If you specify a *vsd_name* that is already the name of another device, the **cfgvsd** command will be unsuccessful for that virtual shared disk. This error ensures that the special device files created for the name do not overlay and destroy files of the same name representing some other device type (such as a logical volume).

Security

You must have `root` authority to run this command.

Restrictions

You must issue this command from a node that is online in the peer domain. To bring a peer domain online, use the **startrpdomain** command. To bring a particular node online in an existing peer domain, use the **startrpnode** command. For more information on creating and administering an RSCT peer domain, refer to *RSCT Administration Guide* .

Examples

1. The following example specifies that, on the globally accessible volume group **vg1n1**, the logical volume known as **lv1vg1n1** is used as a virtual shared disk named **vsd1vg1n1**.

```
defvsd lv1vg1n1 vg1n1 vsd1vg1n1
```

Location

/opt/rsct/vsd/bin/defvsd

deleteX11input Command

Purpose

Deletes an X11 input extension record from the ODM (Object Data Manager) database.

Syntax

deleteX11input *DeviceName ...*

Description

The **deleteX11input** command is used to delete an X11 input extension record from the ODM database. For each *DeviceName* specified, the ODM database finds as many instances of the object as possible. This command queries the user to verify whether to delete each specific device found. A partial name may be specified.

The command is a root or system user command. Its action fails with a permissions error if an unauthorized user attempts to delete a record.

Parameter

Item	Description
DeviceName	Specifies the name of the X11 input extension device.

Error Codes

Item	Description
No DeviceName is found in ODM Database	No objects that match the specified pattern were found in the ODM database.
Usage: deleteX11input DeviceName	The user has not specified a device name.

delta Command

Purpose

Creates a delta in a SCCS file.

Syntax

delta [**-r** *SID*] [**-s**] [**-n**] [**-g** *List*] [**-p**] [**-m** *ModificationRequestList*] [**-y** [*Comment*]] *File ...*

Description

The **delta** command introduces into the named Source Code Control System (SCCS) file any changes that were made to the file version retrieved by a **get -e** command.

The **delta** command reads the g-files that correspond to the specified files (see the **get** command for a description of files created and used by SCCS) and creates a new delta. No line of a g-file can contain more than 512 characters.

If you specify a directory for the *File* value, the **delta** command performs the requested actions on all SCCS files within that directory that have been checked out previously for editing (that is, on all files with an **s.** prefix). If you specify a **-** (minus sign) in place of the *File* value, the **delta** command reads standard

input and interprets each line as the name of an SCCS file. When the **delta** command reads standard input, you must supply the **-y** flag. You must also supply the **-m** flag if the **v** header flag is set. The **delta** command reads standard input until it reaches an end-of-file character.

Note: Lines beginning with an SOH ASCII character (binary 001) cannot be placed in the SCCS file unless the SOH is quoted using a **** (backslash). SOH has special meaning to SCCS and causes an error.

Use of a **get** command on SCCS files, followed by the **delta** command on those same files, should be avoided when the **get** command generates a large amount of data. Instead, you should alternate the use of the **get** and **delta** commands.

The **delta** command saves the changes made to a particular version of an SCCS file. To use the **delta** command:

1. Use the **get -e** command to get an editable version of the file.
2. Edit that file.
3. Use the **delta** command to create a new version of the SCCS file.

The **delta** command prompts you for comments if the **-y** option is not specified. The comments apply to that particular delta and appear in the SCCS file header. The comments are not retrieved when you use the **get** command to get the delta and do not appear in the text of a retrieved file. Use comments to keep track of why a delta was created.

To see the comments, use an editor to look at the SCCS file, write the SCCS file to the display screen with the **cat** command, or print selected parts of the file to standard output using the **prs** command. Remember not to change the contents of the SCCS file directly. To change the delta comments, use the **cdc** command.

Note: Do not use the **delta** command on a file if it contains expanded identification keywords. Read-only file versions replace keywords with text values. Using the **delta** command on a read-only file causes the keywords to be lost. To recover from this situation, remove the delta or edit the file again and replace the identification keywords.

The SCCS does not allow use of the **delta** command unless an editable copy of the file exists.

To prevent the loss of keywords, use the **admin** command with the **-f** flag to specify the **i** header flag. Afterwards, the absence of keywords in a file version will cause an error.

Flags

Item	Description
-g *List*	Specifies a list of SIDs (deltas) to be ignored when the **get** command creates the g-file. After you use this flag, the **get** command ignores the specified delta when it builds the g-file.

Item	Description
-m *ModificationRequestList*	If the SCCS file has the **v** header flag set, then a Modification Request (MR) number must be supplied as the reason for creating the new delta. If you do not specify the **-m** flag, and the **v** header flag is set, the **delta** command reads MRs from standard input. If standard input is a workstation, the **delta** command prompts you for the MRs. The **delta** command continues to take input until it reads an end-of-file character. It always reads MRs before the comments (see the **-y** flag). You can use blanks, tab characters, or both to separate MRs in a list. If the **v** header flag has a value, it is interpreted as the name of a program that validates the MR numbers. If the **delta** command returns a nonzero exit value from the MR validation program, the **delta** command assumes some of the MR numbers were invalid and stops running.
-n	Retains the g-file, which is normally removed at completion of the **delta** command processing.
-p	Writes to standard output (in the format of the **diff** command) the SCCS file differences before and after the delta is applied. See the **diff** command for an explanation of the format.
-r *SID*	Specifies which delta is to be created in the SCCS file. You must use this flag only if two or more outstanding **get -e** commands were done on the same SCCS file by the same person. The *SID* value can be either the SID specified on the **get** command line or the SID to be created (as reported by the **get** command.) An error results if the specified SID cannot be uniquely identified, or if an SID must be specified but it is not.
-s	Suppresses the information normally written to standard output on normal completion of the **delta** command.
-y[*Comment*]	Specifies text that describes the reason for making a delta. A null string is considered a valid *Comment* value. If your comment line includes special characters or blanks, the line must be enclosed in single or double quotation marks. If you do not specify the **-y** flag, the **delta** command reads comments from standard input until it encounters a blank line or an end-of-file character. For keyboard input, the **delta** command prompts for the comments. If the last character of a line is a \ (backslash), it is ignored. Comments must be no longer than 512 characters.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.

Item	Description
>0	An error occurred.

Examples

1. To record changes you have made to an SCCS file, enter:

   ```
   delta s.prog.c
   ```

   This adds a delta to the SCCS file `s.prog.c`, recording the changes made by editing `prog.c`. The `delta` program then asks you for a comment that summarizes the changes you made. Enter the comment, and then enter an end-of-file character or press the return key twice to indicate that you have finished the comment.
2. To record the changes you have made to an SCCS file with a brief descriptive comment, enter:

   ```
   delta -y "This delta contains the payroll function" s.prog.c
   ```

Files

Item	Description
/usr/bin/delta	Contains the **delta** command.

deroff Command

Purpose

Removes **nroff**, **troff**, **tbl**, and **eqn** command constructs from files.

Syntax

deroff { **-ma** **-me** **-ms** [**-mm** [**-ml**]] } [**-i** | **-l**] [**-k**] [**-p**] [**-u**] [**-w**] [*File* ...]

Description

The **deroff** command reads the specified files (standard input by default) containing English-language text, removes all **troff** requests, macro calls, backslash constructs, **eqn** command constructs (between **.EQ** and **.EN** lines and between delimiters), and **tbl** command descriptions, then writes the remainder of the file to standard output.

The **deroff** command normally follows chains of included files (**.so** and **.nx troff** command requests). If a file has already been included, a **.so** request naming it is ignored and an **.nx** request naming that file ends execution.

Note: The **deroff** command is not a complete **troff** command interpreter, so it can be confused by subtle constructs. Most errors result in too much rather than too little output.

Parameters

Item	Description
File	Specifies English-language text files for the **deroff** command to remove the effects of **troff**, **eqn**, and **tbl** command processing. The default file is standard input.

Flags

Item	Description
-ma	Ignores **MA** (**man**) macros in text so that only running text is output.
-me	Ignores **ME** macros in text so that only running text is output. This is the default.
-ml	Ignores **MM** macros in text (**-mm** flag) and also deletes **MM** list structures. The **-mm** flag must be specified with this flag. **Note:** Do not use the **-ml** flag with nested lists.
-mm	Ignores **MM** macros.
-ms	Ignores **MS** macros in text so that only running text is output.
-i	Suppresses the processing of included files.
-l	Suppresses the processing of included files whose names begin with **/usr/lib**, such as macro files in **/usr/lib/tmac**.
-k	Retains blocks specified to be kept together. The default is to remove kept blocks of text; for example, the **.ne** construct is removed.
-p	Processes special paragraphs.
-u	Removes the ASCII underline and boldface control sequences. This flag automatically sets the **-w** flag.
-w	Makes the output a word list, with one word per line and all other characters deleted. Otherwise, the output follows the original. In text, a word is any string that begins with a letter, contains at least two letters, and is composed of letters, digits, ampersands (&), and apostrophes ('). In a macro call, however, a word is a string that begins with at least two letters and contains a total of at least three letters. Delimiters are any characters other than letters, digits, punctuation, apostrophes, and ampersands. Trailing apostrophes and ampersands are removed from words.

detachrset Command

Purpose

Detaches an rset from a process.

Syntax

detachrset [**-P**] *pid*

Description

The **detachrset** command detaches an rset from a process. Detaching an rset from a process will allow the process to use any of the processors and/or memory regions in the system.

Flags

Item	Description
-P	Detaches the partition rset from the specified process (*pid*).

Parameters

Item	Description
pid	Process ID.

Security

The user must have `root` authority or have CAP_NUMA_ATTACH capability and the target process must have the same effective **userid** as the command issuer. The user must have `root` authority to remove the partition rset from a process (the **-P** option).

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Example

To detach the rset from process 21414, type:

```
detachrset 21414
```

Files

Item	Description
/usr/bin/detachrset	Contains the **detachrset** command.

devinstall Command

Purpose

Installs software support for devices.

Syntax

devinstall **-f** *File* **-d** *Device* [**-s**] [**-v**]

Description

The **devinstall** command installs software support for devices. It installs the software packages listed in the file specified by the `-f` flag.

For most new devices that are added after the initial software installation, the software for the new device can be installed using the **-i** flag of the **cfgmgr** command.

In some instances, the new device replaces a device that is needed to start the machine. For example, you might be replacing the SCSI adapter card that supports the root volume group or the graphics adapter card that supports the console. In this case, the machine will not start in normal mode until you have installed software support for this new device. To do this, turn your system off and install the new hardware according to the directions included with your hardware. Next, start up your machine in maintenance mode. During the startup process, the new adapter is detected and the **/tmp/device.pkgs**

file is created containing the name of the software package needed to support the new hardware. Once the machine is in maintenance mode, you can install the software for this new device by running the **devinstall** command.

Flags

Item	Description
-f *File*	Specifies the file containing the list of packages to be installed. Typically, this will be the **/tmp/device.pkgs** file generated by the **cfgmgr** command.
-d *Device*	Specifies where the installation medium can be found. This can be a hardware device, such as tape or diskette; it can be a directory that contains installation images; or it can be the installation image file itself. When the installation media is an IBM Installation tape or IBM Corrective Service tape, the tape device should be specified as no-rewind-on-close and no-retension-on-open. Examples of this would be **/dev/rmt0.1** for a high-density tape or **/dev/rmt0.5** for a low-density tape. For non-IBM-supplied tapes, use the options specified by the tape supplier.
-s	Overwrites the **/var/adm/dev_pkg.fail** file. This file contains a list of all packages that did not install successfully and can be used to facilitate recovery or installation from a different source.
-v	Specifies the verbose option, causing the **devinstall** command to display additional information while processing.

The **devinstall** command installs the device packages listed in the file specified on the command line. It runs the **geninstall** command with the **-I** "acXge **/var/adm/ras/devinst.log**", where a: apply, c: commit, X: extend fs, e: log and **/var/adm/ras/devinst.log** is the log file full path name, g: auto_include. (See the **geninstall** command for more information on these flags.) The **devinstall** command checks the summary file generated by the **geninstall** command for the results of each package install attempt and, based on this information, creates two files. The **/var/adm/dev_pkg.fail** file lists the packages that fail to install (if any). The `/var/adm/dev_pkg.success` file lists all packages that are installed successfully.

Return Values

A return value of 0 indicates that no packages were installed.

A return value of 1 indicates that at least one package was successfully installed, and the **bosboot** command should be executed.

A return value of 2 indicates that the `devinstall` command failed.

The `/var/adm/dev_pkg.success` file lists those packages that successfully installed. The **/var/adm/dev_pkg.fail** file lists those packages that failed installation.

Security

Privilege Control: Only the root user can run this command.

Examples

To install software to support a new device after you have started the machine from the device installation tape and entered maintenance mode, enter:

```
devinstall -f /../tmp/device.pkgs -d /dev/rmt0.1
```

Then, run the **bosboot** command.

```
bosboot -ad /dev/ipldevice
```

File

Item	Description
/dev/rmtn	Specifies the raw streaming tape interface.

devnm Command

Purpose

Names a device.

Syntax

devnm *Path* ...

Description

The **devnm** command reads the *Path* parameter, identifies the special file associated with the mounted file system where the *Path* parameter resides, and writes the special file name to standard output. Each *Path* parameter must be a full path name.

The most common use of the **devnm** command is by the **/etc/rc** command file to construct a mount table entry for the root device.

Note: This command is for local file systems only.

Examples

1. To identify the device on which a file resides, enter:

   ```
   devnm /diskette0/bob/textfile
   ```

   This displays the name of the special device file on which the `/diskette0/bob/textfile` file resides. If a diskette is mounted as the `/diskette0` device, the **devnm** command displays:

   ```
   fd0 /diskette0/bob/textfile
   rfd0 /diskette0/bob/textfile
   ```

   This means the `/diskette0/bob/textfile` file resides on the **/dev/fd0** diskette drive.
2. To identify the device on which a file system resides, enter:

   ```
   devnm /
   ```

   This displays the name of the device on which the root file system(/) resides. The following list is displayed on the screen:

   ```
   hd0 /
   ```

   This means that the root file system (/) resides on the **/dev/hd0** device.

Files

Item	Description
/dev	Specifies the directory.
/usr/sbin/devnm	Contains the **devnm** command.

devrsrv Command

Purpose

Queries and breaks the single-path and persistent reservations on a device.

Syntax

devrsrv **-c** *query* [**-e**] | *release* | **prin** **-s** *sa* | (**prout** **-s** *sa* **-r** *rkey* **-k** *sa_key* **-t** *prtype*) **-l** *devicename*

devrsrv **-f** **-l** *devicename*

devrsrv **-d**

Description

The **devrsrv** command queries and breaks the single-path and persistent reservations on the device. The command runs the persistent reserve in (**prin**) and persistent reserve out (**prout**) service actions.

The **query** subcommand queries and displays the current reservation status of the device. The **release** subcommand releases the reservation on the device by using the single-path reservation.

The **prin** subcommand displays all the registered reservation keys, reservation key holder, and capabilities information. The **prout** subcommand requests service action that reserves a device for the exclusive or shared use of a particular I/O path to the device. The **prout** subcommand supports the following service actions:

Item	Description
RELEASE	Releases the specified persistent reservation for the device.
CLEAR	Clears all the reservation keys and all the persistent reservations.
PREEMPT	Preempts the persistent reservations or removes registrations, or both.
PREEMPT AND ABORT	Preempts persistent reservations or removes registrations, or both and stops all tasks for all preempted I/O paths to the device.
REGISTER AND IGNORE KEY	Registers the new key value in place of the old key value.

Flags

Item	Description
-c	Specifies the following subcommands: **query** Queries and displays the status of reservations on a device. **release** Releases the device with the single-path reservation by using SCSI-2. **prin** Specifies the persistent reservation in service action. **prout** Specifies the persistent reservation out service action.
-d	Lists the disk name and other identifying information for all disks that are queried or manipulated by using the **devrsrv** command.

Item	Description
-e	Avoids opening the disk in exclusive mode, which includes both single and diagnostic modes. This flag is applicable only for PR_exclusive and PR_shared reservation types. If Object Data Manager (ODM) reservation policy is single_path, this flag is ignored. **Note:** In some cases, if you use this flag, the **devrsrv** command might not determine the reservation status of the disk or whether the disk is already open on the local host.
-f	Breaks the reservation that is held by other I/O path or host. For single-path reservations, the **devrsrv** command issues a SC_FORCED_OPEN action to break the reservation. For persistent reservations, the **devrsrv** command issues a **prout** subcommand along with the CLEAR service action to clear the persistent reservation and the registrations.
-k	Specifies the service action reservation key. The **-k** flag is required for the REGISTER, PREEMPT, and PREEMPT_ABORT service actions.
-l	Specifies the name of the device.
-r	Specifies the reservation key. The **-r** flag is required for the REGISTER, PREEMPT, PREEMPT AND ABORT, and RELEASE service actions.
-s	Specifies the service action for persistent reservations. The valid service actions for the **prin** subcommand follow: **0** READ KEYS **1** READ RESERVATION **2** REPORT CAPABILITIES The valid service actions for the **prout** subcommand follow: **2** RELEASE **3** CLEAR **4** PREEMPT **5** PREEMPT AND ABORT **6** REGISTER AND IGNORE EXISTING KEY

Item	Description
-t	Specifies the persistent reservation type. The types of persistent reservations follow: **1** Write exclusive **2** Exclusive access **3** Write exclusive registrants only **4** Exclusive access registrants only **5** Write exclusive all registrants **6** Exclusive access all registrants

Examples

The following are the examples that are related to different scenarios.

`Query operation`

1. To query the reservation status of the `hdisk0` device when it is not reserved by any host, enter the following command:

```
# devrsrv -c query -l hdisk0
```

```
Device Reservation State Information
================================================
Device Name                     :  hdisk0
Device Open On Current Host?    :  NO
ODM Reservation Policy          :  SINGLE PATH RESERVE
Device Reservation State        :  NO RESERVE
```

   The output shows that the device is not opened on the current host and the Object Data Manager (ODM) reservation policy is SINGLE PATH RESERVE. It indicates that the reservation policy is set in the ODM for this device. The device reservation state indicates the reservation that is present on the device. You can find the device reservation state by running a sequence of SCSI commands.

2. To query the reservation status of the `hdisk1` device when it is reserved by a host, enter the following command:

```
# devrsrv -c query -l hdisk1
```

   The device is reserved by using the single path reservation by a host.

```
Device Reservation State Information
================================================
Device Name                    :  hdisk1
Device Open On Current Host?   :  NO
ODM Reservation Policy         :  SINGLE PATH RESERVE
Device Reservation State       :  SINGLE PATH RESERVE
```

3. To query the reservation status of the `hdisk2` device when it is reserved on the same host, enter the following command:

```
# devrsrv -c query -l hdisk2
```

```
Device Reservation State Information
================================================
Device Name                    :  hdisk2
```

```
Device Open On Current Host?    :  YES
ODM Reservation Policy          :  SINGLE PATH RESERVE
Device Reservation State        :  SINGLE PATH RESERVE
Path Id of Reserved Path        :  0
```

4. To query the reservation status of the hdisk2 device when the ODM reservation policy is PR SHARED and the device is not reserved by any host, enter the following command:

```
# devrsrv -c query -l hdisk0
```

```
Device Reservation State Information
==================================================
Device Name              :  hdisk0
Device Open              :  NO
ODM Reservation Policy   :  PR SHARED
ODM PR Key Value         :  7777
Device Reservation State :  NO RESERVE
Registered PR Keys       :
555
777
PR Capabilities Byte[2]  :  0xd  SIP_C   ATP_C   PTPL_C
PR Capabilities Byte[3]  :  0x0
PR Types Supported       :  NOT VALID
```

Descriptions of several fields from the query output follow:

Registered PR Keys:
Displays keys that are registered by running the **prout** subcommand along with the REGISTER service action from all I/O paths that are sharing this device.

PR Capabilities Bytes:
Indicates the content of bytes 2 and 3 returned by the REPORT CAPABILITIES service action of the **prin** subcommand. See the SPC standard to interpret the output of the Example 4.

PR Types Supported:
Displays the persistent reservation types that are supported by the device that are reported by the persistent reservation type mask field in the report capabilities output.

If the persistent reservation is held on a device, the query output displays additional information about the device reservation as follows:

PR Reservation Type:
Displays one of the values of the PR Types that are described in the Flags section.

PR Holder key Value:
Displays the PR key value of the current reservation holder. The persistent reservation key value is 0 if the PR Type is 5 or 6.

Persistent reserve in (prin) operation

1. To read all of the registered reservation keys, enter the following command:

```
# devrsrv -c prin -s 0 -l hdisk0
```

```
Registered PR Keys             :
555
777
```

2. To read the current reservation key holder and type, enter the following command:

```
# devrsrv -c prin -s 1 -l hdisk0
```

```
PR Generation Value     :  2
PR Type                 :  PR_EA_RO (EXCLUSIVE ACCESS, REGISTRANTS ONLY)
PR Holder Key Value     :  777
```

3. To return the PR capabilities information that is supported by sending the report capabilities service action, enter the following command:

```
# devrsrv -c prin -s 2 -l hdisk0
```

```
PR Capabilities Byte[2]         :  0xd  SIP_C   ATP_C   PTPL_C
PR Capabilities Byte[3]         :  0x0
PR Types Supported              :  NOT VALID
```

Persistent reserve out (prout) operation

RELEASE service action

To release the persistent reservation from IT-nexus that is registered and reserved with key 1777 and PR reservation type 4, enter the following command:

```
# devrsrv -c prout -s 2 -r 1777 -t 4 -l hdisk0
```

```
Device Reservation State Information
================================================
Device Name                     :  hdisk0
Device Open On Current Host?    :  YES
ODM Reservation Policy          :  PR SHARED
ODM PR Key Value                :  7777
Device Reservation State        :  PR SHARED
Reservation will be cleared on the device. Do you want to continue y/n:y
```

If you run the query now, the result displays the `Device Reservation State` as NO RESERVE.

```
# devrsrv -c query -l hdisk0
```

```
Device Reservation State Information
================================================
Device Name              :  hdisk0
Device Open              :  NO
ODM Reservation Policy   :  PR SHARED
ODM PR Key Value         :  7777
Device Reservation State :  NO RESERVE
Registered PR Keys       :
555
1777
PR Capabilities Byte[2]  :  0xd  SIP_C   ATP_C   PTPL_C
PR Capabilities Byte[3]  :  0x0
PR Types Supported       :  NOT VALID
```

CLEAR service action

To release the persistent reservation and to remove all the registrations from a device server that uses the CLEAR service action by using a registered I/O path with key 555, enter the following command:

```
# devrsrv -c prout -s 3 -r 555 -l hdisk0
```

```
Device Reservation State Information
================================================
Device Name                     :  hdisk0
Device Open On Current Host?    :  YES
ODM Reservation Policy          :  PR SHARED
ODM PR Key Value                :  5555
Device Reservation State        :  PR SHARED
Reservation will be cleared on the device. Do you want to continue y/n:y
```

If you run the query now, the persistent reservation is released and the registrations are removed from the device.

```
# devrsrv -c query -l hdisk0
```

```
Device Reservation State Information
================================================
Device Name              :  hdisk0
Device Open              :  NO
ODM Reservation Policy   :  PR SHARED
ODM PR Key Value         :  5555
Device Reservation State  :  NO RESERVE
```

```
Registered PR Keys        :  No Keys Registered
PR Capabilities Byte[2]   :  0xd  SIP_C   ATP_C   PTPL_C
PR Capabilities Byte[3]   :  0x0
PR Types Supported        :  NOT VALID
```

PREEMPT and PREEMPT_ABORT service actions

To preempt the persistent reservation that is held with reservation holder 444 by another IT-nexus with the registered key 777, enter the following command:

```
# devrsrv -c prout -s 4 -r 777 -k 444 -t 2 -l hdisk0
```

Before you run the `# devrsrv -c prout -s 4 -r 777 -k 444 -t 2 -l hdisk0` command, the query output is displayed as follows.

```
# devrsrv -c query -l hdisk0
```

```
Device Reservation State Information
==================================================
Device Name               :  hdisk0
Device Open               :  NO
ODM Reservation Policy    :  PR SHARED
ODM PR Key Value          :  7777
Device Reservation State  :  PR EXCLUSIVE
PR Generation Value       :  5
PR Type                   :  PR_WE (WRITE EXCLUSIVE)
PR Holder Key Value       :  444
Registered PR Keys        :
777
444
PR Capabilities Byte[2]   :  0xd  SIP_C   ATP_C   PTPL_C
PR Capabilities Byte[3]   :  0x0
PR Types Supported        :  NOT VALID
```

After you run the `# devrsrv -c prout -s 4 -r 777 -k 444 -t 2 -l hdisk0` command, the query output shows that the reservation is preempted by IT-nexus with key 777 and key 444 is unregistered.

```
# devrsrv -c query -l hdisk0
```

```
Device Reservation State Information
==================================================
Device Name              :  hdisk0
Device Open              :  NO
ODM Reservation Policy   :  PR SHARED
ODM PR Key Value         :  7777
Device Reservation State :  PR EXCLUSIVE
PR Generation Value      :  6
PR Type                  :  PR_EA (EXCLUSIVE ACCESS)
PR Holder Key Value      :  777

```

RELEASE operation for SINGLE PATH RESERVE policy

To release the reservation on the `hdisk0` device, enter the following commands:

- Scenario 1: The current host is the owner of the reservation.

```
# devrsrv -c query -l hdisk0

Device Reservation State Information
================================================
Device Name                    :  hdisk0
Device Open On Current Host?   :  YES
ODM Reservation Policy         :  SINGLE PATH RESERVE
Device Reservation State       :  SINGLE PATH RESERVE
Path Id of Reserved Path       :  0
```

```
# devrsrv -c release -l hdisk0

Device Reservation State Information
================================================
Device Name                     :  hdisk0
Device Open On Current Host?    :  YES
ODM Reservation Policy          :  SINGLE PATH RESERVE
Device Reservation State        :  SINGLE PATH RESERVE
Device is currently Open on this host by a process.Do you want to continue y/n:y
Command Successful
Reservation cleared on the device. Query operation may not work properly.
Close the application that holds the reservation and retry.
```

- Scenario 2: The current host is not the owner of the reservation.

```
# devrsrv -c query -l hdisk0

Device Reservation State Information
================================================
Device Name                     :  hdisk0
Device Open On Current Host?    :  NO
ODM Reservation Policy          :  SINGLE PATH RESERVE
Device Reservation State        :  SINGLE PATH RESERVE

Because the current host does not own the reservation on the device,
try the force option if you want to break the reservation.
```

```
# devrsrv -f -l hdisk0
```

The device is already reserved by using the single-path reservation by another host.

```
Device Reservation State Information
================================================
Device Name                     :  hdisk0
Device Open On Current Host?    :  NO
ODM Reservation Policy          :  SINGLE PATH RESERVE
Device Reservation State        :  SINGLE PATH RESERVE
Reservation will be cleared on the device. Do you want to continue y/n:y
```

After you run the release command successfully, the query option must display NO RESERVE as the device reservation state.

```
# devrsrv -c query -l hdisk0

Device Reservation State Information
================================================
Device Name                     :  hdisk0
Device Open On Current Host?    :  NO
ODM Reservation Policy          :  SINGLE PATH RESERVE
Device Reservation State        :  NO RESERVE
```

Forced mode

The hdisk0 device is reserved with key 777 from another I/O path. To release this reservation from the other client, enter the following command:

```
# devrsrv -f -l hdisk0

Device Reservation State Information
================================================
Device Name                     :  hdisk16
Device Open On Current Host?    :  NO
ODM Reservation Policy          :  PR SHARED
ODM PR Key Value                :  5555
Device Reservation State        :  PR SHARED
Reservation will be cleared on the device. Do you want to continue y/n:y
Command Successful
```

Before you run the # devrsrv -f -l hdisk0 command, the query displays the following output:

```
# devrsrv -c query -l hdisk0

Device Reservation State Information
================================================
```

```
Device Name                :  hdisk0
Device Open                :  NO
ODM Reservation Policy     :  PR SHARED
ODM PR Key Value           :  5555
Device Reservation State   :  PR EXCLUSIVE
PR Generation Value        :  1
PR Type                    :  PR_WE (WRITE EXCLUSIVE)
PR Holder Key Value        :  777
Registered PR Keys         :
777
PR Capabilities Byte[2]    :  0xd  SIP_C   ATP_C   PTPL_C
PR Capabilities Byte[3]    :  0x0
PR Types Supported         :  NOT VALID
```

After you execute the `# devrsrv -f -l hdisk0` command, the output indicates that the device is not reserved.

```
# devrsrv -c query -l hdisk0

Device Reservation State Information
================================================
Device Name                    :  hdisk16
Device Open On Current Host?   :  NO
ODM Reservation Policy         :  PR SHARED
ODM PR Key Value               :  5555

PR Capabilities Byte[3]        :  0x0
PR Types Supported             :  NOT VALID
```

df Command

Purpose

Reports information about space on file systems. This document describes the AIX **df** command as well as the System V version of **df**.

Syntax

df [[**-P**] | [**-I** | **-M** | **-i** | **-t** | **-v**]] [**-c**] [**-T** { `local` | `remote` | `vfstype`}] [**-F** {*output1 output2 output3 ...*}] [**-k**] [**-m**] [**-g**] [**-s**] [*FileSystem ...* | *File...*]

Description

The **df** command displays information about total space and available space on a file system. The *FileSystem* parameter specifies the name of the device on which the file system resides, the directory on which the file system is mounted, or the relative path name of a file system. The *File* parameter specifies a file or a directory that is not a mount point. If the *File* parameter is specified, the **df** command displays information for the file system on which the file or directory resides. If you do not specify the *FileSystem* or *File* parameter, the **df** command displays information for all currently mounted file systems. File system statistics are displayed in units of 512-byte blocks by default.

The **df** command gets file system space statistics from the **statfs** system call. However, specifying the **-s** flag gets the statistics from the virtual file system (VFS) specific file system helper. If you do not specify arguments with the **-s** flag and the helper fails to get the statistics, the **statfs** system call statistics are used. Under certain exceptional conditions, such as when a file system is being modified while the **df** command is running, the statistics displayed by the **df** command might not be accurate.

Note: Some remote file systems, such as the Network File System (NFS), do not provide all the information that the **df** command needs. The **df** command prints blanks for statistics that the server does not provide.

The **df** command does not fully support NFSv4 filesystems. Use the **nfs4cl** command to extract block and space information.

Flags

Item	Description
-c	Displays the output in colon separated format.
-F { *output1 output2 output3* ... }	Displays only those values that are specified by the headings in the output parameters. By default, the file system and blocks-allocated headings are always turned on. The following values are acceptable for headings: **%m** Mounted on **%u** Used **%z** Percentage used **%f** Free **%l** Inodes used **%n** Inodes free **%p** Percentage of inodes used
-g	Displays statistics in units of GB blocks. The output values for the file system statistics would be in floating point numbers as value of each unit in bytes is significantly high.
-i	Displays the number of used inodes and the percentage of inodes in use for the file system. This output is the default when the specified file system is mounted.
-I	Displays information on the total number of blocks, the used space, the free space, the percentage of used space, and the mount point for the file system.
-k	Displays statistics in units of 1024-byte blocks.
-m	Displays statistics in units of MB blocks. The output values for the file system statistics would be in floating point numbers as value of each unit in bytes is significantly high.
-M	Displays the mount point information for the file system in the second column.
-P	Displays information on the file system in POSIX portable format. When the **-P** flag is specified, the header line appears similar to: `Filesystem 512-blocks Used Available Capacity Mounted on\n` If the **-k**, **-m** or **-g** flag is specified in addition to the **-P** flag, the column heading 512-blocks is replaced by the respective units, depending on which of these flags is used with the **-P** flag. File system statistics are displayed on one line in the following order: *FileSystem, TotalSpace, UsedSpace, FreeSpace, UsedPercentage, MountPoint*
-s	Displays statistics on unmounted JFS or Enhanced JFS file systems by the command line arguments. If there are no arguments specified, the `-s` flag has no effect. If the file systems specified by the argument are currently mounted or an argument is a file, the `-s` flag has no effect for that particular argument. To collect statistics on unmounted file systems, an argument must be a JFS or Enhanced JFS file system mount point or device, the file system must be listed in **/etc/filesystems**, and the user must have read access to the device.
-t	Includes figures for total allocated space in the output.

Item	Description
-T {local|remote|vfstype}	Filters the output by the type of file system. This flag can have one of the following parameters: **local** Displays only the Journaled File System (JFS) and Enhanced Journaled File System (JFS2) file systems. **remote** Displays all non-local file systems. **vfstype** Displays file systems only of a specific virtual file system (VFS), for example, JFS, JFS2, Network File System version 4 (NFSv4), and so on.
-v	Displays all information for the specified file system.

The values of the output parameters with the flags **-m** and **-g** would be rounded off to nearest second decimal digit. If all or any two of the **-k**, **-m** and **-g** flags are specified, the last one specified takes effect.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To display information about all mounted file systems, enter:

   ```
   df
   ```

   If your system has the **/**, **/usr**, **/site**, and **/usr/venus** file systems mounted, the output from the **df** command resembles the following:

   ```
   Filesystem 512-blocks Free   %Used   Iused  %Iused  Mounted on
   /dev/hd0    19368     9976    48%     4714    5%     /
   /dev/hd1    24212     4808    80%     5031   19%     /usr
   /dev/hd2     9744     9352     4%     1900    4%     /site
   /dev/hd3     3868     3856     0%      986    0%     /usr/venus
   ```

2. To display information about /test file system in 1024-byte blocks, enter:

   ```
   df -k /test
   ```

   ```
   Filesystem    1024 blocks    Free    %Used   Iused  %Iused  Mounted on
   /dev/lv11         16384     15824       4%      18      1%  /tmp/ravi1
   ```

   This displays the file system statistics in 1024-byte disk blocks.

3. To display information about /test file system in MB blocks, enter:

   ```
   df -m /test
   ```

   ```
   Filesystem    MB blocks    Free    %Used    Iused  %Iused  Mounted on
   /dev/lv11       16.00     15.46       4%       18      1%  /tmp/ravi1
   ```

   This displays file system statistics in MB disk blocks rounded off to nearest 2nd decimal digit.

4. To display information about the **/test** file system in GB blocks, enter:

```
df -g /test
```

```
Filesystem    GB blocks   Free     %Used    Iused  %Iused  Mounted on
/dev/lv11          0.02   0.02        0%       18      1%  /tmp/ravi1
```

   This displays file system statistics in GB disk blocks rounded off to nearest 2nd decimal digit.

5. To display available space on the file system in which your current directory resides, enter:

```
cd/
df .
```

   The output from this command resembles the following:

```
Device   512-blocks  free   %used   iused   %iused  Mounted on
/dev/hd4    19368    9976    48%     4714    5%     /
```

6. To display the output in a colon separated format, enter:

```
df -c
```

   The output resembles the following example:

```
Filesystem:512-blocks:Free:%Used:Iused:%Iused:Mounted on
/dev/hd4:491520:113168:77%:9930:42%:/
/dev/hd2:5046272:27696:100%:43014:86%:/usr
```

7. To display information about all the file systems that are mounted locally, enter:

```
df -T local
```

   The output resembles the following example:

```
Filesystem    512-blocks      Free  %Used    Iused %Iused Mounted on
/dev/hd4          5898240   2104184   65%    16390     7%  /
/dev/hd2          7602176   1698696   78%    56001    23%  /usr
/dev/hd9var       3014656   2190976   28%    10987     5%  /var
/dev/hd3          2883584   2137928   26%     1213     1%  /tmp
/dev/hd1          655360    645240    2%     1727     3%   /home
/dev/hd11admin    262144    261384    1%        5     1%   /admin
/proc                  -         -    -         -     -    /proc
/dev/hd10opt      786432    362672   54%     8926    18%   /opt
/dev/livedump     524288    523552    1%        4     1%   /var/adm/ras/livedump
/aha                   -         -    -       328     2%   /aha
```

8. To display information about all the JFS2 file systems, enter:

```
df -T jfs2
```

   The output resembles the following example:

```
Filesystem     512-blocks      Free %Used    Iused %Iused Mounted on
/dev/hd4          5898240   2104184   65%    16390     7%  /
/dev/hd2          7602176   1698696   78%    56001    23%  /usr
/dev/hd9var       3014656   2190976   28%    10987     5%  /var
/dev/hd3          2883584   2137928   26%     1213     1%  /tmp
/dev/hd1          655360    645240    2%     1727     3%   /home
/dev/hd11admin    262144    261384    1%        5     1%   /admin
/dev/hd10opt      786432    362672   54%     8926    18%   /opt
/dev/livedump     524288    523552    1%        4     1%   /var/adm/ras/livedump
```

9. To display the `free`, `used`, and `mounted` on information about all the JFS2 file systems, enter:

```
df -T jfs2 -F %f %u %m
```

   The output resembles the following example:

```
Filesystem    512-blocks      Free %Used    Mounted on
/dev/hd4         5898240   2104184   65%    /
```

```
/dev/hd2         7602176   1698696   78%    /usr
/dev/hd9var      3014656   2190976   28%    /var
/dev/hd3         2883584   2137928   26%    /tmp
/dev/hd1          655360    645240    2%    /home
/dev/hd11admin     262144    261384         /admin
/dev/hd10opt       786432    362672         /opt
/dev/livedump      524288    523552        /var/adm/ras/livedump
```

Files

Item	Description
/etc/filesystems	Lists the known file systems and defines their characteristics.
/etc/vfs	Contains descriptions of virtual file system types.

System V df Command

Purpose

Reports number of free disk blocks and files.

Syntax

/usr/sysv/bin/df [**-a**] [**-l**] [[[**-e**] [**-g**] [**-n**]] | [[**-i**] [**-v**]] | **-t**]] [*FileSystem* ...] [*File* ...]

Description

The **df** command displays information about total space and available space on a file system. File system statistics are displayed in units of 512-byte blocks

Flags

Item	Description
-a	Performs the default operation and prints the mount point, the device name, number of free blocks and number of used inodes (files).
-e	Print only the number of free files.
-g	Print the entire **statvfs** structure. This option overrides the **-a** , **-e**, **-i**, **-n**, **-t** and **-v** options. The numbers for available, total, and free blocks are reported in 512 byte blocks.
-i	Displays the total number of inodes, the number of free inodes, the number of used inodes, and the percentage of inodes in use.
-l	Reports on local file systems only.
-n	Prints the type of filesystem.
-t	Causes total allocated block figures to be reported.
-v	Reports percent of blocks used as well as the number of blocks used and free.

Parameters

Item	Description
File	The *File* parameter specifies a file or a directory that is not a mount point. If the *File* parameter is specified, the **df** command displays information for the file system on which the file or directory resides.
FileSystem	The *FileSystem* parameter specifies the name of the device on which the file system resides, the directory on which the file system is mounted, or the relative path name of a file system.

Note: If the *FileSystem* or *File* parameter is not specified, the **df** command displays information for all currently mounted file systems.

Exit Status

0
The command completed successfully

>0
An error occurred.

Examples

1. To display information about all mounted file systems, enter:

```
/usr/sysv/bin/df
```

   The output looks similar to the following:

```
/              (/dev/hd4       ):     19656 blocks    1504 files
/usr           (/dev/hd2       ):   1139904 blocks   20254 files
/var           (/dev/hd9var    ):     23096 blocks     512 files
/tmp           (/dev/hd3       ):      2464 blocks     204 files
/home          (/dev/hd1       ):     44208 blocks     146 files
/proc          (/proc          ):         0 blocks       0 files
/opt           (/dev/hd10opt   ):     13880 blocks     310 files
```

2. To display information about the file system in which your current directory resides, enter:

```
/usr/sysv/bin/df .
```

3. To display the total number of inode, the number of free inodes and the number of available inodes in all mounted file systems, enter:

```
/usr/sysv/bin/df -i
```

   The output looks similar to the following:

```
Mount Dir  Filesystem      iused    avail    itotal  %iused
/          /dev/hd4         1504     6688      8192     19%
/usr       /dev/hd2        20254   127202    147456     14%
/var       /dev/hd9var       512     3584      4096     13%
/tmp       /dev/hd3          204     5940      6144      4%
/home      /dev/hd1          146    14190     14336      2%
/proc      /proc               0        0         0       0
/opt       /dev/hd10opt      310     5834      6144      6%
```

4. To display the total number of blocks , the number of used blocks and the number of free blocks on a the **/tmp** file system, enter:

```
/usr/sysv/bin/df -v /tmp
```

5. To display the type of filesystem, enter:

```
/usr/sysv/bin/df -n
```

6. To display inode information on all local filesystems, enter:

```
/usr/sysv/bin/df -i -l
```

7. To display the statvfs structure information on all the filesystems, enter:

```
/usr/sysv/bin/df -g
```

8. To display the number of free files on filesystems, enter:

```
/usr/sysv/bin/df -e
```

Files

Item	Description
/usr/sysv/bin/df	Contains the System V **df** command.
/etc/filesystems	Contains filesystem information.

dfmounts Command

Purpose

Displays mounted resource information.

Syntax

dfmounts [**-F** *fstype*] [**-h**] [*server* ...]

Description

The **dfmounts** command prints local systems that are remotely mounted by clients through Network File System (NFS). It also prints the list of clients that have mounted the resource. The **dfmounts** command prints a header that is followed by a list of resource information separated with whitespace characters within fields.

For each resource, the following fields are displayed:

RESOURCE
For NFS, a hyphen "-" is marked.

SERVER
Indicates the machine from which the resource was mounted.

PATHNAME
Indicates the path of the shared resource.

CLIENTS
A comma separated list of systems that currently have the resource mounted.

Flags

Item	Description
-F *fstype*	Specifies the File System Type (fstype). Only **nfs** type of file system is supported.
-h	Suppress the header line in the output of **dfmounts**.

Parameters

Item	Description
Server	Represents a system on the network that had made its resources available to the local system. *Server* prints the resources that is made available from the machine together with the current clients using each resource. If this parameter is not specified, then the **dfmounts** command prints information by assuming that server is the local system. Multiple server names can be provided with the **dfmounts** command.

Exit Status

0
The command completed successfully

>0
An error occurred.

Security

Examples

1. To print the mounted resource information on the system "mercury" for file system type "**nfs**", enter:

```
dfmounts -F nfs mercury
```

2. To print mounted resource information without header on the system for file system type "**nfs**", enter:

```
dfmounts -hF nfs
```

Files

Item	Description
/usr/bin/dfmounts	Contains the generic System V **dfmounts** command.
/usr/lib/fs/nfs/dfmounts	Contains the System V **dfmounts** command for nfs.
/etc/vfs	Contains the description for known virtual file system implementations.

dfpd Command

Purpose

Provides load statistics about servers being load balanced to the Load Manager.

Syntax

/usr/sbin/dfpd [**-d**] [**-f** *ConfigurationFile*]

Description

The DFP daemon (**dfpd**) runs on the server being load balanced and provides load statistics about the server to the Load Manager. This enables the Load Manager to send future connections to the servers that are more available which helps in balancing the load.

When the **dfpd** daemon starts, it reads its configuration information from the file specified in the *ConfigurationFile* parameter. If the parameter is not specified, the **dfpd** daemon reads its configuration information from the **/etc/dfpd.conf** file.

Once started, the **dfpd** daemon listens for connections from the Load Manager on the port specified in the configuration file.

DFP daemon Configuration File

The **/etc/dfpd.conf** file can be updated by editing it. The entries in the **/etc/dfpd.conf** file include the following information:

The MD5 key entry specifies the secret key (up to 64 characters) that should be the same between the DFP clients, server and the Load Manager. An example of the MD5 key entry is:

```
md5key 1234567890abcdefabcdef12345678901234567890abcdefabcdef1234567890
```

The Load Manager listener entry specifies the port on which the DFP server listens for Load Manager connection. An example of the Load Manager entry is:

```
ldlistener 9503
```

The poll idle time entry specifies the period between successive computations of the CPU idle time. An example of the poll idle time entry is:

```
pollidletime 30
```

The computed idle time is multiplied by the *mfactor* value before reporting the time to the Load Manager. This is useful in rationalizing the weights among machines of different capacities. The default value is the number of CPUs on the host. An example of the mfactor entry is:

```
mfactor 1
```

Flags

Item	Description
-d	Runs in debug mode and does not become a daemon process.
-f *ConfigurationFile*	Causes the daemon to use the specified *ConfigurationFile*.

dfsck Command

Purpose

Checks and repairs two file systems simultaneously on different drives.

Syntax

dfsck [*FlagList1*] *FileSystem1* [*FlagList2*] *FileSystem2*

Description

The **dfsck** command lets you simultaneously check two file systems on two different drives. Use the *FlagList1* and *FlagList2* parameters to pass flags and parameters for the two sets of file systems. For a list of valid flags for *FlagList1* and *FlagList2*, see the flags section. Use a **-** (minus sign) to separate the file system groups if you specify flags as part of the arguments.

The **dfsck** command permits you to interact with two **fsck** commands at once. To aid in this, the **dfsck** command displays the file system name with each message. When responding to a question from the **dfsck** command, prefix your response with a 1 or a 2 to indicate whether the answer refers to the first or second file system group.

Attention: Do not use the **dfsck** command to check the root file system.

Flags

Item	Description
-d*BlockNumber*	Searches for references to a specified disk block. Whenever the **fsck** command encounters a file that contains a specified block, it displays the i-node number and all path names that refer to it.

Item	Description
-f	Performs a fast check. Under normal circumstances, the only file systems likely to be affected by halting the system without shutting down properly are those that are mounted when the system stops. The **-f** flag prompts the **fsck** command not to check file systems that were unmounted successfully. The **fsck** command determines this by inspecting the **s_fmod** flag in the file system superblock. This flag is set whenever a file system is mounted and cleared when it is unmounted successfully. If a file system is unmounted successfully, it is unlikely to have any problems. Because most file systems are unmounted successfully, not checking those file systems can reduce the checking time.
-i*i-NodeNumber*	Searches for references to a specified i-node. Whenever the **fsck** command encounters a directory reference to a specified i-node, it displays the full path name of the reference.
-n	Assumes a no response to all questions asked by the **fsck** command; does not open the specified file system for writing.
-o *Options*	Passes comma-separated options to the **fsck** command. These options are assumed to be file system implementation-specific, except that the following are currently supported for all file systems: **mountable** Causes the **fsck** command to exit with success, returning a value of 0, if the file system in question is mountable (clean). If the file system is not mountable, the **fsck** command exits returning with a value of 8. **mytype** Causes the **fsck** command to exit with success (0) if the file system in question is of the same type as either specified in the **/etc/filesystems** file or by the **-V** flag on the command line. Otherwise, 8 is returned. For example, `fsck -o mytype -V jfs /` exits with a value of 0 if **/** (the root file system) is a journaled file system.
-p	Does not display messages about minor problems but fixes them automatically. This flag does not grant the wholesale license that the **-y** flag does and is useful for performing automatic checks when the system is started normally. You should use this flag as part of the system startup procedures, whenever the system is being run automatically. Also allows parallel checks by group.
-t*File*	Specifies a *File* parameter as a scratch file on a file system other than the one being checked, if the **fsck** command cannot obtain enough memory to keep its tables. If you do not specify the **-t** flag and the **fsck** command needs a scratch file, it prompts you for the name of the scratch file. However, if you have specified the **-p** flag, the **fsck** command is unsuccessful. If the scratch file is not a special file, it is removed when the **fsck** command ends.
-V *VfsName*	Uses the description of the virtual file system specified by the *VFSName* variable for the file system instead of using the **/etc/filesystems** file to determine the description. If the **-V** *VfsName* flag is not specified on the command line, the **/etc/filesystems** file is checked and the **vfs=***Attribute* of the matching stanza is assumed to be the correct file system type.
-y	Assumes a yes response to all questions asked by the **fsck** command. This flag lets the **fsck** command take any action it considers necessary. Use this flag only on severely damaged file systems.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges,

see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To simultaneously check two file systems on two different drives, enter:

   ```
   dfsck  -p /dev/hd1 -  -p /dev/hd7
   ```

   This command checks both file systems simultaneously, if the file systems on the **/dev/hd1** and **/dev/hd7** devices are located on two different drives. You can also specify the file system names found in the **/etc/filesystems** file.

Files

Item	Description
/usr/sbin/dfsck	Contains the **dfsck** command.
/etc/filesystems	Lists the known file systems and defines their characteristics.
/etc/vfs	Contains descriptions of virtual file system types.
/etc/rc	Contains commands (including the **fsck** command) that are run when the system is started.

dfshares Command

Purpose

Lists available resources from remote systems.

Syntax

dfshares [**-F** *FileSystemType*] [**-h**] [*Server* ...]

Description

The **dfshares** command provides information about resources that are available to the host through the Network File System. The **dfshares** command prints a header line, followed by a list of lines that contain white spaces as field separators.

For each resource, the following fields are displayed:

RESOURCE
Displays the resource name that is exported in the form of server:path.

SERVER
Displays the machine that is providing the resource.

ACCESS
Displays the access permissions granted to the client systems. However, **dfshares** cannot determine this information for a NFS resource and therefore populates the field with a hyphen ("-").

TRANSPORT
Displays the transport provider over which the resource is shared. However, **dfshares** cannot determine this information for a NFS resource and therefore populates the field with a hyphen ("-").

Flags

Item	Description
-F *FileSystemType*	Specifies the filesystem type. Only **nfs** type of filesystem is supported.
-h	Suppress the header line in the output of **dfshares**.

Parameters

Item	Description
Server	Represents a system on the network that has provided resources to the local machine. If this parameter is not specified, then the **dfshares** command prints the information for the local system, itself. More than one server name can be specified with **dfshares**.

Exit Status

0
The command completed successfully.

>0
An error occurred.

Examples

1. To print the resource information on the system "mercury" for an **nfs** type filesystem, enter:

```
dfshares -F nfs mercury
```

2. To print resource information without header on the system, enter:

```
dfshares -hF nfs
```

Files

Item	Description
/usr/bin/dfshares	Contains the generic System V **dfshares** command.
/usr/lib/fs/nfs/dfshares	Contains the System V **dfshares** command for filesystems of type **nfs**.
/etc/vfs	Contains the descriptions for known virtual filesystem implementations.

dhcpaction Command

Purpose

Provides a script that runs every time that a client updates its lease.

Syntax

/usr/sbin/dhcpaction *HostName DomainName IPAddress LeaseTime ClientID* { **A** | **PTR** | **BOTH** | **NONE** } { **NONIM** | **NIM** }

Description

The **dhcpaction** command provides methods to update the DNS server by calling the **nsupdate** command with the appropriate sequence of events to update the A record, PTR record, or both.

The **dhcpaction** command is called by the DHCP client and server daemons. It is called from the updateDNS string. This setting is configurable because in some environments, mainly heterogeneous ones, some clients might not be able to update the A record or the PTR record. The default action is for the client to update the A record and the server to update the PTR record. The options might be set in the daemon configuration files to allow for any policy that the network administrator wants to implement.

The **dhcpaction** command also runs NIM and DHCP concurrently. The **dhcpaction** command, when provided with the NIM parameter, tries to issue updates to NIM objects when their IP addresses change. This action keeps the objects in sync. To do so, some pending operations might have to be canceled. The objects are commented and a message is sent to the console of the master machine. The objects must not be reset often. Addresses must not commonly change in the DHCP environment. Only the clients must set the NONIM option.

Parameters

Item	Description
ClientID	Specifies the client ID to use when you update the DNS server.
DomainName	Specifies the domain name to use when you update the DNS server.
HostName	Specifies the host name to update in the DNS server.
IPAddress	Specifies the IP address to associate with the host name in the DNS server.
LeaseTime	Specifies the duration of the association between the host name and IP address in the DNS server in seconds.

Options

Item	Description
A | PTR | BOTH | NONE	Specifies which record (if any) is to be updated in the DNS server.
NONIM | NIM	Specifies whether the script must run to help NIM and DHCP interact correctly. It must be set only to NIM on DHCP servers.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Access Control: Any user, but might need to be root for some NIM actions.

Files

Item	Description
/usr/sbin/dhcpaction	Contains the **dhcpaction** command.
/etc/dhcpcd.ini	Contains the DHCP client configuration file.

dhcpcd Daemon

Purpose

Implements a Dynamic Host Configuration Protocol (DHCP) client. Serves addresses and configuration information to the DHCP server.

Syntax

To implement a DHCP client by using the System Resource Controller (SRC):

startsrc -s dhcpcd [**-a** *Argument*] ...

To implement a DHCP client without using SRC:

dhcpcd [**-f** *ConfigurationFile*] [**-i** *IPAddress*] [**-l** *LeaseFile*] [**-n**] [**-o** *OptionsFile*] [**-r**] [**-t** *Seconds*] [**-T** *Minutes*]

Description

The **dhcpcd** daemon implements a DHCP client by setting up IP (Internet Protocol) addresses and other parameters by using the DHCP protocol.

The **dhcpcd** daemon is normally started by the `/etc/rc.tcpip` file that normally runs at start time. By default, it is commented out and not run on system startup. There are System Management Interface Tool (SMIT) options to enable the DHCP client.

The **dhcpcd** daemon reads its configuration file and attempts to start and get an IP address and other configuration options for the interfaces specified within the configuration file. The **dhcpcd** daemon runs in the background while the system is up. It renews an already received address as required.

The **dhcpcd** daemon also runs in DHCP Inform mode when the **-i** flag is used. By using this mode, a client can retrieve configuration information from a DHCP server without getting an IP address. It is useful for static addresses, but not for dynamic items like print servers and other options. When you use the **-i** flag with an IP address parameter, the **dhcpcd** daemon runs once for the specified address.

The **refresh** command can be used to cause the **dhcpcd** daemon to reread the configuration file. A SIGHUP might also be used to get the same response.

The default configuration file for the **dhcpcd** daemon is `/etc/dhcpcd.ini`. It contains logging and network interface information.

You can use the SMIT **smit usedhcp** fast path to run this command.

Flags

Item	Description
-f *ConfigurationFile*	Specifies the configuration file to be used. The default is the `/etc/dhcpcd.ini` file.
-i *IPAddress*	Specifies that the **dhcpcd** daemon must use DHCP Inform mode. The IP address tells DHCP on which interface to get configuration information.
-l *LeaseFile*	Specifies a different lease file. The lease file gets generated by the client when it obtains a lease. By default, the lease file is `/etc/dhcpc.db`.
-n	Prevents the interface from being reconfigured when it receives a new address.
-o *OptionsFile*	Specifies the options file. By default, the options file is `/etc/dhcpc.opt`.

Item	Description
-r	Brings up the client daemon and then down when run once.
-t *Seconds*	Specifies the number of seconds that DHCP waits before it places itself in the background. It allows a system to continue booting if a DHCP server cannot be found.
-T *Minutes*	Specifies the time in minutes. If the DHCP client fails to configure an address for an interface (for example, because of non-availability of DHCP server) within this timeout value, it stops further attempts.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Access Control: You must have root authority to run this command.

Files

Item	Description
`/usr/sbin/dhcpcd`	Contains the **dhcpcd** daemon.
`/etc/dhcpcd.ini`	Contains the default client configuration file
`/etc/services`	Defines sockets and protocols that are used for internet services.
`/etc/inetd.conf`	Defines the services that are controlled by the **inetd** daemon.

dhcpcd6 Daemon

Purpose

Implements a Dynamic Host Configuration Protocol for IPv6 (DHCPv6) client. Obtains IPv6 addresses and configuration information for an IPv6 node from the DHCPv6 server.

Syntax

To start a DHCPv6 client by using the System Resource Controller (SRC):

startsrc -s dhcpcd6 [**-a** *Argument*] ...

To start a DHCPv6 client without using SRC:

dhcpcd6 [**-f** *ConfigurationFileName*] [**-u** *Client_duid_File*] [**-p** *ClientPort*] [**-t** *SolicitTimeout*]

Description

The **dhcpcd6** daemon implements a DHCPv6 client by setting up IPv6 (Internet Protocol version 6) addresses and other parameters by using the DHCPv6 protocol.

The **dhcpcd6** daemon is normally started by the `/etc/rc.net` file that normally runs at boot time. By default, it is commented out and not run on machine startup. The **dhcpcd6** daemon runs in the background while the system is up.

The **dhcpcd6** daemon reads its configuration file and attempts to bring up and get one or more IPv6 addresses and other configuration options for the interfaces specified within the configuration file. The addresses that are obtained from the server are renewed as mandated by the server.

When a DHCPv6 client does not need to have a DHCPv6 server assign it IPv6 addresses, the client can obtain only configuration information such as a list of available DNS servers or NTP servers. It is useful when the node is configured with static addresses.

The **refresh** command can be used to cause the **dhcpcd6** daemon to reread the configuration file. A SIGHUP might also be used to get the same response.

The default **dhcpcd6** configuration file is `/etc/dhcpv6/dhcpc6.cnf`. It contains logging and network interface information.

Flags

Item	Description
-f *ConfigurationFileName*	Specifies the configuration file to be used. Default is `/etc/dhcpv6/dhcpc6.cnf`.
-p *ClientPort*	Specifies the client port to be used. Default is 546.
-t *SolicitTimeout*	Specifies the time until the client solicits configuration information from the server before exiting.
-u *Client_duid_File*	Specifies the client identifier file to be used. Default is `/etc/dhcpv6/dhcpc6.duid`.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Access Control: You must have root authority to run this command.

Examples

1. To start the DHCPv6 client with the configuration file `dhcpcd6.cnf` located in `/usr/local`, type the following command:

```
startsrc -s dhcpcd6 -a "-f /usr/local/dhcpcd6.cnf"
```

Location

`/usr/sbin/dhcpcd6`

Files

Item	Description
`/usr/sbin/dhcpcd6`	Contains the **dhcpcd6** client daemon.
`/etc/dhcpv6/dhcpc6.cnf`	Contains the default configuration file.
`/etc/dhcpv6/dhcpc6.db`	Contains the client lease file. This file is created by the client daemon and is not configurable.
`/etc/dhcpv6/dhcpc6.duid`	Contains the client identifier file. This file is created by the client daemon and is not configurable.

dhcprd Daemon

Purpose

Forwards BOOTP and Dynamic Host Configuration Protocol (DHCP) packets off the local network.

Syntax

To forward information to the DHCP server by using the System Resource Controller (SRC):

startsrc -s dhcprd [**-a** *Argument*] [**-a** *Argument*] ...

To forward information to the DHCP server without using SRC:

dhcprd [**-f** *ConfigurationFile*]

Description

The **dhcprd** daemon listens for broadcast packets, receives them, and forwards them to the appropriate server. It keeps broadcasts from having to be propagated to other networks. The DHCP relay agent handles the forwarding of the DHCP and BOOTP client broadcast packets off the local network and on to a set of servers. The initial packets that are sent by a BOOTP or DHCP client are broadcasts on the local interface of the client system. These packets are not allowed to be passed through network gateways and routers. A BOOTP or DHCP relay agent, the **dhcprd** daemon, sends these packets to the appropriate servers.

The DHCP Server reads `/etc/services` file to determine which port it must use for receiving requests. The default service is **dhcps**. Because it is the same port that the **bootpd** daemon uses, you can have only one (either **dhcprd** or **bootpd**) daemon running. If you choose the **dhcprd** daemon, you must uncomment **bootp** from the `/etc/inetd.conf` file, then type `refresh -s inetd` on the command line.

Note: If the **bootpd** daemon is running, this program must be stopped before you start the daemons.

Flags

Item	Description
-f *ConfigurationFile*	Specifies the configuration file to be used. The default is the `/etc/dhcprd.cnf` file.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Access Control: You must have root authority to run this command.

Files

Item	Description
/usr/sbin/dhcprd	Contains the **dhcprd** daemon.
/etc/dhcprd.cnf	Contains the default configuration file.
/etc/services	Defines sockets and protocols that are used for internet services.
/etc/inetd.conf	Defines the services that are controlled by the **inetd** daemon.

dhcpsconf Command

Purpose

Simplifies DHCP (Dynamic Host Configuration Protocol) server configuration through a graphical user interface (GUI).

Syntax

dhcpsconf

Description

The **dhcpsconf** command opens an X Window System GUI that lets the network administrator read, save, and modify configuration files. It also lets you start, stop, and retrieve statistics from a running server.

The **dhcpsconf** command displays a set of lists. The lists on the left show the available options and keys. The **dhcpsconf** command reads the /etc/options file to determine its basic options and keys and starts with these as generic resource types. The GUI lets the network administrator define a set of named resources by selecting the resource menu button.

The resource definition dialog box lets the network administrator generate all the options and specifics that are on the networks. The network administrator can define and name the network, printers, name servers, DHCP servers, and other valid resource objects. Once it is done, these new resources are added to the key and option display on the main panel. These resources can be used to generate a server configuration file or set of server configuration files.

The GUI starts with an empty master file. A master file might contain either a single server or the definition of many servers and one actual server readable file. The master file is readable by one DHCP server, but multiple server information can be stored in it. It lets the network administrator configure a single server image of the network, create a set of servers to handle the same set of data, and view and maintain it all in one file.

Options and keys are added to the server window by selecting the key or option, selecting where in the edit window the option or key must go, and selecting the add button corresponding to the key or option section. The option is added to the edit window at the position specified. If the item is a named resource,

then it is added as is. If the item is one of the standard defaults, then a window that is requesting a value for the item appears.

DHCP servers are added just like other keys, except that they specify systems in the network that are responsible for the items within their scope. The keys have scoping and syntactic ordering. Comments are not really keys, but they are allowed anywhere.

A server might have a network, class, client, or options that are specified within it. A network might have a subnet, class, client, or option. A subnet might have a class, client, or options. A class and client might have only options.

The servers have a set of configuration parameters that apply only to them. These are specified by the DHCP server key in the key list, or by using the default server options under the Server menu bar. The default server options apply to the master file. A DHCP Server specified within the master file receives the default options, but may be modified.

Any item that is placed in the **Edit** window might be edited, renamed, viewed, or deleted. It lets you place an item, see whether it looks appropriate and change as necessary.

Upon completion of the configuration file, a single master file might be saved and a set of server files might be generated. The `File menu` button and `Server menu` button both have save options. The `File save` button is for saving the master file. The `Server save` button is for saving a particular server to a file.

The `File menu` button also contains a quit option, an open option to retrieve a file, and a new option to erase everything that is created so far.

The `Operations menu` button contains a status button, a start button, a stop button, a refresh, and a send configuration file button. From these buttons, a remote server can report status, refresh itself with a new configuration file, might be stopped, and a configuration file can be sent and restarted.

The `Help` button contains a set of help statements that describe each of the windows items.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Access Control: Any user

Files

Item	Description
`/usr/sbin/dhcpsconf`	Contains the **dhcpsconf** command.
`/etc/dhcpcd.cnf`	Contains the default client configuration file.

dhcpsd Daemon

Purpose

Implements a Dynamic Host Configuration Protocol (DHCP) server. Serves addresses and configuration information to DHCP clients.

Syntax

To serve information to the DHCP clients by using the System Resource Controller (SRC):

startsrc -s dhcpsd [**-a** *Argument*] [**-a** *Argument*] ...

To serve information to the DHCP clients without using SRC:

dhcpsd [**-f** *ConfigurationFile*]

Description

The DHCP server handles the assignment and maintenance of dynamic address assignment. It also handles the distribution of additional configuration information. The **dhcpsd** daemon runs in the background and maintains a database of server information that contains logging parameters, IP (Internet Protocol) address ranges, other network configuration information, and accessibility information. The initial database is specified by the configuration file. The configuration file contains all the data to start configuring DHCP clients.

The DHCP server maintains a database of addresses it provided and who has them. These databases are kept in the files `/etc/dhcpsd.ar` and `/etc/dhcpsd.cr`. A server on startup reads the configuration file and sets up its initial database of available addresses. The server accepts the **refresh** command or a SIGHUP signal to reread the configuration file.

The DHCP server reads `/etc/services` file to determine which port it must use for receiving requests. The default service is **dhcps**. Because it is the same port that the **bootpd** daemon uses, you can have only one (either **dhcpsd** or **bootpd**) daemon running. If you choose the **dhcpsd** daemon, you must comment **bootp** from the `/etc/inetd.conf` file, then enter `refresh -s inetd` on the command line.

Note: If the **bootpd** daemon is running, this program must be stopped before you start the daemons.

Flags

Item	Description
-f *ConfigurationFile*	Specifies the configuration file to be used.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Access Control: You must have root authority to run this command.

Files

Item	Description
`/usr/sbin/dhcpsd`	Contains the **dhcpsd** daemon.
`/etc/services`	Defines sockets and protocols that are used for internet services.
`/etc/inetd.conf`	Defines the services that are controlled by the **inetd** daemon.

dhcpsdv6 Daemon

Purpose

Implements a Dynamic Host Configuration Protocol (DHCPv6) server. Serves addresses and configuration information to DHCPv6 clients.

Syntax

To serve information to the DHCPv6 clients by using the System Resource Controller (SRC):

startsrc -s dhcpsdv6 [**-a** *Argument*]

To serve information to the DHCP clients without using SRC:

dhcpsdv6 [**-d**] [**-f** *ConfigurationFile*] [**-a** *DadminPort*] [**-p** *ServerPort*]

Description

The DHCPv6 server handles the assignment and maintenance of dynamic address assignment. It also handles the distribution of additional configuration information. The **dhcpsd** daemon runs in the background and maintains a database of server information that contains logging parameters, IP (Internet Protocol) address ranges, other network configuration information, and accessibility information. The initial database is specified by the configuration file. The configuration file contains all the data to start configuring DHCP clients.

The DHCPv6 server maintains a database of addresses it provided and who has them. These databases are kept in the files `/etc/dhcpv6/db_file.crbk` and `/etc/dhcpv6/db_file.cr`. A server on startup reads the configuration file and setup its initial database of available addresses. The server accepts the refresh command or a `SIGHUP` signal to reread the configuration file.

Flags

Item	Description
-a	Specifies the Dadmin port; by default it is 942.
-d	Displays debugging information.
-f *ConfigurationFile*	Specifies the configuration file to be used. By default, the configuration file is `/etc/dhcpv6/dhcpsdv6.cnf`.
-p	Specifies the port that is used by the server to listen for incoming request; by default it is 547.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Access Control: You must have root authority to run this command.

Examples

1. To start the DHCPv6 server with the configuration file `dhcpsdv6.cnf` located in `/usr/local`, type:

```
startsrc -s dhcpsdv6 -a "-f /usr/local/dhcpsdv6.cnf"
```

Location

`/usr/sbin/dhcpsdv6`

Files

Item	Description
`/usr/sbin/dhcpsdv6`	Contains the **dhcpsdv6** daemon.
`/etc/dhcpv6/db_file.cr`	Contains the client records. This file is created by the server daemon and is not configurable.
`/etc/dhcpv6/db_file.crbk`	Contains the client records. This file is created by the server daemon and is not configurable.
`/etc/dhcpv6/dhcpsdv6.duid`	Contains the server identifier file. This file is created by the server daemon and is not configurable.

diag Command

Purpose

Performs hardware problem determination.

Syntax

diag [[**-a**] | [**-s** [**-c**]] [**-E** *days*] [**-e**] | [**-d** *Device* [**-c**] [**-v**] [**-e**] [**-A**]] | [**-B** [**-c**]] | [**-T** *taskname*] | [**-S** *testsuite*] | [`-c` `-d` *Device* `-L pending | complete`]

Description

The **diag** command is the starting point to run a wide choice of tasks and service aids. Most of the tasks and service aids are platform-specific. The following tasks and service aids are available:

- Run diagnostics
- Display or change diagnostic run time options
- Display Service Hints
- Display previous diagnostic results
- Display hardware error report
- Display software product data
- Display configuration and resource list
- Display hardware vital product data
- Display resource attributes
- Change hardware vital product data
- Format media
- Certify media
- Display test patterns
- Local area network analyzer

- Add resource to resource list
- Delete resource from resource list
- SCSI bus analyzer
- Download microcode
- Display or change bootlist
- Periodic diagnostics
- Backup and restore media
- Disk maintenance
- Configure dials and LPFkeys
- Add or delete drawer Config
- Create customized configuration diskette
- Update disk based diagnostics
- Configure ISA adapter
- Operating system shell prompt (online service mode only)
- Display or change multiprocessor configuration
  - Enable and disable individual processors
- Display or change BUMP configuration
  - Update the flash EPROM with a new binary image
  - Display or change diagnostic modes
  - Display or change remote phone numbers and modem configurations
- Display or change electronic mode switch
- Process supplemental media (stand-alone mode only)
- Generic microcode download
- Run error log analysis
- Service aids for use with Ethernet
- 7135 RAIDiant array service aids
- SCSI device identification and removal
- SCSD tape drive service aid
- Escon bit error rate service aid
- PCI RAID physical disk identify
- Configure ring indicate Power On Policy (CHRP)
- Configure surveillance policy (CHRP)
- Configure reboot policy (CHRP)
- Configure remote maintenance policy (CHRP)
- Save or restore hardware management policies (CHRP)
- Display firmware device node information (CHRP)
- Spare sector availability
- Update system or service processor flash (CHRP)
- Display system environmental sensors (CHRP)
- Display checkstop analysis results
- Analyze adapter internal log
- Log repair action
- Flash SK-NET FDDI firmware

- Display microcode level
- Run the Non-Volatile Memory Express (NVMe) sanitize command on the NVMe-compliant devices that support the sanitize operation. The NVMe sanitize operation changes the Non-Volatile Memory (NVM) subsystem such that you cannot recover the previous user data from any cache or non-volatile media.

You can use the System Management Interface Tool (SMIT) **smit diag** fast path to run this command.

Flags

Note: Most users do not need to use any flags since the **diag** command is a menu driven program.

Item	Description
-A	Specifies advanced mode. You must also specify a device by using the **-d** flag.
-a	Processes any changes in the hardware configuration by asking if missing resources are removed, turned off, and so on. Missing resources (indicated by an 'M') and missing resource paths (indicated by a 'P') are integrated into the diagnostic resource selection list.
-B	Instructs diagnostic tests to run the base system test. Error log analysis is also done on areas in the base system that supports error log analysis.
-c	Indicates that the machine is not attended. No questions are asked. Results are written to standard output. You must also use an optional flag that specifies a device to be tested (**d**, **B**, or **s**).
-d *Device*	Specifies the device to run the diagnostic tests on.
-E *Days*	Specifies the number of days to be used for searching the error log during run error log analysis. This flag works with any other flag.
-e	Performs error log analysis if supported on the selected device. No tests are performed. This flag must be used with the **-d** flag, otherwise the resource selection menu appears. If used with the **-v** flag, the **-v** flag takes precedence and the **-e** flag is ignored.
-S *testsuite*	Indicates a particular test suite of devices to test: 1. Base system 2. I/O devices 3. Async devices 4. Graphic devices 5. SCSI devices 6. Storage devices 7. Common devices 8. Multimedia devices
-L pending | complete	Logs repair action for a resource that is specified with the `-d` and `-c` options. Use the `pending` parameter if the part is replaced, but it is not yet known whether this part remains in the system. Use the `complete` parameter if the part is replaced and it is known that this part remains in the system.
-s	Runs the diagnostic tests on all resources.

Item	Description
-T *taskname*	Specifies the specific Fastpath task to be run. The following list displays the current fastpath tasks : **format** Format media task **certify** Certify media task **download** Download microcode task **disp_mcode** Display microcode level task **chkspares** Spare sector availability task **identifyRemove** Hot plug task **nvme_sanitize** Sanitize NVMe-compliant devices that support the sanitize operation. When you specify the **nvme_sanitize** task, you must also specify the *force* option by using the **-f** flag. The **-f** flag is only required when the **-c** flag is specified with the **diag** command, otherwise the **diag** command fails with an error. **Note:** Tasks are platform and device dependent. Some tasks might not be available on the system.
-v	Runs the diagnostic tests in the system verification mode, no error log analysis performed. The default is Problem Determination mode that tests the device and runs error log analysis. If used with the **-e** flag, the **-v** flag takes precedence and the **-e** flag is ignored. Must be used with the **-d** flag to specify a device to run the diagnostic tests on.

Security

Access Control: Only the root user can run this command.

Privilege Control: System group.

Examples

1. To run the diagnostic tests on the `scdisk0` device, without questions, enter:

```
diag -d scdisk0 -c
```

2. To run the NVMe sanitize operation on the NVMe device (nvmeX), enter:

```
diag -c -d nvmeX -T "nvme_sanitize -f"
```

File

Item	Description
/usr/sbin/diag	Contains the **diag** command.

diaggetrto Command

Purpose

Displays diagnostic run-time options.

Syntax

diaggetrto [[**-a**] [**-d**] [**-l**] [**-m**] [**-n**] [**-p**] [**-s**]]

Description

The **diaggetrto** command displays the value of one or more diagnostic run time options. The following run-time options can be displayed with the **diaggetrto** command:

Display Diagnostic Mode Selection Menus
When this option is off, diagnostics run in Problem Determination mode only. The default is on.

Include Advanced Diagnostics
When this option is on, diagnostics run in advanced mode when run from the Task Selection Menu or command line. The default is off.

Number of days used to search error log
This option controls how old error log entries must be before they are no longer analyzed by diagnostics. The default is 7.

Display Progress Indicators
When this option is on, diagnostic applications that support progress indicators will display them. The default is on.

Diagnostic Event Logging
When this option is on, diagnostics log events. The default is on.

Diagnostic Event Log file size
This option controls the maximum size of the diagnostic event log. Allowable sizes are in increments of hundreds of kilobytes. The default is 100K.

Flags

Item	Description
-a	Displays the value of **Include Advanced Diagnostics**.
-d	Displays the value of **Diagnostic Event Logging**.
-l	Displays the value of **Diagnostic Event Log file size**.
-m	Displays the value of **Display Diagnostic Mode Selection Menus**.
-n	Displays the value of **Number of days used to search error log**.
-p	Displays the value of **Display Progress Indicators**.
-s	Displays all of the diagnostic run-time options.

Exit Status

0
The command completed successfully.

>0
An error occurred.

Examples

1. To display the diagnostic event log size, type:

```
/usr/lpp/diagnostics/bin/diaggetrto -l
```

2. To check if progress indicators are turned on and to check if diagnostic event logging is turned on, type:

```
/usr/lpp/diagnostics/bin/diaggetrto -p -d
```

3. To display the number of days to search the error log, type:

```
/usr/lpp/diagnostics/bin/diaggetrto -n
```

Files

Item	Description
/usr/lpp/diagnostics/bin/diaggetrto	Contains the **diagsetrto** command.

diagrpt Command

Purpose

Displays previous diagnostic results.

Syntax

diagrpt [[**-o**] | [**-s** *mmddyy*] | [**-a**] | [**-r**]]

Description

The **diagrpt** command displays the results of previous diagnostic sessions. There are three types of results that can be viewed:

- Diagnostic result files stored in **/etc/lpp/diagnostic/data** directory.
- Diagnostic Event Log Information.
- Diagnostic results stored in NVRAM on CHRP systems.

Flags

Item	Description
-o	Displays the last diagnostic results file stored in the **/etc/lpp/diagnostics/data** directory.
-s *mmddyy*	Displays all diagnostic result files logged since the date specified.
-a	Displays the long version of the Diagnostic Event Log.
-r	Displays the short version of the Diagnostic Event Log.

Examples

1. To list all previous diagnostic result files since Jan 31, 1999, enter:

```
/usr/lpp/diagnostics/bin/diagrpt -s 013199
```

2. To view the short version of the diagnostic event log, enter:

```
/usr/lpp/diagnostics/bin/diagrpt -r
```

File

Item	Description
/usr/lpp/diagnostics/bin/diagrpt	Contains the **diagrpt** command.

diagsetrto Command

Purpose

Sets diagnostic run-time options.

Syntax

diagsetrto [[**-a on** | **off**] [**-d on** | **off**] [**-l** *Size*] [**-m on** | **off**] [**-n** *Days*] [**-p on** | **off**]]

Description

The **diagsetrto** command sets the value of any number of diagnostic run-time options. The following run-time options can be altered with the **diagsetrto** command:

Display Diagnostic Mode Selection Menus
When this option is off, diagnostics run in Problem Determination mode only. The default is on.

Include Advanced Diagnostics
When this option is on, diagnostics run in advanced mode when run from the Task Selection Menu or command line. The default is off.

Number of Days Used to Search Error Log
This option controls how old error log entries must be before they are no longer analyzed by diagnostics. The default is 7.

Display Progress Indicators
When this option is on, diagnostic applications that support progress indicators will display them. The default is on.

Diagnostic Event Logging
When this option is on, diagnostics log events. The default is on.

Diagnostic Event Log File Size
This option controls the maximum size of the diagnostic event log. Allowable sizes are in increments of hundreds of kilobytes. The default is 100K.

Flags

Item	Description
-a on | **off**	Sets the value of **Include Advanced Diagnostics**.
-d on | **off**	Sets the value of **Diagnostic Event Logging**.
-l *Size*	Sets the value of **Diagnostic Event Log file size**.
-m on | **off**	Sets the value of **Display Diagnostic Mode Selection Menus**.
-n *Days*	Sets the value of **Number of days used to search the error log**.
-p on | **off**	Sets the value of **Display Progress Indicators**.

Exit Status

0
The command completed successfully.

>0
An error occurred.

Examples

1. To set the diagnostic event log size to 500K, type:

```
/usr/lpp/diagnostics/bin/diagsetrto -l 500
```

2. To turn off progress indicators and turn off diagnostic event logging, type:

```
/usr/lpp/diagnostics/bin/diagsetrto -p off -d off
```

3. To set the number of days to search the error log to 50, type:

```
/usr/lpp/diagnostics/bin/diagsetrto -n 50
```

Files

Item	Description
/usr/lpp/diagnostics/bin/diagsetrto	Contains the **diagsetrto** command.

diction Command

Purpose

Highlights unclear or wordy sentences.

Syntax

diction [**-ml**] [**-mm**] [**-f** *PatternFile*] [**-n**] *File* ...

Description

The **diction** command finds all sentences in an English-language document that contain phrases from a database of unclear or wordy diction. Each phrase is bracketed with [ ] (brackets). Because the **diction** command runs the **deroff** command before looking at the text, include header files that contain appropriate formatting information as part of the input. The **explain** command provides an interactive thesaurus for the phrases found by the **diction** command.

Use of nonstandard formatting macros may cause incorrect sentence breaks. In particular, the **diction** command does not understand the **-me** flag.

Flags

Item	Description
-f *PatternFile*	Specifies a file containing examples of unclear diction; this file is used in addition to the default file.
-ml	Causes the **deroff** command to skip **mm** macro lists; can be used if a document contains many lists of sentence fragments.
-mm	Overrides the default **ms** macro package.

Item	Description
-n	Suppresses the use of the default file when used with the **-f** flag; only the file specified by the *PatternFile* parameter is used.

Files

Item	Description
/usr/lib/dict.d	Contains default pattern.

diff Command

Purpose

Compares text files.

Syntax

To Compare the Contents of Two Files

diff [**-c**| **-C** *Lines* | **-D** [*String*] | **-e** | **-f** | **-n** | **-u** | **-U** *Lines*] [**-b**] [**-i**] [**-t**] [**-w**] *File1 File2*

diff [**-h**] [**-b**] *File1 File2*

To Sort the Contents of Directories and Compare Files That Are Different

diff [**-c** | **-C** *Lines* | **-e** | **-f** | **-n** | **-u** | **-U** *Lines*] [**-b**] [**-i**] [**-l**] [**-r**] [**-s**] [**-S** *File*] [**-t**] [**-w**] *Directory1 Directory2*

diff [**-h**] [**-b**] *Directory1 Directory2*

Description

The **diff** command compares text files. It can compare single files or the contents of directories.

Note: The **diff** command only works with input files that are text files.

If the *Directory1* and *Directory2* parameters are specified, the **diff** command compares the text files that have the same name in both directories. Binary files that differ, common subdirectories, and files that appear in only one directory are listed.

When the **diff** command is run on regular files, and when comparing text files that differ during directory comparison, the **diff** command tells what lines must be changed in the files to make them agree. If neither the *File1* nor *File2* parameter is a directory, then either may be given as - (minus sign), in which case the standard input is used. If the *File1* parameter is a directory, then a file in that directory whose file name is the same as the *File2* parameter is used.

The typical output contains lines of these forms:

```
Lines Affected in File1   Action        Lines Affected in File2
Number1                   a             Number2[,Number3]
Number1[,Number2]         d             Number3
Number1[,Number2]         c             Number3[,Number4]
```

These lines resemble **ed** subcommands to convert *File1* into *File2*. The numbers before the action letters pertain to *File1*; those after pertain to *File2*. Thus, by exchanging **a** for **d** and reading from right to left, you can also tell how to convert *File2* into *File1*. As in the **ed** command, identical pairs (where *Number1* = *Number2*) are abbreviated as a single number.

Following each of these lines, the **diff** command displays all lines affected in the first file preceded by a **<:** (less than sign, colon), then displays all lines affected in the second file are preceded by a **>** (greater than sign).

An exit value of 0 indicates no differences, 1 indicates differences found, and 2 indicates an error.

Note: If more than one of the **-c**, **-C**, **-D**, **-e**, **-f**, or **-n**, **-u**, or **-U** flags are specified, the last one on the command line takes precedence. The system does not issue an error message.

Flags

Item	Description
-b	Causes any amount of white space at the end of a line to be treated as a single newline character (the white-space characters preceding the newline character are ignored) and other strings of white-space characters, not including newline characters, to compare equally.
-C *Lines*	Produces a **diff** command comparison with a number of lines of copied context equal to the value specified by the *Lines* variable. The **-C** flag modifies the output slightly. The output begins with identification of the files involved and their creation dates. Each change is separated by a line with a dozen * (asterisks). The lines removed from *File1* are marked with a - (minus sign) and those added to *File2* are marked with a + (plus sign). Lines changed from one file to the other are marked in both files with an ! (exclamation point). Changes that lie within the specified copied context lines of each other are grouped together as output.
-c	Produces a **diff** command comparison with three lines of copied context. The **-c** flag modifies the output slightly. The output begins with identification of the files involved and their creation dates. Each change is separated by a line with a dozen * (asterisks). The lines removed from *File1* are marked with a - (minus sign) and those added to *File2* are marked with a + (plus sign). Lines changed from one file to the other are marked in both files with an ! (exclamation point). Changes within the specified copied context lines of each other are grouped together as output.
-D [*String*]	Causes the **diff** command to create a merged version of *File1* and *File2* on the standard output. The C preprocessor controls are included so that a compilation of the result without defining *String* is equivalent to compiling *File1*, while defining *String* yields *File2.*
-e	Produces output in a form suitable for use with the **ed** editor to convert *File1* to *File2*. When using this flag, the following shell program may help maintain multiple versions of a file. Only an ancestral file (**$1**) and a chain of version-to-version **ed** scripts (**$2**, **$3**, ...) made by the **diff** command need to be on hand. The latest version appears on the standard output as follows: `(shift; cat $*; echo '1,$p') | ed - $1` Extra commands are added to the output when the **-e** flag is used to compare directories, so the result is a shell script for converting text files that are common to the two directories from their state in *Directory1* to their state in *Directory2.* **Note:** Editing scripts produced by the **-e** or **-f** flags cannot create lines consisting of a single . (period).
-f	Produces output in a form not suitable for use with the **ed** editor, showing the modifications necessary to convert *File1* to *File2* in the reverse order of that produced under the **-e** flag.
-h	Performs an alternate comparison that may be faster if the changed sections are short and well separated. The **-h** flag works on files of any length. The **-c**, **-C**, **-D**, **-e**, **-f**, and **-n** flags cannot be used with the **-h** flag. All other flags except the **-b** flag are ignored when used with the **-h** flag.

Item	Description
-i	Ignores the case of letters. For example, a lowercase **a** is treated the same as an uppercase **A**.
-l	Long output format. Each result from the **diff** command text file comparison is piped through the **pr** command for pagination. Other differences are remembered and summarized after all text file differences are reported.
-n	Produces output similar to that of the **-e** flag, but in the opposite order and with a count of changed lines on each insert or delete command. This is the form used by the revision control system (RCS).
-r	Causes application of the **diff** command recursively to common subdirectories encountered.
-s	Reports files that are the same and otherwise not mentioned.
-S [*File*]	Ignores files whose names collate before the file specified by the *File* variable when comparing directories. The **-S** flag only applies to the directories specified in the *Directory1* and *Directory2* parameters. If you use the **-r** flag with the **-S** flag, the **-S** flag does not work recursively in the *Directory1* and *Directory2* subdirectories.
-t	Expands tabs in output lines. Typical output or the **-c** flag output adds characters to the front of each line, which may affect indentation of the original source lines and makes the output listing difficult to interpret. This flag preserves the original source's indentation.
-u	Produces a **diff** command comparison with three lines of unified context. The output is similar to that of the **-c** flag, except that the context lines are not repeated; instead, the context, deleted, and added lines are shown together, interleaved.
-U *Lines*	Produces a **diff** command comparison with a number of lines of unified context equal to the value specified by the *Lines* variable. The output is similar to that of the **-C** flag, except that the context lines are not repeated; instead, the context, deleted, and added lines are shown together, interleaved.
-w	Ignores all spaces and tab characters and treats all other strings of blanks as equivalent. For example, `if ( a == b )` compares equally to `if(a==b)`.

Exit Status

This command returns the following exit values:

Item	Description
0	No differences were found.
1	Differences were found.
>1	An error occurred.

Examples

1. To compare two files, enter:

   ```
   diff chap1.back chap1
   ```

   This displays the differences between the files `chap1.bak` and `chap1`.
2. To compare two files while ignoring differences in the amount of white space, enter:

```
diff  -w prog.c.bak prog.c
```

If two lines differ only in the number of spaces and tabs between words, the **diff -w** command considers them to be the same.

3. To create a file containing commands that the **ed** command can use to reconstruct one file from another, enter:

```
diff  -e chap2 chap2.old >new.to.old.ed
```

This creates a file named `new.to.old.ed` that contains the **ed** subcommands to change `chap2` back into the version of the text found in `chap2.old`. In most cases, `new.to.old.ed` is a much smaller file than `chap2.old`. You can save disk space by deleting `chap2.old`, and you can reconstruct it at any time by entering:

```
(cat new.to.old.ed ; echo '1,$p') | ed - chap2 >chap2.old
```

The commands in parentheses add `1,$p` to the end of the editing commands sent to the **ed** editor. The `1,$p` causes the **ed** command to write the file to standard output after editing it. This modified command sequence is then piped to the **ed** command (`|  ed`), and the editor reads it as standard input. The **-** flag causes the **ed** command not to display the file size and other extra information because it would be mixed with the text of `chap2.old`.

Files

Item	Description
/usr/bin/diff	Contains the **diff** command.

diff3 Command

Purpose

Compares three files.

Syntax

diff3 [**-e** | **-x** | **-E** | **-X** | **-3**] *File1 File2 File3*

Description

The **diff3** command compares three files and writes to standard output the ranges of text that differ, flagged with the following codes:

Item	Description
====	All three files differ.
====1	*File1* differs.
====2	*File2* differs.
====3	*File3* differs.

The type of change needed to convert a given range of a given file to match another file is indicated in one of these two ways in the output:

Item	Description
File:*Number1* **a**	Text is to be added after line number *Number1* in *File*, where *File* is **1**, **2**, or **3**.

Item	Description
File:*Number1*[,*Number2*]**c**	Text in the range line *Number1* to line *Number2* is to be changed. If *Number1* is the same as *Number2*, the range may be abbreviated to *Number1*.

The contents of the range follows a **c** indication. When the contents of two files are identical, the **diff3** command does not show the contents of the lower-numbered file, although it shows the location of the identical lines for each.

Note: Edit scripts produced by the **-e** flag cannot create lines consisting of a . (period).

Flags

Item	Description
-3	Produces an edit script to incorporate only changes flagged ====3.
-E, **-X**	These are similar to **-e** and **-x** respectively, but treat overlapping changes (that is, changes that would be flagged ==== in the normal listing) differently. The overlapping lines from both files are inserted by the edit script, bracketed by <<<<<< and >>>>>> lines. The **-E** option is used by Revision Control System (RCS) Merge to ensure that overlapping changes in the merged files are preserved and brought to someone's attention.
-e	Creates an edit script for use with the **ed** command to incorporate into *File1* all changes between *File2* and *File3* (that is, the changes that normally would be flagged ==== and ====3).
-x	Produces an edit script to incorporate only changes flagged ====.

Examples

To list the differences among three files:

```
diff3 fruit.a fruit.b fruit.c
```

If `fruit.a`, `fruit.b`, and `fruit.c` contain the following data:

```
fruit.a                 fruit.b                 fruit.c
banana                  apple                   grape
grape                   banana                  grapefruit
kiwi                    grapefruit              kiwi
lemon                   kiwi                    lemon
mango                   orange                  mango
orange                  peach                   orange
peach                   pear                    peach
pare
```

then the output from the **diff3** command shows the differences between these files as follows. (The comments on the right do not appear in the output.)

```
====            All three files are different.
1:1,2c          Lines 1 and 2 of the first file, fruit.a
  banana
  grape
2:1,3c          Lines 1 through 3 of fruit.b
  apple
  banana
  grapefruit
3:1,2c          Lines 1 and 2 of fruit.c
  grape
  grapefruit
====2           The second file, fruit.b, is different.
1:4,5c          Lines 4 and 5 the same in fruit.a and fruit.c.
2:4a            To make fruit.b look same, add after line 4.
3:4,5c
  lemon
  mango
```

```
====            The first file, fruit.a, is different.
1:8c
  pare
2:7c            fruit.b line 7 and fruit.c line 8 are the same
  pear
3:7a
```

Files

Item	Description
/usr/bin/diff3	Indicates the **diff3** command.
/usr/lbin/diff3prog	Called by the **diff3** shell script.

diffmk Command

Purpose

Marks differences between files.

Syntax

diffmk [{ **-ab***X* | **-ae***X*] [**-b**] [**-cb***X* | **-ce***X*] [**-db***X* | **-de***X*] *File1 File2* [*File3*]

Description

The **diffmk** command compares the English-language file specified by the *File1* parameter with the file by the *File2* parameter. It then creates a third file that includes **.mc** requests (for creating change marks) for the **nroff** and **troff** commands. The *File1* and *File2* parameters specify the old and new versions, respectively, of the files. The **diffmk** command writes the newly created file to the *File3* parameter, if specified, or else to standard output. The *File3* file contains the lines of the *File2* file plus inserted formatter **.mc** requests. When the *File3* file is formatted, the changed or inserted text is marked by a | (vertical bar) at the right margin of each line. An * (asterisk) in the margin indicates that a line was deleted.

If the **DIFFMARK** environment variable is defined, it names a command string that the **diffmk** command uses to compare the files. (Normally, the **diffmk** command uses the **diff** command.) For example, to handle extremely large files better, you can set the **DIFFMARK** variable to `diff -h`.

Parameters

Item	Description
File1	Specifies an English-language file that is compared to the file specified by the *File2* parameter. The results of the comparison comprise the file specified by the *File3* parameter. *File1* is considered the "old" file.
File2	Specifies an English-language file that is compared to the file specified by the *File1* parameter. The results of the comparison comprise the file specified by the *File3* parameter. *File2* is considered the "new" file.
File3	Specifies a file that contains lines of the *File2* file and includes inserted formatter **.mc** requests for the **nroff** and **troff** commands. The contents of this file are the results of a comparison between the files specified by the *File1* and *File2* parameters. When formatted, the changed text is marked by a (|) vertical bar at the right margin of each line. An * (asterisk) indicates the line was deleted. If *File3* is not specified, the results of the comparison are written to standard input.

Flags

Item	Description
-ab*X*	Uses *X* to mark where added lines begin.
-ae*X*	Uses *X* to mark where added lines end.
-b	Ignores differences that are only changes in tabs or spaces on a line.
-cb*X*	Uses *X* to mark where changed lines begin.
-ce*X*	Uses *X* to mark where changed lines end.
-db*X*	Uses *X* to mark where deleted lines begin.
-de*X*	Uses *X* to mark where deleted lines end.

Examples

1. To mark the differences between two versions of a text file, enter:

   ```
   diffmk chap1.old chap1 chap1.nroff
   ```

   This produces a copy of `chap1` containing **nroff** and **troff** change mark requests to identify text that has been added to, changed in, or deleted from `chap1.old`. This copy is saved in the `chap1.nroff` file.
2. To mark differences with non-**nroff** and **troff** messages, enter:

   ```
   diffmk -ab'>>New:' -ae'<<End New' \
   chap1.old chap1 chap1.nroff
   ```

   This causes the **diffmk** command to write `>>New:` on the line before a section of newly added lines to `chap1`, and to write `<<End New` on the line following the added lines. Changes and deletions still generate **nroff** and **troff** commands to put a | (vertical bar) or * (asterisk) in the margin.
3. To use different **nroff** and **troff** command-marking requests and ignore changes in white space, enter:

   ```
   diffmk -b -cb'.mc %' chap1.old chap1 chap1.nroff
   ```

   This imbeds commands that mark changes with `%` (percent sign) additions with a | (vertical bar), and deletions with an * (asterisk). It does not mark changes that only involve a different number of spaces or tabs between words (`-b`).

dig Command

Purpose

DNS lookup utility.

Syntax

dig [*@server*] [**-b** *address*] [**-c** *class*] [**-f** *filename*] [**-k** *filename*] [**-p** *port#*] [**-q** *name*] [**-t** *type*] [**-x** *addr*] [**-y** [hmac:] *name:key*] [**-4**] [**-6**] [*name*] [*type*] [*class*] [*queryopt...*]

dig [**-h**]

dig [*global-queryopt...*] [*query...*]

Description

The **dig** (domain information groper) command is a flexible tool for interrogating DNS name servers. It performs DNS lookups and displays the answers that are returned from the queried name server(s). Most

DNS administrators use the **dig** command to troubleshoot DNS problems because of its flexibility, ease of use, and clarity of output. Although **dig** is normally used with command-line arguments, it also has a batch mode for reading lookup requests from a file. Unlike earlier versions, the BIND9 implementation of **dig** allows multiple lookups to be issued from the command line. Unless it is told to query a specific name server, the **dig** command tries each of the servers listed in the **/etc/resolv.conf** file. If you specify no command line arguments or options, the **dig** command performs an NS query for "**.**" (the root).

It is possible to set per-user defaults for the **dig** command through the **${HOME}/.digrc** file. The **dig** command reads this file and applies any options in it before the command line arguments.

The **IN** and **CH** class names overlap with the **IN** and **CH** top level domains names. When you look up these top level domains, you can either use the **-t** and **-c** options to specify the type and class or use the **-q** option to specify the domain name or use the **IN** and **CH** names.

Flags

Item	Description
-b *address*	Sets the source IP address of the query-to address. This must be a valid address on one of the host's network interfaces or "0.0.0.0" or "::". You can specify an optional port by appending "#*port*".
-c *class*	Overrides the default query class (IN for internet). The ***class*** parameter value is any valid class, such as HS for Hesiod records or CH for CHAOSNET records.
-f *filename*	Makes the **dig** command operate in batch mode by reading a list of lookup requests to process from the specified file name. The file contains a number of queries; one per line. Each entry in the file must be organized in the same way they are presented as queries to the **dig** command using the command-line interface.
-h	Prints a brief summary of command-line arguments and options.
-k *filename*	Specifies a TSIG key file using the **-k** option to sign the DNS queries sent by the **dig** command.
-p *port#*	Queries a non-standard port number. The *port#* parameter value is the port number that the **dig** command sends its queries to instead of the standard DNS port number 53. You can use this option to test a name server that has been configured to listen for queries on a non-standard port number.
-q *name*	Distinguishes the name from other arguments. Sets the query name to the *name* parameter value specified.
-t *type*	Sets the query type to the ***type*** parameter value. It can be any valid query type that is supported in BIND9. The default query type is **A**, unless the **-x** option is supplied to indicate a reverse lookup. A zone transfer can be requested by specifying a ***type*** of AXFR. When an incremental zone transfer (IXFR) is required, the ***type*** parameter value is set to **ixfr=N**. The incremental zone transfer contains the changes made to the zone because the serial number in the zone's SOA record was **N**.
-x *addr*	Simplifies reverse lookups (mapping addresses to names). The ***addr*** parameter value is an IPv4 address in dotted-decimal notation, or a colon-delimited IPv6 address. When you use this option, there is no need to provide the *name*, *class*, and *type* arguments. The **dig** command automatically performs a lookup for a name like `11.12.13.10.in-addr.arpa` and sets the query type and class to PTR and IN respectively.

Item	Description
-y [hmac:] *name:key*	Specifies the TSIG key itself on the command line; *hmac* is the type of the TSIG. The default value is HMAC-MD5. The ***name*** parameter value is the name of the TSIG key and the ***key*** parameter value is the actual key. The key is a base-64 encoded string, typically generated by **dnssec-keygen**(8). Caution must be taken when using the **-y** option on multi-user systems as the key can be visible in the output from ps(1) or in the shell's history file. When using TSIG authentication with the **dig** command, the name server that is queried needs to know the key and algorithm that is being used. In BIND, this is done by providing appropriate key and server statements in the **named.conf** file.
-4	Forces the **dig** command to only use the IPv4 query transport.
-6	Forces the **dig** command to only use the IPv6 query transport.

Parameters

Item	Description
global-queryopt...	Global query option (see Multiple Queries).
query	Query option (see Query Options).

Query Options

The **dig** command provides a number of query options that affect the way in which lookups are made and the results displayed. Some of these set or reset flag bits in the query header, some determine which sections of the answer get printed, and others determine the timeout and retry strategies. Each query option is identified by a keyword preceded by a plus sign (+). Some keywords set or reset an option. These can be preceded by the string no to negate the meaning of that keyword. Other keywords assign values to options like the timeout interval. They have the form **+keyword=value**. The query options are:

+[no]tcp
Use or do not use TCP when querying name servers. The default behavior is to use UDP unless an AXFR or IXFR query is requested, in which case a TCP connection is used.

+[no]vc
Use or do not use TCP when querying name servers. This alternate syntax to **+[no]tcp** is provided for backwards compatibility. The **vc** stands for virtual circuit.

+[no]ignore
Ignore truncation in UDP responses instead of retrying with TCP. By default, TCP retries are performed.

+domain=somename
Set the search list to contain the single domain ***somename***, as if specified in a domain directive in the **/etc/resolv.conf** file, and enable search list processing as if the **+search** option was given.

+[no]search
Use or do not use the search list defined by the search list or domain directive in the **/etc/resolv.conf** file (if any). The search list is not used by default.

+[no]defname
Deprecated, treated as a synonym for **+[no]search**.

+[no]aaonly
Sets the "aa" flag in the query.

+[no]adflag
Set or do not set the AD (authentic data) bit in the query. The AD bit currently has a standard meaning only in responses, not in queries, but the ability to set the bit in the query is provided for completeness.

+[no]cdflag
Set or do not set the CD (checking disabled) bit in the query. This requests the server to not perform DNSSEC validation of responses.

+[no]cl
Display or do not display the CLASS when printing the record.

+[no]ttlid
Display or do not display the TTL when printing the record.

+[no]recursive
Toggle the setting of the RD (recursion desired) bit in the query. This bit is set by default, which means **dig** normally sends recursive queries. Recursion is automatically disabled when the **+nssearch** or **+trace** query options are used.

+[no]nssearch
When this option is set, the **dig** command attempts to find the authoritative name servers for the zone containing the name being looked up and display the SOA record that each name server has for the zone.

+[no]trace
Toggle tracing of the delegation path from the root name servers for the name being looked up. Tracing is disabled by default. When tracing is enabled, the **dig** command makes iterative queries to resolve the name being looked up. It follows referrals from the root servers, showing the answer from each server that was used to resolve the lookup.

+[no]cmd
Toggle the printing of the initial comment in the output identifying the version of **dig** and the query options that have been applied. This comment is printed by default.

+[no]short
Provide a terse answer. The default is to print the answer in a verbose form.

+[no]identify
Show or do not show the IP address and port number that supplied the answer when the **+short** option is enabled. If short form answers are requested, the default is not to show the source address and port number of the server that provided the answer.

+[no]comments
Toggle the display of comment lines in the output. The default is to print comments.

+[no]stats
Toggle the printing of statistics: when the query was made, the size of the reply, and so on. The default behavior is to print the query statistics.

+[no]qr
Print or do not print the query as it is sent. By default, the query is not printed.

+[no]question
Print or do not print the question section of a query when an answer is returned. The default is to print the question section as a comment.

+[no]answer
Display or do not display the answer section of a reply. The default is to display it.

+[no]authority
Display or do not display the authority section of a reply. The default is to display it.

+[no]additional
Display or do not display the additional section of a reply. The default is to display it.

+[no]all
Set or clear all display flags.

+time=T
Set the timeout for a query to ***T*** seconds. The default timeout is 5 seconds. An attempt to set the ***T*** parameter value to less than 1 results in a query timeout of 1 second being applied.

+tries=A
Set the number of times to try UDP queries to server to the ***A*** parameter value instead of the default, 3. If the ***A*** parameter value is less than or equal to zero, the number of retries is silently rounded up to 1.

+retry=T
Set the number of times to retry UDP queries to server to the ***T*** parameter value instead of the default, 2. Unlike **+tries**, this does not include the initial query.

+ndots=D
Set the number of dots that have to appear in name to the ***D*** parameter value as it is considered absolute. The default value is one that is defined using the **ndots** statement in the **/etc/resolv.conf** file, or 1 if no **ndots** statement is present. Names with fewer dots are interpreted as relative names and is searched for in the domains listed in the search or domain directive in the **/etc/resolv.conf** file.

+bufsize=B
Set the UDP message buffer size advertised using EDNS0 to ***B*** bytes. The maximum and minimum sizes of this buffer are 65535 and 0, respectively. Values outside of this range are rounded up or down appropriately. Values other than zero cause an EDNS query to be sent.

+edns=#
Specify the EDNS version to query with. Valid values are 0 to 255. Setting the EDNS version causes a EDNS query to be sent. **+noedns** clears the remembered EDNS version.

+[no]multiline
Print records like the SOA records in a verbose multi-line format with human-readable comments. The default is to print each record on a single line to facilitate machine parsing of the **dig** output.

+[no]fail
Do not try the next server if you receive a SERVFAIL. The default is not to try the next server which is the reverse of normal stub resolver behavior.

+[no]besteffort
Attempt to display the contents of messages that are malformed. The default is not to display malformed answers.

+[no]dnssec
Request DNSSEC records to be sent by setting the DNSSEC OK bit (DO) in the OPT record in the additional section of the query.

+[no]sigchase
Chase DNSSEC signature chains. Require the **dig** command to be compiled with -DDIG SIGCHASE.

+trusted-key=####
Specify a file containing trusted keys to be used with **+sigchase**. Each DNSKEY record must be on its own line. If not specified, the **dig** command looks for the **/etc/trusted-key.key** file then the **trusted-key.key** file in the current directory. Require the **dig** command to be compiled with -DDIG SIGCHASE.

+[no]topdown
When chasing DNSSEC signature chains, perform a top down validation. Require the **dig** command to be compiled with -DDIG SIGCHASE.

Multiple Queries

The BIND 9 implementation of **dig** supports specifying multiple queries on the command line (in addition to supporting the **-f** batch file option). Each of those queries can be supplied with its own set of flags, options and query options.

In this case, each query argument represents an individual query in the command-line syntax. Each consists of any of the standard options and flags, the name to be looked up, an optional query type, class, and any query options that must be applied to that query.

A global set of query options, which must be applied to all queries, can also be supplied. These global query options must precede the first tuple of name, class, type, options, flags, and query options supplied

on the command line. Any global query options (except the **+[no]cmd** option) can be overridden by a query-specific set of query options. For example:

```
dig +qr www.isc.org any -x 127.0.0.1 isc.org ns +noqr
```

This **dig** command string shows how the **dig** command could be used from the command line to make three lookups: an ANY query for **www.isc.org**, a reverse lookup of 127.0.0.1, and a query for the NS records of **isc.org**. A global query option of **+qr** is applied, so that the **dig** command shows the initial query it made for each lookup. The final query has a local query option of **+noqr**, which means that the **dig** command does not print the initial query when it looks up the NS records for **isc.org**.

IDN SUPPORT

If the **dig** command has been built with internationalized domain name (IDN) support, it can accept and display non-ASCII domain names. The **dig** command appropriately converts character encoding of domain name before sending a request to the DNS server or displaying a reply from the server. If you would like to turn off the IDN support for some reason, define the IDN DISABLE environment variable; the following IDN support is disabled if the variable is set when the **dig** command runs.

Examples

A typical invocation of **dig** looks like:

```
dig @server name type
```

where:

server
The name or IP address of the name server to query. This can be an IPv4 address in dotted-decimal notation or an IPv6 address in colon-delimited notation. When the supplied server argument is a hostname, the **dig** command resolves that name before querying that name server. If no server argument is provided, the **dig** command consults the **/etc/resolv.conf** file and queries the name servers listed there. The reply from the name server that responds is displayed.

name
The name of the resource record that is to be looked up.

type
Indicates what type of query is required — **ANY**, **A**, **MX**, **SIG**, and so on. The *type* argument value can be any valid query type. If no *type* argument is supplied, the **dig** command performs a lookup for an ***A*** record.

Files

Item	Description
/etc/resolv.conf	
${HOME}/.digrc	

digest Command

Purpose

Converts the ASCII form of the **/etc/qconfig** file into the **/etc/qconfig.bin** file, a binary version of the queue configuration used by the **qdaemon** command. This command should not be entered on the command line; it is called by the **qdaemon** command.

Syntax

/usr/lib/lpd/digest *ASCIIFile BinaryFile*

Description

The **digest** command accepts an input file of ASCII characters and converts it into a binary file. This command is only used by the **qdaemon** command to translate the **/etc/qconfig** file into the binary version of the file, the **/etc/qconfig.bin** file.

Files

Item	Description
/etc/qconfig	Contains the queue configuration file.
/usr/sbin/qdaemon	Contains the queuing daemon.
/etc/qconfig.bin	Contains the digested, binary version of the **/etc/qconfig** file.

dircmp Command

Purpose

Compares two directories and the contents of their common files.

Syntax

dircmp [**-d**] [**-s**] [**-w** *num*] *Directory1 Directory2*

Description

The **dircmp** command compares the two directories specified by the *Directory1* and *Directory2* parameters and writes information about their contents to standard output. First, the **dircmp** command compares the file names in each directory. If the same file name appears in both, the **dircmp** command compares the contents of both files.

In the output, the **dircmp** command lists the files unique to each directory. It then lists the files with identical names in both directories, but with different contents. If no flag is specified, it also lists files that have identical contents as well as identical names in both directories.

The **diff -r** command offers a function similar to the **dircmp** command.

Flags

Item	Description
-d	Displays for each common file name both versions of the differing file contents. The display format is the same as that for the **diff** command.
-s	Does not list the names of identical files.
-w *num*	Change the width of the output to *num* number of characters.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Note: Differences in directory contents are not considered errors.

Examples

1. To summarize the differences between the files in two directories, type the following:

   ```
   dircmp proj.ver1 proj.ver2
   ```

   This displays a summary of the differences between the directories `proj.ver1` and `proj.ver2`. The summary lists separately the files found only in one directory or the other, and those found in both. If a file is found in both directories, the **dircmp** command notes whether the two copies are identical.
2. To show the details of the differences between files, type the following:

   ```
   dircmp  -d  -s proj.ver1 proj.ver2
   ```

   The **-s** flag suppresses information about identical files. The **-d** flag displays a **diff** listing for each of the differing files found in both directories.
3. To show the details of the differences between files with the width of the output line set to 90 characters, type the following:

   ```
   $dircmp -w 90 dir1 dir2
   ```

Files

Item	Description
/usr/bin/dircmp	Contains the **dircmp** command.

Related Information

The **cmp** command, **diff** command.

Directories in *Operating system and device management* describes the structure and characteristics of directories in the file system.

Input and output redirection in *Operating system and device management* describes how the operating system processes input and output.

dirname Command

Purpose

Writes to standard output all but the last part of a specified path.

Syntax

dirname *Path*

Description

The **dirname** command reads the specified path name, deletes all but the last / (slash) and the characters following it, and writes the result to standard output. If no characters follow the last /, the **dirname**

command uses the next to last / and ignores all characters following it. The **dirname** command applies the following rules in creating the path name:

1. If the *Path* parameter is a // (double slash), or if the *Path* parameter consists entirely of slash characters, change the string to a single / (slash). Skip steps 2 through 7.
2. Remove any trailing / characters from the specified path.
3. If there are no / characters remaining in the *Path* parameter, change the path to a single **.** (period). Skip steps 4 through 7.
4. Remove any trailing, non-slash characters from the path.
5. If the remaining path is // (double slash), go to step 6.
6. Remove any trailing slash characters from the path.
7. If the remaining path is empty, change the path to a single /.

For example, entering:

```
dirname //
```

results in a single / (slash). Entering:

```
dirname /a/b/
```

results in /a. Entering:

```
dirname a
```

results in a single . (period). Entering:

```
dirname a/b
```

results in the path name a.

The **dirname** and **basename** commands are generally used inside command substitutions within a shell procedure to specify an output file name that is some variation of a specified input file name.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion
>0	An error occurred.

Examples

To construct the name of a file located in the same directory as another, enter:

```
AOUTFILE=`dirname $TEXTFILE`/a.out
```

This sets the shell variable AOUTFILE to the name of an **a.out** file that is in the same directory as TEXTFILE. If TEXTFILE is **/home/fran/prog.c**, the value of `dirname $TEXTFILE` is **/home/fran** and AOUTFILE becomes **/home/fran/a.out**.

Files

Item	Description
/usr/bin/dirname	Contains the **dirname** command.

disable Command

The **disable** command includes information for the AIX Print Subsystem **disable** and the **System V Print Subsystem disable**.

Purpose

Disables printer queue devices.

Syntax

disable [**-c**] [**-r***Reason*] *PrinterName ...*

Description

The **disable** command disables or brings offline the printer queue devices specified by the *PrinterName* parameter.

Note: You must have root user authority or belong to the printq group to run this command.

Flags

Item	Description
-c	Cancels all job requests. Using this flag is the same as entering the **enq -K** command.
-r*Reason*	Specifies the reason for disabling the printer queue device with the *Reason* variable. This flag is a "no operation" flag, which means that the system ignores this flag.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To bring printer queue `lp0` offline without waiting for the current print jobs to finish, type:

   ```
   disable  -c lp0
   ```

2. To bring printer queue `lp0` offline after all print jobs are finished, type:

   ```
   disable lp0
   ```

Files

Item	Description
/usr/sbin/qdaemon	Queuing daemon
/etc/qconfig	Queue configuration file
/etc/qconfig.bin	Digested, binary version of the **/etc/qconfig** file
/var/spool/lpd/qdir/*	Queue requests
/var/spool/lpd/stat/*	Information on the status of the devices
/var/spool/qdaemon/*	Temporary copies of enqueued files

System V Print Subsystem disable Command

Purpose

Disable LP printers

Syntax

disable [*flags*] *printers*

Description

The **disable** command deactivates the named *printers*, disabling them from printing requests submitted by **lp**. By default, any requests that are currently printing on the designated printers will be reprinted in their entirety either on the same printer or on another member of the same class of printers. If the printer is remote, this command will only stop the transmission of jobs to the remote system. The **disable** command must be run on the remote system to disable the printer. (Run **lpstat -p** to get the status of printers.)

Printer names are *system-defined words* and as such should be restricted to uppercase and lowercase ASCII characters.

If you enter `disable -?`, the system displays the command usage message and returns 0.

Flags

-c
Cancel any requests that are currently printing on any of the designated printers. This flag cannot be used with the **-W** flag. If the printer is remote, the **-c** flag is ignored.

-r *reason*
Assign a *reason* for the disabling of the printers. This *reason* applies to all *printers* specified. This *reason* is reported by **lpstat -p**. *reason* must be enclosed in quotes if it contains blanks. The default reason is *unknown reason* for existing printers, and *new printer* for printers just added to the system but not yet enabled.

-W
Wait until the request currently being printed is finished before disabling the specified printer.

This flag cannot be used with the **-c** flag. If the printer is remote, the **-W** flag will be silently ignored.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **`lssecattr`** command or the **`getcmdattr`** subcommand.

Files

/var/spool/lp/*

diskusg Command

Purpose

Generates disk accounting data by user ID.

Syntax

diskusg [**-X**] [**-U** *MaxUsers*] [**-i** *FileListName*] [**-p** *File*] [**-u** *File*] [**-v**] { **-s** [*File ...*] | *FileSystem ...* }

Description

The **diskusg** command generates intermediate disk-accounting information from data in the files specified with the *File* or *FileSystem* parameters or from standard input. The **diskusg** command writes

one record per user to standard output. This command is called by the **dodisk** command, which can be run under the **cron** daemon. The output is in the following format:

Item	Description
UID	Contains the numerical user ID of the user.
Login	Contains the login name of the user.
Blocks	Contains the total number of 512-byte disk blocks allocated to the user.

The output of this command becomes the input of the **acctdisk** command, which converts the information to a total accounting record. The total accounting record is merged with other total accounting records to produce the daily report.

If you specify the *FileSystem* parameter, the **diskusg** command reads the i-nodes of the specified file systems to generate the usage data. The *FileSystem* parameters must be the special file names of the file system devices. For example, use the **/dev/hd4** device instead of / (root) directory to generate usage data for the root file system.

If you specify the *File* parameter, the input must be in a **diskusg** output format.

For more information on disk usage, see the **acctdusg** command.

Note: This command is for local devices only.

Flags

Item	Description
-i *FileListName*	Ignores the data in the *FileListName* file system. The *FileListName* variable specifies a list of file system names separated by commas or enclosed within quotation marks.
-p *File*	Uses the password file specified by the *File* variable to generate login names. The default is the **/etc/passwd** file.
-s [*File*]	Combines all records from the input file(s) or from standard input into a single record. The input data is already in a **diskusg** output format.
-U *MaxUsers*	Sets the maximum number of users that can be processed by the **diskusg** command. You need to use this flag only if the number of users is greater than the default of 5000.
-u *File*	Writes a record to the specified *File* variable for each file that is charged to a user ID of no one. Each record consists of the special file name, the i-node number, and the user ID.
-v	Writes a list of all files that are charged to no one to the standard error output.
-X	Prints and processes all available characters for each user name instead of truncating to the first 8 characters.

Security

Access Control: This command should grant execute (x) access only to members of the **adm** group.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

To generate daily disk-accounting information, add a line similar to the following to the **/var/spool/cron/crontab/root** file:

```
0 2 * * 4 /usr/sbin/acct/dodisk
```

This command tells the **cron** daemon to run the **dodisk** command at 2 a.m. (02) each Thursday (4). The **dodisk** command calls both the **diskusg** and **acctdisk** commands.

Note: To perform this example, you must have root authority.

Files

Item	Description
/usr/sbin/acct/diskusg	Contains the **diskusg** command.
/etc/passwd	Contains the basic attributes of users.

dispgid Command

Purpose

Displays a list of all valid group names.

Syntax

dispgid

Description

The **dispgid** command can be used to display a list of all group names on the system (one name per line). There are no parameters for this command. The following files are accessed in read-only mode to retrieve the data:

- **/etc/passwd**
- **/etc/group**
- **/etc/security/user**
- **/etc/security/limits**
- **/etc/security/group**
- **/etc/security/environ**

Exit Status

0
The command completed successfully.

>0
An error occurred.

Examples

1. To list all the valid groups in the machine enter the **dispgid** command as follows:

   ```
   dispgid
   ```

   The output looks similar to the following:

```
system
staff
bin
sys
adm
uucp
mail
security
cron
printq
audit
ecs
nobody
usr
perf
```

Files

Item	Description
/usr/sbin/dispgid	Contains the **dispgid** command
/etc/group	Contains group information

dispuid Command

Purpose

Displays a list of all valid user names.

Syntax

dispuid

Description

This command can be used to display a list of all user names on the system (one line per name). There are no parameters for this command. The following files are accessed in read-only mode to retrieve the user data:

- **/etc/passwd**
- **/etc/security/user**
- **/etc/security/user.roles**
- **/etc/security/limits**
- **/etc/security/environ**
- **/etc/group**
- **/etc/group**

Exit Status

0
The command completed successfully.

>0
An error occurred.

Examples

1. To list all the valid users in your machine enter the dispuid command as follows:

```
dispuid
```

The output looks similar to the following:

```
root
daemon
bin
sys
adm
uucp
guest
nobody
lpd
invscout
imnadm
user1
```

Files

Item	Description
/usr/sbin/dispuid	Contains the dispuid command.
/etc/passwd	Contains password information.

dist Command

Purpose

Redistributes a message to additional addresses.

Syntax

dist [**+** Folder] [**-nodraftfolder** | **-draftfolder +***Folder*] [*Message* | **-draftmessage** *Message*] [**-annotate** [**-inplace** | **-noinplace**] | **-noannotate**] [**-form** *FormFile*] [**-editor** *Editor* | **-noedit**] [**-nowhatnowproc** | **-whatnowproc** *Program*]

Description

The **dist** command provides an interface for redistributing existing messages to a new list of addresses. By default, the **dist** command copies the current message in the current folder to the *UserMHDirectory***/draft** file and starts an editor. To specify a message in the current folder other than the default, use the *Message* parameter.

Once started, the editor prompts you to enter values for each header field. The **dist** command uses the header format defined in the *UserMHDirectory***/distcomps** file. (If this file does not exist, the system uses the **/etc/mh/distcomps** file.) Since the body of the message is the message you are redistributing, do not fill in the body. To define a format file other than *UserMHDirectory***/distcomps** file, use the **-form** flag.

To change the default editor, use the **-editor** flag or define the `Editor:` entry in your **$HOME/.mh_profile** file.

Press the Ctrl-D key sequence to exit the editor. Upon exiting the editor, the **dist** command starts the Message Handler (MH) `What Now?` prompt. Press the Enter key to see a list of the available **whatnow** subcommands. These subcommands enable you to continue editing the message header, list the message header, direct the disposition of the message, or end the processing of the **dist** command.

Note: A line of dashes or a blank line must be left between the header and the body of the message for the message to be identified when it is sent.

Redistributed messages consist of the original header and body appended to a new header. The **draft** file you edit using the **dist** command consists of header fields only. A copy of the original message with the new draft message is not automatically stored.

To annotate the original message with redistribution information, use the **-annotate** flag. This flag appends the original message with the `Resent:` field, and the current date and time.

Flags

Item	Description
-annotate	Annotates the message being redistributed with the lines: `Resent: date` `Resent: address` Since the **-annotate** flag is not preserved over multiple executions of the command, annotation is completed only if the message is sent directly from the **dist** command. The **-inplace** flag forces annotation to be done in place in order to preserve links to the annotated message.
-draftfolder *+Folder*	Places the draft message in the specified folder. If **-draftfolder** **+***Folder* flag is followed by a *Message* variable, it is the same as using the **-draftmessage** flag. If *+Folder* is not specified, the draft message is placed in *Current-Folder*.
-draftmessage *Message*	Specifies a draft message. By default, the system creates a new draft message in the current folder. The draft message becomes the current message.
-editor *Editor*	Specifies the initial editor for preparing the message for distribution.
+*Folder*	Identifies the folder that contains the message to redistribute. If a folder is not specified, then *Current-Folder* is assumed.
-form *FormFile*	Determines the message form. The **dist** command treats each line in the specified form file.
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For MH, the name of this flag must be fully spelled out.
-inplace	Forces annotation to be done in place in order to preserve links to the annotated message.
Message	Identifies the message to redistribute. Use the following references to specify messages: ***Number*** Number of the message. **cur or . (period)** Current message. This is the default. **first** First message in a folder. **last** Last message in a folder. **next** Message following the current message. **prev** Message preceding the current message.

Item	Description
-noannotate	Suppresses annotation. This flag is the default.
-nodraftfolder	Places the draft in the *UserMHDirectory***/draft** file.
-noedit	Suppresses the initial edit.
-noinplace	Prevents annotation in place. This flag is the default.
-nowhatnowproc	Suppresses interactive processing of the **dist** command. The **-nowhatnowproc** flag prevents any edit from occurring.
-whatnowproc *Program*	Starts the specified program to guide you through the distribution tasks. If you specify the **whatnow** command as the *Program* variable, the **dist** command starts an internal **whatnow** procedure instead of a program with the file name **whatnow**.

Profile Entries

The following entries are entered in the *UserMHDirectory***/.mh_profile** file:

Item	Description
`Current-Folder:`	Sets the default current folder.
`Draft-Folder:`	Sets the default folder for drafts.
`Editor:`	Sets the default editor.
`fileproc:`	Specifies the program used to refile messages.
`Path:`	Specifies the user's MH directory.
`whatnowproc:`	Specifies the program used to prompt `What now?` questions.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To redistribute the current message from the current folder, enter:

   ```
   dist
   ```

   The system prompts you for the header field values. After entering a value, press the Enter key. To skip an entry, press the Enter key without entering a value. You must fill in the `Resent-to:` field. After completing the headers, do not modify the body of the text. Press the Ctrl-D key sequence to exit the editor. The system prompts you with:

   ```
   What now?
   ```

   Press the Enter key to see a list of available options. If you want to redistribute this message, enter `send.` Your message is redistributed to the new list of addresses.
2. To redistribute a message to a new list of addresses when a message draft exists, enter:

   ```
   dist
   ```

   The system responds with a message similar to the following:

```
Draft "$HOME/Mail/draft" exists (43 bytes).
Disposition? _
```

To redistribute this draft, enter:

```
replace
```

The system prompts you for the header field values. After entering a value, press the Enter key. To skip an entry, press the Enter key without entering a value. You must fill in the `Resent-to:` field. After completing the headers, do not modify the body of the text. Press the Ctrl-D key sequence to exit the editor. The system prompts you with:

```
What now?
```

Press the Enter key to see a list of available options. If you want to redistribute the draft, enter `send`. Your message is redistributed to the new list of addresses.

3. To redistribute message 15 from the `schedules` folder, enter:

   ```
   dist  +schedules 15
   ```

   The system prompts you for the header field values. After entering a value, press the Enter key. To skip an entry, press the Enter key without entering a value. You must fill in the `Resent-to:` field. After completing the headers, do not modify the body of the text. Press the Ctrl-D key sequence to exit the editor. The system prompts you with:

   ```
   What now?
   ```

   Press the Enter key to see a list of available options. To redistribute the message, type `send` and press the Enter key.

Files

Item	Description
/etc/mh/distcomps	Contains the system default message format.
*UserMHDirectory***/distcomps**	Contains the user's default message format.
*UserMHDirectory***/draft**	Contains the current draft file.
/usr/bin/dist	Contains the executable form of the **dist** command.

dmpuncompress Command

Purpose

Restores dump compressed files.

Syntax

`/usr/bin/dmpuncompress` [`-f`] [`-p`] [*File*]

Description

The `dmpuncompress` command restores original dump files that were compressed at dump time.

Each compressed file specified by the *File* parameter is removed and replaced by an expanded copy. The expanded file has the same name as the compressed version, but without the `.BZ` extension. If the user has root authority, the expanded file retains the same owner, group, modes, and modification time as the

original file. If the user does not have root authority, the file retains the same modes and modification time, but acquires a new owner and group.

Flags

Item	Description
`-f` *File*	Forces expansion. Overwrites the file if it already exists. The system does not prompt the user that an existing file will be overwritten. File size might not actually shrink.
`-p` *File*	Preserves original `.BZ` file and uncompressed dump file. This overrides removal of the compressed file when there is a successful restoration of the original dump file. If restoration of the original dump file is incomplete because of an error, this option disables removal of the partial dump.

Exit Status

Item	Description
`0`	Successful completion.
`>0`	An error occurred.

Example

1. To uncompress the `dump.BZ` file, enter:

   ```
   /usr/bin/dmpuncompress dump.BZ
   ```

   The `dump.BZ` file is uncompressed and renamed `dump`.
2. To keep the `dump.BZ` file and the newly created dump file in the file system following completion, enter:

   ```
   /usr/bin/dmpuncompress -p dump.BZ
   ```

Location

`/usr/bin/dmpuncompress`

dnssec-keygen Command

Purpose

Domain name system security extensions (DNSSEC) key generation tool.

Syntax

dnssec-keygen [**-a** *algorithm*] [**-b** *keysize*] [**-n** *nametype*] [**-c** *class*] [**-e**] [**-f** *flag*] [**-g** *generator*] [**-h**] [**-k**] [**-p** *protocol*] [**-r** *randomdev*] [**-s** *strength*] [**-t** *type*] [**-v** *level*] [*name*]

Description

The **dnssec-keygen** command generates keys for DNSSEC (Secure DNS). It can also generate keys to use with Transaction Signatures (TSIG).

Flags

Item	Description
-a *algorithm*	Selects the cryptographic algorithm. The algorithm can have one of the following values: • RSAMD5 • DSA • DH (Diffie-Hellman) • HMAC-MD5 These values are case-sensitive. **Notes:** 1. For DNSSEC, RSASHA1 is a mandatory-implement algorithm, and DSA is preferred. For TSIG, HMAC-MD5 is mandatory. 2. HMAC-MD5 and DH automatically set the **-k** flag.
-b *keysize*	Specifies the number of bits in the key. The choice of key size depends on the algorithm used. RSAMD5 and RSASHA1 keys must be 512 - 4096 bits. DH keys must be 128 - 4096 bits. DSA keys must be 512 - 1024 bits and an exact multiple of 64. HMAC-MD5 keys must be 1 - 512 bits.
-n *nametype*	Specifies the owner type of the key. The value of *nametype* must either be ZONE (for a DNSSEC zone key), HOST, or ENTITY (for a key that is associated with a host), USER (for a key that is associated with a user), or OTHER (DNSKEY). These values are not case-sensitive.
-c *class*	Indicates that the Domain Name Server (DNS) record that contains the key must have the specified class. If not specified, class IN is used.
-e	If you are generating an RSAMD5 or RSASHA1 key, use a large exponent.
-f *flag*	Sets the specified flag in the *flag* field of the KEY or the DNSKEY record. The only recognized flag is KSK (Key Signing Key) DNSKEY.
-g *generator*	If you are generating a DH key, use this generator. The acceptable values are 2 and 5. If generator is not specified, a known prime from RFC 2539 is used if possible; otherwise the default is 2.
-h	Prints a short summary of the options and arguments to the **dnssec-keygen** command.
-k	Generates KEY records rather than DNSKEY records.
-p *protocol*	Sets the protocol value for the generated key. The protocol is a number 0 - 255. The default is 3 (DNSSEC).
-r *randomdev*	Specifies the source of randomness. If the operating system does not provide a /dev/random file or equivalent device, the default source of randomness is keyboard input. The *randomdev* argument specifies the name of a character device or a file that contains random data to be used instead of the default. The special value keyboard indicates that keyboard input must be used.
-s *strength*	Specifies the strength value of the key. The *strength* argument is a number 0 - 15, and currently has no defined purpose in DNSSEC.

Item	Description
-t *type*	Indicates the use of the key. The *type* must be one of AUTHCONF, NOAUTHCONF, NOAUTH, or NOCONF. The default is AUTHCONF. AUTH refers to the ability to authenticate data, and CONF the ability to encrypt data. No key is generated for these algorithms (DH, HMAC-MD5, HMAC-SHA1, HMAC-SHA224, HMAC-SHA256, HMAC-SHA384, HMAC-SHA512) with key type as NOAUTHCONF.
-v *level*	Sets the debugging level.

Parameters

Item	Description
name	The name of the key that is specified on the command line. For DNSSEC keys, this name must match the name of the zone for which the key is being generated.

Generated Keys

When the **dnssec-keygen** command completes successfully, it prints a string of the form Knnnn.+aaa+iiiii to the standard output. It is an identification string for the key that it generated.

- nnnn is the key name.
- aaa is the numeric representation of the algorithm.
- iiiii is the key identifier (or footprint).

The **dnssec-keygen** command creates two files with names based on the printed string: Knnnn.+aaa+iiiii.key contains the public key, and Knnnn.+aaa+iiiii.private contains the private key.

The .key file contains a DNSKEY record that can be inserted into a zone file (directly or with a $INCLUDE statement). The .private file contains algorithm-specific fields. For security reasons, this file does not have general read permission. Both the .key and .private files are generated for symmetric encryption algorithm such as HMAC-MD5, even though the public key and the private key are equivalent.

Examples

To generate a 768 - bit DSA key for the domain example.com, type the following command:

```
dnssec-keygen -a DSA -b 768 -n ZONE example.com
```

The command prints a string of the form:

```
Kexample.com.+003+26160
```

In this example, **dnssec-keygen** creates the files Kexample.com.+003+26160.key and Kexample.com.+003+26160.private.

dnssec-makekeyset command

Purpose

Domain name system security extensions (DNSSEC) zone signing tool.

Syntax

dnssec-makekeyset [**-a**] [**-s** *start-time*] [**-e** *end-time*] [**-h**] [**-p**] [**-r** *randomdev*] [**-t** *ttl*] [**-v** *level*] {*key...*}

Description

The **dnssec-makekeyset** command generates a key set from one or more keys that are created by the **dnssec-keygen** command. It creates a file that contains a KEY record for each key, and self-signs the key set with each zone key. The output file is of the form `keyset-nnnn.`, where *nnnn* is the zone name.

Flags

Item	Description
-a	Verifies all generated signatures.
-s *start-time*	Specifies the date and time when the generated SIG records become valid. It can be either an absolute or relative time. An absolute start time is indicated by a number in YYYYMMDDHHMMSS notation; 20000530144500 denotes 14:45:00 UTC on May 30th, 2000. A relative start time is indicated by +N, which is *N* seconds from the current time. If no *start-time* is specified, the current time is used.
-e *end-time*	Specifies the date and time when the generated SIG records expire. As with the *start-time* value, an absolute time is indicated in YYYYMMDDHHMMSS notation. A time relative to the start time is indicated with +N, which is *N* seconds from the start time. A time relative to the current time is indicated with now+N. If no *end-time* is specified, 30 days time from the start time is used as a default.
-h	Prints a short summary of the options and arguments to the **dnssec-makekeyset** command.
-p	Uses pseudo-random data when you sign the zone. It is faster, but less secure, than using real random data. This option might be useful when you sign large zones or when the entropy source is limited.
-r *randomdev*	Specifies the source of randomness. If the operating system does not provide a `/dev/random` or equivalent device, the default source of randomness is keyboard input. The *randomdev* value specifies the name of a character device or file that contains random data to be used instead of the default. The special value keyboard indicates that keyboard input must be used.
-t *ttl*	Specifies the TTL (time to live) of the KEY and SIG records. The default is 3600 seconds.
-v *level*	Sets the debugging level.

Parameters

Item	Description
key	The list of keys to be included in the key set file. These keys are expressed in the form `Knnnn.+aaa+iiiii` as generated by the **dnssec-keygen** command.

Examples

The following command generates a key set that contains the DSA key for `example.com` generated in the **dnssec-keygen** man page.

```
dnssec-makekeyset -t 86400 -s 20000701120000 -e +2592000 Kexample.com.+003+26160
```

In this example, the **dnssec-makekeyset** command creates the file `keyset-example.com.`. This file contains the specified key and a self-generated signature. The DNS administrator for `example.com` can send `keyset-example.com.` to the DNS administrator for `.com` for signing, if the `.com` zone is DNSSEC-aware and the administrators of the two zones have some mechanism for authenticating each other and exchanging the keys and signatures securely.

dnssec-signkey Command

Purpose

Domain name system security extensions (DNSSEC) key set signing tool.

Syntax

dnssec-signkey [**-a**] [**-c** *class*] [**-s** *start-time*] [**-e** *end-time*] [**-h**] [**-p**] [**-r** *randomdev*] [**-v** *level*] *keyset key*

Description

The **dnssec-signkey** command signs a key set. Typically the key set is for a child zone, and is generated by the **dnssec-makekeyset** command. The child zone's key set is signed with the zone keys for its parent zone. The output file is of the form `signedkey-`*nnnn*`.`, where *nnnn* is the zone name.

Flags

Item	Description
-a	Verify all generated signatures.
-c *class*	Specifies the DNS class of the key sets.
-s *start-time*	Specify the date and time when the generated SIG records become valid. It can be either an absolute or relative time. An absolute start time is indicated by a number in YYYYMMDDHHMMSS notation; 20000530144500 denotes 14:45:00 UTC on May 30th, 2000. A relative start time is indicated by *+N*, which is *N* seconds from the current time. If no *start-time* is specified, the current time is used.
-e *end-time*	Specify the date and time when the generated SIG records expire. As with start-time, an absolute time is indicated in YYYYMMDDHHMMSS notation. A time relative to the start time is indicated with *+N*, which is *N* seconds from the start time. A time relative to the current time is indicated with now+N. If no *end-time* is specified, 30 days time from the start time is used as a default.
-h	Prints a short summary of the options and arguments to the **dnssec-signkey** command.
-p	Use pseudo-random data when you sign the zone. It is faster, but less secure, than using real random data. This option might be useful when you sign large zones or when the entropy source is limited.
-r *randomdev*	Specifies the source of randomness. If the operating system does not provide a `/dev/random` or equivalent device, the default source of randomness is keyboard input. *randomdev* specifies the name of a character device or file that contains random data to be used instead of the default. The special value keyboard indicates that keyboard input must be used.
-v *level*	Sets the debugging level.

Parameters

Item	Description
keyset	The file that contains the child's key set.
key	The keys that are used to sign the child's key set.

Examples

The DNS administrator for a DNSSEC-aware `.com` zone uses the following command to sign the key set file for `example.com` created by the **dnssec-makekeyset** command with a key generated by the **dnssec-keygen** command:

```
dnssec-signkey keyset-example.com. Kcom.+003+51944
```

In this example, **dnssec-signkey** creates the file `signedkey-example.com.`, which contains the `example.com` keys and the signatures by the `.com` keys.

dnssec-signzone Command

Purpose

Domain name system security extensions (DNSSEC) zone signing tool.

Syntax

dnssec-signzone [**-a**] [**-c** *class*] [**-d** *directory*] [**-e** *end-time*] [**-f** *output-file*] [**-g**] [**-h**] [**-k** *key*] [**-l** *domain*] [**-i** *interval*] [**-I** *input-format*] [**-j** *jitter*] [**-N** *soa-serial-format*] [**-o** *origin*] [**-O** *output-format*] [**-p**] [**-r** *randomdev*] [**-s** *start-time*] [**-t**] [**-v** *level*] [**-z**] *zonefile* [*key*...]

Description

The **dnssec-signzone** command signs a zone. It generates NSEC and RRSIG records and produces a signed version of the zone. The presence or absence of a key set file for each child zone determines the security status of delegations from the signed zone (that is, whether the child zones are secure or not).

Flags

Item	Description
-a	Verifies all generated signatures.
-c *class*	Specifies the DNS class of the zone.
-d *directory*	Looks for key set files in the directory that is specified by the *directory* argument.
-k *key*	Treats the specified key as a key-signing key ignoring any key flags. You can specify this option multiple times.
-l *domain*	Generates a DLV set in addition to the key (DNSKEY) and DS sets. The domain is appended to the name of the records.
-g	Generates DS records for child zones from key set files. This flag removes existing DS records.
-s *start-time*	Specifies the date and time when the generated RRSIG records become valid. It can be either an absolute or relative time. An absolute start time is indicated by a number in YYYYMMDDHHMMSS notation; 20000530144500 denotes 14:45:00 UTC on May 30th, 2000. A relative start time is indicated by +*N*, which is *N* seconds from the current time. If you do not specify the *start-time* argument, the command uses the current time minus 1 hour (to allow for clock skew).
-e *end-time*	Specifies the date and time when the generated RRSIG records expire. As with the *start-time* argument, an absolute time is indicated in YYYYMMDDHHMMSS notation. A time relative to the start time is indicated with +*N*, which is *N* seconds from the start time. A time relative to the current time is indicated with now+N. If you do not specify the *end-time* argument, the command uses 30 days from the start time as a default.

Item	Description
-f *output-file*	Specifies the name of the output file that contains the signed zone. The default is to append `.signed` to the input file name.
-h	Prints a short summary of the options and arguments of the **dnssec-signzone** command.
-i *interval*	When a previously signed zone is passed as input, records might be resigned. The interval option specifies the cycle interval as an offset from the current time (in seconds). If an RRSIG record expires after the cycle interval, it is retained. Otherwise, it is considered to be expiring soon, and it is then replaced. The default cycle interval is one quarter of the difference between the signature end and start times. If you specify neither the *end-time* argument or the *start-time* argument, the **dnssec-signzone** command generates signatures that are valid for 30 days, with a cycle interval of 7.5 days. Therefore, if any existing RRSIG records are due to expire in less than 7.5 days, they are replaced.
-I *input-format*	Specifies the format of the input zone file. Possible formats are text (default) and raw.
-j *jitter*	When you sign a zone with a fixed signature lifetime, all RRSIG records issued at the time of signing expire simultaneously. If the zone is incrementally signed, for example, a previously signed zone is passed as input to the signer and all expired signatures must be regenerated at about the same time. The *jitter* argument specifies a jitter window that is used to randomize the signature expire time, thus spreading incremental signature regeneration over time. Signature lifetime jitter can also benefit validators and servers by spreading out cache expiration. For example, if large numbers of RRSIGs do not expire at the same time from all caches, there is less congestion than if all validators must refetch at mostly the same time.
-n *ncpus*	Specifies the number of threads to use. By default, the command starts one thread for each detected processor.
-N *soa-serial-format*	Specifies the SOA serial number format of the signed zone. The *soa-serial-format* argument can be one of the following values: **keep** Does not modify the SOA serial number. It is the default value. **increment** Increases the SOA serial number by using RFC 1982 arithmetic. **unixtime** Sets the SOA serial number to the number of seconds since epoch.
-o *origin*	Specifies the zone origin. If not specified, the name of the zone file is assumed to be the origin.
-O *output-format*	Specifies the format of the output file that contains the signed zone. Possible formats are text (default) and raw.
-p	Uses pseudo-random data when you sign the zone. It is faster, but less secure, than using real random data. This option can be useful when you sign large zones or when the entropy source is limited.
-r *randomdev*	Specifies the source of randomness. If the operating system does not provide a `/dev/random` file or equivalent device, the default source of randomness is keyboard input. The *randomdev* argument specifies the name of a character device or file that contains random data to be used instead of the default. The special value keyboard indicates that keyboard input must be used.
-t	Prints statistics at completion.
-v *level*	Sets the debugging level.
-z	Ignores KSK flag on key when you determine what to sign.

Parameters

Item	Description
zonefile	The file that contains the zone to be signed.
key	The keys that are used to sign the key set. If no keys are specified, the defaults are all zone keys that have private key files in the current directory.

Examples

The following command signs the `example.com` zone with the DSA key generated by the **dnssec-keygen** command. The zone's keys must be in the zone. If there are key set files that are associated with this zone or any child zones, they must be in the current directory, `example.com`. You can issue the following command:

```
dnssec-signzone -o example.com db.example.com Kexample.com.+003+26160
```

In this example, the **dnssec-signzone** command creates the `db.example.com.signed` file. This file must be referenced in a zone statement in a `named.conf` file.

dodisk Command

Purpose

Initiates disk-usage accounting.

Syntax

/usr/sbin/acct/dodisk [**-X**] [**-o**] [*File ...*]

Description

The **dodisk** command initiates disk-usage accounting by calling the **diskusg** command and the **acctdisk** command. If you specify the **-o** flag with the **dodisk** command, a more thorough but slower version of disk accounting by login directory is initiated using the **acctdusg** command. Normally, the **cron** daemon runs the **dodisk** command.

By default, the **dodisk** command does disk accounting only on designated files with stanzas in the **/etc/filesystems** file and that contain the attribute **account=true**. If you specify file names with the *File* parameter, disk accounting is done on only those files.

If you do not specify the **-o** flag, the *File* parameter should contain the special file names of mountable file systems. If you specify both the **-o** flag and the *File* parameter, the files should be mount points of mounted file systems.

Note: You should not share accounting files among nodes in a distributed environment. Each node should have its own copy of the various accounting files.

Flags

Item	Description
-o	Calls the **acctdusg** command, instead of the **diskusg** command, to initiate disk accounting by login directory.
-X	Process all available characters of each user name instead of truncating to the first 8 characters.

Security

Access Control: This command should grant execute (x) access only to members of the **adm** group.

Examples

1. To start automatic disk-usage accounting, add the following to the **/var/spool/cron/crontabs/root** file:

   ```
   0 2 * * 4 /usr/sbin/acct/dodisk
   ```

   This example shows the instructions that the **cron** daemon will read and act upon. The **dodisk** command will run at 2 a.m. (`0 2`) each Thursday (4). This command is only one of the accounting instructions normally given to the **cron** daemon. See "Setting Up an Accounting System" in *Operating system and device management* for more information on typical **cron** accounting entries.
2. To run disk-usage accounting on a system that contains user names greater than 8 character, add the following line to the **/var/spool/cron/crontabs/root** file:

   ```
   0 2 * * 4 /usr/sbin/acct/dodisk -X
   ```

Files

Item	Description
/usr/sbin/acct	The path to the accounting commands
/etc/filesystems	Contains information about file system.

domainname Command

Purpose

Displays or sets the name of the current Network Information Service (NIS) domain.

Syntax

/usr/bin/domainname [*DomainName*]

Description

The **domainname** command displays or sets the name of the current NIS domain. If you do not specify a parameter, the **domainname** command displays the name of the current NIS domain. A domain typically encompasses a group of hosts under the same administration.

Only the root user can set the name of the domain by giving the **domainname** command an argument.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To join a new domain, enter:

   ```
   domainname caesar
   ```

In this example, the `domainname` command sets the NIS domain name to caesar.

2. To find out the name of the domain your machine belongs to, enter:

```
domainname
```

domlist Command

Purpose

Displays domain information for a user or process.

Syntax

domlist -p *pid*

Description

The **domlist** command provides domain information to the invoker about their current assigned domains. If no flags or arguments are specified, the **domlist** command displays the list of domains assigned to the invoker with the text description of each domain if one is provided in the domains database.

The **domlist** command also allows a privileged user to list the domain information for a process. Specifying a process ID with the **-p** flag allows a privileged user to display the domains associated with a process.

Flags

Item	Description
-p *PID*	Displays domain information of the specified process.

Examples

1. To display the list of domains that assigned to you and their text descriptions, use the following command:

```
domlist
```

2. To display the list of domains assigned to a process use the following command:

```
domlist -p <pid>
```

Files Accessed

Item	Description
Files	**Mode**
/etc/security/domains	r

dosdel Command

Purpose

Deletes DOS files.

Syntax

dosdel [**-v**] [**-D** *Device*] *File ...*

Description

The **dosdel** command deletes the DOS file specified by the *File* parameter. Use the **-v** flag to obtain format information about the disk.

DOS file-naming conventions are used with one exception. Since the \ (backslash) character can have special meaning to the operating system, use a / (slash) character as the delimiter to specify subdirectory names in a DOS path name. The **dosdel** command converts lowercase characters in the file or directory name to uppercase before it checks the disk. Because all file names are assumed to be full (not relative) path names, you need not add the initial / (slash).

Flags

Item	Description
-D*Device*	Specifies the name of the DOS device as **/dev/fd0** or **/dev/fd1**. The default device is **/dev/fd0.**
-v	Writes information to standard output about the format of the disk. Use this flag to verify that a device is a DOS disk.

Examples

To delete a DOS file on the default device, enter:

```
dosdel file.ext
```

Files

Item	Description
/usr/bin/dosdel	Contains the **dosdel** command.

dosdir Command

Purpose

Lists the directory for DOS files.

Syntax

dosdir [**-l** [**-e**]] [**-a**] [**-d**] [**-t**] [**-v**] [**-D** *Device*] [*File ...* | *Directory ...*]

Description

The **dosdir** command displays information about the specified DOS files or directories. If you specify a directory without also specifying the **-d** flag, the **dosdir** command displays information about the files in that directory.

DOS file-naming conventions are used with one exception. Since the \ (backslash) character can have special meaning to the operating system, use a / (slash) character as the delimiter to specify subdirectory names in a DOS path name. The **dosdir** command converts lowercase characters in the file or directory name to uppercase before it checks the disk. Because all file names are assumed to be full (not relative) path names, you need not add the initial / (slash).

Flags

Item	Description
-a	Writes information about all files. This includes hidden and system files as well as the . (dot) and .. (dot-dot) files.
-d	Treats the *File* value as a file, even if a directory is specified. When a directory is specified with the *Directory* parameter, information about the directory itself is listed instead of information about the files it contains.
-D*Device*	Specifies the name of the DOS device as **/dev/fd0** or **/dev/fd1**. The default device is **/dev/fd0**.
-e	Uses the **-l** flag to write the list of clusters allocated to the file.
-l	Produces a list of clusters that includes the creation date, size in bytes, and attributes of the file. The size of a subdirectory is specified as 0 bytes. The attributes have the following meanings: **A (Archive)** The file has not been backed up since it was last modified. **D (Directory)** The file is a subdirectory and not included in the normal DOS directory search. **H (Hidden)** The file is not included in the normal DOS directory search. **R (Read-only)** The file cannot be modified. **S (System)** The file is a system file and not included in the normal DOS directory search.
-t	Lists the entire directory tree starting at the named directory.
-v	Writes information to standard output about the format of the disk. Use this flag to verify that a device is a DOS disk.

Examples

To read a directory of the DOS files on **/dev/fd0**, enter:

```
dosdir
```

The command returns the names of the files and disk-space information.

```
PG3-25.TXT
PG4-25.TXT
PG5-25.TXT
PG6-25.TXT
Free space: 312320 bytes
```

To read a directory of the DOS files on **/dev/fd1**, enter:

```
dosdir -D/dev/fd1
```

The command returns the names of the files and disk-space information.

```
PG7-25.TXT
PG8-25.TXT
PG9-25.TXT
PG10-25.TXT
Free space: 312320 bytes
```

Files

Item	Description
/usr/bin/dosdir	Contains the **dosdir** command.

dosformat Command

Purpose

Formats a DOS diskette.

Syntax

dosformat [**-V** *Label*] [**-D** *Device* | **-4**]

Description

The **dosformat** command formats a diskette with the DOS format.

The default device and DOS diskette drive format is **/dev/fd0** for a 3.5-inch diskette. The density is usually either 1.44M-byte or 2.88M-byte, depending on the density that the drive supports. Other DOS diskette drive formats are implemented by using the **-D** or **-4** flags.

To include a volume label, use the **-V** flag.

Note: The purpose of this command is to facilitate file transfer between this operating system and DOS systems. Using this command to format a diskette that needs to have the DOS system startup files on it is not recommended.

Flags

Item	Description
-V	Write the *Label* parameter to the diskette as the DOS volume label.

Item	Description
-D*Device*	Specifies the diskette drive type and size. The *Device* parameter can be specified as: For a 3.5-inch, 1.44M drive: **/dev/fd0** 1.44MB (default) **/dev/fd0h** 1.44MB **/dev/fd0l** 720KB **/dev/fd0.18** 1.44MB **/dev/fd0.9** 720KB For a 3.5-inch, 2.88M drive: **/dev/fd0** 2.88MB (default) **/dev/fd0h** 2.88MB **/dev/fdol** 720KB **/dev/fd0.36** 2.88MB **/dev/fd0.18** 1.44MB **/dev/fd0.9** 720KB For a 5.25-inch, 1.2M drive: **/dev/fd0** 1.2MB (default) **/dev/fd0.15** 1.2MB **/dev/fd0.9** 360KB

Item	Description
-4	Specifies the lower density for the diskette size.

Examples

1. To format a 3.5-inch, 1.44M-byte diskette with the volume label "homework," type the following:

   ```
   dosformat -V homework
   ```

2. To format a 5.25-inch, 360K-byte diskette, type the following:

   ```
   dosformat -D /dev/fd1.9
   ```

   OR

```
dosformat -D /dev/fd1 -4
```

Files

Item	Description
/usr/bin/dosformat	Contains the **dosformat** command.

dosread Command

Purpose

Copies DOS files.

Syntax

dosread [**-a**] [**-v**] [**-D** *Device*] *File1* [*File2*]

Description

The **dosread** command copies the DOS file specified by the *File1* variable to standard output or to the file specified by the *File2* variable. If no pathname is specified for the *File2* variable, the DOS file is copied to the root directory.

Unless otherwise specified, the **dosread** command copies the number of bytes specified in the directory entry for the file specified by the *File1* variable. This means, in particular, that you cannot copy directories because, by convention, directories have a record size of 0.

You can use DOS file-naming conventions with one exception: the \ (backslash). Because the \ character can have special meaning in DOS, use a / (slash) character as the delimiter to specify subdirectory names in a DOS path name. The **dosdir** command converts lowercase characters in the file or directory name to uppercase before it checks the disk. Because all file names are assumed to be full (not relative) path names, you need not add the initial / (slash).

Notes:

1. The **dosread** command does not interpret the * and ? (asterisk and question mark) wildcard characters as having special meaning. If you do not specify a file-name extension, the file name is matched as if you had specified a blank extension.
2. You cannot customize the name of this command. The command must be named **dosread**.
3. The **dosread** command reads files from the default drive containing the DOS diskette. The **dosread** command then copies the files to the current directory as a file recognized by this operating system. If the DOS diskette contains subdirectories, the **dosread** command does not create corresponding new subdirectories in this operating system. You must create the subdirectory and specify each DOS file you want to copy into the new subdirectory.

Flags

Item	Description
-a	Replaces each CR-LF (carriage return, line-feed) key sequence with a new-line character and interprets a Ctrl-Z (ASCII SUB) key sequence as the end-of-line character.
-D*Device*	Specifies the name of the DOS device as **/dev/fd0** or **/dev/fd1**. The default value of the *Device* variable is **/dev/fd0**. This device must have the DOS disk format.
-v	Writes file information to standard output about the format of the disk. Use this flag to verify that a device is a DOS disk.

Examples

1. To copy a text file from a DOS, type:

   ```
   dosread  -a chap1.doc chap1
   ```

   This command sequence copies the DOS text file `\CHAP1.DOC` on default device **/dev/fd0** to `chap1` in the current directory.
2. To copy a binary file from a DOS diskette, type:

   ```
   dosread -D/dev/fd1 /survey/test.dta /home/fran/testdata
   ```

   This command sequence copies the DOS data file `\SURVEY\TEST.DTA` on **/dev/fd1** to `/home/fran/testdata`.
3. To copy every DOS file on a diskette, type:

   ```
   dosdir | awk '!/There are/ {print $1}'|xargs -t -i dosread {} {}
   ```

   This command sequence takes files from the default drive containing the DOS disk and copies them to the current directory.

Files

Item	Description
/usr/bin/dosread	Contains the **dosread** command.
/dev/fd0	Contains the device name for a diskette drive.

doswrite Command

Purpose

Copies files to DOS files.

Syntax

doswrite [**-a**] [**-v**] [**-D***Device*] *File1 File2*

Description

The **doswrite** command copies the file specified by the *File1* parameter to the DOS file specified by the *File2* parameter. The **doswrite** command copies files to a single DOS diskette. The **doswrite** command cannot copy files across multiple DOS diskettes.

The **doswrite** command writes the file specified by the *File2* parameter to the DOS device using standard DOS naming conventions. Because the DOS \ (backslash) character can have a special meaning for the DOS operating system, do not use a \ (backslash) when specifying subdirectory names in the *File2* parameter. Use the / (slash) character instead.

The **doswrite** command converts lowercase characters specified in the *File1* parameter to uppercase before it checks the DOS device. Because all file names are assumed to be full (not relative) path names, you do not need to add the initial / (slash).

If the file specified in the *File2* parameter contains a / (slash), each intervening component must exist as a directory and the last component (the named file) must not exist. Any existing file with the same name is overwritten.

Notes:

1. The wildcard characters * and ? (asterisk and question mark) are not treated in a special way by this command (although they are by the shell). If you do not specify a file-name extension, the file name is matched as if you had specified a blank extension.
2. This command must be named **doswrite**.
3. A DOS directory holds up to 244 files.

Flags

Item	Description
-a	Replaces NL (new-line) characters with the CR-LF (carriage return, line-feed) sequence. Ctrl-Z is added to the output at the end of file.
-D *Device*	Specifies the name of the DOS device as **/dev/fd0** or **/dev/fd1**. The default device is **/dev/fd0**. This device must have the DOS disk format.
-v	Writes information to standard output about the format of the disk. Use this flag to verify that a device is a DOS disk.

Examples

1. To copy a text file to a DOS diskette, enter:

   ```
   doswrite  -a chap1 chap1.doc
   ```

   This copies the file `chap1` in the current directory to the DOS text file `\CHAP1.DOC` on default device **/dev/fd0**.
2. To copy a binary file to a DOS diskette, enter:

   ```
   doswrite -D/dev/fd1 /home/fran/testdata /survey/test.dta
   ```

   This copies the data file `/home/fran/testdata` to the DOS file `\SURVEY\TEST.DTA` on **/dev/fd1**.
3. To copy every file in the current directory to a DOS diskette in your default drive, enter:

   ```
   for i in *
   do
   doswrite $i $i
   done
   ```

Files

Item	Description
/usr/bin/doswrite	Contains the **doswrite** command.
/dev/fd0	Contains the device name for diskette drive.

dp Command

Purpose

Parses and reformats dates.

Syntax

dp [**-form** *File* | **-format** *String*] [**-width** *Number*] *Date*

Description

The **dp** command parses and reformats dates. The **dp** command is not started by the user. The **dp** command is called by other programs, typically by its full path name, **/usr/lib/mh/dp**.

The **dp** command parses each mail header string specified as a date and attempts to reformat the string. The default output format for the **dp** command is the ARPA RFC 822 standard. For each string it is unable to parse, the **dp** command displays an error message.

Parameter

Item	Description
Date	Specifies the date to be parsed.

Flags

Item	Description
-form *File*	Reformats the date specified in the *Date* parameter to the alternate format described by the *File* variable.
-format *String*	Reformats the date specified in the *Date* parameter to the alternate format specified by the *String* variable. The default format string follows: `%<(nodate{text})error:%{text}%|%(putstr(pretty{text}))%>`
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For Message Handler (MH), the name of this flag must be fully spelled out.
-width *Number*	Sets the maximum number of columns the **dp** command uses to display dates and error messages. The default is the width of the display.

Files

Item	Description
$HOME/.mh_profile	Contains the MH user profile.
/etc/mh/mtstailor	Contains MH command definitions.

dpid2 Daemon

Purpose

Starts the **dpid2** Distributed Protocol Interface - SNMP multiplexer protocol (DPI-SMUX) converter daemon as a background process.

Syntax

dpid2 [**-d** [*Level*]]

Description

The **dpid2** command starts the **dpid2** DPI-SMUX converter daemon. This command can be issued only by a user with root privileges or by a member of the system group.

The **dpid2** DPI-SMUX converter daemon complies with the standard Simple Network Management Protocol (SNMP) DPI version 2.0 that is defined by RFC 1592 and SNMP SMUX protocol and Management Information Base (MIB) defined by RFC 1227.

The **dpid2** daemon acts as a DPI 2.0 to SMUX converter. It is used to allow DPI subagents, such as `/usr/sbin/hostmibd`, to communicate with the AIX SNMP version 1 agent. The converter changes DPI2 messages into SMUX protocol messages and vice versa. The **dpid2** daemon itself is implemented as SMUX peer. It connects with the TCP port 199 of the SMUX server that is part of the `snmpd` agent. To a DPI2 subagent (for example, `/usr/sbin/hostmibd`), the **dpid2** daemon behaves like a DPI2 agent. It listens on an arbitrary TCP port for a connection request from a DPI2 subagent. This port number is registered by the **dpid2** daemon with the `snmpd` agent through MIB variable dpiPortForTCP (1.3.6.1.4.1.2.2.1.1.1). The DPI2 subagent learns this port number from the `snmpd` agent by sending a get-request query for the dpiPortForTCP.0 (1.3.6.1.4.1.2.2.1.1.1.0) instance to the `snmpd` agent. After the DPI2 subagent knows the TCP port number, which the DPI2 agent is listening on, it then tries to connect to it.

The **dpid2** daemon is normally run during system startup when the `/etc/rc.tcpip` shell script is called.

The **dpid2** daemon must be controlled by using the System Resource Controller (SRC). Entering `dpid2` at the command line is not recommended.

Use the following SRC commands to manipulate the **dpid2** daemon:

startsrc
Starts a subsystem, group of subsystems, or a subserver.

stopsrc
Stops a subsystem, group of subsystems, or a subserver.

refresh
Causes a subsystem or group of subsystems to reread the appropriate configuration file.

lssrc
Gets the status of a subsystem, group of subsystems, or a subserver.

Note: The `snmpdv3` agent itself acts as a DPI2 agent and listens on the dpiPortForTCP.0 TCP port. Therefore, the **dpid2** daemon is not needed when you use the `snmpdv3` agent. Therefore, the **dpid2** daemon is not run in the system startup and the **dpid2** line in `/etc/rc.tcpip` is commented out.

Flags

Item	Description
-d *Level*	Specifies tracing or debug level. **8** DPI level 1 **16** DPI level 2 **32** Internal level 1 **64** Internal level 2 **128** Internal level 3 Add the numbers for multiple trace levels. **Note:** If the **-d** flag is specified, but the level number is not specified, the default level is 56. If **-d** flag is not specified, the default level is 0.

Examples

1. To start the **dpid2** daemon, enter a command similar to the following command:

   ```
   startsrc -s dpid2 -a "-f /tmp/dpid2.log"
   ```

   This command starts the **dpid2** daemon and logs information to the `/tmp/dpid2.log` file at debug level 0.
2. To stop the **dpid2** daemon normally, enter the following command:

   ```
   stopsrc -s dpid2
   ```

   This command stops the **dpid2** daemon. The **-s** flag specified the subsystem that follows to be stopped.
3. To get the short status from the **dpid2** daemon, enter the following command:

   ```
   lssrc -s dpid2
   ```

   This command returns the name of the daemon, the process ID of the daemon, and the state of the daemon (active or inactive).

Files

Item	Description
`/etc/snmpd.conf`	Specify SMUX peer entry in `snmpd` version 1 agent configuration file.
`/etc/snmpd.peers`	Specify the configuration for SMUX peer.
`/etc/mib.defs`	Defines the MIB variables the SNMP agent and manager must recognize and handle.

dping Command

Purpose

Pings nodes or devices in parallel.

Syntax

dping [**-h**] [**-v**] [**-a**] [**-s**] [**-S**] [**-r**] [**-i** *interface...]* [**-w** " **selectstr**"] [**-H** *host_list*] [**-f** *filename*] [**-N** *nodegroup...*] [**-d** *devicename...*] [**-D** *devicegroup*] [[**-n**] *node_list*]

Description

The **dping** command pings the specified servers. The command can be used to retrieve node status or when you suspect a problem with Rational® Method Composer (RMC) and its heartbeating. The **dping** command is used to ping nodes or devices in parallel. **- Ping** nodes pings every second node interface in the series. For example, **eth1** or **mryi0** and **- Direct** nodes pings other nodes.

Keywords

Item	Description
-a	Specifies to ping all the nodes. This flag cannot be combined with the **-n**, **-N**, **-f**, **-d**, **-H**or **-w** flags.
-c	Collapses identical output from more than 1 node and displays it 1 time.

Item	Description
-d *devicename...*	Specifies one or more comma-separated devices to ping. The asterisk character (*) indicates all devices.
-D *devicegroup...*	Specifies one or more comma-separated device groups to ping.
-f *filename*	Specifies a file that contains a list of nodes. If the file name specified is the dash character (**-**), then the list is read from the standard input. The file can contain multiple lines, and each line can list one or more comma or space-separated node host names or node ranges.
-h	Displays command usage information.
-H *host_list*	Specifies the host name that is separated by comma or space to be pinged. These host names must not be defined NIM nodes. Space separated host names must be specified within double quotation marks. The **-H** flag cannot be specified with the **-n, -N**, **-f, -d, -w,** or the**-a** flags.
-i *interface..*	Specifies one or more comma-separated network interfaces to ping for each node specified. The flag assumes that *nodename-interface.domain* resolves to the IP address of that network adapter on the node. You must set up host name resolution before running **dping**. If one of the host names is an empty string, for example **"eth1,eth2"**, the flag also pings the primary host name.
-n *node_list*	Specifies one or more comma or space-separated node host names or node ranges to ping. This flag can be used simultaneously with **-N** and **-f**. The host name value can be specified without **-n**, if it is the last argument specified. See the noderange file for information about node ranges.
-N *nodegroup..*	Specifies one of more comma-separated node groups on which to run the command.
-r	Pings recursively. This flag runs **dsh** command to the nodes that pinged successfully. It pings all remaining nodes specified with the **dping** command, from those nodes.
-s	Pings the nodes serially instead of in parallel. This flag cannot be used with the **-S** flag.
-S	Displays a summary of the ping results only. This flag cannot be used with the **-s** flag.
-v	Specifies verbose mode.
-w *selectstr*	Displays the nodes that match the "where" clause of the select string. Specifying the entire string within double quotation marks will allow you to specify attribute value strings within single quotation marks. The asterisk character (*) indicates all nodes, as if a "where" clause were not specified. The **-w** flag cannot be specified with the **-n**, **-N**, **-f**, **-d**, **-H**, or **-a** flags.

Security

The command requires root access to the cluster management server.

Examples

1. To ping all nodes, enter:

   ```
   dping -a
   ```

   Output is similar to:

   node1.localdomain: ping (alive)

   node2.localdomain: noping (unreachable)

   node3.localdomain: ping (alive)

2. To ping the **group1** *nodegroup* and **eth1** node interface, enter:

```
dping -N group1 -i eth1
```

Output is similar to:

node1-eth1.localdomain: ping (alive)

node2-eth1.localdomain: noping (unreachable)

3. To ping the hostname **node1-eth2.clusters.com**, enter

```
dping -i eth2 node1.clusters.com
```

Output is similar to:

Exit Status 0 The command completes successfully. **1** The command failed. **10** No nodes or devices were specified.

drmgr Command

Purpose

The **drmgr** command is used to install and configure dynamic logical partitioning (DLPAR) scripts.

Syntax

drmgr { **-i** *script_name* [**-w** *minutes*] [**-f**] | **-u** *script_name* } [**-D** *hostname*]

drmgr [**-b**]

drmgr [**-R** *script_install_root_directory*]

drmgr [**-S** *syslog_ID*]

drmgr [**-l**]

Description

DLPAR scripts are provided by system administrators and vendors to coordinate the consumption of resources (for example, specific processors and large amounts of pinned memory) by applications and middleware with the addition or removal of those resources with respect to the operating system. DLPAR scripts are run both before and after DLPAR operations. DLPAR scripts are provided so that applications can be cleanly quiesced and restarted.

Note: The specified action flags cannot be combined. That is, a user cannot combine **-R** and **-S** flags, **-l** and **-R** flags, and so on.

Flags

Flag	Description
-b	Rebuilds the scripts' information file that is managed by the **drmgr** command. In general, this option must be used only when restoring scripts from another systems.
-D *hostname*	Specifies the hostname of the system on which the script can be started.
-f	Forces the replacement of an existing script.
-i *script_name*	Installs the *script_name* script. The *script_name* must have complete path. If the path is not specified, the current directory is assumed. If any name conflicts, the **drmgr** command issues a warning and does not install the script. Any existing script can be overwritten by specifying the **-f** flag.

Flag	Description
-l	Displays the details on the DLPAR scripts that are currently installed.
-R *base_script_directory*	Changes the base script installation directory.
-S *syslog_ID*	Logs syslog messages with the specified syslog ID string. This ID string is appended to every entry logged in syslog by the **drmgr** command.
-u *script_name*	Uninstalls a DLPAR script. If the script was installed with the **-D** option, the same parameter must be used to uninstall it. If no directory is specified, the **drmgr** command removes the DLPAR script from "all" installation directory.
-w *minutes*	Overrides the time limit value specified by the vendor for the script. The script is stopped if it exceeds the specified time limit.

Exit Status

0
Successfully completed the requested operation.

>0
The command failed. The cause of failure can be:

- File or directory does not exist.
- The length of the parameter exceeds the system limit (PATH_MAX).
- Too many arguments were specified.
- You do not have root authority to run this command.

drslot Command

Purpose

Manages a dynamically reconfigurable slot, such as, a hot plug slot.

Syntax

To Identify a Hot Plug Slot

drslot -i { -s *Slot* | **-l** *DeviceName* } **-c** *ConnectorType*

To Prepare a Hot Plug Slot for Configuring Devices

drslot -a -s *slot* **-c** *ConnectorType* [**-I**]

To Prepare a Hot Plug Slot for Removal of a Device

drslot -r { **-s** *slot* | **-l** *DeviceName*} **-c** *ConnectorType* [**-I**]

To Prepare a Hot Plug Slot for Removal and Replacement of a Device

drslot -R { **-s** *slot* | **-l** *DeviceName* } **-c** *ConnectorType* [**-I**]

Description

The **drslot** command manages dynamically reconfigurable slots, that is, hot plug slots. Hot plug slots are the plug-in points for connecting entities which can be configured without turning the system power off or rebooting the operating system. For the add (**-a**) operation, the slot must be specified directly by using the **-s** flag, giving the unique identifier for the slot. For the identify (**-i**), the remove (**-r**), and the replace (**-R**) operations, the slot may be specified directly with the **-s** flag, or indirectly. The slot may be specified indirectly by using the **-l** flag giving the logical name for a device connected to the slot. The **drslot** command determines to which slot the specified device is connected and manages that slot.

Notes:

1. The remove and replace operations fail unless the device connected to the identified slot has been unconfigured. For more information on how to successfully unconfigure a device, see Managing Hot Plug Connectors in *Operating system and device management*.
2. After an add or replace operation, you must run the **cfgmgr** command in order to make the new device active and ready for use by the operating system.

Flags

Note: Do not use the **-a**, **-i**, **-r**, **-R** flags together.

Item	Description
-a	Prepares a hot plug slot for configuring the device(s) connected to it. The slot is first identified to you and you are prompted for confirmation of the slot. Next, you are prompted for confirmation that the device has been connected to the slot. Upon confirmation that the device has been connected, the slot is prepared and the device is made ready for configuration.
-c *ConnectorType*	Specifies the *ConnectorType* of the *Slot* on which you are operating. For example, the *ConnectorType* for a hot plug PCI slot is `pci`. This flag is must be specified with the **-a**, **-i**, **-r**, and **-R** flags.
-i	Identifies a hot plug slot. The identification of the slot is hardware dependent. For example, if a slot has an LED associated with it, issuing the **drslot -i** command may cause the LED to flash.
-I	Specifies that the identification step should be skipped when using the **-a** (add), **-r** (remove), and **-R** (replace) flags. This flag should only be used when you are sure you have already identified the proper slot.
-l *DeviceName*	Specifies the *DeviceName*, which is the logical device name of the device connected to the slot to be managed. This flag must be used for the **-i** (identify), **-r** (remove) or **-R** (replace) flags if the **-s** flag is not used.
-r	Prepares a hot plug slot for removal of a device that has been previously unconfigured with the **rmdev** command, or the SMIT equivalent. The slot is identified and you are prompted for confirmation of the slot. If a visual indicator is associated with the slot, it is turned off. Finally, the slot is prepared for device removal and you are prompted for confirmation that the device has been removed from the slot.
-R	Prepares a hot plug slot for the removal of a device that has been previously unconfigured and the replacement with an identical device. The device must be unconfigured with the **rmdev** command, or the SMIT equivalent. **drslot** identifies the slot and you are prompted for confirmation of the slot. Next, the slot is prepared for the replacement of the device. You are then prompted to confirm that the device has been replaced. Upon confirmation that the device has been replaced in the hot plug slot, the slot is prepared and the device is made ready for configuration.
-s *Slot*	Specifies the *Slot* on which **drslot** should operate. This flag is required for the add (**-a**) operation. This flag must be used for the identify (**-i**), remove (**-r**) or replace (**-R**) operations if the **-l** flag is not used. The format of *Slot* is Platform/*ConnectorType* dependent.

Examples

1. To identify a specific PCI hot plug slot, enter:

```
drslot  -i  -c pci  -s U0.1-P1-I3
```

In this example, there is an LED associated with this slot. The system may display a message similar to the following:

```
The visual indicator of the specified PCI slot has been set to the identify
state. Press Enter to continue or enter x to exit.
```

The LED for the slot specified by `U0.1-P1-I3` flashes until the you press the Enter key.

2. To add a hot pluggable Ethernet adapter to a hot plug slot without confirmation of the slot, enter:

```
drslot  -a  -I  -c pci  -s U0.1-P1-I3
```

No confirmation prompt is given for identifying the slot. There will be a confirmation prompt displayed when it is time to put the new adapter into the slot, and a message similar to the following displays:

```
The visual indicator for the specified PCI slot has been set to the action
state. Insert the PCI card into the identified slot, connect any devices to
be configured, and press Enter to continue. Enter x to exit.
```

After connecting the adapter, press Enter, and the slot is prepared.

3. To identify a particular PCI slot before replacing the scsi card in it, enter the following:

```
drslot  -R  -c pci  -s U0.2-P1-I3
```

The system displays messages similar to the following:

```
The visual indicator of the specified PCI slot has been set to the identify
state. Press Enter to continue or enter x to exit.
```

The LED for the PCI slot blinks to identify the slot. Pressing any key but the Enter key exits the command. Pressing Enter continues with this slot. If continuing, the LED for the PCI slot is changed to the action state and the system displays a message similar to the following:

```
The visual indicator for the specified PCI slot has been set to the action
state. Replace the PCI card in the identified slot, reconnect any devices
to be configured, and press Enter to continue. Enter x to exit. Exiting now
leaves the PCI slot in the removed state.
```

Files

/usr/sbin/drslot

dscrctl Command

Purpose

Sets the default prefetch characteristics of an operating system.

Syntax

To query the characteristics of the hardware streams on the computer:

dscrctl -q

To set the default prefetch depth of the operating system on the computer, temporarily (for the current session) or permanently (after each restart operation):

dscrctl [**-n**] [**-b**] **-s** *dscr_value*

To cancel a permanent setting of the default prefetch depth of the operating system at start time:

dscrctl -c

Description

The **dscrctl -q** subcommand displays the number of hardware streams, and default prefetch depth of the platform and the operating system. Any user can run this subcommand.

The **dscrctl -s** subcommand sets the default prefetch depth of the operating system. You must have root authority to run this subcommand. This default value can be changed either for the current session by using **-n** flag, at start time by using **-b** flag, or for both current session and at start time by using **-n -b** flags together with the **dscrctl** command.

The **dscrctl -c** option cancels the default prefetch depth setting of the operating system at start time. This option removes the **dscrctl** command from the **/etc/inittab** file, and therefore takes effect after the next restart operation.

Flags

-q
Displays the number of hardware streams that are supported by the platform and also displays the values of the default prefetch depth of the firmware and the operating system.

-c
Cancels a permanent setting of the default prefetch depth at start time by removing the **dscrctl** command from the **/etc/inittab** file.

-n
Changes the run time value of the default prefetch depth of the operating system. This flag is used in conjunction with the **-s** flag. The change is not persistent from one boot operation to the next.

-b
Makes the change persistent across boot operations by adding the **dscrctl** command to the **/etc/inittab** file. This flag is used in conjunction with the **-s** flag.

-s *dscr_value*
Defines the value for the new default prefetch depth of the operating system. The value is treated as a decimal number, unless it starts with `0x` in which case it is treated as a hexadecimal number.

Examples

1. To set the value of the default prefetch depth of the operating system to 13 for the current session, enter:

```
# dscrctl -n -s 13
```

2. To show the current settings of the hardware stream mechanism, enter:

```
# dscrctl -q
```

The following output is displayed:

```
Current DSCR settings:
Data Streams Version = V2.06
number_of_streams = 16
platform_default_pd = 0x5 (DPFD_DEEP)
os_default_pd = 0xd (DSCR_SSE | DPFD_DEEP)
```

dscreen Command

Purpose

Starts the Dynamic Screen utility.

Syntax

dscreen [**-i** *InfoFile*] [**-t** *TermType*]

Description

The **dscreen** command starts the Dynamic Screen utility, which allows a single physical terminal to be connected to several virtual sessions, or screens, at one time.

If no flags are specified, the **dscreen** command reads the description for the terminal specified in the **TERM** environment variable from the file specified in the **DSINFO** environment variable. If the **DSINFO** environment variable is not specified, the terminal description is read from the **/etc/dsinfo** file. A terminal description typically contains the following configuration information:

- Keys used with the Dynamic Screen utility and their function
- Number of pages of screen memory the terminal has available
- Code sequences that must be sent or received to access and use Dynamic Screen features

Flags

Item	Description
-i *InfoFile*	Specifies the file that contains alternate key mappings for use with the Dynamic Screen utility. This option is useful when the originally defined Dynamic Screen keys conflict with one of your applications. If this flag is not specified, terminal configuration information is read from the file specified in the **DSINFO** environment variable, if set. Otherwise, information is read from the **/etc/dsinfo** file.
-t *TermType*	Identifies the terminal description to be read from the file containing the key mappings. This option is useful when the desired terminal type does not match the setting of the **TERM** environment variable.

Examples

1. To start the Dynamic Screen utility using key mapping defaults, enter:

   ```
   dscreen
   ```

   This sets the **DSINFO** and **TERM** environment variables as designated in the default **/etc/dsinfo** file.
2. To start the Dynamic Screen utility and specify a file that contains alternate key mappings and also identifies a terminal description to be read from the file, enter:

   ```
   dscreen -i myfile -t myterm
   ```

   This uses information from a user-created **dsinfo-**type file named `myinfo` to handle unusual key mapping needs. The `myinfo` file also contains a terminal definition named `myterm`.
3. To start the Dynamic Screen utility and specify an alternate terminal setup, enter:

   ```
   dscreen -t wy60-wp
   ```

   This terminal definition (maintained in the **/etc/dsinfo** file) sets **dscreen** assigned key actions so they do not conflict with control key command sequences in the word processing application being used.

Files

Item	Description
/etc/dsinfo	Contains the terminal descriptions for the Dynamic Screen utility.

dshbak Command

This command is part of the IBM Distributed Shell Management (DSM) software. The command is located at the */opt/ibm/sysmgt/dsm/bin/dshbak* location.

Purpose

Presents formatted output from the dsh command.

Syntax

dshbak [**-c** | **-x**]

Description

The **dshbak** command formats output from the dsh command. The syntax of the **dshbak** command is as follows:

host_name: line of output from **remote** command

The **dshbak** command formats the lines and writes them to the standard output as follows. The assumption is that the output from *host_name3* and *host_name4* are identical, and the **-c** flag is specified.

```
HOSTS -------------------------------------------------------
          host_name1
          ---------------------------------------------------------------
          .
          .
          lines from dsh with host_names stripped off
          .
          .
          HOSTS -------------------------------------------------------
          host_name2
          ---------------------------------------------------------------
          .
          .
          lines from dsh with host_names stripped off
          .
          .
          HOSTS -------------------------------------------------------
          host_name3             host_name4
          ---------------------------------------------------------------
          .
          .
          lines from dsh with host_names stripped off
          .
          .
```

The host names are displayed alphabetically, if the output is displayed from more than one node in a collapsed form. The output is sorted alphabetically by host name, if the output is not collapsed. The **dshbak** command writes "." for each 1000 lines of output filtered.

If the **-x** flag is specified, the extra header lines that **dshbak** command displays for each node is excluded. The **dshbak** command sorts the output using the node name to view the content:

```
host_name1: lines from dsh started
          .
          .
          lines from dsh continued
          .
          .
          lines from dsh ended
          host_name2: lines from dsh started
```

```
.
.
lines from dsh continued
.
.
lines from dsh ended
```

Flags

Item	Description
-c	Collapses identical output from more than 1 node to display the output at one time.
-x	Excludes the extra header lines that **dshbak** displays for each node. This flag provides compact output, and **dshbak** command sorts the output by node name to view the content. The flag must not be used with **-c**.

Security

Note: You must run the **kinit** command to obtain a ticket-grant-ticket before running the Kerberos Version 5 **remote** commands. The additional security considerations are like that of the **remote shell** command.

Examples

1. To display the results of a command issued on several nodes, in the format used in the Description, enter the following command:

   ```
   dsh -n node1,node2,node3 cat /etc/passwd | dshbak
   ```

2. To display the results of a command issued on several nodes with identical output, enter the following command:

   ```
   dsh -w host1,host2,host3 pwd | dshbak -c
   ```

3. To display the results of a command issued on several nodes with compact output, enter the following command:

   Note: The output is sorted alphabetically by host name.

   ```
   dsh -w host1,host2,host3 date | dshbak -x
   ```

Standard Error

The error messages on standard error is displayed before all standard output messages, if the **dshbak** filter is used. This behaviour is true with and without the **-c** flag.

dsh Command

Purpose

Runs commands concurrently on multiple nodes and hardware devices.

Syntax

dsh -h dsh -V dsh -q dsh [**-a**] [**--all-nodes** *context_list*]

[**-A**] [**--all-devices** *context_list*] [**-n**

node_list] [**-N** *nodegroups*] [**-d** *device_list*]

[**-D** *devicegroups*] [**-C** *context*]

[**-c**] [**-e**] [**-E** *environment_file*

] [**-f** *fanout*] [**-F** *output_path*]

[**-i**] [**-l** *user_ID]* [**-L**]

[**--log** *log_file*] [**-m**] [**-o**

node_options] [**-O** *device_options*] [**-Q**]

[**-r** *node_remote_shell*] [**--device-rsh**

device_remote_shell] [**-s**] [**-S**

csh | **ksh**] [**-t** *timeout*]

[**-T**] [**-v**] [**-X**

env_list] [**-z**] [**--report**

report_path] [**--report-name** *report_name*] [*command_list*]

Description

The **dsh** command runs commands concurrently on remote targets - nodes, hardware devices, or both. Targets can be selected from multiple contexts. A context is a target database that contains node and device definitions, such as the NIM database. The **dsh** command issues a **remote shell** command for each target specified. It returns output from all targets in a formatted manner to enable the command results from all nodes to be managed easily. The**/usr/bin/rsh** is the model for syntax and security and the dsh command is a DSM Distributed Shell Utility.

Note: The **dsh** command is supported only on IPv4 target devices. IPv6 addresses are not supported currently.

Parameters

Item	Description
TARGET CONTEXT	The **dsh** command target context is the database where the target or target group is defined. A default context can be configured using the **-C** context flag or the **DSH CONTEXT** environment variable. If either parameter is not specified, the default context is **NIM** when the dsh command is run from a NIM management server, else the default context is **DSH** (see **DSH CONTEXT**). A context is used with a **DSH Utilities** command by installing a context extension file in the **/opt/ibm/sysmgt/dsm/pm/Context** directory. The target or target group context can be explicitly specified by qualifying a target name with a context name, or implicitly defined by specifying a default context for unqualified target names (see **Target list**).
DSH CONTEXT	The **DSH CONTEXT** is the in-built context for all the **DSH Utilities** commands. It permits a user-defined node group database contained in the local file system. The **DSH_NODEGROUP_PATH** environment variable specifies the path to the node group database. Each file in this directory represents a node group, and contains one host name or TCP/IP address for each node that is a group member. Blank lines and comment lines beginning with a # symbol are ignored. If all nodes are requested for the **DSH CONTEXT**, a full node list is built from all groups in the **DSH_NODEGROUP_PATH** directory, and cached in **/var/ibm/sysmgt/dsm/dsh/$DSH_NODEGROUP_PATH/AllNodes**. This file is recreated each time a group file is modified or added to the **DSH_NODEGROUP_PATH** directory. Device targets are not supported in the **DSH** context.

Item	Description
TARGET SPECIFICATION	A target is a node or hardware device where a remote command is issued. Node targets are specified using the **-a, --all-nodes** *context_list*, **-n** *node_list* and **-N** *nodegroups* flags, or the **DSH_NODE_LIST** environment variable. If both the **-N** flag and the **DSH_NODE_LIST** environment variable are used, the groups and lists are merged eliminating any duplicates. **Note:** The **DSH_NODE_LIST** environment variable has replaced **WCOLL**. Device targets are specified using the **-A, --all-devices** *context_list*, **-d** *device_list* and **-D** *devicegroups flags*, or the **DSH_DEVICE_LIST** environment variable. If the local host is included as part of the targets, the *command_list* is run directly on the local host and not through the configured remote shell, unless a *user_ID* is specified for execution with the local host (see Remote user). The **DSH_NODE_LIST** and **DSH_DEVICE_LIST** environment variables specify files listing target nodes and devices. The file format is 1 target per line. Blank lines and comment lines beginning with a # symbol are ignored. Both node and device targets can be specified simultaneously, but the same target name cannot be used for both a device and a node. If a similar name is used, the program skips the duplicate targets, and continues execution on the other targets. Node and device targets can also be specified using node ranges; see the **noderange** file for details. If the same target is specified more than one time, the **remote** command is run one time on the specified target.
TARGET LIST	Target and target groups are specified using the following format: [*context*:] [*user_ID*@] *target* [, [*context*:] [*user_ID*@] *target*]... where context is the explicit context specification for the target, *user_ID* is the optional user name to use when remotely running the command on the target, and *target* is the name or TCP/IP address of the target as permitted by the target's context. For a **noderange** expression, the *user_ID* is used for each target in the list that results from the evaluation of the **noderange** expression. If the target list is only specified with a **dash (-)**, targets can be specified interactively. For nodes, the prompt is **dsh node>**; and for devices the prompt is **dsh device>**. Specify the target list using the following syntax on 1 line at a time: [*context*:] [*user_ID*@] *target* where context is the explicit context specification for the target, *user_ID* is the optional user name to use when remotely running the command on the target, and target is the name or TCP/IP address of the target as permitted by the context of the target. For a **noderange** expression, the *user_ID* is used for each target in the list that results from the evaluation of the **noderange** expression. If the target list is only specified with a dash (-), targets can be specified interactively. For nodes, the prompt is **dsh node>**; for devices the prompt is **dsh device>**. Specify the target list using the following syntax on 1line at a time: [*context:*][*user_ID*@]*target* When you are finished, press Ctrl-d to continue.

Item	Description
COMMAND SPECIFICATION	The commands to run on the remote targets are specified by the *command_list* dsh parameter, entering commands on the command line in interactive mode, providing a *command_list* through standard input, or running a local script using the **-e** flag. The syntax for the *command_list* dsh parameter is as follows: "**command[; command]...**" where command is the command to run on the remote target. Quotation marks are required to ensure that all commands in the list are run remotely, and that any special characters are interpreted correctly on the remote target. A script file on the local host is run on each of the remote targets by using the **-e** flag. If **-e** is specified, *command_list* is the script name and arguments to the script. For example: `dsh -e[flags] script_filename [arguments]...` The *script_filename* file is copied to a random file name in the **/tmp** directory on each remote target and then run on the targets. If the *command_list* parameter is not specified, dsh enters interactive command-line mode and prompts the **dsh>** prompt. Enter commands at the **dsh>** prompt using the following syntax: **[!] "command"** where command is the command to run on the remote target. An exclamation point (!) preceding a command causes the command to run on the local host only, and not on remote targets. The dsh command runs command on resolved target, and the result is displayed. It then returns to the dsh> prompt. To exit command-line mode, enter exit at the dsh> prompt. The dsh command does not work with any interactive commands, including those commands read from standard input.
REMOTE USER	The *user_ID* to use for a remote target can be specified as part of the target syntax (see Target lists) or using the **-l** (lowercase L) flag. If both methods are used, the *user_ID* is determined as follows: 1. For targets specified as *user_ID@target*, *user_ID* is used for remote execution on the target, and the *-l* flag is ignored. 2. For targets not specified using *user_ID@target*, the *user_ID* used for remote execution on the target is determined as follows: - The *user_ID* specified with the **-l** flag. If **-l** is not specified, the current user running the command is specified. If a *user_ID* is specified for the local host included in a target list, the **remote shell** command runs the *command_list* on the local host to ensure a secure login ID.
REMOTE SHELL COMMAND	The commands to run on the remote targets are specified by the *command_list* dsh parameter, entering commands on the command line in interactive mode, providing a *command_list* through standard input, or executing a local script using the **-e** flag. The syntax for the *command_list* dsh parameter is as follows: "**command[; command]...**" where command is the command to run on the remote target. Quotation marks are required to ensure that all commands in the list are run remotely, and that any special characters are interpreted correctly on the remote target. A script file on the local host can be run on each of the remote targets by using the **-e** flag. If **-e** is specified, **command_list** is the script name and arguments to the script. For example: dsh *-e[flags] script_filename [arguments]...* The *script_filename* file is copied to a random file name in the **/tmp** directory on each remote target and then run on the targets. If the **command_list** parameter is not specified, dsh enters interactive command-line mode and the dsh> prompt is displayed. Enter commands at the dsh> prompt using the following syntax: **[!] "command"**, where command is the command to run on the remote target. An exclamation point (!) preceding a command causes the command to run on the local host only, and not to any remote targets. The dsh command runs each command to each resolved target, the results are displayed and returns to the dsh> prompt. To exit command-line mode, enter exit at the dsh> prompt. The dsh command does not work with any interactive commands, including those commands that read from standard input.

Item	Description
REMOTE USER	The **user_ID** to use for a remote target can be specified as part of the target syntax (see Target lists) or using the **-l** (lowercase L) flag. If both methods are used, the *user_ID* is determined as follows: 1. For targets specified as *user_ID@target*, *user_ID* is used for remote execution on the target, and the *-l* flag is ignored. 2. For targets not specified using *user_ID@target*, the *user_ID* used for remote execution on the target is determined as follows: - The *user_ID* specified with the *-l* flag. If **-l** is not specified, the current user running the command. If a **user_ID** is specified for the local host included in a target list, the **remote shell** command runs the *command_list* on the local host to ensure a secure login.
REMOTE SHELL ENVIRONMENT	The shell environment used on the remote target defaults to the shell defined for the **user_ID** used for remote command execution. The command syntax used for remote command execution can be specified using the **-S** flag. If **-S** is not specified, the syntax defaults to ksh syntax. When commands are run on the remote target, the path used is determined by the **DSH_PATH** environment variable defined in the shell of the current user. If **DSH_PATH** is not set, the path used is the remote shell default path. For example, to set the local path for the remote targets, use: **DSH_PATH=$PATH**. The **-E** flag exports a local environment definition file to each remote target. Environment variables specified in this file are defined in the remote shell environment before the *command_list* is run.
COMMAND EXECUTION	The maximum concurrent **remote shell** command processes (the fanout) can be specified with the **-f** flag or with the **DSH_FANOUT** environment variable. The fanout is restricted by the number of **remote shell** commands that can be run in parallel. You can experiment with the **DSH_FANOUT** value on your management server to see if higher values are appropriate. A timeout value for remote command execution can be specified with the **-t** flag or with the **DSH_TIMEOUT** environment variable. If any remote target does not provide output to either standard output or standard error within the timeout value, an error message is displayed by the dsh command and exits. If streaming mode is specified with the **-s** flag, the output is returned as it becomes available from each target. This process does not wait for the *command_list* to complete on all targets before returning output. This can improve performance but causes the output to be unsorted. The **-z** flag is used to display the exit code from the last command issued on the remote node in *command_list*. **Note:** OpenSSH returns the exit status of the last remote command issued as its exit status. This affects the behavior of dsh and requires using the **-c** flag. If the command issued on the remote node is run in the background, the command does not display the exit status. The **-m** flag monitors execution of the dsh command by printing status messages to standard output. Each status message is preceded by dsh>. The **-T** flag provides diagnostic trace information for the execution of the dsh command. Default settings and the actual **remote shell** commands run on the remote targets are shown. No error detection or recovery mechanism is provided for remote targets. The dsh command output to standard error and standard output can be analyzed to determine the appropriate course of action. In interactive mode, if a command cannot be run on a remote target (for example, a **remote shell**l command resulting in a non-zero return code), subsequent commands are not sent to this node on this invocation of the dsh command unless the **-c** flag is specified.

Item	Description
COMMAND OUTPUT	The **dsh** command waits to display the output from each remote shell process and then initiates a new remote shell process. This default behavior is overridden by the **-s** flag. The dsh command output consists of standard error and standard output from the remote commands. The dsh standard output is the standard output from the remote shell command. The dsh standard error is the standard error from the remote shell command. Each line is prefixed with the host name of the node that produced the output. The host name is followed by the: character and a command output line. A filter to display identical outputs grouped by node is provided separately. See the **dshbak** command for more information. Output for each target can be copied to a file using the **-F** *output_path* flag. Standard output for each target is written to the *target.output* file in the *output_path* directory, and standard error for each target is written to the *target.error* file in the **output_path** directory. The **-F** flag does not suppress output on the console. A command can be run silently using the **-Q** flag; no output from each target's standard output or standard error is displayed. If the **-F** flag is specified, output continues to be written to output files.
REPORTING	Output from the dsh command can be saved to a report on the local host. The **--report** *report_path* flag enables report generation to the specified *report_path* directory. Reporting is activated by defining the **DSH_REPORT** environment variable with the *report_path*. The **--report flag** overrides the **DSH_REPORT** environment variable. The **--report-name** flag defines a report name, if reporting is activated. The **report name** is also the subdirectory of *report_path* that contains the report files. A numeric index is appended to the subdirectory name to allow multiple reports with the same name. If the **--report-name** flag is not used, the name defaults to Unspecified. Summary HTML and XML report files are created, in addition to an XML results file. SIGNALS: Signal 2 (INT), Signal 3 (QUIT), and Signal 15 (TERM) are propagated to the commands executing on the remote targets. Signal 19 (CONT), Signal 17 (STOP), and Signal 18 (TSTP) default to dsh; the dsh command responds normally to these signals, but the signals does not affect on the remotely executing commands. Other signals are determined by dsh and have their default effects on the dsh command; all current child processes, through propagation to remotely running commands, are terminated (SIGTERM). Parameters *command_list* Specifies a list of commands to execute on the remote targets. The syntax for the *command_list* parameter is as follows: " **command[; command...**"

Keywords

Item	Description
-a	Includes in the target list all nodes that are defined in the default context. The default context can be set using the **-C** flag or the **DSH_CONTEXT** environment variable.
-A	Includes in the target list all devices that are defined in the default context. The default context can be set using the **-C** flag or the **DSH_CONTEXT** environment variable. This flag is disabled on HMCs.
--all-nodes*context_list*	Includes in the target list all nodes defined in the contexts listed in *context_list.* The default context is not implicitly included in this list. This flag is disabled on HMC. **--all-nodes**.
--all-devices *context_list*	Includes in the target list all devices that are defined in the contexts listed in *context_list*. The default context is not implicitly included in this list. This flag is disabled on HMCs.
-C | **--continue**	In interactive mode only, keeps a node in the target list even if the remote shell command for the host has a non-zero exit value.

Item	Description
-C| **--context***context*	The default context to use when resolving target names. The context value must correspond to a valid context extension module in the **/opt/ibm/sysmgt/dsm/pm/Context** directory. For example, the **/opt/ibm/sysmgt/dsm/pm/Context/DSH.pm** file is the module for the DSH context.
-d | **--devices** *device_list*	Specifies a list of device targets to include in the target list. The *device_list* syntax is: [*context:*][*user_ID@]device_name*[,[*context:*]\ [*user_ID@*]*device_name*]... This flag is disabled on HMCs.
--device-rsh*device_remote_shell*	Specifies the full path of the remote shell command used for remote command execution on device targets. A remote shell for a specific context can be defined by including context: before the path. The *device_remote_shell* syntax is: [*context:*]*path*[,[*context:*]*path*]... This flag is disabled on HMCs. -
-D | **--devicegroups** *devicegroups*	Includes in the target list all devices defined in the device groups specified in the *devicegroups* list. The *devicegroups* syntax is: [*context:*] [*user_ID@*]*devicegroup*[,[*context:*]\ [*user_ID@*]*devicegroup*]... This flag is disabled on HMCs.
-e | **--execute**	Indicates that *command_list* specifies a local script filename and arguments to be executed on the remote targets. The script file is copied to the remote targets and then remotely executed with the given arguments. The *DSH_NODE_RCP* and *DSH_DEVICE_RCP* environment variables specify the remote copy command to use to copy the script file to node and device targets, respectively.
-E | **--environment** *environment_file*	Specifies that the *environment_file* contains environment variable definitions to export to the target before executing the*command_list*. The *DSH_NODE_RCP* and *DSH_DEVICE_RCP* environment variables specify the remote copy command to use to export the file to node and device targets, respectively.
-f | **--fanout** *fanout_value*	Specifies a fanout value for the maximum number of concurrently executing remote shell processes. Serial execution can be specified by indicating a fanout value of 1. If **-f** is not specified, a default fanout value of **64** is used.
-F | **--output** *output_path*	Copies standard output to *output_path*/*target_name.output* and standard error to *output_path*/*target_name.error*. Output continues to be sent to standard output and standard error. Use the **-Q** flag to suppress standard output and standard error.
-i | **--notify**	Indicates that a target is not responding and prompts to continue remote execution for the target. Specify the **-v** flag with the **-i** flag.
-l (lowercase L) |**--user** *user_ID*	Specifies a remote user name to use for remote command execution.
-h | **--help**	Displays command usage information.

Item	Description
-n | **--nodes** *node_list*	Specifies a list of node targets to include in the target list. The *node_list* syntax is: [*context:*] [*user_ID@*]*node_name*[, [*context*:]\ [*user_ID@*]*node_name*]...
-L | **--no-locale**	Specifies to not export the locale definitions of the local host to the remote targets. Local host locale definitions are exported by default to each remote target. Output is appended to the file for each execution of the dsh command.
--log *log_file*	Enables logging to the specified *log_file*
-m | **--monitor**	Monitors remote shell execution by displaying status messages during execution on each target.
-N | **--nodegroups** *nodegroups*	Includes in the target list all nodes defined in the node groups specified in the *nodegroups* list. The syntax of *nodegroups* is: [*context:*] [*user_ID@*] *nodegroup* [, [*context*:]\ [*user_ID@*]*nodegroup*]...
-o--node-options *node_options*	Specifies options to pass to the **remote shell command** for node targets. The options must be specified within double quotation marks ("") to distinguish them from dsh options. Options for nodes in a specific context can be defined by including a context: before the option list. The syntax for *node_options* is: [*context:*]" *options* "[,[*context:*]"*options*"]...
-O | **--device**-options *device_options*	Specifies options to pass to the **remote shell command** for device targets. The options must be specified within double quotation marks to distinguish them from dsh options. Options for devices in a specific context can be defined by including context: before the option list. The syntax for *device_options* is [*context*:]"*options*"[,[*context*:]"*options*"]... This flag is disabled on HMCs.
-Q |**--silent**	Specifies silent mode. No target output is written to standard output or standard error. Monitoring messages are written to standard output.
-q | **--show-config**	Displays the current environment settings relevant to all DSH Utilities commands. This includes the values of all environment variables and settings for all currently installed and valid contexts. Each setting is prefixed with context: to identify the source context of the setting.
-r | **--node-rsh** *node_remote_copy*	Specifies the full path of the **remote shell command** used to copy files to or from node targets. A **remote shell command** for a specific context can be defined by including context: before the path. The *node_remote_copy* syntax is: [*context:*]*path*[,[*context:*]*path*]... If path contains **rsync**, it is assumed that the **rsync** command performs the remote copy.

Item	Description
--report *report_path*	Enables report generation and specifies the path to the directory where reports are saved. **--report-name** *report_name* Specifies the name to use when generating the report. If not specified, the name defaults to Unspecified. This flag can only be used with the **--report** flag.
-s| **--stream**	Specifies to return output as it becomes available from each target. It does not wait for the *command_list* to complete on a target before returning output.
-S | **--syntax csh** | **ksh**	Specifies the shell syntax to be used on the remote target. If not specified, the ksh syntax is used.
-t |***--timeout****timeout*	Specifies the time, in seconds, to wait for output from any currently executing remote targets. If no output is available from any target in the specified timeout, an error message is displayed by the dsh command and terminates execution to the remote targets that failed to respond. If timeout is not specified, dsh waits indefinitely to continue processing output from all remote targets. When specified with the **-i** flag, the user is prompted for an additional timeout interval to wait for output.
-T | **--trace**	Enables trace mode. The dsh command prints diagnostic messages to standard output during execution to each target.
-v | **--verify**	Verifies each target before executing any remote commands on the target. If a target is not responding, execution of remote commands for the target is canceled. When specified with the -i flag, the user is prompted to retry the verification request.
-X *env_list*	Ignores dsh environment variables. This option can take an argument which is a comma-separated list of environment variable names that must NOT be ignored. If there is no argument to this option, or the argument is an empty string, all dsh environment variables are ignored. This flag cannot be specified as the last flag.
-V | **--version**	Displays version information for the dsh command.

Item	Description
-z | **--exit-status**	Displays the exit status for the last remotely executed non-asynchronous command on each target. If the command issued on the remote node is run in the background, the exit status is not displayed. Exit Status Exit values for each remote shell execution are displayed in messages from the dsh command, if the remote shell exit values are non-zero. A non-zero return code from a remote shell indicates that an error was encountered in the remote shell. This return code is unrelated to the exit code of the remotely issued command. If a remote shell encounters an error, execution of the remote command on that target is bypassed. The dsh command exit code is 0 if the command executed without errors and all remote shell commands finished with exit codes of 0. If internal dsh errors occur or the remote shell commands do not complete successfully, the dsh command exit value is greater than 0. The exit value is increased by 1 for each successive instance of an unsuccessful remote command execution. If the remotely issued command is run in the background, the exit code of the remotely issued command is 0. Environment Variables **DSH_CONTEXT** Specifies the default context to use when resolving targets. This variable is overridden by the **-C** flag. **DSH_DEVICE_LIST** Specifies a file that contains a list of device targets.

Item	Description
	This variable is overridden by the **-d** flag. This environment variable is ignored on HMCs. **DSH_DEVICE_OPTS** Specifies the options to use for the remote shell command with device targets only. This variable is overridden by the **-O** flag. This environment variable is ignored on HMCs. **DSH_DEVICE_RCP** Specifies the full path of the remote copy command used to copy local scripts and local environment configuration files to device targets. This environment variable is ignored on HMCs. **DSH_DEVICE_RSH** Specifies the full path of the remote shell to use for remote command execution on device targets. This variable is overridden by the **--device-rsh f**lag. This environment variable is ignored on HMCs. **DSH_ENVIRONMENT** Specifies a file that contains environment variable definitions to export to the target before executing the remote command. This variable is overridden by the **-E** flag. **DSH_FANOUT** Specifies the fanout value. This variable is overridden by the **-f** flag. **DSH_LOG** Specifies the full path of the file to use for logging. This variable is overridden by the **--log** flag. **DSH_NODE_LIST** Specifies a file containing a list of node targets. The **DSH_NODE_LIST** variable has replaced WCOLL.Hel DSH_NODE_OPTS . Specifies the options to use for the remote shell command with node targets only. This variable is overridden by the **-o** flag. **DSH_NODE_RCP** Specifies the full path of the remote copy command to use to copy local scripts and local environment configuration files to node targets. **DSH_NODE_RSH** Specifies the full path of the remote shell to use for remote command execution on node targets. This variable is overridden by the **-r** flag. **DSH_NODEGROUP_PATH** Specifies a colon-separated list of directories that contain node group files for the DSH context. When the **-a** flag is specified in the DSH context, a list of unique node names is collected from all node group files in the path. **DSH_OUTPUT** . Specifies the base file name for standard output and standard error copies. Output continues to be sent to standard output and standard error. This variable is overridden by the **-F** flag. **DSH_PATH** Sets the command path to use on the targets. If **DSH_PATH** is not set, the default path defined in the profile of the remote *user_ID* is used. **DSH_PATH** cannot be used to run a dsh command to an HMC. **DSH_REPORT**. Enables reporting when set to the absolute path of the directory where reports are saved. This variable is overridden by the **--report** flag. **DSH_SYNTAX** Specifies the shell syntax to use on remote targets; ksh or csh. If not specified, the ksh syntax is assumed. This variable is overridden by the **-S** flag. **DSH_TIMEOUT** Specifies the time, in seconds, to wait for output from each remote target. This variable is overridden by the **-t** flag. Security The dsh command has no security configuration requirements. All remote command security requirements - configuration, authentication, and authorization - are imposed by the underlying remote command configured for dsh. The command assumes that authentication and authorization are configured between the local host and the remote targets. Interactive password prompting is not supported; an error is displayed and execution is bypassed for a remote target if password prompting occurs, or if either authorization or authentication to the remote target fails. Security configurations as they pertain to the remote environment and remote shell command are user-defined. When the remote command is configured as **/usr/bin/rsh** and this command is configured to use Kerberos Version 5, you must first run the Kerberos **kinit** command to obtain a ticket-granting ticket, and you must ensure that your Kerberos principal is in the. **k5login** file in the home directory of the remote user on the targets.

Examples

1. To run the ps command on node targets **node1** and **node2**, enter:

```
dsh -n node1,node2 "ps"
```

2. To run the **ps** command on each node target listed in the **myhosts** file, enter:

```
DSH_NODE_LIST=./myhosts; dsh ps
```

3. To enter commands in interactive mode for execution on the node targets defined in **NodeGroup1**, enter:

```
dsh -N NodeGroup1
```

4. To display the number of users on all NIM Managed nodes and in the DSH context node group **NodeGroup2**, enter:

```
dsh --all-nodes NIM -N DSH:NodeGroup2 "who | wc -l"
```

5. To enter a list of node targets and device targets interactively and then execute the date command in interactive mode, enter:

```
dsh -n - -d -
```

   Additional input and the output similar to the following is displayed:

```
dsh node> node1
dsh node> gregb@node2
dsh node>
dsh device> CSM:kathyc@device1
dsh device>
dsh> date  node1: Wed Apr 13 17:15:59 EDT 2005
gregb@node2: Wed Apr 13 17:15:59 EDT 2005
kathyc@device1: Wed Apr 13 17:15:59 EDT 2005
dsh> exit #
```

6. To run the **ls** command on all the nodes in the cluster and ignore all the dsh environment variables, enter:

```
dsh -X -a ls
```

7. To run the **ps** command on **node1** and ignore all the dsh environment variables except the **DSH_NODE_OPTS**, enter:

```
dsh -n node1 -X 'DSH_NODE_OPTS' ps
```

dslpaccept Command

Purpose

Accept print queue requests for directory-enabled System V print systems.

Syntax

dslpaccept *PrintQueueName*

Description

The **dslpaccept** and **dslpreject** commands are used to set a print queue so that it will accept or reject print requests being queued for it. Unlike the **accept** and **reject** commands, the directory-enabled commands can control remote print systems, so long as they are directory-enabled. This is because they write directly to the print queue object on the directory server.

The user of this command must be directory-enabled and have permissions set for write, modify, search and read on the directory, in the directory context in which the user is administrator.

Parameters

Item	Description
PrintQueueName	The *PrintQueueName* parameter is the relative distinguished name (RDN) of the print queue object. Multiple print queue names may be specified in a comma-separated list.

Exit Status

0
Indicates success.

1
Indicates invalid options.

2
Indicates that the specified print queue is unknown.

3
Indicates that this user does not have modify permissions.

4
Indicates that an invalid RDN was supplied.

5
Indicates that the value is already set.

6
Indicates that the command is unable to contact the directory service

7
Indicates any other error.

Examples

1. To set the print queue "hpcolor" to accept requests:

```
dslpaccept hpcolor
```

dslpaccess Command

Purpose

Allow or deny non-directory enabled users and systems access to a print queue for a System V print subsystem.

Syntax

dslpaccess **-q** *QueueName* **-a** *AllowList* | **-d** *DenyList*

Description

The **dslpaccess** command either allows or denies users and systems access to a directory-enabled print queue. It is modeled on the **lpadmin** command's **-u** option.

Allow and deny lists consist of a comma-separated list of entries, each of which may specify a login ID, or a system name and login ID, as follows:

```
[[LoginID]|[System!LoginID]],[[LoginID]|[System!Login-ID]],...
```

LoginID or *System*, or both, can be set to the wildcard **all**, allowing or denying all appropriate entries. Use **all** with care. When the **all** entry is added to one list, all non-**all** entries are removed from the other list, for the appropriate value of *LoginID* or *System*. The default for *System* is the local host.

The user of this command must be directory-enabled and have permissions set for write, modify, search and read on the directory, in the directory context in which they are administrator.

Flags

Item	Description
-a *AllowList*	Specifies a list of users to add to the allow list. If present, these are deleted from the deny list. This option can not be used with the **-d** option.
-d *DenyList*	Specifies a list of users to add to the deny list. If present, these are deleted from the allow list. This option can not be used with the **-a** option.
-q *QueueName*	The queue-name parameter is the Relative Distinguished Name (RDN) of the print queue. If the print queue name does not exist in the directory context, the command fails.

Exit Status

0
Indicates success.

1
Indicates invalid options.

2
Indicates that the specified print queue is unknown.

3
Indicates that the user does not have appropriate access control permissions.

4
Indicates that an invalid RDN was supplied.

5
Indicates that the value is already set.

6
Indicates any other error.

Examples

1. The following grants user fredb access to print queue printq1 on host systemX:

```
dslpaccess -q printq1 -a systemX!fredb
```

2. The following denies access to print queue printq1 to user tomt for all hosts:

```
dslpaccess -q printq1 -d all!tomt
```

dslpadmin Command

Purpose

Configure directory-enabled print service for a System V print subsystem.

Syntax

dslpadmin [[**-q** *PrintQueueName* [**-D** *QueueDescription*] [**-n** *LocalQueueName*] [**-o banner** | **nobanner**] [**-A mail** | **none**] [**-F** *FaultRecovery*] [[**-P** *PhysicalPrinterName*] [**-s** *NetworkEntityName*]]] [**-P** *PhysicalPrinterName* [**-T** *PrinterType*] [**-l** *Location*] [**-L** *PDLList*]] [**-q** *PrintQueueName* **-P** *PhysicalPrinterName* [**-I** *ContentType*] [[**-i** *InterfaceScript*] | [**-m** [**Standard** | **PS**]]] [**-o** *PrintOptions*]] [**-q** *PrintQueueName* [**-I** *ContentType*]]] [**-q** *PrintQueueName* **-s** *NetworkEntityName* [**-a** *PrintSystemDNSName* | *PrinterSystemAddress*] [**-t BSD** | **HPNP**]]

dslpadmin [**-q** *PrintQueueName* [**-u** *PhysicalPrinterName*] [**-U** *ObjectRDN*]]

dslpadmin [**-x** *PrintQueueName*] [**-X** *PhysicalPrinterName*] [**-r** *NetworkEntityName*]

dslpadmin [**-h**]

Description

The **dslpadmin** command is used to perform the following functions in order to configure a directory-enabled print service:

- Add print queues and physical printers to the system.
- Modify print queues and physical printers.
- Remove print queues and physical printers from the system.
- Add and delete network entity objects for networked printers.

The dslpadmin command provides directory-aware versions of the functionality supplied by **lpadmin** (which is not directory-aware), and continues to use the traditional ``flat file'' configuration system. Note that where both systems are in use, the printer subsystem employs information found in the directory first. It is the responsibility of the administrator to ensure that naming conflicts do not arise between the two configuration systems.

The directory-enabled commands use Relative Distinguished Names (RDNs), rather than Distinguished Names (DNs). For example, to create a directory-enabled queue with a DN of "`cn=test,ou=printq,ou=print,cn=aixdata`", only the RDN "test" is to be used for the *PrintQueueName*.

When configuring a print queue where the administrator is not on the system that is to host the print queue, the *InterfaceScript* parameter of **-i** and the *PrinterType* parameter of **-T** are not checked. This is because the remote system cannot be accessed in order to do the checks. It is therefore the administrator's responsibility to ensure that the specified *InterfaceScript* and *PrinterType* exist on the remote hosting system.

A command line can contain any combinations of the **-q** , **-P** and **-s** flags, or any combination of the **-x**, **-X** and **-r** flags, but only one of each flag. When multiple directory objects are simultaneously created or modified, appropriate links are set up between the three object types (printers, print queues and network entities).

Flags

Item	Description
-a *PrinterSystemDNSName* | *PrinterSystemAddress*	Associates a DNS name or network address with the system. If the argument given can be interpreted as an IPv4 or IPv6 address, it is an address, if not it is assumed to be a DNS name. The -a flag causes the network entity object specified by **-s** to be modified, or else created if it does not already exist. The administrator should ensure that network entity objects are given unique names, so as to avoid modifying existing UNIX system objects instead of adding new print system objects. This flag requires the **-s** flag.

Item	Description
-A [**mail** | **none**]	Instructs the print system to generate a mail message if a print request fails. The mail is sent to the owner of the physical printer, or to the root user of the system hosting the print queue, if the printer has no owner or the user has no mail address. The default is **none**. This flag requires the **-q** flag.
-D *QueueDescription*	Defines a description comment for the print queue object specified with the **-q** flag. This description is displayed whenever a user asks for a full description of a print queue using the **lpstat** command. Strings containing whitespace should be double quoted. This flag requires the **-q** flag.
-F *FaultRecovery*	Defines the print queue's fault recovery mode. This flag specifies the recovery to be used if the printer on a print queue fails while printing a print request. The value of *FaultRecovery* can be any of the following: **continue** Continue printing on the top of the page where printing stopped. This requires a filter to wait for the fault to clear before automatically continuing. **beginning** Start printing the request again from the beginning. **wait** Disable printing on *PhysicalPrinterName* and wait for the administrator or a user to enable printing again. During the wait the administrator or the user who submitted the stopped print request can issue a change request that specifies where printing should resume. If no change request is made before printing is enabled, printing resumes at the top of the page where it stopped, if the filter allows; otherwise, the request is printed from the beginning. The default value of *FaultRecovery* is **beginning**. This flag requires the **-q** flag.
-h	Displays a brief help screen.
-i *InterfaceScript*	Pathname for the printer's *InterfaceScript* when accessed through the specified print queue. This flag is not valid if the **-P** flag has not been specified. The interface scripts are usually supplied by the user. This flag cannot be used when **-m** has also been specified. This flag requires both the **-q** and the **-P** flags.
-I *ContentType*[, *ContentType*, ...]	Specifies the print queue's content types. Allows the print queue to handle print requests with the content types in the list. If the list contains more than one *ContentType*, the *ContentType* parameters must be separated by commas. See the **lpadmin** manual page for a full description of the format. This also requires the **-P** flag and the **-q** flag.
-l *Location*	Defines the printer's location. This is a string identifying where a printer is physically located, for example "Building X, Room 6". It can be searched on by the **dslpsearch** command. Once set, this value can only be overwritten, not removed. This flag requires the **-P** flag.

Item	Description
-L *PDL*[, *PDL*, ...]	Specifies the list of Page Description Languages (PDLs) supported by the printer. This is used to advertise any PDL the printer supports, and can be searched on, using the **dslpsearch** command. The **AUTOSW**, **PCL**, **PCLXL**, **POSTSCRIPT**, **TEXT**, **ESCP**, **PJL**, **SIMPLE**, and **OTHER** PDLs are supported. If the **-L** flag is used to modify an existing physical printer object, the list replaces the existing list. This flag requires the **-P** flag.
-m [**standard** | **PS**]	Model interface program for the printer when accessed through the specified print queue. It selects the model interface script to be used by the print queue. When a physical printer object is being created, and neither the **-m** nor the **-i** flag has been specified, the default is **standard**. This flag cannot be used when **-i** has also been specified. This flag requires both the **-q** and the **-P** flags.
-n *LocalQueueName*	Defines the local name of a print queue. This name normally only differs from the queue's RDN when the queue is on a non-directory-enabled host. It is used by incoming remote network connections to identify the print queue on the receiving system. The default value is the print queue's RDN. This flag requires the **-q** flag.
-o [**banner** | **nobanner**]	Defines if a banner page will always be produced by this print queue. The default value, **banner**, forces a banner page to be printed for all print requests, whereas **nobanner** allows the user to submit a print job specifying that no banner page is to be printed. This flag requires the **-q** flag.
-o *PrintOption*=*Value*[, ...]	Specifies values for print options. See the **lpadmin** documentation for a detailed description of the print options available with the **-o** flag. This flag requires both the **-q** and the **-P** flags.
-P *PhysicalPrinterName*	Create or modify a physical printer object. The *PhysicalPrinterName* argument specifies the RDN of a printer object. If the object does not already exist, **dslpadmin** creates it.
-q *PrintQueueName*	**dlspadmin** Creates or modifies a print queue object. The *PrintQueueName* argument specifies the RDN of a print queue object. When adding a new print queue, you must specify the **-s** and **-P** flags so the command knows the *NetworkEntityName* and *PhysicalPrinterName* for the print queue being added. If the print queue object does not exist, **dslpadmin** creates it. A command line can contain any combinations of the **-q**, **-P** and **-s**flags , or any combination of the **-x**, **-X** and **-r** flags, but only one of each flag. When multiple directory objects are simultaneously created or modified, appropriate links are set up between the three object types (printers, print queues and network entities).
-r *NetworkEntityName*	Delete the network entity system object. Care needs to be taken not to delete a non-printer system object. It is the responsibility of the administrator to ensure that the correct object is deleted.
-s *NetworkEntityName*	Specifies the network entity system object that hosts the print queue. If **-a** is also given, the object is created or modified. The *NetworkEntityName* argument specifies the RDN of an object in the current directory context. The network entity object defines the network address that remote clients need to use to access the print queue.

Item	Description
-t [**BSD** | **HPNP**]	Defines the print protocol used by this "networked printer" print queue. Retry and timeout values are set to their default values for a networked printer. To change these values, the **dslpprotocol** command should be used. Note that this flag should only be used for networked printers supporting the BSD or HPNP protocol. This flag requires the **-q** flag.
-T *PrinterType*[, *PrinterType*, ...]	List of printer types. It identifies the printer as being of one or more printer types, for example "hplaserjet". See the **lpadmin** manual page for details. This flag requires the **-P** flag.
-u *PhysicalPrinterName*	Unlinks the named physical printer from the print queue (specified with the **-q** flag) without deleting its object. This flag requires the **-q** flag.
-U *ObjectRDN*	Unlinks either the physical printer or the print queue object (specified by *ObjectRDN*) from the print queue (specified with the **-q** flag), without deleting its object. This flag requires the **-q** flag.
-x *PrintQueueName*	Delete a print queue object.
-X *PhysicalPrinterName*	Delete a physical printer object.

Exit Status

0
Indicates success

255 (or -1)
Indicates an error in configuration. Error messages are displayed to explain the error or failure.

Examples

The following examples illustrate use of the dslpadmin command, when the user is logged on to a directory-enabled UNIX system.

1. The following adds an HP LaserJet network printer that uses the BSD remote print protocol, with a print queue RDN of "denlj5n", and a physical printer RDN of "denplj5n". It gives the print queue a description of "HP JetDirect (PostScript)", the printer type "PS-b", and the model interface script as "PS". The printer has a network address of "p_hplj.ibm.com":

   ```
   dslpadmin -q denlj5n -P denplj5n -T PS-b -D "HP JetDirect (Postscript)" \
   -I PS -m PS -A mail -o nobanner  -s denslj5n -a p_hplj.ibm.com -t BSD
   ```

   The print system will allow print requests of content type PS for this print queue, and allow disabling of banner pages.

2. The following adds an HP LaserJet PostScript network printer, using the HPNP remote print protocol, with a print queue RDN of "dehpnp", and a physical printer RDN of "dephpnp". It gives the print queue a description of "HPNP (PCL)", the printer type "hplaserjet", and the model interface script as "standard". The printer has a network address of "p_hplj.ibm.com":

   ```
   dslpadmin -q dehpnp -P dephpnp -T hplaserjet -D "HPNP (PCL)" -I pcl \
   -m standard -A mail -s deshpnp -a p_hplj.ibm.com -t HPNP
   ```

   The print system will allow print requests of content type PCL for this print queue, and reject requests if no banner page is requested. If a printer fault occurs, the print system will mail the owner of the printer.

3. The following deletes an HP LaserJet PostScript printer:

   ```
   dslpadmin -x delj5n  -X deplj5n
   ```

4. The following deletes an HPNP printer:

```
dslpadmin -x dehpnp  -X dephpnp -r deshpnp
```

dslpdisable Command

Purpose

Disable print queue requests for a System V print subsystem.

Syntax

dslpdisable [**-r** *Reason*] *PrintQueueName*

Description

The **dslpenable** and **dslpdisable** commands are used to enable or disable a print queue from processing print requests that have been queued for it. Unlike the **enable** and **disable** commands, the directory-enabled commands can control remote print systems, so long as they are directory-enabled. This is because they write directly to the print queue object on the directory server.

Flags

Item	Description
`-r` *Reason*	Assign the reason for disabling the print queue. Strings containing whitespace should be double quoted. *Reason* is a string that is displayed by the lpstat command. No default reason is set when one is not specified.

Parameters

Item	Description
PrintQueueName	The *PrintQueueName* parameter is the RDN of the print queue. This could be a list of print queues. If the print queue name does not exist in the directory context, the command fails.

Exit Status

0
Indicates success.

1
Indicates invalid options.

2
Indicates that the specified print queue is unknown.

3
Indicates that this user does not have modify permissions.

4
Indicates that an invalid RDN was supplied.

5
Indicates that the value is already set.

6
Indicates that the command is unable to contact the directory service

7
Indicates any other error.

Example

To disable print queue "printer1", specifying the reason "routine maintenance", enter the following:

```
dslpdisable -r "routine maintenance" printer1
```

dslpenable Command

Purpose

Enable print queue requests for a System V print subsystem.

Syntax

dslpenable *PrintQueueName*

Description

The **dslpenable** and **dslpdisable** commands are used to enable or disable a print queue from processing print requests that have been queued for it. Unlike the **enable** and **disable** commands, the directory-enabled commands can control remote print systems, so long as they are directory-enabled. This is because they write directly to the print queue object on the directory server.

Parameters

Item	Description
PrintQueueName	The *PrintQueueName* parameter is the RDN of the print queue. This could be a list of print queues. If the print queue name does not exist in the directory context, the command fails.

Subcommands

Exit Status

0
Indicates success.

1
Indicates invalid options.

2
Indicates that the specified print queue is unknown.

3
Indicates that this user does not have modify permissions.

4
Indicates that an invalid RDN was supplied.

5
Indicates that the value is already set.

6
Indicates that the command is unable to contact the directory service

7
Indicates any other error.

Examples

1. To enable print queue "hpcolor", enter the following:

```
dslpenable hpcolor
```

dslpprotocol Command

Purpose

Configure the remote print protocol of print queue for a System V print subsystem.

Syntax

dslpprotocol **-t** *RemoteProtocol* [**-T** *TimeOut*] [**-R** *Retry*] [**-r**] *PrintQueueName*

dslpprotocol **-l** [**-S**] *PrintQueueName*

Description

The **dslpprotocol** command is used to configure the "remote print protocol" that a remote print client can use when sending print requests to a print queue.

In directory-enabled printing, to print to a remote print queue, the client must first get the remote print protocol it can use. This is obtained from the print queue object in the directory. This can be one or both of BSD and HPNP. Where more than one protocol is configured for a print queue, the UNIX print system uses the first value it reads, so a queue will normally only have a single protocol configured.

The *PrintQueueName* parameter is the Relative Distinguished Name (RDN) of the print queue. If the value assigned to *PrintQueueName* does not exist, the command fails.

The user of this command must be directory-enabled and have permissions set for write, modify, search and read on the directory, in the directory context in which they are administrator.

Flags

Item	Description
-l	Print out a description of the remote print protocol parameters associated with the print queue.
-t *RemoteProtocol*	Specifies the remote print protocol that can be used when sending print requests to this print queue. The protocol type values supported are **bsd** and **hpnp**. The default value is **bsd**.
-T *TimeOut*	Set the network connection timeout value for the specified protocol, that is, the time a network connection should stay alive in an idle condition before disconnection. The value n can also be specified in order to disable timing out. The value 0 causes the connection to be dropped as soon as it becomes idle. The default value is 10 minutes, and there is no practical upper limit. See the **lpsystem** manual page for a full definition of the **-T** option.
-r	This option is used to remove a specified protocol from the print queue object. This option requires that the **-t** option also be specified.

Item	Description
-R *Retry*	Set the network connection retry time for the specified protocol, that is, the time in minutes to wait before trying to re-establish the network connection after a failure. The default value is 2 minutes. A value of 0 causes the connection to be retried immediately. Note that this value must be shorter than the timeout value specified using the **-T** option. The value n can also be specified in order to prevent dropped connections being retried when no work is available. There is no practical upper limit on the value. For "networked printers", the retry time should be set to 0. See the **lpsystem** manual page for a full definition of the **-R** option.
-S	Used with the **-l** option to display the print queue's protocol setup in a simple format.

Parameters

Item	Description
PrintQueueName	The *PrintQueueName* parameter is the Relative Distinguished Name (RDN) of the print queue. If the value assigned to *PrintQueueName* does not exist, the command fails.

Exit Status

0
Indicates success.

1
Indicates invalid options.

2
Indicates that the specified print queue is unknown.

3
Indicates that this user does not have modify permissions.

4
Indicates that an invalid RDN was supplied.

5
Indicates that the value is already set.

6
Indicates any other error.

Examples

1. To set print queue "printq1" to allow the BSD remote print protocol, enter the following:

```
dslpprotocol -t BSD printq1
```

2. To remove the BSD protocol from print queue "hpcolor", enter the following:

```
dslpprotocol -r -t BSD hpcolor
```

dslpreject Command

Purpose

Reject print queue requests for directory-enabled System V print systems.

Syntax

dslpreject [**-r** *Reason*] *PrintQueueName*

Description

The **dslpaccept** and **dslpreject** commands are used to set a print queue so that it will accept or reject print requests being queued for it. Unlike the **accept** and **reject** commands, the directory-enabled commands can control remote print systems, so long as they are directory-enabled. This is because they write directly to the print queue object on the directory server. Print requests that are already queued are not affected by the **dslpreject** command.

The user of this command must be directory-enabled and have permissions set for write, modify, search and read on the directory, in the directory context in which the user is administrator.

Flags

Item	Description
-r *Reason*	Assigns a reason for the rejection. Strings containing whitespace should be within double quotes. *Reason* is a string that is displayed by the **lpstat** command. No default reason is set when one is not specified.

Parameters

Item	Description
PrintQueueName	The *PrintQueueName* parameter is the RDN of the print queue object. Multiple print queue names may be specified in a comma-separated list.

Exit Status

0
Indicates success.

1
Indicates invalid options.

2
Indicates that the specified print queue is unknown.

3
Indicates that this user does not have modify permissions.

4
Indicates that an invalid RDN was supplied.

5
Indicates that the value is already set.

6
Indicates that the command is unable to contact the directory service

7
Indicates any other error.

Examples

1. To set a print queue to reject requests and specify the reason that there is no toner, enter the following:

```
dslpreject -r "no toner" printer1
```

dslpsearch Command

Purpose

Search directory for print system objects on a System V print subsystem.

Syntax

dslpsearch [**-q** [**-p**]] | [**-P**] [**-o** *SearchOptions*]

Description

The **dslpsearch** command allows users and administrators to search the directory for print system objects. For example, a user could search for any printer that can print color PostScript files. The main use of this command will be to search for print queues that match the search string.

The **dslpsearch**command returns the Distinguished Name (DN) of any objects that match the search string. However, the Relative Distinguished Name (RDN) is required for use in the other directory-enabled commands. For example, if the DN "`cn=testqueue,ou=printq,ou=print,cn=aixdata`" is returned by the **dslpsearch** command, only the RDN "`testqueue`" is used to refer to the print queue.

Flags

Item	Description
-q	Search for print queues that match the search options. The search is done on the physical printer objects but the print queues that service those printers are displayed. This is the default search type. The **-q** option cannot be specified with **-P**.
-p	This option is used with the **-q** option, and causes a list of physical printers servicing the print queue also to be displayed.
-P	Search for physical printers that match the search string. The **-P** option cannot be specified with **-q**.
-o *SearchOptions*	Multiple search options may form a comma-separated list. Each option may be constructed from the following: • one or more of the following Page Description Languages (PDLs): **AUTOSW**, **PCL**, **PCLXL**, **POSTSCRIPT**, **TEXT**, **ESCP**, **PJL**, **SIMPLE**, **OTHER** • any of the following printer facilities: **COLOR**, **DUPLEX**, **TRAYS**, **FINISH** • one or more physical printer locations, specified by `location=xxxxxxxx` or `location='aaaa bbbbb'` • The string value defined by location= is searched on with wildcards placed at both ends of the string, so `location=Room1` would find any printer with "Room1" in its location, such as "Building X, Room1, Bay6". The string value can also have wildcards (*) embedded in it, for example `location="Building X*Bay6"`. Multiple location values are OR'd in the search. • The following are valid command lines containing search strings: `dslpsearch -q -o PCL,ESCP,location=room2,COLOR` `dslpsearch -q -p -o "PS, location='Building 1, Room1', DUPLEX"`

Exit Status

0
Indicates success.

1
Indicates invalid options.

2
Indicates that the search on the directory tree failed.

3
Indicates invalid directory context.

4
Indicates the command is unable to contact the directory service.

Examples

1. The following command line searches for any print queues that match the search options:

```
dslpsearch -q -o search-options
```

2. The following searches for any physical printers that match the search options:

```
dslpsearch -P -o search-options
```

dspcat Command

Purpose

Displays all or part of a message catalog.

Syntax

To Display Messages in a Catalog

dspcat *CatalogName* [*SetNumber* [*MessageNumber*]]

To Format Output for the gencat Command

dspcat -g *CatalogName* [*SetNumber*]

Description

The **dspcat** command displays a particular message, all the messages in a set, or all the messages in a catalog. The **dspcat** command directs the messages to standard output.

Note: The **dspcat** command looks for the catalog files under the **NLSPATH** environment variable if the **LC__FASTMSG** attribute is set to `False` in C or POSIX locale environment.

The **LC__FASTMSG** attribute specifies that default messages are used for the C and POSIX locales and that the **NLSPATH** environment variable is ignored when the **LC__FASTMSG** attribute is set to `True`.

The default value for the **LC__FASTMSG** attribute is `True` in the `/etc/environment` path.

The *CatalogName* parameter specifies a message catalog. The *SetNumber* parameter specifies a set in the catalog specified by the *CatalogName* parameter. The *MessageNumber* parameter specifies a particular message in the set specified by the *SetNumber* parameter. If you include all three parameters, the **dspcat** command displays the specified message. If you do not include the *MessageNumber* parameter, the **dspcat** command displays all the messages in the set. If you specify a nonexistent value for the *SetNumber* or *MessageNumber* parameter, the **dspcat** command displays an error message and returns a nonzero return value. If you specify only the *CatalogName* parameter, the **dspcat** command displays all the messages in the catalog. You must include the *SetNumber* parameter if you include the *MessageNumber* parameter.

The **dspcat** command uses the **NLSPATH** environment variable and the **LC_MESSAGES** category to find the specified message catalog if you do not use / (slash) characters in the value of the *CatalogName* parameter.

Flags

Item	Description
-g	Formats output to be used as input to the **gencat** command. The *MessageNumber* parameter is not valid when you use the **-g** flag.

Examples

To display message number 2 in set number 1 of the `test.cat` file, enter:

```
dspcat test.cat 1 2
```

Files

Item	Description
/usr/bin/dspcat	Contains the **dspcat** command.

dspmsg Command

Purpose

Displays a selected message from a message catalog.

Syntax

dspmsg [**-s** *SetNumber*] *CatalogName MessageNumber* [**'***DefaultMessage***'** [*Arguments*]]

Description

The **dspmsg** command displays either the text of a particular message from a message catalog generated with the **gencat** command or, if the message cannot be retrieved, a default message supplied as a parameter to the command. The **dspmsg** command directs the message to standard output. This command is intended for use in shell scripts as a replacement for the **echo** command.

Note: The **dspmsg** command looks for the catalog files under the **NLSPATH** if the **LC_FASTMSG** is set to False in C or POSIX locale environment.

LC__FASTMSG specifies that default messages are used for the C and POSIX locales and that **NLSPATH** is ignored when **LC__FASTMSG** is set to True.

The default value for **LC__FASTMSG** will be True in **/etc/environment**.

The **NLSPATH** environment variable and the **LC_MESSAGES** category are used to find the specified message catalog if no / (slash) characters are used in the value of the *CatalogName* parameter. If the catalog named by the *CatalogName* parameter is not found or if the message named by the *MessageNumber* parameter (and optional *SetNumber* value) is not found, then the supplied *DefaultMessage* value is displayed. If a *DefaultMessage* value is not specified, a system-generated error message is displayed.

The **dspmsg** command allows up to ten string arguments to be substituted into the message if it contains the **%s**, %n$s, **%ld**, or %n$ld **printf** subroutine conversion specification. Missing arguments for

conversion specifications result in a **dspmsg** error message. Normal **printf** subroutine control character escapes (for example, **\n**) are recognized.

The use of **printf** subroutine format strings is recommended in the catalog. This format provides for correct insertion of arguments even if the format strings in the message are in a different order than the default message. You must enclose the default message in single quotation marks if using the **%n$s** notation for message inserts.

Flags

Item	Description
-s *SetNumber*	Specifies an optional set number. The default value for the *SetNumber* variable is 1.

Examples

To display set number 1, message number 2 of the `test.cat` catalog, enter:

```
dspmsg    -s    1    test.cat    2    'message    %s    not    found'    2
```

If the message is not found, `message 2 not found` is displayed.

Files

Item	Description
/usr/bin/dspmsg	Contains the **dspmsg** command.

dtaction Command

Purpose

Invokes a CDE action with specified arguments.

Syntax

`dtaction` [`-contextDir` *context_dir*]\

[`-execHost` *host_name*] [`-termOpts` *terminal_arguments*]

[`-user` *user_name*] *action_name*

[*action_arg*] ...

Description

The `dtaction` command allows applications or shell scripts, which are otherwise not connected into the CDE development environment, to invoke action requests.

The action called *action_name* is called with the *action_arg* provided on the command line.

A single *action_name* is required; the user can provide any number of *action_args*.

Interpretation of the *action_name* and *action_args* depends on the definition of the action in the action database.

The action might be defined in one of the system action database files, or in one of the user's private action database files.

The *action_args* are absolute or relative path names of files. The `dtaction` command passes this list of files on to the specified action.

Error dialogs are posted when the following conditions are detected:

- Desktop environment could not be initialized
- Invalid user or password
- Unable to change ID to the requested user
- No action name specified

Flags

Item	Description
`contextDir` *context_dir*	Specifies a default directory context if the definition of *action_name* does not define a current working directory for command actions.
`execHost` *host_name*	Specifies an alternative execution host, *host_name*, for a command action. If the action is not a command action, the `dtaction` command ignores this option. The action is attempted on *host_name* instead of the hosts specified in the action's EXEC_HOST specification. An error is posted if it is not possible to invoke the specified action on any eligible host.
`termOpts` *terminal_arguments*	Specifies arguments intended for the terminal emulator that is provided for command actions that are not of type NO_STDIO. If there are white-space characters in the *terminal_arguments* string, that string must be quoted to protect it from the shell. These arguments are passed unchanged to the terminal emulator, so the user must ensure that the strings are reasonable. In particular, *terminal_arguments* does not allow the argument that specifies the command to be run in a terminal emulator window (that is, using `dtterm1` with the `-e` flag).
`user` *user_name*	Specifies a user name. If `dtaction` is not currently running as that user, a prompt dialog collects the specified user password or the root user password. After a valid password is entered, the `dtaction` command changes so that it is running as the requested user and then starts the requested action.

Parameters

Item	Description
action_name	Specifies the name of the action to be invoked.
action_arg	Specifies the absolute or relative file names of files.

Environment Variables

Item	Description
`DTDATABASESEARCHPATH`	A comma-separated list of directories (with optional host: prefix) that tells the action service where to find the action databases.

Exit Status

The following exit values are returned:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

The dtaction command is an application enabled by PAM with service name dtaction.

If the user name specified by user *user_name* option is different from the login user name,

The dtaction command authenticates the user before invoking the specified action. It is capable of performing PAM authentication as well as traditional authentication.

To use PAM for authentication system-wide, establish root user permissions and modify the value of the *auth_type* attribute in the usw stanza of the /etc/security/login.cfg file toPAM_AUTH.

The authentication mechanisms used when PAM is enabled depend on the configuration for the login service in /etc/pam.conf.

The dtaction command requires an /etc/pam.conf entry for the auth module type.

The following configuration is recommended in /etc/pam.conf for the dtaction service:

```
dtaction        auth            required        /usr/lib/security/pam_aix
```

Examples

1. To invoke an action, enter:

   ```
   dtaction Xterm
   ```

   This launches X Windows terminal emulator (Xterm).
2. To invoke an action on a remote host, enter:

   ```
   dtaction -execHost hostname Xterm
   ```

   This executes Xterm on the specified remote host.
3. To invoke an action as a different user, enter:

   ```
   dtaction -user username Xterm
   ```

   This executes Xterm as the specified user.

Location

/usr/dt/bin/dtaction

Standard Error

The dtaction command writes diagnostic error messages to standard error, which is redirected to $HOME/.dt/errorlog.

Files

Item	Description
/etc/pam.conf	Determines PAM authentication mechanisms.

Item	Description
`/etc/security/login.cfg`	Determines PAM authentication system-wide.

dtappintegrate Command

Purpose

The Common Desktop Environment application integration tool.

Syntax

dtappintegrate -s *ApplicationRoot* [**-t** *TargetPath*] [**-l** *Language*] [**-u**]

Description

The **dtappintegrate** command links the application CDE configuration files from application-specific locations to system locations and updates the system's Browser help volumes for the languages affected. The **dtappintegrate** command is used during the installation process of an application. The application installation script should invoke the **dtappintegrate** command at the end.

There are four key subdirectories under the application root (referred to as **$APP_ROOT**) dictated by CDE policy. The directories are:

Item	Description
$APP_ROOT/dt/appconfig/types/ *Language*	For filetype, Front Panel, and action files.
$APP_ROOT/dt/appconfig/appmanager/ *Language*	For application group files.
$APP_ROOT/dt/appconfig/icons/ *Language*	For icons used by the CDE managers.
$APP_ROOT/dt/appconfig/help/ *Language*	For application help. For example, the default-language application **SpreadSheet** would load its desktop icons under: **/opt/SpreadSheet/dt/appconfig/icons/C/*.bm** and **/opt/SpreadSheet/dt/appconfig/icons/C/*.pm**, where **/opt/SpreadSheet** is the value of **$APP_ROOT**.

Note: $APP_ROOT is a syntactical convention of this document and is not used by the runtime environment.) All of these CDE configuration files and subdirectories are placed under a common top and should always include the default language subdirectory **C**.

In the simplest case, the command takes as input the application root, for example, **/opt/thisapp**. The outputs from this operation are corresponding subdirectories and files on the application server that contain relative symbolic links to the applications CDE configuration files described above, under the following system locations:

Item	Description
/etc/dt/appconfig	Top-level application configuration subdirectory, consists of following subdirectories: **/etc/dt/appconfig/types/*Language*/** Contains the ***.dt** and any ***.fp** links. **/etc/dt/appconfig/appmanager/*Language*/** Contains links to the application group subdirectory and the action script files to appear as actions under the Application Manager. **/etc/dt/appconfig/help/*Language*/** Contains symbolic links to the help files installed under the application's root. **/etc/dt/appconfig/icons/*Language*/** Contains symbolic links to the CDE icons for the application.

Flags

Item	Description
-s *ApplicationRoot*	Integrates the application located at *ApplicationRoot*. This flag is required.
-t *TargetPath*	Links the application CDE configuration files from the application-specific location to *TargetPath* rather than to the system locations. This flag is optional. If the **-t** flag is supplied, the files are linked under the specified subdirectory. For example, specifying **-t /etc/dt/private** would cause the application help files to be symbolically linked under **/etc/dt/private/help/***Language*. This flag is typically used only by system administrators who want to create separate applications and not by the application post-installation script. By default (with no **-t** specified), the application subdirectory root is global to the application host. All applications installed on the host will have their configuration files copied to the same place for merging with other application configuration files.
-l *Language*	Specifies the language to integrate. Basically, this flag indicates the directories under which to find the application CDE configuration files. If this parameter is not specified, all languages will be integrated. This parameter is optional.
-u	Integration of application is canceled. This flag is optional.

dtlogin Command

Purpose

Performs a CDE login service.

Syntax

`dtlogin` [`-config` *configuration_file*] [`-daemon`] [`-debug` *debug_level*] [`-error` *error_log_file*] [`-nodaemon`] [`-resources` *resource_file*] [`-server` *server_entry*] [`-session` *session_program*] [`-udpPort` *port_number*]

Description

The dtlogin command supports the following key tasks:

- Launching dtgreet login screen for explicitly managed local and remote displays and XDMCP-managed remote displays.
- Accessing traditional terminal (character) login from GUI login screen
- Authenticating and logging in system-dependent users
- Launching the selected session

The dtlogin command provides services similar to those provided by init, getty, and login on character terminals, which include prompting for login and password, authenticating the user, and running a session. A *session* is defined by the lifetime of a particular process. In the traditional character-based terminal world, a session is the user's login shell process; in the DT context, it is the DT Session Manager. If the DT Session Manager is not used, the typical substitute is either a window manager with an exit option, or a terminal emulator running a shell, where the lifetime of the terminal emulator is the lifetime of the shell process that it is running. This reduces the X session to an emulation of the character-based terminal session. When the session is terminated, dtlogin resets the X server and (optionally) restarts the whole process.

The dtlogin command supports management of remote displays using the X Display Manager Control Protocol, Version 1.0. (XDMCP). When dtlogin receives an indirect query from XDMCP, it can run a chooser process to perform an XDMCP BroadcastQuery (or an XDMCP Query to specified hosts) on behalf of the display and offer a menu of possible hosts that offer XDMCP display management. This feature is useful with X terminals that do not offer a host menu.

Because dtlogin provides the first interface that users see, it is designed to be simple to use and easy to customize according to the needs of a particular site.

Login Window

The Login window allows users to enter a user ID and password, select a startup session, and select a startup locale. Users can also reset the X server or temporarily suspend the X server to access the character login prompt.

The contents of the Login window are as follows:

login field
Provides an entry field in which users enter their IDs.

password field
Provides an entry field in which users enter their passwords (no-echo).

OK button
Authenticates a user and launches a session.

Clear button
Clears login and password fields.

Options
Lets users select a locale name and login session type. It also lets users restart the X server or switch to a character login prompt (for local displays). The contents of the Options menu are as follows:

Languages
Displays the Languages menu. Selecting the language from the login screen Options menu immediately localizes the login screen and sets the LANG variable for the next session. Login screen localization and LANG return to the default value upon conclusion of the session. The contents of this menu can vary depending upon the locales installed on the system. They can be overridden by using the languageList resource. The default locale of C can be overridden using the language resource. The system or languageList locales specified are displayed as menu items in the Languages menu. Alternate text to be displayed can be specified for a given locale name by using the languageName resource.

No-windows
Displays character login prompt (local displays only).

Reload Login
Restarts the X Server and returns to login screen.

Resources
Lists resources to be used.

Sessions
Displays Sessions menu. Allows users to select which session type should be started upon login. Menu items include the following:

DT Session
Starts a regular desktop session (Xsession).

Fail-safe Session
Starts a fail-safe session (Xfailsafe).

Help
Displays help messages.

Controlling the Server

The `dtlogin` command controls local servers using POSIX signals. The SIGHUP signal is expected to reset the server, closing all client connections and performing other clean up duties. The SIGTERM signal is expected to terminate the server. If these signals do not perform the expected actions, the `resetSignal` and `termSignal` resources can specify alternate signals.

To control remote servers that are not using XDMCP, `dtlogin` searches the window hierarchy on the display and uses the KillClient X protocol request in an attempt to clean up the terminal for the next session. This might not actually kill all of the clients, because only those that have created windows are noticed. XDMCP provides a more sure mechanism; when `dtlogin` closes its initial connection, the session is over and the terminal is required to close all other connections.

Controlling dtlogin

The `dtlogin` command responds to two signals: SIGHUP and SIGTERM. When it is sent a SIGHUP, `dtlogin` rereads the configuration file and the file specified by the servers resource, and determines whether entries have been added or removed. If a new entry has been added, `dtlogin` starts a session on the associated display. Entries that have been removed are disabled immediately, meaning that any session in progress is terminated without notice, and no new session is started. When sent a SIGTERM, `dtlogin` terminates all sessions in progress and exits. This can be used when shutting down the system.

Internationalization

All labels and messages are localizable. The `dtlogin.cat` message catalog contains the localized representations of the default labels and messages. The `dtlogin` command reads the appropriate message catalog indicated by the LANG environment variable and displays the localized strings. An option on the authentication screen allows the user to override the default language for the subsequent session. If the authentication screen has been localized for the selected language, the screen is redisplayed in that language; otherwise, it is displayed in the default language. In either case, the LANG environment variable is set appropriately for the resulting session.

The resource language is available in the dtlogin configuration file to change the default language for a display. The `languageList` resource is available in the `dtlogin` configuration file to override the default set of languages displayed on the authentication screen. The `languageName` resource is available to provide a mapping from locale names to the text displayed on the Language menu.

Authentication and Auditing

The `dtlogin` command is a login service enabled by PAM with service name `dtlogin`. The `dtlogin` client supports PAM authentication in addition to traditional local UNIX login and auditing. Additional authentication or auditing functions, such as Kerberos or B1 can be added by individual vendors.

To use PAM for system-wide authentication, establish root user permissions and modify the value of the *auth_type* attribute in the `usw` stanza of the `/etc/security/login.cfg` file to PAM_AUTH.

The authentication mechanisms used when PAM is enabled depend on the configuration for the login service in `/etc/pam.conf`. The `dtlogin` command requires an `/etc/pam.conf` entry for the `auth`,

account, password, and session module types. The following configuration is recommended in /etc/pam.conf for the dtlogin service:

```
dtlogin        auth              required       /usr/lib/security/pam_aix
dtlogin        account           required       /usr/lib/security/pam_aix
dtlogin        password          required       /usr/lib/security/pam_aix
dtlogin        session           required       /usr/lib/security/pam_aix
```

X Server Security

The X server provides both user-based and host-based access control. By default, dtlogin uses user-based access control to the X server (MIT-MAGIC-COOKIE-1). This level of security allows access control on a per-user basis. It is based on a scheme where if a client passes authorization data that matches what the server has, the client is allowed access. When a user logs in, this authorization data is by default stored and protected in the $HOME/.Xauthority file.

However, using host-based access control mechanisms might be preferable in environments with unsecure networks, because user-based access control allows any host to connect if the host has discovered the private key. Another drawback to user-based access control is that R2 or R3 clients are unable to connect to the server.

The authorize resource controls whether user-based or host-based access control is used by dtlogin. See the xhost, and xauth commands for more information.

Resources

The dtlogin command is controlled by the contents of the dtlogin configuration file, which defaults to /usr/dt/config/Xconfig. Some resources control the behavior of dtlogin in general, and others can be specified for a particular display.

General Resources

The following dtlogin general resources are not display-specific and apply to all displays where appropriate.

Item	Description
accessFile	**Class:** AccessFile **ClassType:** String **Default:** Null **Description:** To prevent unauthorized XDMCP service and to allow forwarding of XDMCP IndirectQuery requests, this file contains a database of host names that are either allowed direct access to this machine or have a list of hosts to which queries should be forwarded to. Refer to the Xaccess file section for a description of the format. If this resource is not set, all hosts will be allowed XDMCP service.
authDir	**Class:** AuthDir **ClassType:** String **Default:** /var/dt **Description:** The directory name that dtlogin uses to temporarily store authorization files for displays using XDMCP.

Item	Description
autoRescan	**Class:** AutoRescan **ClassType:** Boolean **Default:** True **Description:** Controls whether dtlogin rescans the configuration file and server file after a session terminates and the files have changed. You can force dtlogin to reread these files by sending a SIGHUP signal to the main process.
daemonMode	**Class:** DaemonMode **ClassType:** Boolean **Default:** False **Description:** The dtlogin command can make itself into an unassociated daemon process. This is accomplished by forking and leaving the parent process to exit, then closing file descriptors and releasing the controlling terminal. This is inconvenient when attempting to debug dtlogin. Setting this resource to False disables daemonMode.
debugLevel	**Class:** DebugLevel **ClassType:** Int **Default:** 0 **Description:** A nonzero value specified for this integer resource enables debugging information to be printed. It also disables daemon mode, which redirects the information into the normally unuseful bit-bucket.
errorLogFile	**Class:** ErrorLogFile **ClassType:** String **Default:** NULL **Description:** Error output is normally directed at the system console. To redirect it, set this resource to any file name. This file contains any output directed to stderr by Xsetup, Xstartup, and Xreset.

Item	Description
errorLogSize	**Class:** errorLogSize **ClassType:** Int **Default:** 50 **Description:** This resource specifies the maximum size of the error log file in kilobytes. When the limit is reached, dtlogin deletes the oldest entries in the file until the file size is reduced to 75 percent of the maximum. After the file is truncated, any user who is accessing the error log file (for example, using cat or tail) will need to close the file and reopen it for access in order to see subsequent information that is logged to the file.
exportList	**Class:** ExportList **ClassType:** String **Default:** NULL **Description:** Contain a set of variable names separated by a space or tab. Each variable named is obtained from the dtlogin environment and loaded into the environment of the server and session. See the Environment section for details.
fontPathHead	**Class:** FontPathHead **ClassType:** String **Default:** NULL **Description:** Value that is prepended to the default X server font path.
fontPathTail	**Class:** fontPathTail **ClassType:** String **Default:** NULL **Description:** Value that is appended to the default X server font path.

Item	Description
keyFile	**Class:** KeyFile **ClassType:** String **Default:** /usr/dt/config/Xkeys **Description:** XDM-AUTHENTICATION-1 style XDMCP authentication requires that a private key be shared between dtlogin and the terminal. This resource specifies the file containing those values. Each entry in the file consists of a display name and the shared key. By default, dtlogin does not include support for XDM-AUTHENTICATION-1 because it requires DES, which is not generally distributable.
lockPidFile	**Class:** LockPidFile **ClassType:** Boolean **Default:** True **Description:** Controls whether dtlogin uses file locking to prevent multiple instances of dtlogin from executing concurrently.
networkDevice	**Class:** NetworkDevice **ClassType:** String **Default:** /dev/dtremote **Description:** For remote connections, the value for line in /etc/utmp must also exist as a device in the /dev directory for commands such as finger to operate properly. This resource specifies the path name of the /dev file dtlogin creates when a remote display connects. For most platforms, the file is created as a symbolic link to /dev/null. The specified value must start with /dev/, or else the value is discarded and no file is created.
pidFile	**Class:** PidFile **ClassType:** STring **Default:** NULL **Description:** The filename specified is created to contain an ASCII representation of the process-ID of the main dtlogin process. This can be used when sending signals to dtlogin. The dtlogin client also uses file locking to attempt to prevent more than one dtlogin from running on the same machine. See the lockPidFile resource for more information.

Item	Description
removeDomainname	**Class:** RemoveDomainname **ClassType:** Boolean **Default:** True **Description:** When computing the display name for XDMCP clients, dtlogin typically creates a fully qualified host name for the terminal. Because this is sometimes confusing, dtlogin removes the domain name portion of the host name if it is the same as the domain name for the local host when this variable is set.
requestPort	**Class:** RequestPort **ClassType:** int **Default:** 177 **Description:** Indicates the UDP port number that dtlogin uses to listen for incoming XDMCP requests. Unless the system needs to be debugged the system, the default value for this resource should remain.

Item	Description
servers	**Class:** Servers **ClassType:** String **Default:** :0 Local local /system_dependent_path/X :0 **Description:** Either specifies a file name full of server entries, one per line (if the value starts with a slash), or a single server entry. Each entry indicates a display that should be managed constantly and that is not using XDMCP. The general syntax for each entry is as follows: *DisplayName DisplayClass DisplayType*[@ite] [Command [options]] where: ***DisplayName*** A value that can be passed in the `-display` option to any X program. This string is used in the display-specific resources to specify the particular display, so caution must be taken to match the names. For example, use `:0 local /usr/bin/X11/X :0` instead of `localhost:0 local /usr/bin/X11/X :0` if your other resources are specified as `Dtlogin._0.session`). A asterisk (*) in this field expands to `hostname:0` by `dtlogin`. ***DisplayClass*** The display class portion is also used in the display-specific resources as the class portion of the resource. This is useful if you have a large collection of similar displays (a group of X terminals, for example) and want to set resources for groups of them. When using XDMCP, the display is required to specify the display class. Refer to your X terminal documentation for information on a reasonably standard display class string for your device. ***DisplayType*** If specified as `local`, indicates that an X server should be started for this entry. A value of `remote` indicates that an existing X server should be attached. **@ite** On local bitmaps, the user can choose a `Command Line Login` option using the login screen, which temporarily suspends the X-server and presents the traditional character `login:` prompt. The user can then log in and perform non-X related tasks. When the user finishes and logs out, the X-server is restarted, and the login screen is redisplayed. In order to support `Command Line Login` mode, the display must have an associated Internal Terminal Emulator (ITE) device. By default, `dtlogin` associates the ITE device "console" (`/dev/console`) with display `:0`. If your configuration does not match this default, specify `@device` for any displays with an associated ITE, and specify `@none` for all other displays listed in the servers file. **Command [options]** The string that starts the X server. The `dtlogin` client will always connect to the X server using the *DisplayName* specified, so you might need to specify an explicit connection number as an option to your X server (`:0` in the preceding example).

Item	Description
sysParmsFile	**Class:** SysParmsFile **ClassType:** String **Default:** /system_dependent_path **Description:** Specifies a file containing shell commands, one of which sets the time zone environment variable (TZ) for the system. If the time zone is set using the shell syntax TZ=, dtlogin can use this information to set the time zone for the user session.
timeZone	**Class:** TimeZone **ClassType:** String **Default:** NULL **Description:** Specifies the local time zone for dtlogin. It is loaded into the environment of dtlogin as the value of the TZ variable and inherited by all subsequent sessions. Some systems maintain a configuration file that contains the time zone setting (for example, /etc/src.sh). See also the sysParmsFile resource.
wakeupInterval	**Class:** WakeupInterval **ClassType:** Int **Default:** 10 **Description:** If the user selects Command Line Login mode from the login screen, dtlogin terminates the X-server and allows the traditional character-based login prompt login: to become visible. If the user does not log in within 2 times the wakeupInterval seconds, the X-server is restarted. After the user has logged in, dtlogin checks every wakeupInterval seconds to see if the user has logged out. If so, the X-server is restarted and the login screen is redisplayed.

Display Resources

The dtlogin command display resources can be specified for all displays or for a particular display. To specify a particular display, the display name is inserted into the resource name between Dtlogin and the final resource name segment. For example, Dtlogin.expo_0.startup is the name of the resource defining the startup shell file on the expo:0 display. The resource manager separates the name of the resource from its value with colons, and separates resource name parts with dots, so dtlogin uses underscores (_) for the dots (.) and colons (:) when generating the resource name.

Resources can also be specified for a class of displays by inserting the class name instead of a display name. A display that is not managed by XDMCP can have its class affiliation specified in the file referenced by the servers resource. A display using XDMCP supplies its class affiliation as part of the XDMCP packet.

The following dtlogin general resources are not display-specific and apply to all displays where appropriate.

Item	Description
authorize	**ClassClass:** Authorize **Type:** Boolean **Default:** False **Description:** Authorize is a Boolean resource that controls whether dtlogin generates and uses authorization for the server connections. Refer also to the authName resource.
authName	**ClassClass:** AuthName **Type:** String **Default:** MIT-MAGIC-COOKIE-1 **Description:** If the authorize resource is used, authName specifies the type of authorization to be used. Currently, dtlogin supports only MIT-MAGIC-COOKIE-1 authorization. XDM-AUTHORIZATION-1 could be supported, but DES is not generally distributable. XDMCP connections state which authorization types are supported dynamically, so authName is ignored in this case. Refer also to the authorize resource.)
authFile	**ClassClass:** AuthFile **Type:** String **Default:** NULL **Description:** Communicates the authorization data from dtlogin to the server, using the -auth server command line option. Keep this resource in a write-protected directory to prevent its erasure, which would disable the authorization mechanism in the server. If NULL, dtlogin generates a file name.
chooser	**ClassClass:** Chooser **Type:** **Default:** **Description:** Specifies the program run to offer a host menu for indirect queries redirected to the special host name CHOOSER. The default is /usr/dt/bin/dtchooser. See the Xaccess file section.

Item	Description
cpp	**ClassClass:** Cpp **Type:** String **Default:** system dep. **Description:** Specifies the path of the C preprocessor that is used by xrdb.
environment	**ClassClass:** Environment **Type:** String **Default:** system dep. **Description:** Contains a set of *name=value* pairs separated by a space or tab. Each item is loaded into the environment of the server and session. See the Environment section for more information.
failsafeClient	**ClassClass:** FailsafeClient **Type:** String **Default:** /system_dep./xterm **Description:** If the default session fails to execute, dtlogin falls back to this program. This program is executed with no arguments, but executes using the same environment variables as the session would have had.
grabServer	**ClassClass:** GrabServer **Type:** Boolean **Default:** True **Description:** To improve security, dtlogin grabs the server and keyboard while reading the name and password. The grabServer resource specifies if the server should be held while the name and password is read. When FALSE, the server is ungrabbed after the keyboard grab succeeds; otherwise, the server is grabbed until just before the session begins.

Item	Description
grabTimeout	**ClassClass:** GrabTimeout **Type:** Int **Default:** 3 seconds **Description:** Specifies the maximum time dtlogin will wait for the grab to succeed. The grab can fail if another client has the server grabbed, or possibly if the network latencies are very high. The grabTimeout resource has a default of 3 seconds; use this resource with care, because a user can be deceived by a look-alike window on the display. If the grab fails, dtlogin kills and restarts the server (if possible) and session. Some X-terminals cannot display their login screens while the server is grabbed. Setting grabServer to FALSE allows the screen to be displayed but opens the possibility that a user's login name can be stolen by copying the contents of the login screen. Because the keyboard is still grabbed and the password is not echoed, the password cannot be stolen.
language	**ClassClass:** Language **Type:** String **Default:** system dep. **Description:** Specifies the default setting for the LANG environment variable. If the dtlogin screen is localized for that language, it is displayed appropriately; otherwise, it is displayed in the C language The user can temporarily override this setting using an option on the login screen. When the subsequent session terminates, the LANG variable reverts to this setting.
languageList	**ClassClass:** LanguageList **Type:** String **Default:** NULL **Description:** Allows the user to override the default set of languages displayed in the Language menu of the login screen. It is useful if the set of languages actually used on a particular display is smaller than the set installed on the system. The resource value is a list of valid values for the LANG environment variable. Language values should be separated by one or more spaces or tabs.

Item	Description
languageName	**ClassClass:** LanguageName **Type:** String **Default:** NULL **Description:** Allows the user to override the default locale name displayed in the Language menu of the login screen with alternate text. This way, instead of users seeing a En_US item, they could see an English (United States) item instead. This resource is specified as Dtlogin*_local_name_.languageName: *text* as follows: `Dtlogin*En_US.languageName: English (United States)` `Dtlogin*Fr_CA.languageName: French (Canadian)`
openDelay	**ClassClass:** OpenDelay **Type:** Int **Default:** 5 seconds **Description:** Specifies the duration (in seconds) between successive attempts to open reluctant servers.
openRepeat	**ClassClass:** OpenRepeat **Type:** Int **Default:** 5 seconds **Description:** Specifies the number of successive attempts to open reluctant servers.
openTimeout	**ClassClass:** OpenTimeout **Type:** Int **Default:** 30 seconds **Description:** Specifies the amount of time to wait while actually attempting to open reluctant servers. This time is the same as the maximum time spent in the connect system call.

Item	Description
pingInterval	**ClassClass:** PingInterval **Type:** Int **Default:** 5 minutes **Description:** To discover when remote displays disappear, dtlogin occasionally pings them, using an X connection and sending XSync requests. The pingInterval resource specifies the time (in minutes) between successive ping attempts.
pingTimeout	**ClassClass:** PingTimeout **Type:** int **Default:** 5 minutes **Description:** Specifies the maximum wait time (in minutes) for the terminal to respond to the request. If the terminal does not respond, the session is terminated. The dtlogin client does not ping local displays. A local session should never be terminated as a result of the server waiting (for remote file system service, for example) and not responding to the ping.
reset	**ClassClass:** Reset **Type:** String **Default:** NULL **Description:** specifies a program that is run (as root) after the session terminates. If this resource is not set, no program is run. The conventional name is Xreset. See the Xreset File.
resetForAuth	**ClassClass:** ResetForAuth **Type:** Boolean **Default:** False **Description:** During the original implementation of authorization in the sample server, the authorization file was reread at server reset time instead of when checking the initial connection. Because dtlogin generates the authorization information just before connecting to the display, an old server does not get current authorization information. This resource causes dtlogin to send SIGHUP to the server after setting up the file, causing an additional server reset to occur, during which time the new authorization information is read.

Item	Description
resetSignal	**ClassClass:** Signal **Type:** Int **Default:** 1 SIGHUP **Description:** Specifies the signal dtlogin sends to reset the server.
resources	**ClassClass:** Resource **Type:** String **Default:** NULL **Description:** Specifies the name of the file to be loaded by xrdb as the resource database onto the root window of screen 0 of the display. This resource database is loaded just before the authentication procedure is started, so it can control the appearance of the login window. See the section on the authentication screen, which describes the various resources that are appropriate to place in this file. There is no default value for this resource, but the conventional name is Xresources.
session	**ClassClass:** Session **Type:** String **Default:** /usr/dt/bin/Xsession **Description:** Specifies the session to be executed for the authenticated user. By default, the /usr/dt/bin/Xsession file is run. The conventional name is Xsession. Refer to the Xsession file.
setup	**ClassClass:** Setup **Type:** String **Default:** NULL **Description:** Specifies a program that is run (as root) prior to the display of the authentication screen. By default, no program is run. The conventional name is Xsetup. Refer to the Xsetup file.

Item	Description
startAttempts	**ClassClass:** StartAttempts **Type:** Int **Default:** 4 **Description:** Four numeric resources control the behavior of dtlogin when attempting to open reluctant servers: openDelay, openRepeat, openTimeout, and startAttempts. This resource specifies the number of times the entire process occurs before giving up on the server. After openRepeat attempts have been made, or if openTimeout seconds elapse in any particular attempt, dtlogin terminates and restarts the server, attempting to connect again. This process is repeated startAttempts time, at which point the display is declared dead and disabled.
startup	**ClassClass:** Startup **Type:** String **Default:** NULL **Description:** Specifies a program that is run (as root) after the authentication process succeeds. By default, no program is run. The conventional name for a file used here is Xstartup. See the Xstartup file section.
systemPath	**ClassClass:** SystemPath **Type:** String **Default:** system_dep._path **Description:** The dtlogin client sets the PATH environment variable for the startup and reset scripts to the value of this resource. Note the conspicuous absence of "." from this entry. This is a good practice to follow for root because it avoids many system penetration schemes.
systemShell	**ClassClass:** SystemShell **Type:** String **Default:** /bin/sh **Description:** The dtlogin client sets the SHELL environment variable for the startup and reset scripts to the value of this resource.

Item	Description
terminateServer	**ClassClass:** TerminateServer **Type:** Boolean **Default:** False **Description:** Specifies whether the X server should be terminated when a session ends (instead of resetting it). This option can be used if the server tends to grow indefinitely over time in order to limit the amount of time the server is run continuously.
termSignal	**ClassClass:** Signal **Type:** Int **Default:** 15 (SIGTERM) **Description:** Specifies the signal dtlogin sends to terminate the server.
userAuthDir	**ClassClass:** UserAuthDir **Type:** String **Default:** /var/dt **Description:** When dtlogin cannot write to the usual user authorization file ($HOME/.Xauthority), it creates a unique file name in this directory and points the environment variable XAUTHORITY at the created file.
userPath	**ClassClass:** UserPath **Type:** String **Default:** system_dep._path **Description:** The dtlogin client sets the PATH environment variable for the session to this value. It should be a colon-separated list of directories.
xdmMode	**ClassClass:** XdmMode **Type:** Boolean **Default:** False **Description:** If True, the $HOME/.xsession file will be executed from Xsession upon user authentication, rather than from dtsession.

Item	Description
xrdb	**ClassClass:** Xrdb **Type:** String **Default:** /system_dep./xrdb **Description:** Specifies the program used to load the resources. The authentication screen reads a *name-password* pair from the keyboard. Because this is a Motif toolkit client, colors, fonts and some layout options can be controlled with resources. General resources for this screen should be put into the file named by the resources resource (Xresources is the default). Specify language-specific values, such as text or fonts, in the Dtlogin app-defaults file.

Logo Resources

The default logo on the authentication screen can be replaced with a bitmap or pixmap of the user's choice. The resources should be prefaced with the string Dtlogin*logo* when specified.

Item	Description
bitmapFile	**ClassClass:** BitmapFile **Type:** String **Default:** NULL **Description:** Specifies the absolute path name to the bitmap or pixmap file to be used for the logo.
background	**ClassClass:** Background **Type:** Pixel **Default:** #a8a8a8 **Description:** Specifies the background color for the logo.
topShadowPixmap	**ClassClass:** topShadowPixmap **Type:** String **Default:** 25_foreground **Description:** Specifies the pixmap to use for the logo border shadow.

The following resources describe the greeting string used on the login screen. The resources should be prefaced with the string Dtlogin*greeting* when specified.

Item	Description
foreground	**ClassClass:** Foreground **Type:** Pixel **Default:** black **Description:** Specifies the foreground color for the welcome message.
background	**ClassClass:** Background **Type:** Pixel **Default:** dynamic **Description:** Specifies the background color for the welcome message. The default is light gray for color systems or white for monochrome systems.
fontlist	**ClassClass:** FontList **Type:** FontList **Default:** -*-*schoolbook-medium-i-normal--18-* **Description:** Specifies the font to use for the welcome message.
labelString	**ClassClass:** LabelString **Type:** String **Default:** Welcome to %LocalHost% **Description:** Specifies the string to use for the welcome message. Multiple lines can be specified by including newline characters (0 in the text. If the token %LocalHost% is included in the text, it will be replaced with the name of the host providing login service. If the token %DisplayName% is included in the text, it will be replaced with the display name.
perLabelString	**ClassClass:** LabelString **Type:** String **Default:** Welcome %s **Description:** Specifies the string to use for the personalized welcome message. This is the message displayed after the user name has been entered. The %s will be replaced with the user name entered.

Item	Description
alignment	**ClassClass:** Alignment **Type:** String **Default:** ALIGNMENT_CENTER **Description:** Specifies the string to use for the alignment of the Welcome message. Valid values are ALIGNMENT_BEGINNING, ALIGNMENT_CENTER and ALIGNMENT_END.

Matte Resources

The following resources describe the matte layout used on the login screen. The resources should be prefaced with the `Dtlogin*matte.` string when specified.

Item	Description
width	**ClassClass:** Width **Type:** Int **Default:** 806 for high-resolution displays 755 for medium-resolution displays 585 for low-resolution displays **Description:** Specifies the width to use for the `login_matte`.
height	**ClassClass:** Height **Type:** Int **Default:** 412 for high-resolution displays 385 for medium-resolution displays 300 for low-resolution displays **Description:** Specifies the height to use for the `login_matte`.

Label Resources

The following resources describe the fonts layout used on the login screen. The resources should be prefaced with the `string Dtlogin*.` when specified.

Item	Description
`labelFont`	**ClassClass:** LabelFont **Type:** String **Default:** -*-swiss 742-medium-r-normal-*-140-*-p-110-* for high-resolution displays -*-swiss 742-bold-r-normal-*-140-*-p-100-* for low-resolution displays **Description:** Specifies the `labelFont` to use for the push buttons and labels.
`textFont`	**ClassClass:** TextFont **Type:** String **Default:** -*-prestige-medium-r-normal-*-128-72-* for high-resolution displays -*-helvetica-bold-r-normal-*-100-* for low-resolution displays **Description:** Specifies the `textFont` to use for the push buttons and labels.

Flags

All flags, except `-config`, specify values that can also be specified in the configuration file as resources. Typically, customization is done using the configuration file rather than command line options. These flags are most useful for debugging and one-shot tests.

Item	Description
`-config` *configuration_file*	Specifies a resource file that specifies the remaining configuration parameters. This replaces the `dtlogin` default `Xconfig` file. See the Xconfig file section for more information.
`-daemon`	Specifies `true` as the value for the `daemonMode` resource. This makes `dtlogin` close all file descriptors, disassociate the controlling terminal, and put itself in the background when it first starts up (just like the host of other daemons).
`-debug` *debug_level*	Specifies the numeric value for the *debug_level* resource. A nonzero value causes `dtlogin` to print debugging statements to the terminal; it also disables the `daemonMode` resource, forcing `dtlogin` to run synchronously.
`-error` *error_log_file*	Specifies the value for the *error_log_file* resource. See the Xerrors file section for more information.
`-nodaemon`	Specifies `false` as the value for the resources.
`-resources` *resource_file*	Specifies the value for the *resource_file* resource. See the the Xresources file section for more information.

Item	Description
`-server` *server_entry*	Specifies the value for the *server_entry* resource. See the the Xservers file section for more information.
`-udpPort` *port_number*	Specifies the value for the `requestPort` resource. This sets the port number that `dtlogin` monitors for XDMCP requests. Because XDMCP uses the well-known registered udp port 177, avoid changing this resource except for debugging.
`-session` *session_program*	Specifies the value for the *session_program* resource. See the Xconfig file section for more information.

Environment Variables

The `dtlogin` command invokes the user's session with the following default environment:

Item	Description
`DISPLAY`	Set to the associated display name.
`EDITOR`	Set to `/usr/dt/bin/dtpad`.
`HOME`	Set to the home directory of the user.
`KBD_LANG`	Set to the value of `LANG` for applicable languages.
`LANG`	Set to the current NLS language (if any).
`LC_ALL`	Set to the current NLS language (if any).
`LC_MESSAGES`	Set to the current NLS language (if any).
`LOGNAME`	Set to the user name.
`MAIL`	Set to `/usr/mail/$USER` (system dependent).
`PATH`	Set to the value of the `userPath` resource.
`USER`	Set to the user name.
`SHELL`	Set to the user's default shell (from `/etc/passwd`).
`TERM`	Set to `dtterm`.
`TZ`	Set to the value of the *timeZone* resource or system default.
`XAUTHORITY`	Set to authority file.

Adding to the Environment List

Four methods are available to modify or add to the preceding list depending on the desired scope of the resulting environment variable:

- The `exportList` resource is available to allow the export of variables provided to the `dtlogin` process by its parent. Variables specified by this method are available to both the display's X server process and the user's session, and they override any default settings. The resource accepts a string of *name*=*value* separated by at least one space or tab.
- The `environment` resource is available in the `dtlogin` configuration file to allow setting of environment variables on a global or per-display basis. Variables specified by this method are available to both the display's X server process and the user's session, and they override any default settings. The

resource accepts a string of *name*=*value* separated by at least one space or tab. The values specified must be constants because no shell is used to parse the string. For example:

```
Dtlogin*environment:MAIL_HOST=blanco MAIL_SERVER=pablo
```

Note: The LANG and TZ environment variables have their own dedicated resources in the configuration file and should not be set by the environment.

- Environment variables that require processing by a shell or are dependent on the value of another environment variable can be specified in the startup script Xsession. These variables are loaded into the environment of all users on the display, but not to the X server process. They override any previous settings of the same variable. The Xsession script accepts ksh syntax for setting environment variables. For example:

```
MAIL=/usr/mail/$USER
```

- Personal environment variables can be set on a per-user basis in the $HOME/.dtprofile script file. The dtlogin command accepts either sh, ksh, or csh syntax for the commands in this file. The commands should only be those that set environment variables, not any that perform terminal I/O, with the exception of tset or stty. If the first line of .dtprofile is #!/bin/sh, #!/bin/ksh or #!/bin/csh, dtlogin uses the appropriate shell to parse .dtprofile. Otherwise, the user's default shell ($SHELL) is used.

Exit Status

The following exit values are returned:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To start the CDE login service as a daemon, enter:

```
/usr/dt/bin/dtlogin -daemon
```

2. To start the CDE login service in debug mode, enter:

```
/usr/dt/bin/dtlogin -debug 1
```

Location

/usr/dt/bin/dtlogin

Standard Errors

The dtlogin command returns the following error messages:

- Login incorrect; please try again.
- Unable to change to home directory.
- Sorry. Maximum number of users already logged in.
- Login error, invalid user ID.
- Login error, invalid group ID.
- Login error, invalid audit ID.
- Login error, invalid audit flag.
- Logins are currently disabled.

• Your current password has expired.

Files

The dtlogin command is designed to operate in a wide variety of environments and provides a suite of configuration files that can be changed to suit a particular system. The default dtlogin configuration files can be found in /usr/dt/config with the exception of Xsession, which is stored in /usr/dt/bin. They are as follows:

Item	Description
/usr/dt/config/Xconfig	Specifies other dtlogin configuration files and dtlogin behavior.
/usr/dt/config/Xaccess	Controls access from displays requesting XDMCP service.
/usr/dt/config/Xservers	Contains the list of displays for dtlogin to explicitly manage.
/usr/dt/config/Xresources	Contains resource definitions specifying the appearance of the login screen.
/usr/dt/config/Xsetup	A script executed as root prior to display of the login screen.
/usr/dt/config/Xstartup	A script executed as root after the user has successfully authenticated.
/usr/dt/bin/Xsession	A script executed as the authenticated user that starts the user's session.
/usr/dt/config/Xfailsafe	A script executed as the authenticated user that starts a fail-safe session.
/usr/dt/config/Xreset	A script executed as root after the user's session has exited.

The Xconfig File

The Xconfig file contains the general resources for dtlogin and is at the top of the dtlogin configuration file tree. Xconfig specifies the location of other dtlogin configuration and log files and specifies dtlogin behavior. The location of other dtlogin configuration and log files are specified by resource definitions. The defaults are as follows:

Dtlogin.errorLogFile
/var/dt/Xerrors

Dtlogin.pidFile
/var/dt/Xpid

Dtlogin.accessFile
Xaccess

Dtlogin.servers
Xservers

Dtlogin*resources
%L/Xresources

Dtlogin*setup
Xsetup

Dtlogin*startup
Xstartup

Dtlogin*reset
Xreset

Dtlogin*failsafeClient
Xfailsafe

Dtlogin*session
/usr/dt/bin/Xsession

If the path specified for `accessFile`, `servers`, `resources`, `setup`, `startup`, `reset`, `failsafeClient`, or `session` is relative, `dtlogin` will first look for the file in directory `/etc/dt/config`, then `/usr/dt/config`.

Note: Some of the resources are specified with * separating the components. These resources can be made unique for each different display, by replacing the * with the display-name. Refer to Display Resources for more information.

The default `Xconfig` file is `/usr/dt/config/Xconfig`. A system administrator can customize `Xconfig` by copying `/usr/dt/config/Xconfig` to `/etc/dt/config/Xconfig` and modifying `/etc/dt/config/Xconfig`. The default `Xconfig` file contains the preceding configuration and log file entries in addition to a few vendor specific resource definitions and examples.

The Xaccess File

The database file specified by the `accessFile` resource provides information which `dtlogin` uses to control access from displays requesting XDMCP service. This file contains three types of entries: entries which control the response to Direct and Broadcast queries, entries which control the response to Indirect queries, and macro definitions.

The format of a Direct entry is either a host name or a pattern. A pattern is distinguished from a host name by the inclusion of one or more meta characters (* matches any sequence of 0 or more characters, and ? matches any single character) which are compared against the host name of the display device. If the entry is a host name, all comparisons are done using network addresses, so any name which converts to the correct network address can be used. For patterns, only canonical host names are used in the comparison, so ensure that you do not attempt to match aliases. Putting an exclamation point (`!`) character before either a host name or a pattern causes hosts that match that entry to be excluded.

An Indirect entry also contains a host name or pattern, but follows it with a list of host names or macros to which indirect queries should be sent. Indirect entries can also specify to have `dtlogin` run `dtchooser` to offer a menu of hosts to which a login screen can be displayed.

A macro definition contains a macro name and a list of host names and other macros that the macro expands to. To distinguish macros from host names, macro names start with a % character. Macros can be nested.

When the access for a particular display host is checked, each entry is scanned in turn and the first matching entry determines the response. Direct and Broadcast entries are ignored when scanning for an Indirect entry and vice-versa. Blank lines are ignored, # is treated as a comment delimiter causing the rest of that line to be ignored, and `\newline` causes the newline to be ignored, allowing indirect host lists to span multiple lines.

The following example shows an Xaccess file:

```
#
# Xaccess - XDMCP access control file
#

#
# Direct/Broadcast query entries
#
!xtra.lcs.mit.edu # disallow direct/broadcast service for xtra
bambi.ogi.edu     # allow access from this particular display
*.lcs.mit.edu     # allow access from any display in LCS

#
# Indirect query entries
#

#define %HOSTS macro
%HOSTS                expo.lcs.mit.edu xenon.lcs.mit.edu \
                      excess.lcs.mit.edu kanga.lcs.mit.edu
```

```
#force extract to contact xenon
extract.lcs.mit.edu xenon.lcs.mit.edu

#disallow indirect access by xtra
!xtra.lcs.mit.edu   dummy

#all others get to choose among %HOSTS
*.lcs.mit.edu       %HOSTS
```

If XDMCP access is granted, a temporary file can be created in the directory specified by `authDir` which contains authorization information for the X-terminal. It is deleted when the session starts.

For X terminals that do not offer a host menu for use with Broadcast or Indirect queries, the `chooser` program can do this for them. In the `Xaccess` file, specify CHOOSER as the first entry in the Indirect host list. The `chooser` program sends a Query request to each of the remaining host names in the list and displays a menu of all the hosts that respond. The list might consist of the word BROADCAST, in which case `chooser` sends a Broadcast instead, again displaying a menu of all hosts that respond. On some operating systems, UDP packets cannot be broadcast, so this feature will not work.

An example of an `Xaccess` file using the `chooser` program is as follows:

```
#offer a menu of these hosts to extract
extract.lcs.mit.edu CHOOSER %HOSTS

#offer a menu of all hosts to xtra
xtra.lcs.mit.edu    CHOOSER BROADCAST
```

The program to use for `chooser` is specified by the `chooser` resource. Resources for this program can be put into the file named by resources. The default `Xaccess` file is `/usr/dt/config/Xaccess`. A system administrator can customize `Xaccess` by copying `/usr/dt/config/Xaccess` to `/etc/dt/config/Xaccess` and then modifying `/etc/dt/config/Xaccess`. The default `Xaccess` file contains no entries.

The Xservers File

The `Xservers` file contains the list of displays to manage. The default `Xservers` file is `/usr/dt/config/Xservers`. A system administrator can customize `Xservers` by copying `/usr/dt/config/Xservers` to `/etc/dt/config/Xservers` and then modifying `/etc/dt/config/Xservers`. The default `Xservers` file contains an entry for one local display.

The Xresources File

The `Xservers` file contains the resource definitions specifying the appearance of the login screen. The default `Xresources` file is `/usr/dt/config/Xresources`. A system administrator can customize `Xresources` by copying `/usr/dt/config/Xresources` to `/etc/dt/config/Xresources` and then modifying `/etc/dt/config/Xresources`.

The Xsetup File

The `Xsetup` file typically a shell script. Only root users can run it, and they should be very careful about security. This script is run before the login screen is displayed. No arguments of any kind are passed to the script. The `dtlogin` command waits until this script exits before displaying the login screen.

The default `Xsetup` file is `/usr/dt/config/Xsetup`. A system administrator can customize `Xsetup` by copying `/usr/dt/config/Xsetup` to `/etc/dt/config/Xsetup` and then modifying `/etc/dt/config/Xsetup`. The default `Xsetup` file contains vendor specific code but typically contains code that sets up the X server prior to the display of the login screen, such as setting up keyboard maps.

The Xstartup File

The `Xstartup` file typically a shell script. Only root users can run it, and they should be very careful about security. This is the place to put commands that display the message of the day or do other system-level functions on behalf of the user. The following environment variables are set for the use of this script:

DISPLAY
Set to the associated display name.

HOME
Set to the home directory of the user.

PATH
Set to the value of the systemPath resource.

USER
Set to the user name.

SHELL
Set to the value of the systemShell resource.

No arguments of any kind are passed to the script. The dtlogin command waits until this script exits before starting the user session. If the exit value of this script is nonzero, dtlogin discontinues the session immediately and starts another authentication cycle.

The default Xstartup file is /usr/dt/config/Xstartup. A system administrator can customize Xstartup by copying /usr/dt/config/Xstartup to /etc/dt/config/Xstartup and then modifying /etc/dt/config/Xstartup. The default Xstartup file contains code to change ownership of /dev/console to the user whose session is running on the console.

The Xsession File

The Xsession script initializes a user's session and invokes the desktop session manager. It is run with the permissions of the authorized user, and has several environment variables preset. See Environment Variables for a list of the preset variables.

The default Xsession file is /usr/dt/bin/Xsession. A system administrator can customize Xsession by copying /usr/dt/bin/Xsession to /etc/dt/config/Xsession and then modifying /etc/dt/config/Xsession. The session resource defined in Xconfig must also be changed to reference the customized Xsession file. See The Xconfig File for information on how to update the Xconfig file. The default Xsession file contains session initialization code. It does contain some vendor specific code, but its general function is as follows:

- Sources the user's $HOME/.dtprofile
- Sources any /etc/dt/config/Xsession.d/* scripts
- Sources any /usr/dt/config/Xsession.d/* scripts
- Launches the desktop welcome client, dthello, in the background
- Sources the application search path setup script, dtsearchpath
- Launches the help setup client, dthelpgen, in the background
- Launches the application manager directory setup client, dtappgather, in the background
- Execs the desktop session manager, dtsession
-

System administrators are discouraged from customizing the Xsession file.

The Xreset File

Symmetrical with Xstartup, the Xreset script is run after the user session has terminated. Because it is run by a root user, the Xreset script should contain commands that undo the effects of commands in Xstartup, such as unmounting directories from file servers. The collection of environment variables that were passed to Xstartup are also given to Xreset.

The default Xreset file is /usr/dt/config/Xreset. A system administrator can customize Xreset by copying /usr/dt/config/Xreset to /etc/dt/config/Xreset and then modifying /etc/dt/config/Xreset. The default Xreset file contains code change ownership of /dev/console back to root.

The Xerrors File

The Xerrors script contains error messages from dtlogin and anything output to stderr by Xsetup, Xstartup or Xreset. The system administrator can use the contents of this file for dtlogin troubleshooting. The errorLogSize resource limits the size of the Xerrors file and can prevent it from growing without bound. If the file does grow larger than the requested size and is truncated by dtlogin,

any user who is accessing the file (for example, using `cat` or `tail`) will need to close the file (after the file is truncated) and reopen it for access in order to see subsequent information that is logged to the file.

A system administrator can change the path name of the `Xerrors` by setting the `errorLogFile` resource in the `Xconfig` file.

The Xpid File

The `Xpid` script contains the process ID of the master `dtlogin` process, which can be used when sending signals to `dtlogin`. A system administrator can change the path name of the `Xpid` by setting the `pidFile` resource in the `Xconfig` file.

dtscript Command

Purpose

Builds simple dialogs used in the X Window System environment.

Syntax

dtscript [**-xrm** *options*] [**-dir** *Path*] [**-file** *FileName*] [**-workspace** *WorkspaceName*]

Note: The **-xrm** *options* must be specified, if used, before any other flag.

Description

Desktop Script supports a subset of Motif widgets you drag and drop from the palette into your dialog. You can move or resize any widget in a dialog. You can also edit widget properties using the specialized editors provided.

You can enter callbacks to give widgets desired behavior. When a dialog is complete, Desktop Script generates dtksh code for it.

Flags

Item	Description
-dir *Path*	Sets Desktop Script's current directory shown in the File Select dialog to *Path*.
-file *FileName*	Loads an existing dialog called: *FileName*. The *FileName* argument can be an absolute path name, a path name relative to the current directory, or a path name relative to the **-dir** value.
-workspace *WorkspaceName*	Loads Desktop Script into the corresponding CDE workspace.
-xrm *options*	Enables you to enter any of the specifications (*options*) that you would otherwise put into a resource file.

Examples

To invoke the Desktop Script from a window, enter:

```
dtscript
```

Files

Item	Description
/usr/dt/bin/dtscript	Contains the **dtscript** command.

dtsession Command

Purpose

Manages a CDE session.

Syntax

`dtsession` [*options*] ...

Description

The `dtsession` command provides session management functionality, compliant with ICCCM 1.1, during a user session, from login to logout. It starts a window manager and allows users to save a session, restore a session, lock a session, start screen savers, and allocate colors for desktop-compatible clients.

Note: The desktop login manager `dtlogin` automatically invokes the `dtsession` client through the `Xsession` script. The `dtsession` client can also be started through the `Xsession` script on an existing X server. The `dtsession` session manager automatically starts a window manager.

The `dtsession` command supports the following tasks:

- Initializing a session
- Starting a window manager
- Restoring a home or current session
- Providing session lock on command or timeout
- Providing session screen saver on command or timeout
- Acting as a color allocation server for other desktop clients
- Saving a home or current session
- Displaying confirmation dialog at logout
- Displaying session selection dialog at logout
- Terminating a session

Sessions

A session is the collection of applications, settings, and resources that are present on the user desktop. Session management is a set of conventions and protocols that allow a special session manager, such as `dtsession`, to save and restore a user session. A user can log in to a system and be presented with the same set of running applications, settings, and resources that were present when the user logged off. When a user logs in to the desktop for the first time, a default initial session is loaded. Afterward, `dtsession` supports the notion of a current and a home session.

The following sessions are defined:

Initial session
: When a user logs in to the desktop for the first time, `dtsession` generates the user's initial session by using system default values. For more information, refer to Session Resource Management and Session Application Management.

Current session
: The user session that is running is always considered the current session, whether restored upon login from a saved home session, a saved current session, or the system default initial session. Based on the user's Style Manager Startup settings, when the user exits the session, the current session is automatically saved. When the user next logs in to the desktop, the previously saved current session is restarted. The desktop is restored to the same state it was in when the user last logged out.

Home session
Another option restores the desktop to the same state every time the user logs in, regardless of its state when the user logged out. The user can save the state of the current session, then sets the Style Manager Startup so that the desktop starts that session every time the user logs in.

Display-specific sessions
To run a specific session for a specific display, users can create a display-specific session. To do so, users can copy the `$HOME/.dt/sessions` directory to `$HOME/.dt/`*display*, where display is the real, unqualified host name (for example, `pablo:0` is valid, but `pablo.gato.com:0` or `local:0` is not). When the user logs in on display `pablo:0`, that display-specific session takes precedence.

ICCCM Session Management Protocol

For an application to be saved upon logout and restarted upon login, it must participate in a simple session management protocol. The `dtsession` command supports the ICCCM 1.1 Session Management Protocol.

Applications that want to save their state can take part in the WM_SAVE_YOURSELF protocol. To do so, an application requires to set the WM_SAVE_YOURSELF property on only one of its top-level windows. When a session is saved, `dtsession` sends the application's top-level window a WM_SAVE_YOURSELF client message. The application proceeds to quietly save its state. The application cannot interact with the user in any way while it is saving its state. Because an application likely saves its state into a file, the session manager provides a convenience function, `DtSessionSavePath`, which returns a full path name of a file in which an application can save its state. While the application is saving its state, `dtsession` awaits notice from the application that it is finished. To tell `dtsession` that the save is complete, the application must update the WM_COMMAND property on its top-level window.

The WM_COMMAND property on an application's top-level window serves two purposes. First, a change of this property indicates to `dtsession` that an application is finished saving its state and `dtsession` can proceed to the next application. Second, the WM_COMMAND property value is expected to contain the command line that `dtsession` uses to restart the application at session startup. If an application is started with a full path name, it must use the full path name when setting the WM_COMMAND value. Applications that do not require to save their state but want to be restarted can set the WM_COMMAND value once during application startup.

Restoring a Session

At session startup time, `dtsession` determines which session to restore. The following list describes the order of precedence:

1. Display-specific current of home session
2. Current or home session
3. Initial session

Session Resource Management

The session manager uses the X Server RESOURCE_MANAGER property on which to make available desktop resources to all applications. The session manager loads the RESOURCE_MANAGER in the following manner:

1. Loads the system default resources.
2. Merges any system administrator-specified resources.
3. Merges any user-specified resources.

The desktop default resources can be found in the `/usr/dt/config/$LANG/sys.resources` file. These resources are made available to each user session through the RESOURCE_MANAGER property. Do not edit this file because it is unconditionally overwritten during subsequent desktop installations.

By creating a `/etc/dt/config/$LANG/sys.resources` file, a system administrator can override system default resources or specify more resources. Because this file is merged into the desktop default

resources during session startup, only new or updated resource specifications must be placed in this file. It is preferable to making a copy of the desktop default resource file. Resources that are specified in this file are made available to each user session through the RESOURCE_MANAGER property. Resources that are specified in this file take precedence over those resources that are specified in the desktop default resource file.

By editing the `$HOME/.Xdefaults` file, a user can override the desktop default and system administrator resources. Resources that are specified in this file are made available to only that user session through the RESOURCE_MANAGER property and take precedence over those resources that are specified in the desktop default or system administrator resource files.

Note: The X Toolkit Intrinsics specify that it loads application resources from either RESOURCE_MANAGER or from `$HOME/.Xdefaults`, but not both. Ordinarily, it means that the user's `$HOME/.Xdefaults` file is ignored. However, the session manager accommodates `$HOME/.Xdefaults` by merging it into the RESOURCE_MANAGER at session startup. When users change their `$HOME/.Xdefaults` files, their changes are not visible to new applications until the users invoke the `ReloadResources` action.

The `ReloadResources` action instructs the session manager to reload the RESOURCE_MANAGER with the system-specified, system administrator-specified, and user-specified resources. It makes available to new applications changes that were made to system administrator-specified or user-specified resource files.

Session Application Management

At session startup, the session manager restarts any applications that were saved as part of the session. The system's default set of applications to be restored as part of the user's initial session can be found in the `/usr/dt/config/$LANG/sys.session` file. Do not edit this file because it is unconditionally overwritten during subsequent desktop installations.

A system administrator can replace the set of applications that are restored as part of the user's initial session by creating a `/etc/dt/config/$LANG/sys.session` file. Unlike the resource files, this file is used as a complete replacement for the desktop default file, so you can make a copy of the system default file and make any necessary modifications.

The Window Manager

The `dtsession` command starts the window manager. By default, `/usr/dt/bin/dtwm` is started. An alternative window manager can be specified by using the `wmStartupCommand` resource. For more information, refer to the Workspace Manager specification.

The Style Manager

The style manager provides the interface by which a user can change various desktop and X server settings for the current session. For more information, refer to the Style Manager specification.

The Color Server

The `dtsession` command serves as the color server for the desktop and provides the following set of resources that can be used to configure it:

foregroundColor
Controls whether a pixel is allocated for the foreground color.

dynamicColor
Specifies whether read-only colors are allocated.

shadowPixmaps
Specifies whether colors are allocated for top shadow or bottom shadow.

colorUse
Limits color allocation.

writeXrdbColors
Specifies whether the *background and *foreground resources are placed in the resource database.

For more information, see the Color Server Resources section.

Session Lock

The dtsession command provides locking of session. The current session can be locked directly by pressing the lock icon on the front panel. If supported by the X server, the current session can be locked after a specified period of inactivity. To unlock the session, users must enter their login password, the login password for the root user, or the login password for any of the users specified by the keys resource. See Screen Lock and Screen Save Resources for more information on the keys resource.

The dtsession command is a PAM-enabled session manager with service name dtsession. It supports traditional local UNIX authentication as well as PAM authentication for unlocking the session. Additional reauthentication functionality, such as that required by DCE, can be added by individual vendors.

System-wide configuration to use PAM for authentication is set by establishing root user permissions and modifying the value of the *auth_type* attribute in the usw stanza of the /etc/security/login.cfg file to PAM_AUTH.

The authentication mechanisms that are used when PAM is enabled depend on the configuration for the login service in /etc/pam.conf. The dtsession command requires an /etc/pam.conf entry for the auth module type. The following configuration is recommended in /etc/pam.conf for the dtsession service:

```
dtsession       auth            required        /usr/lib/security/pam_aix
```

Screen Savers

The dtsession command provides support for the launching of external screen savers as a part of session locking from the front panel or, if supported by the X server, after a specified period of inactivity. Refer to the Screen Saver specification for information as to how screen savers are integrated into the desktop.

X Server Screen Saver Extensions

The dtsession command's ability to provide session lock or screen saver launch after a specified period of inactivity depends upon the availability of an X server screen saver extension. The dtsession command supports the X Consortium Sample X11 Screen Saver Extension 1.0 and the HP X Screen Saver Extension. The ability of the dtsession command to recognize both, either, or none of these extensions is vendor-specific.

Starting the Session Manager

The dtsession command must be started from the Xsession script. Xsession is described in the login manager specification. Although starting Xsession from dtlogin as part of the default login sequence is recommended, some systems allow proxy programs, such as **xinit**, **x11start**, or **startx**, to start Xsession.

Color Server Resources

Item	Description

Item	Description
colorUse	**ClassClass:** ColorUse **Type:** String **Default:** DEFAULT **Description:** Specifies the number of colors to use for the user interface. Color server determines type of monitor based upon number of display planes of the screen as follows: **1, 2, or 3 planes (B_W)** Specifies a black-and-white system. The color palettes use 2 color cells for the user interface. In this configuration, only 2 color palettes are available: BlackWhite and WhiteBlack. These palettes cannot dynamically change. To change a palette, all applications that use the color palette must be restarted. This resource value forces ShadowPixmaps to True, and ForegroundColor to either black or white (depending on the palette chosen). **4 or 5 planes (LOW_COLOR)** Specifies a low-color system. The color palettes have two color sets and use a maximum of 12 color cells for the user interface, including black and white (color cells 0 and 1). The number of color cells can be reduced by using the resources ShadowPixmaps and ForegroundColor. **6 planes (MEDIUM_COLOR)** Specifies a medium-color system. The color palettes have four color sets and use a maximum of 22 color cells for the user interface, including black and white (color cells 0 and 1). The number of color cells can be reduced by using the resources ShadowPixmaps and ForegroundColor. **7+ planes (HIGH_COLOR)** Specifies a high-color system. The color palettes have eight color sets and use a maximum of 42 color cells for the user interface, including black and white (color cells 0 and 1). The number of color cells can be reduced by using the resources ShadowPixmaps and ForegroundColor.
dynamicColor	**ClassClass:** DynamicColor **Type:** Boolean **Default:** True **Description:** This resource can have values of True or False. The dynamicColor resource is used to reduce the number of color cells that are being used. After a palette is selected and it is not likely to be changed, dynamicColor can be set to False. If set to False, colors cannot be dynamically changed by using the desktop style manager. A selected palette takes effect the next session. The next time that the session comes up, the color server uses Read Only color cells that can be shared by all clients, reducing the number of color cells used.

Item	Description
foregroundColor	**ClassClass:** ForegroundColor **Type:** String **Default:** DYNAMIC **Description:** This resource can have values of White, Black, or Dynamic. The foregroundColor resource causes all text (foreground) to use either pixel 0 or 1 (Black or White) or to have a color cell that is dedicated to foreground and changes in response to the background color (Dynamic) for each ColorSet. If set to White or Black, the number of color cells that are used per ColorSet is reduced by 1.
shadowPixmaps	**ClassClass:** ShadowPixmaps **Type:** String **Default:** DEFAULT **Description:** For color systems, this resource can have a value of True or False. If True, topShadowColor and bottomShadowColor use the same pixel as background and topShadowPixmap and bottomShadowPixmap are specified instead of solid color to create the 3-D look. It reduces the number of color cells per ColorSet by 2. This resource defaults to True for systems with four or less color planes (16 or less color cells), and False for systems with more than four color planes.
writeXrdbColors	**ClassClass:** WriteXrdbColors **Type:** Boolean **Default:** True

Screen Lock and Screen Save Resources

Item	Description

Item	Description
keys	**ClassClass:** Keys **Type:** unsigned char **Default:** NULL **Description:** Lists key holders that can unlock the screen any time it is locked by the user. The list is a list of user IDs separated by commas. For example, if user `kim` has the following resource active during a session, users `fred` and `keith` can unlock the display when `kim` locks it: `Dtsession*keys: fred,keith`
passwordTimeout	**ClassClass:** passwordTimeout **Type:** unsigned int **Default:** 10 **Description:** Specifies (in seconds) the amount of time before the password dialog is removed from the screen. When the display is locked, the pointer shows a lock cursor, and a dialog is displayed that asks for the user password. If no activity from the pointer or keyboard is detected for *passwordTimeout* seconds, the dialog is removed from the screen. The dialog is redisplayed as soon as a pointer or keyboard event is detected. A *passwordTimeout* of 0 leaves the password dialog in place for the entire time the display is locked. The default value is 10 seconds.

Miscellaneous Resources

Item	Description
queryServerSettings	**ClassClass:** QueryServerSettings **Type:** Boolean **Default:** False **Description:** Specifies whether the `dtsession` command queries the server at logout for all its settings, or whether it saves only those settings that are set by using the desktop Style Manager. Querying the server ensures that all settings are saved; however, there is a degradation in performance when a full query is done. The default value is False, which means that the server is not queried.

Item	Description
saveFontPath	**ClassClass:** SaveFontPath **Type:** Boolean **Default:** False
wmStartupCommand	**ClassClass:** WmStartupCommand **Type:** executable path **Default:** NULL **Description:** Allows for an alternative window manager to be started at login. If this resource is NULL, dtsession starts /usr/dt/bin/dtwm. An alternative startup might look like: `Dtsession*wmStartupCommand: /usr/bin/X11/mwm` The command must not have any commands to a shell in it, and it must not be surrounded by quotes. If any other window manager other than /usr/dt/bin/dtwm is used, clients are restored but might not be restored to the correct position. By default, this resource contains a NULL value.

Exit Status

The following exit values are returned:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To start the session manager from the command line without restoring the previous session, enter:

```
dtsession -norestore
```

Location

/usr/dt/bin/dtsession

Files

Item	Description
/usr/dt/config/$LANG/sys.session	The desktop default set of applications for the user's initial session.
/etc/dt/config/$LANG/sys.session	System administrator-specified set of applications for the user's initial session.

Item	Description
`/usr/dt/config/$LANG/sys.resources`	The desktop default resources.
`/etc/dt/config/$LANG/sys.resources`	The system administrator-specified resources.
`$HOME/.Xdefaults`	The user-specified resources.
	Note: The `dtsession` command stores session information in `$HOME/.dt/display` or `$HOME/.dt/sessions`. The content of these directories must not be directly edited by the user.
`/usr/dt/app-defaults/$LANG/Dtsession`	Default `dtsession` resources.

dtterm Command

Purpose

Provides runtime support of existing applications.

Syntax

dtterm [Flags...]

Description

The **dtterm** client provides runtime support of existing applications that are written for ANSI X3.64-1979 and ISO 6429:1992(E) conformant character terminals.

Flags

Note: The **dtterm** terminal emulator accepts all of the standard X Toolkit command line flags along with additional flags, all of which are listed below (if the flag begins with a **+** instead of a **-**, the flag is restored to its default value):

Item	Description
-132	Causes the DECCOLM escape sequence to be recognized, and the **dtterm** window will resize appropriately. Normally the DECCOLM escape sequence that switches between 80 and 132 column mode is ignored. Associated resource: c132.
+132	Causes the DECCOLM escape sequence to be ignored. This is the default behavior. Associated resource: c132.
-aw	Indicates that auto-wraparound should be allowed. This allows the cursor to automatically wrap to the beginning of the next line when it is at the right-most position of a line and text is output. This is the default behavior. Associated resource: autoWrap.
+aw	Indicates that auto-wraparound should not be allowed. Associated resource: autoWrap.
-background *background_color*	Specifies the background of the terminal window as well as the default background used for the scroll bar and the X11 pointer cursor. Under CDE, this flag defaults to the primary colorset select pixel or background pixel, see -bs. Without CDE, this flag defaults to *background/*Background with an ultimate fallback color of black. *background_color* describes the background color to use. Associated resource: background.

Item	Description
-bd *border_color*	Specifies the border color for all windows. The shell widget's border may not be visible when reparenting window managers such as **dtwm** and **mwm** are used. The default color is black. *border_color* describes the border color to use. Associated resource: borderColor.
-bg *background_color*	Identical to -background. *background_color* describes the background color to use. Associated resource: background.
-bordercolor *border_color*	Identical to -bd above. *border_color* describes the border color to use. Associated resource: borderColor.
-borderwidth *border_width*	Specifies the border width of the shell widget's window. This value may be overridden by reparenting window managers such as **dtwm** and **mwm**. The default is 0. *border_width* specifies the width of the window border in pixels. Associated resource: borderWidth.
-bs	Specifies that the terminal window should use the Motif select color instead of the background color for the terminal window's background color. This is the default behavior. Associated resource: backgroundIsSelect.
+bs	Specifies that the terminal window should not use the Motif select color instead of the background color for the terminal window's background color. Associated resource: backgroundIsSelect.
-bw *border_width*	Identical to -borderwidth. Associated resource: borderWidth.
-C	Specifies that output directed at **/dev/console** should be directed instead to the terminal window. It is provided as a way to prevent output that would normally be displayed on the ITE from overwriting the X server's display. It is not provided as a general mechanism to direct the output from an arbitrary system's **/dev/console** to an arbitrary X server.

Note: You must have ownership of and read/write access to **/dev/console** for this flag to work.

Item	Description
-display *display_name*	Specifies the X11 display server to be used by **dtterm**. This defaults to the value in the $DISPLAY environment variable. *display_name* specifies the X11 server to connect to.
-e *program_argument*...	Specifies an executable program to be invoked as a subprocess when **dtterm** is started. This flag must be the last flag on the command line. *program_argument* specifies the program and command line arguments to run.
-fb *fontset*	Specifies an XFontSet to be used when displaying bold terminal text. It should be specified as a Motif XmFontList. Only character or mono spaced fonts are supported. The behavior when using proportional fonts is undefined. A default bold font will be generated based on the XLFD name of the userFont. If that font is not available, bold text will be generated by overstriking (with a one pixel offset) the userFont. *fontset* specifies the bold terminal XFontSet to use. Associated resource: userFont.
-fg *foreground_color*	Specifies the foreground color of the terminal window as well as the default foreground color used for the scroll bar and for the X11 pointer cursor. Under CDE, this resource will default to the primary color set foreground pixel. Without CDE, this resource will default to *foreground or *Foreground with an ultimate fallback color of white. *foreground_color* specifies the foreground color to use. Associated resource: foreground.

Item	Description
-fn *fontset*	Specifies an XFontSet to be used when displaying terminal text. It should be specified as a Motif XmFontList. Only character or mono spaced fonts are supported. The behavior when using proportional fonts is undefined. This font will not be used to display non-terminal text (menu bar, popup menus, dialogs, etc.). The default is to use the XmNtextFontList value of the parent bulletin board (see XmBulletinBoard) in the same manner as the XmText widget. *fontset* specifies the terminal XFontSet to use. Associated resource: userFont.
-font *fontset*	Identical to -fn. *fontset* specifies the terminal XFontSet to use. Associated resource: userFont.
-foreground *foreground*	Identical to -fg. *foreground* specifies the foreground color to use. Associated resource: foreground.
-geometry *geometry_string*	Specifies the preferred size and position of the terminal window. The default size is 24 lines of 80 characters each. There is no default position. *geometry_string* specifies the terminal geometry to use. Associated resource: geometry.
-help	Displays a message summarizing the usage of **dtterm**.
-iconic	Specifies that the terminal emulator should initially be placed on the display iconified. Associated resource: iconic.
+iconic	Specifies that the terminal emulator should initially be placed on the display as a normal window. This is the default behavior. Associated resource: iconic.
-j	Specifies that jump scrolling should be used. Under jump scrolling, the screen may be scrolled more than one line at a time. This provides for faster screen updates when multiple lines of text are being sent to the terminal. The maximum number of lines that may be jump scrolled is limited to the number of lines in the terminal window. All lines are displayed. This is the default behavior. Associated resource: jumpScroll.
+j	Specifies that jump scrolling should not be used. For a description of jump scrolling, see -j. Associated resource: jumpScroll.
-kshMode	Specifies that **ksh** mode should be enabled. Under **ksh** mode, a key pressed with the extend modifier bit set will generate an escape character followed by the character generated by the un-extended keystroke. This flag is provided for use with emacs and the emacs command line editor mode of **ksh** or **ied**. It conflicts with **** the normal use of the meta key for generating extended single byte characters, and for generating multi-byte Asian characters. Associated resource: kshMode.
+kshMode	Specifies that the **ksh** mode should not be enabled. This is the default behavior. Associated resource: kshMode.
-l	Enables output logging. When logging is enabled, all output received from the subprocess is logged either to a file or to a command pipeline (as specified via the -If flag). Since the data is being logged directly from the subprocess, it includes all escape characters and carriage return/newline pairs sent by the terminal line discipline. Output may be enabled and disabled via escape sequences. Associated resource: logging.
+l	Disables output logging. For a description of output logging, see -l. This flag is the default. Associated resource: logging.

Item	Description
-lf *file_name*	Specifies the name of the file to which the output log described in the -l flag. If *file_name* begins with a pipe symbol (|), the rest of the string is assumed to be a command to be used as the endpoint of a pipe. The default filename is DttermLog*XXXXX* (where *XXXXX* is the process id of **dtterm**) and is created in the directory from which **dtterm** was started. If the last five characters are *XXXXX*, they are replaced by the process ID. *file_name* specifies the log file name to use. Associated resource: logFile.
-ls	Indicates that the shell that is started should be a login shell (i.e. the first character of argv[0] will be a dash, indicating to the shell that it should read the system's profile and the user's **$HOME/.profile** (for **ksh** and **sh**) or the system's **csh.login** and the user's **$HOME.login** (for **csh**). Associated resource: loginShell.
+ls	Specifies that a normal (non-login) shell should be started. This is the default behavior. Associated resource: loginShell.
-map	Indicates that **dtterm** should map (de-iconify) itself upon subprocess output if it is unmapped (iconified). An initial period of time during which **dtterm** will not map itself upon subprocess output may be specified via the mapOnOutputDelay resource. Associated resource: mapOnOutput.
+map	Specifies that there should be no special mapping behavior. This is the default behavior. Associated resource: mapOnOutput.
-mb	Indicates that **dtterm** should ring a margin bell when the user types near the right margin. The actual distance involved is specified by the -nb flag. Associated resource: marginBell.
+mb	Indicates that margin bell should not be rung when the user types near the right margin. This is the default. Associated resource: marginBell.
-ms *pointer_color*	Specifies the foreground color to use for the terminal window's (X11) pointer cursor. The default is to use the terminal window's foreground color. See foreground. *pointer_color* specifies the pointer foreground color to use. Associated resource: pointerColor.

Item	Description
-name *prog_name*	Specifies the X11 name of the **dtterm** window. *prog_name* the name to use.
-nb *number*	Specifies the number of characters from the right margin at which the margin bell will ring, if enabled. The default is 10. Associated resource: nMarginBell.
-r	Causes the **dtterm** window to be displayed with the foreground and background colors reversed. This is identical to the -rv and -reverse flags.
+r	Causes the **dtterm** window to be displayed with the normal foreground and background colors. This is the default, and is also identical to the +rv flag.
-reverse	Causes the **dtterm** window to be displayed with the foreground and background colors reversed. This is identical to the -r and -rv flag.
-rv	Causes the **dtterm** window to be displayed with the foreground and background colors reversed. This is identical to choosing Options | Global Options, and then changing the ``windowBackground'' options menu to ``Inverse.'' A **dtterm** window started with this flag has the`` Window Background'' options menu set to ``Inverse.'' See ``Global Options''.
+rv	Causes the **dtterm** window to be displayed with the normal foreground and background colors. This is the default.

Item	Description
-rw	Specifies that reverse-wraparound should be enabled. Associated resource: reverseWrap.
+rw	Indicates that reverse-wraparound should not be enabled. This is the default. Associated resource: reverseWrap.
-Sccn	Specifies that the terminal emulator should be run against a pre-opened pty or STREAMS device. This flag is provided for use where the pty or STREAMS device's worker name is of the form tty?? (i.e., exactly two characters following the tty). This flag is intended for use when **dtterm** is invoked programmatically from another application. *cc* specifies the last two characters of the pty or STREAMS device's worker name, where the worker name is of the form tty??. This value is ignored, but must be exactly two characters in length. *n* specifies the number of the file descriptor that corresponds to the pty or STREAMS device's already-opened controller side.
-Sc.n	This flag is identical to **-Sccn** above, but is provided for systems with a larger pty name space. *c* specifies the last component of the pty worker name. This values is ignored and may be empty. *n* specifies the number of the file descriptor that corresponds to the pty's already-opened controller side.
-sb	Indicates that a scrollbar should be displayed. This is the default. Associated resource: scrollBar.
+sb	Indicates that a scrollbar should not be displayed. Associated resource: scrollBar.
-sf	Indicates that Sun Function Key escape codes should be generated for function keys instead of standard VT220 escape sequences. Associated resource: sunFunctionKeys.
+sf	Indicates that the standard escape sequences should be generated for function keys instead of the Sun Function Key escape codes. This is the default behavior. Associated resource: sunFunctionKeys.
-sl *screens[s|l]*	Specifies the number of lines in the terminal buffer beyond the length of the window. The flag value consists of a number followed by an optional suffix. If no suffix is included, or the suffix is **l** (ell), the total length of the terminal buffer will be screens plus the length of the terminal window. If the suffix is **s** (ess), the total length of the terminal buffer will be (screens plus one) times the length of the terminal window. **dtterm** will try to maintain the same buffer-to-window ratio when the window is resized larger. The default is **4s**. *screens* specifies the number of screens or lines to save. Associated resource: saveLines.
-ti *term_id*	Supplies the name used to select the correct response to terminal ID queries. Valid values are vt100, vt101, vt102, and vt220. The default is vt220. *term_id* specifies the terminal ID to use.
-title *title_string*	Specifies the window title. If the -e flag is used, the default will be the last component of the program's path. If the -e flag is not used, the default will be the last component of the name used to run **dtterm** (i.e., argv[0]). *title_string* specifies the title to use. Associated resource: title.

Item	Description
-tm *term_modes*	Specifies a string containing terminal-setting keywords and the characters to which they may be bound. Allowable keywords include intr, quit, erase, kill, eof, eol, swtch, start, stop, brk, susp, dsusp, rprnt, flush, weras, and lnext. Keywords that do not apply to a specific architecture will be correctly parsed and ignored. Control characters may be specified as ^ followed by char (e.g. ^c or ^u), and ^? may be used to indicate delete. This is useful for overridding the default terminal settings without having to do an **stty** every time a terminal process is started. The default is NULL. *term_modes* specifies the terminal mode string. Associated resource: ttyModes.
-tn *term_name*	Specifies a name to set the $TERM environment variable to. The default is **vt220**. *term_name* specifies the terminal name to use. Associated resource: termName.
-usage	Prints a usage message on the screen.
-vb	Indicates that a visual bell is preferred over an audible one. Instead of ringing the terminal bell whenever a Control-G is received, the window will be flashed. Associated resource: visualBell.
+vb	Indicates that an audio bell is preferred over a visual one. This is the default behavior. Associated resource: visualBell.
-w *border_width*	Identical to -borderwidth. *border_width* specifies the width of the window border in pixels.
-xrm *resource_string*	Allows X11 Resource Manager-style resources to be specified on the command line. *resource_string* specifies an X11 resource string.

Resources

Item	Description
allowSendEvents	Specifies that the terminal emulator should allow synthetic events (generated and sent by another application). Enabling this resource opens up a possible security risk. The default is False.
appCursorDefault	If True, the cursor keys are initially in application mode. If False, they are initially in cursor mode. The default is False.
appKeypadDefault	If True, the keypad keys are initially in application mode. If False, they are initially in numeric mode. The default is False.
autoWrap	Specifies whether or not auto-wraparound is initially enabled. The default is True.
background	Specifies the background color of the terminal window as well as the default background color used for the scrollbar. Under CDE, this resource defaults to either the primary color set select pixel or the primary color set background pixe, see backgroundIsSelect. The default is the primary color set background pixel. Without CDE, this resource defaults to black.
backgroundIsSelect	When True, this resource specifies that the terminal window should use the Motif select color instead of the background color for the terminal window's background color. The default is False.
blinkRate	Specifies the number of milliseconds the cursor is in the on and off states while blinking. A value of 250 will blink the cursor two times per second. A value of 0 will turn blinking off. The default is 250.

Item	Description
borderColor	Defines the border color for the window. The window border may not be visible when reparenting window managers such as **dtwm** and **mwm** are used. The default is ``black''.
borderWidth	Specifies the border width of the shell widget's window. This value may be overridden by reparenting window managers such as **dtwm** and **mwm**. The default is 0.
c132	Specifies whether or not the DECCOLM escape sequence that switches to window with between 80 and 132 columns should be honored. The default is False.
charCursorStyle	Specifies the shape of the text cursor. A value of char_cursor_box specifies a cursor with the width and height of the base font's bounding box. A value of char_cursor_bar specifies a cursor with the width of the base font's bounding box, a height of two pixels, and drawn with it's top on the baseline. The default is char_cursor_box.
consoleMode	Specifies that output directed at **/dev/console** should be directed instead to the terminal window. It is provided as a way to prevent output that would normally be displayed on the ITE from overwriting the X server's display. It is not provided as a general mechanism to direct the output from an arbitrary system's **/dev/console** to an arbitrary X server. Note that you must have ownership of and read/write access to **/dev/console** for this flag to work. The default is False.
foreground	Specifies the foreground color of the terminal window as well as the default foreground color used for the scrollbar and the color used for the pointer cursor. Under CDE, this resource will default to the primary colorset foreground. Otherwise, it defaults to ``white''.
geometry	Specifies the preferred size and position of the terminal window. The default size is 24 lines of 80 characters each. There is no default position.
iconGeometry	Specifies the preferred position of the terminal emulator's icon. Window managers may ignore this value. There is no default.
iconic	If true, specifies that the terminal emulator should initially be placed on the display iconified. Window managers (including **dtwm** and **mwm** may ignore this value. The default is False.
iconicName	Specifies the name for the icon. If the -e flag is used, the default will be the last component of the program's path. If the -e flag is not used, the default will be the base name of the name used to run **dtterm** (i.e., argv[0]).
jumpScroll	Specifies that jump scrolling should be used. Under jump scrolling, the screen may be scrolled more than one line at a time. This provides for faster screen updates when multiple lines of text are being sent to the terminal. The maximum number of lines that may be jump scrolled is limited to the number of lines in the display. It is guaranteed that all lines will be displayed. The default is True.
kshMode	Specifies that **ksh** mode should be enabled. Under **ksh** mode, a key pressed with the extend modifier bit set will generate an escape character followed by the character generated by the un- extended keystroke. This flag is provided for use with emacs and emacs command line editor mode of **ksh** or **ied**. It conflicts with the normal use of the meta key for generating extended single byte characters and for generating multi-byte Asian characters. The default is False.

Item	Description
logFile	Specifies the name of the file to which the output log described below is written. If the filename begins with a pipe symbol (|), the rest of the string is assumed to be a command to be used as the endpoint of a pipe. The default filename is DttermLog*XXXXX* (where *XXXXX* is a unique character string) and is created in the directory from which the subprocess was started. If the last five characters are *XXXXX*, they are replaced by a unique character string.
logging	Enables output logging. When logging is enabled, all output received from the subprocess is logged either to a file or to a command pipeline (as specified via the logFile flag). Since the data is being logged directly from the subprocess, it includes all escape characters and carriage return/ newline pairs sent by the terminal line discipline. Output may be enabled and disabled via escape sequences. The default is False.
logInhibit	Specifies that device and file logging should be inhibited. The default is False.
loginShell	Specifies that the shell that is started should be a login shell (i.e. the first character of argv[0] will be a dash, indicating to the shell that it should read the system's profile and the user's **$HOME/.profile** (for **ksh** and **sh**) or the system's **csh.login** and the user's **$HOME/.login** (for **csh**). The default is False.

Item	Description
mapOnOutput	Indicates that the terminal emulator should map (de-iconify) itself upon subprocess output if it is unmapped (iconified). An initial period of time during which it will not map itself upon subprocess output may be specified via the mapOnOutputDelay resource. The default is False.
mapOnOutputDelay	Specifies the number of seconds after start-up that **dtterm** will not honor the mapOnOutput resource. This allows for initial output (e.g., shell prompts) to be sent to the terminal without auto mapping the window. The default is 0 (no delay)
marginBell	Specifies whether or not the bell should be run when the user types near the right margin. The default is False.
menuBar	Specifies that a pulldown menu should be displayed. The default is True.
menuPopup	Specifies that a popup menu should be enabled. The default is True.
nMarginBell	Specifies the number of characters from the right margin at which the margin bell should be rung, when enabled. The default is 10.
pointerBlank	Specifies that the pointer cursor should be put into blanking mode. In this mode, the cursor will turn on when the pointer is moved, and will be blanked either after a selectable number of seconds or after keyboard input has occurred. The delay is set via the pointerBlankDelay resource. The default is False.
pointerBlankDelay	Defines the number of seconds to wait before blanking the pointer cursor after the pointer has been moved. A value of 0 invokes pointer blanking only on keyboard input. The default is 2 seconds.
pointerColor	Specifies the foreground color to use for the terminal window's pointer (X11) cursor. The default is to use the terminal window's foreground color. See foreground.

Item	Description
pointerColorBackground	Specifies the background color to use for the terminal windows pointer (X11) cursor. The default is to use the terminal windows background color See background.
pointerShape	Specifies the X cursor font character to use as the pointer cursor. It should be specified as a string from the include file with the leading XC_ removed. The default is **xterm**.
reverseVideo	Specifies whether or not reverse video should be used. The default is False.
reverseWrap	Specifies whether or not reverse-wraparound should be enabled. The default is False.
saveLines	Specifies the number of lines in the terminal buffer beyond length of the window. The value consists of a number followed by an optional suffix. If no suffix is included, or the suffix is **l** (ell), the total length of the terminal buffer will be screens plus the length of the terminal window. If the suffix is **s** (ess), the total length of the terminal buffer will be (screens plus one) times the length of the terminal window. **dtterm** will try to maintain the same buffer-to-window ratio when the window is resized larger. The default is **4s**.
scrollBar	Specifies whether or not the scrollbar should be visible. The default is True.
sunFunctionKeys	Specifies whether or not Sun Function Key escape codes should be generated for function keys instead of standard VT220 escape sequences. The default is False.
termId	Supplies the name used to select the correct response to terminal ID queries. Valid values are vt100, vt101, vt102, and vt220. The default is vt220.
termName	Defines the name for the $TERM environment variable. The default is vt220.
title	Specifies the window title. If the -e flag is used, the default will be the last component of the program's path. If the -e flag is not used, the default will be the last component of the name used to run **dtterm** (i.e., argv[0]).
ttyModes	Specifies a string containing terminal-setting keywords and the characters to which they may be bound. Allowable keywords include: intr, quit, erase, kill, eof, eol, swtch, start, stop, brk, susp, dsusp, rprnt, flush, weras, and Inext. Keywords that do not apply to a specific architecture will be correctly parsed and ignored. Control characters may be specified as ^ followed by char (e.g. ^c or ^u), and ^? may be used to indicate delete. This is very useful for overriding the default terminal settings without having to do an **stty** every time a terminal process is started. The default is NULL.
userBoldFont	Specifies an XFontSet to be used when displaying bold terminal text. It should be specified as a Motif XmFontList. Only character or mono spaced fonts are supported. The behavior when using proportional fonts is undefined. A default bold font will be generated based on the XLFD name of the userFont. If that font is not available, bold text will be generated by overstriking (with a one pixel offset) the userFont.
userFont	Specifies an XFontSet to be used when displaying terminal text. It should be specified as a Motif XmFontList. Only character or mono spaced fonts are supported. The behavior when using proportional fonts is undefined. This font will not be used to display non-terminal text (menu bar, popup menu, dialog, etc.). The default is to use the XmNtextFontList value of the parent bulletin board (see XmBulletinBoard(3X)) in the same manner as the XmText widget.

Item	Description
visualBell	Specifies that a visual bell is preferred over an audible one. Instead of ringing the terminal bell whenever a CTRL-G is received, the windows will be flashed. The default is False.

Pointer Usage

Note: dtterm allows you to select regions of text. Selection is based on the model specified in the Inter-Client Communication Conventions Manual (ICCCM). **dtterm** supports primary selection only. You can copy or paste selected text using primary transfer. Input is treated as keyboard input, and is inserted at the cursor. The select/insert operations and their default assignments are described below.

Item	Description
select	The left button is used to select the text to be copied. Move the pointer to the beginning of the text to copy, press and hold the left button, move the cursor to the end of the text to copy, and release the button. Any currently selected text can be deselected by clicking the left button once without moving the mouse.
insert	The middle button pastes the text from the primary selection, treating it as keyboard input.

Actions

Item	Description
bell *([Percentage])*	This action rings the keyboard bell at the specified percentage above or below the base volume.
break ( )	This action send a break signal to the child process.
cancel ( )	This action sends a **CAN** (cancel) character to the child process.
do ( )	This action sends the escape sequence associated with the **Do** key to the child process.
edit-key *(string)*	This action sends the escape sequence associated with the corresponding edit key to the child process. The interpretation of these keys is application specific. Valid values for string are find, insert, next, prior, remove, and select.
extend-start ( )	Start the extension of the currently selected text. extend-end ( ) **Note:** Extends the current selection. The amount of text selected depends on the number of mouse clicks.
function-key-execute *(num [,type])*	This action sends the escape sequence associated with the corresponding function key *num* to the child process. Valid values for *num* are 1 through 35. If type is set to function (or not set at all), the escape sequence associated with function key *num* is sent to the child process. If *type* is set to **UDK**, then the string associated with user defined key *num* is sent to the child process.
grab-focus ( )	This action performs one of the following depending on the number of multiple mouse clicks. One click will deselect any selected text and set the selection anchor at the pointer position, two clicks will select a word, three clicks will select a line of text, and four clicks will select all text.
hard-reset ( )	This action will perform a hard reset on the terminal emulator.
help ( )	This action sends the escape sequence associated with the DEC VT220 Help key to the child process. The interpretation of this key is application specific.

Item	Description
keymap *(name)*	This action dynamically defines a new translation table whose resource name is name with the suffix Keymap (case is significant). The name "None" restores the original translation table.
keypad-key-execute *(string)*	This action sends the escape sequence associated with the corresponding keypad key to the child process. The interpretation of these keys are application specific. Valid values for *string* include: f1-f4, space, tab, enter, equal, multiply, add, separator, subtract, decimal, divide, and 0 - 9.
move-cursor *(direction)*	This action sends the escape sequence associated with the corresponding cursor motion to the child process. The interpretation of these keys are application specific. Valid values for *direction* include: up, down, backward, and forward.
redraw-display ( )	This action redraws the contents of the text window.
scroll *(count [,units])*	This action will scroll the display memory down if count is less than zero, or up if *count* is greater than zero. The number of lines scrolled is based on *count* and *units*. Valid values for *units* are page, halfpage, or line. The default for *units* is line.
select-adjust ( )	This action extends the selection. The amount of text selected depends on the number of mouse clicks: 1 click = char 2 clicks = word 3 clicks = line 4 clicks = buffer
select-all ( )	This action selects all text.
select-page ( )	This action selects all text on the screen.
self-insert ( )	This action sends the character associated with the key pressed to the child process.
soft-reset ( )	This action perform a soft reset of the terminal.
stop *(state)*	This action either toggles, starts, or stops the process of reading data from the child process. Valid values for *state* are toggle, on, and off.
string *(string)*	This action inserts the specified text *string* as if it had been typed. The *string* must be quoted if it contains whitespace or non-alphanumeric characters. The *string* is interpreted as a hex character constant if it begins with the characters 0x.
tab ( )	This action sends a tab to the child process.
visual-bell ( )	This action flashes the window quickly.
Virtual Bindings	The bindings for virtual keys are vendor specific. Virtual bindings do not apply when the **dtterm** widget has input focus. For information about bindings for virtual buttons and keys, see VirtualBindings.

Files

Item	Description
/usr/bin/diff	Contains the **diff** command.

du Command

Purpose

Summarizes disk usage.

Syntax

du [**-a** | **-s**] [**-k**] [**-m**] [**-g**][**-l**] [**-r**] [**-x**] [**-H** | **-L**][*File ...*]

Description

The **du** command displays the number of blocks used for files. If the *File* parameter specified is actually a directory, all files within the directory are reported on. If no *File* parameter is provided, the **du** command uses the files in the current directory.

If the *File* parameter is a directory, then the number of blocks reported is the sum of blocks allocated for the files in the directory and the blocks allocated for the directory itself.

If the object of the **du** command is a file or directory that exists inside a JFS2 snapshot, the **du** command gives information for the point-in-time object when the snapshot is created. This information does not include how much space is recovered if the snapshot itself is deleted.

Specifying the **-a** flag reports the number of blocks in individual files. Whether the **-a** flag is used or not, individual files specified by the *File* parameter are always listed.

Specifying the **-s** flag reports the total blocks for all specified files or all files in a directory.

The block count includes indirect blocks of each file. Block count is calculated in 512-byte units independent of the cluster size used by the system. Specifying the **-k** flag calculates the block count in 1024-byte units.

Notes:

1. Files with multiple links are counted and written for only one entry.
2. Block counts are based only on file size; therefore, deallocated blocks are not accounted for in the reported block counts.
3. If **du** cannot obtain the file attributes or cannot read directories, it reports an error and the exit status of the command is affected.

Flags

Item	Description
-a	For each file specified, displays the disk usage of the file. For each directory specified, displays the disk usage of each individual file within the directory, including all subdirectories. Contrast this flag with the **-s** flag.
-g	Calculates the block count in GB units rather than the default 512-byte units. The output values for the disk usage would be in floating point numbers as value of each unit in bytes is significantly high.
-H	If a symbolic link is specified on the command line, the **du** command shall count the size of the file or file hierarchy referenced by the link.
-k	Calculates the block count in 1024-byte units rather than the default 512-byte units.
-l	Allocates blocks evenly among the links for files with multiple links. By default, a file with two or more links is counted only once.

Item	Description
-L	If a symbolic link is specified on the command line or encountered during the traversal of a file hierarchy, the **du** command shall count the size of the file or file hierarchy referenced by the link.
-m	Calculates the block count in MB units rather than the default 512-byte units. The output values for the disk usage would be in floating point numbers as value of each unit in bytes is significantly high.
-r	Reports names of inaccessible files and directories. This is the default.
-s	For each file specified, displays the disk usage of the file. For each directory specified, displays the total disk usage of all files within the directory, including all subdirectories. Contrast this flag with the **-a** flag.
-x	When evaluating file sizes, evaluates only those files that reside on the same device as the file or directory specified by the *File* parameter. For example, you may specify a directory that contains files on several devices. In this case, the **-x** flag displays block sizes for all files that reside on the same device as the directory.

Notes:

1. If all or any two of the **-k**, **-m** and **-g** flags are specified, the last one specified takes effect. The output of the disk usage with the flags **-m** and **-g** would be rounded off to the nearest second decimal digit.
2. If both the mutually exclusive options **-H** and **-L** are specified simultaneously, the command does not report an error. The last specified option determines the behavior of the utility.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To summarize the disk usage of a directory tree and each of its subtrees, enter:

   ```
   du /home/fran
   ```

   This displays the number of disk blocks in the `/home/fran` directory and each of its subdirectories.
2. To summarize the disk usage of a directory tree and each of its subtrees in 1024-byte blocks, enter:

   ```
   du -k /home/fran
   ```

   This displays the number of 1024-byte disk blocks in the **/home/fran** directory and each of its subdirectories.
3. To summarize the disk usage of a directory tree and each of its subtrees in MB blocks, enter:

   ```
   du -m /home/fran
   ```

   This displays the number of MB disk blocks rounded off to nearest 2nd decimal digit in the **/home/fran** directory and each of its subdirectories.
4. To summarize the disk usage of a directory tree and each of its subtrees in GB blocks, enter:

   ```
   du -g /home/fran
   ```

This displays the number of GB disk blocks rounded off to nearest 2nd decimal digit in the **/home/fran** directory and each of its subdirectories.

5. To display the disk usage of each file, enter:

```
du  -a /home/fran
```

This displays the number of disk blocks contained in each file and subdirectory of the `/home/fran` directory. The number beside a directory is the disk usage of that directory tree. The number beside a regular file is the disk usage of that file alone.

6. To display only the total disk usage of a directory tree, enter:

```
du  -s /home/fran
```

The **-s** flag instructs the **du** command to display only the sum total disk usage of the `/home/fran` directory and the files it contains. By default, the **du** command displays an error message if it cannot read a file or directory.

7. To display the disk usage of the files and file hierarchies referenced by all the symbolic links in addition to the normal files found during traversal of a the `/home/fran` directory, type:

```
du -L /home/fran
```

8. To report the disk usage of the file or file hierarchy referenced by the symbolic link `mylink`, type:

```
du -H mylink
```

Files

Item	Description
/usr/bin/du	Contains the **du** command.

dump Command

Purpose

Dumps selected parts of an object file.

Syntax

dump { **-a** **-c** **-d** **-g** **-h** **-l** **-n** **-o** **-p-r** **-s** **-t** **-u** **-v** **-H** **-R** **-T**} [**-z***Name* [,*Number*] [**+z***Number*]] [**-t***Index* [**+t***Index*]] [**-X** {**32**|**64**|**32_64**|**d64**|**any**}] *File* ...

Note: Do not put a space between the **-z** *Name* flag and the ,*Number* parameter.

Description

The **dump** command dumps selected parts of the specified *File* parameter. The **dump** command accepts object files, archive object files, and executable files.

Flags

Item	Description
-a	Dumps the archive header of each member of each specified archive.
-c	Dumps the string table.
-d	Dumps the raw data for each section.
-g	Dumps the global symbols in the archive symbol table.

Item	Description
-h	Dumps section headers.
-l	Dumps line number information.
-n	Dumps all loader section information.
-o	Dumps each optional header.
-p	Suppresses header printing.
-r	Dumps relocation information.
-s	Dumps the raw data for each selection.
-t	Dumps symbol table entries.
-t*Index*	Dumps only the index symbol table entry specified with the *Index* parameter. Use the **-t** flag with the **+t** flag to specify a range of symbol table entries.
+t*Index*	Dumps the symbol entry in the range that ends with the *Index* parameter. The range starts at the first symbol table entry or at the entry specified by the **-t** flag.
-u	Underlines the name of the *File* parameter.
-v	Dumps the information in symbolic representation rather than numeric. Any flag except the **-o** flag and **-s** flag can be used with the **-v** flag.
-z*Name*[,*Number*]	Dumps line number entries for the *Name* parameter or a range of line number entries that starts at the specified number.
+z*Number*	Dumps all line numbers up to the *Number* parameter.
-H	Dumps the header of the loader section. The **-H** flag applies only to executable files.
-R	Dumps the relocation entries for the leader section. The **-R** flag applies only to executable files.
-T	Dumps the symbol table entries for the loader section. The **-T** flag applies only to executable files.
-X *mode*	Specifies the type of object file **dump** should examine. The *mode* must be one of the following: **32** Processes only 32-bit object files. **64** Processes only 64-bit object files. **32_64** Processes both 32-bit and 64-bit object files. **d64** Examines discontinued 64-bit XCOFF files (magic number = U803XTOCMAGIC). **any** Processes all of the supported object files. The default is to process 32-bit object files (ignore 64-bit objects). The *mode* can also be set with the **OBJECT_MODE** environment variable. For example, **OBJECT_MODE=64** causes **dump** to process any 64-bit objects and ignore 32-bit objects. The **-X** flag overrides the **OBJECT_MODE** variable.

Examples

1. To dump the string table of the `a.out` file, enter:

```
dump -c a.out
```

2. To dump the contents of an XCOFF data section to standard output, enter:

```
dump -d a.out
```

3. To dump the object file headers, enter:

```
dump -o a.out
```

4. To dump line number information for the `a.out` file, enter:

```
dump -l a.out
```

5. To dump relocation information for the `a.out` file, enter:

```
dump -r a.out
```

6. To dump the contents of the `a.out` object file text section, enter:

```
dump -s a.out
```

7. To dump symbol table information for the `a.out` object file, enter:

```
dump -t a.out
```

8. To print symbol table entries 20 to 31 without header information, enter:

```
dump -p -t20 +t30 a.out
```

9. To dump the object file headers from only 64-bit objects in lib.a, enter:

```
dump -X64 -o lib.a
```

dumpcheck Command

Purpose

Checks to see that the dump device and copy directory are able to receive the system dump. An error is logged by default if there will likely be insufficient resources to accommodate the dump.

Syntax

/usr/lib/ras/dumpcheck [[**-l**] [**-p**] [**-t** *TimeParameters*] [**-P**]] | [**-r**]

Description

The **/usr/lib/ras/dumpcheck** command is used to check the disk resources used by the system dump. The command logs an error if either the largest dump device is too small to receive the dump or there is insufficient space in the copy directory when the dump is to paging space.

dumpcheck is normally run by cron at 3:00 pm local time each day. This can be varied using the **-r** flag to remove it from root's **crontab** or **-t** *TimeParameters* to change the time at which dumpcheck is executed. It may also be configured from SMIT. **dumpcheck** is automatically added to root's **crontab** when the service aids are installed.

For maximum effectiveness, **dumpcheck** should be run when the system is most heavily loaded. At such times, the system dump is most likely to be at its maximum size. Also, even with **dumpcheck** watching

the dump size, it may still happen that the dump would not fit on the dump device or in the copy directory at the time it happens. This could occur if there is a peak in system load right at dump time.

The **dumpcheck** function is installed as part of the service aids file set, installed automatically.

Flags

Item	Description
-l	Logs any warnings to the error log. This is the default if no parameters are specified.
-p	Prints any warnings produced to stdout.
-P	Indicates that the changes are to be made permanently; that is, they apply to subsequent executions of the **dumpcheck** facility. The **-P** flag is unnecessary with the **-t** and **-r** flags. If the **-P** flag is specified, **dumpcheck** simply changes the **crontab** entry without performing any checks.
-r	Removes the **crontab** entry for this function, effectively unconfiguring it. This command is normally run by **cron**. The **-r** flag must be specified alone. It is not valid with any other flags.
`-t` *TimeParameters*	Changes the time when **dumpcheck** is executed. The *TimeParameters* flag must be enclosed within single or double quotes. It specifies the **crontab** time parameters, the first five parameters of a line in the **crontab** file. See the **crontab** command for the format of the time parameters. The **-t** flag is invalid with the **-r** flag. If the **-t** flag is specified, **dumpcheck** just changes the **crontab** entry without performing any checks.

Security

This command can only be executed by the root user.

Examples

1. To check dump resources and have the results printed to standard output rather than logged, type:

   ```
   /usr/lib/ras/dumpcheck -p
   ```

   To make this change permanently; that is, to have it made in the **crontab** entry, type:

   ```
   /usr/lib/ras/dumpcheck -p -P
   ```

2. To have **dumpcheck** run at 9:00 am and 3:00 pm Monday through Friday, type:

   ```
   /usr/lib/ras/dumpcheck -t "0 9,15 * * 1-5"
   ```

   To return to the default, type:

   ```
   /usr/lib/ras/dumpcheck -t "0 15 * * *"
   ```

   You may also use SMIT to configure the times when **dumpcheck** executes.

3. To discontinue running this feature, type:

   ```
   /usr/lib/ras/dumpcheck -r
   ```

   You may also use SMIT for this task.

dumpctrl Command

Purpose

Manages system dumps and live dumps.

Syntax

dumpctrl **-k**

dumpctrl **-R** [**l** | **s**] [**-P**]

dumpctrl **-s** [**-c** | **-C** *comp-path-list*] [**-l** | **-L** *comp-alias-list*] [**-t** | **-T** *type_subtype*] [**-r**] [**-u**]

dumpctrl **-q***c* [**-c** *comp-path-list*] [**-l** *comp-alias-list*] [**-t** *type_subtype*] [**-r**] [**-u**] [**-p** | **-P**]

dumpctrl **-q***l* [**-p** | **-P**]

dumpctrl **-q***s* [**-p** | **-P**]

dumpctrl [**-P**] [*global_attribute*]

dumpctrl [**-c** *comp-path-list*] [**l** *comp-alias-list*] [**-t** *type_subtype*] [**-r**] [**-u**] [**-n** | **-p** | **-P** | **-x**] [*per-component_attribute*]

Description

There are two types of dump components:

component
Refers to a component specified with the RAS infrastructure (one created with the `ras_register()` kernel service).

legacy component
Refers to a dump component specified with either the `dmp_add()` or the `dmp_ctl()` kernel service.

The **dumpctrl** command is used to obtain information about which components are registered for live dumps or system dumps, and to query and change dump characteristics.

Components are specified with the full path name, device logical alias, type or subtype. You can use multiple flags to specify multiple components or component lists.

Flags

At least one flag must be specified.

Item	Description
-c *comp-path-list*	Specifies components by path name. Wildcards are allowed. Use the **-c all** command to specify all of the components.
-k	Refreshes the list of dumps of the kernel. This flag is run every 5 minutes by default. This period can be changed by editing the **crontab** command for the root user and changing the entry for **/usr/sbin/dumpctrl -k**. For more information, see the **crontab** command. You must run the **dumpctrl -k** command after you add or remove dumps by hand. If the system is holding any dumps in the heap that it previously could not write to the file system, the system attempts to write those dumps and reclaim their storage space now.
-l *comp-alias-list*	Specifies components by alias. Wildcards are allowed.
-r	Dumps any subcomponents of the specified components.

Item	Description
-q *cmd*	Queries attributes for the live dump or system dump. • The **-qc** flag shows component-specific live dump attributes and system dump attributes. The **-qc** flag can be used with the **-p** or **-P** flag to query persistent per-component attributes. The **-qc** flag shows the attributes for all components if neither the **-c**, **-l**, nor **-t** flag is specified. In other words, **-c all** is the default. The following is a sample output for this command: • The **-ql** flag lists global live dump settings. The **-ql** flag can be used with the **-p** or **-P** flag to query persistent global live dump settings. • The **-qs** *type* flag shows global system dump attributes. The **-qs** can be used with the **-p** or **-P** flag to query global system dump attributes.
-r	Includes components below the specified components in the component hierarchy.
-**Rx**	Restores dump settings to their defaults. *x* can be `l` for live dump settings, or `s` for system dump settings. It resets only the global dump settings. Individual components cannot be specified. The **-P** flag and a new boot image are required to ensure all of these settings remain in effect across a restart.
-t *type_subtype*	Specifies a component by *type_subtype* names.
-s	Lists the path names and titles of all live dumps in the dump repository. If components are specified with the **-c**, **-l**, or **-t** flag, the list of dumps that are shown contains dumps only with the specified components. If components are specified with the **-C**, **-L**, or **-T** flag, the list of dumps that are shown contains dumps only with the specified failing components.
-C *comp-path-list*	Specifies components by path name. Wildcards are allowed. The reserved name `all` is also allowed to indicate all components. The **-C** flag is only valid with the **-s** flag.
-L *comp-alias-list*	Specifies components by alias. Wildcards are allowed. The **-L** flag is only valid with the **-s** flag.
-T *type_subtype*	Specifies a component by *type_subtype* names. The **-T** flag is valid only with the **-s** flag.
-u	Includes components above the specified components in the component hierarchy.

```
dumpctrl -qc -r -l vmm -l proc

-------------------------------------------------------------------------------
     Component name                       | Have | Live Dump | System Dump
                                          |Alias |  /level   |  /level
-------------------------------------------------------------------------------
vmm                                       | no   |  on/3     |  on/3
     .pft                                 | no   |  on/3     |  on/3
     ...
proc                                      | no   |  on/4     |  on/3
     ...
```

Persistence flags

Item	Description
-p	Changes apply only to newly created components, which are RAS infrastructure components that are created after the **dumpctrl** command runs.

Item	Description
-P	Makes the specified changes permanent. Any changes that are made remain in effect across a restart. If a new boot image is required, a message is produced to notify you about it. The **-P** flag applies to component attributes, the global enabling or disabling of live dump, the global live dump level, the enabling or disabling of legacy components, and the system dump device specifications.
-n	Changes apply to existing components. The **-n** flag is the default if neither **-p** nor **-P** is specified. To apply changes to both current and newly created components, use the **-n** and **-p** flags.
-x	Deletes this persistence specification. The **-x** flag deletes a permanent (**-P**) persistence specification. The specification must be specified in the same manner as it was originally specified with the **-P** flag.

Recursive-down customization (specified by the **-r** flag) take precedence over all other customization, regardless of the order in which they are specified relative to other non-recursive-down customization.

If you do not know the customization that is made but want to restore the default system setting, you can do one of the following actions:

- In the `/var/adm/ras/raspertune` file, delete the lines relevant to the customization and run the **bosboot** command to restart AIX.
- Read the `/var/adm/ras/raspertune` file to figure out the appropriate flags and parameters that are specified. Then, use the **-x** flag to delete the customization. Run the **bosboot** command and restart AIX.

For more information about how the various dump attributes interact with persistence, see the live dump and system dump attribute tables in "Attributes" on page 1126.

Attributes

The dump attributes can take the form `attribute=value`. For example,

```
dumpctrl dir=/usr/dumps freespc=20
```

This example sets dump directory to `/usr/dumps`, and the free space threshold to 20%.

Some shortcuts are provided, such as the **ldmpon** attribute, which is the same as `ldmpenable=yes`.

If components are given, unrecognized attributes are passed to callbacks of those components by using **RASCD_DMP_PASS_THROUGH**.

The following table lists live dump attributes.

Table 1. Live dump attributes and defaults

Attribute	Specification	Default value
ldmpenable	Specifies whether live dump is enabled. The possible values are yes and no. You can use the **ldmpon** attribute instead of `ldmpenable=yes`, and the **ldmpoff** attribute instead of `ldmpenable=no`.	yes For more information, see the following note "1" on page 1128.
dir	Specifies a live dump directory name.	`/var/adm/ras/livedump`
freespc	Specifies live dump free space threshold by using a decimal value from 0 to 99.	25 (means 25%)

Table 1. Live dump attributes and defaults (continued)		
Attribute	**Specification**	**Default value**
ldmplevel	Specifies the live dump level by using a decimal value from 0 to 9. You can specify the **ldmpminimal**, **ldmpnormal**, or **ldmpdetail** attribute instead of `ldmplevel=1, 3, 7`	3 (normal) For more information, see the following note "1" on page 1128.
heapsz	Specifies live dump heap size by using a decimal value in megabytes.	0 For more information, see the following note "2" on page 1128.
duptype	Specifies duplicate dump suppression type. The following are the possible values: • all • pre • post • none	all
maxfreeze	Specifies the maximum recommended system freeze interval by using a decimal number in milliseconds.	100 ms

The following table lists system dump attributes.

Table 2. System dump attributes and defaults		
Attribute	**Specification**	**Default value**
sdmpenable	Specifies whether system dump is enabled. The possible values are yes and no. You can also specify the **sdmpon** or **sdmpoff** instead of `sdmpenable=yes` or `sdmpenable=no`.	yes For more information, see the following note "3" on page 1128.
legacyenable	Specifies whether dump legacy components are enabled. The possible values are yes and no. You can also specify the **legacyon** or **legacyoff** instead of `legacyenable=yes` or `legacyenable=no`.	yes
sdmplevel	Specifies the system dump level by using a decimal value from 0 to 9. You can specify the **sdmpminimal**, **sdmpnormal**, or **sdmpdetail** attribute instead of `sdmplevel=1, 3, 7`	3 (normal) For more information, see the following note "4" on page 1128.
copydir	Specifies a copy directory path name.	`/var/adm/ras`

Table 2. System dump attributes and defaults (continued)		
Attribute	**Specification**	**Default value**
forcecopy	Specifies whether the **forcecopy** attribute is enabled. The possible values are yes and no. If a dump must be copied from paging space at boot time, and there is not enough space in the copy directory, you are prompted to copy the dump to removable media if the **forcecopy** value is yes. If the value is no, the dump is not copied and the system boots normally, although the dump might be lost.	yes
keyseq	Specifies whether the key sequences always cause a dump. The possible values are yes and no.	no
primary	Specifies the primary dump device path name.	/dev/hd6 or /dev/lg_dumplv
secondary	Specifies the secondary dump device path name.	/dev/sysdumpnull

Notes:

1. The **ldmpenable** and **ldmplevel** attributes can be specified with or without components. If specified without components, the attributes apply to the corresponding global attributes.
2. The **heapsz** attribute (heap size) can be set to 0, meaning that, at dump initialization time, the system calculates the live dump heap size that is based on the amount of real memory, which is the minimum of 64 MB and 1/64 the size of real memory.
3. Individual components must be specified when the **sdmpenable** attribute is given. If no components are given, the **sdmpenable** attribute cannot be specified because the system dump cannot be disabled.
4. The **sdmplevel** attribute can be specified with or without components. If specified without components, it applies to the system default level. The components with **sdmplevel** that are greater than the global **sdmplevel** value are not included in a system dump.

The following table lists live dump attributes and their persistence.

Table 3. Live dump attributes and persistence		
Attribute	**Description**	**Persistence**
ldmpenable	Live dump enabled	Controlled by persistence flags, new boot image is required with the **-P** flag.
dir	Live dump directory	Takes effect immediately and upon system restart.
freespc	Live dump free space threshold	Takes effect immediately and upon system restart.
ldmplevel	Live dump level	Controlled by persistence flags, new boot image is required with the **-P** flag.
heapsz	Live dump heap size	Takes effect immediately and upon system restart.

Table 3. Live dump attributes and persistence (continued)		
Attribute	**Description**	**Persistence**
duptype	Duplicate dump suppression type	Takes effect immediately and upon system restart.
maxfreeze	Maximum recommended system freeze interval	Takes effect immediately and upon system restart.

Note: Persistence affects the attributes only when they apply to RAS infrastructure components. Persistence also controls the global live dump level and global enabled or disabled status.

The following table lists system dump attributes and their persistence.

Table 4. System dump attributes and persistence		
Attribute	**Description**	**Persistence**
sdmpenable	System dump enabled	Controlled by persistence flags, new boot image is required with the **-P** flag.
legacyenable	Dump legacy components	Takes effect immediately, and upon system restart with the **-P** flag. No new boot image is required with the **-P** flag.
sdmplevel	System dump level	Controlled by persistence flags, new boot image is required with the **-P** flag.
copydir	Copy directory	Takes effect immediately and upon system restart.
forcecopy	Brings up the boot time menu if it cannot copy	Takes effect immediately and upon system restart.
keyseq	Key sequences always cause a dump	Takes effect immediately and upon system restart.
primary	Primary dump device	Takes effect immediately, and upon system restart with the **-P** flag. No new boot image is required with the **-P** flag.
secondary	Secondary dump device	Takes effect immediately, and upon system restart with the **-P** flag. No new boot image is required with the **-P** flag.

Note: Persistence affects the attributes when they apply to components.

The **copydir, forcecopy, keyseq, primary**, and **secondary** attributes behave like their **sysdumpdev** command counterparts that are specified with the **-d**, **-D**, **-k**, **-K**, **-p**, and **-s** flags.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.

Item	Description
non-zero	An error occurred. This command fails under the following conditions: • One or more parameters are invalid. • One or more attributes are invalid. • A component cannot be specified. • At least one component must be specified. • The persistent specification cannot be found. (It can occur with the **-x** flag.)

Security

Only the root user can use this command.

dumpfs Command

Purpose

Dumps file system information.

Syntax

dumpfs { *FileSystem* | *Device* }

Description

The **dumpfs** command prints out the superblock, i-node map, and disk map information for the file system or special device specified. This listing is used to find out file system information. Primarily, the **dumpfs** command is for debugging purposes.

The **dumpfs** command can also run against a JFS2 snapshot. The **dumpfs** command prints out the superblock, snapshot map, and block map xtree copy for the specified snapshot.

Note: The `dumpfs` command will not work on UDF, NFS, or JFS diskettes.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **`lssecattr`** command or the **`getcmdattr`** subcommand.

Examples

To print the information for **/dev/hd4**, enter:

```
dumpfs /dev/hd4
```

e

The following AIX commands begin with the letter e.

echo Command

Purpose

Writes character strings to standard output.

Syntax

echo [*String ...*]

Description

The **echo** command writes character strings to standard output. *String*s are separated by spaces, and a new-line character follows the last *String* parameter specified. If no *String* parameter is specified, a blank line (new-line character) is displayed.

Normally you could distinguish between a flag and a string that begins with a hyphen by using a -- (double hyphen). Since no flags are supported with the **echo** command, a -- (double hyphen) is treated literally.

The **echo** command recognizes the following escape conventions:

Item	Description
\a	Displays an alert character.
\b	Displays a backspace character.
\c	Suppresses the new-line character that otherwise follows the final argument in the output. All characters following the **\c** sequence are ignored.
\f	Displays a form-feed character.
\n	Displays a new-line character.
\r	Displays a carriage return character.
\t	Displays a tab character.
\v	Displays a vertical tab character.
****	Displays a backslash character.
\0*Number*	Displays an 8-bit character whose ASCII value is a 0-, 1-, 2-, or 3-digit octal number.

Note: The **bsh**, **ksh**, and **csh** commands each contain a built-in **echo** subcommand. The **echo** command and the **bsh** and **ksh echo** subcommands work the same way. The **csh echo** subcommand does not work the same way as the **echo** command.

The \ (backslash) is a quote character in the shell. This means that unless the \ is used with an escape character or enclosed in quotes, for example "\" or '\', the shell removes the backslashes when the command is expanded.

After shell expansion, the **echo** command writes the output based on the escape sequences in the input. Refer to the Backslash Reduction table for an example comparison of how backslashes in a command are first reduced by the shell and then by the **echo** command:

Backslash Reduction

Command Entered	After Shell Expansion	After echo Command Processing
echo hi\\\\there	echo hi\\there	hi\there
echo 'hi\\\\there'	echo 'hi\\\\there'	hi\\there
echo "hi\\\\there'	echo "hi\\there"	hi\there

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To write a message to standard output, enter:

   ```
   echo Please insert diskette . . .
   ```

2. To display a message containing special characters, enter:

   ```
   echo "\n\n\nI'm at lunch.\nI'll be back at 1:00."
   ```

   This skips three lines and displays the message:

   ```
   I'm at lunch.
   I'll be back at 1:00.
   ```

   Note: You must put the message in quotation marks if it contains escape sequences. Otherwise, the shell interprets the \ (backslash) as a metacharacter and treats the \ differently.

3. To use the **echo** command with pattern-matching characters, enter:

   ```
   echo The back-up files are: *.bak
   ```

   This usage displays the message `The back-up files are:` followed by the file names in the current directory ending with `.bak`.

4. To add a single line of text to a file, enter:

   ```
   echo Remember to set the shell search path to $PATH. >>notes
   ```

   This usage adds the message to the end of the file notes after the shell substitutes the value of the **PATH** shell variable.

5. To write a message to the standard error output, enter:

   ```
   echo Error: file already exists. >&2
   ```

   This command redirects the error message to standard error. If the >&2 is omitted, the message is written to standard output.

File

Item	Description
/usr/bin/echo	Contains the **echo** command.

ed or red Command

Purpose

Line editor for text files.

Syntax

ed [**-p** *String*] [**-s** | **-**] [*File*]

red [**-p***String*] [**-s** | **-**] [*File*]

Description

The **ed** command starts the ed editor line-editing program. The ed editor works on only one file at a time by copying it into a temporary edit buffer and making changes to that copy. The ed editor is part of a family of editors that also includes the edit editor, ex editor, and vi editor. The ed editor makes the changes you specify in a buffer. It does not alter the file itself until you use the write (**w**) subcommand.

You can specify the name of the file you want to edit when you start the ed editor with the **ed** command, or you can use the **e** subcommand. When the **ed** command reads a new file into the buffer, the contents of that file replace the buffer's previous contents.

The **red** command is a restricted version of the **ed** command, for use with the restricted shell (**rsh**). With the **red** command, you edit only files that reside in the current directory or in the **/tmp** directory; you cannot use the **!** subcommand.

An ed editor subcommand consists of zero, one, or two addresses, followed by a single-character subcommand, followed by optional parameters to that subcommand. The addresses specify one or more lines in the buffer. Because every subcommand has default addresses, it is frequently unnecessary to specify addresses.

The ed editor allows editing only the current line unless you address another line in the buffer. You can move and copy only complete lines of data. The ed editor is useful for editing large files or for editing within a shell program.

The ed editor operates in one of two modes:

Item	Description
command mode	In command mode, the ed editor recognizes and runs subcommands. When you start the ed editor, it is in command mode. Type a **.** (period) and press Enter to confirm that you are in command mode.
text input mode	In text input mode, the ed editor allows you to enter text into the file buffer but does not recognize subcommands. You enter text input mode by using the **a**subcommand, **c** subcommand, or **i** subcommand. You exit text input mode and return to the command mode by typing a **.** (period) alone at the beginning of a line. To place a **.** (period) into the buffer while in text input mode, enter a character followed by the **.** (period). Then, exit text input mode and use the **s** subcommand to remove the character.

The following list provides the maximum limits of the **ed** editor.

- 64 characters per file name
- 256 characters per global subcommand list
- 128,000 character buffer size

  Note: The buffer contains the original file as well as editing information.

The maximum number of lines depends on the amount of memory available. The maximum file size depends on the amount of physical data storage (disk or tape drive) available or on the maximum number of lines permitted in user memory.

Flags

Item	Description
-p *String*	Sets the editor prompt to the *String* parameter. The default for *String* is a null value (no prompt).
-s	Suppresses character counts that the editor displays with the **e** subcommand, **r** subcommand, and **w** subcommand. This flag also suppresses diagnostic messages for the **e** subcommand and the **q** subcommand, and suppresses the ! (exclamation point) prompt after an **!** subcommand.
-	Provides the same functions as the **-s** flag.

Pattern Matching

The ed editor supports a limited form of special pattern-matching characters that you can use as regular expressions (REs) to construct pattern strings. You can use these patterns in addresses to specify lines and in some subcommands to specify portions of a line.

Regular Expressions

The following REs match a single character or a collating element as follows:

Item	Description
Character	Matches itself and can be any ordinary character (other than one of the special pattern-matching symbols).
.	Matches any single character except the new-line character.
[*String*]	Matches any one character in the string. Certain pattern-matching characters have special meanings within brackets as follows: **^** Matches any character except the characters in the *String* parameter and the new-line character if the first character of the *String* parameter is a ^ (circumflex). This condition is true only if the ^ is the first character in the string, [^*String*]. **-** Indicates a range of consecutive ASCII characters according to the current collating sequence. For example, [a-f] can be equivalent to [abcdef] or [aAbBcCdDeEfF] or [abcdef] and could even include accented a and e characters. A collating sequence can define equivalence classes for characters. The minus sign loses its significance if it occurs as the first character in the string, [-*String*]; if it immediately follows an initial circumflex, [^-*String*]; or if it appears as the last character in the string, [*String*-]. **]** Functions as a part of the string rather than as the string terminator, when the] (right bracket) is the first character in the string, []*String*], or when it immediately follows an initial circumflex, [^]*String*].

Forming Patterns

The following rules describe how to form patterns from REs:

- An RE that consists of a single, ordinary character matches that same character in a string.

- An RE followed by an * (asterisk) matches zero or more occurrences of the character that the RE matches. For example, the following pattern:

```
ab*cd
```

matches each of the following strings:

```
acd
abcd
abbcd
abbbcd
```

but not the following string:

```
abd
```

If a choice exists, the longest matching leftmost string is chosen. For example, given the following string:

```
122333444
```

the pattern .* matches 122333444, the pattern .*3 matches 122333, and the pattern .*2 matches 122.

- An RE followed by:

Item	Description
\{*m*\}	Matches *exactly m* occurrences of the character matched by the RE.
\{*m*,\}	Matches *at least m* occurrences of the character matched by the RE.
\{*m*,*n*\}	Matches *any number* of occurrences of the character matched by the RE from *m* to *n* inclusive.

The numbers *m* and *n* must be integers from 0 to 255, inclusive. Whenever a choice exists, this pattern matches as many occurrences as possible.

- You can combine REs into patterns that match strings containing that same sequence of characters. For example, the pattern AB*CD matches the string AB*CD, and the pattern [A-Za-z]*[0-9]* matches any string that contains any combination of alphabetic characters (including none), followed by any combination of numerals (including none).
- The character sequence \(*Pattern*\) marks a subpattern that matches the same string the sequence would match if it were not enclosed.
- The characters *Number* match the same string of characters that a subpattern matched earlier in the pattern (see the preceding rule). The pattern of the *Number* parameter represents a digit. The pattern *Number* matches the string matched by the occurrence of the subpattern specified by the *Number* parameter, counting from left to right.

  For example, the following pattern:

```
\(A\)\(B\)C\2\1
```

matches the string ABCBA. You can nest subpatterns.

Restricting What Patterns Match

You can restrict a pattern to match only the first segment of a line, the final segment, or the entire line. The null pattern, // (two slashes), duplicates the previous pattern.

Matching the First Segment of a Line

The ^*Pattern* parameter matches only a string that begins in the first character position on a line.

Matching the Last Segment of a Line

The *Pattern*$ parameter matches only a string that ends with the last character (not including the new-line character) on a line.

Matching the Entire Line

The ^*Pattern*$ parameter restricts the pattern to match an entire line.

Addressing Lines

The ed editor uses three types of addresses: line number addresses, addresses relative to the current line, and pattern addresses. The current line (usually the last line affected by a subcommand) is the point of reference in the buffer.

You can use line addressing to do the following:

- Designate a new current line
- Display the addressed line or lines
- Cause a command to act on a certain line or lines

Subcommands that do not accept addresses regard the presence of an address as an error. Subcommands that accept addresses can use either given or default addresses. When given more addresses than it accepts, a command uses the last (rightmost) ones.

In most cases, commas (,) separate addresses (for example 2 , 8). Semicolons (;) also can separate addresses. A semicolon between addresses causes the ed editor to set the current line to the first address and then calculate the second address (for example, to set the starting line for a search). In a pair of addresses, the first address must be numerically smaller than the second.

You can use line numbers and symbolic addresses to perform the following tasks:

- Addressing the current line
- Addressing a line by number
- Addressing the line before the first line
- Addressing the last line
- Addressing a line above an addressed line
- Addressing a line below an addressed line
- Addressing the first line through the last line
- Addressing the current line through the last line
- Addressing a group of lines
- Addressing the next line that contains a specified pattern
- Addressing the previous line that contains a specified pattern
- Addressing a marked line

Addressing the Current Line

A . (period) addresses the current line. The . (period) is the default for most ed editor subcommands and does not need to be specified.

Addressing a Line by Number

To address a specified line of the buffer, type:

```
Number
```

where the *Number* parameter represents a line number. For example:

```
2253
```

addresses line number 2253 as the current line.

Addressing the Line before the First Line

To address the line before the first line of the buffer, type:

```
0
```

Addressing the Last Line

To address the last line of the buffer, type:

```
$
```

Addressing a Line above an Addressed Line

To specify an address that is a specified number of lines above the current line, type:

```
-Number
```

where the *Number* parameter is the specified number of lines above the current line that you want to address. For example:

```
-5
```

addresses the line five lines above the current line as the current line.

You also can specify only a - to address the line immediately above the current line. The minus sign has a cumulative effect. For example, the address - - (two minus signs) addresses the line two lines above the current line.

Addressing a Line below an Addressed Line

To specify an address that is a specified number of lines below the current line, type:

```
+Number
```

where the *Number* parameter is the specified number of lines below the current line that you want to address. The + (plus sign) is optional. For example:

```
+11
```

addresses the line 11 lines below the current line as the current line.

You also can specify only a + to address the line immediately below the current line. The + has a cumulative effect. For example, the address + + (two plus signs) addresses the line two lines below the current line.

Addressing the First Line through the Last Line

To address the first line through the last line, type:

```
,
```

The , (comma) represents the address pair 1,$ (first line through last line). The first line becomes the current line.

Addressing the Current Line through the Last Line

To address the current line through the last line, type:

```
;
```

The ; (semicolon) represents the address pair .,$ (current line through last line).

Addressing a Group of Lines

To address a group of lines, type:

```
FirstAddress,LastAddress
```

where the *FirstAddress* parameter is the line number (or symbolic address) of the first line in the group you want to address, and the *LastAddress* parameter is the line number (or symbolic address) of the last line in the group. The first line in the group becomes the current line. For example:

```
3421,4456
```

addresses the lines 3421 through 4456. Line 3421 becomes the current line.

Addressing the Next Line That Contains a Specified Pattern

To address the next line that contains a matching string, type:

```
/Pattern/
```

where the *Pattern* parameter is a character string or regular expression. The search begins with the line after the current line and stops when it finds a match for the pattern. If necessary, the search moves to the end of the buffer, wraps around to the beginning of the buffer, and continues until it either finds a match or returns to the current line. For example:

```
/Austin, Texas/
```

addresses the next line that contains Austin, Texas as the current line.

Addressing the Previous Line That Contains a Specified Pattern

To address the previous line that contains a match for the pattern, type:

```
?Pattern?
```

where the *Pattern* parameter is a character string or regular expression. The ?*Pattern*? construction, like /*Pattern*/, can search the entire buffer, but it searches in the opposite direction. For example:

```
?Austin, Texas?
```

addresses the previous line that contains Austin, Texas as the current line.

Addressing a Marked Line

To address a marked line with the **k** subcommand, type:

```
'x
```

where the *x* parameter is a lowercase letter *a* to *z*. For example:

```
'c
```

addresses the line marked as c with the **k** subcommand.

Subcommands

Use the ed editor subcommands to perform the following actions:

- Editing a file
- Manipulating files
- Performing miscellaneous functions
  - Changing the prompt string
  - Entering system commands
  - Exiting the ed editor
  - Requesting help

In most cases, you can enter only one ed editor subcommand on a line. However, you can add the **l** (list) and **p** (print) subcommands to any subcommand except the **e** (edit), **E** (Edit), **f** (file), **q** (quit), **Q** (Quit), **r** (read), **w** (write), and **!** (operating system commands) subcommands.

The **e**, **f**, **r**, and **w** subcommands accept file names as parameters. The ed editor stores the last file name used with a subcommand as a default file name. The next **e**, **E**, **f**, **r**, or **w** subcommand given without a file name uses the default file name.

The ed editor responds to an error condition with one of two messages: ? (question mark) or `?File`. When the ed editor receives an Interrupt signal (the Ctrl-C key sequence), it displays a ? and returns to command mode. When the ed editor reads a file, it discards ASCII null characters and all characters after the last new-line character.

Editing a File

You can use the ed editor subcommands to perform the following tasks:

- Adding text
- Changing text
- Copying text
- Deleting text
- Displaying text
- Joining and splitting lines
- Making global changes
- Marking text
- Moving text
- Saving text
- Searching text
- Substituting text
- Undoing text changes

Note: In the following descriptions of ed editor subcommands, default addresses are shown in parentheses. Do not type the parentheses. The address . (period) refers to the current line. A . (period) in the first position of an otherwise empty line is the signal to return to command mode.

Adding Text

Item	Description
(.)**a** [**l**] [**n**] [**p**] *Text***.**	The **a** (append) subcommand adds text to the buffer *after* the addressed line. The **a** subcommand sets the current line to the last inserted line, or, if no lines were inserted, to the addressed line. A 0 address adds text to the beginning of the buffer. Type the **l** (list), **n** (number), or **p** (print) optional subcommand if you want to display the added text. Type your text, pressing the Enter key at the end of each line. If you do not press Enter at the end of each line, the ed editor automatically moves your cursor to the next line after you fill a line with characters. The ed editor treats everything you type before you press Enter as one line, regardless of how many lines it takes up on the screen. Type a . (period) at the start of a new line, after you have typed all of your text.

Item	Description
(.)**i** [**l**] [**n**] [**p**]*Text***.**	The **i** (insert) subcommand inserts text *before* the addressed line and sets the current line to the last inserted line. If no lines are inserted, the **i** subcommand sets the current line to the addressed line. You cannot use a 0 address for this subcommand. Type the **l** (list), **n** (number), or **p** (print) optional subcommand if you want to display the inserted text. Type your text, pressing the Enter key at the end of each line. If you do not press Enter at the end of each line, the ed editor automatically moves your cursor to the next line after you fill a line with characters. The ed editor treats everything you type before you press Enter as one line, regardless of how many lines it takes up on the screen. Type a . (period) at the start of a new line, after you have typed all of your text. **Note:** The **i** subcommand differs from the **a** subcommand only in the placement of the text.

You can use different ed editor subcommands to add text in different locations. Use the preceding format to perform the following editing tasks:

- Adding text after the current line
- Adding text before the current line
- Adding text after an addressed line
- Adding text before an addressed line
- Adding text after lines that contain a search pattern
- Adding text before lines that contain a search pattern
- Adding text after lines that do not contain a search pattern
- Adding text before lines that do not contain a search pattern

To Add Text after the Current Line

1. Type the following subcommand:

   ```
   a[l][n][p]
   ```

   where **l**, **n**, and **p** are optional subcommands that display the added text.
2. Type the text, and press Enter.
3. Type a **.** (period), and press Enter again to return to command mode.

To Add Text before the Current Line

1. Type the following subcommand:

   ```
   i[l][n][p]
   ```

   where **l**, **n**, and **p** are optional subcommands that display the added text.
2. Type the text, and press Enter.
3. Type a **.** (period), and press Enter again to return to command mode.

To Add Text after an Addressed Line

1. Type the following subcommand:

   ```
   Addressa[l][n][p]
   ```

where the *Address* parameter is the line number of the line that the inserted text should follow. The **l**, **n**, and **p** optional subcommands display the added text.

2. Type the text, and press Enter.
3. Type a **.** (period), and press Enter again to return to command mode.

To Add Text before an Addressed Line

1. Type the following subcommand:

```
Addressi[l][n][p]
```

where the *Address* parameter is the line number of the line that the inserted text should precede. The **l**, **n**, and **p** optional subcommands display the added text.

2. Type the text, and press Enter.
3. Type a **.** (period), and press Enter again to return to command mode.

To Add Text after Lines That Contain a Search Pattern

1. Type the following subcommand:

```
[Address]g/Pattern/a[l][n][p]
```

where *Address* is an optional parameter that specifies the range of lines to search for the pattern specified in the *Pattern* parameter. The *Pattern* parameter is a character string or regular expression. If you omit the *Address* parameter, the ed editor searches the entire file for lines that contain the pattern. The **l**, **n**, and **p** optional subcommands display the added text.

2. Type a backslash:

```
\
```

3. Type the text. To start new lines within the added text, type a backslash:

```
\
```

and press Enter. The text you type is added after every line that contains the pattern specified in the command.

4. To return to command mode, press Enter.

To Add Text before Lines That Contain a Search Pattern

1. Type the following subcommand:

```
[Address]g/Pattern/i[l][n][p]
```

where *Address* is an optional parameter that specifies the range of lines to search for the pattern specified in the *Pattern* parameter. The *Pattern* parameter is a character string or regular expression. If you omit the *Address* parameter, the ed editor searches the entire file for lines that contain the pattern. The **l**, **n**, and **p** optional subcommands display the added text.

2. Type a backslash:

```
\
```

3. Type the text. To start new lines within the added text, type a backslash:

```
\
```

and press Enter. The text you type is added before every line that contains the pattern specified in the command.

4. To return to command mode, press Enter.

To Add Text after Lines That Do Not Contain a Search Pattern

1. Type the following subcommand:

```
[Address]g/Pattern/a[l][n][p]
```

   where *Address* is an optional parameter that specifies the range of lines to search for lines that do not contain the pattern specified in the *Pattern* parameter. The *Pattern* parameter is a character string or regular expression. If you omit the *Address*, the ed editor searches the entire file for lines that do not contain the pattern. The **l**, **n**, and **p** optional subcommands display the added text.
2. Type a backslash:

```
\
```

3. Type the text. To start new lines within the added text, type a backslash:

```
\
```

   and press Enter. The text you type is added after every line that does not contain the pattern specified in the command.
4. To return to command mode, press Enter.

To Add Text before Lines That Do Not Contain a Search Pattern

1. Type the following subcommand:

```
[Address]g/Pattern/i[l][n][p]
```

   where *Address* is an optional parameter that specifies the range of lines to search for lines that do not contain the pattern specified in the *Pattern* parameter. The *Pattern* parameter is a character string or regular expression. If you omit the *Address* parameter, the ed editor searches the entire file for lines that do not contain the pattern. The **l**, **n**, and **p** optional subcommands display the added text.
2. Type a backslash:

```
\
```

3. Type the text. To start new lines within the added text, type a backslash:

```
\
```

   and press Enter. The text you type is added before every line that does not contain the pattern specified in the command.
4. To return to command mode, press Enter.

Changing Text

Item	Description
(.,.)**c** [**l**] [**n**] [**p**]*Text***.**	The **c** (change) subcommand deletes the addressed lines you want to replace and then replaces them with the new lines you enter. The **c** subcommand sets the current line to the last new line of input, or, if no input existed, to the first line that was not deleted. Type the **l** (list), **n** (number), or **p** (print) optional subcommand if you want to display the inserted text. Type the new text, and press Enter at the end of each line. When you have entered all of the new text, type a . (period) on a line by itself.

You can change text in several different ways with the ed editor. Use the preceding format to perform the following editing tasks:

- Changing the text of the current line

- Changing the text of a line or group of lines
- Changing text of lines that contain a specified pattern
- Changing text of lines that do not contain a specified pattern

To Change the Text of the Current LIne

1. Type the following subcommand:

   ```
   c[l][n][p]
   ```

   where **l**, **n**, and **p** are optional subcommands that display the changed text.
2. Type the text, and press Enter.
3. Type a **.** (period), and press Enter again to return to command mode.

To Change the Text of a Line or Group of Lines

1. Type the following subcommand:

   ```
   Addressc[l][n][p]
   ```

   where the *Address* parameter is the address of the line or group of lines to change. The **l**, **n**, and **p** optional subcommands display the changed text.
2. Type the text, and press Enter.
3. Type a **.** (period), and press Enter again to return to command mode.

To Change the Text of Lines That Contain a Specified Pattern

1. Type the following subcommand:

   ```
   Addressg/Pattern/c[l][n][p]
   ```

   where the *Address* parameter is the address of the group of lines that you want to search for the pattern specified with the *Pattern* parameter. The **l**, **n**, and **p** optional subcommands display the changed text.
2. Type a backslash:

   ```
   \
   ```
3. Type the new text. To start new lines within the new text, type a backslash:

   ```
   \
   ```

   and press Enter.
4. To return to command mode, press Enter again, type a . (period), and press Enter again.

To Change the Text of Lines That Do Not Contain a Specified Pattern

1. Type the following subcommand:

   ```
   Addressv/Pattern/c[l][n][p]
   ```

   where the *Address* parameter is the address of the group of lines that you want to search for the pattern specified with the *Pattern* parameter. The **l**, **n**, and **p** optional subcommands display the changed text.
2. Type a backslash:

   ```
   \
   ```
3. Type the new text. To start new lines within the new text, type a backslash:

   ```
   \
   ```

and press Enter.

4. To return to command mode, press Enter again, type a . (period), and press Enter again.

Copying Text

Item	Description
(.,.)**t***Address* [**p**] [**l**] [**n**]	The **t** (transfer) subcommand inserts a copy of the addressed lines after the line specified by the *Address* parameter. The **t** subcommand accepts the 0 address to insert lines at the beginning of the buffer. The **t** subcommand sets the current line to the last line copied. Type the **l** (list), **n** (number), or **p** (print) optional subcommand if you want to display the transferred text.

Copying a line or a set of lines leaves the specified lines in their original location and puts a copy in the new location. You can select the lines to copy by specifying an address or pattern. Use the preceding format to perform the following editing tasks:

- Copying the current line
- Copying lines specified by address
- Copying lines that contain a specified pattern
- Copying lines that do not contain a specified pattern

To Copy the Current Line

1. Type the following subcommand:

   ```
   tAddress[l][n][p]
   ```

   where the *Address* parameter is the line number or symbolic address of the line you want a copy of the current line to follow. The **l**, **n**, and **p** optional subcommands display the copied line.
2. Type the text, and press Enter.
3. Type a **.** (period), and press Enter again to return to command mode.

To Copy Lines Specified by Address

1. Type the following subcommand:

   ```
   LineNumbertDestinationAddress[l][n][p]
   ```

   where the *LineNumber* parameter is the address of the lines you want to copy, and the *DestinationAddress* parameter is the line you want the copy to follow. The **l**, **n**, and **p** optional subcommands display the copied line.
2. Type the text, and press Enter.
3. Type a **.** (period), and press Enter again to return to command mode.

To Copy Lines That Contain a Specified Pattern

Type the following subcommand:

```
[Address]g/Pattern/t[DestinationAddress][l][n][p]
```

where *Address* is an optional parameter that specifies the range of lines to search for lines that contain the specified pattern, the *Pattern* parameter is the text you are searching for, and the *DestinationAddress* is an optional parameter that identifies the line you want the copied text to follow. The **l**, **n**, and **p** optional subcommands display the copied line.

If you omit the *Address* parameter, the ed editor searches the entire file for lines that contain the pattern. If you omit the *DestinationAddress* parameter, the copied text is placed after the current line.

To Copy Lines That Do Not Contain a Specified Pattern

Type the following subcommand:

```
[Address]v/Pattern/t[DestinationAddress][l][n][p]
```

where *Address* is an optional parameter that specifies the range of lines to search for lines that do not contain the specified pattern, the *Pattern* parameter is the text, and the *DestinationAddress* is an optional parameter that identifies the line you want the copied text to follow. The **l**, **n**, and **p** optional subcommands display the copied line.

If you omit the *Address* parameter, the ed editor searches the entire file for lines that do not contain the pattern. If you omit the *DestinationAddress* parameter, the copied text is placed after the current line.

Deleting Text

Item	Description
(.,.)**d** [**l**] [**n**] [**p**]	The **d** (delete) subcommand removes the addressed lines from the buffer. The line after the last line deleted becomes the current line. If the deleted lines were originally at the end of the buffer, the new last line becomes the current line. Type the **l** (list), **n** (number), or **p** (print) optional subcommand if you want to display the deletion.

The ed editor provides several ways to delete text. Use the preceding format to perform the following editing tasks:

- Deleting the current line
- Deleting a line or group of lines
- Deleting a line or group of lines that contain a specified pattern
- Deleting a line or group of lines that does not contain a specified pattern
- Deleting text from the current line
- Deleting text within selected lines
- Deleting text from addressed lines
- Deleting text from lines that contain a specified pattern
- Deleting a pattern from lines that contain a different specified pattern
- Deleting a pattern from lines that do not contain a different specified pattern

To Delete the Current Line

Type the following subcommand:

```
d[l][n][p]
```

where **l**, **n**, and **p** are optional subcommands that display the deleted line.

To Delete a Line or Group of Lines

Type the following subcommand:

```
Addressd[l][n][p]
```

where the *Address* parameter is the line number or symbolic address of the lines you want to delete, and **l**, **n**, and **p** are optional subcommands that display the deleted line or lines.

To Delete a Line or Group of Lines That Contain a Specified Pattern

Type the following subcommand:

```
[Address]g/Pattern/d[l][n][p]
```

where *Address* is an optional parameter that specifies the line number or symbolic address of the lines you want to search, and the *Pattern* parameter is a character string or regular expression that represents the text you want to find. If you omit the *Address* parameter, the ed editor searches the entire file for lines that contain the specified pattern. The **l**, **n**, and **p** optional subcommands display the deleted line or lines.

To Delete a Line or Group of Lines That Does Not Contain a Specified Pattern

Type the following subcommand:

```
[Address]v/Pattern/d[l][n][p]
```

where *Address* is an optional parameter that specifies the line number or symbolic address of the lines you want to search, and the *Pattern* parameter is a character string or regular expression that represents the text you want to find. If you omit the *Address* parameter, the ed editor searches the entire file for lines that do not contain the specified pattern. The **l**, **n**, and **p** optional subcommands display the deleted line or lines.

To Delete Text from the Current Line

1. Type the following subcommand:

   ```
   s/Pattern
   ```

   where the *Pattern* parameter is a character string or regular expression that represents the text you want to delete.
2. To delete the *first instance* of the pattern from the line, type:

   ```
   //
   ```

   OR

   To delete *every instance* of the pattern from the line, type:

   ```
   //g
   ```
3. If you want to display the deletion, type one of the following optional subcommands:

   l

   n

   p
4. Press Enter.

To Delete Text within Selected Lines

1. Type the address of a group of lines to select (or skip this step to select all lines).
2. To select the lines indicated by the *Pattern* parameter in step 4, type:

   ```
   g
   ```

   OR

   To select the lines *not* indicated by the *Pattern* parameter in step 4, type:

   ```
   v
   ```
3. To enter the text you want to search, type the following subcommand:

   ```
   /Pattern/s
   ```

where the *Pattern* parameter is the text you want to search.

4. Type one of the following commands to make the desired deletion:

   To delete the first instance of the *Pattern* parameter within each selected line, type:

   ```
   ///
   ```

   To delete every instance of the *Pattern* parameter within each selected line, type:

   ```
   ///g
   ```

   To delete the first specified number of occurrences of the *Pattern* parameter on each selected line (where the *Number* parameter is an integer), type:

   ```
   ///Number
   ```

   To delete the first character string indicated by the *OtherPattern* parameter within each line selected by the *Pattern* parameter (where the *OtherPattern* parameter is the pattern you want to search), type:

   ```
   /OtherPattern//
   ```

   To delete every instance of the *OtherPattern* parameter within each line selected by the *Pattern* parameter, type:

   ```
   /OtherPattern//g
   ```

   To delete the first specified number of occurrences of the *OtherPattern* parameter on each line selected by the *Pattern* parameter (where the *Number* parameter is an integer), type:

   ```
   /OtherPattern//Number
   ```

5. If you want to display the deletion, type one of the following optional subcommands:

   l

   n

   p

6. Press Enter.

For example, to delete all instances of a pattern from *a range of lines*, type:

```
38,$g/tmp/s/gn
```

The previous example searches all the lines from line 38 to the last line (`38,$`) for the `tmp` character string and deletes every instance (`/g`) of that character string within those lines. It then displays the lines that had text deleted from them and their line numbers (`n`).

To delete all instances of a pattern from *all lines* that contain that pattern, type:

```
g/rem/s///gl
```

The previous example searches the entire file (address parameter is omitted) for all lines that contain (`g`) the `rem` character string. It deletes all instances (`///g`) of the `rem` character string from each of those lines and then displays the lines that had text deleted from them, including the nonprinting characters in those lines (`l`).

To Delete Text from Addressed Lines

1. Type the following subcommand:

   ```
   Addresss/Pattern
   ```

Note: The *Address* parameter is followed by the **s** subcommand, where the *Address* parameter is the line number, range of line numbers, or symbolic address of the lines from which you want to delete the pattern, and the *Pattern* parameter is a character string or regular expression that represents the text you want to delete.

2. To delete the *first instance* of the pattern from each line, type:

```
//
```

   OR

   To delete *every instance* of the pattern from each line, type:

```
//g
```

3. If you want to display the deletion, type one of the following optional subcommands:

   l

   n

   p

4. Press Enter.

To Delete Text from Lines That Contain a Specified Pattern

1. Type the following subcommand:

```
[Address]g/Pattern/s
```

   where *Address* is an optional parameter that specifies the line number, range of line numbers, or symbolic address of the lines that contains a specified pattern, and the *Pattern* parameter is a character string or regular expression that represents the text you want to find and delete. If you omit the *Address* parameter, the ed editor searches all lines in the file for the pattern.

2. To delete the *first instance* of the pattern from each line that contains it, type:

```
///
```

   OR

   To delete *every instance* of the pattern from each line that contains it, type:

```
///g
```

3. If you want to display the deletion, type one of the following optional subcommands:

   l

   n

   p

4. Press Enter.

To Delete a Pattern from Lines That Contain a Different Specified Pattern

1. Type the following subcommand:

```
[Address]g/SearchPattern/s
```

   where *Address* is an optional parameter that specifies the line number, range of line numbers, or symbolic address of the lines that contains a specified pattern, and the *SearchPattern* parameter is a character string or regular expression that represents text that is in the lines you want to change. If you omit the *Address* parameter, the ed editor searches all lines in the file for the specified pattern.

2. To specify the text you want to delete, type:

```
/DeletePattern/
```

3. To delete the *first instance* of the pattern from each line, type:

```
/
```

OR

To delete *every instance* of the pattern from each line, type:

```
/g
```

Note: The entire subcommand string looks like this:

```
[Address]g/SearchPattern/s/DeletePattern//[g]
```

4. If you want to display the deletion, type one of the following optional subcommands:

l

n

p

5. Press Enter.

For example, to delete the first instance of a pattern from lines that contain a different specified pattern, type:

```
1,.g/rem/s/tmp//l
```

The previous example searches from the first line to the current line (`1,.`) for all lines that contain (g) the `rem` character string. It deletes the first instance of the `tmp` character string from each of those lines (/), then displays the lines that had text deleted from them, including the nonprinting characters in those lines (l).

To Delete a Pattern from Lines That Do Not Contain a Different Specified Pattern

1. Type the following subcommand:

```
[Address]v/SearchPattern/s
```

where *Address* is an optional parameter that specifies the line number, range of line numbers, or symbolic address of the lines that contains a specified pattern, and the *SearchPattern* parameter is a character string or regular expression that represents text that is not in the lines you want to find and change. If you omit the *Address* parameter, the ed editor searches all lines in the file for the specified pattern.

2. To specify the text you want to delete, type:

```
/DeletePattern/
```

3. To delete the *first instance* of the pattern, type:

```
/
```

OR

To delete *every instance* of the pattern from each line, type:

```
/g
```

Note: The entire subcommand string looks like this:

```
[Address]v/SearchPattern/s/DeletePattern//[g]
```

4. If you want to display the deletion, type one of the following optional subcommands:

   l

   n

   p

5. Press Enter.

For example, to delete the first instance of a pattern from lines that do not contain a specified pattern, type:

```
1,.v/rem/s/tmp//l
```

The previous example searches from the first line to the current line (`1,.`) for all lines that do not contain (v) the `rem` character string. It deletes the first instance of the `tmp` character string from each of those lines (/), then displays the lines that had text deleted from them, including the nonprinting characters in those lines (`l`).

Displaying Text

Item	Description
(.,.)**l**	The **l** (list) subcommand writes the addressed lines to standard output in a visually unambiguous form and writes the characters `\\\`, `\\a`, `\\b`, `\\f`, `\\r`, `\\t`, and `\\v` in the corresponding escape sequence. The **l**subcommand writes nonprintable characters as one 3-digit octal number, with a preceding \ (backslash) for each byte in the character (most significant byte first). The **l** subcommand wraps long lines, and you can indicate the wrap point by writing the \ (backslash)/new-line character sequence. Wrapping occurs at the 72nd column position. The $ (dollar sign) marks the end of each line. You can append the **l** subcommand to any ed editor subcommand except the **e**, **E**, **f**, **q**, **Q**, **r**, **w**, or **!** subcommand. The current line number is set to the address of the last line written.
(.,.)**n**	The **n** (number) subcommand displays the addressed lines, each preceded by its line number and a tab character (displayed as blank spaces); **n** sets the current line to the last line displayed. You can append the **n** subcommand to any ed editor subcommand except **e**, **f**, **r**, or **w**. For example, the **dn** subcommand deletes the current line and displays the new current line and line number.
(.,.)**p**	The **p** (print) subcommand displays the addressed lines and sets the current line to the last line displayed. You can append the **p** subcommand to any ed editor subcommand except **e**, **f**, **r**, or **w**. For example, the **dp** subcommand deletes the current line and displays the new current line.
(.)**=**	Without an address, the **=** (equal sign) subcommand displays the current line number. When preceded by the $ address, the **=** subcommand displays the number of the last line in the buffer. The **=** subcommand does not change the current line and cannot be appended to a **g** subcommand or **v** subcommand.

When you search for lines that contain or do not contain a specified pattern, you can select a range of line numbers to search. You can select and display one line or a group of lines in an ed editor file several different ways. Use the preceding format to perform the following editing tasks:

- Displaying an addressed line or group of lines
- Displaying an addressed line or group of lines and their nonprinting characters
- Displaying an addressed line or group of lines and their line numbers

- Displaying lines that contain a search pattern
- Displaying lines that contain a search pattern, including their nonprinting characters
- Displaying lines that contain a search pattern, including their line numbers
- Displaying lines that do not contain a search pattern
- Displaying lines that do not contain a search pattern, including their nonprinting characters
- Displaying lines that do not contain a search pattern, including their line numbers

To Display an Addressed Line or Group of Lines

Type the following subcommand:

```
Addressp
```

where the *Address* parameter is the line number or symbolic address of the lines you want to display.

The line or lines addressed are displayed on the screen. If the group of lines is too long to fit on the screen, the ed editor displays as many as will fit, beginning with the first line addressed.

To Display an Addressed Line or Group of Lines and Their Nonprinting Characters

Type the following subcommand:

```
Addressl
```

where the *Address* parameter is the line number or symbolic address of the lines you want to display.

The line or lines addressed and their nonprinting characters are displayed on the screen. If the group of lines is too long to fit on the screen, the ed editor displays as many as will fit, beginning with the first line addressed.

To Display an Addressed Line or Group of Lines and Their Line Numbers

Type the following subcommand:

```
Addressn
```

where the *Address* parameter is the line number or symbolic address of the lines you want to display.

The line or lines addressed are displayed on the screen. The line number for each line is displayed beside the line. If the group of lines is too long to fit on the screen, the ed editor displays as many as will fit, beginning with the first line addressed.

To Display Lines That Contain a Search Pattern

Type the following subcommand:

```
Addressg/Pattern/p
```

where the *Address* parameter is the range of lines and the *Pattern* parameter is the character string or regular expression that you want to search.

The line or lines that contain the specified pattern are displayed on the screen. If the group of lines is too long to fit on the screen, the ed editor displays as many as will fit, beginning with the first line addressed.

To Display Lines That Contain a Search Pattern, Including Their Nonprinting Characters

Type the following subcommand:

```
[Address]g/Pattern/l
```

where *Address* is an optional parameter that specifies the range of lines and the *Pattern* parameter is the character string or regular expression that you want to search. If you omit the *Address* parameter, the ed editor searches the entire file.

The line or lines that contain the specified pattern are displayed on the screen. Nonprinting characters show up in the display. If the group of lines is too long to fit on the screen, the ed editor displays as many as will fit, beginning with the first line addressed.

To Display Lines That Contain a Search Pattern, Including Their Line Numbers

Type the following subcommand:

```
[Address]g/Pattern/n
```

where *Address* is an optional parameter that specifies the range of lines and the *Pattern* parameter is the character string or regular expression that you want to search. If you omit the *Address* parameter, the ed editor searches the entire file.

The line or lines that contain the specified pattern are displayed on the screen. The line number for each line is displayed beside the line. If the group of lines is too long to fit on the screen, the ed editor displays as many as will fit, beginning with the first line addressed.

To Display Lines That Do Not Contain a Search Pattern

Type the following subcommand:

```
[Address]v/Pattern/p
```

where *Address* is an optional parameter that specifies the range of lines and the *Pattern* parameter is the character string or regular expression that you want to search. If you omit the *Address* parameter, the ed editor searches the entire file.

The line or lines that do not contain the specified pattern are displayed on the screen. If the group of lines is too long to fit on the screen, the ed editor displays as many as will fit, beginning with the first line addressed.

To Display Lines That Do Not Contain a Search Pattern, Including Their Nonprinting Characters

Type the following subcommand:

```
[Address]v/Pattern/l
```

where *Address* is an optional parameter that specifies the range of lines and the *Pattern* parameter is the character string or regular expression that you want to search. If you omit the *Address* parameter, the ed editor searches the entire file.

The line or lines that do not contain the specified pattern are displayed on the screen, including the nonprinting characters. If the group of lines is too long to fit on the screen, the ed editor displays as many as will fit, beginning with the first line addressed.

To Display Lines That Do Not Contain a Search Pattern, Including Their Line Numbers

Type the following subcommand:

```
[Address]v/Pattern/n
```

where *Address* is an optional parameter that specifies the range of lines and the *Pattern* parameter is the character string or regular expression that you want to search. If you omit the *Address* parameter, the ed editor searches the entire file.

The line or lines that do not contain the specified pattern are displayed on the screen, along with their line numbers. If the group of lines is too long to fit on the screen, the ed editor displays as many as will fit, beginning with the first line addressed.

Joining and Splitting Lines

Item	Description
(.,.+1)**j** [**l**] [**n**] [**p**]	The **j** (join) subcommand joins contiguous lines by removing the intervening new-line characters. If given only one address, the **j** subcommand does nothing. Type the **l** (list), **n** (number), or **p** (print) subcommand if you want to display the joined lines. These subcommands are optional.

The ed editor provides several ways to join or split a line. Use the preceding format to perform the following editing tasks:

- Joining the current and next lines
- Joining addressed lines
- Splitting the current line
- Splitting an addressed line

To Join the Current and Next Lines

Type the following subcommand:

```
j[l][n][p]
```

where **l**, **n**, and **p** are optional subcommands that display the joined lines.

To Join Addressed Lines

Type the following subcommand:

```
Addressj[l][n][p]
```

where the *Address* parameter is a set of contiguous lines that will form one line, and **l**, **n**, and **p** are optional subcommands that display the joined lines.

To Split the Current Line

1. To split the current line after a specified pattern, type the following subcommand:

   ```
   s/Pattern/Pattern\
   ```

   where the *Pattern* parameter is the character string that you want to split the line after.

   Note: Make sure that both strings represented by the *Pattern* parameter are exactly alike.
2. Press Enter.
3. Type the following backslash:

   ```
   /
   ```
4. To display the split line, type one of the following optional subcommands:

   l

   n

   p
5. Press Enter.

To Split an Addressed Line

1. To split an addressed line after a specified pattern, type the following subcommand:

   ```
   Addresss/Pattern/Pattern\
   ```

where the *Address* parameter is the address of the line to split, and the *Pattern* parameter is the character string to split the line after.

Note: Make sure that both strings represented by the *Pattern* parameter are exactly alike.

2. Press Enter.
3. Type the following backslash:

```
/
```

4. To display the split line, type one of the following optional subcommands:

   l

   n

   p

5. Press Enter.

Making Global Changes

Item	Description
(1,$)**g/***Pattern***/***SubcommandList* [**l**] [**n**] [**p**]	The **g** (global) subcommand first marks every line that matches the *Pattern* parameter. The pattern can be a fixed character string or a regular expression. Then, for each marked line, this subcommand sets the current line to the marked line and runs the *SubcommandList* parameter. Enter a single subcommand or the first subcommand of a list of subcommands on the same line with the **g** subcommand; enter subsequent subcommands on separate lines. Except for the last line, each of the lines should end with a \ (backslash). The *SubcommandList* parameter can include the **a**, **i**, and **c** subcommands and their input. If the last command in the *SubcommandList* parameter would usually be the . (period) that ends input mode, the . (period) is optional. If no *SubcommandList* parameter exists, the current line is displayed. The *SubcommandList* parameter cannot include the **g** , **G**, **v**, or **V** subcommand. Type the **l** (list), **n** (number), or **p** (print) subcommand if you want to display the changes. These subcommands are optional. **Note:** The **g** subcommand is similar to the **v** subcommand, which runs the *SubcommandList* parameter for every line that does not contain a match for the pattern.
(1,$)**G/***Pattern***/** [**l**] [**n**] [**p**]	The interactive **G** (Global) subcommand marks every line that matches the *Pattern* parameter, displays the first marked line, sets the current line to that line, and then waits for a subcommand. A pattern can be a fixed character string or a regular expression. The **G** subcommand does not accept the **a**, **i**, **c**, **g**, **G**, **v**, and **V** subcommands. After the subcommand finishes, the **G** subcommand displays the next marked line, and so on. The **G** subcommand takes a new-line character as a null subcommand. A :& (colon ampersand) causes the **G** subcommand to run the previous subcommand again. You can stop the **G** subcommand by pressing Ctrl+C. Type the **l** (list), **n** (number), or **p** (print) subcommand if you want to display the changes. These subcommands are optional.

Item	Description
(1,$)**v/***Pattern***/***SubcommandList* [**l**] [**n**] [**p**]	The **v** subcommand runs the subcommands in the *SubcommandList* parameter for each line that does not contain a match for the *Pattern* parameter. A pattern can be a fixed character string or a regular expression. Type the **l** (list), **n** (number), or **p** (print) subcommand if you want to display the changes. These subcommands are optional. The **v** subcommand does not accept the **a**, **i**, **c**, **g**, **G**, and **V** subcommands. **Note:** The **v** subcommand complements the **g** subcommand, which runs the *SubcommandList* parameter for every line that contains a match for the pattern.
(1,$)**V/***Pattern*/ [**l**] [**n**] [**p**]	The **V** subcommand marks every line that does not match the *Pattern* parameter, displays the first marked line, sets the current line to that line, and then waits for a subcommand. A pattern can be a fixed character string or a regular expression. Type the **l** (list), **n** (number), or **p** (print) subcommand if you want to display the changes. These subcommands are optional. The **V** subcommand does not accept the **a**, **i**, **c**, **g**, **G**, and **v** subcommands. **Note:** The **V** subcommand complements the **G** subcommand, which marks the lines that match the pattern.

Marking Text

Item	Description
(.)**k***x* [**l**] [**n**] [**p**]	The **k** (mark) subcommand marks the addressed line with the name specified by the *x* parameter, which must be a lowercase ASCII letter. The address '*x* (single quotation mark before the marking character) then addresses this line. The **k** subcommand does not change the current line. Type the **l** (list), **n** (number), or **p** (print) subcommand if you want to display the marked text. These subcommands are optional.

To Mark the Current Line

Type the following subcommand:

```
kLetter[l][n][p]
```

where the *Letter* parameter is the letter *a* through *z* for a mark, and **l**, **n**, and **p** are optional subcommands that display the marked text.

To Mark an Addressed Line

Type the following subcommand:

```
AddresskLetter[l][n][p]
```

where the *Address* parameter is the line number or symbolic address of the line you want to mark, and the *Letter* parameter is the letter *a* through *z* for a mark. The **l**, **n**, and **p** optional subcommands display the marked text.

Moving Text

Item	Description
(.,.)**m***A* [**l**] [**n**] [**p**]	The **m** (move) subcommand repositions the addressed line or lines. The first moved line follows the line addressed by the *A* parameter. A parameter of 0 moves the addressed line or lines to the beginning of the file. The address specified by the *A* parameter cannot be one of the lines to be moved. The **m** subcommand sets the current line to the last moved line. Type the **l** (list), **n** (number), or **p** (print) subcommands if you want to display the deletion. These subcommands are optional.

Moving a line or a set of lines deletes the specified lines from their original location and places them in a new location. You can select which lines to move by address or pattern. Use the preceding format to perform the following editing tasks:

- Moving the current line
- Moving lines specified by address
- Moving lines that contain a specified pattern
- Moving lines that do not contain a specified pattern

To Move the Current Line

Type the following subcommand:

```
mAddress[l][n][p]
```

where the *Address* parameter is the line number or symbolic address of the line you want the current line to follow, and **l**, **n**, and **p** are optional subcommands that display the moved line.

To Move Lines Specified by Address

Type the following subcommand:

```
LineNumbermDestinationAddress[l][n][p]
```

where the *LineNumber* parameter is the address of the lines you want to move, and the *DestinationAddress* parameter is the line you want the moved lines to follow. The **l**, **n**, and **p** optional subcommands display the moved lines.

To Move Lines That Contain a Specified Pattern

Type the following subcommand:

```
[Address]g/Pattern/m[DestinationAddress][l][n][p]
```

where *Address* is an optional parameter that specifies the range of lines to search for lines that contain the specified pattern, the *Pattern* parameter is the text you are searching for, and *DestinationAddress* is an optional parameter that represents the line you want the moved lines to follow. The **l**, **n**, and **p** optional subcommands display the moved lines.

If you omit the *Address* parameter, the ed editor searches the entire file for lines that contain the pattern. If you omit the *DestinationAddress* parameter, the moved text is placed after the current line.

To Move Lines That Do Not Contain a Specified Pattern

Type the following subcommand:

```
[Address]v/Pattern/m[DestinationAddress][l][n][p]
```

where *Address* is an optional parameter that specifies the range of lines to search for lines that do not contain the specified pattern, the *Pattern* parameter is the text, and *DestinationAddress* is an

optional parameter that represents the line you want the moved text to follow. The **l**, **n**, and **p** optional subcommands display the moved lines.

If you omit the *Address* parameter, the ed editor searches the entire file for lines that do not contain the pattern. If you omit the *DestinationAddress* parameter, the moved text is placed after the current line.

Saving Text

Item	Description
(1,$)**w** *File*	The **w** (write) subcommand copies the addressed lines from the buffer to the file specified by the *File* parameter. If the file does not exist, the **w** subcommand creates it with permission code 666 (read and write permission for everyone), unless the **umask** setting specifies another file creation mode. The **w** subcommand does not change the default file name (unless the *File* parameter is the first file name used since you started the ed editor). If you do not provide a file name, the **w** subcommand uses the default file name. The **w** subcommand does not change the current line. If the ed editor successfully writes the file from the buffer, it displays the number of characters written. If you specify the **!** *Command* subcommand instead of a file name, the **w** subcommand reads the output of the operating system command specified by the *Command* parameter. The **w** subcommand does not save the name of the operating system command you specified as a default file name. **Note:** Because 0 is not a legal address for the **w** subcommand, you cannot create an empty file with the **ed** command.

You can save changes to a file in several ways. Use the preceding format to perform the following actions:

- Saving a file to the current file
- Saving part of a file to the current file
- Saving a file to a different file
- Saving part of a file to a different file

To Save a File to the Current File

Type the following subcommand:

```
w
```

The current file is saved under its current name, and the ed editor displays the number of characters written.

To Save Part of a File to the Current File

Type the following subcommand:

```
Addressw
```

where the *Address* parameter specifies the line or group of lines to write. The ed editor displays the number of characters written.

To Save a File to a Different File

Type the following subcommand:

```
w File
```

where the *File* parameter is the name of the file to write to.

The current file is saved to the file specified by the *File* parameter. The ed editor displays the number of characters written.

To Save Part of a File to a Different File

Type the following subcommand:

```
Addressw File
```

where the *Address* parameter specifies the line or group of lines to write and the *File* parameter specifies the file to write to.

The specified lines are saved to the file specified by the *File* parameter. The ed editor displays the number of characters written.

Searching Text

You can search forward or backward from the current line for a pattern of text. The pattern can be a character string or a regular expression made up of literal characters and the special characters ^ (circumflex), $ (dollar sign), . (period), [(left bracket),] (right bracket), * (asterisk), \ (backslash), % (percent sign), and the & key.

You can use the ed editor to perform the following text searches:

- Searching forward
- Searching backward
- Repeating a search in the same direction
- Repeating a search in the opposite direction

To Search Forward

Type the following subcommand:

```
/Pattern
```

where the *Pattern* parameter is a character string or regular expression that specifies the text to search for.

The cursor moves to the first character of the text specified by the pattern.

To Search Backward

Type the following subcommand:

```
?Pattern
```

where the *Pattern* parameter is a character string or regular expression that specifies the text to search for.

The cursor moves to the first character of the text specified by the pattern.

To Repeat a Search in the Same Direction

Type the following subcommand:

```
/
```

The cursor moves to the first character of the closest instance of the text specified by the pattern in the last search command.

To Repeat a Search in the Opposite Direction

Type the following subcommand:

```
?
```

The cursor moves to the first character of the closest instance of the text specified by the pattern in the last search command.

Substituting Text

Item	Description
(.,.)**s/***Pattern***/***Replacement***/** [**l**] [**n**] [**p**] (.,.)**s/***Pattern***/** *Replacement***/ng** [**l**] [**n**] [**p**]	The **s** (substitute) subcommand searches each addressed line for a string that matches the *Pattern* parameter and replaces the string with the specified *Replacement* parameter. A pattern can be a fixed character string or a regular expression. Without the global subcommand (**g**), the **s** subcommand replaces only the first matching string on each addressed line. With the **g** subcommand, the **s** subcommand replaces every occurrence of the matching string on each addressed line. If the **s** subcommand does not find a match for the pattern, it returns the error message ? (question mark). Type the **l** (list), **n** (number), or **p** (print) subcommand to display the substituted text. These subcommands are optional. **Note:** Any character except a space or a new-line character can separate (delimit) the *Pattern* and *Replacement* parameters. The **s** subcommand sets the current line to the last line changed. If the *Number* parameter (an integer) is specified, then the first number that matches strings in each addressed line is replaced. An & (ampersand) character used in the *Replacement* parameter has the same value as the *Pattern* parameter. For example, the subcommand **s/are/&n't/** has the same effect as the subcommand **s/are/aren't/** and replaces **are** with **aren't** on the current line. A \& (backslash, ampersand) removes the special meaning of the & character in the *Replacement* parameter. A subpattern is part of a pattern enclosed by the strings \((backslash, left parenthesis) and \) (backslash, right parenthesis); the pattern works as if the enclosing characters were not present. In the *Replacement* parameter, *Number* refers to strings that match subpatterns. For example, the **s/\(t\)\(h\) \(e\)/t\1\2ose)** subcommand replaces **the** with **those** if a match for the pattern **the** exists on the current line. Whether subpatterns are nested or in a series, *Number* refers to the occurrence specified by the *Number* parameter, counting from the left of the delimiting characters, \) (backslash, right parenthesis). The % (percent sign), when used alone as the *Replacement* parameter, causes the **s** subcommand to repeat the previous *Replacement* parameter. The % does not have this special meaning if it is part of a longer *Replacement* parameter or if it is preceded by a \ (backslash). You can split lines by substituting new-line characters into them. In the *Replacement* parameter. Pressing the \+Enter key sequence quotes the new-line character (not displayed) and moves the cursor to the next line for the remainder of the string. New-line characters cannot be substituted as part of a **g** subcommand or **v** subcommand list.

The ed editor provides several ways to substitute text. Use the preceding format to perform the following editing tasks:

- Substituting text within the current line
- Substituting text within an addressed line or group of lines

- Substituting a specified pattern within lines that contain that pattern
- Substituting a pattern within lines that contain a different pattern
- Substituting a pattern within lines that do not contain a different pattern

To Substitute Text within the Current Line

1. Type the following subcommand:

   ```
   s/OldString/NewString
   ```

   where the *OldString* parameter is the existing text and the *NewString* parameter is the text you want to substitute for it.
2. Type one of the following actions:

   To substitute the *NewString* parameter for the first instance of the *OldString* parameter within the current line, type:

   ```
   /
   ```

   To substitute the *NewString* parameter for every instance of the *OldPattern* parameter within the current line, type:

   ```
   /g
   ```
3. To display the changed text, type one of the following optional subcommands:

   l

   n

   p
4. Press Enter.

To Substitute Text within an Addressed Line or Group of Lines

1. Type the following subcommand:

   ```
   Addresss/OldPattern/NewString
   ```

   where the *Address* parameter is the address of the line or group of lines where you want to substitute text, the *OldPattern* parameter is the existing text, and the *NewString* parameter is the text you want to substitute.
2. Type one of the following actions:

   To substitute the *NewString* parameter for the first instance of the *OldPattern* parameter within each line, type:

   ```
   /NewString/
   ```

   To substitute the *NewString* parameter for every instance of the *OldPattern* parameter within each line, type:

   ```
   /NewString/g
   ```

   To substitute the *NewString* parameter for the first instance of the *NumberOldPattern* parameter on each address line, type:

   ```
   /NewString/Number
   ```
3. To display the changed text, type one of the following optional subcommands:

   l

n

p

4. Press Enter.

To Substitute a Specified Pattern within Lines That Contain That Pattern

1. Type the following subcommand:

```
Addressg/Pattern/s//NewString
```

where the *Address* parameter is the address of the group of lines that you want to search for the pattern specified with the *Pattern* parameter, and the *NewString* parameter is the text you want to substitute for the *Pattern* parameter.

2. Type one of the following actions:

To substitute the *NewString* parameter for the first instance of the *Pattern* parameter within each line, type:

```
/
```

To substitute the *NewString* parameter for every instance of the *Pattern* parameter within each line, type:

```
/g
```

3. To display the changed text, type one of the following optional subcommands:

l

n

p

4. Press Enter.

To Substitute a Pattern within Lines That Contain a Different Pattern

1. Type the following subcommand:

```
Addressg/Pattern/s/OldString/NewString
```

where the *Address* parameter is the address of the group of lines that you want to search for the pattern specified with the *Pattern* parameter, the *OldString* parameter is the text you want to replace, and the *NewString* parameter is the text you want to substitute in place of the *OldString* parameter.

2. Type one of the following actions:

To substitute the *NewString* parameter for the first instance of the *OldString* parameter within each line that contains the *Pattern* parameter, type:

```
/
```

To substitute the *NewString* parameter for every instance of the *OldString* parameter within each line that contains the *Pattern* parameter, type:

```
/g
```

3. To display the changed text, type one of the following optional subcommands:

l

n

p

4. Press Enter.

To Substitute a Pattern within Lines That Do Not Contain a Different Pattern

1. Type the following subcommand:

```
Addressv/Pattern/s/OldString/NewString
```

   where the *Address* parameter is the address of the group of lines that you want to search for the pattern specified with the *Pattern* parameter, the *OldString* parameter is the text you want to replace, and the *NewString* parameter is the text you want to substitute in place of the *OldString* parameter.
2. Type one of the following actions:

   To substitute the *NewString* parameter for the first instance of the *OldString* parameter within each line that does not contain the *Pattern* parameter, type:

```
/
```

   To substitute the *NewString* parameter for every instance of the *OldString* parameter within each line that does not contain the *Pattern* parameter, type:

```
/g
```

3. To display the changed text, type one of the following optional subcommands:

   l

   n

   p
4. Press Enter.

Undoing Text Changes

Item	Description
u [**l**] [**n**] [**p**]	The **u** (undo) subcommand restores the buffer to the state it was in before it was last modified by an ed editor subcommand. The **u** subcommand cannot undo the **e**, **f**, and **w** subcommands. Type the **l** (list), **n** (number), or **p** (print) subcommand if you want to display the changes. These subcommands are optional.

To Undo Text Changes

Type the following subcommand:

```
u[l][n][p]
```

where **l**, **n**, and **p** are optional subcommands that display the changes. All add, change, move, copy, or delete editing functions performed to the text after the last save are undone.

Manipulating Files

You can use ed editor subcommands to manipulate files to perform the following tasks:

- Adding another file to the current file
- Changing the default file name
- Editing additional files

Adding Another File to the Current File

Item	Description
($)**r** *File*	The **r** (read) subcommand reads a file into the buffer after the addressed line. The **r** subcommand does not delete the previous contents of the buffer. When entered without the *File* parameter, the **r** subcommand reads the default file, if any, into the buffer. The **r** subcommand does not change the default file name. A 0 address causes the **r** subcommand to read a file in at the beginning of the buffer. After it reads a file successfully, the **r** subcommand displays the number of characters read into the buffer and sets the current line to the last line read. If ! (exclamation point) replaces the *File* parameter in an **r** subcommand, the rest of the line is taken as an operating system shell command whose output is to be read. The **r** subcommand does not store the names of operating system commands as default file names.

To Insert a File after the Current Line

Type the following subcommand:

```
r File
```

where the *File* parameter is the name of the file to be inserted.

The ed editor reads the file specified by the *File* parameter into the current file after the current line and displays the number of characters read into the current file.

To Insert a File after a Line Specified by Address

Type the following subcommand:

```
Addressr File
```

where the *Address* parameter specifies the line that you want the inserted file to follow, and the *File* parameter is the name of the file to be inserted.

The ed editor reads the file specified by the *File* parameter into the current file after the specified line and displays the number of characters read into the current file.

Changing the Default File Name

Item	Description
f [*File*]	The **f** (file name) subcommand changes the default file name (the stored name of the last file used) to the name specified by the *File* parameter. If a *File* parameter is not specified, the **f** subcommand displays the default file name. (The **e** subcommand stores the default file name.)

To Display the Name of a File

Type the following subcommand:

```
f
```

The ed editor displays the name of the file in the edit buffer.

To Name a File

Type the following subcommand:

```
f File
```

where the *File* parameter is the new name for the file in the edit buffer.

The file in the edit buffer is renamed.

Editing Additional Files

Item	Description
e *File*	The **e** (edit) subcommand first deletes any contents from the buffer, sets the current line to the last line of the buffer, and displays the number of characters read into the buffer. If the buffer has been changed since its contents were saved (with the **w** subcommand), the ed editor displays a ? (question mark) before it clears the buffer. The **e** subcommand stores the *File* parameter as the default file name to be used, if necessary, by subsequent **e**, **r**, or **w** subcommands. (To change the name of the default file name, use the **f** subcommand.) When an ! (exclamation point) replaces the *File* parameter, the **e** subcommand takes the rest of the line as an operating system shell command and reads the command output. The **e** subcommand does not store the name of the shell command as a default file name.
E *File*	The **E** (Edit) subcommand works like the **e** subcommand with one exception; the **E** subcommand does not check for changes made to the buffer after the last **w** subcommand. Any changes you made before re-editing the file are lost.

You can use the **e** or **E** subcommands to perform the following tasks:

- Re-editing the current file without saving it
- Re-editing the current file after saving it
- Editing a file after the current file Is saved
- Editing a file without saving the current file

To Re-Edit the Current File without Saving It

Type the following subcommand:

```
E
```

The ed editor displays the number of characters in the file. Any changes you made before re-editing the file are lost.

To Re-Edit the Current File after Saving It

Type the following subcommand:

```
e
```

The ed editor displays the number of characters in the file.

To Edit a File after the Current File Is Saved

Type the following subcommand:

```
e File
```

where the *File* parameter is the name of a new or existing file that you want to edit.

For an existing file, the ed editor displays the number of characters in the file. For a new file, the ed editor displays a ? (question mark) and the name of the file.

To Edit a File without Saving the Current File

Type the following subcommand:

```
E File
```

where the *File* parameter is the name of a new or existing file that you want to edit.

For an existing file, the editor displays the number of characters in the file. For a new file, the ed editor displays a ? (question mark) and the name of the file.

Miscellaneous Functions of the ed Editor Subcommands

You can use ed editor subcommands to perform the following tasks:

- Changing the prompt string
- Entering system commands
- Exiting the ed editor
- Requesting help

Changing the Prompt String

Item	Description
P	The **P** (Prompt) subcommand turns on or off the ed editor prompt string, which is represented by an * (asterisk). Initially, the **P** subcommand is turned off.

To Start or Stop Displaying the Prompt String

Type the following subcommand:

```
P
```

The ed editor prompt, an * (asterisk), is displayed or not displayed, depending on its previous setting.

Entering System Commands

Item	Description
! *Command*	The **!** subcommand allows you to run operating system commands without leaving the ed editor. Anything that follows the **!** subcommand on an ed editor subcommand line is interpreted as an operating system command. Within the text of that command string, the ed editor replaces the unescaped % (percent sign) with the current file name, if one exists. You can repeat the previous operating system command by entering an ! (exclamation point) after the **!** ed editor subcommand. If the operating system command interpreter (the **sh** command) expands the command string, the ed editor echoes the expanded line. The **!** subcommand does not change the current line.

You can use the **!** subcommand to perform the following actions:

- Running one operating system command
- Repeating an operating system command
- Running several operating system commands

To Run One Operating System Command

Type the following subcommand:

```
!Command
```

where the *Command* parameter specifies an operating system command usually entered at the prompt.

The command runs and displays its output. After the command completes, the editor displays an **!** (exclamation point).

To Repeat an Operating System Command

Type the following subcommand:

```
!
```

The previously run operating system command runs and displays its output. After the command completes, the editor displays an **!** (exclamation point).

To Run Several Operating System Commands

1. Type the following subcommand to display an operating system prompt:

   ```
   !sh
   ```

2. Type an operating system command.
3. Press Enter to run the command and display its output.
4. Repeat steps 2 and 3 to run more operating system commands.
5. Press Ctrl+D to return to command mode. The editor displays an **!** (exclamation point).

Exiting the ed Editor

Item	Description
q	The **q** (quit) subcommand exits the ed editor after checking whether the buffer has been saved to a file after the last changes were entered. If the buffer has not been saved to a file, the **q** subcommand displays the ? (question mark) message. Enter the **q** subcommand again to exit the ed editor anyway. The changes to the current file are lost.
Q	The **Q** (Quit) subcommand exits the ed editor without checking whether any changes were made since the buffer was saved to a file. Any changes made to the buffer since the last save are lost.

To Quit after Checking for Edits

1. Type the following subcommand:

   ```
   q
   ```

2. If the ed editor displays a ?, type one of the following subcommands:

   To save changes before quitting, type:

   ```
   w
   ```

   then press Enter.

   To quit without saving changes, type:

   ```
   q
   ```

3. Press Enter.

To Quit and Discard Edits

1. Type the following subcommand:

   ```
   Q
   ```

2. Press Enter. Any changes made to the buffer since the last save are lost.

Requesting Help

Item	Description
h	The **h** (help) subcommand provides a brief help message for the most recent ? diagnostic or error message displayed.
H	The **H** (Help) subcommand causes the ed editor to display help messages for all subsequent ? diagnostic messages. The **H** subcommand also explains the previous ? if one existed. The **H** subcommand alternately turns this mode on and off; it is initially off.

To Start or Stop Displaying Help Messages

Type the following subcommand:

```
H
```

The help messages are displayed or not displayed for ? responses from the ed editor, depending on the previous setting.

To Display the Last Help Message

Type the following subcommand:

```
h
```

A help message is displayed for the last ? response from the ed editor.

Character Class Support in the ed Editor

In standard *Patterns* expression, a range expression matches the set of all characters that fall between two characters in the collation sequence of the current locale. The syntax of the range expression is as follows:

```
[character-character]
```

The first character must be lower than or equal to the second character in the collation sequence. For example, [a-c] matches any of the characters a, b, or c in the En_US locale.

The range expression is commonly used to match a character class. For example, [0-9] is used to mean all digits, and [a-z A-Z] is used to mean all letters. This form may produce unexpected results when ranges are interpreted according to the collating sequence in the current locale.

Instead of the preceding form, use a character class expression within [ ] (brackets) to match characters. The system interprets this type of expression according to the character class definition in the current locale. However, you cannot use character class expressions in range expressions.

The syntax of a character class expression is as follows:

```
[:CharacterClass:]
```

That is, a left bracket, a colon, the name of the character class, another colon, and then a right bracket.

The following character classes are supported in all locales:

Item	Description
[:upper:]	Uppercase letters
[:lower:]	Lowercase letters
[:alpha:]	Uppercase and lowercase letters
[:digit:]	Digits
[:alnum:]	Alphanumeric characters
[:xdigit:]	Hexadecimal digits
[:punct:]	Punctuation character (neither a control character nor alphanumeric)
[:space:]	Space, tab, carriage return, new-line, vertical tab, or form feed character
[:print:]	Printable characters, including space
[:graph:]	Printable characters, not including space
[:cntrl:]	Control characters
[:blank:]	Space and tab characters

The brackets are part of the character class definition. To match any uppercase ASCII letter or ASCII digit, use the following regular expression:

```
[[:upper:] [:digit:]]
```

Do not use the expression `[A-Z0-9]`.

A locale may support additional character classes.

The newline character is part of the `[:space:]` character class but will not be matched by this character class. The newline character may only be matched by the special search characters $ (dollar sign) and ^ (caret).

Exit Status

The **ed** and **red** commands return the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

edit Command

Purpose

Provides a simple line editor for the new user.

Syntax

edit [**-r**] [*File* ...]

Description

The **edit** command starts a line editor designed for beginning users, a simplified version of the ex editor. The edit editor belongs to a family of editors that includes the ed editor, ex editor, and vi editor. Knowing about the edit editor can help you learn the more advanced features of the other editors. To edit the contents of a file, enter:

```
edit  File
```

When the file specified by the *File* parameter names an existing file, the **edit** command copies it to a buffer and displays the number of lines and characters in it. It then displays a **:** (colon) prompt to show that it is ready to read subcommands from standard input.

If the file specified in the *File* parameter does not already exist, the **edit** command indicates this information and creates the new file. You can specify more than one file name for the *File* parameter, in which case the **edit** command copies the first file into its buffer and stores the remaining file names in an argument list for later use. The edit editor does not make changes to the edited file until you use the **w** subcommand to write the changes.

The edit editor operates in one of the following two modes:

Item	Description
command mode	Recognizes and runs the edit editor subcommands. When you start the edit editor, it is in command mode. To enter command mode at other times, enter only a **.** (period) at the beginning of a line.

Item	Description
text input mode	Allows you to enter text into the edit editor buffer. Enter text input mode by using the **append (a)** subcommand, **change (c)** subcommand, or **insert (i)** subcommand. To end text input mode, enter only a **.** (period) at the beginning of a line.

Flags

Item	Description
-r	Recovers the file being edited after an editor or system malfunction.

Addressing Lines in a File

The edit editor uses the following three types of addresses:

- Line number addresses
- Relative position addresses
- Pattern addresses

Line Number Addresses

Line number addresses specify a line within a file by its line number or symbolic name. This method is the simplest way to address a line or lines.

To address the first line by its symbolic name, enter:

```
.
```

To address the last line by its symbolic name, enter:

```
$
```

You also can specify a range of lines by separating the line numbers or symbolic addresses with a comma or a semicolon. The second address must refer to a line that follows the first addressed line in the range.

For example:

```
1,5
```

addresses the lines 1 through 5.

```
.,$
```

addresses the first through the last lines.

Relative Position Addresses

The edit editor can address a line by its relative position to the current line. An address that begins with the -*Number* or +*Number* parameter addresses a line the specified number of lines before or after the current line, respectively.

For example:

```
+8
```

addresses 8 lines after the current line.

You can also address a line relative to the first or last line by using the symbolic names in combination with the -*Number* or +*Number* addresses.

For example:

```
.+3
```

addresses 3 lines after the first line, and:

```
$-10
```

addresses 10 lines before the last line.

Pattern Addresses

You can specify an address line by searching the buffer for a particular pattern. The edit editor searches forward or backward and stops at the first line that contains the match for the *Pattern* parameter. If necessary, the search wraps past the end or beginning of the buffer until it finds a match or returns to the current line.

To search forward, enter:

```
/Pattern/
```

To search backward, enter:

```
?Pattern?
```

You also can specify a range of lines by separating the *Pattern* parameters with a comma or a semicolon. The second address must refer to a line that follows the first addressed line in the range.

For example:

```
Pattern,Pattern
```

The following characters have special meanings when used as part of the *Pattern* parameter:

Item	Description
^	Matches the beginning of a line when used as the first character of the *Pattern* parameter.
$	Matches the end of a line when used as the last character of the *Pattern* parameter.

Using edit Editor Subcommands

The edit editor subcommands affect the current line, which is represented by a **.** (period). When you start the edit editor, the current line is the last line in the buffer. As the buffer is edited, the current line changes to the last line affected by a subcommand. To work with different parts of a file, you must know how to find the current line and how to address different lines in a file.

You can use the edit editor subcommands to perform the following tasks:

- Adding text
- Changing the name of the current file
- Changing text
- Deleting text
- Displaying the current file name and status
- Displaying text and finding the current line
- Editing additional files
- Ending and exiting the edit editor
- Making global changes
- Moving or copying text
- Saving a file after a system crash

- Saving text
- Substituting text
- Undoing a change

Adding Text

In the following subcommands, the *Address* parameter is optional. If you specify an address, do not type the brackets. You can use the full subcommand or its abbreviation, which is shown in parentheses.

Item	Description
[*Address*]**append** (**a**) *Text* **.**	Appends the text you type after the current line if you do not specify an *Address* parameter. You may need to find the current line or specify an address if you are not in the correct position in the buffer. If you specify an address, the **a** subcommand appends text after the specified line. If you specify a 0 address, the **a** subcommand places the text at the beginning of the buffer. Type the text, pressing the Enter key at the end of each line. When you have entered all the text, type a **.** (period) alone at the start of a line to end text input mode and return to command mode. You can use the **1,$p** subcommand to display the entire contents of the buffer. **Note:** The **a** subcommand differs from the **i** subcommand in the placement of text.
[*Address*]**insert** (**i**)*Text***.**	Inserts text before the current line if you do not specify an *Address* parameter. You may need to find the current line or specify an address if you are not in the correct position in the buffer. If you specify an address, the **i** subcommand inserts text before the specified line. You cannot specify a 0 address. Type your text, pressing the Enter key at the end of each line. When you have entered all your text, type a **.** (period) alone at the start of a line to end text input mode and return to command mode. You can use the **1,$p** subcommand to display the entire contents of the buffer. **Note:** The **i** subcommand differs from the **a** subcommand in the placement of text.

Changing the Name of the Current File

Item	Description
file *File*	Changes the name of the current file to the name specified by the *File* parameter. The edit editor does not consider this file to be edited.

Changing Text

In the following subcommand, the *Address* parameters are optional. If you specify an address, do not type the brackets. You can use the full subcommand or its abbreviation, which is shown in parentheses.

Item	Description
[*Address1*,*Address2*]**change** (**c**). *Text*	Replaces the current line with the text you type if you do not specify the *Address* parameters. You may need to find the current line or specify an address if you are not in the correct position in the buffer. If you specify an address, the **c** subcommand replaces the addressed line or lines. You can specify a range of lines by separating the addresses with a comma. Type your text, pressing the Enter key at the end of each line. When you have entered all your text, type a **.** (period) alone at the start of a line to end text input mode and return to command mode. You can use the **1,$p** subcommand to display the entire contents of the buffer. The last input line becomes the current line.

Deleting Text

In the following subcommand, the *Address* and *Buffer* parameters are optional. If you specify an address or buffer, do not type the brackets. You can use the full subcommand or its abbreviation, which is shown in parentheses.

Item	Description
[*Address1*,*Address2*] **delete** [*Buffer*] (**d**)	Deletes the current line if you do not specify the *Address* parameters. You may need to find the current line or specify an address if you are not in the correct position in the buffer. If you specify an address, the **d** subcommand deletes the addressed line or lines. You can specify a range of lines by separating the addresses with a comma. The line following the last deleted line becomes the current line. If you specify a buffer by giving a lowercase letter from a to z, the edit editor saves the addressed lines in that buffer. If you specify an uppercase letter, the ed editor appends the lines to that buffer. You can use the **pu** subcommand to put the deleted lines back into the buffer.

Displaying the Current File Name and Status

In the following subcommand, you can use the full subcommand or its abbreviation, which is shown in parentheses.

Item	Description
file (**f**)	Displays the current file name along with the following related information: • Whether the file was modified since the last **w** subcommand • Current line number • Number of lines in the buffer • Percentage of the buffer indicating the current line location

Displaying Text and Finding the Current Line

In the following subcommands, the *Address* parameters are optional. If you specify an address, do not type the brackets. You can use either the full subcommand or its abbreviation, which is shown in parentheses.

Item	Description
[*Address1*,*Address2*]**number** (**nu**)	Displays the addressed line or lines preceded by its buffer line number. If you do not specify the *Address* parameters, the **nu** subcommand displays the current line and number. If you specify an address, the **nu** subcommand displays the addressed line or lines. You can specify a range of lines by separating the addresses with a comma. The last line displayed becomes the current line.
[*Address1*,*Address2*]**print** (**p**)	Displays the addressed line or lines. If you do not specify the *Address* parameters, the **p** subcommand displays the current line. If you specify an address, the **p** subcommand displays the addressed line or lines. You can specify a range of lines by separating the addresses with a comma. The last line displayed becomes the current line.
[*Address*]**=**	Displays the line number of the addressed line. If you do not specify an *Address* parameter, the **=** subcommand displays the line number of the current line.
[*Address*]**z**	Displays a screen of text beginning with the addressed line. If an *Address* parameter is not specified, the **z** subcommand displays a screen of text beginning with the current line.
[*Address*]**z-**	Displays a screen of text with the addressed line at the bottom. If an *Address* parameter is not specified, the **z-** subcommand displays a screen of text with the current line at the bottom.
[*Address*]**z.**	Displays a screen of text with the addressed line in the middle. If an *Address* parameter is not specified, the **z.** subcommand displays a screen of text with the current line in the middle.

Editing Additional Files

In the following subcommand, you can use the full subcommand or its abbreviation, which is shown in parentheses.

Item	Description
edit *File* (**e**)	Begins an editing session on a new file specified by the *File* parameter. The editor first checks to see if the buffer was edited since the last **write (w)** subcommand. If the file was edited since the last **w** subcommand, the edit editor issues a warning and cancels the **e** subcommand. Otherwise, the edit editor deletes the contents of the editor buffer, makes the named file the current file, and displays the new file name. After insuring that this file can be edited, the edit editor reads the file into its buffer. If the edit editor reads the file without error, it displays the number of lines and characters that it read. The last line read becomes the new current line.
next (**n**)	Copies the next file named in the command line argument list to the buffer for editing.

Ending and Exiting the edit Editor

In the following subcommands, you can use the full subcommand or its abbreviation, which is shown in parentheses.

Item	Description
quit (**q**)	Ends the editing session after using the **write (w)** subcommand. If you have modified the buffer and have not written the changes, the edit editor displays a warning message and does not end the editing session.
quit! (**q!**)	Ends the editing session, discarding any changes made to the buffer since the last **w** subcommand.

Making Global Changes

In the following subcommand, the *Address* parameters are optional. If you specify an address, do not type the brackets. You can use the full subcommand or its abbreviation, which is shown in parentheses.

Item	Description
[*Address1*,*Address2*]**global/** *Pattern***/***SubcommandList* (**g**)	Marks each of the addressed lines that match the *Pattern* parameter. The edit editor then performs the list of subcommands specified in the *SubcommandList* parameter on each marked line. If you do not specify the *Address* parameters, the **g** subcommand works on the current line. You may need to find the current line or specify an address if you are not in the correct position in the buffer. If you specify an address, the **g** subcommand works on the addressed line or lines. You can specify a range of lines by separating the addresses with a comma. A single subcommand or the first subcommand in a subcommand list appears on same line as the **g** subcommand. The remaining subcommands must appear on separate lines, where each line (except the last) ends with a **** (backslash). The default subcommand is the **print (p)** subcommand. The subcommand list can include the **append (a)** subcommand, **insert (i)** subcommand, and **change (c)** subcommand, and their associated input. In this case, if the ending period is on the last line of the command list, you can omit it. **Note:** The **undo (u)** subcommand and the **g** subcommand cannot appear in the subcommand list.

Moving or Copying Text

In the following subcommands, the *Address1* and *Address2* parameters are optional. If you specify an address, do not type the brackets. You must specify the *Address3* parameter. You can use either the full subcommand or its abbreviation, which is shown in parentheses.

Item	Description
[*Address1,Address2*]**move** *Address3* (**m**)	Moves the current line after the line specified by the *Address3* parameter if you do not specify an address or an address range. You may need to find the current line or specify an address if you are not in the correct position in the buffer. If you specify an address, the **m** subcommand moves the addressed line or lines. You can specify a range of addresses by separating the addresses with a comma. The first of the moved lines becomes the current line.
[*Address1*,*Address2*]**yank** [*Buffer*] (**ya**)	Copies the specified line or lines into the *Buffer*, an optional parameter specified by a single alpha character a to z. You can use the **pu** subcommand to put these lines into another file.

Item	Description
[*Address*]**put** [*Buffer*] (**pu**)	Retrieves the contents of the specified *Buffer* parameter and places it after the current line if you do not specify an address. You may need to find the current line or specify an address if you are not in the correct position in the buffer. If you specify an address, the **pu** subcommand retrieves the contents of the specified buffer and places it after the addressed line. If you do not specify a *Buffer* parameter, the **pu** subcommand restores the last deleted or copied text. You can use the **pu** subcommand with the **delete (d)** subcommand to move lines within a file or with the **yank (ya)** subcommand to duplicate lines between files. You cannot use the **pu** and **ya** subcommands inside a macro.

Saving a File after a System Malfunction

Item	Description
preserve	Saves the current editor buffer as though the system had just malfunctioned. Use this subcommand when a **write (w)** subcommand has resulted in an error and you do not know how to save your work. Use the **recover** subcommand to recover the file.
recover *File*	Recovers the file specified by the *File* parameter from the system save area. Use this subcommand after a system crash or after a **preserve** subcommand.

Saving Text

In the following subcommand, the *Address* parameters are optional. If you specify an address, do not type the brackets. You can use the full subcommand or its abbreviation, which is shown in parentheses.

Item	Description
[*Address1*,*Address2*]**write** [*File*] (**w**)	Writes the entire contents of the buffer to the file specified by the *File* parameter if you do not specify an address. If you specify an address, the **w** subcommand writes the addressed line or lines to the file specified. You can specify a range of lines by separating the addresses with a comma. The edit editor displays the number of lines and characters that it writes. If you do not specify a file, the edit editor uses the current file name. If a *File* parameter does not exist, the editor creates one.

Substituting Text

In the following subcommand, the *Address* parameters are optional. If you specify an address, do not type the brackets. You can use either the full subcommand or its abbreviation, which is shown in parentheses.

Item	Description
[*Address1*,*Address2*] **substitute/***Pattern***/** *Replacement***/** (**s**)	Replaces the first instance of the specified *Pattern* parameter on each addressed line. You can replace every instance of the *Pattern* parameter by adding the **global (g)** subcommand to the end of the **s** subcommand.
[*Address1*,*Address2*] **substitute/***Pattern***/** *Replacement*/**g**	If you do not specify an address, the **s** subcommand works on the current line. You may need to find the current line or specify an address if you are not in the correct position in the buffer. If you specify an address, the **s** subcommand works on the addressed line or lines. You can specify a range of lines by separating the addresses with a comma.

Undoing a Change

In the following subcommand, you can use the full subcommand or its abbreviation, which is shown in parentheses.

Item	Description
undo (**u**)	Reverses the changes made in the buffer by the last buffer editing subcommand. You cannot undo a **write (w)** subcommand or an **edit (e)** subcommand. **Note:** The **global** subcommands are considered a single subcommand to a **u** subcommand.

edquota Command

Purpose

Edits user and group quotas.

Syntax

To Edit User Quotas

edquota [**-u**] [**-p** *Proto-UserName*] *UserName* ...

To Edit Group Quotas

edquota [**-g** [**-p** *Proto-GroupName*] *GroupName* ...]

To Edit Change User or Group Grace Period

edquota -t [**-u** | **-g**]

Description

The **edquota** command creates and edits quotas for JFS file systems.

The **edquota** command creates a temporary file that contains current disk quotas of each user and group. It determines the list of file systems with established quotas from the **/etc/filesystems** file. The **edquota** command also invokes the vi editor (or the editor specified by the **EDITOR** environment variable) on the temporary file so that quotas can be added and modified.

Note: If you specify an editor in the **EDITOR** environment variable, you must specify the full path name of the editor.

Quotas are maintained separately for each file system. When you create or edit a quota for a user or a group, the quota applies to a specific file system. A quota must be set in each file system where you want to use quotas.

By default, or when used with the **-u** flag, the **edquota** command edits the quotas of one or more users specified by the *UserName* parameter on the command line. When used with the **-g** flag, the **edquota**

command edits the quotas of one or more groups specified by the *GroupName* parameter. The **-p** flag identifies a prototypical user (*UserName*) or a prototypical group *(Proto-GroupName*) and duplicates these quotas for a specified user or group.

A user can exceed established soft limits for a default grace period of 1 week. Upon expiration of the grace period, the soft limit is enforced as a hard limit. The grace period can be specified in days, hours, minutes, or seconds. A value of 0 indicates that the default grace period is imposed; a value of 1 second indicates that no grace period is granted. The **-t** flag changes the grace period.

Fields displayed in the temporary file are:

Item	Description
Blocks in use	The current number of 1KB file system blocks used by this user or group.
Inodes in use	The current number of files used by this user or group.
Block soft limit	The number of 1KB blocks the user or group will be allowed to use during normal operations.
Block hard limit	The total amount of 1KB blocks the user or group will be allowed to use, including temporary storage during a quota grace period.
Inode soft limit	The number of files the user or group will be allowed to create during normal operations.
Inode hard limit	The total number of files the user or group will be allowed to create, including temporary files created during a quota grace period.

Note: A hard limit with a value of 1 indicates that no allocations are permitted. A soft limit with a value of 1, in conjunction with a hard limit with a value of 0, indicates that allocations are permitted only on a temporary basis.

When the editor is exited, the **edquota** command reads the temporary file and modifies the binary quota files to reflect any changes.

Hard or soft limits can only be specified in whole 1 KB block amounts.

Flags

Item	Description
-g	Edits the quotas of one or more specified groups.
-p	When invoked with the **-u** flag, duplicates the quotas established for a prototypical user for each specified user. When invoked with the **-g** flag, the **-p** flag duplicates the quotas established for a prototypical group for each listed group.
-t	Changes the grace period during which quotas can be exceeded before a soft limit is imposed as a hard limit. The default value of the grace period is 1 week. When invoked with the **-u** flag, the grace period is set for all file systems with user quotas specified in the **/etc/filesystems** file. When invoked with the **-g** flag, the grace period is set for all file systems with group quotas specified in the **/etc/filesystems** file. **Note:** After changing a grace period using the **edquota** command, the new grace period value will not go into effect until the **quota.user** and **quota.group** files are refreshed by running the **quotaoff** command followed by the **quotaon** command. Users who have already reached their old grace period must reduce their file system usage to a level below their soft limits in order to use the new grace period. In the future, when these users exceed their soft limits, the new grace period will be in effect.
-u	Edits the quotas of one or more users.

Note: If the user or group names contains all numbers then it will be treated as a user or group ID. Quotas will then be edited for the ID rather than the name.

Security

Item	Description
Access Control:	Only the root user can execute this command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

To create quotas for user `sharl`, using the quotas established for user `davec` as a prototype, enter:

```
edquota -u -p davec sharl
```

Files

Item	Description
quota.user	Specifies user quotas.
quota.group	Specifies group quotas.
/etc/filesystems	Contains file system names and locations.

efsenable Command

Purpose

Activates Encrypted File System (EFS) capability on a system.

Syntax

efsenable **-a** [**-v**] [**-k** <*algo*>] [**-f** <*cipher*>] [**-m** <*mode*>] [**-u** <yes|no>] [**-e** <*algo*>] [**-d** *Basedn*]

efsenable **-q**

Description

The **efsenable** command activates the EFS capability on a system. It creates the EFS administration keystore, the user keystore and the security group keystore. Keystore is a key repository that contains EFS security information. The access key to the EFS administration keystore is stored in the newly created active user's keystore and in the security group keystore. The **efsenable** command creates the **/var/efs** directory. The **/etc/security/user** and **/etc/security/group** files are updated with new EFS attributes. The **efsenable** command also updates the **Config_Rules** ODM database.

Note: The Crypto Library (CLiC) package **clic.rte** must be installed on the system for this command to succeed. This EFS command also requires that Role Based Access Control (RBAC) is enabled on the system, which is the default setting.

Note: The Crypto Library (CLiC) fileset **clic.rte.lib** needs to be minimally at 4.6 for AIX releases of **efsenable** 6.1 TL3 and later.

Flags

Item	Description
-a	Activates the EFS capability on a system.
-d *Basedn*	Sets up the base distinguished names (DN) ou=UsrKeystore, ou=GrpKeystore, ou=EfsCookies and ou=AdmKeystore on the LDAP server to facilitate for the keystore entries to be created along with the local directory structure for the keystore. The *Basedn* passed as argument along with this flag will be used as the *Basedn* for the keystore base distinguished names.
-v	Verbose mode.
-k *algo*	Default algorithm for keys. The *algo* flag can be one of the following values: • RSA_1024 (by default) • RSA_2048 • RSA_4096
-f *cipher*	Default cipher for files. The *cipher* flag can be one of the following values: • AES_128_CBC (by default) • AES_192_CBC • AES_256_CBC • AES_128_ECB • AES_192_ECB • AES_256_ECB
-m *mode*	Default mode for keystores. The *mode* flag can be one of the following values: • admin (by default) • guard
-u [yes|no]	Specifies if the user can change the mode. Default value is "yes".
-e *algo*	Algorithm for the EFS administration key. The possible *algo* values are the same as those of the **-k** flag.
-q	Displays the list of available algorithms.

Exit status

Item	Description
0	The command executed successfully.
1	An error occurred during the execution of the command.
2	A syntax error occurred on the command line.

Security

Item	Description
Access Control:	Only the root user or a user with the **aix.security.efs** authorization and being a member of the security group can run this command.

Examples

1. To display the available algorithms, enter:

```
efsenable -q
```

2. To activate an EFS with default parameters, enter:

```
efsenable –a
```

3. To activate an EFS with a non-default algorithm for keys, and cipher for files, enter:

```
efsenable –a –k RSA_4096 –f AES_256_CBC –e RSA_4096
```

4. To activate an EFS with base DN created on LDAP server along with the local directory structure, type the following command:

```
efsenable –a –d cn=aixdata
```

Files

Item	Description
/etc/security/user	Contains the updates of EFS attributes.
/etc/security/group	Contains the updates of EFS attributes.
/var/efs/users/	Contains the directory for user keystores.
/var/efs/groups/	Contains the directory for group keystores.
/var/efs/efs_admin/	Contains the directory for EFS administration keystore.
/var/efs/efsenabled	Instructs that the EFS is enabled on the system.

efskeymgr Command

Purpose

Manages user and group repositories for the Encrypted File System (EFS) keys (or keystores).

Syntax

efskeymgr -?

efskeymgr -q

efskeymgr -V

efskeymgr [-L *load_module*]**-C** <*group*>

efskeymgr -P < *Open-SSH Public Key file* >

Note: The public key file is located in the **~/.ssh/ directory** directory.

efskeymgr [-L *load_module*] [**-d**] [**-k** <*ks*>] [**-g**] [**-p** <*pw*>] **-v**

efskeymgr [-L *load_module*] [**-d**] [**-k** <*ks*>] **-m**

efskeymgr [-L *load_module*] [**-d**] [**-k** <*ks*>] [**-g**] [**-p** <*pw*>] **-o** <*cmd*>

efskeymgr [-L *load_module*] [**-d**] [**-c** <*cmd*>]

efskeymgr [-L *load_module*] [**-d**] [**-k** <*ks*>] [**-g**] [**-p** <*pw*>] **-n**

efskeymgr [-L *load_module*] [**-d**] [**-k** <*ks*>] [**-g**] [**-p** <*pw*>] **-r** <*mode*>

efskeymgr [-L *load_module*] [**-d**] [**-k** <*ks*>] [**-g**] [**-p** <*pw*>] **-s** <*ks2*>

efskeymgr [-L *load_module*] [**-d**] [**-k** <*ks*>] [**-g**] [**-p** <*pw*>] **-S** <*ks2*>

efskeymgr[-L *load_module*] [**-d**] [**-k** <*ks*>] [**-g**] [**-p** <*pw*>] **-R** <*algo*>

efskeymgr [-L *load_module*] [**-d**] [**-k** <*ks*>] [**-g**] [**-p** <*pw*>] **-D** <*fp*>

efskeymgr [-L *load_module*] [**-d**] [**-k** <*ks*>] [**-g**] [**-p** <*pw*>] **-e** <*file*>

Description

The **efskeymgr** command is dedicated to all key management operations needed by an EFS. Once an EFS is enabled on the system with the **efsenable** command, the keystores (public and private key repositories) are created in the **/var/efs** directory.

The initial password of a user keystore is the user login password. Group keystores and admin keystores are not protected by a password but by an access key. Access keys are stored inside all user keystores that belong to this group.

When you open a keystore (at login or explicitly with the **efskeymgr** command), the private keys contained in this keystore are pushed to the kernel and associated with the process. If access keys are found in the keystore, the corresponding keystores are also opened and the keys are automatically pushed into their kernel.

Keystores support two administration modes: admin mode and guard mode.

admin mode
: When a keystore is set to this mode, an EFS administrator with the **aix.security.efs** RBAC authorization and the access key to admin keystore can open the keystore for management including password reset, key regeneration, access key addition or removal, and so on.

guard mode
: When a keystore is set to this mode, the EFS administrator cannot get access to the keystore. In this mode, if the password to keystore is lost, there is no possible recovery of the private key.

When the keystore password is the same as the login password, the keystore is automatically opened at the login time and the keys are available in the session. The keystore password is kept in sync with the login password when the **passwd** command is used and the old password is provided. If at some point the keystore password is not in sync with the login password, you can change the keystore password using the **efskeymgr** command. When the passwords are not synchronized, the keys are no longer automatically associated with the session when you log in.

The following command grants or removes the EFS credentials only for the execution of the *cmd* command. When the *cmd* command returns, the previous process credentials are restored.

```
efskeymgr –o <cmd> and efskeymgr –c <cmd>
```

When a private key is regenerated in a keystore, a new private key is created and the old key is marked "deprecated".

Note: The new key is not pushed into the kernel. You must open your keystore again, either with the **efskeymgr** command or by closing and opening your session, for the new key to be available for file operations.

The deprecated key can still be used to decrypt files, but is no longer used to encrypt files. The deprecated key can be removed from the keystore, but in this case all files that were encrypted with the old key will no longer be accessible.

Note: This EFS command requires that Role Based Access Control (RBAC) is enabled on the system, which is the default setting.

Delayed operations

In some cases, the keystore cannot be modified directly by a command or an action. When this occurs, a special file is created in the keystore directory, and will be parsed next time the keystore is opened. This special file is called a cookie. For keystores in admin mode, the cookies are parsed automatically when the keystore is opened (at login or when the **efskeymgr** command is run). For keystores in guard mode, the cookies are never automatically parsed. The user must give its approval for each modification of its

keystore. When you open a session, a message is displayed if one or more operations are pending on your EFS keystore:

- Your private key must be regenerated.
- You are granted access to **group**/*group1* keystore.

You must run the **efskeymgr -v** command to process pending operations.

The following actions are possible:

- Private key regeneration. This results in a new private key being generated, and the old one being marked "deprecated".
- New access key. When you accept this cookie, you obtain access to a new keystore (for example, keystore of a group to which you are added).
- Remove access key. When you accept this cookie (for example, when the access key is removed from a group), you loose your access to a keystore.

Note: When you run the **efskeymgr** command with any flag that opens your keystore, for example, the **-v** flag, you are prompted what you want to do with each cookie. The choices are as follows:

- Accept the cookie: your keystore is modified according to the cookie, then the cookie is destroyed.
- Postpone the cookie: your keystore is not modified and the cookie is not removed. You will be prompted next time for action.
- Delete the cookie: your keystore is not modified and the cookie is removed. You must use the **efskeymgr** command to do the action again.

Flags

Item	Description
General flags:	
-d	Verbose mode.
-g	Does not process pending operations when opening the keystore.
-k *ks*	The operation is targeted to the *ks* keystore instead of the active user's keystore. The *ks* value can be as follows: **user/<login>** User <login> keystore. **group/<grpname>** Group <grpname> keystore. **admin/** EFS administration keystore.
-L *load_module*	Specifies the loadable module to use for keystore operations.
-p *pw*	Password to use to open the keystore. It is not advised to use this flag as it can be seen by other users using the **ps** command, for example.
-P *filename*	Push the public key cookies for all the keys present in the OpenSSH file located in the **~/.ssh/authorized_keys** directory.

Item	Description
Flags for commands (no access to the keystore files):	
-?	Displays the command help and exits.
-q	Displays a list of supported algorithms for the key regeneration.
-V	Displays the keys associated with the active process credentials in the kernel.
Flags for commands (read-only access to keystores):	
-c <*cmd*>	Removes all keys from the kernel, then runs the *cmd* command. The keys are restored when the *cmd* command terminates.
-m	Lists all pending operations on the keystore.
-o <*cmd*>	Opens the keystore and pushes the keys, then runs the *cmd* command. The keys are discarded when the *cmd* command terminates.
-v	Displays the content of the keystore file.
Flags for commands (read/write access to keystores):	
-C <*group*>	Creates the keystore of the *group* group.
-D <*fp*>	Removes a deprecated private key from the keystore. The *fp* value is the key fingerprint.
-e <*file*>	Exports a keystore to a file. The file is PKCS#12 encoded and contains the public and private keys from the keystore. This file can be used in openssh, for example.
-n	For user keystores, prompts for a new password for the keystore. For group keystores, generates a new access key and sends to group members. For admin keystores, generates a new access key. The key must then be sent to the EFS administrators with the **efskeymgr** command.
-R <*algo*>	Regenerates the keystore private key. See the **-q** flag for the valid values for the *algo* parameter.
-r <*mode*>	Changes the keystore administration mode. The *mode* value can be as follows: **admin** The EFS administrator can administer the keystore. Pending operations are applied automatically. **guard** The EFS administrator cannot manage the keystore. The user is prompted for any pending operation.
-S <*ks2*>	Removes the *ks2* access key from the keystore. On subsequent opening of keystore, the *ks2* private key is no longer pushed automatically.
-s <*ks2*>	Sends the keystore access key to the *ks2* keystore. On subsequent opening of the *ks2* key, the keystore private key is loaded automatically.

Exit status

Item	Description
0	The command ran successfully.
1	An error occurred during the execution of the command.
2	A syntax error occurred on the command line.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To view your keystore content, enter:

```
efskeymgr –v
```

2. To view the keys associated with the active shell, enter:

```
efskeymgr -V
```

3. To regenerate the private key from your keystore, enter:

```
efskeymgr –R RSA_1024
```

4. To delete a deprecated key, enter:

```
efskeymgr –D dbb62547:d6925088:45357fd3:54cddbba:27b255a9
```

5. To send the access key of the group "students" to the user "joe", enter:

```
efskeymgr –k group/students –s user/joe
```

6. To push the Open-SSH Client users Open-SSH Public key cookies in the target keystore, where the **~/.ssh/authorized_keys** file contains the installed public keys, enter:

```
efskeymgr  -P  ~/.ssh/authorized_keys
```

7. To create Group keystore directly on LDAP, if configured:

```
efskeymgr -L LDAP -C staff
```

Files

Item	Description
/var/efs	Contains all keystores.
/etc/security/user	Contains the EFS attributes for the creation and management of users keystore.
/etc/security/group	Contains the EFS attributes for the creation of groups keystore.

efskstoldif Command

Purpose

Prints certain EFS users or groups keystore that are defined locally to **stdout** in ldif format.

Syntax

efskstoldif -d *baseDN* [**-u** | **-g**] {ALL | *Name* [*Name*] ...}

Description

The **efskstoldif** command reads data from locally defined EFS users or groups keystore files and prints the result to **stdout** in ldif format. If redirected to a file, the result can be added to a LDAP server with the **ldapadd** command with the **-b** flag or the **ldif2db** command.

The **efskstoldif** command reads the **/etc/security/ldap/sectoldif.cfg** file to determine what to name the user, group and cookie sub-trees that the data will be exported to. The **efskstoldif** command only exports data to the USERKEYSTORE, GROUPKEYSTORE, EFSCOOKIES and ADMINKEYSTORE types defined in the file. The names specified in the file will be used to create sub-trees under the base distinguished name (DN) specified with the **–d** flag. For more information, see the /etc/security/ldap/sectoldif.cfg file in AIX Version 6.1 TL 4 for reference.

The LDIF output generation does not look the **efs_keystore_access** nor the **efs_adminks_access** attribute of the users/groups. Whatever will be its value either “file” or “ldap” the LDIF format will be generated. For whatever users or groups keystore the ldif format is generated, if any cookies exist for those keystore then even for them the ldif generation takes place.

Note: If there are any cookies present on files, even the LDIF generation happens for them too. System Administrator has to take care of the consistency of the keystore entries on LDAP and files if required.

Flags

Item	Description
-d *baseDN*	Specifies the base distinguished names (DN) under which to place the EFS Keystore data.
-g **ALL***Names* . ..	Directs the command to generate the output for the groups specified in the succeeding arguments. **ALL** Specifies that all the groups must be considered. **Name** Specifies the single group name or list of group names separated by blanks.
-u **ALL***Names* . ..	Directs the command to generate the output for the users specified in the succeeding arguments. **ALL** Specifies that all the users must be considered. **Name** Specifies the single user name or list of user names separated by blanks.

Exit status

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Access Control: This command should grant execute (x) access only to the root user.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Files

Item	Description
/etc/security/user	Contains the EFS attributes for the creation and management of users keystore.
/etc/security/group	Contains the EFS attributes for the creation and management of users keystore.
/var/efs	Contains all keystores.

Examples

1. To export all the users and groups keystore content to ldif format with the base DN of cn=aixdata, type the following command:

   ```
   efskstoldif -d cn=aixdata
   ```

2. To export all the users keystore content to ldif format with the base DN of cn=aixdata, type the following command:

   ```
   efskstoldif -d cn=aixdata -u ALL
   ```

3. To export all the groups keystore content to ldif format with the base DN of cn=aixdata, type the following command:

   ```
   efskstoldif -d cn=aixdata -g ALL
   ```

4. To export only selected users keystore content to ldif format with the base DN of cn=aixdata, type the following command:

   ```
   efskstoldif -d cn=aixdata -u davis smith
   ```

5. To export only selected groups keystore content to ldif format with the base DN of cn=aixdata, type the following command:

   ```
   efskstoldif -d cn=aixdata -g finance managers
   ```

efsmgr Command

Purpose

Manages the files encryption and decryption for the Encrypted File System (EFS).

Syntax

efsmgr -?

efsmgr -q [**-v**]

efsmgr -C <*cipher*> [**-v**]

efsmgr [**-c** <*file*>] **-e** <*file*> [**-v**]

efsmgr [**-c** <*cipher*>] [**-s**] **-E** <*dir*> [**-v**]

efsmgr [**-c** <*cipher*>] **-t** <*file*> [**-v**]

efsmgr [**-c** <*cipher*>] [**-s**] **-T** <*dir*> [**-v**]

efsmgr -d <*file*> [**-v**]

efsmgr [**-s**] **-D** <*dir*> [**-v**]

efsmgr -l <*file*> [**-v**]

efsmgr [**-s**] **-L** <dir> [**-v**]

efsmgr -a <*file*> [**-u** <*user*> | **-g** <*group*>] [**-v**]

efsmgr -r <*file*> [**-u** <*user*> | **-g** <*group*>] [**-v**]

Description

The **efsmgr** command is dedicated to the files encryption management inside EFS. Encrypted files can only be created on the EFS-enabled JFS2 file systems. For more information about enabling EFS on your system, see the **mkfs**, **chfs**, **crfs**, and **efsenable** commands.

There are two ways to create encrypted files: either explicitly by using the following command, or implicitly when inheritance is set on the file system or the directory where the file is being created.

```
efsmgr -e <file>
```

When inheritance is set on a directory, all new files created in this directory are encrypted by default. The cipher used to encrypt files is the inherited cipher. New directories also inherit the same cipher. If inheritance is disabled on a subdirectory, the new files created in this subdirectory will not be encrypted.

When inheritance is set on a file system, all new files created in this file system are encrypted using the inherited cipher. If inheritance is set both on a directory and a file system with different ciphers, new files created in this directory will be encrypted using the cipher inherited from the directory.

Setting or removing inheritance on a directory or a file system has no effect on the existing files. The **efsmgr** command must be used explicitly to encrypt or decrypt files.

The file owner's private key must be loaded into the process before the encrypted file can be created. The access to the encrypted file can be granted to any user or group with a keystore, which is a key repository that contains EFS security information. For more information about managing user and group repositories, see the **efskeymgr** command.

When an encrypted file is being opened, the Discretionary Access Control (DAC) and the Access Control List (ACL) are checked for the file access permission. If the access is granted, the keys loaded into the kernel for the process are searched for a private key matching one of the file's protection keys. If a matching key is found, the file content can be read, otherwise the access is denied.

Note: This EFS command requires that Role Based Access Control (RBAC) is enabled on the system, which is the default setting.

Flags

Item	Description
-c <*cipher*>	Uses this cipher instead of the inherited or the default cipher. See the **-q** command for the valid *cipher* values.
-g <*group*>	This group must be added or removed from the EFS access list. The *group* value can be either the gid or the group name.

Item	Description
-s	The operation is targeted to a file system rather than a directory. In this case, the *dir* parameter must be the mount point of a file system with EFS support.
-u <*user*>	This user must be added or removed from the EFS access list. The *user* value can be either the uid or the login name.
-v	Verbose mode.
-?	Displays the command help and exits.
-a <*file*>	Adds access to the specified file to a list of users and groups specified with the **-u** and **-g** flags.
-C <*cipher*>	Changes the default cipher for your user to the *cipher* value.
-D <*dir*>	Removes the inheritance on the directory. To apply the command on the whole file system, you must add the **-s** flag.
-d <file>	Decrypts the specified file.
-E <*dir*>	Sets the inheritance on the *dir* directory. To apply the command on the whole file system, you must add the **-s** flag.
-e <file>	Encrypts the specified file.
-L <*dir*>	Displays the inherited cipher on the specified directory.
-l <*file*>	Lists the encryption information of the specified file: cipher, and keys that can decrypt the file.
-q	Displays a list of supported ciphers.
-r <*file*>	Revokes access to the specified file to a list of users and groups specified with the **-u** and **-g** flags.
-T <*dir*>	Changes the inherited cipher on the specified directory. To apply the command on the complete file system, you must add the **-s** flag.
-t <*file*>	Refreshes the encryption keys of the specified file. This can also be used to change the file cipher.

Exit status

Item	Description
0	The command executed successfully.
1	An error occurred during the execution of the command.
2	A syntax error occurred on the command line.

Examples

1. To encrypt the **database.txt** file using a strong cipher, enter:

```
efsmgr –e database.txt –c AES_256_CBC
```

2. To display the list of keys that can open the file, enter:

```
efsmgr –l database.txt
```

3. To add access to user joe and to group maintainers to the file, enter:

```
efsmgr –a database.txt –u joe –g maintainers
```

4. To set the inheritance on the file system of the home directory, enter:

```
efsmgr -c AES_128_CBC -s -E /home
```

Files

Item	Description
/etc/security/user	Contains the default cipher attributes for the user.

egrep Command

Purpose

Searches a file for a pattern.

Syntax

egrep [**-h**] [**-i**] [**-p**[*Separator*]] [**-s**] [**-u**] [**-v**] [**-w**] [**-x**] [**-y**] [[**-b**] [**-n**] | [**-c** | **-l** | **-q**]] { { **-e***Pattern* | **-f***StringFile* } ... | *Pattern* } [*File ...*]

Description

The **egrep** command searches an input file (standard input by default) for lines matching a pattern specified by the *Pattern* parameter. These patterns are full regular expressions as in the **ed** command (except for the \ (backslash) and \\ (double backslash)). The following rules also apply to the **egrep** command:

- A regular expression followed by a + (plus sign) matches one or more occurrences of the regular expression.
- A regular expression followed by a ? (question mark) matches zero or one occurrence of the regular expression.
- Multiple regular expressions separated by a | (vertical bar) or by a new-line character match strings that are matched by any of the regular expressions.
- A regular expression may be enclosed in ( ) (parentheses) for grouping.

The new-line character will not be matched by the regular expressions.

The order of precedence for operators is [,], *, ?, +, concatenation, | and the new-line character.

> **Note:** The **egrep** command is the same as the **grep** command with the **-E** flag, except that error and usage messages are different and the **-s** flag functions differently.

The **egrep** command displays the file containing the matched line if you specify more than one *File* parameter. Characters with special meaning to the shell ($, *, [, |, ^, (,), \ ) must be in quotation marks when they appear in the *Pattern* parameter. When the *Pattern* parameter is not a simple string, you usually must enclose the entire pattern in single quotation marks. In an expression such as `[a-z]`, the minus means through according to the current collating sequence. A collating sequence may define equivalence classes for use in character ranges. It uses a fast, deterministic algorithm that sometimes needs exponential space.

Notes:

1. Lines are limited to 2048 bytes.
2. Paragraphs (under the **-p** flag) are currently limited to a length of 5000 characters.
3. Do not run the **grep** command on a special file because it produces unpredictable results.
4. Input lines should not contain the NULL character.
5. Input files should end with the newline character.

6. Although some flags can be specified simultaneously, some flags override others. For example, if you specify **-l** and **-n** together, only file names are written to standard output.

Flags

Item	Description
-b	Precedes each line by the block number on which it was found. Use this flag to help find disk block numbers by context. The **-b** flag cannot be used with input from stdin or pipes.
-c	Displays only a count of matching lines.
-e *Pattern*	Specifies a *Pattern*. This works like a simple *Pattern* but is useful when the *Pattern* begins with a - (minus sign).
-f *StringFile*	Specifies a file that contains strings.
-h	Suppresses file names when multiple files are being processed.
-i	Ignores the case of letters when making comparisons.
-l	Lists just the names of files (once) with matching lines. Each file name is separated by a new-line character. If standard input is searched, a path name of "`(StandardInput)`" is returned.
-n	Precedes each line with its relative line number in the file.
-p[*Separator*]	Displays the entire paragraph containing matched lines. Paragraphs are delimited by paragraph separators, as specified by the *Separator* parameter, which are patterns in the same form as the search pattern. Lines containing the paragraph separators are used only as separators; they are never included in the output. The default paragraph separator is a blank line.
-q	Suppresses all output to standard output, regardless of matching lines. Exits with a 0 status if an input line is selected.
-s	Displays only error messages. This is useful for checking status.
-u	Causes output to be unbuffered.
-v	Displays all lines except those that match the specified pattern.
-w	Does a word search.
-x	Displays lines that match the specified pattern exactly with no additional characters.
-y	Ignores the case of letters when making comparisons.

Exit Status

This command returns the following exit values:

Item	Description
0	A match was found.
1	No match was found.
>1	A syntax error was found or a file was inaccessible (even if matches were found).

Examples

To use an extended pattern that contains some of the pattern-matching characters +, ?, |, (, and), enter:

```
egrep "\(([A-z]+|[0-9]+)\)" my.txt
```

This displays lines that contain letters in parentheses or digits in parentheses, but not parenthesized letter-digit combinations. It matches `(y)` and `(783902)`, but not `(alpha19c)`.

> **Note:** When using the **egrep** command, \ ((backslash followed by open parenthesis) or \ ((backslash followed by close parenthesis) match parentheses in the text, but ((open parenthesis) and) (closed parenthesis) are special characters that group parts of the pattern. The reverse is true when using the **grep** command.

Files

Item	Description
/usr/bin/egrep	Contains the hard link to the **egrep** command.
/bin/egrep	Specifies the symbolic link to the **egrep** command.

eimadmin Command

Purpose

Manages Enterprise Identity Mapping (EIM) domains.

Syntax

`eimadmin -a | -p | -l | -m | -e -D | -R | -I | -A | -C [-s` *switch*`] [-v` *verboseLevel*`] [-c` *accessType*`] [-f` *accessUserType*`] [-g` *registryParent*`] [-i` *identifier*`] [-j` *otherIdentifier*`] [-k` *URI*`] [-n` *description*`] [-o` *information*`] [-q` *accessUser*`] [-r` *registryName*`] [-t` *associationType*`] [-u` *registryUser*`] [-x` *registryAlias*`] [-y` *registryType*`] [-z` *registryAliasType*`] [-d` *domainDN*`] [-h` *ldapHost*`] [-b` *bindDN*`] [-w` *bindPassword*`] [-K` *keyFile* `[ -P` *keyFilePassword*`] [-N` *certificateLabel*`]] [-S` *connectType*`]`

Description

The `eimadmin` command is an AIX System Services Shell tool. An administrator can use it to define an EIM domain and prime the domain with registries, identifiers, and associations between identifiers and registry users. An administrator can also use `eimadmin` to give users (and other administrators) access to an EIM domain, or list or remove the EIM entities.

Administrators can use the `eimadmin` command in two ways:

- By including information with command-line options on an `eimadmin` command
- By including information in an input file that an `eimadmin` command references

You can create the file manually or by exporting records from a database. The administrator directs utility processing by specifying a combination of command-line options.

The `eimadmin` command can perform the following actions:

- Add an object (`-a`)
- Purge an object (`-d`)
- List objects (`-l`)
- Modify attributes associated with objects (`-m`)
- Erase attributes (`-e`)

on the following objects:

- Domains (`-D`)

- Registries (`-R`)
- Identifiers (`-I`)
- Associations (`-A`)
- Access authorities (`-C`)

Note:

1. Each `eimadmin` command must include one action and one object type. Depending on the object and the action you are performing on it, EIM might require additional parameters.
2. Some options are for multivalue attributes, which you can specify more than once. Other options are for single-value attributes, which you can specify only once. (If you repeat an option that is for a single-value attribute, `eimadmin` processes only the first value it encounters in the command.) Apart from these stipulations, the order in which you specify parameters is not important.
3. You can code the parameters of the `eimadmin` command in several ways:
   - Concatenate an action and an object, omitting the embedded hyphen: `-aD`
   - Include both hyphens, and separate the two options with a space: `-a -D`

   In other words, the following example is *not* valid because it includes both hyphens and there is no space before `-D`: `-a-D`

Flags

The `eimadmin` command takes the following action flags.

Item	Description
-a	Adds an object. (Creates an object definition and its attributes.)
-e	Erases an attribute. (Clears a single-value attribute or removes a multivalue attribute.)
-l	Lists an object. (Retrieves an object definition and its attributes.)
-m	Modifies an attribute. (Alters an attribute of an existing object, either by changing a single-value attribute or adding a multivalue attribute.)
-p	Purges an object. (Removes an object definition and its attributes.)

The `eimadmin` command takes the following object flags.

Item	Description
-A	An association. This is a relationship between an identifier in the EIM domain and a user ID.
-C	An access authority. This is an EIM-defined LDAP access control group.
-D	A domain. This is a collection of identifiers, user registries, and associations between identifiers and user IDs, stored within an LDAP directory.
-I	An identifier. This is the name of a person or entity participating in an EIM domain.
-R	A registry. This is the name of a user registry. Associations are defined between identifiers and user IDs in the user registry.

The `eimadmin` command takes the following processing control flags.

Item	Description
-s *switch*	The *switch* specifies a value that affects the way the `eimadmin` command functions operate. You can specify the following value: **RMDEPS** Removes dependents when removing a domain or system registry. This makes it easier to remove a domain by first removing all identifiers and registries defined for the domain. It also makes it easier to remove a system registry by first removing all application registries defined for the registry.  **Attention: Attention:** The `eimadmin` command does not warn you that dependents exist before removing them, so use this switch carefully.
-v *verboseLevel*	The *verboseLevel* parameter is an integer from 1 to 10 that controls the amount of trace detail that the `eimadmin` command displays. (It is for diagnosing problems in the `eimadmin` utility.) The default value of 0 indicates no trace information. You can specify an integer value from 1 to 10, from the least to greatest amount of trace information. The utility checks the value and displays trace information defined for the level and all lower levels. The following levels trigger specific information: • 3–indicates EIM API call parameters and return values • 6–indicates option values and input file labels • 9–indicates utility routine entry and exit statements

The `eimadmin` command takes the required and optional attribute flags listed in the following table. The flag options are single-valued unless otherwise indicated. If you specify an option more than once, the utility processes only the first occurrence.

Note:

1. You can specify these attributes as command options or as fields in input files. If you are specifying command options, you must enclose values with imbedded blanks within quotation marks (") or ('). Quotation marks are optional for single-word values. Specifying a multiword value without quotation marks in effect truncates the command line options; values after the first word are truncated.
2. The following special characters are not allowed in *registryName*, *registryParent*, or *identifier*:

```
, = + < > # ; \ *
```

Item	Description
-c *accessType*	Specifies the scope of access authority the user has over the EIM domain. *accessType* must be one of the following values: **ADMIN** Specifies administrative access. **REGISTRY** Specifies registry access. If you specify REGISTRY, you must also specify a registry value (`-r`). The registry value can be a specific registry name or it can be an asterisk (*) to indicate access to all registries. **IDENTIFIER** Specifies identifier access. **MAPPING** Specifies mapping operations access.

Item	Description
-f *accessUserType*	Specifies the type for the access user name. *accessUserType* must be one of the following types: **DN** The *accessUser* is a distinguished name. **KERBEROS** The *accessUser* is a Kerberos identity.
-g *registryParent*	Specifies the name of a system registry. An application registry is a subset of a system registry. If you are adding an application registry, you must use the -r option and the -g option. The -r value is the application registry you are defining. The -g option is the preexisting system registry.
-i *identifier*	Specifies a unique identifier name. For example: John Day.
-j *otherIdentifier*	Specifies a nonunique identifier name. For example: John. **Note:** You can specify this option multiple times to assign multiple nonunique identifiers.
-k *URI*	Specifies the Universal Resource Identifier (URI) for the registry (if one exists).
-n *description*	Specifies any text (that you provide) to associate with the domain, registry, identifier, or association. **Note:** You can define a user description only for target associations.
-o *information*	Specifies additional information to associate with an identifier or association. **Note:** You can define user information only for target associations. You can specify this option multiple times to assign multiple pieces of information.
-q *accessUser*	Specifies the user distinguished name (DN) or the Kerberos identity with EIM access, depending on the *accessUserType* specified.
-r *registryName*	Specifies the name of a registry. When you add a new registry, eimadmin treats the registry as a system registry unless you also specify the -g option. If you specify the -g option, eimadmin treats the registry as an application registry.
-t *associationType*	Specifies the relationship between an identifier and a registry. *associationType* must be one of the following: **ADMIN** Indicates associating a user ID with an identifier for administrative purposes. **SOURCE** Indicates that the user ID is the source (or from) of a lookup operation. **TARGET** Indicates that the user ID is the target (or to) of a lookup operation. **Note:** You can specify this option multiple times to define multiple relationships.
-u *registryUser*	Specifies the user ID of the user defined in the registry.
-x *registryAlias*	Specifies another name for a registry. You must specify this option multiple times to assign multiple aliases.

Item	Description
-y *registryType*	Specifies the type of registry. Predefined types that `eimadmin` recognizes include the following: • RACF® • OS/400® • KERBEROS (for case ignore) • KERBEROSX (for case exact) • AIX • NDS • LDAP • PD (Policy Director) • WIN2K You can also create your own types by concatenating a unique OID with one of the following two normalization methods: • caseIgnore • caseExact
-z *registryAliasType*	Specifies the type for a registry alias. You can invent your own value or use one of the following suggested values: • DNSHostName • KerberosRealm • IssuerDN • RootDN • TCPIPAddress • LdapDnsHostName **Note:** For a set of command line options or single input data record, the `eimadmin` command recognizes only the first specification of *registryAliasType*. However, the `eimadmin` command does recognize multiple registry aliases and associates all of them with the single *registryAliasType*.

The `eimadmin` command takes the following connection type flags.

Item	Description
-b *bindDN*	Specifies the distinguished name to use for the simple bind to LDAP.
-d *domainDN*	Specifies the full distinguished name (DN) of the EIM domain. *domainDN* begins with `'ibm-eimDomainName='` and consists of the following elements: ***domainName*** The name of the EIM domain you are creating. For example, `MyDomain`. **parent distinguished name** The distinguished name for the entry immediately above the given entry in the directory information tree hierarchy, such as `o=ibm,c=us`. For example: `ibm-eimDomainName=MyDomain,o=ibm,c=us`

Item	Description
-h *ldapHost*	Specifies the URL and port for the LDAP server controlling the EIM data. The format is: `ldap://some.ldap.host:389` `ldaps://secure.ldap.host:636`
-K *keyFile*	Specifies the name of the SSL key database file, including the full path name. If the file cannot be found, it is assumed to be the name of a RACF key ring that contains authentication certificates. This value is required for SSL communications with a secure LDAP host (prefixed `ldaps://`). For example: `/u/eimuser/ldap.kdb`
-N *certificateLabel*	Specifies which certificate to use from the key database file or RACF key ring. If this option is not specified, the certificate marked as the default in the file or ring is used.
-P *keyFilePassword*	Specifies the password required to access the encrypted information in the key database file. Alternatively, you can specify an SSL password stash file for this option by prefixing the stash file name with `file://`. For example: `secret  or file:///u/eimuser/ldapclient.sth` **Note:** The `eimadmin` command prompts for a key file password if you specify the name of a key database file for the `-K` option but not the `-P` option on the command line.
-S *connectType*	Specifies the method of authentication to the LDAP server. *connectType* must be one of the following values: • `SIMPLE` (bind DN and password) • `CRAM-MD5` (bind DN and protected password) • `EXTERNAL` (digital certificate) • `GSSAPI` (Kerberos) If not specified, *connectType* defaults to `SIMPLE`. For connect type `GSSAPI`, the default Kerberos credential is used. This credential must be established using a service such as kinit prior to running `eimadmin`. For KINIT and related information, refer to the AIX Authentication Service Administration.
-w *bindPassword*	Specifies the password associated with the bind DN.

The connection information needed by the utility includes the EIM domain (`-d`) and its controlling server (`-h`), the identity (`-b`,`-w`; or `-K`,`-P`,`-N`) with which to authenticate (bind) to the server, and the authentication method (`-S`).

For object types other than domain (`-D`), specifying the domain, server and bind identity is optional. If these are not specified, the information is retrieved from a RACF profile.

Note: If any of the connect information is specified, the full set of values required for the connect type must also be specified. Omitting one or more values (but not all) results in an error. The following table shows the required and optional values for each connect and host type when specified with the `eimadmin` command.

Connection Type/Host Type	Required Values	Optional Values
SIMPLE or CRAM-MD5/secure (`ldaps://`)	-d, -h, -b, -w, -K, -P	-N
SIMPLE or CRAM-MD5/nonsecure (`ldap://`)	-d, -h, -b, -w	

Connection Type/Host Type	Required Values	Optional Values
EXTERNAL/secure (`ldaps://`)	-d, -h, -K, -P, -S	-N
EXTERNAL/nonsecure (`ldap://`)	unsupported	unsupported
GSSAPI/secure (`ldaps://`)	-d, -h, -K, -P, -S	-N
GSSAPI/nonsecure (`ldap://`)	-d, -h, -S	

Note:

1. There are two exceptions to the preceding table:
   - The domain option (`-d`) is not required for domain functions if the value is specified through an input file.
   - An SSL key database file password or stash file (-P) is not required when -K specifies a RACF key ring.
2. The `eimadmin` command prompts for the simple bind password if it is required and `-w` is not specified on the command line, and prompts for the SSL key database file password if it is required and `-P` is not specified on the command line.

The following table summarizes required and optional flags for each object type and action pair. You can specify the value for most options in an input file instead of specifying it on the command line.

Object Type (Action)	Flags	Comments
`D` (a)	• Required: d, h • Optional: n	Add a domain.
`D` (p)	• Required: d, h • Optional: s	Remove a domain. If the domain is not empty, include `-s RMDEPS`.
`D` (l)	• Required: d, h • Optional:	List domains. Specify `-d*` to list all domains.
`D` (m)	• Required: d, h • Optional: n	Modify or add a domain attribute.
`D` (e)	• Required: d, h • Optional: n	Remove or clear a domain attribute.
`R` (a)	• Required: `r`, y • Optional: g, k, n, x, z	Add a registry. The value specified for `-r` is assumed to be a new system registry unless `-g` is also specified, in which case the `-r` value indicates a new application registry.
`R` (p)	• Required: `r` • Optional: s	Remove a registry.
`R` (l)	• Required: `r` • Optional: y	List registries. Return all registry entries in the domain that match the specified `-r` value search filter, which might contain the wild card `*`.
`R` (m)	• Required: `r` • Optional: k, n, x, z	Modify or add a registry attribute, including a registry alias.

Object Type (Action)	Flags	Comments
R (e)	• Required: r • Optional: k, n, x, z	Remove or clear a registry attribute, including a registry alias.
I (a)	• Required: i • Optional: j, n, o	Add an identifier.
I (p)	• Required: i • Optional:	Remove an identifier.
I (l)	• Required: i • Optional:	List an identifier by unique identifier name. Return all identifier entries in the domain that matches the specified -i value search filter, which might contain the wild card *.
I (l)	• Required: j • Optional:	List an identifier by nonunique identifier name. Return all identifier entries in the domain that have a nonunique identifier matching the specified -j value search filter, which might contain the wild card *.
I (m)	• Required: i • Optional: j, n, o	Modify or add an identifier attribute.
I (e)	• Required: i • Optional: j, n, o	Remove or clear an identifier attribute.
A (a)	• Required: i, r, u, t • Optional: n, o	Add an association. You can repeat the -t option to add multiple associations types. The -n and -o flags are relevant only to TARGET associations.
A (p)	• Required: i, r, u, t • Optional:	Remove an association. You can repeat the -t option to remove multiple associations types.
A (l)	• Required: i • Optional: t	List associations. Return all associations in the domain for specified -i unique identifier. Specify a -t value to limit the entries returned to the given association type.
A (m)	• Required: r, u • Optional: n, o	Modify or add an association attribute. The -n and -o flags are relevant only to TARGET associations.
A (e)	• Required: r, u • Optional: n, o	Remove or clear an association attribute. The -n and -o flags are relevant only to TARGET associations.
C (a)	• Required: c, q, f • Optional: r	Add access. For access type REGISTRY, provide a specific -r registry value, or a wild card * indicating access to all registries in the domain.
C (p)	• Required: c, q, f • Optional: r	Remove access. For access type REGISTRY, provide a specific -r registry value, or a wild card * indicating access to all registries in the domain.
C (l)	• Required: c • Optional: r	List access by type. For access type REGISTRY, provide a specific -r registry value, or a wild card * indicating access to all registries in the domain.

Object Type (Action)	Flags	Comments
C (l)	• Required: q, f • Optional:	List access by user.

Exit Status

The eimadmin command returns one of the following exit codes upon completion:

Item	Description
0	Successful.
4	One or more errors encountered but, if you specified an input file, all records were processed.
8	A severe error occurred that caused processing to stop before reaching the end of an input file, if specified.

Examples

1. To list a single domain, type:

   ```
   eimadmin -lD -h ldap://my.server -b "cn=EIM admin,o=MyCompany,c=US" -d "ibm-eimDomainName=My Employees,o=My Company,c=US"
   ```

   This returns something similar to the following output:

   ```
   domain name: My Employees
   domain DN: ibm-eimDomainName=My Employees,o=My Company,c=US
   description: employees in my company
   ```

2. To list a single registry, type:

   ```
   eimadmin -lR -r MyRegistry
   ```

   This returns something similar to the following output:

   ```
   registry: MyRegistry
   registry kind: APPLICATION
   registry parent: MySystemRegistry
   registry type: RACF
   description: my racf registry
   URI: ldap://some.big.host:389/profileType=User,cn=RACFA,o=My Company,c=US
   registry alias: TCPGROUP
   registry alias type: DNSHostName
   ```

3. To list identifiers, type:

   ```
   eimadmin -lI -i "J.C.Smith"
   ```

   This returns something similar to the following output:

   ```
   unique identifier: J.C.Smith
   other identifier: J.C.Smith
   other identifier: Joseph
   other identifier: Joe
   description: 004321
   information: D01
   information: 1990-04-11
   ```

4. To list target associations, type:

   ```
   eimadmin -lA -i "J.C.Smith" -t target
   ```

   This returns something similar to the following output:

```
unique identifier: J.C.Smith
registry: MyRegistry
registry type: RACF
association: target
registry user: SMITH
description: TSO
information: 1989-08-01
information: ADMIN1
```

5. To list accesses, type:

```
eimadmin -lC -c admin
```

This returns something similar to the following output:

```
access user: cn=JoeUser,o=My Company,c=us
access user: cn=admin1,o=My Company,c=us
access user: cn=admin2,o=My Company,c=us
```

Location

/usr/bin/eimadmin

Security

The LDAP administrator has the authority to use the `eimadmin` command and access to all the functions it provides. EIM administrators can use the command as long as the following conditions are true:

- They have a bind distinguished name and password defined at the LDAP server containing the EIM domain
- Their bind distinguished name has one of the EIM authorities:
  - EIM administrator
  - EIM registries administrator
  - EIM registry X administrator
  - EIM identifiers administrator

Standard Error

The `eimadmin` command issues a message to prompt for a password or to indicate an error. Do not expect to receive a message for successful completion unless you use an input file. When processing records in an input file, `eimadmin` issues an informational message as the process starts and stops, in addition to a progress message every 50 records.

Note: The `eimadmin` command returns one or more data lines for list (-l) requests unless it finds no matching EIM entries, or the bind identity is not authorized to access that data.

elogevent Command

Purpose

Logs event information generated by the event response resource manager (ERRM) to a specified log file.

Syntax

elogevent [-h] *log_file*

Description

The `elogevent` captures event information that is posted by the event response resource manager (ERRM) in environment variables the ERRM generates when an event occurs. This script can be used as an action that is run by an event response resource. It can also be used as a template to create other user-defined actions. This script always return messages in English.

Event information that is returned about the ERRM environment variables includes the following:

Local Time
Time when the event or rearm event is observed. The actual environment variable supplied by ERRM is ERRM_TIME. This value is localized and converted to readable form before being displayed.

This script uses the `alog` command to write event information to and read event information from the specified *log_file*.

Flags

-h
Writes the script's usage statement to standard output.

Parameters

log_file
Specifies the name of the file where event information is logged. An absolute path for the *log_file* parameter should be specified.

The *log_file* is treated as a circular log and has a fixed size of 64KB. When *log_file* is full, new entries are written over the oldest existing entries.

If *log_file* already exists, event information is appended to it. If *log_file* does not exist, it is created so that event information can be written to it.

Exit Status

0
The script has run successfully.

1
A required *log_file* is not specified.

2
The *log_file* path is not valid.

Restrictions

- This script must be run on the node where the ERRM is running.
- The user who runs this script must have write permission for the *log_file* where the event information is logged.

Standard Output

When the `-h` flag is specified, the script's usage statement is written to standard output.

Examples

1. To log information, specify the log file as `/tmp/event.log`. ERRM runs this command:

```
/opt/rsct/bin/elogevent/tmp/event.log
```

The `/tmp/event.log` file does not need to exist when the command is run.

2. To see the contents of the /tmp/event.log file, run this command:

```
alog -f /tmp/event.log -o
```

The following sample output shows a warning event for the /var file system (a file system resource):

```
===============================================================================
Event reported at Mon Mar 27 16:38:03 2007

Condition Name:                         /var space used
Severity:                               Warning
Event Type:                             Event
Expression:                             PercentTotUsed>90

Resource Name:                          /var
Resource Class Name:                    IBM.FileSystem
Data Type:                              CT_UINT32
Data Value:                             91
```

Location

/opt/rsct/bin/elogevent

emgr Command

Purpose

Starts the interim fix manager, which installs, removes, lists, and checks system interim fixes.

Syntax

emgr **-l** [**-L** *Label* | **-n** *interimfixNumber* | **-u** *VUID*] [**-v**{**1**|**2**|**3**}] [**-X**] [-a *path*]

emgr **-e** *interimfixPackage* | **-f** *ListFile* [**-w** *Directory*] [**-b** | **-k** | **-I**] [**-p**] [**-q**] [**-m**] [**-o**] [**-X**] [-a *path*]

emgr **-i** *interimfixPackage* | **-f** *ListFile* [**-w** *Directory*] [**-C**] [**-p**] [**-q**] [**-X**] [**-a** *path*]

emgr **-C** **-i** *interimfixPackage* | **-f** *ListFile* [**-w** *Directory*] [**-p**] [**-q**] [**-X**] [**-a** *path*]

emgr **-C** **-L** *Label* [**-p**] [**-q**] [**-X**]

emgr **-r** **-L** *Label* | **-n** *interimfixNumber* | **-u** *VUID* | **-f** *ListFile* [**-w** *Directory*] [-a *path*] [**-b** | **-k** | **-I**] [**-p**] [**-q**] [**-X**]

emgr **-c** [**-L** *Label* | **-n** *interimfixNumber* | **-u** *VUID* | **-f** *ListFile*] [**-w** *Directory*] [-a *path*] [**-v**{**1**|**2**|**3**}] [**-X**]

emgr **-M** | **-U** [**-L** *Label* | **-n** *interimfixNumber* | **-u** *VUID* | **-f** *ListFile*] [**-w** *Directory*] [-a *path*] [**-X**]

emgr **-R** *interimfixLabel* [**-w** *Directory*] [-a *path*] [**-X**]

emgr **-P** [*Package*] [-a *path*] [**-X**]

emgr **-d** **-e** *interimfixPackage* | **-f** *ListFile* [**-w** *Directory*] [**-v**{**1**|**2**|**3**}]

Description

The **emgr** (interim fix manager) command can be used to install and manage system interim fixes. The interim fix manager installs packages created with the **epkg** command and maintains a database containing interim fix information. The **emgr** command performs the following operations:

- interim fix package installation
- interim fix removal
- interim fix listing
- interim fix checking
- interim fix mounting

- interim fix unmounting
- package locks displaying
- installed interim fix forced removal

Note:

- If an attempt is made to update a fileset (using the **installp**, **install_all_updates**, or **smit update_all** command) that has been locked by the interim fix manager, a notice will be displayed indicating which filesets are locked. In some cases, there is no notice to indicate why a fileset was prevented from being installed. The **lslpp** command shows that any locked filesets are in the IFIXLOCKED state.
- Any library or executable program updated by an interim fix or service update which is in use by an active process will not be reflected in that process unless it is restarted. For example, an update that changes the ksh will not have the changes reflected in any ksh processes that are already running. Likewise, an update to the **libc.a** library will not be reflected in any process that is already running. In addition, any process that is using a library and does a **dlopen** operation of the same library after the library has been updated could experience inconsistencies if it is not restarted.

Referencing an Ifix

The ways to reference an interim fix are as follows:

Reference by Label

Each interim fix that is installed on a given system will have a unique interim fix label. This is the unique key that binds all of the different database objects. To reference an interim fix by label, pass the label as a parameter to the **-L** flag. For example, to run a check operation on an interim fix with label **ABC123**, enter:

```
emgr -cL ABC123
```

Reference by Ifix ID

Each interim fix that is installed on a given system has an interim fix ID. The interim fix ID is simply the order number in which the interim fix is listed in the interim fix database. Using this option may be convenient if you are performing operations on interim fixes based on interim fix listings. The **emgr** command will convert the interim fix ID into an interim fix label before performing the given operation. To reference an interim fix by ID, pass the ID as an parameter to the **-n** flag.

Note: Ifix IDs can change as interim fixes are removed and added. Always verify the current interim fix ID number by using the **-l** flag to list the specific interim fix or all interim fixes.

For example, to run a check operation on the first interim fix with ID equal to 1, enter:

```
emgr -cn1
```

Reference by VUID

Because interim fix packages are not formally tracked by any entity, it is possible that the same interim fix label could be used for more than one interim fix package. However, the **emgr** command does not accept the installation of more than one interim fix with the same interim fix label at the same time. The VUID (Virtually Unique ID) can be used to differentiate packages with the same interim fix label. The **emgr** command converts the VUID into an interim fix label before performing the given operation. For example, to list an installed interim fix with VUID equal to **000775364C00020316020703**, enter:

```
emgr -l -u 000775364C00020316020703
```

Note: The VUID is displayed in the preview phase of interim fix installation and removal. The VUID is also displayed when listing with verbosity level set to 3 with the **-v** flag.

Ifix Logging

The following operations are logged to the **emgr** command log file, **/var/adm/ras/emgr.log**:

- Installation
- Removal

- Checking
- Mounting
- Unmounting
- Forced Removal

Enabling Automatic Interim Fix Removal by installp

An interim fix can be packaged by the **epkg** command to contain an APAR reference file containing APAR reference numbers. An APAR reference number will allow **installp** to map an interim fix back to the APARs for all the Technology Levels where the fix was shipped. If **installp** determines that the interim fix is contained in the Technology Level, Service Pack, or PTF being applied, **installp** will automatically remove the interim fix prior to applying the updates.

If an interim fix is enabled for automatic removal, the **emgr** command will display the following message during the installation of the interim fix:

```
ATTENTION: Interim fix is enabled for automatic removal by installp.
```

Concurrent Updates

The **emgr** command supports the installation of a new kind of interim fix called a concurrent update. This form of interim fix contains a modification to the AIX kernel, or one of its kernel extensions, that can be applied directly to the system memory and does not require the system to be rebooted. This direct patching to the system memory allows you to safely evaluate and test a kernel modification without modifying the file containing the system's current kernel on the disk. Any concurrent update applied to the system memory will not persist after a system reboot unless you choose to commit the changes introduced by the concurrent update to the disk using the **-C** flag. You can apply a concurrent update directly over another patch for the same module. You do not need to remove the previous patch. However, there must be only one version of the module loaded. Also, you cannot run any concurrent update operations (in-memory or on disk) for interim fixes in the REBOOT_REQUIRED state until the system is rebooted.

The **emgr** command supports the apply of in-memory concurrent updates on NIM thin servers (diskless or dataless clients). Since thin servers share operating system files with other clients (**/usr** directory is read-only), the **emgr** option to commit a concurrent update to disk (**-C** flag) is not valid on a thin servers.

Note: If the shared operating system files of a thin server need to be patched to disk, an interim fix may be applied to the SPOT resource on the NIM master that serves the thin server. Please refer to the Installing an Interim Fix into a SPOT resource section of Installation Guide or the **/usr/lpp/bos.sysmgt/nim/README file** (NIM IFIX/EMGR section) on your NIM master for details on installing an interim fix into a SPOT.

The **emgr** database will be located in the **/var/emgrdata** directory on thin servers, since the **/usr** file system is read-only on thin servers.

Certain **emgr** operations can not be supported in a thin server environment, such as bosboot and file system expansion. As a result, the following **emgr** flags are not supported in a thin server environment: **-C**, **-e**, **-I**, **-k**, and **–X**. Also, the **–b** flag, which skips the bosboot process for interim fixes that require rebooting, will always be utilized when applicable since the bosboot operation cannot be supported for thin servers.

Flags

Item	Description
-a *path*	Specifies an alternative directory path for installation. **Note:** The **-a** flag works during the removal of an interim fix only if the **-e** and **-a** flags of the **emgr** command were used during the installation of the interim fix. If the interim fix was not installed by using the **-e** and **-a** flags, the **emgr** command does not completely remove an interim fix from the alternative directory path. As a workaround, use the following command to remove an interim fix that was installed in the alternative directory: `chroot /alt_inst /usr/sbin/emgr -r -L efix_label`
-b	Causes the **emgr** command to skip the usual AIX **bosboot** process for interim fixes that require rebooting.
-c	Specifies the check operation. Instructs the **emgr** command to run a check operation on the specified interim fix or interim fixes.
-C	Commits an interim fix containing concurrent updates to the disk. This option must be used along with the **-i** option, or can be used after an interim fix has been applied with the **-i** option. This causes the concurrent updates to persist across system reboots. After a concurrent update has been committed, removal will result in the module being restored to its original un-patched state, regardless of whether other patches for the module exist or not. All prior patches for the module are removed at the time the commit is performed.
-d	Displays the contents and topology. This option is useful with the -v flag in displaying verbosity output.
-e *interimfixPackage*	Specifies the path of the interim fix package file, and installs the interim fix package. The interim fix package file must be created with the **epkg** command and must end with the 16-bit compression extension, **.Z**.
-f *ListFile*	Specifies a file that contains one of the following: • A list of package locations for the installation operation (one per line) • A list of interim fix labels for the remove, mount, unmount, and check operations (one per line) The **emgr** command ignores any blank lines or lines where the first non-white-space character is the **#** character.
-i *interimfixPackage*	Specifies the path of an interim fix package file containing a concurrent update, and applies the concurrent update to the system memory. The update does not persist across system reboots unless the **-C** flag is used. You can also use the **-i** flag to apply one concurrent update over another for the same module. Such a concurrent update is termed a "follow-on".
-I	Runs the low-level debugger for AIX **bosboot** by using the **bosboot** command's **-I** flag.
-k	Loads the low-level debugger during AIX **bosboot** using the **bosboot** command's **-D** flag.
-l	Instructs the **emgr** command to run the list operation on the specified interim fix or interim fixes.
-L *Label*	Selects the interim fix for this operation by interim fix label.
-m	Instructs the **emgr** command to perform a mount installation. When and interim fix is mount-installed, the interim fix files are mounted over the target files.

Item	Description
-M	Instructs the **emgr** command to mount an interim fix or interim fixes that have been mount-installed by using the **-m** flag. The **-M** flag can be used to mount an interim fix that was installed using the **-m** flag and has been unmounted by the **-U** flag or by some other means, such as rebooting the system.
-n *interimfixID*	Selects the interim fix for this operation by specifying the interim fix ID.
-o	Specifies that the interim fix installation can overwrite an existing package.
-p	Instructs the **emgr** command to perform a preview for either installation or removal. The preview runs all of the check operations, but does not make any changes.
-P [*Package*]	Specifies the package-view operation, which displays all packages that are locked by the interim fix manager, their installer, and the locking label or labels.
-q	Suppresses all output other than errors and strong warnings.
-r	Instructs the **emgr** command to run a remove operation on the specified interim fix or interim fixes. Removal of an active patch reinstates any prior patch for the module, provided one exists. If no prior patch exists, the module is restored to its original un-patched state.
-R *Label*	Instructs the **emgr** command to run a force-remove operation. This option removes interim fix data and package locks associated with the interim fix label without actually removing interim fix files, running any remove scripts, or boot processing. This option can be used for only one interim fix at a time. The interim fix label is required to identify the target interim fix. **Attention:** • This method of interim fix removal should be considered an emergency procedure. Because this method can create inconsistencies on the target system, the force remove method should be used only if all other methods of removing the interim fix are unsuccessful. • You must use the standard removal process (**-r** flag) to remove an installed interim fix. In emergency procedures, you can use the **-R** flag to force-remove a label. The **-R** flag requires the **-F** flag to remove a label. When you specify the **-F** flag with the **-R** flag, for example, `emgr -FR` *`ifix_label`*, the force-remove option does not delete any of the interim fix files, saved data, or execute remove scripts. This option must be used only if the standard remove process cannot be accomplished.
-u *VUID*	Selects the interim fix for this operation by specifying the VUID.
-U	Instructs the **emgr** command to unmount an interim fix or interim fixes that have been mount-installed by using the **-m** flag.
-v{**1**|**2**|**3**}	Specifies the verbosity level for the listing operation or the verification level for the check operation. Valid levels are 1, 2, and 3.
-w *Directory*	Instructs the **emgr** command to use the specified working directory instead of the default **/tmp** directory.

Item	Description
-X	Attempts to expand any file systems where there is insufficient space to perform the requested **emgr** operation. This option expands file systems based on available space and size estimates that are provided by the interim fix package and the **emgr** command. **Note:** 1. It is possible to exhaust available disk space during an installation even if the **-X** flag is used. This is more likely if other files are being created or expanded in the same file systems during an installation. 2. Remote file systems cannot be expanded by the **emgr** command.

Exit Status

0
All of the **emgr** command operations completed successfully.

>0
An error occurred.

Security

System administrators or users with the **aix.system.install** authorization can run the **emgr** command on a multi-level secure (MLS) system. Ifix data, saved files, and temporary files are accessible only by the root user.

The **emgr** command looks for a supported MD5 generating command on the system. If one is located, the **emgr** command displays the MD5 checksum to the user. The user can then cross check this MD5 sum with a secured source. If an MD5 generating command is not located, the **emgr** command takes no further action.

The user can force set the path to an MD5 command by exporting the EMGR_MD5_CMD shell variable. This variable should contain the absolute path to the MD5 generating command.

Notes:

- This feature is not supported in the original release of interim fix management. It is recommended that the user updates to the latest level of interim fix management by updating **bos.rte.install** to the latest level.
- If Trusted Execution (TE) policy is turned on along with the TSD_LOCK policy or the TSD_FILE_LOCK policy, the **emgr** command fails. To continue with the installation,manually turn off the TSD_LOCK policy or the TSD_FILE_LOCK policy. The **emgr** command runs successfully with TE policies other than the TSD_LOCK policy or the TSD_FILE_LOCK policy.

  Also, when a TE policy is turned on, only one instance of the **emgr** command is supported.

Examples

1. To preview the installation of an interim fix package called **games.020303.epkg.Z**, enter:

   ```
   emgr -p -e games.020303.epkg.Z
   ```

2. To install the interim fix package called **games.020303.epkg.Z** and automatically expand file systems if additional space is needed, enter:

   ```
   emgr -X -e games.020303.epkg.Z
   ```

3. To list all interim fixes on the system, enter:

   ```
   emgr -l
   ```

4. To do a level 3 listing of interim fix label **games**, enter:

```
emgr -lv3 -L games
```

5. To remove the interim fix with label **games**, enter:

```
emgr -r -L games
```

6. To preview the removal of the interim fix labels in file **/tmp/myfixes**, enter:

```
emgr -rp -f /tmp/myfixes
```

7. To check all interim fixes with verification level 2, enter:

```
emgr -cv2
```

8. To check interim fix ID number 3 with verification level 1 (the default verification level), enter:

```
emgr -c -n3
```

9. To check interim fix with VUID of **000775364C00020316020703** and verification level 3, enter:

```
emgr -u 000775364C00020316020703 -c -v3
```

10. To list all locked packages and their interim fix labels, enter:

```
emgr -P
```

11. To list all interim fix labels that have locked the **installp** package **bos.rte.lvm**, enter:

```
emgr -P bos.rte.lvm
```

12. To mount-install the interim fix package called **games.020303.epkg.Z** and suppress AIX **bosboot**, enter:

```
emgr -e games.020303.epkg.Z -mb
```

13. To mount all interim fix files that have been mount-installed on the system by using the **-m** option, enter:

```
emgr -M
```

14. To unmount all interim fix files associated with interim fix label **games**, enter:

```
emgr -U -L games
```

15. To apply an interim fix package called **kernelmod.031007.epkg.Z** with concurrent updates to the system memory, enter:

```
emgr -i kernelmod.031007.epkg.Z
```

16. To commit the concurrent updates associated with the interim fix label **kernelmod** to the disk, enter:

```
emgr -C -L kernelmod
```

17. To apply an interim fix package called **kernelmod2.031007.epkg.Z** with concurrent updates to the system memory, and also to commit the concurrent updates to the disk, enter:

```
emgr -i kernelmod2.031007.epkg.Z -C
```

18. To display level 3 verbosity output on interim fix package `test.102403.epkg.Z`, enter:

```
emgr -v3 -d test.102403.epkg.Z
```

Files

Item	Description
/usr/sbin/emgr	Contains the **emgr** command
/usr/emgrdata/DBS/ifix.db	Contains the interim fix header database
/usr/emgrdata/DBS/files.db	Contains the interim fix files database
/usr/emgrdata/DBS/pkglck.db	Contains the package locks database
/usr/emgrdata/DBS/prereq.db	Contains the prerequisite database

/usr/emgrdata/DBS/aparref.db	Contains the APAR reference file database

emstat Command

Purpose

Shows emulation exception statistics.

Syntax

emstat [**-a** | **-v**] [*Interval*] [*Count*]

Description

The **emstat** command displays emulation exception statistics. Emulation exceptions can occur when some existing applications or libraries, which contain instructions that have been deleted from older processor architectures, are executed on newer processors. These instructions may cause illegal instruction program exceptions. The operating system catches these exceptions and emulates the older instruction(s) to maintain program functionality, potentially at the expense of program performance.

The emulation exception count since the last time the machine was rebooted and the count in the current interval are displayed. The user can optionally display alignment exception statistics or individual processor emulation statistics.

The default output displays statistics every second. The sampling interval and number of iterations can also be specified.

Parameters

Item	Description
Interval	Interval between samples.
Count	Number of iterations.

Flags

Item	Description
-a	Displays alignment exception statistics. This flag cannot be used with the **-v** flag.
-v	Display individual processor statistics. This flag cannot be used with the **-a** flag.

Examples

1. To display the emulation statistics every second, type:

```
emstat
```

This produces the following output:

```
  Emulation  Emulation
  SinceBoot      Delta
    8845591          0
    8845591          0
    8845591          0
    8845591          0
    8845591          0
    8845591          0
  ...
```

2. To display emulation and alignment exception statistics every two seconds, a total of 5 times, type:

```
emstat -a 2 5
```

This produces the following output:

```
  Alignment  Alignment  Emulation  Emulation
  SinceBoot      Delta  SinceBoot      Delta
   21260604          0   70091846          0
   23423104    2162500   72193861    2102015
   25609796    2186692   74292759    2098898
   27772897    2163101   76392234    2099475
   29958509    2185612   78490284    2098050
```

3. To display emulation statistics, every 5 seconds, for each processor, type:

```
emstat -v 5
```

This produces the following output:

```
  Emulation  Emulation  Emulation  Emulation
  SinceBoot      Delta    Delta00    Delta01
   88406295          0          0          0
   93697825    5291530          0    5291530
   98930330    5232505    5232505          0
  102595591    3665261     232697    3432564
  102595591          0          0          0
```

emsvcsctrl Command

Purpose

Starts the event management subsystem.

Syntax

`emsvcsctrl [-a | -s | -k | -d | -c | -t | -o | -h ]`

Description

`emsvcsctrl` is a control script that starts the event management subsystem. Event management is a distributed subsystem of RSCT that provides a set of high-availability services for the IBM RS/6000 server. By matching information about the state of system resources with information about resource conditions that are of interest to client programs, it creates events. Client programs can use events to detect and recover from system failures, thus enhancing the availability of the system. The emsvcsctrl control script controls the operation of the Event Management subsystem. The subsystem is under the control of the System Resource Controller (SRC) and belongs to a subsystem group called emsvcs. A daemon is associated with each subsystem. The emsvcsctrl script also controls the operation of the AIX Resource Monitor subsystem. The subsystem is under SRC control and also belongs to the emsvcs subsystem group. A daemon is associated with each subsystem.

Instances of the Event Management and AIX Resource Monitor subsystems execute on each node in the HACMP/ES cluster. From an operational point of view, the Event Management subsystem group is organized as follows:

Subsystem
Event Management

Subsystem Group
emsvcs

SRC Subsystem
The emsvcs subsystem is associated with the haemd daemon.

emaixos
The emaixos is associated with the harmad daemon.

Daemons
The haemd daemon provides the Event Management services. The harmad daemon is the resource monitor for AIX operating system resources.

The emsvcsctrl script is not normally executed from the command line. It is normally called by the HACMP/ES startup script command during installation of the system.

The emsvcsctrl script provides a variety of controls for operating the Event Management subsystem:

- Adding, starting, stopping, and deleting the subsystem
- Cleaning up the subsystems
- Turning tracing on and off

`Adding the Subsystem:` When the -a flag is specified, the control script uses the mkssys command to add the Event Management and AIX Resource Monitor subsystems to the SRC. The control script operates as follows:

1. It makes sure that the emsvcs and emaixos subsystems are stopped.
2. It removes the emsvcs and emaixos subsystems from the SRC (just in case they are still there).
3. It adds the emsvcs subsystem to the SRC.
4. It adds the emaixos subsystem to the SRC.
5. It adds haemrm group using the mkgroup command, if it does not already exist. Any errors that occur are written to a log file named /var/ha/log/em.mkgroup.
6. It creates the /var/ha/lck/haem and /var/ha/soc/haem directories, if they don't already exist. Any errors that occur are written to a log file named /var/ha/log/em.mkdir.
7. It copies the Event Management Configuration Database, (EMCDB) from its install location, /opt/rsct/install/config/em.HACMP.cdb to its run-time location, /etc/ha/cfg/em.HACMP.cdb. Any errors resulting from the copy are written to a log file named /var/ha/log/em.cp.

`Starting the Subsystem:` When the -s flag is specified, the control script uses the startsrc command to start the Event Management subsystem, emsvcs, and the AIX Resource Monitor subsystem, emaixos.

`Stopping the Subsystem:` When the -k flag is specified, the control script uses the stopsrc command to stop the Event Management subsystem, emsvcs, and the AIX Resource Monitor subsystem, emaixos.

`Deleting the Subsystem:` When the -d flag is specified, the control script uses the rmssys command to remove the Event Management and AIX Resource Monitor subsystems from the SRC. The control script operates as follows:

1. It makes sure that the emsvcs and emaixos subsystems are stopped.
2. It removes the emsvcs and emaixos subsystems from the SRC using the rmssys command.

`Cleaning Up the Subsystems:` When the -c flag is specified, the control script stops and removes the Event Management subsystems for all system partitions from the SRC. The control script operates as follows:

1. It stops all instances of subsystems in the subsystem group by using the stopsrc -g emsvcs command.

2. It removes all instances of subsystems in the subsystem group from the SRC using the rmssys command.
3. It removes the Event Management Configuration Database (EMCDB) from its run-time location, /etc/ha/cfg/em.HACMP.cdb.

`Turning Tracing On:` When the -t flag is specified, the control script turns tracing on for the haemd daemon, using the haemtrcon command. Tracing for the harmad daemon is also enabled, using the traceson command.

`Turning Tracing Off:` When the -o flag is specified, the control script turns tracing off for the haemd daemon, using the haemtrcoff command. Tracing for the harmad daemon is also disabled, using the tracesoff command.

`Logging:` While it is running, the Event Management daemon normally provides information about its operation and errors by writing entries to the AIX error log. If it cannot, errors are written to a log file called /var/ha/log/em.default.cluster_name.

Flags

-a
Adds the subsystem.

-s
Starts the subsystem.

-k
Stops the subsystem.

-d
Deletes the subsystem.

-c
Cleans the subsystem.

-t
Turns tracing on for the subsystem.

-o
Turns tracing off for the subsystem.

-h
Displays usage information.

Security

You must be running with an effective user ID of `root`.

Exit Status

0
Indicates the successful completion of the command.

1
Indicates that an error occurred.

Restrictions

This command is valid in an HACMP environment only.

Standard Error

This command writes error messages (as necessary) to standard error.

Examples

1. To add the Event Management subsystem to the SRC, enter:

```
emsvcsctrl -a
```

2. To start the Event Management subsystem, enter:

```
emsvcsctrl -s
```

3. To stop the Event Management subsystem, enter:

```
emsvcsctrl -k
```

4. To delete the Event Management subsystem from the SRC, enter:

```
emsvcsctrl -d
```

5. To clean up the Event Management subsystem, enter:

```
emsvcsctrl -c
```

6. To turn tracing on for the Event Management daemon, enter:

```
emsvcsctrl -t
```

7. To turn tracing off for the Event Management daemon, enter:

```
emsvcsctrl -o
```

Location

/opt/rsct/bin/emsvcsctrl
Contains the `emsvcsctrl` script

Files

/var/ha/log/em.default.cluster_name
Contains the default log of the haemd daemon on the cluster named cluster_name.

/var/ha/log/em.cp
Contains a log of any errors that occurred while copying the Event Management Configuration Database.

/var/ha/log/em.trace.cluster_name
Contains the trace log of the haemd daemon on the cluster named cluster_name.

/var/ha/log/em.mkgroup
Contains a log of any errors that occurred while creating the haemrm group.

/var/ha/log/em.mkdir
Contains a log of any errors that occurred while creating the /var/ha/lck/haem and /var/ha/soc/haem directories.

enable Command

The **enable** command includes information for **AIX Print Subsystem enable** and the **System V Print Subsystem enable**.

AIX Print Subsystem enable Command

Purpose

Enables printer queue devices.

Syntax

enable *PrinterName ...*

Description

The **enable** command brings the printer queue devices specified by the *PrinterName* parameter on line, or enables the printer queue devices to be used with the system.

Notes:

1. You must have root user authority or belong to the printq group to run this command.
2. If you enter `enable -?`, the system displays the following error message:

```
enq: (FATAL ERROR): 0781-048: Bad queue or device name: -?
```

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

To enable the print queue device `lp0:lpd0`, enter:

```
enable lp0:lpd0
```

Files

/etc/qconfig
Contains the queue configuration file.

/etc/qconfig.bin
Contains the digested, binary version of the **/etc/qconfig** file.

/usr/sbin/qdaemon
Contains the queuing daemon.

/var/spool/lpd/qdir/*
Contains the queue requests.

/var/spool/lpd/stat/*
Contains information on the status of the devices.

/var/spool/qdaemon/*
Contains temporary copies of enqueued files.

System V Print Subsystem enable Command

Purpose (System V Print Subsystem enable Command)

Enable LP printers

Syntax (System V Print Subsystem enable Command)

enable ***printers***

Description (System V Print Subsystem enable Command)

The **enable** command activates the named ***printers***, enabling them to print requests submitted by the **lp** command. If the printer is remote, the command will only enable the transfer of requests to the remote system; the **enable** command must be run again, on the remote system, to activate the printer. (Run **lpstat -p** to get the status of printers.)

When changes are made to the attributes of a print device, they are recognized by **enable**. Therefore to change the definition or allocation for a device, you must disable the printer on that device, change the device, and then run **enable**. The new device attributes will become effective when **enable** is executed.

Printer names are *system-defined words* and as such should be restricted to uppercase and lowercase ASCII characters.

If you enter `enable -?`, the system displays the command usage message and returns 0.

Security (System V Print Subsystem enable Command)

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **`lssecattr`** command or the **`getcmdattr`** subcommand.

Files (System V Print Subsystem enable Command)

/var/spool/lp/*

enotifyevent Command, notifyevent Command

Purpose

Mails event information generated by the event response resource manager (ERRM) to a specified user ID.

Syntax

`enotifyevent` [`-h`] [*user-ID*]

`notifyevent` [`-h`] [*user-ID*]

Description

The `enotifyevent` script always return messages in English. The language in which the messages of the `notifyevent` script are returned depend on the locale settings.

These scripts capture event information that is posted by the event response resource manager (ERRM) in environment variables that are generated by the ERRM when an event occurs. These scripts can be used as actions that are run by an event response resource. They can also be used as templates to create other user-defined actions.

Event information is returned about the ERRM environment variables, and also includes the following:

Local Time
Time when the event or rearm event is observed. The actual environment variable supplied by ERRM is ERRM_TIME. This value is localized and converted to readable form before being displayed.

In AIX, these scripts use the `mail` command to send event information to the specified user ID. When a user ID is specified, it is assumed to be valid, and it is used without verifying it. If a user ID is not specified, the user who is running the command is used as the default.

user-ID is the optional ID of the user to whom the event information will be mailed. If *user-ID* is not specified, the user who is running the command is used as the default.

Flags

-h
Writes the script's usage statement to standard output.

Parameters

log_file
Specifies the name of the file where event information is logged. An absolute path for the *log_file* parameter should be specified.

For AIX, the *log_file* is treated as a circular log and has a fixed size of 64KB. When *log_file* is full, new entries are written over the oldest existing entries.

For other platforms, the size of the *log_file* is not limited, and it will not overwrite itself. The file size will increase indefinitely unless the administrator periodically removes entries.

If *log_file* already exists, event information is appended to it. If *log_file* does not exist, it is created so that event information can be written to it.

Exit Status

0
Command has run successfully.

Restrictions

1. These scripts must be run on the node where the ERRM is running.
2. The `mail` command is used to read the file.

Standard Output

When the `-h` flag is specified, the script's usage statement is written to standard output.

Examples

1. You can use the **mail** command to read the contents of the event information. The following example shows how a warning event for the `/var` file system (a file system resource) is formatted and logged:

```
============================================================================
Event reported at Sun Mar 26 16:38:03 2002

Condition Name:                      /var space used
Severity:                   Warning
Event Type:                    Event
Expression:                    PercentTotUsed>90

Resource Name:                   /var
Resource Class Name:               IBM.FileSystem
Data Type:                    CT_UINT32
Data Value:                    91
```

Location

/opt/rsct/bin/enotifyevent
Contains the `enotifyevent` script

/opt/rsct/bin/notifyevent
Contains the `notifyevent` script

enq Command

Purpose

Enqueues a file.

Syntax

To process a file

enq [**-**] [**-B** *CharacterPair*] [**-c**] [**-C**] [**-G**] [**-j**] [**-m** *Text*] [**-M** *File*] [**-n**] [**-N** *Number*] [**-o** *Option*] [**-P** *Queue*] [**-r**] [**-R** *Number*] [**-t** "*User*"] [**-T** *Title*] [**-Y**] [**-Z** *Name*] *File*

To change the priority of print jobs

enq -a *Number* **-#** *JobNumber*

To display status

enq [**-q** | **-A**] [**-L**] [**-W**] [**-e**] [**-#** *JobNumber*] [**-u** *Name*] [**-w** *Seconds*] [**-s**]

To change queue and queue daemon status

enq [**-d**] [**-D**] [**-G**] [**-K**] [**-L**] [**-q** | **-A**] [**-U**]

To cancel options

enq [**-X**] [**-x***Number*] [**-P***Printer*]

To hold, release, or move a print job to another queue

enq { **-h** | **-p** | **-Q** *NewQueue* } { **-#** *JobNumber* [**-P** *Queue*] | **-u** *User* | **-P** *Queue* }

To queue and hold a print job

enq -H *File ...*

Description

The **enq** command is a general-purpose utility for enqueuing requests to a shared resource, typically a printer device. Use the **enq** command to enqueue requests, cancel requests, alter the priority of a request, and display the status of queues and devices.

The **enq** command has five different syntax diagrams because all the flags are not meant to work together. Some of these flags are meant for file processing and accept *FileName* as an option. The other flags are used for changing the priority of a print job, displaying the status, changing the status of the queue or the queue daemon, and canceling a print job.

To enqueue files on a specific queue, use the **-P** flag (**-P** *Queue*). If more than one device services a queue, you can also request a particular device by specifying that device (*:device*) after the name of the queue. If you do not specify a device, the job is sent to the first available device. If you do not specify a file, the **enq** command copies standard input into a file and enqueues it for printing.

The **enq** command requests can have operator messages that are associated with them. This feature is useful in a distributed environment or on a system with many users. The messages are used to tell the printer operator such information as a request to load a special form or different color paper into the printer before allowing the job to print. These messages are specified with the **-m** and **-M** flags. The **qdaemon** command processes the **enq** command requests. When the **qdaemon** is ready to begin a request that has an associated message, the system displays the message on the console of the machine where the **qdaemon** process is running. The text of the message is accompanied by a prompt that tells the printer operator how to signal the request to continue or how to cancel the request.

The display that is generated by the **enq -A** command contains two entries for remote queues. The first entry contains the client's local queue and local device name and its status information. The second entry follows immediately; it contains the client's local queue name (again), followed by the remote queue

name. Any jobs that are submitted to a remote queue are displayed first on the local side and are moved to the remote device as the job is processed on the remote machine.

Since the status commands communicate with remote machines, the status display might occasionally appear to hang when waiting for a response from the remote machine. The command eventually times out if a connection cannot be established between the two machines.

Notes:

1. Before you can enqueue a file, you must have read access to it. To remove a file, (see the **-r** flag) you must also have write access to the directory that contains the file.
2. If you want to continue changing the file after you issue the **enq** command but before it is printed, you must use the **-c** flag.
3. When enqueuing files on a printer, flags can be interspersed in any order.
4. The **-d** and **-G** flags are acted upon immediately. Syntax error that appears before these flags on the command line are reported. Syntax errors that appears after these flags on the command line are ignored.

Flags

File processing options

If you give the **enq** command a list of file names, it enqueues them all for file processing on the default device or on the specified device.

Item	Description
-	Causes the **enq** command to act as a filter. The **enq** command automatically reads standard input if you do not specify a file or files. However, if you do specify a file, you can also use the dash (**-**) to force the **enq** command to read standard input. The dash (**-**) is actually not a flag, but a special type of file name. Therefore, it must come after all other flags are specified on the command line.

Item	Description
-B *CharacterPair*	Controls the printing of burst pages according to the value of *CharacterPair* as follows. (**n** = never, **a** = always, **g** = group. The first character is for header, the second character is for trailer.) **HT** Description **nn** No headers, no trailers **na** No headers, trailer on every file **ng** No header, trailer at the end of the job **an** Header on every file, no trailers **aa** Headers and trailers on every file in the job **ag** Header on every file, trailer after job **gn** Header at the beginning of job, no trailer **ga** Header at beginning of job, trailer after every file **gg** Header at beginning of job, trailer at end of job The header and trailer stanzas in the **/etc/qconfig** file define the default treatment of burst pages. **Note:** In a remote print environment, the default is to print a header page and not a trailer page.
-c	Copies the file. To save disk space, the **enq** command remembers the name of the file, but does not actually copy the file itself. Use the **-c** flag if you want to continue changing the file while you are waiting for the current copy to be printed.
-C	Specifies that the **mail** command is to be used instead of the **write** command for error messages and job completion notification. (Using this flag is useful for writing PostScript applications since it allows better feedback from the printer.) Error messages and job completion messages (both generated by the **piobe** command) and any data read from the printer are also sent back by mail. The **-C** flag applies only to local print jobs. If you want to be notified when a job sent to a remote printer is completed, use the **-n** flag to receive a mail message. **Note:** There are some messages that cannot be redirected from **qdaemon** and the printer back-end in any way. These messages are system errors and are sent directly to the /**dev**/**console** file.
-j	Specifies that the message `Job number is: nnn`, where nnn is the assigned job number, be displayed to standard output. It occurs only if the job is submitted to a local print queue.
-m *Text*	Submits an operator message with an **enq** command request. The specified text contains the message.

Item	Description
-M *File*	Submits an operator message with an **enq** command request. The specified file contains the text of the message.
-n	Notifies you when your job is finished. If the **-t** flag is also used, the **enq** command also notifies the user for whom the request is intended (see the **-t** flag).
-N *Number*	Prints *Number* copies of the file. Normally, a file is printed only once.
-o *Option*	Specifies that flags that are specific to the backend be passed to the backend. Thus, for each queue there are flags that are not described in this section that can be included on the **enq** command line. See the **piobe** command for a list of these flags.
-P *Queue*	Specifies the queue to which the job is sent. A particular device on a queue can be specified by typing `-P Queue:Device`.
-r	Removes the file after it is successfully printed.
-R *Number*	Sets the priority of the current job to *Number*. This flag is used at job submission time. Use the **-a** flag to alter priority after the job is submitted. Higher numbers assign higher priority. The default priority is 15. The maximum priority is 20 for most users and 30 for the users with root user authority.
-t "*User*"	Labels the output for delivery to *User*. Normally the output is labeled for delivery to the user name of the person who is issuing the **enq** command request. The value of *User* must be a single word that meets the same requirements of a regular user ID.
-T *Title*	Puts title on the header page and displays it when the **-q** flag is specified. Normally the job title is the name of the file. If the **enq** command reads from standard input, the job title is **STDIN.#** where **#** is the process ID of the **enq** command.
-Y	Tells the **enq** command to ignore the rest of the command line after this flag. This is useful for discovering whether a queue is valid (if it is in the **/etc/qconfig** file). For example, typing `enq -P lp4 -Y` returns with an exit value of 0 if the line printer **lp4** is a valid queue; if otherwise, a nonzero value is returned. Using this flag is also good for forcing the **qdaemon** command to redigest the **/etc/qconfig** file.
-Z *Name*	Specifies originator of remote print jobs.

Print job priority options

Item	Description
-a *Number*	Changes the priority of the named job to *Number*. The job must be submitted for printing before entering the **enq** command with this flag. See the **-R** flag for a description of priorities. Use the **-#** flag to specify the job number. This flag is only valid for local print jobs.

Item	Description
-# *JobNumber*	Specifies the job number that is used by the **enq -q** command or the **enq -a** command, and displays only the job that is specified in status output. **Note:** 1. Specify the **-P** *Queue* to override the default destination printer. 2. If jobs 1, 2, and 3 are in the printer queue, and you specify that you want the status of job 3 while job 1 is running, the status information shows job 1 and job 3, not only job 3. 3. If you specify a job number that does not exist, the system displays the current job number on the queue instead of an error message.

Display status options

Item	Description
-A	Provides status for all queues. It is like running the **enq -q** command once for each queue in the **qconfig** file.
-e	Excludes status information from queues that are not under the control of the **qdaemon** command. The status from such queues might be in different formats. The **-e** flag can be used with any combination of flags.
-L	Specifies the long status. This flag can be used with the **-A**, **-q**, or **-W** flag. If the **-L** flag and the **-W** flag are used simultaneously, the result displays the long status of the print job in the semicolon-separated format. Use the **-L** flag to show multiple files to be printed in a single print job.
-q	Displays the status of the default queue. The **LPDEST** and **PRINTER** environment variable control the name of the default printer. If the **LPDEST** environment variable contains a value, that value is always used first. If the **LPDEST** variable has no value, the **enq** command uses the **PRINTER** environment variable. If the **PRINTER** environment variable contains no value, then the **enq** command uses the system default. **Notes:** 1. Use the **-P** *Queue* flag with the **-q** flag to display the status of a particular queue. 2. Any destination command-line options override both the **LPDEST** and the **PRINTER** environment variables.
-s	Obtains the status of print queues without listing any files.
-u *Name*	Specifies the user name for which to print job status.
-w *Seconds*	Specifies continuous output of the queue status, updating the screen every *Seconds* specified until the queue is empty (see the **lpq** command). When the queue is empty, the process halts. This flag is only used with either the **-q** flag, or the **-A** flag, or the **-L** flag.
-W	Specifies the wide status format with longer queue names, device names, and job numbers. This flag can be used with the **-A**, **-q**, or **-L** flag. If the **-L** and **-W** flags are used simultaneously, the result displays the long status of the print job in the semicolon-separated format.

Change the queue and queue daemon status options

Item	Description
-d	Runs the **digest** command on the **/etc/qconfig** file. Once the digest is completed, any changes to the **/etc/qconfig** file are reflected in the **/etc/qconfig.bin** file. A user must have root user authority to run this option.

In addition to the previous flags available to all users, the **enq** command accepts the following flags when they are entered by users that have root user authority. Root user authority means that you are root or you belong to the **printq** group.

Note: The following flags can be used only on local print jobs.

Item	Description
-D	Device DOWN. Turns off the device that is associated with the queue. The **qdaemon** process no longer sends jobs to the device, and entering the **enq -q** command shows its status as DOWN. Any job currently running on the device is allowed to finish.
-G	Die GRACEFULLY. Ends the **qdaemon** process after all currently running jobs are finished. Use of this flag is the only clean way to bring the **qdaemon** process down. Use of the **kill** command might cause problems, such as jobs hanging up in the queue. If the **qdaemon** process is running under **srcmstr** (the default configuration), **enq -G** does not prevent **qdaemon** from being restarted automatically. You must use the **chssys** command, which changes the default configuration and prevents the automatic restart of the **qdaemon** process. The following command: `chssys -s qdaemon -O` issued before the **enq -G** command, prevents the automatic restart of the **qdaemon** command. The following command: `startsrc -s qdaemon` restarts the **qdaemon** process manually.
-K	Acts the same as the **-D** flag, except that all current jobs are killed. They remain in the queue, and are run again when the device is turned on.
-L	Specifies the long status. This flag can be used with the **-A**, **-q**, or **-W** flag. Use the **-L** flag to show multiple files to be printed in a single print job.
-U	Brings UP the device that is associated with a queue. The **qdaemon** process sends jobs to it again and entering the **enq -q** command shows its status as ready.

Note: If more than one device is associated with a queue, you must specify the device and the queue when you use the **-D** flag, the **-K** flag, and the **-U** flags. For example, entering `-P lp:lpd` designates the same device only if there is no other device on that queue.

Cancel options

Item	Description
-X	Cancels the printing of your jobs. If you have root user authority, all jobs on the specified queue are deleted. This flag is only valid on local print jobs.
-x *Number*	Cancels the printing of the specified job *Number*.
-P *Printer*	Specifies the *Printer* where either all jobs or the selected job number is to be canceled.

Attention: If you have root user authority and do not specify a queue, all jobs on all queues are deleted.

Holding and releasing a print job options

Item	Description
-# *JobNumber*	Designates the number of the print job to be held or released.
-h	Holds the specified print job.
-H	Queues and holds the file indicated with the *File* parameter.
-p	Releases the specified print job.
-P *Queue*	Designates the print queue to be held or released.
-u *User*	Designates the user whose print jobs are to be held or released.

Moving print job options

Item	Description
-# *JobNumber*	Designates the number of the print job to be moved.
-P *Queue*	Designates the print queue to be moved. The value of the *Queue* variable can be a queue name or in the form queue:device name.
-Q *NewQueue*	Designates the target queue where the print job is moved to. The value of the *NewQueue* variable can be in the form of a queue name or in the form queue:device name.
-u *User*	Designates the user whose print jobs are to be moved.

Security

Auditing Events:

Event	Information
ENQUE_admin	Queue name, device name, job name, user name

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To print the file `memo` on the default printer, enter:

   ```
   enq memo
   ```

2. To print the file `prog.c` with page numbers, enter:

   ```
   pr prog.c | enq
   ```

   The **pr** command puts a heading at the top of each page that includes the date that the file was last modified, the name of the file, and the page number. The **enq** command then prints the file.

3. To print a file with page numbers, reading from standard input, enter:

   ```
   pr x | enq  -P bill  -n  -r fn1 - fn3
   ```

   The dash (**-**) special file name tells the **enq** command to read from standard input. Normally the **enq** command does not read from standard input if there are file names on the command line. It also indicates the order in which to print things. The **pr** command creates a page numbered version of the file x and passes it to the **enq** command, which creates a temporary file that contains that output in the **/var/spool/qdaemon** file.

The **enq** command creates a job with four files and submits it to the queue named `bill`. It prints the `fn1` file twice. Then, it prints whatever the output of the **pr** command was. Lastly, it prints the file `fn3`. The four files are treated as one job for the purposes of burst pages. Notification is sent (the `-n` flag) when the job is complete. Since the `-r` flag was specified, the `fn1` and `fn3` files are removed at job completion. The temporary file that is created by the dash (**-**) file is always deleted.

The **pr** command puts a heading at the top of each page that includes the date that the file was last modified, the name of the file, and the page number. The **enq** command then prints the file.

4. To print the file `report` on the next available printer that is configured for the `fred` queue, enter:

```
enq -P fred report
```

5. To print several files that begin with the prefix `sam` on the next available printer that is configured for the `fred` queue, enter:

```
enq -P fred sam*
```

All files that begin with the prefix `sam` are included in one print job. Normal status commands show only the title of the print job, which in this case is the name of the first file in the queue unless a different value was specified with the **-T** flag. To list the names of all the files in the print job, use the long status command **enq -A -L**.

6. To check the print queue to see whether a file is still waiting to be printed, enter:

```
enq  -q
```

This command displays the status of the user's default queue. If the file is not yet printed, then it appears in the queue status listing. The system default queue is defined as the first queue in the **/etc/qconfig[.bin]** file. Users can have their own default override by setting and exporting the **PRINTER** environment variable.

7. To display the status of a nondefault queue, `lp0`, enter:

```
enq  -q  -P lp0
```

8. To obtain the long queue status, enter:

```
enq  -L
```

9. To obtain status on all queues, enter:

```
enq  -A
```

10. To obtain long status on all queues, enter:

```
enq  -A  -L
```

11. To obtain the status of the default queue, in wide format, enter:

```
enq  -W
```

12. To obtain the wide status of all queues, enter:

```
enq  -W  -A
```

13. To stop printing a job (a job is one or more files), enter:

```
enq  -x 413
```

This command cancels the request that you made earlier to print a job. The number was obtained from the listing that is obtained by entering the **enq -q** command. If the job is being printed, the printer stops immediately. If the job is not printed yet, it is removed from the queue so that it is not printed. If the job is not in the queue, the **enq** command displays a message similar to the following output:

```
no such request from you -- perhaps it's done?
```

14. To disconnect a printer from the queuing system, enter:

```
enq  -P lp0:dlp0  -D
```

Entering this command stops the **enq** command requests from being sent to the printer that serves the `lp0` queue. If a file is printing, it is allowed to finish. You must be able to run the **qadm** command to run the **enq** command.

Note: The printers that serve a specified queue are named by the device stanza name as it appears in the **/etc/qconfig[.bin]** file.

15. To print a file with page numbers by using the **piobe** command backend on the default printer, enter:

```
enq  -o -p filename
```

The `-p` flag is not looked at by the **enq** command. The `-o` flag tells the **enq** command to pass the next item, which can be in quotes, to the backend unchanged. So, the **enq** command passes the `-p` flag to the **qdaemon** process, which in turn passes it to the backend **piobe**. The `-p` flag causes **piobe** to run the **/usr/bin/pr** filter to apply page numbers to the document before giving data to the device. Multiple options can be given in quotes preceded by one **-o** flag. Multiple options can also be given without quotes with each option preceded by the **-o** flag.

16. Assuming a **qconfig** file with the following information:

```
qname:
                device = fred
fred:
                file = /tmp/hello
                backend = /usr/bin/sh /usr/bin/diff
```

And given the following commands:

```
rm /tmp/hello
touch /tmp/hello
pr /etc/hosts|enq  -P qname:fred - /etc/hosts
```

The **qdaemon** process runs the `/usr/bin/diff` program with two arguments, one of which is a temporary file name and the other being the `/etc/hosts` file. The only difference between the two files is that one was run through the **pr** command. The `/tmp/hello` file contains the differences between the two files. The **qdaemon** process does not create the `/tmp/hello` file if it does not exist.

17. The following command:

```
enq  -m'i want pink paper for this job' /etc/passwd
```

sends the specified operator message to the operator's console just before the print job is to print. The operator must respond to this message to continue or cancel the job.

```
enq  -M pink /etc/passwd
```

This command accomplishes the same thing, only the message is contained in a file called `pink`.

18. To cancel all jobs in the `fred` queue, enter:

```
enq  -X  -P fred
```

If the user who entered this command has root user authority, all the jobs from the `fred` queue are deleted. If the user does not have root user authority, only the users jobs are deleted from that queue.

19. To queue the file named `MyFile` and return the `MyFile` job number to the **jdf** file, enter:

```
enq  -j MyFile
```

20. To hold print job number `310`, enter:

```
enq  -h  -#310
```

To release the hold on print job number `310`, enter:

```
enq  -p -#310
```

21. To hold all the print jobs on queue `lp0`, enter:

    ```
    enq  -h  -P lp0
    ```

    To release the `lp0` queue, enter:

    ```
    enq  -p -P lp0
    ```

22. To hold all print jobs that are created by `fred`, enter:

    ```
    enq  -h  -u fred
    ```

    To release the print jobs that are created by `fred`, enter:

    ```
    enq  -p -u fred
    ```

23. To move job number 318 to queue `lp0`, enter:

    ```
    enq  -Q lp0  -#318
    ```

    The flags that control moving print jobs work in the same way as the flags that hold the print files. The hold flags and variables are illustrated in the preceding examples.

Files

Item	Description
/usr/sbin/qdaemon	Queuing daemon.
/etc/qconfig	Queue configuration file.
/var/spool/lpd/qdir/*	Queue requests.
/var/spool/lpd/stat/*	Information about the status of the devices.
/var/spool/qdaemon/*	Temporary copies of enqueued files.
/etc/qconfig.bin	Digested, binary version of the **/etc/qconfig** file.

enroll Command

Purpose

Sets up a password used to implement a secure communication channel.

Syntax

enroll

Description

The **enroll** command establishes a password and secures a communication channel in which messages can only be read by the intended recipient. The password is used to receive secret mail.

The **enroll** command is used with the **xsend** and **xget** commands to send and receive secret mail. The **xsend** command sends secret mail. The **xget** command asks for your password and gives you your secret mail.

Examples

To set up a password, enter:

```
enroll
```

When prompted, enter your password. This allows other users on your system to send you secret mail. Use the **xget** command to read the secret mail.

Files

Item	Description
/var/spool/secretmail/User.key	Contains the encrypted key for the user.
/usr/bin/enroll	Contains the **enroll** command.

enscript Command

Purpose

Converts text files to PostScript format for printing.

Syntax

enscript [**-1** **-2** **-c** **-g** **-k** **-l** **-m** **-o** **-q** **-r** **-B** **-G** **-K** **-R**] [**-b** *Header*] [**-f** *Font*] [**-f0** *CodeSet*:*Font*] [**-f1** *CodeSet*:*Font*] [**-p** *Out*] [**-F** *Hfont*] [**-F0** *CodeSet*:*Font*] [**-F1** *CodeSet*:*Font*] [**-L** *Lines*] [**-M** *MediaName*] [**-X** *CodesetName*] [*SpoolerOptions*] [*File* ...]

Description

The **enscript** command reads a text file, converts it to PostScript format, and spools the file for printing on a PostScript printer. You can use this command to specify fonts, headings, limited formatting options, and spooling options.

For example:

```
enscript -daleph bubble.txt
```

prints a copy of the **bubble.txt** file on the printer called aleph, and

```
enscript -2r finder.c
```

prints a two-up landscape listing of the **finder.c** file on the default printer.

The **ENSCRIPT** environment variable can be used to specify defaults. The value of **ENSCRIPT** is parsed as a string of arguments before the arguments that are displayed on the command line. For example:

```
ENSCRIPT='-fTimes-Roman8'
```

sets your default body type size and font to 8-point Times Roman.

Information containing various media sizes for the **psdit** command and the **enscript** command are contained in the file **/usr/lib/ps/MediaSizes**.

The information required for each entry in the **MediaSizes** file can be obtained from the **PostScript Printer Description**, or **PPD**, file that matches the PostScript printer used with TranScript. The **PPD** files are available from Adobe Systems, Incorporated. The measurements extracted from the **PPD** files are expressed in a printer's measure called points. A printer's point is 1/72 of an inch.

Any line in the **MediaSizes** file beginning with an ASCII ***** (asterisk) is ignored when matching media-size names provided on the command line to the **enscript** command and the **psdit** command.

Each entry in the **MediaSizes** file contains either 8 or 9 fields. The first 8 fields are required for all entries. The 9th field is optional. Fields are separated by white space. The fields for each entry are as follows:

Field Name	Description
EntryName	Contains a character string to match against a media name provided with the **-M** flag with the **enscript** command or the **psdit** command.
MediaWidth	Specifies the media width in points.
MediaDepth	Specifies the media depth in points.
ImageableLLX	Specifies the imageable lower left-hand corner x coordinate in points.
ImageableLLY	Specifies the imageable lower left-hand corner y coordinate in points.
ImageableURX	Specifies the imageable upper right-hand corner x coordinate in points.
ImageableURY	Specifies the imageable upper right-hand corner y coordinate in points.
PageRegionName	Specifies the PostScript sequence for the particular printer to identify the size of the imageable area.
PaperTrayName	Specifies the PostScript sequence for the particular printer to select a particular paper/media tray. This field is optional. **Note:** The sequence can be multiple PostScript operators or words for both the PageRegionName field and the PaperTrayName field. To specify such a sequence, use the ASCII " (double quotation character) to delimit the entire sequence.

The following table shows examples of field entries in the **MediaSizes** file:

Name	Field Values
Letter	**Width** 612 **Depth** 792 **llx** 18 **lly** 17 **urx** 597 **ury** 776 **Page- Region- Name** Letter **Paper- Tray- Name** Letter

Name	Field Values
Legal	**Width** 612 **Depth** 1008 **llx** 18 **lly** 17 **urx** 597 **ury** 992 **Page- Region- Name** Legal **Paper- Tray- Name** Legal

PostScript Font Information

The PostScript Fonts for Transcript table shows the fonts available for the enscript command. The Font Name is specified with the **-F** and **-f encscipt** command flags. The alphabetic characters are case-sensitive:

Parameters

Item	Description
SpoolerOptions	Provides options for spooling the print file. The following are the *SpoolerOptions* flags: **{-d | -P}*Queue*** Queues the output to the named queue. **-n*Number*** Produces the specified number of copies. The default is 1. **-t*Title*** Sets job title for use on the first banner page. ***File*** Specifies the text file to be converted into PostScript format. If you leave this parameter blank, the **enscript** command reads from standard input.

Flags

Item	Description
-1	Sets in 1 column (the default).
-2	Sets in 2 columns.
-c	Truncates (cuts) lines that are longer than the page width. Normally, long lines are wrapped around to the following line on the page.
-g	Performs no function, but the **-g** flag is still accepted for backwards compatibility.
-k	Enables page prefeed (if the printer supports it). This allows simple documents (such as program listings in a single font) to print somewhat faster by keeping the printer running between pages.
-l	Simulates a line printer printing pages 66 lines long and omitting headers.
-m	Sends mail after the files are printed.
-o	Lists the missing characters if the **enscript** command cannot find characters in a font.
-q	Causes the **enscript** command to not report about what it is doing. The **enscript** command cannot report on pages, destination, omitted characters, and so on. Fatal errors are still reported to the standard error output.
-r	Rotates the output 90 degrees (landscape mode). Use this flag for output that requires a wide page or for program listings when used in conjunction with the **-2** flag. The following example shows one way to get program listings: `enscript -2r File . . .`
-B	Omits page headings.
-G	Prints in gaudy mode, causing page headings, dates, and page numbers to be printed in a flashy style, at some slight performance expense.
-K	Disables page prefeed (the default).
-R	Prints in portrait mode (unrotated), which is the default.

Item	Description
-b*Header*	Sets the string to be used for page headings to the value of the *Header* variable. The default header is constructed from the file name, its last modification date, and a page number.
-f*Font*	Sets the font to be used for the body of each page. The default is Courier10, unless the two-column rotated mode is used, in which case it defaults to Courier7. **Note:** 1. A PostScript font name (such as Times-Roman, Times-BoldItalic, Helvetica, Courier). 2. A point size (1 point = 1/72 inch). Fonts are specified in this fashion: Courier-Bold8 is 8-point Courier Bold; Helvetica12 is 12-point Helvetica.
-f0 *Codeset***:***Font*	Sets the character codeset name, which is written into the PostScript file, and the SBCS font to use for the body of each page. The default is determined by the **/usr/lib/ps/transcript.conf** configuration file for each locale.
-f1 *Codeset***:***Font*	Sets the character codeset name, which is written into the PostScript file, and the MBCS font to use for the body of each page. The default is determined by the **/usr/lib/ps/transcript.conf** configuration file for each locale.
-p*Out*	Causes the PostScript file to be written to the named file rather than being spooled for printing. As a special case, entering the following will send the PostScript file to standard output: `-p -`
-F*Hfont*	Sets the font to be used for page headings. The default is Courier Bold10. **Note:** Font specifications have two parts: • A PostScript font name (such as Times-Roman, Times-BoldItalic, Helvetica, Courier). • A point size (1 point = 1/72 inch). Fonts are specified in this fashion: Courier-Bold8 is 8-point Courier Bold; Helvetica12 is 12-point Helvetica.
-F0 *Codeset***:***Font*	Sets the character codeset name, which is written into the PostScript file, and the SBCS font to use for the header of each page. The default is determined by the **/usr/lib/ps/transcript.conf** configuration file for each locale.
-F1 *Codeset***:***Font*	Sets the character codeset name, which is written into the PostScript file, and the MBCS font to use for the header of each page. The default is determined by the **/usr/lib/ps/transcript.conf** configuration file for each locale.
-L*Lines*	Sets the maximum number of lines to print on a page. The **enscript** command usually computes how many lines to put on a page based on point size. (It might put fewer per page than requested by the **-L** flag.)
-M*MediaName*	Specifies a media name to use to determine the amount of imageable area on the paper. The name provided is matched against entries in the **MediaSizes** file. For instance, `-M legal` would request a legal size of paper as the imageable area. If this flag is not used, the default size is letter size, which is 8.5 inches wide by 11.0 inches deep (21.6 cent. wide by 27.9 cent. deep).

Item	Description
-X*CodesetName*	Specifies the code set for the input data. By default, the input code set is determined by the **nl_langinfo** subroutine. If this flag is used, the codeset is determined by the *CodesetName*.

International Character Support

All characters not found in a font will be replaced with the character ? (question mark). For a complete list of characters that were not found, use the **-o** flag. The **NLSvec** file provides information about character translation.

Environment Variables

Item	Description
ENSCRIPT	Specifies a string of options to be used by the **enscript** command.
LPDEST	Specifies a printer destination. The **-d** spooler option overrides this environment variable.
PSLIBDIR	Provides a path name of a directory to use instead of the **/usr/lib/ps** directory for the **enscript** command prologue and font metric files.
PSTEMPDIR	Provides a path name of temporary directory to use instead of the **/var/tmp** directory of spooled temporary files.
TRANSCRIPT	Provides the absolute path name of a file to use, instead of the **/usr/lib/ps/transcript.conf** configuration file, for MBCS handling.

Files

Item	Description
/usr/lib/ps/*.afm	Contains Adobe Font Metrics (AFM) files.
/usr/lib/ps/font.map	Contains the list of font names with their abbreviations.
/usr/lib/ps/enscript.pro	Contains prologue for **enscript** command files.
/usr/lib/ps/MediaSizes	Contains the default file used for media sizes.

entstat Command

Purpose

Shows ethernet device driver and device statistics.

Syntax

entstat [**-d** **-r** **-t**] *Device_Name*

Description

The **entstat** command displays the statistics gathered by the specified Ethernet device driver. The user can optionally specify that the device-specific statistics be displayed in addition to the device generic statistics. If no flags are specified, only the device generic statistics are displayed.

This command is also invoked when the **netstat** command is run with the **-v** flag. The **netstat** command does not issue any **entstat** command flags.

If an invalid *Device_Name* is specified, the **entstat** command produces an error message stating that it could not connect to the device.

Flags

Item	Description
-d	Displays all the statistics, including the device-specific statistics.
-r	Resets all the statistics back to their initial values. This flag can only be issued by privileged users.
-t	Toggles debug trace in some device drivers.

Parameters

Item	Description
Device_Name	The name of the Ethernet device, for example, **ent0**.

Statistic Fields

> **Note:** Some adapters may not support a specific statistic. The value of non-supported statistic fields is always 0.

The statistic fields displayed in the output of the **entstat** command and their descriptions are:

Title Fields

Item	Description
`Device Type`	Displays the description of the adapter type.
`Hardware Address`	Displays the Ethernet network address currently used by the device.
`Elapsed Time`	Displays the real time period which has elapsed since last time the statistics were reset. Part of the statistics may be reset by the device driver during error recovery when a hardware error is detected. There will be another Elapsed Time displayed in the middle of the output when this situation has occurred in order to reflect the time differences between the statistics.

Transmit Statistics Fields

Item	Description
`Packets`	The number of packets transmitted successfully by the device.
`Bytes`	The number of bytes transmitted successfully by the device.
`Interrupts`	The number of transmit interrupts received by the driver from the adapter.
`Transmit Errors`	The number of output errors encountered on this device. This is a counter for unsuccessful transmissions due to hardware/ network errors.
`Packets Dropped`	The number of packets accepted by the device driver for transmission which were not (for any reason) given to the device.
`Max Packets on S/W Transmit Queue`	The maximum number of outgoing packets ever queued to the software transmit queue.

Item	Description
S/W Transmit Queue Overflow	The number of outgoing packets which have overflowed the software transmit queue.
Current S/W+H/W Transmit Queue Length	The number of pending outgoing packets on either the software transmit queue or the hardware transmit queue.
Broadcast Packets	The number of broadcast packets transmitted without any error.
Multicast Packets	The number of multicast packets transmitted without any error.
No Carrier Sense	The number of unsuccessful transmissions due to the no carrier sense error.
DMA Underrun	The number of unsuccessful transmissions due to the DMA underrun error.
Lost CTS Errors	The number of unsuccessful transmissions due to the loss of the Clear-to-Send signal error.
Max Collision Errors	The number of unsuccessful transmissions due to too many collisions. The number of collisions encountered exceeded the number of retries on the adapter.
Late Collision Errors	The number of unsuccessful transmissions due to the late collision error.
Deferred	The number of outgoing packets deferred during transmission. Deferred means that the adapter had to defer while trying to transmit a frame. This condition occurs if the network is busy when the adapter is ready to transmit. The adapter will only defer the first attempt to send a packet. After that the adapter will transmit the packet without checking. If the network is still busy then a collision will be recorded.
SQE Test	Contains the number of "Signal Quality Error" Tests (i.e. Heartbeat) performed successfully during transmission.
Timeout Errors	The number of unsuccessful transmissions due to adapter reported timeout errors.
Single Collision Count	The number of outgoing packets with single (only one) collision encountered during transmission.
Multiple Collision Count	The number of outgoing packets with multiple (2 - 15) collisions encountered during transmission.
Current HW Transmit Queue Length	The number of outgoing packets which currently exist on the hardware transmit queue.
CRC Errors	The number of incoming packets with the Checksum (FCS) error.
DMA Overrun	The number of incoming packets with the DMA overrun error.
Alignment Errors	The number of incoming packets with the alignment error.
No Resource Errors	The number of incoming packets dropped by the hardware due to the no resource error. This error usually occurs because the receive buffers on the adapter were exhausted. Some adapters may have the size of the receive buffers as a configurable parameter. Check the device configuration attributes (or smit helps) for possible tuning information.

Item	Description
Receive Collision Errors	The number of incoming packets with the collision errors during the reception.
Packet Too Short Errors	The number of incoming packets with the length error indicating that the packet size is less than the Ethernet minimum packet size.
Packet Too Long Errors	The number of incoming packets with the length error indicating that the packet size is bigger than the Ethernet maximum packet size.
Packets Discarded by Adapter	The number of incoming packets dropped by the hardware for any other reasons.
Receiver Start Count	The number of times that the receiver (receive unit) on the adapter has been started.

Receive Statistics Fields

Item	Description
Packets	The number of packets received successfully by the device.
Bytes	The number of bytes received successfully by the device.
Interrupts	The number of receive interrupts received by the driver from the adapter.
Receive Errors	The number of input errors encountered on this device. This is a counter for unsuccessful reception due to hardware/network errors.
Packets Dropped	The number of packets received by the device driver from this device which were not (for any reason) given to a network demuxer.
Bad Packets	The number of bad packets received (i.e. saved) by the device driver.
Broadcast Packets	The number of broadcast packets received without any error.
Multicast Packets	The number of multicast packets received without any error.
CRC Errors	The number of incoming packets with the Checksum (FCS) error.
DMA Overrun	The number of incoming packets with the DMA overrun error.
Alignment Errors	The number of incoming packets with the alignment error.
No Resource Errors	The number of incoming packets dropped by the hardware due to the no resource error.
Receive Collision Errors	The number of incoming packets with the collision errors during the reception.
Packet Too Short Errors	The number of incoming packets with the length error indicating that the packet size is less than the Ethernet minimum packet size.

Item	Description
Packet Too Long Errors	The number of incoming packets with the length error indicating that the packet size is bigger than the Ethernet maximum packet size.
Packets Discarded by Adapter	The number of incoming packets dropped by the hardware for any other reasons.
Receiver Start Count	The number of times that the receiver (receive unit) on the adapter has been started.

General Statistics Fields

Item	Description
No mbuf Errors	The number of times that mbufs were not available to the device driver. This usually occurs during receive operations when the driver must obtain mbuf buffers to process inbound packets. If the mbuf pool for the requested size is empty, the packet will be discarded. The **netstat -m** command can be used to confirm this.
Adapter Reset Count	The number of times that the adapter has been restarted (re-initialized).
Adapter Data Rate	The maximum data rate of the adapter in Mbps (megabits per second).
Driver Flags	The device driver internal status flags that are currently turned on.

Device Specific Statistics Fields

This part of the display may be different for each type of the adapter. It may contain adapter specific information and some extended statistics that were not included in the generic statistics. Some adapters may not have any device specific statistics.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To display the device generic statistics for **ent0**, enter:

```
entstat ent0
```

This produces the following output:

```
ETHERNET STATISTICS (ent0) :
Device Type: Ethernet High Performance LAN Adapter
Hardware Address: 02:60:8c:2e:d0:1d
Elapsed Time: 0 days 0 hours 8 minutes 41 seconds

Transmit Statistics:     Receive Statistics:
--------------------     -------------------
Packets: 3               Packets: 2
Bytes: 272               Bytes: 146
Interrupts: 3            Interrupts: 2
Transmit Errors: 0       Receive Errors: 0
Packets Dropped: 0       Packets Dropped: 0
Max Packets on S/W       Bad Packets: 0
Transmit Queue:0
S/W Transmit Queue
Overflow: 0
Current S/W+H/W Transmit
```

```
Queue Length: 0

Broadcast Packets: 2     CRC Errors: 0
Multicast Packets: 0     Broadcast Packets: 1
No Carrier Sense: 0      Multicast Packets: 0
DMA Underrun: 0          DMA Overrun: 0
Lost CTS Errors: 0       Alignment Errors: 0
Max Collision Errors: 0  No Resource Errors: 0
Late Collision Errors: 0 Receive Collision Errors: 0
Deferred: 0              Packet Too Short Errors: 0

env Command

Purpose

Displays the current environment or sets the environment for the execution of a command.

Syntax

To Display Multiple Environment Variables

env [**-i** | **-**] [*Name*=*Value*]... [*Command* [*Argument* ...]]

To Display A Single Environment Variable

env [*Name*]

Description

The **env** command allows you to display your current environment or run a specified command in a changed environment.

If no flags or parameters are specified, the **env** command displays your current environment, showing one *Name*=*Value* pair per line.

Flags

Item	Description
-i	Ignores the inherited environment and invokes the command specified by the *Command* parameter with the environment specified by the *Name*=*Value* parameters.

Parameters

Item	Description
Name=Value	You can run a command in a modified version of the current environment by specifying one or more *Name=Value* parameters. Use the **-i** flag if you wish to replace the entire current environment with the specified *Name =Value* parameters. In either case, environment changes are effective only while the specified command is running.
Command	The *Command* parameter has an optional *Argument* variable. If the specified command is one of the Korn shell special built-in commands, results are unspecified. Korn shell built-in commands are described in the **ksh** command.

Exit Status

If the *Command* parameter is specified, the exit status of the **env** command is the exit status of the command specified in the *Command* parameter. Otherwise, the **env** command exits with one of the following values:

Item	Description
0	The **env** command completed successfully.
1-125	An error occurred in the **env** command.
126	The command specified by the *Command* parameter was found, but could not be invoked.

Item	Description
127	The command specified by the *Command* parameter was not found.

Examples

1. To change the **TZ** environment variable while running the **date** command, type:

   ```
   TZ=MST7MDT date
   ```

   OR

   ```
   env TZ=MST7MDT date
   ```

   Each of these commands displays the time in mountain time and the current date. The two commands shown are equivalent. When the **date** command is finished, the previous value of the **TZ** environment variable takes effect again.
2. To run the **make** command in an environment that consists only of definitions for the **PATH, IDIR,** and **LIBDIR** environment variables, type:

   ```
   env -i PATH=$PATH IDIR=/$HOME/include LIBDIR=/$HOME/lib make
   ```

   You must specify the **PATH** environment variable so that the shell can find the **make** command. When the **make** command is finished, the previous environment takes effect.

Files

Item	Description
/usr/bin/env	Contains the **env** command.

epkg Command

Purpose

Creates interim fix packages that can be installed by the interim fix manager, **emgr**.

Syntax

epkg [**-w** *WorkDirectory*] [**-a** *APARrefFile*] [**-p** *PrerequisiteFile*] [**-d** *DescriptionFile*] [**-e** *interimfixControlFile*] [**-g** *PrerequisiteFile*] [**-l** *LockFile*] [**-S** *SupersedeFile*] [**-u** {**y**|**n**}]] [**-r** {**y**|**n**|o}] [**-s**] [**-T** {**y**|**n**}] [**-X**] [**-v**] *interimfixLabel*

Description

The **epkg** tool can be run in two different modes: *interactive* and *template-based*. The interactive mode prompts you with several questions and constructs the interim fix package based on the answers. The template-based mode uses an interim fix control file that is provided with the answers to questions that are asked in interactive mode. The interim fix package is installed by the interim fix manager, which is started with the **emgr** command.

Interactive mode

The **epkg** command runs in interactive mode by default. The only required parameter is the interim fix label. If you interrupt an **epkg** session, the interim fix control file will be saved. If you start a new session with the same interim fix label, you will be asked whether you want to keep working with the previous interim fix control file. To provide this information before you start the interactive **epkg** session, run **epkg** with the **-u** flag.

The **epkg** command maintains a record of the question order and allows you to navigate between questions by using subcommands. Also, the **epkg** command remembers the previous answer you provided and sets that answer as the default answer. The **epkg** subcommands are described in the Subcommands section.

After you answer all the questions, the **epkg** command verifies the interim fix control file and creates a compressed tar package that can be installed with the **emgr** command.

Using the control file template

You can create interim fix packages noninteractively by using an interim fix control file as a template. The following is an example of a completed interim fix control file:

```
# interim fix control file complete example
ABSTRACT=This is a test of epkg.
PRE_INSTALL=/tmp/pre_install
POST_INSTALL=.
PRE_REMOVE=/tmp/pre_remove
POST_REMOVE=.
REBOOT=yes
PREREQ=.
DESCRIPTION=/tmp/description
EFIX_FILES=2
APARREF=/tmp/aparref
LKU_CAPABLE=no

EFIX_FILE:
        EFIX_FILE_NUM=1
        SHIP_FILE=/home/test/ls
        TARGET_FILE=/usr/bin/ls
        TYPE= 1
        INSTALLER= 1
        ACL= DEFAULT
        AR_MEM=.

EFIX_FILE:
        EFIX_FILE_NUM=2
        SHIP_FILE=/home/test/mystrcat.o
        TARGET_FILE=/usr/ccs/lib/libc.a
        TYPE= 2
        INSTALLER= 1
        ACL= root:system:555
        AR_MEM=strcat.o
```

The interim fix control file values, are as follows:

ABSTRACT
Briefly describes the interim fix package. The abstract is limited to 38 bytes.

PRE_INSTALL
Specifies the location of a script that is run after the installation preview and before any interim fix files are installed. Failure in the PRE_INSTALL script will cause the interim fix package installation to be aborted. This component is optional.

POST_INSTALL
Specifies the location of a script that is run after all interim fix files have been successfully installed. This component is optional.

PRE_REMOVE
Specifies the location of a script that is run after the removal preview and before any interim fix files are removed during a remove operation. This component is optional.

POST_REMOVE
Specifies the location of a script that is run after interim fix files are removed during a remove operation. This component is optional.

REBOOT
Specifies whether a reboot is required for this interim fix. Allowable values are yes or no. If this value is set to yes, the **emgr** command will make changes as necessary to the boot image and issue a message instructing the user to reboot after installation.

PREREQ
Specifies the location of a file that contains **installp** prerequisites. This component is optional.

APARREF
Specifies the location of a file that contains the APAR reference numbers and abstracts associated with this interim fix. Each line of the file contains an APAR reference number, an APAR number, and an APAR abstract. The format of the file is as follows:

```
APAR reference|:|APAR number|:|APAR abstract
```

Not all fields are required to make a valid APARREF file. If a particular field is unknown or not required, simply specify NONE or leave the field blank. Some examples of valid APARREF files follow:

Example 1

```
123456|:|IV12345|:|This is the APAR abstract
789012|:|IV67890|:|This is another APAR abstract
```

Example 2

```
123456|:|NONE|:|NONE
789012|:|NONE
345678
```

Example 3

```
NONE|:|IV12345|:|This is the APAR abstract
```

Example 4

```
NONE
```

If you provide an APAR reference file with the APAR reference numbers, the automatic removal feature by the **installp** command is enabled for the interim fix. The automatic removal by the **installp** command means the capability to automatically remove an interim fix if the fix is present in the Technology Level, Service Pack, or PTF that the **installp** command is applying. If NONE is listed in the APAR reference field, the automatic removal feature is not enabled for the interim fix.

DESCRIPTION
Specifies the location of a file that contains a detailed description of the interim fix package that is being installed.

EFIX_FILES
Specifies the total number of files in the interim fix.

EFIX_FILE_NUM
Specifies the number of the file in the interim fix. Each file in the interim fix must have a unique number, from 1 to 400. The **epkg** command can support a maximum of 400 files per interim fix.

SHIP_FILE
Specifies the location of a file that **epkg** will archive into the interim fix package. You can specify either an absolute path or a relative path to this file.

TARGET_FILE
Specifies the location where the **SHIP_FILE** will be installed. This location is on the system where the interim fix package will be installed. You must specify an absolute path to this file. If this file is part of a registered package, such as an RPM Package Manager (RPM) or **installp** package, you must specify the tracked location.

TYPE
Specifies the type of file that is being installed. The valid choices are as follows:

1
File (standard or executable)

2
Library or archive member

INSTALLER
Specifies the type of installer, if any, that will track the interim fix package. The valid choices are as follows:

1
Currently tracked by **installp**

2
Currently tracked by RPM

3
Currently tracked by **ISMP**

4
Currently tracked by another installer

5
This is a new file that will be tracked by **installp**

6
New file that will be tracked by RPM

7
New file that will be tracked by **ISMP**

8
New file that will be tracked by another installer

9
Not tracked by any installer

ACL
Specifies the access attributes (mode and ownership) for the file. If this attribute is set to **DEFAULT**, the **emgr** command maintains the current permissions of the file to be replaced. However, if the target file is a new file or if the user wants to specify permissions with the **-v** flag, the **ACL** attribute can be entered with the syntax *Owner*:*Group*:*OctalModes*, similar to the following:

```
ACL= root:system:555
```

AR_MEM
Specifies the name of the archive member. This option is only valid if **TYPE**=2. In this case, **SHIP_FILE** is the local location of the archive member that is being shipped, **TARGET_FILE** is the target archive, and **ACL** applies to the archive member. For example, the following value settings would make the local file **myshr.o** the member **shr.o** in the target archive **/usr/ccs/lib/libc.a**:

```
TYPE=2
SHIP_FILE=/home/myshr.o
TARGET_FILE=/usr/ccs/lib/libc.a
AR_MEM=shr.o
```

BUILD_BOOT_IMAGE
Specifies whether the boot image needs to be rebuilt. Allowable values are yes or no. A reboot is required if this field is set to yes. If this field is set to yes and the REB00T field is set to no, **epkg** returns an error.

E2E_PREREQ
Specifies the location of the interim fix prerequisite file in the interim fix control file.

PKGLOCKS
Specifies the local file location of the package lock file in the interim fix control file.

SUPERSEDE
Specifies the local file location of the superseded file in the interim fix control file.

FIXTESTED
Specifies whether this interim fix has been tested. Allowable values are yes or no.

LKU_CAPABLE
Specifies whether this interim fix is compatible with the Live Update operation. This attribute can have a value of yes or no. Ideally, all interim fixes must be marked as Live Update capable. This compatibility is needed to install interim fixes as a group. If an interim fix is not suitable for a Live Update operation, the LKU_CAPABLE attribute is set to the value of no, however most of the interim fixes have this attribute set to the value of yes.

Support for Superseding

The packager can specify a file containing the interim fix label names that are to be superseded when an epkg is installed. This will cause the **emgr** command to remove any interim fix labels that are specified in this file (if they are installed) before installing the interim fix package. Failure to remove an installed superseded interim fix will abort the installation of the interim fix package. The maximum supported number of superseded labels is 32. The packager can specify the supersede file with the **epkg** command in the following ways:

- Specify the file location with the **-S *supersede_file*** flag. For example:

```
epkg -S /tmp/superseded.epkg myefix
```

- The **epkg** command will prompt for the superseded file if the extended options flag (**-v**) is used in interactive mode. For example:

```
Enter the location for the supersede file or "." to skip.
-> /tmp/superseded.epkg
```

- Set the SUPERSEDE attribute to the local file location of the superseded file in the interim fix control file. For example:

```
SUPERSEDE=/tmp/superseded.epkg
```

The format of the superseded file is one interim fix label to be superseded per line. Comments beginning with a *#* sign and leading white space are ignored. For example:

```
# Requisites for efix myefix3
myefix1
myefix2
```

Support for prereqs and xreqs

The packager can specify a file containing the interim fix label names of interim fixes that are requisites to the interim fix package being installed. This will cause the **emgr** command to check if the interim fix label is installed (PREREQ). If the requisite is not installed, the **emgr** command will abort installation of the interim fix package. The user can also specify an XREQ interim fix label. This will cause the **emgr** command *not* to install the interim fix if the named xreq interim fix is installed.

The packager can specify the interim fix prerequisite file with the **epkg** command in the following ways:

- Specify the file location with the **-g *efix_prereq_file*** flag. For example:

```
epkg -g /tmp/efixprereq.epkg myefix
```

- The **epkg** command will prompt for the interim fix prereq file if the extended options flag (**-v**) is used in interactive mode. For example:

```
Enter the location for the efix prerequisite file or "." to skip.
-> /tmp/efixprereq.epkg
```

- Set the E2E_PREREQ attribute to the local file location of the interim fix prerequisite file in the interim fix control file. For example:

```
E2E_PREREQ=/tmp/efixprereq.epkg
```

The format of the interim fix prerequisite file entries is as follows:

```
EfixLabel  RequisiteType: PREREQ/XREQ
```

For example:

```
oldefix1 PREREQ  # Make sure oldefix1 is already installed
oldefix4 XREQ    # Make sure oldefix4 is NOT installed
```

The maximum number of supported interim fix prerequisites is 32.

Support for enabling automatic interim fix removal by installp

The packager can specify an APAR reference file containing APAR reference numbers. An APAR reference number will allow **installp** to map an interim fix back to the APARs for all the Technology Levels where the fix was shipped. If **installp** determines that the interim fix is contained in the Technology Level, Service Pack, or PTF being applied, **installp** will automatically remove the interim fix prior to applying the updates.

Output and Topology

The **emgr -d** flag displays the contents and topology of the interim fix package. The **-d** option will work with the **-v** verbose option. Valid levels of verbosity are 1-3.

Verbosity level 1 (default) will display:

- LABEL
- EFIX FILES
- TARGET LOCATION

Verbosity level 2 will display:

- All level 1 output
- ABSTRACT
- REBOOT
- PRE-REQUISITES
- PRE_INSTALL
- POST_INSTALL
- PRE_REMOVE
- POST_REMOVE
- FILE TYPE

Verbosity level 3 will display:

- All level 2 output
- PACKAGING DATE
- VUID
- SIZE
- ACL
- CKSUM
- PACKAGE
- EFIX DESCRIPTION
- CONTENTS OF INSTALL SCRIPTS (if text files)

For example:

- To get level 1 verbosity output on interim fix package `test.102403.epkg.Z`, type:

```
emgr -d test.102403.epkg.Z
```

- To get level 3 verbosity output on interim fix package `test.102403.epkg.Z`, type:

```
emgr -v3 -d test.102403.epkg.Z
```

Support for Additional Package Locking

The packager can specify a file containing package names that should be locked by the **emgr** command in addition to those that are automatically locked based on file ownership. The packager must specify the name of the package, the installer, and the type of package lock action (ALWAYS/IFINST). The packager can specify the package lock file using the **epkg** command in the following ways:

- Specify the file location with the **-l** ***pkg_locks_file*** flag. For example:

```
epkg -l /tmp/pkglock.epkg myefix
```

- The **epkg** command will prompt for the package locks file if the extended options flag (**-v**) is used. For example:

```
Enter the location for the package locks file or "." to skip.
-> /tmp/pkglock.epkg
```

- Set the PKGLOCKS attribute to the local file location of the package lock file in the interim fix control file. For example:

```
PKGLOCKS=/tmp/pkglock.epkg
```

The format of the package locks file is as follows:

```
PackageName PackageAction PackageType
```

where *PackageName* is the name of the package to be locked and *PackageAction* is one of the following:

Item	Description
ALWAYS	Always attempt to lock this package. Failure to lock the package results in installation failure.
IFINST	Attempt to lock this package only if the package is installed. Failure to lock an *installed* package results in installation failure.

PackageType is installp (default), rpm, ISMP, other.

Note: Only installp locking is supported.

The maximum number of supported package lock entries is 32.

Example:

```
bos.rte.lvm ALWAYS installp
bos.games   IFINST installp
```

In the above example, the **emgr** command will always attempt to lock **bos.rte.lvm** during installation and will unlock it on removal. The **emgr** command will lock **bos.games** if, and only if, it is installed, and will unlock it on removal (if locked).

Support for the bosboot Option

The **epkg** command reboot options include rebooting without rebuilding the boot image.

The user can specify a reboot without bosboot in the following ways:

- The o argument for the **epkg -r** flag indicates that reboot ("only") is required, but the **emgr** command should not call bosboot (that is, rebuild the boot image).

- The reboot prompt in interactive mode indicates the following choices:

```
Select reboot policy for this efix package:
1) Reboot is NOT required.
2) Reboot is required. The boot image will be rebuilt.
3) Reboot is required. The boot image will NOT be rebuilt.
```

- Set the BUILD_BOOT_IMAGE and REBOOT attribute to "yes" or "no" in the interim fix control file. The following REBOOT and BUILD_BOOT_IMAGE options are supported:

Item	Description
REBOOT=no & BUILD_BOOT_IMAGE=no	Reboot is NOT required.
REBOOT=yes & BUILD_BOOT_IMAGE=yes	Reboot is required. The boot image will be rebuilt.
REBOOT=yes & BUILD_BOOT_IMAGE=no	Reboot is required. The boot image will *not* be rebuilt.

Note: `REBOOT=no & BUILD_BOOT_IMAGE=yes` will result in an error from the **epkg** command.

Flags

Item	Description
-a *APARrefFile*	Specifies the file containing APAR reference number(s).
-d *DescriptionFile*	Specifies the file containing the interim fix description.
-e *interimfixControlFile*	Specifies the interim fix control file that controls how the interim fix is constructed.
-g *PrerequisiteFile*	Specifies the location of the interim fix prerequisite file that contains the interim fix label names. These labels are required before an interim fix package is installed.
-l *LockFile*	Specifies the location of the locked file that contains the package names. These packages are locked by the `emgr` command or automatically based on file ownership.
-p *PrerequisiteFile*	Specifies the file containing installp prerequisites.
-r {y|n|o}	Sets the **epkg REBOOT** attribute. This causes the **emgr** command to make changes as necessary to the boot image and issue a message instructing the user to reboot after installation. The y argument specifies that a reboot and a `bosboot` are required. The n argument specifies that a reboot is not required. The o argument indicates that a reboot is required, but `emgr` should not call `bosboot`.
-S *SupersedeFile*	Specifies the location of the interim fix supersede file that contains the interim fix label names. These labels are to be superseded when an `epkg` is installed.
-s	Causes the **epkg** command to skip questions regarding scripts and the prerequisite file.
-T	Specifies whether this interim fix was tested. Allowable values are yes or no. The default is no.
-u {**yes**|**no**}	Specifies whether you will use an existing interim fix control file.
-v	Causes the **epkg** command to ask more questions for extended options. This includes asking you to specify permissions on all interim fix files.
-w *WorkDirectory*	Specifies the alternate work directory that the **epkg** command will use. The default work directory is **$HOME/epkgwork**.

Item	Description
-X	Causes the **emgr** command to automatically expand file systems when the interim fix is installed, if space is required and expansion is possible.

Parameters

interim fixLabel
Specifies a string that uniquely identifies this interim fix package. The maximum length of an interim fix label is 10 bytes.

Note: The interim fix manager requires each interim fix label on the system to be unique.

Subcommands

b!
Returns to the previous question.

s!
Shows the status of the current interim fix control file

q!
Quits without saving the interim fix control file. (Using the Ctrl+C key sequence causes the **epkg** command to ask you whether you want to save the interim fix control file.)

h!
Displays help information for the current question.

Exit Status

0
The **epkg** command operations completed successfully.

>0
An error occurred.

Examples

1. To run the **epkg** command in interactive mode and create an interim fix package with the interim fix label of **myfix**, type:

   ```
   epkg myfix
   ```

2. To create an interim fix package with the interim fix label of **myfix** using an existing interim fix control file named **/tmp/ecfile**, type:

   ```
   epkg -e /tmp/ecfile myfix
   ```

3. To create an interim fix package with the interim fix label of **myfix** and specify prerequisite file **/tmp/prereq**, description **/tmp/description**, and extended options, type:

   ```
   epkg -v -p /tmp/prereq -d /tmp/description myfix
   ```

Files

Item	Description
/usr/sbin/epkg	Contains the **epkg** command.

eqn Command

Purpose

Formats mathematical text for the **troff** command.

Syntax

eqn [**-d** *Delimiter1Delimiter2*] [**-f** *Font*] [**-p** *Number*] [**-s** *Size*] [**-T** *Name*] [**—**] [*File* ... | **-**]

Description

The **eqn** command is a **troff** preprocessor for typesetting mathematical text on a phototypesetter or comparable device. The output of the **eqn** command is generally piped into the **troff** command, as follows:

eqn [*Flag*...] *File*... **| troff** [*Flag*...] **|** [*Typesetter*]

The **eqn** command reads files specified by the *File* parameter. It reads standard input when a - (minus sign) is specified as the last parameter. A line beginning with the **.EQ** macro marks the start of equation text. The end of equation text is marked by a line beginning with the **.EN** macro. These lines are not altered by the **troff** command, so they can be defined in macro packages to provide additional formatting function such as centering and numbering.

Keywords

The following are keywords known to both the **eqn** and **neqn** commands.

```
above     dot       gsize     over      tdefine
back      dotdot    hat       pile      tilde
bar       down      italic    rcol      to
bold      dyad      lcol      right     under
ceiling   fat       left      roman     up
ccol      floor     lineup    rpile     vec
col       font      lpile     size
cpile     from      mark      sqrt
define    fwd       matrix    sub
delim     gfont     ndefine   sup
```

Keywords recognized by the **eqn** command can be set apart with spaces, tabs, new lines, braces, double quotes, tildes, and circumflexes. Use { } (braces) for groupings; anywhere you can use a single character, such as X, you can substitute a complicated construction enclosed in braces. The ~ (tilde) represents a full space in the output, and the ^ (circumflex) represents a half-space.

Produce subscripts and superscripts using the **sub** and **sup** keywords. Produce fractions with the **over**keyword. Produce square roots with the **sqrt** keyword.

Introduce lower and upper limits using the **from** and **to** keywords. Produce delimiters (such as left and right brackets and braces) of the correct height using the **left** and **right** keywords. Legal characters after the **left** and **right** keywords are braces, brackets, bars, **c** and **f** for ceiling and floor, and **“ ”** (double quotes) for nothing at all (which is useful for a right-side-only bracket). A **left** character does not need a matching **right** character, but a **right** character must have a matching **left** character.

Vertical lists (piles) of things are made with the **pile**, **lpile**, **cpile**, and **rpile** keywords. Piles can have arbitrary numbers of elements. The **lpile** keyword left-justifies, the **pile** and **cpile** keywords center (but with different vertical spacing), and the **rpile** keyword right-justifies. Matrices are made with the **matrix** keyword. In addition, there is an **rcol** keyword for a right-justified column.

Diacritical marks are made with the **dot**, **dotdot**, **hat**, **tilde**, **bar**, **vec**, **dyad**, and **under** keywords.

You can change point sizes and fonts with the **size** *Number* (or **size +/-***Number*), **roman**, **italic**, **bold**, and **font** *Number* keywords. You can change point sizes and fonts globally in a document with the **gsize** *Number* and **gfont** *Number* keywords, or with the command-line **-s***Number* and **-f***Number* flags.

Normally, subscripts and superscripts are reduced by three points from the previous size. You can change this with the command-line **-p***Number* flag.

You can line up successive display parameters. Place the **mark** keyword before the desired lineup point in the first equation; place the **lineup** keyword where it is to line up vertically in subsequent equations.

You can define shorthands or redefine existing keywords with the **define** keyword; for example:

```
define  Thing%Replacement%
```

The preceding example defines a new token called *Thing* that is replaced by *Replacement* whenever it appears thereafter. The % (percent sign) can be any character that does not occur in *Replacement*.

Keywords such as **sum**, **int**, **inf**, and shorthands such as **>=**, **!=**, and **->** are recognized. Greek letters are spelled out in the desired case, as in **alpha** or **GAMMA**. Mathematical words such as **sin**, **cos**, and **log** are made Roman automatically. The **troff** command 4-character escapes, such as **\(dd**, which produces the double dagger, can be used anywhere. Strings enclosed in **“ ”** (double quotes) are passed through untouched. This permits keywords to be entered as text, and can always be used to communicate with the **troff** command.

Flags

Item	Description
-d*Delimiter1Delimiter2*	Sets two ASCII characters, *Delimiter1* and *Delimiter2,* as delimiters of the text to be processed by the **eqn** command, in addition to the input enclosed by the **.EQ** and **.EN** macros. The text between these delimiters is treated as input to the **eqn** command. **Note:** Within a file, you can also set delimiters for **eqn** text using the **delim** *Delimiter1Delimiter2*command. They are turned off by the **delim off** command. All text not between **.EQ** and **.EN** macros is passed through unprocessed.
-f*Font*	Changes font in all the **eqn** command processed text to the value specified by the *Font* variable. The *Font* value (a font name or position) must be one or two ASCII characters.
-p*Number*	Reduces subscripts and superscripts the specified number of points in size (the default is 3).
-s*Size*	Changes point size in all the **eqn** command processed text to the value specified by the *Size* variable.
-T*Name*	Prepares the output for the specified printing device. Terminal Names for Phototypesetter or Comparable Devices provides *Name* variables. The default is **ibm3816**.
-	Forces input to be read from standard input.
—	(double dash) Indicates the end of flags.

Files

Item	Description
/usr/share/lib/pub/eqnchar	Contains special character definitions.

errclear Command

Purpose

Deletes entries from the error log.

Syntax

errclear [**-d** *ErrorClassList*] [**-i** *File*] [**-J** *ErrorLabel* [*,Errorlabel*]] | [**-K** *ErrorLabel* [*,Errorlabel*]] [**-l** *SequenceNumber*] [**-m** *Machine*] [**-n** *Node*] [**-N** *ResourceNameList*] [**-R** *ResourceTypeList*] [**-S** *ResourceClassList*] [**-T** *ErrorTypeList*] [**-y** *FileName*] [**-j** *ErrorID* [**,***ErrorID*]] | [**-k** *ErrorID* [**,***ErrorID*]] *Days*

Description

The **errclear** command deletes error-log entries older than the number of days specified by the *Days* parameter. To delete all error-log entries, specify a value of **0** for the *Days* parameter.

If the **-i** flag is not used with the **errclear** command, the error log file cleared by **errclear** is the one specified in the error log configuration database. (To view the information in the error log configuration database, use the **errdemon** command.)

> **Note:** The **errclear** command clears the specified entries, but does not decrease the error log file size.

You can use the System Management Interface Tool (SMIT) **smit errclear** fast path to run this command.

Flags

Item	Description
-d *List*	Deletes error-log entries in the error classes specified by the *List* variable. The *List* variable values can be separated by , (commas), or enclosed in " " (double quotation marks) and separated by , (commas) or space characters. The valid *List* variable values are **H** (hardware), **S** (software), **O** (**errlogger** messages), and **U** (undetermined).
-i *File*	Uses the error-log file specified by the *File* variable. If this flag is not specified, the **errclear** command uses the value from the error-log configuration database.
-j *ErrorID*[,*ErrorID*]	Deletes the error-log entries specified by the *ErrorID* (error identifier) variable. The *ErrorID* variable values can be separated by , (commas), or enclosed in " " (double quotation marks) and separated by , (commas) or space characters.
-J *ErrorLabel*	Deletes the error-log entries specified by the *ErrorLabel* variable. The *ErrorLabel* variable values can be separated by , (commas), or enclosed in " " (double quotation marks) and separated by , (commas) or space characters.
-k *ErrorID*[,*ErrorID*]	Deletes all error-log entries except those specified by the *ErrorID* (error identifier) variable. The *ErrorID* variable values can be separated by , (commas), or enclosed in " " (double quotation marks) and separated by , (commas) or space characters.
-K *ErrorLabel*	Deletes all error-log entries except those specified by the *ErrorLabel* variable. The *ErrorLabel* variable values can be separated by , (commas), or enclosed in " " (double quotation marks) and separated by , (commas) or space characters.

Item	Description
-l *SequenceNumber*	Deletes error-log entries with the specified sequence numbers. The *SequenceNumber* variable values can be separated by , (commas), or enclosed in " " (double quotation marks) and separated by , (commas) or space characters.
-m *Machine*	Deletes error-log entries for the machine specified by the *Machine* variable. The **uname -m** command returns the value of the *Machine* variable.
-n *Node*	Deletes error-log entries for the node specified by the *Node* variable. The **uname -n** command returns the value of the *Node* variable.
-N *List*	Deletes error-log entries for the resource names specified by the *List* variable. The *List* variable is list of names of resources that have detected errors. For software errors, these are the names of resources that have detected errors. For hardware errors, these are names of devices or system components. It does not indicate that the component is faulty or needs replacement. Instead, it is used to determine the appropriate diagnostic modules to be used to analyze the error. The *List* variable values can be separated by , (commas), or enclosed in " " (double quotation marks) and separated by , (commas) or space characters.
-R *List*	Deletes error-log entries for the resource types specified by the *List* variable. For hardware errors, the *List* variable is a device type. For software errors, the value of the *List* variable is **LPP**. The *List* variable values can be separated by , (commas), or enclosed in " " (double quotation marks) and separated by , (commas) or space characters.
-S *List*	Deletes error-log entries for the resource classes specified by the *List* variable. For hardware errors, the *List* variable is a device class. The *List* variable values can be separated by , (commas), or enclosed in " " (double quotation marks) and separated by , (commas) or space characters.
-T *List*	Deletes error-log entries for error types specified by the *List* variable. Valid *List* variable values are: **PERM**, **TEMP**, **PERF**, **PEND**, **INFO**, and **UNKN**. The *List* variable values can be separated by , (commas), or enclosed in " " (double quotation marks) and separated by , (commas) or space characters.
-y *FileName*	Uses the error-record template file specified by the *FileName* variable.

Security

Access Control: Only the root user can run this command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To delete all entries from the error log, enter:

```
errclear 0
```

2. To delete all entries in the error log classified as software errors, enter:

```
errclear -d S 0
```

3. To clear all entries from the alternate error-log file `/var/adm/ras/errlog.alternate`, enter:

```
errclear -i /var/adm/ras/errlog.alternate 0
```

4. To clear all hardware entries from the alternate error-log file `/var/adm/ras/errlog.alternate`, enter:

```
errclear -i /var/adm/ras/errlog.alternate -d H 0
```

Files

Item	Description
/etc/objrepos/SWservAt	Contains the Software Service Aids Attributes object class, which is the error-log configuration database.

errctrl Command

Purpose

Modifies or displays the error-checking attributes of system components. Persistent attribute values can also be specified for components that have not yet been created.

Syntax

errctrl [**-nru**] *ComponentSelector ... subcommand ...*

errctrl -p [**-ru**] *ComponentSelector ... subcommand ...*

errctrl -P [**-ru**] *ComponentSelector ... subcommand ...*

errctrl -x { **-P** | **-p** } [**-ru**] *ComponentSelector ...*

errctrl -q [**-rupP**] {*ComponentSelector ...*}

errctrl {**-h** | **-?**}

errctrl -P {**errcheckon** | **errcheckoff**}

Description

The **errctrl** command modifies or displays the error-checking attribute values of some or all components. Components are selected by name, by alias, or by type or subtype.

The supported value of a *ComponentSelector* is as follows:

-c
componentPatternList

-l
aliasPatternList

-t
typePatternList

Each list consists of one or more patterns separated by quoted spaces or commas. Patterns can contain special characters as described by the **fnmatch** subroutine. The pattern characters question mark (?), asterisk (*), and brackets ([ ]) are supported, but character classes and collation sequences are not allowed inside brackets ([ ]). Specifying **-c all** selects all components, if no other *ComponentSelector* is used.

The **errctrl** command can also be used with the **-p** or **-P** flag to specify persistent attribute customizations. For more information about persistent attribute customizations, see **Persistent Customizations**.

To enable or disable error checking for all components immediately and persistently, specify the **errcheckon** or **errcheckoff** subcommand with the **-P** flag. No other flags or subcommands are allowed with this form of the command. A **bosboot** command is required to make settings persistent across restarts.

The modified attributes depend on the subcommand specified on the command line. Multiple subcommands can be specified in a single invocation. The following subcommands are available:

Item	Description
errcheckon	Turns on error checking.
errcheckoff	Turns off error checking.
errcheckminimal	Sets the error checking level to 1.
errchecknormal	Sets the error checking level to 3.
errcheckdetail	Sets the error checking level to 7.
errchecklevel={0-9}	Sets the error checking level to the specified value.
lowsevdisposition={disp}	Sets the disposition for low-severity errors to the specified value.
medsevdisposition={disp}	Sets the disposition for medium-severity errors to the specified value.

The **disp** error disposition is one of the following values:

- ignore (or 48)
- log (or 64)
- livedump (or 80)
- isolate (or 96)
- sysdump (or 112)

Other subcommands can be recognized by individual components. A subcommand that is not recognized by a component is ignored.

Current attribute values can be displayed with the **-q** flag. If no *ComponentSelector* is used, attribute values are displayed for all components for which error-checking is supported.

Memory overlay detection system for network memory can be enabled by setting the detailed error level for the netmalloc component. Raise the errlevel for the netmalloc component to five or more (default: 3(normal)) to collect complete network memory police buffer information for all network memory allocation and free events. Note that raising the error level to seven (detail) or more also enables network memory overlay detection system. To enable only the **net_malloc_police** option and outstanding memory allocation (OSTD) logging for all network memory allocations and free events, raise the error level to five.

For more information about modifying the errlevel, see the “Examples” on page 1258 . For more information about raising the trace level to collect trace data in the netmalloc component, see the **ctctrl** command.

This command can be used to set the probability (frequency) and values to the following **netmalloc** functions.

- police_frequency
- frag_mask

Probability is the numerator out of 1024 (for example, 10%: 102, 5%: 51, 1%: 10, 0.1%: 1)

Persistent Customizations

The **-p** and **-P** flags allow attribute values to be specified for system components that have not been created yet. Thus, attributes for newly created components can be customized before the components become active. The **-p** flag is used to specify customizations for components that will be created in the future, but before you restart AIX. The **-P** flag is used to specify customizations that will take effect after the next restart. These customizations are added to the **/var/adm/ras/raspertune** file. You must run the **bosboot** command to save these customizations in the boot image and restart AIX for the customizations to take effect.

The *ComponentSelectors* can contain pattern-matching characters. Thus, a persistent customization can apply to more than one component. In addition, multiple customizations can apply to the same component, if different *ComponentSelectors* are used. If conflicting attribute values are specified in multiple customizations, the last customization takes precedence. If a customization already exists for a specified *ComponentSelector*, the new customization replaces the old one.

Multiple *ComponentSelectors* are allowed when persistent customizations are specified, but in all cases, using multiple selectors is equivalent to specifying multiple commands, each with a single component selector. For example, the customization "`errctrl -p -l hdisk0 -l hdisk1 errchecknormal`" is equivalent to the following two customizations:

```
errctrl -p -l hdisk0 errchecknormal
errctrl -p -l hdisk1 errchecknormal
```

Customizations specified with the **-p** or **-P** flag are not deleted after they are used. Therefore, a single customization can affect multiple new components. Persistent customization can be deleted with the **-x** flag. The *ComponentSelector* must be specified identically to the way it was specified when the customization was created. For example, if a customization is created with the *ComponentSelector* `-l hdisk0`, the customization cannot be deleted with the *ComponentSelector* `-l hdisk[0]`, even though both *ComponentSelectors* match the same component alias. When a persistent customization is deleted, no change is made to the attributes of components that were created when the customization was active.

Persistent customizations deleted with the **-x** and **-P** flags will remain in effect unless you run the **bosboot** command and restart AIX. A persistent customization that was created with the **-P** flag can be deleted after the restart by using the **-x** and **-p** flags. In this case, the customization will be active again if you restart AIX.

If you do not know the customizations that have been made but want to restore the default system setting, you can do one of the following:

- In the **/var/adm/ras/raspertune** file, delete the lines relevant to the customizations and run the **bosboot** command to restart AIX.
- Read the **/var/adm/ras/raspertune** file to figure out the appropriate flags and parameters that have been specified. Then use the **-x** flag to delete the customizations as shown in example “6” on page 1258. Run the **bosboot** command and restart AIX.

The **-r** and **-u** flags can be used when specifying persistent customizations. Using one flag specifies a different name space for the specified component selectors. Using both flags at the same time is equivalent to two separate command invocations, each with one of the flags. For example, the persistent customization "`errctrl -p -l hdisk0 -u -r errcheckdetail`" is equivalent to the following two separate customizations:

```
errctrl -p -l hdisk0 -u errcheckdetail
errctrl -p -l hdisk0 -r errcheckdetail
```

The following persistent customizations are all distinct, and can be modified or deleted independently.

```
errctrl -p -l hdisk0 errcheckdetail
errctrl -p -l hdisk0 -r errcheckdetail
errctrl -p -l hdisk0 -u errcheckdetail
```

Recursive-down customizations (specified by the **-r** flag) take precedence over all other customizations, regardless of the order in which they are specified relative to other non-recursive-down customizations.

Persistent customizations can be queried by using the **-q** flag with either the **-P** or **-p** flag. Specifying the **-q** flag with the **-P** flag displays lines from the **/var/adm/ras/raspertune** file. Specifying the **-q** flag with the **-p** and **-r** flags displays the persistent customizations originally specified with the **-r** flag. Without the **-r** flag, the **-q** and **-p** flags display the persistent customizations specified with or without the **-u** flag.

A persistent customization allows multiple subcommands to be specified. If conflicting subcommands are used, the last subcommand is used. For example, the **errchecknormal** and **errcheckdetail** subcommands specify different values for the same error-checking attribute, so the last specified subcommand will be used.

Flags

Item	Description
-c *ComponentList*	Specifies a comma-separated or space-separated list of component names. The **-c all** flag selects all components if it is the only *ComponentSelector*.
-h or **-?**	Displays a usage message.
-l *aliasList*	Specifies a comma-separated or space-separated list of component aliases.
-n	Applies subcommands immediately. This flag is the default if neither the **-p** nor the **-P** flag is used.
-P	Specifies the subcommands that will persist across restarts. You must run the **bosboot** command and restart AIX for these subcommands to be active.
-x	Deletes the persistent customization for the specified components. The *ComponentSelector* must be entered exactly as they were entered when the customization was originally specified.
-p	Specifies persistent subcommands. The specified subcommands will be applied to newly-created components.
-q	Queries the attribute settings of selected components. This flag can also be used with the **-p** or the **-P** flag to display persistent customizations.
-r	Applies the subcommands recursively to all subcomponents of the selected components.
-t *type_subtypeList*	Specifies a space-separated or a comma-separated list of *type* or *type_subtype* names. Valid *type* names include `device`, `filesystem`, `network`, `services`, `storage`, and `ui`. A complete list of *type* and *type_subtype* names is located in the **/usr/include/sys/ras_base.h** header file.
-u	Applies the subcommands recursively to the ancestors of the specified components.

Note: The **-u** and **-r** flags can be used together. Multiple **-c**, **-l** and **-t** flags can be used on the command line.

Exit Status

Item	Description
`0`	Successful completion.
`>0`	An error occurred.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To turn on detailed error checking for all JFS2 userdata components, enter:

   ```
   errctrl -c 'jfs2.filesystem.*.userdata' errcheckdetail
   ```

2. To specify a persistent customization for the userdata component of new JFS2 file systems, enter:

   ```
   errctrl -p -c 'jfs2.filesystem.*.userdata' errcheckminimal
   ```

   The existing userdata components are not affected.

3. To specify a customization that will persist across restarts, enter:

   ```
   errctrl -P -c 'jfs2.filesystem.*.userdata' errcheckminimal
   ```

   If you run the **bosboot** command and restart AIX, minimal error checking will be in effect for all JFS2 userdata components.

4. To set minimal error checking for all current and future JFS2 userdata components., enter:

   ```
   errctrl -npP -c 'jfs2.filesystem.*.userdata' errcheckminimal
   ```

5. To specify multiple persistent attribute values for the ethernet component, enter:

   ```
   errctrl -P -c ethernet errcheckminimal medsevdisposition=80
   ```

6. To delete the customization specified in Example 2, enter:

   ```
   errctrl -p -x -c 'jfs2.filesystem.*.userdata'
   ```

7. To list all persistent, recursive-down attribute customizations, enter:

   ```
   errctrl -q -p -r
   ```

8. To list the current error-checking attribute values for the JFS2 components and its descendants, enter:

   ```
   errctrl -q -c jfs2 -r
   ```

9. To enable memory overlay detection system (MODS) for network memory (raise the error level to detailed level for the netmalloc component), enter:

   ```
   errctrl errcheckdetail -c netmalloc
   ```

   or

   ```
   errctrl errchecklevel=7 -c netmalloc
   ```

   Note: This also enables the **net_malloc_police** option for all network memory allocations and free events.

10. To enable the **net_malloc_police** option for all network memory allocations and free events, raise the netmalloc component error level to five or greater, enter:

    ```
    errctrl errchecklevel=5 -c netmalloc
    ```

    This command also enables outstanding memory allocation (OSTD) logging for network memory.

11. To change the frequency of netmalloc police allocation and free events to 25%, change the probability of police_frequency function to 256, enter:

```
errctrl police_frequency=256 -c netmalloc.police
```

Location

`/usr/sbin/errctrl`

Files

Item	Description
/var/adm/ras/raspertune	File containing persistent attribute customization that will apply after a restart, if you run the **bosboot** command first.

errdead Command

Purpose

Extracts error records from a system dump or live dump.

Syntax

/usr/lib/errdead [**-i** *FileName*] *DumpFile* [*UnixFile*]

Description

The **errdead** command extracts error records from a system dump or live dump containing the internal buffer maintained by the **/dev/error** file. The **errdead** command extracts the error records from the dump file and adds those error records directly to the error log.

The error log daemon need not be running when the **errdead** command is run.

Flag

Item	Description
-i *FileName*	Adds the extracted error records to the error log file specified by the *FileName* variable. If the file does not exist, the **errdead** command creates it. If this flag is not specified, the value from the error log configuration database is used.

Parameters

Item	Description
DumpFile	Specifies the dump image to operate on.
UnixFile	Specifies the UNIX file that is in use when the system dump or live dump is taken. This is not necessary if using **errdead** command on the same system that the dump originated from.

Security

Access Control: Only the root user can run this command.

Example

To capture error log information from a dump image that resides in the `/var/adm/ras/vmcore.0` file, enter:

```
/usr/lib/errdead /var/adm/ras/vmcore.0
```

Error logging information is in the dump image if the **errdemon** daemon was not running when the dump occurred.

File

Item	Description
/etc/objrepos/SWservAt	Contains the software service aids attributes object class; that is, the error log configuration database.

errdemon Daemon

Purpose

Starts error logging daemon (**errdemon**) and writes entries to the error log.

Syntax

errdemon [[**-B** *BufferSize*] [**-d** | **-D**] [**-i** *File*] [**-s** *LogSize*] [**-t** *Time*] [**-m** *MaxDups*] | **-l**] [**-R** *enable* | *disable*]

Description

The error logging daemon reads error records from the **/dev/error** file and creates error log entries in the system error log. Besides writing an entry to the system error log each time an error is logged, the error logging daemon performs error notification as specified in the error notification database. The **/etc/objrepos/errnotify** file is the error notification database. The default system error log is maintained in the **/var/adm/ras/errlog** file. The last error entry is placed in nonvolatile random access memory (NVRAM). During system startup, this last error entry is read from NVRAM and added to the error log when the error logging daemon is started.

The error logging daemon does not create an error log entry for the logged error if the error record template specifies `Log=FALSE`.

If you use the error logging daemon without flags, the system restarts the error logging daemon using the configuration values stored in the error log configuration database. By default, the **errdemon** daemon removes duplicate error log entries when they are logged very rapidly. This is to prevent run away error logging from adversely effecting system performance. The number of duplicate entries can be seen with a detailed error report.

If the PowerHA pureScale® error logging is enabled, error log entries are sent to the PowerHA pureScale logstream, in addition to the local system error log. The PowerHA pureScale error logging status and logstream name are specified with the **errlg_pscale_enabled** and **errlg_pscale_logstream** values of the error log configuration database. The PowerHA pureScale client fileset must be installed on the system and bindings information for the service named **CentralizedLogService** must be setup. The log space and log stream objects specified as the PowerHA pureScale logstream must exist.

Use the **errclear** command to remove entries from the system error log.

Attention: The error logging daemon is normally started during system initialization. Stopping the error logging daemon can cause error data temporarily stored in internal buffers to be overwritten before it can be recorded in the error log file.

Flags

Item	Description
-B *BufferSize*	Uses the number of bytes specified by the *BufferSize* parameter for the error log device driver's in-memory buffer. The specified buffer size is saved in the error log configuration database. If the *BufferSize* parameter is larger than the buffer size currently in use, the in-memory buffer is immediately increased. If the *BufferSize* parameter is smaller than the buffer size currently in use, the new size is put into effect the next time the error logging daemon is started after the system is rebooted. The buffer cannot be made smaller than the hard-coded default of 8KB. If this parameter is not specified, the error logging daemon uses the buffer size from the error log configuration database. The size you specify is rounded up to the next integral multiple of the memory page size (4KB). The memory used for the error log device driver's in-memory buffer is not available for use by other processes. (The buffer is pinned). Be careful not to impact your system's performance by making the buffer excessively large. On the other hand, if you make the buffer too small, the buffer can become full if error entries arrive faster than they can be read from the buffer and put into the log file. When the buffer is full, new entries are discarded until space becomes available in the buffer. When this situation occurs, the error logging daemon creates an error log entry to inform you of the problem. You can correct the problem by enlarging the buffer.
-d	Specifies that duplicate error log entries cannot be removed. The default behavior is to remove duplicates, which is indicated with the **-D** flag.
-D	Specifies that duplicate entries are to be removed. This is the default.
-i *File*	Uses the error log file specified by the *File* variable. The specified file name is saved in the error log configuration database and is immediately put into use.
-l	Displays the values for the error log file name, file size, buffer size, and duplicate handling values from the error log configuration database.
-m *MaxDups*	Specifies the maximum number of duplicate entries allowed before a duplicate error is forced out. The default is 1000. When an error has been duplicated the number of times that is specified in *MaxDups*, a duplicate error is written just as it would be if a unique error was logged. The values allowed for *MaxDups* are 1 to 2147483647.
-R *enable* | *disable*	Restricts the **errpt** command to only the privileged users. If the `-R` option is disabled, the **errpt** command is available to all users. The default value is *disable*. For more information, see the `Security` section of the **errpt** command.
-s *LogSize*	Uses the size specified by the *LogSize* variable for the maximum size of the error log file. The specified log file size limit is saved in the error log configuration database, and it is immediately put into use. If the log file size limit is smaller than the size of the log file currently in use, the error logging daemon renames the current log file by appending **.old** to the file name. The error logging daemon creates a new log file with the specified size limit. Generate a report from the old log file using the **-i** flag of the **errpt** command. If this parameter is not specified, the error logging daemon uses the log file size from the error log configuration database.

Item	Description
-t *Time*	Specifies the approximate time interval (in milliseconds) within which an error is considered a duplicate if it is identical to the previous error. Errors occurring after this time interval are not considered duplicates even if they are identical to the previous error. The default interval is 10000, or 10 seconds. The values allowed for Time are 1 to 2147483647. **Note:** This flag eliminates duplicate entries in the case of an error logger rapidly logging the same error, this usually indicates a loop condition. It is not intended to catch all duplicate errors for which there may be error notification objects. Making this value sufficiently large may compromise error notification by eliminating too many errors. See the **errpt** command for a description of eliminating duplicate errors in an error report.

Examples

1. To start the error-logging daemon, enter:

```
/usr/lib/errdemon
```

2. To view the current maximum error-log size, enter:

```
/usr/lib/errdemon -l
```

3. To change the current maximum error-log size from 1MB to 64KB, enter:

```
/usr/lib/errdemon -s 65536
```

4. To only consider errors that are logged within the last 10 milliseconds to be duplicates, enter

```
/usr/lib/errdemon -t 10
```

Files

Item	Description
/dev/error	Source of error records.
/var/adm/ras/errtmplt	Contains the error template repository.
/usr/lib/errdemon	Contains the **errdemon** daemon.
/etc/objrepos/SWservAt	Contains the software service aids attributes object class; that is, the error log configuration database.

errinstall Command

Purpose

Installs messages in the error logging message sets.

Syntax

errinstall [**-c**] [**-f**] [**-q**] [**-z** *FileName*] *File*

Description

The **errinstall** command is an installation aid that adds or replaces messages in the Error Description, Probable Cause, User Cause, Install Cause, Failure Cause, Recommended Action, and Detailed Data data id message sets of the error log message catalog.

The *File* parameter specifies an input file containing messages to be added or replaced. If you do not specify the *File* parameter or if you specify it as the **-** (minus sign), the **errinstall** command reads from standard input.

Note: Licensed programs and in-house applications must use predefined messages from the error logging message sets. List the predefined messages using the **errmsg -w** command. To add new messages, third-party software vendors should contact IBM Developer Solutions to register new messages. During the development of in-house applications, the **errmsg** command can be used to add new messages, but the new messages must not conflict with the messages added for other in-house applications.

Undo Feature

The **errinstall** command creates an undo file in the current directory named the *File*.**undo** file. (If the **errinstall** command is reading from standard input, the undo file information is written to standard output.) The *File***.undo** file can be used as input to the **errinstall** command to undo the changes the **errinstall** command has just made. To undo changes, run the **errinstall** command with the **-f** flag and specify the *File***.undo** file for the *File* parameter.

Input File (or Standard In) File Format

Two separate lines of information are required to add or replace a single message in the error log message catalog. You can include multiple additions or replacements in a single file. The first line is required to identify the message set to which the message is to be added or replaced. Use the following format:

```
SET MessageSetID
```

where the *MessageSetID* parameter is one of the following single characters:

Item	Description
E	Identifies Error Description
P	Identifies Probable Cause
U	Identifies User Cause
I	Identifies Install Cause
F	Identifies Failure Cause
R	Identifies Recommended Action
D	Identifies Detailed Data

The second line lists the message ID with the message to be added or replaced. At least one line is required, and multiple lines can be included, following a single line that identifies a message set. As described earlier, users should contact their service representative to obtain the message ID, unless it is required for an in-house application only (in which case, use the **errmsg** command to install the error message without a predetermined error message ID).

You must put a space between the message ID and the message text, and enclose the text of the message in double quotes as follows:

```
message ID "message text"
```

In addition to the two required lines of information, you can also include lines of comments. A comment line must have a $ (dollar sign) or an * (asterisk) operator in the first column. The asterisk is the preferred choice.

Note: Messages added to the Error Description, Probable Cause, and Detailed Data ID message sets must not exceed 40 characters in length. Messages added to the User Cause, Install Cause, Failure Cause, and Recommended Action message sets must not exceed 128 characters in length. If messages exceed these lengths, the **errinstall** command displays a warning message, but adds the messages to the codepoint catalogue. These messages will be truncated when displayed by the summary errpt command.

Flags

Item	Description
-c	Checks the input *File* parameter for syntax errors.
-f	Replaces messages having duplicate IDs. When an attempt is made to add a message using a message ID that is already in use, the **-f** flag forces the **errinstall** command to replace the old message text with the new message text. If the **-f** flag is not specified, the old message text is not replaced and a warning message is written to standard error. The **-f** flag is also required to undo a message installation.
-q	Suppresses the creation of an **undo** file.
-z *FileName*	Uses the error logging message catalog specified by the *FileName* parameter.

Security

Access Control: Only the root user can run this command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To install the error log messages for the licensed product lpp, enter:

```
errinstall -f /tmp/lpp.desc
```

2. To undo the changes made to the error log message catalog by the above example of the **errinstall** command, enter:

```
errinstall -f /tmp/lpp.desc.undo
```

3. To install an error message in the Probable Cause message set, enter:

```
errinstall

* Add a probable cause for widget failure:
SET P
E100 "widget adapter"
```

4. To replace a message with a duplicate ID in the Probable Cause message set, enter:

```
errinstall -f

* Replace the message associated with ID E100 in the
* Recommended Action message set
SET R
E100 "Replace disk drive"
```

5. If you name your input file **in_file** and then want to use it to install new error messages, enter:

```
errinstall in_file
```

6. To overwrite existing error messages in message sets, use the previously defined ID numbers in your **in_file**, and specify the **-f** flag with the **errinstall** command as follows:

```
errinstall -f in_file
```

7. The following example illustrates sample contents of an input file to be installed.

```
*
* Add these error messages to the Detailed Data message set:
*
SET D
8105 "Logical channel number"
8106 "Timer reference stamp"
*
* Add these error messages to the Probable Cause message set:
*
SET P
E861 "Bad memory card"
E865 "Unexpected System Halt"
E876 "Fiber Optic Cable"
*
* Add this message to the Recommended Action message set:
*
SET R
E850 "Install updated driver code"
```

Files

Item	Description
/usr/lib/nls/msg/$LANG/codepoint.cat	Contains the error log message catalog. In the United States, the value of the **$LANG** environment variable is **En_US**.

errlogger Command

Purpose

Logs an operator message.

Syntax

errlogger *Message*

Description

The **errlogger** command creates an operator error log entry that contains an operator message up to 1024 bytes in length.

Security

Access Control: Only the root user can run this command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

To create an operator message for system drive reconfiguration, enter:

```
errlogger system drive reconfigured
```

errmsg Command

Purpose

Adds a message to the error log message catalog.

Syntax

errmsg [**-c**] [**-z** *FileName*] [**-w** *Set_List* | *File*]

Description

The **errmsg** command updates and displays the error-log message catalog containing the Error Description, Probable Cause, User Cause, Install Cause, Failure Cause, Recommended Action, and Detailed Data ID message sets.

The message sets to which messages are to be added or deleted are listed in the input *File* parameter as follows:

Item	Description
***** or **$**	Comment lines must have an * (asterisk) or $ (dollar sign) comment operator in the first column. The * is the preferred choice.
+	Messages to be added must be preceded by a + (plus sign).
-	Messages to be deleted must be preceded by a - (minus sign).
SET	Message set ID.
"Message Text"	Message text must be enclosed in double quotation marks.
Message ID	Message ID of the message to be deleted.

Messages added to the Error Description, Probable Cause, and Detailed Data ID message sets must not exceed 40 characters in length. Messages added to the User Cause, Install Cause, Failure Cause, and Recommended Action message sets must not exceed 128 characters in length. A maximum of 2047 user-defined messages can be added to each message set.

The **errmsg** command is used by application developers to create new messages used in the Error Record Templates Repository. An existing message should always be used, if possible.

If no flags are specified on the command line, the default operation is an update. Updates are specified in the input *File* parameter. If the input *File* parameter is not specified or if a **-** (minus sign) is specified instead of the *File* parameter, the **errmsg** command reads from standard input. For each message that is added, the **errmsg** command assigns an identifier. In addition to adding the message to the message catalog, the **errmsg** command writes the identifier and message text to the *File***.out** file. The *File***.out** file is also created when deletions are made from the message catalog. If the **errmsg** command is reading from standard input, the identifier and message text are written to standard output.

Flags

Item	Description
-c	Checks the input file for syntax errors.

Item	Description
-w *Set_List*	Displays the error log message sets specified by the *Set_List* variables. This option displays the messages contained in the Error Log message sets and their identifiers. Output is written to standard output. The *Set_List* variables can be separated by commas or enclosed in double-quotation marks and separated by commas or blanks. The *Set_List* variables are the message set IDs or, if the value of the *Set_List* variable **all** is specified, the contents of all of the Error Log message sets are displayed. The valid values of the *Set_List* variables are: **all** Displays all message sets **D** Displays Detailed Data ID message set **E** Displays Error Description message set **F** Displays Failure Cause message set **I** Displays Install Cause message set **P** Displays Probable Cause message set **R** Displays Recommended Action message set **U** Displays User Cause message set
-z *Filename*	Uses the error-logging message catalog specified by the *Filename* variable.

Security

Access Control: Only the root user can run this command.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To delete messages from the Probable Cause message set, enter:

```
errmsg
* Delete messages FF1A, FF1B, and FF1C from the Probable Cause
* message set
SET P
- FF1A
- FF1B
- FF1C
```

2. To add a message to the Probable Cause message set for the Widget Failure error, enter:

```
errmsg
* Add a Probable Cause for Widget Failure
SET P
+ "WIDGET ADAPTER"
```

File

Item	Description
/usr/lib/nls/msg/$LANG/codepoint.cat	Contains the error log message catalog. In the United States, the value of **$LANG** is **En_US**.

errpt Command

Purpose

Generates a report of logged errors.

Syntax

To Process a Report from the Error Log

errpt [**-@** *wpar_name*] [**-a**] [**-A**] [**-c**] [**-d** *ErrorClassList*] [**-D**] [**-e** *EndDate*] [**-g**] [**-i** *File*] [**-I** *File*] [**-j** *ErrorID* [**,***ErrorID*]] | [**-k** *ErrorID* [**,***ErrorID*]] [**-J** *ErrorLabel* [**,***ErrorLabel*]] | [**-K** *ErrorLabel* [**,***ErrorLabel*]] [**-l** *SequenceNumber*] [**-m** *Machine*] [**-n** *Node*] [**-s** *StartDate*] [**-F** *FlagList*] [**-N** *ResourceNameList*] [**-P**] [**-R** *ResourceTypeList*] [**-S** *ResourceClassList*] [**-T** *ErrorTypeList*] [**-y** *File*] [**-z** *File*]

To Process a Report from the Error Record Template Repository

errpt [**-a**] [**-A**] [**-I** *File*] [**-t**] [**-d** *ErrorClassList*] [**-j** *ErrorID* [**,***ErrorID*]] | [**-k** *ErrorID* [**,***ErrorID*]] [**-J** *ErrorLabel* [**,***ErrorLabel*]] | [**-K** *ErrorLabel* [**,***ErrorLabel*]] [**-F** *FlagList*] [**-P**] [**-T** *ErrorTypeList*] [**-y** *File*] [**-z** *File*]

Description

The **errpt** command generates an error report from entries in an error log. It includes flags for selecting errors that match specific criteria. By using the default condition, you can display error log entries in the reverse order they occurred and were recorded. By using the **-c** (concurrent) flag, you can display errors as they occur. If the **-i** flag is not used with the **errpt** command, the error log file processed by **errpt** is the one specified in the error log configuration database. (To view the information in the error log configuration database, use the **errdemon** command.)

The default summary report contains one line of data for each error. You can use flags to generate reports with different formats.

> **Note:** The **errpt** command does not perform error log analysis; for analysis, use the **diag** command. When error log analysis is performed, however, diagnostics may add diagnostic information back into the error log. Such information is shown following the detailed data of the corresponding error log entry.

You can use the System Management Interface Tool (SMIT) **smit errpt** fast path to run this command.

Flags

-@*wpar_name*
Selects the error entries for the specified WPAR name.

-a
Displays information about errors in the error log file in detailed format. If used in conjunction with the **-t** flag, all the information from the template file is displayed.

-A
Displays a shortened version of the detailed report produced by the **-a** flag. The **-A** flag is not valid with the **-a**, **-g**, or **-t** flags. The items reported are the label, date and time, type, resource name, description, and detail data. The example output of this flag is in the following format:

```
LABEL:           STOK_RCVRY_EXIT
Date/Time:       Tue Dec 14 15:25:33
Type:            TEMP
Resource Name:   tok0
Description
PROBLEM RESOLVED
Detail Data
FILE NAME
line: 273 file: stok_wdt.c
SENSE DATA
0000 0000 0000 0000 0000 0000
DEVICE ADDRESS
0004 AC62 25F1
```

-c
Formats and displays each of the error entries concurrently, that is, at the time they are logged. The existing entries in the log file are displayed in the order in which they were logged.

-d *ErrorClassList*
Limits the error report to certain types of error records specified by the valid *ErrorClassList* variable: **H** (hardware), **S** (software), **0** (**errlogger** command messages), and **U** (undetermined). The error records in the *ErrorClassList* variable can be separated by a **,** (comma), or enclosed in " " (double quotation marks) and separated by a **,** (comma), or a space character.

-D
Consolidates duplicate errors. The detailed error report, obtained with the **-a** flag, reports the number, and first and last times of the duplicates. See Error Logging Overview in *General Programming Concepts: Writing and Debugging Programs*.

Note: The **-D** flag is not valid with the **-c**, **-g**, **-l**, **-t**, and **-P** flags.

-e *EndDate*
Specifies all records posted prior to and including the *EndDate* variable, where the *EndDate* variable has the form *mmddhhmmyy* (month, day, hour, minute, and year).

-g
Displays the ASCII representation of unformatted error-log entries. The output of this flag is in the following format:

el_sequence
Error-log stamp number

el_label
Error label

el_timestamp
Error-log entry time stamp

el_crcid
Unique cyclic-redundancy-check (CRC) error identifier

el_machineid
Machine ID variable

el_nodeid
Node ID variable

el_class
Error class

el_type
Error type

el_resource
Resource name

el_rclass
Resource class

el_rtype
Resource type

el_vpd_ibm
IBM vital product data (VPD)

el_vpd_user
User VPD

el_in
Location code of a device

el_connwhere
Hardware-connection ID (location on a specific device, such as slot number)

et_label
Error label

et_class
Error class

et_type
Error type

et_desc
Error description

et_probcauses
Probable causes

et_usercauses
User causes

et_useraction
User actions

et_instcauses
Installation causes

et_instaction
Installation actions

et_failcauses
Failure causes

et_failaction
Failure actions

et_detail_length
Detail-data field length

et_detail_descid
Detail-data identifiers

et_detail_encode
Description of detail-data input format

et_logflg
Log flag

et_alertflg
Alertable error flag

et_reportflg
Error report flag

el_detail_length
Detail-data input length

el_detail_data
Detail-data input

-F ***FlagList***
Selects error-record templates according to the value of the `Alert`, `Log`, or `Report` field of the template. The *FlagList* variable can be separated by a **,** (comma), or enclosed in " " (double quotation marks) and separated by a **,** (comma), or a space character. The **-F** flag is used with the **-t** flag only.

Valid values of the *FlagList* variable include:

alert=0
Selects error-record templates with the `Alert` field set to False.

alert=1
Selects error-record templates with the `Alert` field set to True.

log=0
Selects error-record templates with the `Log` field set to False.

log=1
Selects error-record templates with the `Log` field set to True.

report=0
Selects error-record templates with the `Report` field set to False.

report=1
Selects error-record templates with the `Report` field set to True.

-i *File*
Uses the error log file specified by the *File* variable. If this flag is not specified, the value from the error log configuration database is used.

-I *File*
Uses the diagnostic log file specified by *File*. If this flag is not specified, the default pathname, **/var/adm/ras/diag_log**, is used.

-j *ErrorID*[,*ErrorID*]
Includes only the error-log entries specified by the *ErrorID* (error identifier) variable. The *ErrorID* variables can be separated by a **,** (comma), or enclosed in " " (double quotation marks) and separated by a **,** (comma), or a space character. When combined with the **-t** flag, entries are processed from the error-template repository. (Otherwise entries are processed from the error-log repository.)

-J *ErrorLabel*
Includes the error log entries specified by the *ErrorLabel* variable. The *ErrorLabel* variable values can be separated by commas or enclosed in double-quotation marks and separated by commas or blanks. When combined with the **-t** flag, entries are processed from the error template repository. (Otherwise, entries are processed from the error log repository.)

-k *ErrorID*[,*ErrorID*]
Excludes the error-log entries specified by the *ErrorID* variable. The *ErrorID* variables can be separated by a **,** (comma), or enclosed in " " (double quotation marks) and separated by a **,** (comma), or a space character. When combined with the **-t** flag, entries are processed from the error-template repository. (Otherwise entries are processed from the error-log repository.)

-K *ErrorLabel*
Excludes the error log entries specified by the *ErrorLabel* variable. The *ErrorLabel* variable values can be separated by commas or enclosed in double-quotation marks and separated by commas or blanks. When combined with the **-t** flag, entries are processed from the error template repository. (Otherwise, entries are processed from the error log repository).

-l *SequenceNumber*
Selects a unique error-log entry specified by the *SequenceNumber* variable. This flag is used by methods in the error-notification object class. The *SequenceNumber* variable can be separated by a **,** (comma), or enclosed in " " (double quotation marks) and separated by a **,** (comma), or a space character.

-m *Machine*
Includes error-log entries for the specified *Machine* variable. The **uname -m** command returns the *Machine* variable value.

-n *Node*
Includes error-log entries for the specified *Node* variable. The **uname -n** command returns the *Node* variable value.

-N *ResourceNameList*
Generates a report of resource names specified by the *ResourceNameList* variable. The *ResourceNameList* variable is a list of names of resources that have detected errors. For software errors, the *ResourceNameList* variable lists the names of resources that have detected errors. For hardware errors, it lists names of devices or system components. It does not indicate that the component is faulty or needs replacement. Instead, it is used to determine the appropriate diagnostic modules to be used to analyze the error.

The names of the *ResourceNameList* variable can be separated by a **,** (comma), or enclosed in " " (double quotation marks) and separated by a **,** (comma), or a space character.

-P
Shows only errors which are duplicates of the previous error. The **-P** flag applies only to duplicate errors generated by the error log device driver. These errors are duplicates that occurred within the approximate time interval specified by the **errlg_duptime** error logging attribute controlled by the **errdemon** daemon **-t** flag. The **-P** flag is invalid with the **-D** flag.

-R *ResourceTypeList*
Generates a report of resource types specified by the *ResourceTypeList* variable. For hardware errors, the *ResourceTypeList* variable is a device type. For software errors, it is the **LPP** value. The items in the *ResourceTypeList* variable can be each separated by a **,** (comma), or enclosed in " " (double quotation marks) and separated by a **,** (comma), or a space character.

-s *StartDate*
Specifies all records posted on and after the *StartDate* variable, where the *StartDate* variable has the format *mmddhhmmyy* (month, day, hour, minute, and year).

-S *ResourceClassList*
Generates a report of resource classes specified by the *ResourceClassList* variable. For hardware errors, the *ResourceClassList* variable is a device class. The resource classes must be each separated by a **,** (comma), or enclosed in " " (double quotation marks) and separated by a **,** (comma), or a space character.

-t
Processes the error-record template repository instead of the error log. The **-t** flag can be used to view error-record templates in report form.

-T *ErrorTypeList*
Limits the error report to error types specified by the valid *ErrorTypeList* variables: **INFO**, **PEND**, **PERF**, **PERM**, **TEMP**, and **UNKN**. The error types can be each separated by a **,** (comma), or enclosed in " " (double quotation marks) and separated by a **,** or a space character.

-y *File*
Uses the error record template file specified by the *File* variable. When combined with the **-t** flag, entries are processed from the specified error template repository. (Otherwise, entries are processed from the error log repository, using the specified error template repository.)

-z *File*
Uses the error logging message catalog specified by the *File* variable. When combined with the **-t** flag, entries are processed from the error template repository. (Otherwise, entries are processed from the error log repository.)

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

To run the **errpt** command, you must have the following additional authorizations, if **errpt** restriction is enabled in the **errdemon** command:

aix.ras.error.errpt
Required to run the **errpt** command.

Note: By default, the root and system group users are privileged users.

Examples

1. To display a complete summary report, enter:

   ```
   errpt
   ```

2. To display a complete detailed report, enter:

   ```
   errpt  -a
   ```

3. To display a detailed report of all errors logged for the error identifier E19E094F, enter:

   ```
   errpt  -a  -j E19E094F
   ```

4. To display a detailed report of all errors logged in the past 24 hours, enter:

   ```
   errpt  -a  -s mmddhhmmyy
   ```

   where the mmddhhmmyy string equals the current month, day, hour, minute, and year, minus 24 hours.

5. To list error-record templates for which logging is turned off for any error-log entries, enter:

   ```
   errpt  -t  -F log=0
   ```

6. To view all entries from the alternate error-log file /var/adm/ras/errlog.alternate, enter:

   ```
   errpt  -i /var/adm/ras/errlog.alternate
   ```

7. To view all hardware entries from the alternate error-log file /var/adm/ras/errlog.alternate, enter:

   ```
   errpt  -i /var/adm/ras/errlog.alternate -d H
   ```

8. To display a detailed report of all errors logged for the error label ERRLOG_ON, enter:

   ```
   errpt  -a  -J ERRLOG_ON
   ```

9. To display a detailed report of all errors and group duplicate errors, enter:

   ```
   errpt -aD
   ```

10. To display a detailed report of all errors logged for the error labels DISK_ERR1 and DISK_ERR2 during the month of August, enter:

    ```
    errpt -a -J DISK_ERR1,DISK_ERR2 -s 0801000004 -e 0831235904"
    ```

Files

/etc/objrepos/SWservAt
Contains the software service aids attributes object class; that is, the error log configuration database.

errstop Command

Purpose

Terminates the error logging daemon.

Syntax

errstop

Description

Attention: Running the **errstop** command disables diagnostic and recovery functions. Normally the **errdemon** command is started automatically during system initialization and stopped during system shutdown. The error log should never be stopped during normal operations. The **errstop** command should only be used during special circumstances when it is absolutely required and the consequences are clearly understood.

The **errstop** command stops the error logging daemon initiated by the **errdemon** command.

Security

Access Control: Only a root user can run this command.

Examples

To terminate the **errdemon** daemon, enter:

```
/usr/lib/errstop
```

errupdate Command

Purpose

Updates the Error Record Template Repository.

Syntax

errupdate [**-c**] [**-f**] [**-h**] [**-n**] [**-p**] [**-q**] [**-y** *FileName*] [*File*]

Description

The **errupdate** command adds or deletes entries in the Error Record Template Repository, or modifies the log, report, or alert characteristics of existing entries. The **errupdate** command reads from the specified *File* parameter. If the *File* parameter is not specified, the **errupdate** command reads from standard input and writes to standard output.

Each entry to be added, deleted, or modified must be preceded by an operator. The valid operators are:

Item	Description
+	Adds an entry (add operator).
-	Deletes an entry (delete operator).
=	Modifies the log, report, or alert characteristics of an entry.

Entries in the input file must be separated by a blank line.

Comments in the input file can be placed between templates and are indicated by an * (asterisk) in the first column.

If X/Open Portability Guide Issue 4 messages are used in error templates, a message catalog must be specified. This can be done with a line of the form:

```
<*!catalog-name>
```

For example

```
*!mycat.cat
```

The catalog specified applies to XPG4 messages found in subsequent templates, until another "*!" catalog specifier is encountered. Also, the "*!" specifier may be overridden on an individual template basis with the "catname" keyword.

Unless a full pathname to the catalog is specified, the normal rules for retrieving a message catalog are followed. For example, in the above example, mycat.cat is assumed to be in **/usr/lib/nls/msg/%L**.

Entries to be added must be defined in a specific format. The general form of the error record template is:

```
Error Record Template

        + LABEL:
                        Comment=
                        Class=
                        Log=
                        Report=
                        Alert=
                        Err_Type=
                        Err_Desc=
                        Prob_Causes=
                        User_Causes=
                        User_Actions=
                        Inst_Causes=
                        Inst_Actions=
                        Fail_Causes=
                        Fail_Actions=
                        Detail_Data= <data_len>, <data_id>,
                        <data_encoding>
```

Additionally, a catalog name for XPG4 messages can be specified with:

```
catname = <catalog>
```

Any template which contains XPG4 messages, the catname keyword, more than eight detail data items will be referred to as an XPG4 template. An XPG4 template is not alertable, and uses a slightly different calculation for the error id.

The error record template fields are described as follows:

Item	Description
`Alert`	Indicates that the error log entry can be processed by products that conform to the SNA Generic Alert Architecture. The `Alert` field can be set to True or False. If this field is omitted from the template, its value will default to False. If the `Alert` field is set to True, the **errupdate** command does not add the template unless the contents of the `Err_Desc` , `Inst_Actions` , `Fail_Cause, Fail_Actions` , and `Detail_Data data_id` fields are values recognized by the SNA Generic Alert Architecture (in publication GA27-3136). If any of the values used are not recognized by the SNA Generic Alert Architecture or the template is an XPG4 template, and the `Alert` field is set to True, the **-p** flag must be specified to add or update the template.
`Class`	Describes whether the error occurred in hardware or software, is an operator message, or is undetermined. One of the following class descriptors must be specified: **H** Indicates the error is a hardware failure. **O** Indicates the error is an operator message. **S** Indicates the error is a software failure. **U** Indicates the error is undetermined.

Item	Description
Comment	Specifies a comment to be included with the **#define** statement that was created for the Error ID message set. The comment must not exceed 40 characters and must be enclosed in double quotation marks. Comments longer than 40 characters are automatically truncated. The **errupdate** command encloses the comment in the C language comment delimiters, /* (slash, asterisk) and */ (asterisk, slash).
Detail_Data	Describes detailed data, such as detecting module names, sense data, or return codes, that are logged with the error when the error occurs. If no detailed data is logged with the error, this field can be left blank or it can display a message from the Detailed Data ID message set by specifying a **data_len** value of zero. The following three values are required for each **Detail_Data** field and must be separated by commas: **data_len** Number of bytes of data to be associated with the **data_id** value. The **data_len** value is interpreted as a decimal value. To specify environment dependent size, use "W". "W" will be treated as 8 bytes if error is logged from a 64-bit environment, otherwise 4 bytes. **Note:** During detail data length calculation, each "W" is treated as 8 bytes long, and it is not case sensitive. **data_id** Identifies a text message from the Detailed Data ID message set “D” to be printed in the error report in front of the detailed data. The value is interpreted as an unsigned hexadecimal up to 4 digits in length. **data_encoding** Describes how detailed data is to be printed in an error report. Valid values are: **ALPHA** The detailed data is a printable ASCII character string. **DEC** The detailed data is the binary representation of an integer value, and the decimal equivalent is to be printed. **LDEC** The detailed data is the binary representation of a 64-bit value, and the decimal equivalent is to be printed. **HEX** The detailed data is to be printed in hexadecimal. Up to 16 Detail_Data entries may be specified per template. The amount of data logged with an error must not exceed ERR_REC_MAX defined in the **/usr/include/sys/err_rec.h** file. Error data that cannot be contained in an error log entry should be saved elsewhere. Detailed data in the error log entry should contain information that can be used to correlate the error data and the error log entry.
Err_Desc	Describes the error that has occurred. An Error Description message identifier must be specified in this field. This value identifies a text message from the Error Description message set “E” to be displayed for an occurrence of the error. The value is interpreted as an unsigned hexadecimal up to 4 digits in length. The field may also specify an XPG4 style message. This is discussed later.

Item	Description
Err_Type	Describes the severity of the error that has occurred. One of the following values must be specified: **PERF** Condition where the performance of the device or component has degraded to below an acceptable level (performance). **PERM** Condition that cannot be recovered from (permanent). **PEND** Condition signifying that the loss of availability of a device or component is imminent (impending). **TEMP** Condition that was recovered from after a number of unsuccessful attempts (temporary). **UNKN** Condition where it is not possible to determine the severity of the error (unknown). **INFO** Condition for informational error log entry.
Fail_Actions	Describes recommended actions for correcting an error that resulted from a failure cause. A list of up to 4 Recommended Action message identifiers separated by commas can be specified. This value identifies a text message from the Recommended Action message set “R” to be displayed for an occurrence of the error. The value is interpreted as an unsigned hexadecimal up to four digits in length. This field must be blank if the Fail_Causes field is blank. The order in which the recommended actions are listed should be determined by the expense of the action and the probability that the action will correct the error. Always list the actions that have little or no cost (or little or no impact) on the system first. List the actions for which the probability of correcting the error is equal or nearly equal next, with the least expensive actions first. List the remaining actions in order of decreasing probability. The field may also specify an XPG4 style message. This is discussed later.
Fail_Causes	Describes failure causes for the error that has occurred. A failure cause is defined as a condition that resulted from the failure of a resource. This field can list up to four Failure Cause message identifiers separated by commas. This value identifies a text message from the Failure Cause messages set “F” to be displayed for an occurrence of the error. The value is interpreted as an unsigned hexadecimal up to 4 digits in length. List the failure causes in order of decreasing probability. This field can be left blank if it does not apply to the error that has occurred. If this field is blank, either the User_Causes or the Inst_Causes field must not be blank. The field may also specify an XPG4 style message. This is discussed later.

Item	Description
Inst_Actions	Describes recommended actions for correcting an install caused error. This field can list of up to 4 Recommended Action message identifiers separated by commas. This value identifies a text message from the Recommended Action message set "R" to be displayed for an occurrence of the error. The value is interpreted as an unsigned hexadecimal up to four digits in length. This field must be blank if the Inst_Causes field was left blank. The order in which the recommended actions are listed is determined by the expense of the action and the probability that the action will correct the error. The actions that have little or no cost or little or no impact on the system should always be listed first. Actions for which the probability of correcting the error are equal or nearly equal should be listed next, with the least expensive actions first. The remaining actions should be listed in order of decreasing probability. The field may also specify an XPG4 style message. This is discussed later.
Inst_Causes	Describes install causes for the error that has occurred. An install cause is defined to be a condition that resulted from the initial installation or setup of a resource. A list of up to 4 Install Cause message identifiers separated by commas can be specified. This value identifies a text message from the Install Cause message set "I" to be displayed for an occurrence of the error. The value is interpreted as an unsigned hexadecimal up to four digits in length. Install causes should be listed in order of decreasing probability. This field can be left blank if it is not applicable to the error that has occurred. If this field is left blank, the User_Causes or the Fail_Causes field must be non-blank. The field may also specify an XPG4 style message. This is discussed later.
LABEL	Specifies a unique label of up to 19 characters that must be provided for each error logging template. A string containing " #define #ERRID_label Error_ID ", where the **Error_ID** value is the unique ID assigned to the Error Record Template is written to standard output if the **-h** flag was specified at the command line. **Note:** If the LABEL field exceeds 19 characters, the first 19 characters are accepted.
Log	Specifies whether an error log entry should be created for this error when it occurs. The log field can be set to True or False. If this field is omitted from the template, its value will default to True. When this field is set to False, the Report and Alert fields are ignored.
Prob_Causes	Describes 1 or more probable causes for the error that has occurred. A list of up to 4 Probable Cause message identifiers separated by commas can be specified. This value identifies a text message from the Probable Cause message set "P" to be displayed for an occurrence of the error. The value is interpreted as an unsigned hexadecimal up to 4 digits in length. Probable causes should be listed in order of decreasing probability. At least one probable cause is required. The field may also specify an XPG4 style message. This is discussed later.
Report	Specifies whether logged occurrences of this error should be reported when an error report is printed. The Report field can be set to True or False. If this field is omitted from the template, its value will default to True.

Item	Description
User_Actions	Describes recommended actions for correcting a user-caused error. A list of up to 4 Recommended Action message identifiers separated by commas can be specified. This value identifies a text message from the Recommended Action message set “R” to be displayed for an occurrence of the error. The value is interpreted as an unsigned hexadecimal up to 4 digits in length. This field must be left blank if the User_Causes field was left blank. The order in which the recommended actions are listed is determined by the expense of the error and the probability that the action will correct the error. The actions that have little or no cost, or little or no impact on the system should always be listed first. Actions for which the probability of correcting the error are equal or nearly equal should be listed next, with the least expensive actions first. The remaining actions should be listed in order of decreasing probability. The field may also specify an XPG4 style message. This is discussed later.
User_Causes	Describes user causes for the error that has occurred. A user cause is defined as a condition that can be corrected without contacting a service organization. A list of up to four User Cause message identifiers separated by commas can be specified. This value identifies a text message from the User Cause message set “U” to be displayed for an occurrence of the error. The value is interpreted as an unsigned hexadecimal up to four digits in length. User causes should be listed in order of decreasing probability. This field can be left blank if it is not applicable to the error that has occurred. If this field is left blank, the Inst_Causes or the Fail_Causes field must be non-blank. The field may also specify an XPG4 style message. This is discussed later.

The catname is used to specify a message catalog to be used for retrieving XPG4 messages for the current template. This will override a catalog specified with a previous "*!" catalog specifier. Any template containing XPG4 messages must have a catalog specified either with catname or "*!". The catalog name must be enclosed in quotes. Unless a full pathname to the catalog is specified, the normal rules for retrieving a message catalog are followed.

For example, if

```
catname = "mycat.cat"
```

is specified, mycat.cat is assumed to be in **/usr/lib/nls/msg/%L**.

The Error Description, Probable Cause, User Cause, Install Cause, Failure Cause, Recommended Actions, and Detailed Data ID messages must be either an error message identifier maintained in the error log message catalog, or an XPG4 message.

An error message identifier consists of up to 4 hexadecimal digits, without any leading "0x". For example, 1234 or ABCD. The **errmsg -w** command can be used to print these messages along with their identifiers. The **errmsg** command can be used to add new messages.

An XPG4 message is specified using the form

```
{<set>, <number>, <"default text">}
```

The set, number, and default text are all required. Symbolic message references are not supported. Also, templates which contain XPG4 messages are not alertable.

A message catalog must be specified for XPG4 messages. This is done with either the "*!" catalog specifier, or the catname keyword.

Error logging does not support all the features of normal error messaging. Strings used in error log templates must conform to some restrictions.

- Variable substitution is not supported. For example, the strings may not be used as format specifiers to print values. The strings may only contain the formatting characters "\t" and "\n".

- The default text strings may not be longer than 1 kb, 1024 bytes.
- It must be noted that the error description is printed in a 40 character area on the non-detailed reports. No string formatting is done for these reports, and only the first 40 characters will be printed.
- The strings should not contain a trailing new line. This is supplied by errpt.

For each entry added, the errupdate command assigns a unique Error ID that is written to the header file specified by *File*.h (where the *File* parameter is the name of the errupdate command input file). If the errupdate command is reading from standard input, the #`define` statement is written to standard output. The values supplied for the `Class` , `Err_Desc` , `Err_Type` , `Fail_Actions` , `Fail_Causes` , `Inst_Actions` , `Inst_Causes` , `Prob_Causes` , `User_Actions` , `User_Causes` fields, and the `Detail_Data` . `data_id` value, are used to calculate the unique Error ID for that error. For XPG4 templates, the Label is also included in the calculation.

The contents of the `Log` , `Report` , and `Alert` fields are not included in the calculation of the unique Error ID; therefore, the log, report, and alert characteristics of a particular error can be modified at any time in the error entry definition stored in the Error Record Template Repository using the **errupdate** command. Also note that the data_len and data_encode portions of the detail data field are not used.

The **errupdate** command also creates an undo file in the current directory named *File*.**undo**. If the **errupdate** command is reading from standard input, the **undo** file is written to **errids.undo** file. The **undo** file contains inputs to the **errupdate** command to undo changes the **errupdate** command has made.

The **errpt -t** command can be used to view the contents of the Error Record Template Repository. The templates are processed and printed as they would appear in an actual error report.

> **Attention:** If you change the error templates be aware that these templates may be changed by a subsequent update. You should keep a record of all changes made and re-apply the changes when your system is updated. This is usually only necessary after a major system update such as moving to a new level of the operating system. Also, such a record allows you to change your templates if you re-install. The easiest way to keep such a record is to always make your template modifications from one errupdate source file.

Flags

Item	Description
-c	Checks the input file for syntax errors.
-f	Forces all templates to be updated, including any templates with error ids identical to ones in the input templates
-h	Creates a #`define` statement for each Error ID assigned to an error template. If a file name was supplied on the command line, the header file name will be that supplied file name appended with **.h**. Otherwise, the #`define` statements are written to standard output.
-n	Suppresses the addition of the error record template to the Error Record Template Repository.
-p	Adds or updates a template with the `Alert` field set to True that contains Error Description, Probable Cause, User Cause, User Action, Install Cause, Install Action, Failure Cause, Fail Action, or Detailed Data data id values that are not recognized by the SNA Generic Alert Architecture (in publication GA27-3136). The **errupdate** command will not let you add a template with these characteristics unless you specify this flag.
-q	Suppresses the creation of an undo file.
-y *FileName*	Uses the error record template file specified by the *FileName* parameter.

Security

Access Control: None, but you must have write authority to a template file you're changing, /var/adm/ras/errtmplt by default.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To add an entry, define the entry in the input file in the following manner:

```
+ CDROM_ERR22:
        Comment=        “Temporary CDROM read error”
        Class=  H
        Log=            True
        Report= True
        Alert=          False
        Err_Type=       TEMP
        Err_Desc=       E801
        Prob_Causes=    5004
        Fail_Causes=    E800, 6312
        Fail_Actions=   1601, 0000
        Detail_Data=    120, 11, HEX
        Detail_Data=    4, 8058, DEC
        Detail_Data=    4, 8059, DEC
```

   To enter the data,

```
errupdate <input file>
```

2. To modify the log, report, and alert characteristics of entry 99999999 , specify the modify operator = (equal sign) followed by the unique Error ID, and the new characteristics for the entry to be modified:

```
errupdate
 =99999999:
 Report = False
 Log = True
```

3. To delete entry 99999999 from the Error Record Template Repository, specify the delete operator - (minus sign) followed by the unique Error ID of the entry to be deleted:

```
errupdate
 -99999999:
```

4. To override the XPG4 message catalog specified for this input stream with "*!", use the "catname" keyword.

```
*!mycat.cat
```

   `* mycat.cat` is used for all XPG4 messages from now on.

   * except for this one:

```
+ CDROM_ERR23:
         Comment=        "Temporary CDROM read error"
         catname= "othercat.cat"
         Class=  H
         Log=            True
         Report= True
         Alert=          False
         Err_Type=       TEMP
         Err_Desc=       {1, 1, "CD ROM is broken"}
         Prob_Causes=    {2, 1, "cause 1"},\
                        {2, 2, "Cause 2"}
         Fail_Causes=    E800, 6312
         Fail_Actions=   1601, 0000
         Detail_Data=    120, 11, HEX
```

```
        Detail_Data=    4, 8058, DEC
        Detail_Data=    4, 8059, DEC
```

The catalog othercat.cat will be used for the CDROM_ERR23 template only.

Note: A template may contain both XPG4 messages and the traditional error ids or codepoints.

Files

Item	Description
/usr/include/sys/errids.h	Contains the header file that contains Error IDs.
/usr/include/sys/err_rec.h	Contains the header file that contains structures for logging errors.

ethchan_config Command

Purpose

Adds adapters to an EtherChannel or removes adapters from an EtherChannel.

Syntax

ethchan_config { **-a** [**-b**] | **-d** } [**-p** *ParentName*] *EtherChannel Adapter*

ethchan_config -c [**-p** *ParentName*] *EtherChannel Attribute NewValue*

ethchan_config -f [**-p** *ParentName*] *EtherChannel*

Description

This command adds adapters to an EtherChannel or removes adapters from an EtherChannel.
This command can also be used to modify *EtherChannel* attributes. These additions, deletions, or modifications can take place even if the EtherChannel's interface is configured; that is, it is not necessary to detach the interface of EtherChannel to add or remove adapters or modify most EtherChannel attributes.

Flags

Item	Description
-a	Adds the specified *Adapter* to the specified *EtherChannel*. If the adapter must be added as a backup adapter, the **-b** flag must be specified.
-b	Specifies that the *Adapter* is being added as a backup adapter. This flag is only valid when used with the **-a** flag.
-c	Changes the specified *Attribute* of the specified *EtherChannel* attribute to the specified *NewValue*.
-d	Deletes the specified *Adapter* from the specified *EtherChannel*. The **-b** flag must not be used with the **-d** flag.
-f	Forces a failover of the specified *EtherChannel*. The failover occurs only if the adapter in the idle channel is up. If the adapter in the idle channel is down, the *EtherChannel* keeps operating on the active one and no failover takes place.
-p	Specifies the parent adapter of an EtherChannel. If a Shared Ethernet Adapter (SEA) is configured over an EtherChannel, this flag must be used along with the other flags to change any attribute of the EtherChannel (for example, adding or deleting adapters).

Parameters

Item	Description
Adapter	Specifies the adapter to add or delete.
Attribute	Specifies an attribute of the specified EtherChannel.
EtherChannel	Specifies the EtherChannel.
NewValue	Specifies the new value for the specified attribute of the specified EtherChannel.
ParentName	Specifies the parent adapter of an EtherChannel.

Exit Status

Item	Description
0	The command completed successfully.
>0	An error occurred.

Examples

1. To add the adapter `ent0` as the backup adapter in the EtherChannel called `ent7`, enter the following command:

   ```
   /usr/lib/methods/ethchan_config -a -b ent7 ent0
   ```

2. To change the address to ping attribute of an EtherChannel called `ent7` to `10.10.10.10`, enter the following command:

   ```
   /usr/lib/methods/ethchan_config -c ent7 netaddr 10.10.10.10
   ```

3. To force a failover of an EtherChannel called `ent7` from the currently active channel to the idle channel, enter the following command:

   ```
   /usr/lib/methods/ethchan_config -f ent7
   ```

4. To delete the adapter `ent13` from an EtherChannel called `ent18`, which belongs to an SEA called `ent32`, enter the following command:

   ```
   /usr/lib/methods/ethchan_config -d -p ent32 ent18 ent13
   ```

Restrictions

The use of the *use_jumbo_frame* attribute cannot be modified by this command. If you attempt to modify this attribute, this command prints an error message.

Location

/usr/lib/methods

ewallevent Command

Purpose

Broadcasts an event or a rearm event to all users who are logged in.

Syntax

`ewallevent [-c] [-h]`

Description

The `ewallevent` script broadcasts a message on an event or a rearm event to all users who are currently logged in to the host when the event or the rearm event occurs. Event or rearm event information is captured and posted by the event response resource manager in environment variables that are generated by the event response resource manager when an event or a rearm event occurs. This script can be used as an action that is run by an event response resource. It can also be used as a template to create other user-defined actions. This script always returns messages in English.

Messages are displayed in this format at the consoles of all users who are logged in when an event or a rearm event occurs for which this script is a response action :

```
Broadcast message from user@host (tty) at hh:mm:ss...

severity event_type occurred for Condition condition_name
on the resource resource_name of resource_class_name at hh:mm:ss mm/dd/yy
The resource was monitored on node_name and resided on {node_names}.
```

Event information is returned about the ERRM environment variables, and also includes the following:

Local Time
Time when the event or rearm event is observed. The actual environment variable supplied by ERRM is ERRM_TIME. This value is localized and converted to readable form before being displayed.

This script captures the environment variable values and uses the `wall` command to write a message to the currently logged-in user consoles.

Flags

-c
Instructs `ewallevent` to broadcast the ERRM_VALUE of an ERRM event. When the `-c` flag is specified, `ewallevent` broadcasts the SNMP trap message.

-h
Writes the script's usage statement to standard output.

Parameters

log_file
Specifies the name of the file where event information is logged. An absolute path for the *log_file* parameter should be specified.

The *log_file* is treated as a circular log and has a fixed size of 64KB. When *log_file* is full, new entries are written over the oldest existing entries.

If *log_file* already exists, event information is appended to it. If *log_file* does not exist, it is created so that event information can be written to it.

Exit Status

0
Script has run successfully.

1
Error occurred when the script was run.

Restrictions

1. This script must be run on the node where the ERRM is running.

2. The `wall` command is used to write a message to currently logged-in user consoles. Refer to the `wall` man page for more information on the `wall` command.

Standard Output

When the `-h` flag is specified, the script's usage statement is written to standard output.

Examples

1. Suppose the `ewallevent` script is a predefined action in the critical-notification response, which is associated with the `/var space used` condition on the resource `/var`. The threshold of the event expression defined for this condition is met, and an event occurs. The critical-notification response takes place, and `ewallevent` is run. The following message is displayed on the consoles of all users who are logged in:

```
Broadcast message from joe@neverland.com (pts/6) at 18:42:03...

Critical event occurred for Condition /var space used
on the resource /var of filesys of IBM.FileSystem at 18:41:50 03/28/02
The resource was monitored on c174n05 and resided on {c174n05}.
```

2. When a rearm event occurs for the `/var space used` condition on the resource `/var`, the following message is displayed on the consoles of all users who are logged in:

```
Broadcast message from joe@neverland.com (pts/6) at 18:42:03...

Critical rearm event occurred for Condition /var space used
on the resource /var of filesys of IBM.FileSystem at 18:41:50 03/28/02
The resource was monitored on c174n05 and resided on {c174n05}.
```

Location

/opt/rsct/bin/ewallevent

ex Command

Purpose

Editor for text files.

Syntax

ex[**-c** *Subcommand*] [**-l**] [**-R**] [**-s**] [**-t***Tag*] [**-V**] [**-w***Number*] [**-v**| **-**] [**+**[*Subcommand*]] [**-r**[*File*]] [*File...*]

Description

The **ex** command starts the ex editor. The ex editor is part of a family of editors that includes the **edit** command editor, which is a simpler version of the ex editor for novice or casual use, and the **vi** command editor, which is a full-screen display editor. Calling the vi editor directly sets environment variables for screen editing. The ex editor is more powerful than a simple line editor because it is a subset of the vi editor and can access the screen editing capabilities of the vi editor.

The *File* parameter specifies the file or files to be edited. If you supply more than one file name, the ex editor edits each file in the specified order.

Notes:

1. To determine how your workstation can perform more efficiently, the ex editor uses the workstation capability database **terminfo** and the type of the workstation you are using from the **TERM** environment variable.

2. The **ex** command affects the current line unless you specify otherwise. In order to work with different parts of the file, you need to know how to address lines in a file.
3. If the standard input is not a terminal device, it shall be as if you have specified the **-s** flag.

Flags

Item	Description
-c *Subcommand*	Carries out the ex editor subcommand before editing begins. When a null operand is typed, as in `-c ''`, the editor places the current line at the bottom of the file. (Usually, the ex editor sets the current line at the start of the file or at some specified tag or pattern.)
-l	Indents appropriately for LISP code and accepts the ( ) (open or close parenthesis), { } (left or right brace), and the [[ ]] (double left or double right bracket) characters as text rather than interpreting them as vi subcommands. This flag is active in visual and open modes.
-R	Sets the **readonly** option, preventing you from altering the file.
-s	Suppresses all interactive-user feedback. If you use this flag, file input and output errors do not generate a helpful error message. Using this flag is the same as using the **-** flag. Ignore the value of TERM and any implementation default terminal type and assume the terminal is a type incapable of supporting open or visual modes.
-t *Tag*	Loads the file that contains the tag indicated by the parameter *Tag* and positions the editor at that tag. To use this flag, you must first create a database of function names and their locations using the **ctags** command.
-w*Number*	Sets the default window size to *Number*.
-v	Invokes the vi editor. **Note:** When the **-v** flag is selected, an enlarged set of subcommands are available, including screen editing and cursor movement features. See the **vi** command.
-V	Invokes the editor in verbose mode.
-	Suppresses all interactive-user feedback. If you use this flag, file input/output errors do not generate a helpful error message. Using this flag is the same as using the **-s** flag.
+[*Subcommand*]	Begins an edit at the specified editor search or subcommand. When no parameter is typed, the **+***Subcommand* places the current line at the bottom of the file. Usually, the ex editor sets the current line to the start of the file, or to some specified tag or pattern.
-r [*File*]	Recovers a file after an editor or system crash. If you do not specify the *File* parameter, a list of all saved files is displayed.

Exit Status

The following exit values are returned:

Item	Description
0	Successful completion.
>0	An error occurred.

Files

Item	Description
/usr/lbin/exrecover	Recover subcommand
/usr/lbin/expreserve	Preserve subcommand
$HOME/.exrc	Editor startup file
./.exrc	Editor startup file
/var/tmp/Ex*nnnnn*	Editor temporary
/var/tmp/Rx*nnnnn*	Names buffer temporary
/var/preserve	Preservation directory

execerror Command

Purpose

Writes error messages to standard error.

Syntax

execerror

Description

The **execerror** command is executed by an **exec** subroutine when the load of the real program is unsuccessful. It is passed the name of the file being executed and zero or more loader error message strings. Each loader error message string contains an error number followed by error data.

Examples

The **execerror** command is used as follows:

```
char *buffer[1024];
buffer[0] = "execerror" ;
buffer[1] = "name of program that failed to load";
loadquery(L_GETMESSAGES, &buffer[2], sizeof buffer -8);
execvp("/usr/sbin/execerror",buffer);
```

This sample code causes the application to terminate after the messages are written to standard error.

Files

Item	Description
/usr/sbin/execerror	Contains the **execerror** command.

execrset Command

Purpose

Runs a program or command attached to an rset.

Syntax

execrset [**-P**] [**-F**] **-c** *CPUlist* [**-m** *MEMlist*] **-e** *command* [*parameters*]

or

execrset [**-P**] [**-F**] [**-S**] *rsetname* [**-e**] *command* [*parameters*]

Description

The **execrset** command executes a command with an attachment to an **rset**. It causes the specified command to be limited to running only on the processors and/or memory regions contained in the rset. An **rset** name in the system registry can be used to specify the processors and/or memory regions the command is allowed to use. Or, an **rset** containing the specified processors and memory regions can be attached to the process.

Flags

Item	Description
-F	Force the **execrset** command to occur. This flag removes a bindprocessor bind and all threads' `rset` in the process before issuing the command. If the **-P** flag is also specified, it detaches the effective **rset** and all threads' `rset` from the process before issuing the command.
-P	Attaches an **rset** as a partition rset.
-c *CPUlist*	List of CPUs to be in the **rset** to be attached to the process which executes the program or command. This can be one or more CPUs or CPU ranges.
-m *MEMlist*	List of memory regions to be in the **rset**. This can be one or more memory regions or ranges.
-e *command* [*parameters*]	Specifies the command to run followed by any parameters. The **-e** flag must be the last flag used in the command.
-S	A hint that indicates that the process must be scheduled to run in single-threaded mode. Only one of the hardware threads of each physical processor that is included in the specified rset will be used to schedule the job. If all the hardware threads of a physical processor are not included in the specified rset, that processor will be ignored. The specified rset must be an exclusive rset or the command fails. Specifying this flag allows jobs to run with single-thread behavior.

Parameters

Item	Description
rsetname	The name of the **rset** in the system registry to be attached to the process executing the program or command

Security

The user must have root authority or have **CAP_NUMA_ATTACH** capability. The user must have root authority to attach a partition rset to the command's process (the **-P** flag).

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To run the test1 program on CPUs 0-7, type:

```
execrset -c 0-7 -e test1
```

2. To run the 'test2 parm1 parm2' program with an attachment to rset named **test/cpus0to15**, type:

```
execrset test/cpus0to15 test parm1 parm2
```

3. To run the **ls -l** command on CPU 0, type:

```
execrset -c 0 -e ls -l
```

Files

Item	Description
/usr/bin/execrset	Contains the **execrset** command.

expand Command

Purpose

Writes to standard output with tabs changed to spaces.

Syntax

expand [**-t** *TabList*] [*File ...*]

expand [*-tabstop*]|[*-tab1*,*tab2*,...,*tabn*] [*File ...*]

Description

The **expand** command writes the named files or standard input to standard output, and replaces the tab characters with one or more space characters. Any backspace characters are copied to the output and cause the column position count for tab stop calculations to decrement; the column position count will not decrement below zero.

Note: The *File* parameter must be a text file.

Flags

Item	Description
-t *TabList*	Specifies the position of the tab stops. The default value of a tab stop is 8 column positions. The *TabList* variable must consist of a single positive-decimal integer or multiple positive-decimal integers. The multiple integers must be in ascending order, and must be separated by commas or by blank characters with quotation marks around the integers. The single *TabList* variable sets the tab stops an equal number of column positions apart. The multiple *TabList* variable sets the tab stops at column positions that correspond to the integers in the *TabList* variable. If the **expand** command processes a tab stop beyond the last one specified in the *TabList* variable, the tab stop is replaced by a single-space character in the output.

Parameters

Item	Description
tabstop	Specified as a single argument. It sets *tabstop* SPACE characters apart instead of the default 8.
tab1, tab2,..., tabn	Sets TAB characters at the columns specified by *-tab1,tab2,...,tabn*.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To adjust the tab stops an equidistance amount in `text.fil`, enter:

   ```
   expand -t 3 text.fil
   ```

   If `text.fil` contains:

   ```
   1       2        3456789
   ```

   then the **expand** command displays:

   ```
   1  2        3456789
   ```

2. To adjust the tab stops a varied amount in `text.fil`, enter:

   ```
   expand -t 3,15,22  text.fil
   ```

   OR

   ```
   expand -t "3 15 22" text.fil
   ```

   If `text.fil` contains:

   ```
   1      2       3      456789
   ```

   then the **expand** command displays:

   ```
   1  2       3      456789
   ```

Files

Item	Description
/usr/bin/expand	Contains the **expand** command.

expfilt Command

Purpose

Exports filter rules to an export file.

Syntax

expfilt [**-p**] [**-q**] [**-r**] [**-v 4** | **6**] **-f** *directory* [**-l** *filt_id_list*]

Description

Use the **expfilt** command to export filter rules into export text files, which can be used by the **impfilt** command. This is useful if you want to define similar rules on multiple machines.

Note: The filter description on one machine might be meaningless or misleading in another machine. This field is not exported.

IPsec filter rules for this command can be configured by using the **genfilt** command, or IPsec smit (IP version 4 or IP version 6).

Flags

Item	Description
-f *directory*	Specifies the directory to create the exported text files. The directory will be created if it does not exist.
-l *filt_id_list*	Lists the IDs of the filter rules you want to export. The filter rule IDs can be separated by "**,**" or "**-**". If this flag is not used, all the filter rules defined in the filter rule table for the applicable IP versions will be exported.
-p	Allows predefined rules.
-q	Specifies quiet mode. Suppresses output to **stdout**.
-r	Specifies raw mode. Exports filter rules as is and does not reverse direction on rules. Use this flag when filter rules are exported and imported as is; for example, to save a configuration or replicate a configuration to another machine. With the **-r** flag, the direction of the traffic will be preserved. For instance if there is a rule on host 10.0.0.1 to permit inbound traffic from 10.0.0.2, expfilt with the -r flag will write the same filter rule. Omitting the **-r** flag will cause the direction to be switched from inbound to outbound in the export file.
-v	IP version of the filter rules you want to export. The value of **4** specifies IP version 4 and the value of **6** specifies IP version 6. When this flag is not used, both IP version 4 and IP version 6 rules are exported.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

explain Command

Purpose

Provides an interactive thesaurus.

Syntax

explain

Description

The **explain** command provides an interactive thesaurus for the English-language phrases found by the **diction** command. Before using the **explain** command, use the **diction** command to obtain a list of poorly worded phrases. When you use the **explain** command, the system prompts you for a phrase and responds with a grammatically acceptable alternative. You can continue typing phrases, or you can exit by entering the Ctrl-D key sequence.

No other command line parameters are valid.

Files

Item	Description
/usr/lib/explain.d	Contains thesaurus.

explore Command

Purpose

Starts the WebExplorer World Wide Web browser.

Syntax

explore [**-i***FileName*] [**-t***Number*] [**-q**] [[**-url**] *URL*]

Description

The **explore** command opens the WebExplorer main window and connects to the Uniform Resource Locator (URL) for the home document.

Flags

Item	Description
-i*FileName*	Specifies an alternate initialization file, where *FileName* is the full path name of the file to use instead of the default **$HOME/.explore-preferences**. This allows you to start the WebExplorer with an alternate set of user preferences.
-t*Number*	Specifies the number of threads to use for loading images, where *Number* is the number of image loader threads. Each thread is represented in the status area of the main window. A maximum of eight can be specified, and the default is four.
-q	Specifies quiet mode. This suppresses the WebExplorer title window when you start the application and bypasses the confirmation window when you exit.
-url *URL*	Specifies a particular document to load when starting WebExplorer, where *URL* is the URL of the document to load. If WebExplorer has a home document defined, this URL will override it. You do not have to precede the URL with the **-url** flag. If you specify the URL by itself, WebExplorer will accept it.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.

Item	Description
>0	An error occurred.

Security

Access Control: Any User

Auditing Events: N/A

Examples

To start the browser without the title window appearing and go directly to the Dilbert Zone URL, enter:

```
explore -q  http://www.unitedmedia.com/comics/dilbert/
```

or

```
explore -q  -url http://www.unitedmedia.com/comics/dilbert/
```

Files

Item	Description
/usr/lpp/explorer/bin/explore	Contains the **explore** command.
$HOME/.explore-preferences	Contains the initialization file that specifies user preferences for settings such as the number of colors used.
$HOME/.mailcap	Contains the configuration file that maps mimetype to external viewers.
$HOME/.mimetypes	Contains the user-defined configuration file that maps mimetype to external viewers. It is set through the **Configure Viewers** dialog. this file overrides the **.mailcap** settings.

exportfs Command

Purpose

Exports and unexports directories to NFS clients.

Syntax

/usr/sbin/exportfs [**-a**] [**-v**] [**-u**] [**-i**] [**-f***File*] [**-F**] [**-o***Option* [,*Option* ...]] [**-V** *Exported Version*] [*Directory*]

Description

The **exportfs** command makes local directories available for Network File System (NFS) clients to mount. This command is normally invoked during system startup by the **/etc/rc.nfs**file and uses information in the **/etc/exports** file to export one or more directories, which must be specified with full path names.

The **/etc/xtab** file lists directories that are currently exported. To display this file, enter the **exportfs** command without flags or arguments. To alter the file or to alter the characteristics of one of its directories, root users can edit the **/etc/exports** file and run the **exportfs** command. Such alterations can be done at any time. Never edit the **/etc/xtab** file directly.

Note:

1. You cannot export a directory that is either a parent directory or a subdirectory of one that is currently exported and within the same file system.
2. NFS versions 2 and 3 allow both directories and files to be exported. Only directories can be exported for NFS version 4 access.
3. If two entries for the same directory with different versions 2 (or 3) and 4 exist in the **/etc/exports** file, the **exportfs** command exports both of the entries.
4. If the options for NFS versions 2 (or 3) and 4 are the same for a directory, there can be one entry in the **/etc/exports** file specifying `-vers=3:4`.

Flags

Item	Description
-a	Exports all directories listed in the exports file.
-v	Prints the name of each directory as it is exported or unexported.
-u	Unexports the directories you specify. When used with the **-a** flag, unexports all exported directories. When used with both the **-a** and **-f** flags, unexports all directories in the specified export file.
-i	Allows the exporting of directories not specified in the exports file or ignores the options in the exports file. Unless the **-f** flag is used to specify an alternate file, the **exportfs** command will normally consult the **/etc/exports** file for the options associated with the exported directory."
-f *File*	Specifies an export file, instead of the **/etc/exports** file, that contains a list of directories that you can export. This file should follow the same format as the **/etc/exports** file. NOTE: This alternate file will not be used for exporting directories automatically when the system and NFS is started. The **/etc/exports** file is the only file that is supported for specifying directories to export at system start.
-F	Specifies that a forced unexport should be performed. Use this flag only with the **-u** flag. This flag has no effect when unexporting a V2/V3 export. A V4 unexport can fail due to associated state. This flag forces the release of any state associated with a V4 export.

Item	Description
-o*Options*	Specifies the optional characteristics for the directory being exported. You can enter more than one variable by separating them with commas. For options taking a *Client* parameter, *Client* can specify a hostname, a dotted IP address, a network name, or a subnet designator. A subnet designator is of the form "@*host*/*mask*", where *host* is either a hostname or a dotted IP address and *mask* specifies the number of bits to use when checking access. If *mask* is not specified, a full mask is used. For example, the designator `@client.group.company.com/16` will match all Clients on the `company.com` subnet. A designator of `@client.group.company.com/24` will match only the Clients on the `group.company.com` subnet. Choose from the following options: **ro** Exports the directory with read-only permission. If not specified, the directory is exported with read-write permission. **ro=*Client[:Client]*** Exports the directory with read-only permission to the specified Clients. Exports the directory with read-write permissions to Clients not specified in the list. A read-only list cannot be specified if a read-write list has been specified. **rw** Exports the directory with read-write permission to all Clients. **rw=*Client [:Client]*** Exports the directory with read-write permission to the specified Clients. Exports the directory read-only to Clients not in the list. A read-write list cannot be specified if a read-only list has been specified. **anon =*UID*** Uses the *UID* value as the effective user ID, if a request comes from a root user. The default value for this option is -2. In NFS version 2 and NFS version 3, setting the value of the *anon* option to -1 disables anonymous access. Thus, by default, secure NFS accepts nonsecure requests as anonymous, and users who want more security can disable this feature by setting *anon* to a value of -1. **root=*Client[:Client]*** Allows root access from the specified clients in the list. Putting a host in the root list does not override the semantics of the other options. For example, this option denies the mount access from a host present in the root list but absent in the access list. **access=*Client[:Client,...]*** Gives mount access to each client listed. A client can be either a host name or a net group name. Each client in the list is first checked for in the **/etc/netgroup** database and then in the **/etc/hosts** database. The default value allows any machine to mount the given directory. **secure** Requires clients to use a more secure protocol when accessing the directory.

Item	Description
-o *Options* (continued)	**sec=*flavor[:flavor...]*** This option is used to specify a list of security methods that may be used to access files under the exported directory. Most exportfs options can be clustered using the `sec` option. Options following a `sec` option are presumed to belong with the preceding `sec` option. Any number of `sec` stanzas may be specified, but each security method can be specified only once. Within each `sec` stanza the `ro`, `rw`, `root`, and `access` options may be specified once. Only the `public`, `anon` and `vers` options are considered global for the export. If the `sec` option is used to specify any security method, it must be used to specify all security methods. In the absence of any `sec` option, all authentication flavors are allowed. Allowable flavor values are: **sys** UNIX authentication. This is the default method. **dh** DES authentication. **none** Allow mount requests to proceed with anonymous credentials if the mount request uses an authentication flavor not specified in the export. **krb5** Kerberos. Authentication only. **krb5i** Kerberos. Authentication and integrity. **krb5p** Kerberos. Authentication, integrity, and privacy. The `secure` option may be specified, but not in conjunction with a `sec` option. The `secure` option is deprecated and may be eliminated. Use `sec=dh` instead. **vers=*version_number[:version_number...]*** Specifies which versions of NFS are allowed to access the exported directory. Valid versions are 2, 3, and 4. Versions 2 and 3 cannot be selected exclusively. Specifying either version 2 or version 3 will allow access by both NFS version 2 and NFS version 3. Version 4 can be selected exclusively. The default is to allow access using NFS protocol versions 2 and 3. **exname=*external-name*** Exports the directory by the specified external name. The external name must begin with the `nfsroot` name. See the description of the `/etc/exports` file for a description of the `nfsroot` name. This option applies only to directories exported for access by NFS version 4 protocol. **deleg={yes | no}** Enables or disables file delegation for the specified export. This option overrides the system-wide delegation enablement for this export. The system-wide enablement is done through **nfso**.

Item	Description
-o *Options* (continued)	**refer=*rootpath*@*host*[+*host*][:*rootpath*@*host*[+*host*]]** A namespace referral will be created at the specified path. The referral directs clients to the specified alternate locations where they can continue operations. A referral is a special object. If a nonreferral object exists at the specified path, the export is disallowed and an error message is printed. If nothing exists at the specified path, a referral object is created there that includes the path name directories leading to the object. Multiple referrals can be created within a file system. A referral cannot be specified for the `nfsroot`. The name `localhost` cannot be used as a *hostname*. This `refer` option is allowed only for version 4 exports. If the export specification allows version 2 or version 3 access, an error message will be printed and the export will be disallowed. Unexporting the referral object has the effect of removing the referral locations information from the referral object. The object itself is not removed by unexporting. Use `rm` if you want to remove the object. The administrator must ensure that appropriate data is available at the referral servers. This option is available only on AIX 5L Version 5.3 with the 5300-03 Recommended Maintenance package or later. **Note:** A referral export can only be made if replication is enabled on the server. Use `chnfs -R` on to enable replication.

Item	Description
-o *Options* (continued)	**replicas=*rootpath*@*host*[+*host*][:*rootpath*@*host*[+*host*]]** Replica location information will be associated with the export path. The replica information can be used by NFS version 4 clients to redirect operations to the specified alternate locations if the current server becomes unavailable. The administrator should ensure that appropriate data is available at the replica servers. Because replica information applies to an entire file system, the specified path must be the root of a file system. If the path is not a file system root, the export is disallowed and an error message is printed. The name `localhost` cannot be used as a *hostname*. This `replicas` option is meaningful only for version 4 exports. If the option is used on an export that allows version 2 or version 3 access, the operation is allowed, but the replica information is ignored by the version 2 and version 3 servers. If the directory being exported is not in the replica list, the entry *exported directory*@*current host* will be added as the first replica location. This option is available only on AIX 5.3 with 5300-03 or later. A replica export can only be made if replication is enabled on the server. By default, replication is not enabled. If replica exports will be made at system boot, replication should be enabled by using the `chnfs -R on` command. Replica locations can also be specified for the `nfsroot`. This can be done only using `chnfs -R` *host*[+*host*]. If the current host is not specified in the list, it will be added as the first replica host. The *rootpath* is not needed or allowed in this case because `nfsroot` is replicated only to the `nfsroots` of the specified hosts. The `chnfs` program can be used to enable or disable replication. Changing the replication mode can only be done if no NFS version 4 exports are active. If the server's replication mode is changed, file handles issued by the server during the previous replication mode will not be honored by the server. This can cause application errors on clients holding old file handles. Be careful when changing the replication mode of the server. If possible, all clients who have mounts to the server should unmount them before the server's replication mode is changed. The replica location information associated with the directory can be changed by modifying the replica list and reexporting the directory. The new replica information replaces the old replica information. NFS clients are expected to refresh replica information on a regular basis. If the server changes the replica information for an export, it might take time for the client to notice. This is not much of a problem if new replica locations are added, because clients holding the old information still have correct, if incomplete, replica information. Removing replica information can be problematic because it can result in clients holding incorrect replica information for a period of time. To aid clients in detecting the new information, `exportfs` will attempt to touch the replicated directory. This changes the timestamps on the directory, which in turn causes the client to refetch the directory's attributes. This operation might not be possible, however, if the replicated file system is read-only. When changing replica information for a directory, be aware that there could be some latency between changing the information and clients noticing the new information.

Item	Description
-o *Options* (continued)	**noauto** Accepts the replicas specification as-is. Does not automatically insert the primary hostname as one of the replica locations if it has not been specified. **scatter** Defines how the alternate locations list is generated from the servers specified on the **refer** or **replicas** option. If the **noauto** option is not used, the alternate locations list also includes the primary host name as one of the replica locations. The **scatter** option applies only to directories exported for access by NFS version 4 protocol. The **scatter** option has three allowable values: **full** All of the servers are scattered to form the combinations of alternate locations. **partial** The first location of all the combinations is fixed to the first server specified on the **refer** or **replicas** option. The rest of the locations and the first location are scattered as if they are scattered using the `scatter=full` method. **none** No scatter is to be used. The value can also be used to disable scattering if enabled previously. Whenever the attributes of a Client change, all export entries that contain that Client as a parameter should be exported again. Events that can change a Client's attributes include modifying a netgroup or changing the IP address of a client. Failure to do so can result in the server using old client information.
-V *Exported Version*	Specifies the version number. Valid version numbers are 2, 3 and 4.

Solaris Compatibility

The **exportfs** command may be invoked as **share**, **shareall**, **unshare**, or **unshareall**. When the **exportfs** command is invoked as **share** or **shareall**, the functionality is equivalent to **exportfs** and **exportfs -a**, respectively, except that the **sec** option must be used to specify the security methods. When the **exportfs** command is invoked as **unshare** or **unshareall**, the functionality is equivalent to **exportfs -u** and **exportfs -u -a**, respectively.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **`lssecattr`** command or the **`getcmdattr`** subcommand.

Examples

1. To export all directories in the **/etc/exports** file, enter:

   ```
   exportfs -a
   ```

2. To export one directory from the **/etc/exports** file, enter:

   ```
   exportfs /home/notes
   ```

   In this example, the `/home/notes` directory is exported.

Note: For this command to work, the **/home/notes** directory must be specified in the **/etc/exports** file.

3. To unexport a directory, enter:

```
exportfs -u /home/notes
```

   In this example, the /home/notes directory is unexported.

4. To display the name of the directory currently being exported, enter:

```
exportfs -v
```

5. To export a directory that is not specified in the **/etc/exports** file, enter:

```
exportfs -i /home/zeus
```

   In this example, the /home/zeus directory is exported without restrictions.

6. To export a directory and give netgroup members permission to access this directory, enter:

```
exportfs access=cowboys:oilers /home/notes -o
```

   In this example, the /home/notes directory is exported and permits users of cowboys and oilers host machines to have access.

7. To export a directory with different options from the **/etc/exports** file, enter:

```
exportfs -i -o root=zorro:silver /directory
```

   In this example, the /directory directory is exported and allows root user access to zorro and silver host machines, regardless of the access permissions specified in the **/etc/exports** file.

8. To export the **/common/docs** directory with write permissions to clients using Kerberos authentication, but read-only permissions to clients using UNIX authentication, add the following text to the **/etc/exports** file:

```
/common/docs -sec=krb5,rw,sec=sys,ro
```

   Then enter exportfs /common/docs to perform the export.

9. To create a referral at /usr/info to the /usr/info directory on host infoserver, add the following line to /etc/exports and then export /usr/info:

```
/usr/info -vers=4,refer=/usr/info@infoserver
```

10. To specify replicas for the /common/info directory at hosts backup1 and backup2, add the following line to /etc/exports and then export /common/info:

```
/common/info -vers=4,replicas=/common/info@backup1:/common/info@backup2,<other options>
```

11. To export the **/common/docs** directory with both version 3 and version 4, enter the following command:

```
exportfs -V 3:4 /common/docs
```

12. To export all of the version 4 entries in the **/etc/exports** file, enter the following command:

```
exportfs -a -V 4
```

13. To unexport the **/common/docs** directory only for version 3, enter the following command:

```
exportfs -u -V 3 /common/docs
```

14. To unexport all of the version 3 entries in the **/etc/xtab** file, enter the following command:

```
exportfs -ua -V 3
```

15. To specify referrals for the **/common/docs** directory at hosts named s1, s2, and s3 and scatter them fully, add the following line to the **/etc/exports** file and then export the **/common/docs** directory:

```
/common/docs -vers=4,refer=/common/docs@s1:/common/docs@s2:/common/docs@s3,scatter=full
```

16. To specify replicas for the **/common/docs** directory at hosts named s1, s2, s3, and s4 and scatter them partially (the first fail over server is s1 for all combinations), add the following line to the **/etc/exports** file and then export the **/common/docs** directory:

```
/common/docs -vers=4,noauto,replicas=/common/docs@s1:/common/docs@s2:/common/docs@s3:/common/docs@s4,scatter=partial
```

Files

Item	Description
/etc/exports	Lists the directories that the server can export.
/etc/xtab	Lists currently exported directories.
/etc/hosts	Contains an entry for each host on the network.
/etc/netgroup	Contains information about each user group on the network.
/etc/rc.nfs	Contains the startup script for the NFS and NIS daemons.

exportvg Command

Purpose

Exports the definition of a volume group from a set of physical volumes.

Syntax

```
exportvg [-b] VolumeGroup
```

Description

The **exportvg** command removes the definition of the volume group specified by the *VolumeGroup* parameter from the system. Since all system knowledge of the volume group and its contents are removed, an exported volume group can no longer be accessed. The **exportvg** command does not modify any user data in the volume group.

A volume group is a nonshared resource within the system; it should not be accessed by another processor until it has been explicitly exported from its current processor and imported on another. The primary use of the **exportvg** command, coupled with the **importvg** command, is to allow portable volumes to be exchanged between processors. Only a complete volume group can be exported, not individual physical volumes.

Using the **exportvg** command and the **importvg** command, you can also switch ownership of data on physical volumes shared between two processors.

Note: To use this command, you must either have root user authority or be a member of the **system** group.

You can use the System Management Interface Tool (SMIT) **smit exportvg** fast path to run this command.

Notes:

1. A volume group that has a paging space volume on it cannot be exported while the paging space is active. Before exporting a volume group with an active paging space volume, ensure that the paging space is not activated automatically at system initialization, and then reboot the system.
2. The mount point information of a logical volume would be missing from the LVCB (logical volume control block) if it is longer than 128 characters. If the mount points are longer than 128 characters, you must edit the `/etc/filesystems` file manually when you run the **importvg** command to import this volume group completely.

Flags

-b
Backs up the performance tunable parameters of the volume group that are set with the **lvmo** command before the **exportvg** command exports the volume group. When you use this flag, the **exportvg** command output displays the name of the file in which the performance tunable parameters are saved.

Exit Status

This command returns the following exit values:

Item	Description
`0`	Successful completion.
`>0`	An error occurred.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

To remove volume group `vg02` from the system, enter:

```
exportvg vg02
```

Note: The volume group must be varied off before exporting.

The definition of `vg02` is removed from the system and the volume group cannot be accessed.

Files

Item	Description
/usr/sbin	Directory where the **exportvg** command resides.

expr Command

Purpose

Evaluates arguments as expressions.

Syntax

expr *Expression*

Description

The **expr** command reads the *Expression* parameter, evaluates it, and writes the result to standard output.

You must apply the following rules to the *Expression* parameter:

- Separate each term with blanks.
- Precede characters special to the shell with a \ (backslash).
- Quote strings containing blanks or other special characters.

Integers may be preceded by a unary hyphen. Internally, integers are treated as 32-bit, twos complement numbers.

Note: The **expr** command returns 0 to indicate a zero value, rather than the null string.

The following items describe *Expression* parameter operators and keywords. Characters that need to be escaped are preceded by a \ (backslash). The items are listed in order of increasing precedence, with equal precedence operators grouped within { } (braces):

Item	Description
Expression1 **|** *Expression2*	Returns *Expression1* if it is neither a null value nor a 0 value; otherwise, it returns *Expression2*.
Expression1 **\&** *Expression2*	Returns *Expression1* if both expressions are neither a null value nor a 0 value; otherwise, it returns a value of 0.
Expression1 **{ =, \>, \>=, \<, \<=, != }** *Expression2*	Returns the result of an integer comparison if both expressions are integers; otherwise, it returns the result of a string comparison.
Expression1 **{+, - }** *Expression2*	Adds or subtracts integer-valued arguments.
Expression1 **{ *, /, % }** *Expression2*	Multiplies, divides, or provides the remainder from the division of integer-valued arguments.
Expression1 **:** *Expression2*	Compares the string resulting from the evaluation of *Expression1* with the regular expression pattern resulting from the evaluation of *Expression2*. Regular expression syntax is the same as that of the **ed** command, except that all patterns are anchored to the beginning of the string (that is, only sequences starting at the first character of a string are matched by the regular expression). Therefore, a ^ (caret) is not a special character in this context. Normally the matching operator returns the number of characters matched (0 on failure). If the pattern contains a subexpression, that is: `\( Expression \)` then a string containing the actual matched characters is returned. A collating sequence can define equivalence classes for use in character ranges. See "Understanding Locale Environment Variables" in *Globalization Guide and Reference* for more information on collating sequences and equivalence classes.

Note: The following string arguments are extensions beyond that of the standards, and the behavior may be different across operating systems. These string arguments are NOT portable.

Item	Description
match *String1 String2*	Same as *Expression1* **:** *Expression2*.
length *String1*	Returns the length of the *String1*.
index *String1 String2*	Returns the first position in *String1* where any character in *String2* exists.
substr *String1 StartPosition Length*	Returns a string that starts with the character at *StartPosition* in *String1* and continuies for *Length* characters

Exit Status

This command returns the following exit values:

Item	Description
0	The *Expression* parameter evaluates to neither null nor 0.
1	The *Expression* parameter evaluates to null or 0.
2	The *Expression* parameter is not valid.
>2	An error occurred.

Note: After parameter processing by the shell, the **expr** command cannot distinguish between an operator and an operand except by the value. Thus, if the value of $a is `j`, the command:

```
expr $a = j
```

looks like:

```
expr j = j
```

after the shell passes the arguments to the **expr** command. The following is also true:

```
expr X$a = Xj
```

Examples

1. To modify a shell variable, enter:

   ```
   COUNT=`expr $COUNT + 1`
   ```

   This adds 1 to the shell variable $COUNT. The **expr** command is enclosed in grave accents, which causes the shell to substitute the standard output from the **expr** command into the COUNT= command. The $COUNT variable must be initialized before using.

2. To find the length of the **$STR** shell variable, enter:

   ```
   LENGTH=`expr $STR : ".*"`
   ```

   This sets the LENGTH variable to the value given by the: (colon) operator. The pattern .* (dot, asterisk) matches any string from beginning to end, so the colon operator gives the length of the $STR variable as the number of characters matched. Note that `.*` must be within quotes to prevent the shell from treating the * (asterisk) as a pattern-matching character. The quotes are not part of the pattern.

If the $STR variable is set to the null string or contains any white space (blanks or tabs), then the command displays the error message `expr: syntax error`. This happens because the shell does not normally pass null strings to commands. In this case, the **expr** command sees only:

```
:.*
```

The shell also removes the single quotation marks. This does not work because the colon operator requires two values. The problem is fixed by enclosing the shell variable in double quotation marks:

```
LENGTH=`expr "$STR" : ".*"`
```

Now if the value of the $STR variable is null, the LENGTH variable is set to a value of 0. Enclosing shell variables in double quotation marks is generally recommended. Do not enclose shell variables in single quotation marks.

3. To use part of a string, enter:

```
FLAG=`expr "$FLAG" : "-*\(.*\)"`
```

This removes leading hyphens, if any, from the $FLAG shell variable. The colon operator gives the part of the FLAG variable matched by the subexpression enclosed between \(and \) characters (backslash, open parenthesis and backslash, close parenthesis). If you omit the \(and \) subexpression characters, the colon operator gives the number of characters matched.

If the $FLAG variable is set to - (hyphen), the command displays a syntax error message. This happens because the shell substitutes the value of the $FLAG variable before running the **expr** command. The **expr** command does not know that the hyphen is the value of a variable. It can only see:

```
- : -*\(.*\)
```

and it interprets the first hyphen as the subtraction operator. To eliminate this problem, use:

```
FLAG=`expr "x$FLAG" : "x-*\(.*\)"`
```

4. To use the **expr** command in an **if** statement, enter:

```
if expr "$ANSWER" : "[yY]" >/dev/null
then
echo ANSWER begins with "y" or "Y"
fi
```

If the $ANSWER variable begins with y or Y, the `then` part of the **if** statement is performed. If the match succeeds, the result of the expression is 1 and the **expr** command returns an exit value of 0, which is recognized as the logical value True by the **if** statement. If the match fails, the result is 0 and the exit value 1 (False).

Redirecting the standard output of the **expr** command to the **/dev/null** special file discards the result of the expression. If you do not redirect it, the result is written to the standard output, which is usually your workstation display.

5. Consider the following expression:

```
expr "$STR" = "="
```

If the $STR variable has the value = (equal sign), then after the shell processes this command the **expr** command sees the expression:

```
= = =
```

The **expr** command interprets this as three = operators in a row and displays a syntax error message. This happens whenever the value of a shell variable is the same as that of one of the **expr** operators. You can avoid this problem by phrasing the expression as:

```
expr "x$STR" = "x="
```

6. To return the length of the $SHELL environment variable, /usr/bin/ksh, enter:

```
expr length $SHELL
```

   The following is displayed:

```
12
```

7. To return the first position of where any characters in the string "de" is found in "abcdef", enter:

```
expr index abcdef de
```

   The following is displayed:

```
4
```

8. To return the first position of where any characters in the string "fd" is found in "abcdef", enter:

```
expr index abcdef fd
```

   The following is displayed:

```
4
```

9. To return the string starting at position 11, for a length of 6 of the string "Goodnight Ladies", enter:

```
expr substr "Goodnight Ladies" 11 6
```

   The following is displayed:

```
Ladies
```

Files

Item	Description
/usr/bin/expr	Contains the **expr** command.

exptun Command

Purpose

Exports a tunnel definition and, optionally, all the user defined filter rules associated with the tunnel. Creates a tunnel export file and an optional filter rule export file that can be used for the tunnel partner.

Syntax

exptun [**-v 4**|**6**] **-f** *directory* [**-t** *tid_list*] [**-r**] [**-l manual**]

Description

Use the **exptun** command to create a tunnel context export file and, optionally, a filter rule appendage file for a tunnel partner to import. This command does not activate a tunnel, it simply creates the required files for the tunnel partner.

Note: Generated export files contain keys used by the tunnel. Protect these files with the operating system file system protection features.

Flags

Item	Description
-f	Defines the directory where the export files are to be written. The directory will be created if it does not exist. The export files may then be sent to the tunnel partner to be imported. It is recommended that export files for each tunnel partner have a different directory specification.
-l	The type of the tunnel(s) you want to export. If manual is specified, only manual ibm tunnel(s)are exported.
-r	Exports all the user defined filter rules associated with the tunnel(s). If this flag is not used, only the tunnel definitions will be exported.
-t	Specifies the list of tunnel IDs to be used for the export files. The list may be specified as a sequence of tunnel IDs separated by a **","** or **"-"** (1, 3, 10, 50-55). If this flag is not used, all tunnel definitions from the tunnel database will be exported.
-v	The IP version of the tunnels being exported. Value **4** specifies IP version 4 tunnels. Value **6** specifies IP version 6 tunnels. If this flag is not used, both IP version 4 and IP version 6 tunnel definitions will be exported.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

extendlv Command

Purpose

Increases the size of a logical volume by adding deallocated physical partitions from within the volume group.

Syntax

To Add Available Physical Partitions

extendlv [**-a** *Position*] [**-e** *Range*] [**-u** *Upperbound*] [**-s** *Strict*] *LogicalVolume Partitions* [*PhysicalVolume ...*]

To Add Specific Physical Partitions

extendlv [**-m***MapFile*] *LogicalVolume Partitions*

Description

The **extendlv** command increases the number of logical partitions allocated to the *LogicalVolume* by allocating the number of additional logical partitions represented by the *Partitions* parameter. The *LogicalVolume* parameter can be a logical volume name or a logical volume ID. To limit the allocation to specific physical volumes, use the names of one or more physical volumes in the *PhysicalVolume* parameter; otherwise, all the physical volumes in a volume group are available for allocating new physical partitions.

By default, the logical volume is expanded using the existing characteristics that are displayed when you use the lslv command. To override these existing characteristics for the new partitions only, choose different values for these characteristics by using the flags.

The default maximum number of partitions for a logical volume is 512. Before extending a logical volume more than 512 logical partitions, use the **chlv** command to increase the default value.

The default allocation policy is to use a minimum number of physical volumes per logical volume copy, to place the physical partitions belonging to a copy as contiguously as possible, and then to place the physical partitions in the desired region specified by the **-a** flag. Also, by default, each copy of a logical partition is placed on a separate physical volume.

You can specify logical volumes sizes in 512 Blocks/KB/MB/GB when using the **extendlv** command. (See “Examples” on page 1309.)

Note:

1. When extending a striped logical volume, the number of partitions must be in an even multiple of the striping width.
2. It is recommended that a logical volume using a large number of partitions (more than 800MB) be extended gradually in sections.
3. Changes made to the logical volume are not reflected in the file systems. To change file system characteristics, use the **chfs** command.
4. You must either have root user authority or be a member of the **system** group to use this command.
5. The **extendlv** command is not allowed on a snapshot volume group.

You can use the System Management Interface Tool (SMIT) **smit extendlv** fast path to run this command.

Flags

Note: The **-e** and **-s** flags are not valid with a striped logical volume.

Item	Description
-a *Position*	Sets the intraphysical volume allocation policy (the position of the logical partitions on the physical volume). The *Position* variable can be one of the following: **m** Allocates logical partitions in the outer middle section of each physical volume. This is the default position. **c** Allocates logical partitions in the center section of each physical volume. **e** Allocates logical partitions in the outer edge section of each physical volume. **ie** Allocates logical partitions in the inner edge section of each physical volume. **im** Allocates logical partitions in the inner middle section of each physical volume.
-e *Range*	Sets the interphysical volume allocation policy (the number of physical volumes to extend across, using the volumes that provide the best allocation). The value of the *Range* variable is limited by the *Upperbound* variable (set with the -u flag) and can be one of the following: **x** Allocates logical partitions across the maximum number of physical volumes. **m** Allocates logical partitions across the minimum number of physical volumes.

Item	Description
-m *MapFile*	Specifies the exact physical partitions to allocate. Partitions are used in the order given by the file designated by the *MapFile* parameter. All physical partitions belonging to a copy are allocated before allocating for the next copy. The *MapFile* format is: **PVname:PPnum1[-PPnum2]** where *PVname* is a physical volume name (for example, `hdisk0`). It is one record per physical partition or a range of consecutive physical partitions. **PVname** Name of the physical volume as specified by the system. **PPnum** Physical partition number. **Important:** When you use map files, you must understand and adhere to all LV-allocation parameters such as strictness, upperbound, and stripe width. Using map files bypasses the checks done in the LVM-allocation routines. This is important for striped LVs, which are assumed to have a typical striped allocation pattern conforming to the stripe width.
-s *Strict*	Determines the strict allocation policy. Copies of a logical partition can be allocated to share or not to share the same physical volume. The *Strict* variable is represented by one of the following: **y** Sets a strict allocation policy, so copies for a logical partition cannot share the same physical volume. **n** Does not set a strict allocation policy, so copies for a logical partition can share the same physical volume. **s** Sets a super strict allocation policy, so that the partitions allocated for one mirror cannot share a physical volume with the partitions from another mirror. **Note:** When changing a non superstrict logical volume to a superstrict logical volume you must specify physical volumes or use the **-u** flag.
-u *Upperbound*	Sets the maximum number of physical volumes for new allocation. The value of the *Upperbound* variable should be between one and the total number of physical volumes. When using super strictness, the upper bound indicates the maximum number of physical volumes allowed for each mirror copy. When using striped logical volumes, the upper bound must be multiple of *Stripe_width*.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To increase the size of the logical volume represented by the `lv05` directory by three logical partitions, type:

```
extendlv lv05 3
```

2. To request a logical volume named `lv05` with a minimum size of 10MB, type:

```
extendlv lv05 10M #
```

The **extendlv** command will determine the number of partitions needed to create a logical volume of at least that size.

You can use uppercase and lowercase letters as follows:

```
    B/b       512 byte blocks
    K/k       KB
    M/m       MB
    G/g       GB
```

Files

Item	Description
/usr/sbin/	Directory where the **extendlv** command resides.

extendvg Command

Purpose

Adds physical volumes to a volume group.

Syntax

extendvg [**-f**] [**-p** *mirrorpool*] *volumegroup physicalvolume ...*

Description

The **extendvg** command increases the size of the *volumegroup* by adding one or more *physicalvolumes*.

The physical volume is checked to verify that it is not already in another volume group. If the system believes the physical volume belongs to a volume group that is varied on, it exits. But if the system detects a description area from a volume group that is not varied on, it prompts the user for confirmation in continuing with the command. The previous contents of the physical volume are lost, so the user must be cautious when using the override function.

Note: To use this command, you must either have root user authority or be a member of the **system** group.

For volume groups created prior to AIX 5.3, or for volume groups created on AIX 5.3 but varied on with the **varyonvg -M** flag, the **extendvg** will fail if the physical volume has a max transfer size that is smaller than the logical track group size of the volume group. For volume groups created on AIX 5.3 and varied on without the **varyonvg -M** flag, **extendvg** will dynamically lower the logical track group size of the volume group if the physical volume has a max transfer size that is smaller than the logical track group size of the volume group.

Note: The **extendvg** command is not allowed on a snapshot volume group.

You can use the System Management Interface Tool (SMIT) **smit extendvg** fast path to run this command.

Note: This command will fail to add a disk to the volume group if the disk indicates that it is managed by a third party volume manager. To override and clear the disk of the third party volume manger use **chpv -C** *HDiskName*.

Note: When extending a concurrent Volume Group (VG), you must first ensure that each new disk to be added to the VG has a Physical Volume Identifier (PVID) assigned, and that the PVID stored in the

Object Data Manager (ODM) is the same one on every node. When using the Cluster Single Point of Control (C-SPOC) utility to extend the VG, this check is done automatically.

Note: The VG is checked to determine if an existing PV type restriction is in place. If such a restriction exists, the physical volume(s) list on the **extendvg** command line are examined to ensure that they meet the restriction. If one or more of the disks is found to not meet the PV type restriction, the command will fail.

Note: You cannot mix physical volume (PV) of 4 KB block size with PV blocks of other sizes. The block size of all PVs in the volume group must be the same.

Flags

Item	Description
-f	Forces the physical volume to be added to the specified volume group unless it is a member of another volume group in the Device Configuration Database or of a volume group that is active.
-p *mirrorpool*	Assigns each of the physical volumes being added to the specified mirror pool. After mirror pools are enabled in a volume group, the volume group can no longer be imported into a version of AIX that does not support mirror pools.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

To add physical volumes hdisk3 and hdisk8 to volume group vg3, enter:

```
extendvg vg3 hdisk3 hdisk8
```

Note: The volume group must be varied on before extending.

Restrictions

The **extendvg** command cannot be run on a snapshot volume group.

Files

Item	Description
/usr/sbin/extendvg	Contains the **extendvg** command.

f

The following AIX commands begin with the letter f.

f Command

Purpose

Shows user information. This command is the same as the **finger** command.

Syntax

{ **f** | **finger** } [[**-b**] [**-h**] [**-l**] [**-p**]] | [**-i**] [**-q**] [**-s**] [**-w**]]

[**-f**] [**-m**] [*User* | *User* **@***Host* | **@***Host*]

Description

The **/usr/bin/f** command displays information about the users currently logged in to a host. The format of the output varies with the options for the information presented.

Default Format

The default format includes the following items:

- Login name
- Full user name
- Terminal name
- Write status (an * (asterisk) before the terminal name indicates that write permission is denied)

For each user on the host, the default information list also includes, if known, the following items:

- Idle time (Idle time is minutes if it is a single integer, hours and minutes if a : (colon) is present, or days and hours if a "d" is present.)
- Login time
- Site-specific information

  The site-specific information is retrieved from the gecos field in the **/etc/passwd** file. The gecos field may contain the Full user name followed by a comma. All information that follows the comma is displayed by the finger command with the Site-specific information.

Longer Format

A longer format is used by the **f** command whenever a list of user's names is given. (Account names as well as first and last names of users are accepted.) This format is multiline, and includes all the information described above along with the following:

- User's **$HOME** directory
- User's login shell
- Contents of the **.plan** file in the user's **$HOME** directory
- Contents of the **.project** file in the user's **$HOME** directory

The **f** command may also be used to look up users on a remote system. The format is to specify the user as *User@Host*. If you omit the user name, the **f** command provides the standard format listing on the remote system.

Create the **.plan** and **.project** files using your favorite text editor and place the files in your **$HOME** directory. The **f** command uses the **toascii** subroutine to convert characters outside the normal ASCII

character range when displaying the contents of the **.plan** and **.project** files. The **f** command displays a `M-` before each converted character.

When you specify users with the *User* parameter, you can specify either the user's first name, last name, or account name. When you specify users, the **f** command, at the specified host, returns information about those users only in long format.

For other information about the **f** command, see "Installation of TCP/IP" in *Networks and communication management*.

Flags

Item	Description
-b	Gives a brief, long-form listing.
-f	Suppresses printing of header line on output (the first line that defines the fields that are being displayed).
-h	Suppresses printing of **.project** files on long and brief long formats.
-i	Gives a quick listing with idle times.
-l	Gives a long-form listing.
-m	Assumes that the *User* parameter specifies a user ID (used for discretionary access control), *not* a user login name.
-p	Suppresses printing of **.plan** files on long-form and brief long-form formats.
-q	Gives a quick listing.
-s	Gives a short format list.
-w	Gives a narrow, short-format list.

Parameters

Item	Description
@Host	Specifies all logged-in users on the remote host.
User	Specifies a local user ID (used for discretionary access control) or local user login name, as specified in the **/etc/passwd** file.
User@Host	Specifies a user ID on the remote host, displayed in long format.

Examples

1. To get information about all users logged in to host `alcatraz`, enter:

   ```
   f @alcatraz
   ```

   Information similar to the following is displayed:

   ```
   [alcatraz.austin.ibm.com]
   Login     Name        TTY Idle         When      Site Info
   brown    Bob Brown   console   2d   Mar 15 13:19
   smith    Susan Smith    pts0  11:   Mar 15 13:01
   jones    Joe Jones      tty0    3   Mar 15 13:01
   ```

   User `brown` is logged in at the `console`, user `smith` is logged in from pseudo teletype line `pts0`, and user `jones` is logged in from `tty0`.

2. To get information about user brown at alcatraz, enter:

```
f brown@alcatraz
```

Information similar to the following is displayed:

```
Login name: brown
Directory: /home/brown    Shell: /home/bin/xinit -L -n Startup
On since May 8 07:13:49 on console
No Plan.
```

3. To get information about user brown at a local host in short form, enter:

```
f -q brown
```

Information similar to the following is displayed:

```
Login           TTY             When
brown           pts/6           Mon Dec 17 10:58
```

Files

Item	Description
/usr/bin/f	Contains the **f** command.
/etc/utmp	Contains list of users currently logged in.
/etc/passwd	Defines user accounts, names, and home directories.
/etc/security/passwd	Defines user passwords.
/var/adm/lastlog	Contains last login times.
$HOME/.plan	Optional file that contains a one-line description of a user's plan.
$HOME/.project	Optional file that contains a user's project assignment.

factor Command

Purpose

Factors a number.

Syntax

factor [*Number*]

Description

When called without specifying a value for the *Number* parameter, the **factor** command waits for you to enter a positive number less than 1E14 (100,000,000,000,000). It then writes the prime factors of that number to standard output. It displays each factor the proper number of times. To exit, enter 0 or any nonnumeric character.

When called with an argument, the **factor** command determines the prime factors of the *Number* parameter, writes the results to standard output, and exits.

Examples

To calculate the prime factors of 123, enter:

```
factor 123
```

The following is displayed:

```
123
     3
     41
```

Files

Item	Description
/usr/bin/factor	Contains the **factor** command.

true or false Command

Purpose

Returns an exit value of zero (true) or a nonzero exit value (false).

Syntax

true

false

Description

The **true** command returns a zero exit value. The **false** command returns a nonzero exit value. These commands are most often used as part of a shell script.

Examples

To construct a loop that displays the date and time once each minute, use the following code in a shell script:

```
while true
do
   date
   sleep 60
done
```

reboot or fastboot Command

Purpose

Restarts the system.

Syntax

{ **reboot** | **fastboot** } [**-l**] [**-n**] [**-q**] [**-t** *mmddHHMM* [*yy*]]

Description

The **reboot** command can be used to perform a reboot operation if no other users are logged into the system. The **lsattr** command and enter `lsattr -D -l sys0`. The default value is **true**. To reset the autorestart attribute value to **false**, use the **/var/adm/wtmp**, the login accounting file. These actions are inhibited if the **-l**, **-n**, or **-q** flags are present.

The **fastboot** command restarts the system by calling the **reboot** command. The **fsck** command runs during system startup to check file systems. This command provides BSD compatibility.

Flags

Item	Description
-l	Does not log the reboot or place a shutdown record in the accounting file. The **-l** flag does not suppress accounting file update. The **-n** and **-q** flags imply **-l**.
-n	Does not perform the **sync** command. Use of this flag can cause file system damage.
-q	Restarts without first shutting down running processes. **Note:** A file system synchronization will not occur if the **-q** flag is used. If you want the file system to be synchronized, manually run the **sync** command or use the **shutdown -r** command.
-t	Shuts down the system immediately and then restarts the system on the specified date. A valid date has the following format: *mmddHHMM* [*yy*] where: ***mm*** Specifies the month. ***dd*** Specifies the day. ***HH*** Specifies the hour. ***MM*** Specifies the minute. ***yy*** Specifies the year (optional). The two digit value represents the value of the year in the current century (based on the system time). For example, if the current year based on the systems time is 1985, 99 means 1999 and if the current year is 2005 then 99 means 2099 and 04 means 2004.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

To shut down the system without logging the reboot, enter:

```
reboot  -l
```

Files

Item	Description
/etc/rc	Specifies the system startup script.
/var/adm/wtmp	Specifies login accounting file.

fc Command

Purpose

Processes the command history list.

Syntax

To Open an Editor to Modify and Reexecute Previously Entered Commands

fc [**-r**] [**-e** *Editor*] [*First* [*Last*]]

To Generate a Listing of Previously Entered Commands

fc -l [**-n**] [**-r**] [*First* [*Last*]]

To Generate a Listing of Previously Entered Commands with Time of Execution

fc -t [**-n**] [**-r**] [*First* [*Last*]]

To Re-execute a Previously Entered Command

fc -s [*Old*=*New*] [*First*]

Description

The **fc** command displays the contents of your command history file or invokes an editor to modify and reexecutes commands previously entered in the shell.

The command history file lists commands by number. The first number in the list is selected arbitrarily. The relationship of a number to its command does not change except when the user logs in and no other process is accessing the list. In that case, the system resets the numbering to start the oldest retained command at 1.

If the numbers in the command history file reach a limit greater than the value of the **HISTSIZE** environment variable or 32767, whichever is greater, the shell wraps to 1. Despite this optional number wrapping, the **fc** command maintains the time-ordering sequence of the commands. For example, if three commands in sequence are given the numbers 32766, 32767, and 1 (wrapped), command 32767 is still considered previous to command 1.

The commands in the history file can be displayed using the **-l** (lowercase L) flag. When the **-l** flag is not specified and commands are edited using the **-e** *Editor* flag, the resulting lines are entered at the end of the history file and then reexecuted by the shell (the **fc -e** *Editor* command is not entered into the command history list). If the editor returns a non-zero exit status, this suppresses entry in the history file and command reexecution.

Any command-line variable assignments or redirection operators used with the **fc** command again invoke the previous command, suppressing standard error for both the **fc** command and the previous command. For example:

```
fc -s -- -1 2>/dev/null
```

Flags

Item	Description
-e *Editor*	Edits commands using the specified editor. The *Editor* parameter should be a command name. The command is located using the **PATH** environment variable. The value in the **FCEDIT** environment variable is used as a default when the **-e** flag is not specified. If the **FCEDIT** environment variable is null or unset, the ed editor is used.

Item	Description
-l	(lowercase L) Lists the commands in your history file. No editor is invoked to modify them. The commands are written in the sequence indicated by the *First* and *Last* parameters, as affected by the **-r** flag, with each command preceded by the command number.
-n	Suppresses command numbers when used with the **-l** flag.
-r	Reverses the order of the commands listed (when used with the **-l** flag) or reverses the order of the commands edited (when the **-l** flag is not specified).
-s	Reexecutes a command without invoking an editor. If the *First* parameter is not also specified, the **-s** flag re-executes the previous command.
-t	Lists the commands in your history file along with there time of execution. The working is similar to **-l** flag but the time of execution of the command is displayed. **Note:** If the time field is recorded previously by setting `EXTENDED_HISTORY=ON`, then formatted time field is displayed, else "?".

Parameters

Item	Description
First or *Last*	Selects the commands to list or edit. The number of previous commands that can be accessed is determined by the value of the **HISTSIZE** environment variable. The *First* and *Last* parameters must have one of the following values: **[+] *Number*** Represents a specific command number. Command numbers can be displayed with the **-l** flag. A + (plus sign) is the default. ***-Number*** Represents a command that was previously executed, specified by the number of commands to back up in the history list. For example, -1 indicates the immediately previous command. ***String*** Indicates the most recently entered command that begins with the specified string. If the *Old*=*New* parameter is specified without the **-s** flag, the string from the *First* parameter cannot contain an embedded **=** (equal sign). When using the **-s** flag, omission of the *First* parameter causes the previous command to be used.

When the **-s** flag is not specified, the following rules apply:

- When using the **-l** flag, omission of the *Last* parameter causes a default to the previous command.
- When using the **-r**, **-n**, and **-e** flags, omission of the *Last* parameter causes a default to the *First* parameter.
- If both the *First* and *Last* parameters are omitted, the previous 16 commands are listed or the previous single command is edited (depending on whether or not the **-l** flag is used).
- If both the *First* and *Last* parameters are present, all commands are listed (when the **-l** flag is specified) or edited (when the **-l** flag is not specified). Editing multiple commands is accomplished by presenting to the editor all the commands at one time, each command starting on a new line. If the *First* parameter represents a newer command than the *Last* parameter, the commands are listed or edited in reverse sequence. This is equivalent to using the **-r** flag. For example, the following commands on the first line are equivalent to the corresponding commands on the second line:

```
fc  -r  10  20          fc      30  40
fc      20  10          fc  -r  40  30
```

- When a range of commands is used, it is not an error to specify *First* or *Last* values that are not in the history list. The **fc** command substitutes the value representing the oldest or newest command in the list, as appropriate. For example, if there are only ten commands in the history list, numbered 1 to 10, the commands:

```
fc  -l
fc   1   99
```

  list and edit, respectively, all ten commands.

Item	Description
Old=*New*	In commands to be reexecuted, replaces the fist occurrence of the old string with the new string.

Environment Variables

The following environment variables affect the execution of the **fc** command:

Item	Description
EXTENDED_HISTORY	Used to control the recording of time of command execution in the history file. If the variable is set to ON then the time is recorded, otherwise, it is not recorded.
FCEDIT	When expanded by the shell, determines the default value for the **-e** *editor* variable. If the **FCEDIT** environment variable is null or is not set, the ed editor is the default.
HISTDATEFMT	This is used to control the format of the time displayed by the **fc –t** command. For example, if HISTDATEFMT=%Y, then **fc -t** will display the year when the command is executed. The formatting is similar to that done by **date** command.
HISTFILE	Determines the path name of the command history file. If the **HISTFILE** environment variable is not set, the shell may attempt to access or create the **.sh_history** file in the user's home directory.
HISTSIZE	Determines a decimal number representing the limit to the number of previous commands that are accessible. If this variable is not set, a default value of128 is used.

Exit Status

The following exit values are returned:

Item	Description
0	Successful completion of the listing.
>0	An error occurred.

Otherwise, the exit status is that of the commands executed by the **fc** command.

Examples

1. To invoke the editor defined by the **FCEDIT** environment variable on the most recent command (the default editor is **/usr/bin/ed**), enter:

```
fc
```

   The command is executed when you finish editing.

2. To list the previous two commands that were executed, enter:

```
fc -l -2
```

3. To find the command that starts with `cc`, change `foo` to `bar`, and display and execute the command, enter:

```
fc -s foo=bar cc
```

4. To list the previously executed commands along with there time of execution, type:

```
fc –t
```

Files

Item	Description
/usr/bin/ksh	Contains the Korn shell **fc** built-in command.
/usr/bin/fc	Contains the **fc** command.

fccheck Command

Purpose

Performs basic problem determination on the First Failure Data Capture (FFDC) utilities.

Syntax

`/opt/rsct/bin/fccheck [ -q ] | [ -h ]`

Description

fccheck performs basic problem determination for the First Failure Data Capture utilities. The command checks for the following conditions and information on the local node:

- Checks if FFDC Error Stack usage has been disabled in the current process environment.
- Obtains the IP address that would be currently used by FFDC to identify the local node.
- Checks if **/var/adm/ffdc/stacks** is available, and if so, how much space is available in the file system where the directory resides. Checks to see if there is insufficient space to create FFDC Error Stacks.
- Checks if **/var/adm/ffdc/dumps** is available, and if so, how much space is available in the file system where the directory resides.

Results of these tests are displayed to standard output unless the "quiet" option has been specified. **fccheck** sets an exist status value to indicate the most severe condition it detected during the execution of its tests.

Flags

-h
Displays help and usage information to standard output. No other processing is performed.

-q
Specified "quiet" mode. The command does not display the results of each test to standard output. The exit status of the command must be used to determine the results of the tests. If more than one condition was detected, the exit status will reflect the most severe condition detected by **fccheck**.

Exit Status

The following integer exit status codes can be generated by this command:

0
All conditions tested by **fccheck** were found to be in normal operational parameters.

2
Help information successfully displayed. No further processing is performed.

12
No checking performed. Invalid option specified to this command.

19
The directory **/var/adm/ffdc/stacks** is not mounted or does not exist.

20
Cannot access or examine one or more directories in the path **/var/adm/ffdc/stacks**. Permissions may have been changed on one or more of the directories in this path to prevent access.

24
Cannot access or examine one or more directories in the path **/var/adm/ffdc/dumps**. Permissions may have been changed on one or more of the directories in this path to prevent access.

32
The directory **/var/adm/ffdc/dumps** is not mounted or does not exist.

40
Insufficient space is available in the **/var/adm/ffdc/stacks** directory to create FFDC Error Stacks on the local node.

41
Unable to obtain file system information from the operating system. This indicates a potential problem with the operating system itself.

42
FFDC Error Stack creation and usage has been disabled in this process environment.

Examples

To check for possible problems with the FFDC utilities on the local node:

```
fccheck
fccheck Status: All tests completed
```

If the local node had disabled the creation of FFDC Error Stacks, `fccheck` would indicate this as a problem:

```
fccheck

fccheck Status: Creation and use of FFDC Error Stacks has been expressly
disabled in the current execution environment. Any processes created in
the current execution environment cannot create their own FFDC Error Stacks
or inherit use of existing FFDC Error Stacks.

fccheck Status: All checks completed. Examine the previous status output for
possible FFDC problem conditions and take the recommended actions listed in
these messages.
```

Implementation Specifics

This command is part of the Reliable Scalable Cluster Technology (RSCT) fileset.

fcclear Command

Purpose

Removes FFDC Error Stacks and detail data files from the local node.

Syntax

`/opt/rsct/bin/fcclear -h` | [`-d` *filename* [,*filename*,...]] [`-D` *filename* [,*filename*,...]] [`-f` *FFDC_Failure_ID* [,*FFDC_Failure_ID*,...]] [`-F` *FFDC_Failure_ID* [,*FFDC_Failure_ID*,...]] [`-s` *file_name*[,*filename*,...]] [`-S` *file_name* [,*filename*,...]] [`-t` *days*]]

Description

fcclear is used to remove FFDC Error Stack files that are no longer needed for problem determination efforts from the local node. Specific FFDC Error Stack files can be removed, as well as FFDC Error Stack files containing the records of specific FFDC Failure Identifiers. Individual entries within an FFDC Error Stack cannot be removed.

Using the **-t** option, **fcclear** can be used to remove FFDC Error Stack files older than a specific number of days. To use **fcclear** in an automatic fashion to clean out unneeded FFDC Error Stacks, see the **cron** command for automating the execution of commands.

To remove all FFDC Error Stacks from the local node, specify a value of zero (0) for the number of days option argument.

Flags

-d
Removes detail data files by specifying a list of one or more detail data file names. These file names may be absolute path names, or relative to the **/var/adm/ffdc/dumps** directory. These files are removed if they exist on the local node. Files on remote nodes cannot be removed through this command. If more than one file name is provided, they must be separated by a comma (,) without any intervening white space.

-D
Preserves detail data files by specifying a list of one or more detail data file names. These file names may be absolute path names, or relative to the **/var/adm/ffdc/dumps** directory. These files are retained if they exist on the local node. Files on remote nodes cannot be retained through this command. If more than one file name is provided, they must be separated by a comma (,) without any intervening white space.

-f
Removes FFDC Error Stack files by specifying a list of one or more FFDC Failure Identifiers. The FFDC Error Stacks associated with these FFDC Error Identifiers are located and removed if they are present on the local node. FFDC Error Stacks on remote nodes will not be removed. If more than one FFDC Failure Identifier is supplied, they must be separated by a comma (,) with no intervening white space.

-F
Preserves FFDC Error Stack files by specifying a list of one or more FFDC Failure Identifiers. The FFDC Error Stacks associated with these FFDC Error Identifiers are located and retained if they are present on the local node. FFDC Error Stacks on remote nodes will not be retained. If more than one FFDC Failure Identifier is supplied, they must be separated by a comma (,) with no intervening white space.

-h
Displays help and usage information to the standard output device. No other processing is performed.

-s
Removes FFDC Error Stack files by specifying a list of one or more FFDC Error Stack file names. These file names can be absolute path names or file names relative to the **/var/adm/ffdc/stacks** directory. These files are removed if they exist on the local node. FFDC Error Stacks on remote nodes cannot be

removed through this command. If more than one file name is provided, each must be separated by a comma (,) without any intervening white space.

-S
Removes FFDC Error Stack files by specifying a list of one or more FFDC Error Stack file names. These file names can be absolute path names or file names relative to the **/var/adm/ffdc/stacks** directory. These files are removed if they exist on the local node. FFDC Error Stacks on remote nodes cannot be removed through this command. If more than one file name is provided, each must be separated by a comma (,) without any intervening white space.

-t
Indicates that FFDC Error Stacks and detail data files that are older than a specific number of days should be removed from the local node. This selection criteria is independent of the other selection criteria.

Exit Status

fcclear generates the following exit status values upon completion:

0
Successful completion of the command. The command may complete successfully if no FFDC Error Stack files or detail data files match the selection criteria.

2
Help information successfully displayed. No further processing is performed.

10
No files are removed from the local system. A required option was not specified to this command.

11
No files are removed from the local system. The argument of the -t option is not numeric.

12
No files are removed from the local system. Unknown option specified by the caller.

19
The directory **/var/adm/ffdc/stacks** does not exist or is not mounted.

26
No files are removed from the local system. The same option was specified more than once.

28
No files were removed from the system. The caller provided options that instruct the command to both remove and retain the same file. This condition can occur when the command user specified an FFDC Failure Identifier that is recorded in an FFDC Error Stack file specified by name to this command.

Examples

To remove any FFDC Error Stack and detail data files older than seven days from the local node:

```
fcclear -t 7
```

To remove all FFDC Error Stack and detail data files older than seven days, but retain the FFDC Error Stack that contains information for the FFDC Failure Identifier **/3Iv04ZVVfvp.wtY0xRXQ7.....**, issue the command:

```
fcclear -t 7 -F /3Iv04ZVVfvp.wtY0xRXQ7...................
```

To remove the FFDC Error Stack file that contains the record for the FFDC Failure Identifier **/3Iv04ZVVfvp.wtY0xRXQ7.....**, issue the command:

```
fcclear -f /3Iv04ZVVfvp.wtY0xRXQ7...................
```

To remove the FFDC Error Stack files **myprog.14528.19990204134809** and **a.out.5134.19990130093256** from the system, plus the detail data file **myprog.14528.19990204135227**:

```
fcclear -s myprog.14528.19990204134809,a.out.5134.19990130093256
    -d myprog.14528.19990204135227
```

To extend the previous command to remove the named files plus any FFDC Error Stack and detail data files older that 14 days:

```
fcclear -s myprog.14528.19990204134809,a.out.5134.19990130093256
    -d myprog.14528.19990204135227 -t 14
```

Implementation Specifics

This command is part of the Reliable Scalable Cluster Technology (RSCT) fileset.

fcdecode Command

Purpose

Translates a First Failure Data Capture (FFDC) Failure Identifier from its standard form into its component parts, displaying this information to the standard output device in human readable format.

Syntax

`/opt/rsct/bin/fcdecode` *FFDC_Failure_ID* [,*FFDC_Failure_ID*,...] | `-h`

Description

fcdecode decodes the 42-character FFDC Failure Identifier into its component parts, and displays these parts in human readable format. The output of this command displays the following information, extracted from the FFDC Failure Identifier:

- The network address (in ASCII format) of the node where this report resides
- The time when this recording was made, expressed using the currently active time zone settings
- One of the following, depending on where the information is recorded:
- The AIX Error Log template ID used to make this recording, if the record was filed in the AIX Error Log on that node, or
- The name of the FFDC Error Stack file containing this recording, if the record was file in the FFDC Error Stack and the FFDC Error Stack resides on this node
- A suggested command that can be used to obtain the specific report associated with this FFDC Failure Identifier.

Flags

-h

Displays a help message to standard output and exits. No other processing is performed, regardless of the options specified.

Parameters

FFDC_Failure_ID

An FFDC Failure Identifier, returned from previous calls to the **fcpushstk** and **fclogerr** commands, or returned from previous calls to the **fc_push_stack** or **fc_log_error** subroutines. This identifier

indicates an entry made to report a failure or other noteworthy incident. More than one FFDC Failure Identifier can be provided as an argument to this command, however, each identifier must be separated by a comma (,) with no intervening white space between the identifiers.

Exit Status

fcdecode returns one of the following integer status codes upon completion:

0
FFDC Failure Identifier successfully decoded.

2
Help information displayed and processing ended.

10
An FFDC Failure Identifier was not provided as an argument to this command.

12
Invalid or unsupported option provided to this command.

27
No information written to the standard output device. The FFDC Failure Identifier argument was not valid.

Examples

The FFDC Failure Identifier is represented by a base-64 value, read from right to left. Each dot represents a leading zero. To decode the FFDC Failure Identifier **.3Iv04ZVVfvp.wtY0xRXQ7.**.....into its component parts:

```
fcdecode .3Iv04ZVVfvp.wtY0xRXQ7.....................

Information for First Failure Data Capture identifier
        .3Iv04ZVVfvp.wtY0xRXQ7.....................
        Generated by the local system
        Generated Thu Sep 3 11:40:17 1998 EDT
        Recorded to the AIX Error Log using template 460bb505
        To obtain the AIX Error Log information for this entry, issue
        the following command on the local system:
        TZ=EST5EDT errpt -a -j 460bb505 -s 0903114098 | more
        Search this output for an AIX Error Log entry that contains
        the following ERROR ID code:
         .3Iv04ZVVfvp.wtY0xRXQ7.....................
```

The same command run on a different node has the following results:

```
fcdecode .3Iv04ZVVfvp.wtY0xRXQ7.....................

Information for First Failure Data Capture identifier
        .3Iv04ZVVfvp.wtY0xRXQ7.....................
        Generated on a remote system with the following Internet address:
          9.114.55.125
        Generated Thu Sep 3 11:40:17 1998 EDT
        Recorded to the AIX Error Log using template 460bb505
        TZ=EST5EDT errpt -a -j 460bb505 -s 0903114098 | more
        Search this output for an AIX Error Log entry that contains
        the following ERROR ID code:
         .3Iv04ZVVfvp.wtY0xRXQ7.....................
```

Implementation Specifics

This command is part of the Reliable Scalable Cluster Technology (RSCT) fileset.

fcdispfid Command

Purpose

Displays the First Failure Data Capture Failure Identifier (FFDC Failure Identifier) to the standard error device.

Syntax

`/opt/rsct/bin/fcdispfid` [`-q`]*FFDC_Failure_ID* | `-h`

Description

This command is used by scripts to display an FFDC Failure Identifier value to the standard error device. This interface is provided because script programs do not have a mechanism for passing data back to its client except through exit status codes, signals, standard output, and standard error. To accomplish the task of "passing back" an FFDC Failure Identifier to a client in such an environment, **fcdispfid** uses XPG/4 cataloged message number **2615-000** to display this information to the standard error device. Clients of the script can capture the standard error information, search for the specific message number, and obtain the FFDC Failure Identifier from the script.

The script must indicate that any FFDC Failure Identifiers generated by the script will be directed to the standard error device in the script's user documentation. The client cannot be expected to know this behavior by default.

Flags

-h
Displays a help message to standard output and exits. No other processing is performed, regardless of the options specified.

-q
Suppresses warning messages from this command. If this option is not provided, this command will display messages when an invalid FFDC Failure Identifier is detected.

Parameters

FFDC_Failure_ID

Specifies an FFDC Failure Identifier. This is an identifier returned from a previous call to **fcpushstk** or **fclogerr**, and indicates an entry made to report a failure encountered by the script. This identifier is written to the standard error device using FFDC message **2615-000**.

Exit Status

0
FFDC Failure Identifier displayed to standard error.

2
Help information displayed and processing ended.

12
No information written to the standard error device. An invalid option was specified.

27
No information written to the standard error device. The *FFDC_Failure_ID* argument does not appear to be in a valid format.

Examples

To display an FFDC Failure Identifier to the client through the standard output device:

```
   FID=$(fclogerr -e FFDC_ERROR -t ERRID_SP_FFDCEXMPL_ER -i /usr/lpp/ssp/inc/
myprog.h -r myprog -s myprog.ksh -p $LINEPOS -v "1.1" -l PSSP -d $MINUSDOPTS -x
$MINUSXOPTS -y $MINUSYOPTS -b "myprog Configuration Failure - Exiting")
    RC=$?
    if ((RC == 0))
    then
         fcdispfid $FID
         return 1
    else
         :
    fi
```

Implementation Specifics

This command is part of the Reliable Scalable Cluster Technology (RSCT) fileset.

fcfilter Command

Purpose

Locates and displays any First Failure Data Capture (FFDC) Failure Identifiers in a file or in standard input. More than one file may be specified.

Syntax

`/opt/rsct/bin/fcfilter` [*file_name*] [. . .]

Description

This commands scans any files listed as arguments for First Failure Data Capture (FFDC) Failure Identifiers. If a file name is not provided as an argument, this command examines standard input for FFDC Failure Identifiers. If an FFDC Failure Identifier is detected, **fcfilter** displays the identifier to standard output on its own line.

fcfilter can be used by scripts to extract FFDC Failure Identifiers returned by child processes via the standard error device.

If **fcfilter** detects more than one FFDC Failure Identifier in the input, the command will display all FFDC Failure Identifiers found, each one on a separate output line.

Parameters

file_name

The name of the file to be searched for an FFDC Failure Identifier. More than one file may be provided. If a file name is not provided, **fcfilter** reads from standard input.

Exit Status

fcfilter returns the following integer status codes upon completion:

0
fcfilter completed its execution. This exit status does not necessarily mean that any FFDC Failure Identifiers were detected.

> 0
fcfilter was interrupted or stopped by a signal. The exit status is the integer value of the signal that stopped the command.

Examples

The FFDC Failure Identifier is represented by a base-64 value, read from right to left. Each dot represents a leading zero. To obtain the list of all FFDC Failure Identifiers generated by a run of the command *mycmd*:

```
 mycmd 2> /tmp/errout
 fcfilter /tmp/errout
/.00...JMr4r.p9E.xRXQ7...................
/.00...JMr4r.pMx.xRXQ7...................
```

To obtain the FFDC Failure Identifier from a child process in a parent script, the script can use the **fcfilter** command as follows:

```
RESULTS=$(mychild 2> /tmp/errout)
if (($? != 0))              # mychild ended in failure, get FFDC ID
then
    cat /tmp/errout | fcfilter | read FIRST_FFDCID
else
    rm -f /tmp/errout
fi
```

Implementation Specifics

This command is part of the Reliable Scalable Cluster Technology (RSCT) fileset.

fcinit Command

Purpose

Establishes or inherits a First Failure Data Capture execution environment.

Syntax

For Bourne and Korn shells:

`/opt/rsct/bin/fcinit.sh [ [ -l ] [ -s { c | i } ] ] | [ -h ]`

For C shells:

`source /opt/rsct/bin/fcinit.csh [ [ -l ] [ -s { c | i } ] ] | [ -h ]`

Description

This interface must be used by a script program that wishes to use the FFDC interfaces for recording information to the AIX Error Log, the BSD System Log, or the FFDC Error Stack .

Applications may wish to establish an FFDC Environment for one of the following reasons:

- The script may wish to record information to the AIX Error Log. Scripts can use **fcinit** to establish a basic FFDC Environment
- The script wants to have itself and any descendant processes created by itself or its children to record failure information to the FFDC Error Stack. In this case, the script considers itself a "top-level" application that will cause multiple "lower-level" applications to be created, and the success of the "top-level" application depends upon the success of these "lower-level" applications. When using **fcinit** in this fashion, the process is said to *establish* or *create* the FFDC Error Stack Environment.
- The script uses the FFDC Error Stack or the FFDC Trace only in those cases when the script is invoked by an ancestor process that wants failure information or trace information recorded to these devices. In all other cases, the script does not wish to use these devices. When using **fcinit** in this fashion, the process is said to *inherit* the FFDC Error Stack Environment.

Any process wishing to record information to the AIX Error Log or the BSD System Log through the FFDC interfaces must establish an FFDC Environment. If the process does not wish to make use of an FFDC

Error Stack, the process can establish a basic FFDC Environment that does not make use of an FFDC Error Stack. An FFDC Error Stack Environment, which contains an FFDC Error Stack, is established by a process when that process wants to have failure information from itself, any threads it may create, and any descendant processes it may create to be recorded in an FFDC Error Stack. An *FFDC Error Stack Environment*, which contains an FFDC Error Stack, is inherited by a process when that process wants to record failure information to an FFDC Error Stack file only when one of its ancestors has requested for processes to do so; in all other cases, the process will not record failure information to the FFDC Error Stack.

The FFDC Error Stack Environment, which contains an FFDC Error Stack, reserves an FFDC Error Stack file, so that failure information is recorded to a file in the **/var/adm/ffdc/stacks** directory. These files use the naming format ***script_name.PID.date_and_time***, where *script_name* is the name of the script itself, *PID* is the process identifier of the script, and *date_and_time* is the date and time when the script was executed. Whenever this script or children processes of this script record failure information to the FFDC Error Stack, it will be recorded in this file.

In order for information to be recorded in the FFDC Error Stack by a process, the process must use the **fcpushstk** FFDC interface, and the process has to be operating within an established FFDC Error Stack Environment. If an FFDC Error Stack Environment does not exist, or if the **fcpushstk** interface is not used when an FFDC Error Stack Environment exists, no information is recorded by that process in the FFDC Error Stack. This function permits processes to run in a normal or "silent" mode when failure debugging information is not wanted or needed, but also permits this information to be available when the process is invoked within a special environment for debugging.

fcinit must be executed within the FFDC client's process environment ("sourced") in order for the command to properly set the FFDC Environment for the script. Script-based FFDC clients using this command must "source" the command in order for **fcinit** to execute within the client's process image. If this is not done. the FFDC interface is executed within its own process image; any settings of the FFDC Environment are lost after the FFDC interface completes. To demonstrate how a script-based application would "source" the **fcinit** command, a Korn Shell program would issue the following instruction:

```
. fcinit.sh <options and arguments>
```

A C Shell script would do the following:

```
source fcinit.csh <options and arguments>
```

Processes that use the **fclogerr** FFDC interface must establish an *FFDC Environment*. If the process only wishes to use the **fclogerr** interface, the *FFDC Environment* can be established without an FFDC Error Stack.

If an FFDC Environment already exists when a script attempts to create one, the script inherits the existing FFDC Environment instead of creating its own.

Flags

-h
Displays a help message to standard output and exits. No other processing is performed, regardless of the options specified.

-l
Indicates that the process wishes to make use of the AIX Error Log only. This option is not necessary when the **-s** option is specified, since use of the AIX Error Log is permitted within an FFDC Error Stack Environment.

-s
Indicates that an FFDC Error Stack Environment is to be established. Applications wishing to use the **fcpushstk** interface must specify this flag. Upon successful completion of this command, an FFDC Error Stack file is reserved for the script in the **/var/adm/ffdc/stacks** directory. This flag must be specified with one of two possible options:

c

Requests that the FFDC Error Stack Environment be *created*. If an FFDC Error Stack Environment was not created by an ancestor process, it will be created. If such an environment was previously created by an ancestor process, this process will *inherit* the FFDC Error Stack Environment as if the **i** option had been specified.

i

Specifies that an FFDC Error Stack Environment is to be *inherited* if it was previously established by an ancestor process. If an FFDC Error Stack Environment was not previously established by an ancestor process, an FFDC Error Stack Environment is not established for this process, and this process cannot make use of an FFDC Error Stack (although it may make use of the AIX Error Log and the BSD System Log).

Parameters

file_name

The name of the file to be searched for an FFDC Failure Identifier. More than one file may be provided. If a file name is not provided, **fcfilter** reads from standard input.

Exit Status

fcinit returns the following exit status codes upon completion:

0

FFDC Environment successfully established.

1

FFDC Environment successfully inherited.

2

Help information displayed and processing ended.

fcinit returns the following exit status codes upon detection of a failure:

12

FFDC Environment not established or inherited - Unknown function parameter provided.

13

FFDC Error Stack Environment not established or inherited - caller indicated that the FFDC Environment should be both created and inherited.

14

FFDC Environment not established in this call - the caller already has an FFDC Environment established for itself - this routine may have been executed multiple times.

15

FFDC Error Stack Environment not established or inherited - an FFDC Error Stack Environment did not exist, and the FC_INHERIT option was specified.

16

FFDC Environment not established or inherited - the client's process environment could not be modified by this routine.

17

FFDC Environment not established or inherited - the FFDC Environment appears to be corrupted and should be considered unusable.

18

FFDC Environment not established or inherited - the routine could not allocate the memory required to modify the client's process environment.

19

FFDC Error Stack Environment not established or inherited - Unable to reserve the FFDC Error Stack file for the calling process - the FFDC Error Stack directory does not exist or cannot be used.

21
FFDC Error Stack Environment not established or inherited - Unable to reserve the FFDC Error Stack file for the calling process - the file already exists

42
FFDC Error Stack Environment not established or inherited - creation and use of FFDC Error Stacks has been disabled by the system administrator. Scripts can establish only a basic FFDC Environment that makes use of the AIX Error Log and the BSD System Log.

99
FFDC Environment not established or inherited - an unexpected internal failure occurred within **fcinit**. This condition may require the attention of customer and application-support services.

Examples

For a Korn Shell script to establish a basic FFDC Environment for using the AIX Error Log and the BSD System Log only (an FFDC Error Stack is not to be used or reserved):

```
# Set up an FFDC Environment to use the AIX Error Log only. An FFDC Error
# Stack is not needed for this script.
. fcinit.sh -1
rc=$?
if ((rc != 0))
    then
         print "fcinit failed with exit code of $rc"
         exit 1
fi
# Normal processing starts
```

For a Korn Shell script to establish an FFDC Error Stack Environment that causes the script and any descendant process to record failure information to the FFDC Error Stack:

```
# Set up FFDC Environment to record failure information to the FFDC Error
# Stack
. fcinit.sh -sc
rc=$?
if ((rc != 0))
then
    print "fcinit failed with a code of $rc"
    exit 1
fi
# Normal processing starts
```

Note: The FFDC client may receive an indication that an FFDC Error Stack Environment was inherited, instead of created by the **fcinit** call. This occurs when an FFDC Error Stack Environment was already established by one of the process's ancestors.

To inherit an FFDC Error Stack Environment from the process's parent process:

```
# Inherit an FFDC Environment from parent process if it exists - otherwise,
# operate in a normal "silent" mode
. fcinit.sh -si
rc=$?
if ((rc != 0))
then
    print "fcinit failed with a code of $rc"
    exit 1
fi
# Normal processing starts
```

Implementation Specifics

This command is part of the Reliable Scalable Cluster Technology (RSCT) fileset.

fclogerr Command

Purpose

Records information about failure or noteworthy conditions to the AIX error log and the BSD system log.

Syntax

`/opt/rsct/bin/fclogerr` { `-e` *event* `-t` *error_template_label* `-i` *error_template_headerfile* `-r` *resource* `-s` *source_filename* `-p` *line_of_code_pos* `-v` *sidlevel* `-l` *lpp_name* `-a` *assoc_fid* { [`-d` *detail_data_item*[,*detail_data_item*,...] `-x` *detail_data_type*[,*detail_data_type*,...] `-y` *detail_data_len*[,*detail_data_len*,...]] | [`-f` *detail_data_file*] } `-b` *BSD_syslog_message_text* } | `-h`

Description

This interface is used by any script program that wishes to record information to the AIX Error Log and the BSD System Log. The information written to this device is intended for use by the system administrator or operator to determine what failure conditions or other noteworthy conditions have occurred on the system that require attention. The purpose of the AIX Error Log and the BSD System Log is to record enough information about a condition so that the nature, impact, and response to the condition can be determined from the report, without requiring a recreation of the condition to detect what condition occurred and where. Any software that encounters permanent failure conditions that will persist until some type of direct intervention occurs, or encounters a condition that should be brought to the attention of the system administrator, should use **fclogerr** to record this information in the AIX Error Log and the BSD System Log.

Scripts should establish a basic FFDC Environment or an FFDC Error Stack Environment before using **fclogerr**, either by creating or inheriting the environment. **fclogerr** records information to the AIX Error Log and the BSD System Log even if these environments are not established, but the interface will not be capable of generating an FFDC Failure Identifier unless one of these environments exists.

Processes designed to use the FFDC Error Stack can also make use of the **fclogerr** interface, and should make use of it if they encounter conditions that require administrator attention or intervention to resolve.

To ensure proper identification of the condition and the location at which it was encountered, the FFDC Policy recommends that **fclogerr** should be called in-line in the script's source code module and invoked as soon as the condition is detected. **fclogerr** will record source code file name and line of code information to assist in identifying and locating the source code that encountered the condition. **fclogerr** can be invoked by a subroutine or autoloaded routine to record this information if this is necessary, provided that all location information and necessary failure detail information is made available to this external routine. The external recording routine must record the true location where incident was detected.

Although **fclogerr** reports information to both the AIX Error Log and the BSD System Log, different options must be provided to this interface for each recording device. The Detail Data information recorded to the AIX Error Log is not also recorded to the BSD System Log; BSD System Log information is provided through different command options. This may require the **fclogerr** user to duplicate some information in this call.

Flags

-a

Contains the FFDC Failure Identifier for a failure condition reported by software used by this application which causes or influenced the condition being recorded at this time. This identifier should have been returned to this application as part of the software's result indication. The caller provides this identifier here so that the FFDC Error Stack can associate the failure report it is making at this time with the previously recorded failure report. This permits problem investigators to trace the cause of a failure from its various symptoms in this application and others to the root cause in the other

software. If no other software failure is responsible for this condition, or if the other software did not return an FFDC Failure Identifier as part of its result information, this option should be omitted.

-b

Specifies the text message to be written to the BSD System Log.

-d

One or more data items that provides detailed information on the condition, used to provide the Detail Data in the AIX Error Log entry. If details of the information are too lengthy, these details can be written to a file, and the name of that file provided as the *detail_data_file* parameter. If a detail data file name is provided, this option should be omitted. If neither the *detail_data* or the *detail_data_file* parameters are provided or appear valid, null information will be recorded for the detail data in the AIX Error Log.

More than one data item may be provided with this option. Each data item must be separated by commas (,) with no intervening white-space characters. If a data item has imbedded whitespace characters, the data item must be enclosed in double quotes ("). The data items themselves must not contain commas (,), as the command interprets commands a field separators.

This option *must* be accompanied by the **-x** and **-y** options.

-e

Specifies the FFDC Log Event Type. Current valid values are FFDC_EMERG, FFDC_ERROR, FFDC_STATE, FFDC_TRACE, FFDC_RECOV, and FFDC_DEBUG. This code gives a general description of the type of event being logged (emergency condition, permanent condition, informational notification, debugging information, etc.) and the severity of the condition. If this option is not specified, the event type FFDC_DEBUG is assigned to this incident record.

-f

Name of a file containing details about the condition being reported. This option is used when the details are too lengthy to record within the remaining 100 bytes of Detail Data information left to the application by **fclogerr**, or when a utility exists that can analyze the detail information. The contents of this file is copied to the **/var/adm/ffdc/dumps** directory, and the file's new location is recorded as the Detail Data in the AIX Error Log entry.

-h

Displays a help message to standard output and exits. No other processing is performed, regardless of the options specified.

-i

Specifies the absolute path name of the header file (.h) that contains the error logging template identification number that corresponds to the *error_template_label* specified in the **-l** option. This template must also be found in the node's error logging template repository (**/var/adm/ras/errtmplt**). This header file was generated by the **errupdate** command as part of the source code's building procedures, and should have been included in the LPP's packaging to be installed on the node with the software. If this option is not specified or the header file cannot be found when the script is executed, **fclogerr** will record the failure information using its own default error template (label FFDC_DEF_TPLT_TR, identifier code 2B4F5CAB).

-l

Specifies an abbreviation of the name of the licensed programming product in which this software was shipped. This value should be recognizable to both customer and application-support services as an acceptable name for the LPP. Examples of such values are: PSSP, GPFS, LoadLeveler®, and RSCT. If this option is not provided or appears invalid, the character string **PPS_PRODUCT** is used.

-p

Specifies the line of code location within the source code module where the condition is being reported. The value provided must be a valid integer value. To allow for proper identification and location of the condition, this value should be as close to the line of code that detected the condition as possible. Korn Shell scripts can use the value of **$LINENO**. Script languages that do not provide a special line count variable can provide a symbolic value here that a developer can use to locate the spot in the source code where **fclogerr** is being used. If this option is not valid or not provided, the value of **0** is used.

-q
Suppresses the generation of warning messages from the command. Warning are generated when the command must substitute default information for missing information, or when the command is unable to copy the *detail_data_file* to the **/var/adm/ffdc/dumps** directory.

-r
Specifies the software component name. This is a symbolic name for the software making the report and should be a name recognizable to both customer and application-support services. The character string is limited to 16 characters.

-s
Specifies the name of the source file containing the line of code that encountered the condition being reported. For Korn and Borne Shell scripts, the argument to this option should be set to **$0**; C Shell scripts would set this argument to **${0}**. If this option is not provided or not valid, the character string **unknown_file** is used.

-t
Indicates the symbolic label given to the AIX Error Logging template in the error log repository. The **errupdate** command that builds error logging templates creates a macro that maps this label to an integer code. This label begins with the characters **ERRID_** and is a maximum of 19 characters. If this option is not specified or the header file cannot be found when the script is executed, **fclogerr** will invoke the **errlogger** to create a message in the AIX Error Log using the OPMSG template.

-v
Indicates the SCCS version number of the source code module that detected the condition being recorded. For source code built under SCCS control, this should be set to **"1.1"** (the double-quotes are necessary). If this option is not provided or is not valid, the character string **unknown** is used.

-x
Indicates how the data items specified by the **-d** option are to be interpreted when recording this information to the AIX Error Log. These types must agree with the corresponding fields of the AIX Error Logging template specified in the **-t** option. Each type indicates how the corresponding data item in the **-d** list is interpreted. Acceptable values for this option are ALPHA, HEX, and DEC. There must be a matching type listed in the **-x** argument for each argument in the **-d** list.

This option *must* be supplied if the **-d** option is provided.

-y
Indicates the length of the data items (in bytes) specified by the **-d** option. These lengths must agree with the corresponding fields of the AIX Error Logging template specified in the **-t** option. There must be a matching type listed in the **-y** argument for each argument in the **-d** list.

This option *must* be supplied if the **-d** option is provided.

Parameters

file_name
The name of the file to be searched for an FFDC Failure Identifier. More than one file may be provided. If a file name is not provided, **fcfilter** reads from standard input.

Exit Status

fclogerr returns the following exit status codes upon successful completion:

0
Information successfully queued to be written to the AIX Error Log and the BSD System Log. An FFDC Failure Identifier for the record is displayed to standard output. The caller should capture standard output to obtain this value.

2
Help information displayed and processing ended.

12
No information recorded to the AIX Error Log, and no FFDC Failure Identifier is provided by the command. The command user provided an invalid option to this command.

On AIX platforms other than AIX, **fclogerr** returns the following exit status codes when a failure occurs:

38
A record could not be made int he BSD System Log for this incident. The System Log is experiencing a failure condition. On AIX systems, a report was recorded to the AIX Error Log; on other systems, this should be considered a failure.

When **fclogerr** is provided with incomplete information, it substitutes default information for the missing information and attempts to make a record in the FFDC Error Stack. Warnings are generated in these cases, and warning messages are generated unless the **-q** option is specified. In cases where more than one warning condition was detected, the command returns an exit status code for the condition it considered the most severe. The following exit status codes are returned by **fclogerr** when warning conditions are detected:

10
The command user failed to provide the **-i** option to this command, or the header file named as the argument to the -i option could not be located. The command will record generic information to the AIX Error Log in this case, using the First Failure Data Capture default template (label FFDC_DEF_TPLT_TR, identifier code 2B4F5CAB).

26
Both a detailed data string and a detail data file were provided to this routine. The routine chose the detail data string and ignored the detail data file.

28
The name of the resource detecting the incident was not provided. The default resource name **ffdc** was substituted for the missing resource name.

29
At least one component of the detecting application information—source code file name, source code file version, LPP name, line of code position—was not provided. Default information was substituted for the missing information.

32
The file named in the *detail_data_file* parameter could not be copied to the **/var/adm/ffdc/dumps** directory. The FFDC Error Stack entry cites the original version of this file. Do not discard the original copy of this file.

33
The **-e** option was not specified, or did not specify a valid FFDC event type. The event type FFDC_DEBUG has been assigned to this incident record.

34
A message was not supplied in the *format* parameter. As a result, a generic message was recorded to the BSD System Log for this incident.

35
No detailed information was provided for this incident. Later problem analysis may be difficult without these details to indicate specifics on the incident.

36
The length of the detail data string was greater than the capacity of the AIX Error Log entry limit. Detail data was truncated to fit in the available space. Some information on the incident may have been lost in this truncation.

37
An FFDC Error Identifier could not be constructed for the report created by this routine. An FFDC Failure Identifier is not written to standard output, but information on the incident was recorded to the AIX Error Log and the BSD System Log.

38
A record could not be made in the BSD System Log for this incident. The System Log may not be enabled, or may be experiencing problems. On AIX systems, a report was recorded to the AIX Error Log; on other systems, this should be considered a failure.

Examples

For this example, a Korn Shell script attempts to access configuration information from a file. If this attempt fails, the code will record a failure to the AIX Error Log using the following template source code:

```
*! mymesgcat.cat
+ SP_FFDCEXMPL_ER:
    Comment        = "Configuration Failed - Exiting"
    Class          = S
    Log       = true
    Report         = true
    Alert          = false
    Err_Type  = PERM
    Err_Desc  = {3, 10, "CONFIGURATION FAILURE - EXITING"}
    Prob_Causes    = E89B
    User_Causes    = E811
    User_Actions   = 1056
    Fail_Causes    = E906, E915, F072, 108E
    Fail_Actions   = {5, 14, "VERIFY USER HAS CORRECT PERMISSIONS TO ACCESS FILE"},
                {5, 15, "VERIFY CONFIGURATION FILE"}
    Detail_Data    = 46, 00A2, ALPHA
    Detail_Data    = 42, EB2B, ALPHA
    Detail_Data    = 42, 0030, ALPHA
    Detail_Data    = 16, EB00, ALPHA
    Detail_Data    = 16, 0027, ALPHA
    Detail_Data    = 4, 8183, DEC
    Detail_Data    = 4, 8015, DEC
    Detail_Data    = 60, 8172, ALPHA
```

This definition yields the following AIX Error Logging Template:

```
LABEL:            ERRID_SP_FFDCEXMPL_ER
IDENTIFIER:        <calculated by errupdate during source code build>

Date/Time:         <filled in by AIX Error Log subsystem>
Sequence Number:   <filled in by AIX Error Log subsystem>
Machine Id:        <filled in by AIX Error Log subsystem>
Node Id:           <filled in by AIX Error Log subsystem>
Class:             S
Type:              PERM
Resource Name:     <filled in by -r option to fclogerr>

Description
CONFIGURATION FAILURE - EXITING

FILE IS CORRUPT

    Recommended Actions
    VERIFY USER HAS CORRECT PERMISSIONS TO ACCESS FILE
    VERIFY CONFIGURATION FILE

Detail Data
DETECTING MODULE
<filled in by fclogerr options>
ERROR ID
<The FFDC Failure Identifier created by fclogerr>
REFERENCE CODE
```

```
<The -a option value to fclogerr>
FILE NAME
<Must be supplied as part of -d option list to fclogerr>
FUNCTION
<Must be supplied as part of -d option list to fclogerr>
RETURN CODE<Must be supplied as part of -d option list to fclogerr>
ERROR CODE AS DEFINED IN sys/errno.h
<Must be supplied as part of -d option list to fclogerr>
USER ID<Must be supplied as part of -d option list to fclogerr>
```

The first three Detail Data Fields are constructed by the **fclogerr** routine from information passed in the parameters. The remaining Detail Data must be supplied with the **-d** option, and the type of data supplied must be indicated by the **-x** option. The example source code segment below demonstrates how this is done, and how **fclogerr** is invoked to record the information in the AIX Error Log and the BSD System Log.

```
typeset CONFIG_FNAME
typeset INBUF
typeset MINUSDOPTS
typeset MINUSXOPTS
typeset MINUSYOPTS
typeset FID
integer MYCLIENT
integer RC
    :
MYCLIENT=$$
CONFIG_FNAME="/configfile.bin"
exec 3< $CONFIG_FNAME
    :
read -u3 INBUF
RC=$?
if ((RC != 0))
then
    # Create Detail Data Memory Block for AIX Error Log Template
    # Need to know the EXACT structure of the Template to do this correctly.
    #    Field 1 - filled in by fc_log_error
    #    Field 2 - filled in by fc_log_error
    #    Field 3 - filled in by fc_log_error
    #    Field 4 - name of configuration file being used - 16 bytes
    #    Field 5 - name of function call that failed - 16 bytes
    #    Field 6 - return code from failing function - 4 byte integer
    #    Field 7 - errno from failing function call (unused) - 4 byte integer
    #    Field 8 - user ID using this software - remaining space (62 bytes)
    # This source code supplied fields 4 through 8 in the "-d" option, and
    # describes the data types for each in the "-x" option.
    MINUSDOPTS=$CONFIG_FNAME
    MINUSXOPTS="ALPHA"
    MINUSYOPTS="16"
    MINUSDOPTS="$MINUSDOPTS,read"
    MINUSXOPTS="$MINUSXOPTS,ALPHA"
    MINUSYOPTS="$MINUSYOPTS,16"
    MINUSDOPTS="$MINUSDOPTS,$RC"
    MINUSXOPTS="$MINUSXOPTS,DEC"
    MINUSYOPTS="$MINUSYOPTS,4"
    MINUSDOPTS="$MINUSDOPTS,0"
    MINUSXOPTS="$MINUSXOPTS,DEC"
    MINUSYOPTS="$MINUSYOPTS,4"
    MINUSDOPTS="$MINUSDOPTS,$MYCLIENT"
    MINUSXOPTS="$MINUSXOPTS,DEC"
    MINUSYOPTS="$MINUSYOPTS,60"
    FID=$(fclogerr -e FFDC_ERROR -t ERRID_SP_FFDCEXMPL_ER -i /usr/lpp/ssp/inc/
myprog.h -r myprog -s myprog.ksh -p $LINEPOS -v "1.1" -l PSSP -d $MINUSDOPTS -x
$MINUSXOPTS -y $MINUSYOPTS -b "myprog Configuration Failure - Exiting")
    RC=$?
    if ((RC == 0))
    then
         fcdispfid $FID
         return 1
    else
         :
    fi
fi
```

Now consider a slight variation on the above example, using the same AIX Error Logging template, but this time using an external command to obtain the configuration data from a file that this source code supplies. The command exits with a non-zero exit status and prints an FFDC Failure Identifier to standard

output if it encounters any failure conditions. Also, to demonstrate the use of double-quotes in the **-d** list, the configuration file will have an embedded space in the name:

```
typeset CONFIG_FNAME
typeset INBUF
typeset MINUSDOPTS
typeset MINUSXOPTS
typeset MINUSYOPTS
typeset FID
typeset OUTPUT
integer MYCLIENT
integer RC
    :
MYCLIENT=$$
CONFIG_FNAME="This is a test"
OUTPUT=$(configdabeast $CONFIG_FNAME)
RC=$?
if ((RC != 0))
then
    # Create Detail Data Memory Block for AIX Error Log Template
    # Need to know the EXACT structure of the Template to do this correctly.
    #    Field 1 - filled in by fc_log_error
    #    Field 2 - filled in by fc_log_error
    #    Field 3 - filled in by fc_log_error
    #    Field 4 - name of configuration file being used - 16 bytes
    #    Field 5 - name of function call that failed - 16 bytes
    #    Field 6 - return code from failing function - 4 byte integer
    #    Field 7 - errno from failing function call (unused) - 4 byte integer
    #    Field 8 - user ID using this software - remaining space (62 bytes)
    # This source code supplied fields 4 through 8 in the "-d" option, and
    # describes the data types for each in the "-x" option.
    MINUSDOPTS="\""$CONFIG_FNAME"\""
    MINUSXOPTS="ALPHA"
    MINUSYOPTS="16"
    MINUSDOPTS="$MINUSDOPTS,configdabeast"
    MINUSXOPTS="$MINUSXOPTS,ALPHA"
    MINUSYOPTS="$MINUSYOPTS,16"
    MINUSDOPTS="$MINUSDOPTS,$RC"
    MINUSXOPTS="$MINUSXOPTS,DEC"
    MINUSYOPTS="$MINUSYOPTS,4"
    MINUSDOPTS="$MINUSDOPTS,0"
    MINUSXOPTS="$MINUSXOPTS,DEC"
    MINUSYOPTS="$MINUSYOPTS,4"
    MINUSDOPTS="$MINUSDOPTS,$MYCLIENT"
    MINUSXOPTS="$MINUSXOPTS,DEC"
    MINUSYOPTS="$MINUSYOPTS,60"
    FID=$(fclogerr -e FFDC_ERROR -t ERRID_SP_FFDCEXMPL_ER -i /usr/lpp/ssp/inc/

```

Implementation Specifics

This command is part of the Reliable Scalable Cluster Technology (RSCT) fileset.

fcpushstk Command

Purpose

Records information about failure or noteworthy conditions to the First Failure Data Capture Error Stack.

Syntax

`/opt/rsct/bin/fcpushstk` { [`-a` *assoc_fid*] `-c` *message_catalog_name* `-m` *message_set* `-n` *message_number* [`-o` *message_param* [,*message_param*,...]] `-l` *lpp_name* `-p` *line_of_code_pos* `-r` *resource* `-s` *source_filename* `-v` *sidlevel* {[`-d` *detail_data*] | [`-f` *detail_data_file*]} } *default_message* | `-h`

Description

fcpushstk is used by scripts to record failure information to the FFDC Error Stack. Scripts record descriptive information and debugging data to the FFDC Error Stack for use in later problem determination efforts.

The FFDC Error Stack is used to help understand failure conditions that occur when multiple related processes or threads are executing together on a node to perform a common task. This device is best applied to an application that creates one or more threads or subprocesses, which in turn, may also create threads or subprocesses themselves. To use the FFDC Error Stack, the script establishes an *FFDC Error Stack Environment* using the **fcinit** interface. After this environment is established, the application and any of its descendants can make use of the FFDC Error Stack.

Not all software applications will establish an FFDC Error Stack Environment. However, these applications may be invoked by other applications or scripts that establish FFDC Error Stack Environments. In these cases, the scripts or applications invoking this software may wish to capture the failure information from this software, to analyze it along with other failure information from other software it invokes to discover any relationships or patterns in the failures. For this reason, software that ordinarily would not make use of the FFDC Error Stack under normal operational conditions should at least support the use of the FFDC Error Stack when it is used by any client invoking the software. This is accomplished by *inheriting* the FFDC Error Stack Environment from the parent process through the **fcinit** interface.

fcpushstk records descriptions and details about noteworthy conditions to the FFDC Error Stack. If an *FFDC Error Stack Environment* has not been established by the script, either by creation or inheritance, **fcpushstk** does not record any information and returns control back to the caller. This action permits the script to run in a normal "silent" mode when debugging information is not requested, but also permits the script to support the use of the FFDC Error Stack when debugging information is requested.

Scripts must make explicit calls to **fcpushstk** to record information to the FFDC Error Stack when an FFDC Error Stack Environment is established. Merely establishing the environment is not enough to result in failure data being recorded. The **fclogerr** command will not make any records to the FFDC Error Stack.

To ensure proper identification of the condition and the location at which it was encountered, **fcpushstk** should be called in-line in the script's source code module, invoked as soon as the condition is detected. **fcpushstk** will record source code file name and line of code information to assist in identifying and locating the source code that encountered the condition. **fcpushstk** can be invoked by a subroutine or autoloaded routine to record this information if this is necessary, provided that all location information and necessary failure detail information is made available to this external routine. The external recording routine must record the true location where the incident was detected.

The maximum size of an FFDC Error Stack entry is given by the FC_STACK_MAX definition in the **<rsct/ct_ffdc.h>** header file. FC_STACK_MAX defines a length in bytes. This value should be used only as a rough guide, since this length includes data that will be used by **fcpushstk** to record the detecting file information, description information, and FFDC Failure Identifier information. Any records longer than FC_STACK_MAX bytes will be truncated to fit within the FC_STACK_MAX limit.

Flags

-a
: Specifies an FFDC Failure Identifier for a failure condition reported by software used by this application which causes or influenced the condition being recorded at this time. This identifier should have been returned to this application as part of the software's result indication. The caller provides this identifier here so that the FFDC Error Stack can associate the failure report it is making at this time with the previously recorded failure report. This permits problem investigators to trace the cause

of a failure from its various symptoms in this application and others to the root cause in the other software. If no other software failure is responsible for this condition, or if the other software did not return an FFDC Failure Identifier as part of its result information, the **-a** option should not be provided.

-c

Indicates the name of the XPG/4-compliant message catalog that contains a description of the failure being recorded. This name is relative to the **/usr/lib/nls/msg/$LANG** directory. If the message catalog cannot be found, the *default_message* will be displayed to describe the failure. Note that the *default_message* will not be translated between locales.

-d

A character string that provides detailed information on the condition, similar to the Detail Data concept used by the AIX Error Log. If details of the information are too lengthy, these details can be written to a file, and the name of that file provided as an argument to the **-f** option. The **-d** and **-f** options cannot be specified at the same time. If neither the **-d** or the **-f** options are provided or appear valid, the character string **no detail data** is recorded.

-f

Specifies the name of a file containing details about the condition being reported, similar to the Detail Data concept used by the AIX Error Log. This option is used when the details are too lengthy to record within the FFDC Error Stack itself, or when a utility exists that can analyze the detail information. The contents of this file is copied to the **/var/adm/ffdc/dumps** directory, and the file's new location is recorded as the Detail Data in the FFDC Error Stack. If a file containing details of the condition does not exist, do not specify this option. The **-d** and **-f** options cannot be specified at the same time.

-h

Displays a help message to standard output and exits. No other processing is performed, regardless of the options specified.

-l

Specifies an abbreviation of the name of the licensed program in which this software was shipped. This value should be recognizable to customer and application-support services as an acceptable name for the licensed program (AIX, for example). If this option is not provided or does not appear to be valid, the character string **PPS_PRODUCT** is used.

-m

Specifies the message set containing the message describing the failure in the message catalog file. If this message set cannot be located, the *default_message* will be displayed to describe the failure. Note that **default_message** will not be translated to the user's locale.

-n

Specifies the message number that describes the failure being recorded. If this message cannot be located, the *default_message* will be displayed to describe the failure. Note that *default_message* will not be translated to the user's locale.

-o

Specifies a list of substitution parameters within the message indicated by the **-n** option. **fcpushstk** only supports character strings as substitutional parameters (%s) due to the shell operating environment. If multiple substitutional parameters are provided, each one must be separated by a comma (,). If any of these substitution parameters contain imbedded white space, they must be enclosed in double quotes ("").

-q

Suppresses the generation of warning messages from the command. Warning are generated when the command must substitute default information for missing information, or when the command is unable to copy the *detail_data_file* to the **/var/adm/ffdc/dumps** directory.

-r

Specifies the software component name. This is a symbolic name for the software making the report, and should be a name recognizable to both customer and application-support services.

-p

Specifies the line of code location within the source code module where the condition is being reported. The value provided must be a valid integer value. To allow for proper identification and location of the condition, this value should be as close to the line of code that detected the condition

as possible. Korn Shell scripts can use the value of **$LINENO**. Script languages that do not provide a special line count variable can provide a symbolic value here that a developer can use to locate the spot in the source code where **fcpushstk** is being used. If this option is not valid or not provided, the value of **0** is used.

-s
Specifies the name of the source file containing the line of code that encountered the condition being reported. For Korn and Borne Shell scripts, the argument to this option should be set to **$0**; C Shell scripts would set this argument to ${0}. If this option is not provided or not valid, the character string **unknown_file** is used.

-v
Indicates the SCCS version number of the source code module that detected the condition being recorded. For source code under SCCS control, this should be set to **"1.1"** (the double-quotes are necessary). If this option is not provided or is not valid, the character string **unknown** is used.

Parameters

default_message
Indicates a default message to be used as a description of the failure, when the information cannot be retrieved from the message catalog information supplied through the **-c**, **-m**, and **-n** options. If this string contains positional parameters, all positional parameters must be specified to be character strings (%s). The message should be enclosed in double quotes ("") if it contains any embedded white space. **fcpushstk** limits the overall length of this string to 72 characters.

Exit Status

fcpushstk returns the following exit status codes upon successful completion:

0
FFDC Error Stack Environment exists, and failure information successfully recorded in the FFDC Error Stack. An FFDC Failure Identifier for the record is displayed to standard output. The caller should capture standard output to obtain this value.

2
Help information displayed and processing ended.

fcpushstk returns the following exit status codes when a failure occurs:

11
No information recorded to the FFDC Error Stack, and no FFDC Failure Identifier is provided by this command. The client requested to use an option not supported in this release of the FFDC software

12
No information recorded to the FFDC Error Stack, and no FFDC Failure Identifier is provided by this command. Unknown function parameter provided to the interface.

15
FFDC Error Stack Environment does not exist. No information recorded to the FFDC Error Stack. No FFDC Failure Identifier is generated by this command. This is the normal return code to the FFDC client when an FFDC Error Stack Environment did not exist to be inherited via **fcinit**.

17
No information recorded to the FFDC Error Stack, and no FFDC Failure Identifier is provided by this command. The FFDC Error Stack Environment appears to be corrupted and should be considered unusable.

19
No information recorded to the FFDC Error Stack - the FFDC Error Stack directory does not exist or cannot be used. No FFDC Failure Identifier is provided by this command.

20
No information recorded to the FFDC Error Stack, and no FFDC Failure Identifier is provided by this command. Unable to access the FFDC Error Stack file. The file may have been removed, or permissions on the file or its directory have been changed to prohibit access to the FFDC Error Stack.

22
No information recorded to the FFDC Error Stack - the FFDC Error Stack file could not be locked for exclusive use by this interface. Repeated attempts had been made to lock this file, and all attempts failed. Another process may have locked the file and failed to release it, or the other process may be hung and is preventing other processes from using the FFDC Error Stack. No FFDC Failure Identifier is provided by this command.

24
No information recorded to the FFDC Error Stack, and no FFDC Failure Identifier is provided by this command. The FFDC Error Stack file appears to be corrupted. The client should consider the FFDC Error Stack Environment unusable.

25
No information recorded to the FFDC Error Stack, and no FFDC Failure Identifier is provided by this command. The FFDC Error Stack file name is set to a directory name. The FFDC Error Stack Environment should be considered corrupted and unusable.

32
A dump file could not be copied to the **/var/adm/ffdc/dumps** directory. There is insufficient space in the file system containing the **/var/adm/ffdc** directory. The **fcclear** command should be used to remove unneeded FFDC Error Stacks and dump files, or the system administrator needs to add more space to the file system. No FFDC Failure Identifier is provided by this command.

40
No information recorded to the FFDC Error Stack - information could not be recorded in the FFDC Error Stack. There is insufficient space in the file system containing the **/var/adm/ffdc** directory. The **fcclear** command should be used to remove unneeded FFDC Error Stacks and dump files, or the system administrator needs to add more space to the file system. No FFDC Failure Identifier is provided by this command.

41
No information recorded to the FFDC Error Stack, and no FFDC Failure Identifier is provided by this command. A failure occurred when reading control information from the FFDC Error Stack or writing incident information to the FFDC Error Stack. The client should conclude that the entry was not recorded for this incident.

99
No information recorded to the FFDC Error Stack, and no FFDC Failure Identifier is provided by this command. An unexpected internal failure occurred in the **fc_push_stack** routine.This problem may require the attention of application-support services.

When **fcpushstk** is provided with incomplete information, it substitutes default information for the missing information and attempts to make a record in the FFDC Error Stack. Warnings are generated in these cases, and warning messages are displayed to the standard error device unless the **-q** option has been specified. In cases where more than one warning condition was detected, the command generates an exit status code corresponding to the most severe warning condition it detected. The following exit status codes are returned by **fcpushstk** when warning conditions are detected:

26
Both a detailed data string and a detail data file were provided to this routine. The routine chose the detail data string and ignored the detail data file.

28
The name of the resource detecting the incident was not provided. The default resource name was substituted for the missing resource name.

29
At least one component of the detecting application information—source code file name, source code file version, LPP name, line of code position—was not provided. Default information was substituted for the missing information.

30
No default message was provided to describe the nature of the incident. If the XPG/4 message catalog containing the description message cannot be found, no description for this condition will be displayed by the **fcstkrpt** command.

31
No message was provided to describe the nature of the incident, or a component of the XPG/4 information—catalog file name, message set number, message number—was not provided. No description for this condition can be displayed by the **fcstkrpt** command.

32
The file named in the *detail_data_file* parameter could not be copied to the **/var/adm/ffdc/dumps** directory. The FFDC Error Stack entry cites the original version of this file. Do not discard the original copy of this file.

35
No detailed information was provided for this incident. Later problem analysis may be difficult without these details to indicate specifics on the incident.

37
An FFDC Failure Identifier could not be constructed for the report created by this routine. No FFDC Failure Identifier is provided by this command, but information on the incident was recorded to the FFDC Error Stack.

44
The information provided to this command would have caused an FFDC Error Stack record to exceed the FC_STACK_MAX limit. The record was truncated to allow it to be recorded within the system limits. Important information about the failure may have been lost during the truncation process. Modify the script to provide less information, or to record the information to a detail data file and submit the detail data file name to this command instead.

Examples

To record information about a failure to the FFDC Error Stack when the FFDC Environment is established or inherited by the process:

```
#!/bin/ksh
    :
    :
cp /tmp/workfile $FILENAME
RC=$?
if ((RC != 0))
then
    FFDCID=$(fcpushstk -c mymsg.cat -m2 -n10 -o$FILENAME -r myprog
         -d"cp exit status $RC - file being copied /tmp/workfile" -s$0
         -p$LINENO -v"1.1" -lPSSP "Cannot update configuration file %1$s")
    if (($? == 0))
    then
         fcdispfid $FFDCID
         return 1
    fi
fi
    :
    :
```

To make the same recording from a script language that does not have a line of code variable available:

```
#!/bin/bsh
    :
    :
CODESCTN=14             # Used to identify where in the script code we are
cp /tmp/workfile $FILENAME
RC=$?
if test $RC -ne 0
then
    FFDCID=`fcpushstk -c mymsg.cat -m2 -n10 -o$FILENAME -r myprog
         -d"cp exit status $RC - file being copied /tmp/workfile" -s$0
         -p$CODESCTN -v"1.1" -lPSSP "Cannot update configuration file %1$s"`
    if test $? -eq 0
    then
         fcdispfid $FFDCID
         return 1
    fi
fi
CODESECTION=15              # New code section begins - a different task starts
```

```
    :
    :
```

To record information about a failure condition that is related to another failure condition previously recorded to the FFDC Error Stack by an application exploiting FFDC:

```
#!/bin/ksh
    :
    :
ASSOC_FID=$(/usr/lpp/ssp/bin/somecmd -a -b)
RC=$?if ((RC != 0))
then
    FFDCID=$(fcpushstk -a$ASSOC_FID -c mymsg.cat -m2 -n10 -o$FILENAME -r myprog
         -d"cp exit status $RC - file being copied /tmp/workfile" -s$0
         -p$LINENO -v"1.1" -lPSSP "Cannot update configuration file %1$s")
    if (($? == 0))
    then
         fcdispfid $FFDCID
         return 1
    fi
fi
    :
    :
```

Implementation Specifics

This command is part of the Reliable Scalable Cluster Technology (RSCT) fileset.

fcreport Command

Purpose

Locates and displays the report of a failure and any failures associated with the failure.

Syntax

`/opt/rsct/bin/fcreport { [ -a ] FFDC_Failure_ID } | -h`

Description

fcreport decodes an FFDC Failure Identifier, and obtains reports on the failure identified by it. The command also detects if any failure was associated with the FFDC Failure Identifier, and if so, obtains the report on that failure. The command continues to examine the report of each failure it locates for associated failures and to obtain reports on the associated failures until one of the following conditions is met:

- No further associated failures are detected.
- The report for an associated failure cannot be found. This may occur when the associated failure report resides on a remote node that cannot be reached at the moment, or the record of the failure has been removed from the node where it resided.

Using this command, the user can obtain a report for the entire list of failures that caused a specific failure. **fcreport** is not capable of locating reports for any failures that may have been caused by the initial failure provided to the command; it can only obtain reports of failures that caused this failure.

Flags

-a
: Displays all information contained in a report for a failure. The default is to display the network address of the node where the failure report was generated, the time stamp on the failure report, and the description of the incident recorded in the failure report.

-h
Displays a help message to standard output and exits. No other processing is performed, regardless of the options specified.

Parameters

FFDC_Failure_ID
Specifies the FFDC Failure Identifier of the failure to begin the report. **fcreport** will attempt to obtain the failure information for this failure, as well as any failures that this report lists as an associated failure. Only one FFDC Failure Identifier may be provided to this command.

Security

`fcreport` uses `rsh` to obtain failure reports that may reside on remote nodes. The user must have sufficient privilege to execute `rsh` commands to these remote nodes. If the user does not have this permission, `fcreport` can only trace the list of related failures so long as they exist on the local node.

Exit Status

fcreport generates one of the following exit status codes upon completion:

0
Failure report located and displayed for the FFDC Failure Identifier provided. Zero or more related failure reports may have been located and displayed as well.

2
Help information displayed and processing ended.

10
Required options or arguments are not provided.

11
The FFDC Failure Identifier provided to this command was generated by a later release of the FFDC software. The command is not capable of correctly interpreting this identifier.

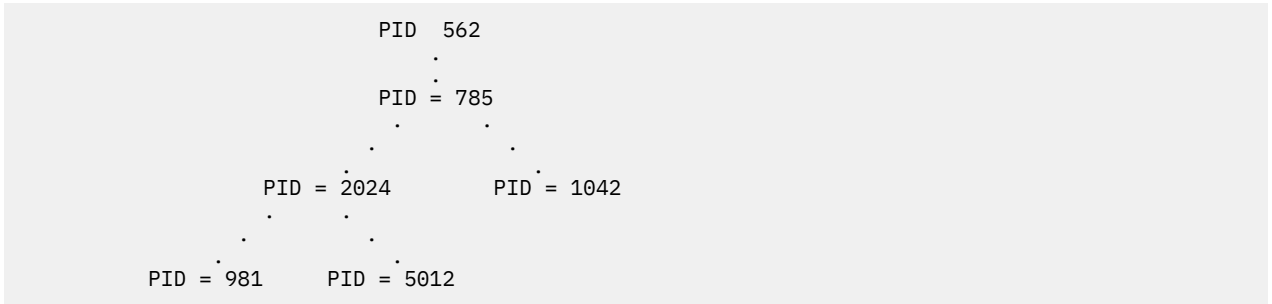
12
Unknown option specified to this command.

20
The FFDC Failure Identifier refers to an entry made in an FFDC Error Stack on this system, but the FFDC Error Stack file cannot be accessed. The file may have been removed, or permissions may have been altered on the file to prevent access to it.

27
The FFDC Failure Identifier provided to this command is not a valid identifier.

Examples

Consider the case where several processes were created in the following parent-child order:



In this example, process 785 generated the FFDC Failure Identifier `.3Iv04ZVVfvp.wtY0xRXQ7.....` and passed it back to Process 562. To obtain

a detailed report for FFDC Failure Identifier `.3Iv04ZVVfvp.wtY0xRXQ7....................` and any previous failures that led to this specific failure:

```
$ fcreport -a .3Iv04ZVVfvp.wtY0xRXQ7...................
```

This report will contain the details of the specified FFDC Failure Identifier, as well as any failures in processes 2024, 1042, 981, and 5012 that may have caused it. The report will not contain any failures in process 562 that may have been caused as a result of process 785's failure.

Implementation Specifics

This command is part of the Reliable Scalable Cluster Technology (RSCT) fileset.

fcstat Command

Purpose

Displays statistics gathered by the specified Fibre Channel device driver.

Syntax

`fcstat` [**-z** [**-d** | **-c**] | **-d** | **-e** [**-d** | **-c**] | **-c**] *Device_Name*

Description

The `fcstat` command displays the statistics gathered by the specified Fibre Channel device driver. You can optionally specify that the device-specific statistics are displayed in addition to the device-generic statistics. If you specify no flags, the `fcstat` command displays only the device-generic statistics. The `fcstat` command collects the statistics by using the following procedure:

1. Opens the message catalog of `fcstat` and checks the parameter list.
2. Accesses the Object Data Manager (ODM) database for information relating to the selected adapter.
3. Accesses the ODM database for information relating to ports of the selected adapter.
4. Opens and accesses adapter statistics.
5. Resets some of the statistics if you specify the **-z** flag.
6. Reports statistics and exits.

If an invalid *Device_Name* is specified, the `fcstat` command returns an error message stating that it cannot find the device in the ODM database.

The **fcstat** command also reports the statistics if the specified *Device_Name* is not connected to a network (that is, the link is down), by opening the device in diagnostic mode by using the **-d** flag. When the link is down and the device is opened in non-diagnostic mode, the **fcstat** command delays in generating the output. You can use the **-c** flag to remove this delay. If the device is already opened and the **fcstat** command is started with the **–d** flag, the open operation on the device fails with an EACCESS error.

When the `fcstat` command is not able to extract statistics from the specified *Device_Name*, it still reports the information that it extracted from the ODM database.

Flags

Item	Description
-c	Removes the delay in generating the output when the device is opened in non-diagnostic mode and the link is down.

Item	Description
-d	Displays the statistics by opening the adapter in diagnostic mode.
-e	Displays all the statistics, which includes the device-specific statistics (driver statistics, link statistics, and FC4 types).
-z	Resets some of the statistics back to their initial values. Only privileged users can issue this flag.

Parameters

Item	Description
Device_Name	The name of the Fibre Channel device. For example, `fcs0`.

Statistics fields

Note: Some adapters might not support a specific statistic. The value of non-supported statistic fields is always 0. All the parameters marked with the asterisk (*) are reset to their initial values when you use the **fcstat** command with the **–z** flag.

The statistic fields displayed in the output of the `fcstat` command and their descriptions follow:

	Item	Description
	`Device Type`	Displays the description of the adapter.
	`Serial Number`	Displays the serial number from the adapter.
	`Option ROM Version`	Displays the version of the Options ROM on the adapter.
	`ZA`	Displays the ZA field from the VPD of the adapter.
	`Node WWN`	Displays the worldwide name of the adapter.
	`Port FC ID`	Displays the SCSI ID of the adapter.
	`Port Type`	Displays the connection type of the adapter.
	`Port Speed`	Displays the speed of the adapter.
	`Port WWN`	Displays the worldwide name of the port.
	`Seconds Since Last Reset`	Displays the seconds since last reset of the statistics on the adapter.
*	`Frames`	Displays the number of frames transmitted and received.
*	`Words`	Displays the number of words transmitted and received.
*	`LIP Count`	Displays the LIP count.
*	`NOS Count`	Displays the NOS count.
	`Error Frames`	Displays the number of frames that were in error.
*	`Dumped Frames`	Displays the frames that were dumped.
	`Link Failure Count`	Displays the Link Failure Count.
	`Loss of Sync Count`	Displays the number of times Sync was lost.

	Item	Description
	Loss of Signal	Displays the number of times signal was lost.
	Primitive Seq Protocol Err Count	Displays the number of times a primitive sequence was in error.
	Invalid Tx Word Count	Displays the number of invalid transfers that occurred.
	Invalid CRC Count	Displays the number of CRC errors that occurred.
	FC SCSI Adapter Driver Information: No DMA Resource Count	Displays the number of times DMA resources were not available.
	FC SCSI Adapter Driver Information: No Adapter Elements Count	Displays the number of times there were no adapter elements available.
	FC SCSI Adapter Driver Information: No Command Resource Count	Displays the number of times there were no command resources available.
*	FC SCSI Traffic Statistics: Input Requests	Displays the number of input requests.
*	FC SCSI Traffic Statistics: Output Requests	Displays the number of output requests.
*	FC SCSI Traffic Statistics: Control Requests	Displays the number of control requests.
*	FC SCSI Traffic Statistics: Input Bytes	Displays the number of input bytes.
*	FC SCSI Traffic Statistics: Output Bytes	Displays the number of output bytes.
	Adapter Effective Max Transfer Value	Displays the effective max transfer value.
	FC4 Types: Supported ULP	Displays the supported ULP.
	FC4 Types: Active ULP	Displays the active ULP.

Exit Status

Item	Description
0	The command completed successfully.
>0	An error occurred.

Examples

1. To display the statistics for Fibre Channel device driver fcs0, enter:

```
fcstat fcs0
```

Output similar to the following is displayed.

Note: The output format of various AIX commands is not always static. Do not write programs with the expectation that the output for the fcstat command remains as follows.

```
FIBRE CHANNEL STATISTICS REPORT: fcs0

    Device Type: FC Adapter (df1000f9)
```

```

Location

`/usr/sbin/fcstat`

fcstkrpt Command

Purpose

Displays the contents of an FFDC Error Stack file.

Syntax

`/opt/rsct/bin/fcstkrpt` { [`-a`] [`-p` | `-r`] { `-f` *FFDC_Failure_Identifier* [`-i`] | `-s` *FFDC_Error_Stack_File_Name* } } | [`-h`]

Description

fcstkrpt reads an existing FFDC Error Stack file and displays its contents to the standard output device. The FFDC Error Stack file is indicated either through the name of the file itself, or by using an FFDC Failure Identifier that references a specific record within that file.

Information from the FFDC Error Stack can be displayed in one of two formats: by *related failure conditions* (the default) or by *software layer*.

Flags

-a
Indicates that all information be displayed for entries in the FFDC Error Stack. The default action is to display the time stamp for the record and the description of the incident.

-f
Specifies the FFDC Failure Identifier to use in locating the FFDC Error Stack. **fcstkrpt** decodes the FFDC Failure Identifier, locates the FFDC Error Stack associated with that FFDC Failure Identifier, and processes the FFDC Error Stack. Only one FFDC Failure Identifier can be specified by this flag.

-h
Displays a help message to standard output and exits. No other processing is performed regardless of the options specified.

-i
Displays only the information associated with the specific failure report identified by the **-f** flag. By default, all records in the FFDC Error Stack are displayed.

-p
Displays information from the FFDC Error Stack by process orientation. The output is ordered so that it reflects the order in which the processes were created (parent-child process relationship). Child process information is shown first, followed by parent process information. This view is used to understand which incidents occurred first, and which incidents occurred later because of them.

-r
Displays information from the FFDC Error Stack by incident relationships. Incidents are presented along with those incidents that are related to them. This view is used to understand which incidents occurred because of the occurrence of other incidents. This is the default.

-s
Specifies the name of the FFDC Error Stack to be examined. This name may be either the absolute or relative path name of the FFDC Error Stack. Only one FFDC Error Stack file name can be specified by this flag. If a relative file name is used, the file is assumed to be located in the **/var/adm/ffdc/stacks** directory of the node where the file resides.

Parameters

FFDC_Failure_ID
Specifies the FFDC Failure Identifier of the failure to begin the report. **fcreport** will attempt to obtain the failure information for this failure, as well as any failures that this report lists as an associated failure. Only one FFDC Failure Identifier may be provided to this command.

Security

`fcreport` uses `rsh` to obtain failure reports that may reside on remote nodes. The user must have sufficient privilege to execute `rsh` commands to these remote nodes. If the user does not have this permission, `fcreport` can only trace the list of related failures so long as they exist on the local node.

Exit Status

fcstkrpt issues the following integer exit status codes upon completion:

0
FFDC Error Stack file successfully located, and contents displayed to the standard output device.

2
Help information displayed and processing ended.

12
An invalid option was specified.

14
No information written to the standard output device. The **-f** option was used and the *FFDC Error Identifier* argument was not valid.

20
No information written to the standard output device. The **-s** option was used and the *FFDC Error Stack File* argument was not found.

27
No information written to the standard output device. The caller provided a valid *FFDC Failure Identifier*, but the file referenced by the FFDC Failure Identifier was not recorded on this node. Use the **fcdecode** command to locate the node where this FFDC Error Stack resides.

81
No information written to the standard output device. A failure occurred while writing information to standard output. The application should conclude that standard output cannot accept output.

85
No information written to the standard output device. The caller provided a valid FFDC Failure Identifier, but the file referenced by the FFDC Failure Identifier does not exist.

Examples

To obtain a brief report of the information stored in the FFDC Error Stack file **/var/adm/ffdc/stacks/myprog.562.19981001143052**:

```
$ fcstkrpt -r -s myprog.562.19981001143052
```

To obtain a detailed report of the information contained in the FFDC Error Stack where the FFDC Failure Identifier **.3Iv04ZVVfvp.wtY0xRXQ7.....** was recorded, and present this information in parent-child ordering:

```
$ fcstkrpt -p -f .3Iv04ZVVfvp.wtY0xRXQ7...................
```

Implementation Specifics

This command is part of the Reliable Scalable Cluster Technology (RSCT) fileset.

fcteststk Command

Purpose

Test for the presence of a First Failure Data Capture Error Stack environment.

Syntax

`/opt/rsct/bin/fcteststk [-q] | [-h]`

Description

fcteststk can be called by any application program that wishes to use the FFDC Error Stack to test if these facilities have been activated . By performing this test, applications can avoid the performance burden of collecting failure information in cases where an *FFDC Environment* has not been established. This interface is provided primarily for use by library routines, which would not have any knowledge of whether their client application established or inherited an *FFDC Environment*.

An *FFDC Error Stack Environment* is established by a process when that process wants to have failure information from itself, any threads it may create, and any descendant processes it may create to be recorded in an FFDC Error Stack. An *FFDC Error Stack Environment* is inherited by a process when that process wants to record failure information to an FFDC Error Stack file only when one of its ancestors has

requested for processes to do so; in all other cases, the process will not record failure information to the FFDC Error Stack. Processes use **fcinit** to either establish or inherit the FFDC Error Stack Environment.

The FFDC Error Stack Environment reserves an FFDC Error Stack file, so that failure information is recorded to a file in the **/var/adm/ffdc/stacks** directory. These files use the naming format ***script_name.PID.date_and_time***, where *script_name* is the name of the script itself, *PID* is the process identifier of the script, and *date_and_time* is the date and time when the script was executed. Whenever this script or children processes of this script record failure information to the FFDC Error Stack, it will be recorded in this file.

Applications use the **fcpushstk** interface to record failure information to the FFDC Error Stack. However, the application may need to collect this information from various locations before recording the information, and obtaining this information can impact the application's overall performance. The application should not need to collect this information if the *FFDC Error Stack Environment* was not established or inherited. To avoid this performance impact, the application can issue **fcteststk** to determine if an *FFDC Error Stack Environment* is available, and if so, begin collecting the failure information. If the *FFDC Error Stack Environment* does not exist, the application can avoid collecting this information.

Processes that use the **fclogerr** FFDC interface can use **fclogerr** when an *FFDC Environment* exists, whether or not an FFDC Error Stack is in use by the *FFDC Environment*. Whenever **fclogerr** is used, failure information is recorded to the AIX Error Log and the BSD System Log, regardless of whether an FFDC Error Stack was reserved. Any application that records information using the **fclogerr** interface must *always* collect the failure information and record it, regardless of whether an FFDC Error Stack is in use.

Flags

Item	Description
`-h`	Displays a usage message for this command. No further processing is performed.
`-q`	Suppresses output from this command that explains whether or not an FFDC Environment was established. The command user will be required to test the exit status from the command to determine whether an FFDC Environment is established for this process.

Parameters

FFDC_Failure_ID

Specifies the FFDC Failure Identifier of the failure to begin the report. **fcreport** will attempt to obtain the failure information for this failure, as well as any failures that this report lists as an associated failure. Only one FFDC Failure Identifier may be provided to this command.

Security

`fcreport` uses `rsh` to obtain failure reports that may reside on remote nodes. The user must have sufficient privilege to execute `rsh` commands to these remote nodes. If the user does not have this permission, `fcreport` can only trace the list of related failures so long as they exist on the local node.

Exit Status

0

An FFDC Error Stack Environment exists.

2

Help information displayed and processing ended.

12

No processing performed. An invalid option was specified.

15

FFDC Error Stack Environment has not been established or inherited by the client at this point in time.

17
FFDC Error Stack Environment appears to be corrupted and should be considered unusable.

Examples

To test whether an FFDC Error Stack Environment exists for an application:

```
fcteststk -q
if (($? == 0))
then
    # Collect failure information
          :
          :
    # Use fcpushstk to record failure info
          :
          :
fi
```

Implementation Specifics

This command is part of the Reliable Scalable Cluster Technology (RSCT) fileset.

fddistat Command

Purpose

Shows FDDI device driver and device statistics.

Syntax

fddistat [**-r** **-t**] *Device_Name*

Description

The **fddistat** command displays the statistics gathered by the specified FDDI device driver. If no flags are specified, only the device driver statistics are displayed. This command is also invoked when the **netstat** command is run with the **-v** flag. The **netstat** command does not issue any **fddistat** command flags.

If an invalid *Device_Name* is specified, the **fddistat** command will produce an error message stating that it could not connect to the device.

Flags

Item	Description
-r	Resets all the statistics back to their initial values. This flag can only be issued by privileged users.
-t	Toggles debug trace in some device drivers.

Parameter

Item	Description
Device_Name	The name of the FDDI device, for example, **fddi0**.

Statistic Fields

Note: Some adapters may not support a specific statistic. The value of non-supported statistic fields is always 0.

The statistic fields displayed in the output of the **fddistat** command and their descriptions are:

Title Fields

Item	Description
Elapsed Time	Displays the real time period has elapsed since last time the statistics was reset. Since part of the statistics may be reset by the device driver during error recovery when a hardware error was detected, there will be another Elapsed Time displayed in the middle of the output when this situation has occurred in order to reflect the time differences between the statistics.

Transmit Statistics Fields

Item	Description
Packets	The number of packets transmitted successfully by the device.
Bytes	The number of bytes transmitted successfully by the device.
Interrupt	The number of transmit interrupts received by the driver from the adapter.
Transmit Errors	The number of output errors encountered on this device. This is a counter for unsuccessful transmissions due to hardware/network errors.
Packets Dropped	The number of packets accepted by the device driver for transmission which were not (for any reason) given to the device.
Max Packets on S/W Transmit Queue	The maximum number of outgoing packets ever queued to the software transmit queue.
S/W Transmit Queue Overflow	The number of outgoing packets overflowed the software transmit queue.
Current S/W+H/W Transmit Queue Length	The number of pending outgoing packets on either the software transmit queue or the hardware transmit queue.
Broadcast Packets	The number of broadcast packets has been transmitted without any error.
Multicast Packets	The number of multicast packets has been transmitted without any error.

Receive Statistics Fields

Item	Description
Packets	The number of packets has been received successfully by the device.
Bytes	The number of bytes received successfully by the device.
Interrupts	The number of receive interrupts received by the driver from the adapter.

Item	Description
Receive Errors	The number of input errors encountered on this device. This is a counter for unsuccessful reception due to hardware/network errors.
Packets Dropped	The number of packets received by the device driver from this device which were not (for any reason) given to a network demuxer.
Bad Packets	The number of bad packets received (i.e.saved) by the device driver.
Broadcast Packets	The number of broadcast packets received without any error.
Multicast Packets	The number of multicast packets received without any error.

General Statistics Fields

Item	Description
No mbuf Errors	The number of times that mbufs were not available to the device driver. This usually occurs during receive operations when the driver must obtain mbuf buffers to process inbound packets. If the mbuf pool for the requested size is empty, the packet will be discarded. The **netstat -m** command can be used to confirm this.
SMT Error Word	The adapter's SMT error status.
SMT Event Word	The adapter's SMT event status.
Connection Policy Violation	The status of the adapter's connection to the ring.
Port Event	The adapter's port status.
Set Count	The current set count value.
Adapter Check Code	The adapter's most recent adapter check status.
Purged Frames	Receive frames dropped by the adapter due to lack of available descriptors.
ECM State Machine	Entity Coordination Management State Machine.
PCM State Machine: Port A	Physical Connection Management for the primary adapter State Machine
PCM State Machine: Port B	Physical Connection Management for the secondary adapter State Machine
CFM State Machine: Port A	Configuration Management for the primary adapter State Machine
CFM State Machine: Port B	Configuration Management for the secondary adapter State Machine
CF State Machine	Overall Configuration State Machine.
MAC CFM State Machine	Configuration Management for the MAC State Machine.
RMT State Machine	Ring Management State Machine.
Driver Flags	The device driver internal status flags that are currently turned on.

Example

To display the device driver statistics for **fddi0**, enter:

```
fddistat fddi0
```

This produces the following output:

```
------------------------------------------------------------
FDDI STATISTICS (fddi0) :
Elapsed Time: 0 days 0 hours 1 minutes 3 seconds
```

```
Transmit Statistics:                          Receive Statistics:
--------------------                          -------------------
Packets: 100                                  Packets: 100
Bytes: 113800                                 Bytes: 104700
Interrupts: 100                               Interrupts: 100
Transmit Errors: 0                            Receive Errors: 0
Packets Dropped: 0                            Packets Dropped: 0
Max Packets on S/W Transmit Queue: 0          Bad Packets: 0
S/W Transmit Queue Overflow: 0
Current S/W+H/W Transmit Queue Length: 0
```

```
Broadcast Packets: 0                          Broadcast Packets: 0
Multicast Packets: 0                          Multicast Packets: 0
```

```
General Statistics:
-------------------
No mbuf Errors: 0
SMT Error Word: 00040080                      SMT Event Word: 000004a0
Connection Policy Violation: 0000             Port Event: 0000
Set Count Hi: 0000                            Set Count Lo: 0003
Adapter Check Code: 0000                      Purged Frames: 0
```

```
ECM State Machine:        IN
PCM State Machine Port A: CONNECT
PCM State Machine Port B: ACTIVE
CFM State Machine Port A: ISOLATED
CFM State Machine Port B: CONCATENATED
CF State Machine:         C_WRAP_B
MAC CFM State Machine:    PRIMARY
RMT State Machine:        RING_OP
```

```
Driver Flags: Up Broadcast Running
        Simplex DualAttachStation
```

fdformat Command

Purpose

The **fdformat** command formats diskettes.

Syntax

fdformat [*Device*] [**-h**]

Description

Attention: Formatting a diskette or read/write optical disk destroys any existing data on it.

The **fdformat** command formats diskettes in the diskette drive specified for low density unless the **-h** flag is specified.

All new, blank diskettes must be formatted before they can be used.

Before formatting a diskette or read/write optical disk, the **fdformat** command prompts for verification. This allows you to end the operation cleanly.

Flags

Item	Description
-h	Forces high-density formatting. This flag is used only with the **fdformat** command.

Parameters

Item	Description
Device	Specifies the device containing the diskette to be formatted. The default is the **/dev/rfd0** device for drive 0.

Examples

To force high-density formatting of a diskette when using the **fdformat** command, enter:

```
fdformat -h
```

Files

Item	Description
/usr/sbin/fdformat	Contains the **fdformat** command.
/dev/rfd*	Specifies the device parameters.
/dev/fd*	Specifies the device parameters.
/dev/romd*	Specifies the device parameters.
/dev/omd*	Specifies the device parameters.

fdpr Command

Item	Description
-analyse_asm_csects	Analyze csects written in assembly (when used, must be specified at both the -1 and -3 phases).
-extra_safe_analysis	Do not attempt to analyze unconventional csects containing hand-written assembly code (when used, must be specified at both the -1 and -3 phases).
-ignore_info	Ignore **.info** sections produced with the **-qfdpr** option during compile time (when used, must be specified at both -1 and -3 phases).
-align *bytes*	Align frequently executed code according to given number of bytes, for improving code prefetch buffer ratio. If this option is omitted, the **fdpr** command aligns the code with variable default number of bytes.
-lr_opt	Eliminate stores and restores of the link register in frequently executed procedures.
-bt_csect_anchor_removal	Eliminate load instructions related to the usage of branch tables in the code.
-dead_code_removal	Remove unreachable code.

Item	Description
-selective_inline	Perform selective inlining for functions that are frequently called from a single dominant call site.
-sid_fac *percent*	Set a dominant factor percentage for selective inline optimization. The allowed range is between 50 - 100 (applicable only with the **-selective_inline** flag).
-inline_small_funcs *size*	Inline all functions that are smaller or equal to the given size in bytes.
-inline_hot_funcs *percent*	Inline all functions with an execution frequency equals or greater than the given percentage. The input percent range is between 0 - 100.
-inline	Perform **-inline_small_funcs 12** with **-selective_inline**.
-hco_resched	Relocate instructions from frequently executed code to rarely executed code area, when possible.
-dcbt_opt	Insert **dcbt** instructions to improve data-cache performance.
-killed_regs	Eliminate stores and restores of registers that are *killed* (overwritten) after frequently executed function calls.
-tb	Force the restructuring of traceback tables in reordered code. If **-tb** option is omitted, traceback tables are automatically restored for C++ applications using Try & Catch mechanism.
-pc	Preserve csects' boundaries in reordered code.
-pp	Preserve functions' boundaries in reordered code.
-RD	Perform static data reordering.
-dpnf *factor*	Data Placement Normalization Factor between 0 - 1; where 0 causes static variables to be reordered regardless of their size, whereas 1 will locate only small sized variables first (applicable only with the **-RD** flag).
-dpht *threshold*	Data Placement Hotness Threshold between 0 - 1; where 0 reorders the static variables in large groups based on the control flow, and whereas 1 will reorder the variables in very small groups based on their access frequency (applicable only with the **-RD** flag).
-build_dcg	Build DCG (Data Connectivity Graph) for enhanced data reordering (applicable only with the **-RD** flag).
-tocload	Perform tocload optimization.
-reduce_toc *removal_factor*	Perform TOC entries removal accordingly to removal factor between 0 - 1, where 0 removes only non-accessed TOC entries and 1 removes all non-exported TOC entries.
-strip	Strip the output file (if any is produced).
-ptrgl_opt	Perform optimization of indirect call instructions by way of registers by replacing them with direct jumps.
-no_ptrgl_r11	Do not perform removal of R11 load instruction in _ptrgl csect (the **-ptrgl_r11** optimization is applied by default).
-O	Perform code reordering with branch prediction bit setting, branch folding and NOOP instructions removal. The **-O** flag is applied by default.
-O2	Switch on all less aggressive optimization flags.

Item	Description
-O3	Switch on all aggressive optimization flags.
-O4	Switch on all aggressive optimization flags.

Purpose

A performance tuning utility for improving execution time and real memory utilization of user-level post-link application programs.

Syntax

Most Common Usage:

fdpr -p *ProgramFile* **-x** *WorkloadCommand*

Detailed Usage:

fdpr -p *ProgramFile* [**-M** *SegNum*] [**-fd** *Fdesc*] [**-o** *OutputFile*] [**-armember** *ArchiveMemberList*] [OptimizationFlags] [**-map**] [**-disasm**] [**-disasm_data**] [**-disasm_bss**] [**-profcount**] [**-quiet**] [**-v**] [**-1 | -2** | **-3 | -12** | **-23 | -123**] [**-x** *WorkloadCommand*]

Optimization Flags

[**-tb**] [**-pc**] [**-pp**] [**-O**][**-O2**] [**-O3**] [**-O4**] [**-selective_inline**] [**-sid_fac** *percent*] [**-inline_small_funcs** *size*] [**-inline_hot_funcs** *percent*] [**-hco_resched**] [**-killed_regs**] [**-lr_opt**] [**-align** *bytes*] [**-RD**] [**-dpnf** *factor*] [**-dpht** *threshold*] [**-build_dcg**] [**-tocload**] [**-ptrgl_opt**] [**-no_ptrgl_r11**] [**-dcbt_opt**] [**-ignore_info**] [**-dead_code_removal**] [**-bt_csect_anchor_removal**] [**-strip**] [**-analyse_asm_csects**] [**-extra_safe_analysis**] [**-inline**] [**-reduce_toc** *removal_factor*]

Description

The **fdpr** command (Feedback Directed Program Restructuring) is a performance-tuning utility that may help improve the execution time and the real memory utilization of user-level application programs. The **fdpr** program optimizes the executable image of a program by collecting information on the behavior of the program while the program is used for some typical workload, and then creating a new version of the program that is optimized for that workload. The new program generated by **fdpr** typically runs faster and uses less real memory.

Attention: The **fdpr** command applies advanced optimization techniques to a program which may result in programs that do not behave as expected; programs which are optimized using this tool should be used with due caution and should be rigorously retested with, at a minimum, the same test suite used to test the original program in order to verify expected functionality. The optimized program is not supported.

The **fdpr** command builds an optimized executable program in 3 distinct phases:

- Phase 1 (**-1** flag): Creates an instrumented executable program and an empty template profile file.
- Phase 2 (**-2** flag): Runs the instrumented program and updates the profile data.
- Phase 3 (**-3** flag): Generates the optimized executable program file.

These phases can be run separately or in partial or full combination, but must be run in order (i.e., **-1** then **-2** then **-3** or **-12** then **-3**). The default is to run all three phases.

Note: The instrumented executable, created in phase 1 and run in phase 2, typically runs several times slower than the original program. Due to the increased execution time required by the instrumented program, the executable should be invoked in such a way as to minimize execution duration, while still fully exercising the desired code areas. The **fdpr** command user should also attempt to eliminate, where feasible, any time dependent aspects of the program.

Flags

Item	Description
-1,**-2**, **-3**	Specifies the phase to run. The default is all 3 phases (**-123**). The **-s** flag must be used when running separate phases so that the succeeding phases can access the required intermediate files. The phases must be run in order (for example, **-1**, then **-2**, then **-3**, or **-1**, then **-23**). The **-2** flag must be used along with the invocation flag **-x**.
-M *SegNum*	Specifies where to map shared memory for profiling. The default is **0x30000000**. Specify an alternate shared memory address if the program to be optimized or any of the workload command strings invoked with the **-x** flag use conflicting shared-memory addresses. Typical alternative values are **0x40000000**, **0x50000000**, ... up to **0xC0000000**).
-fd *Fdesc*	Specifies which file descriptor number is to be used for the **profile** file that is mapped to the above shared memory area. The default of *Fdesc* is set to 1999.
-o *OutFile*	Specifies the name of the output file from the optimizer. The default is *program***.fdpr**
-p *ProgramFile*	Contains the name of the executable program file or shared object file or shared library containing shared objects/executables, to optimize. This program must be an unstripped executable.
-armember *ArchiveMemberList*	List of archive members to be optimized, within a shared archive file specified by the **-p** flag. If **-armember** is not specified, all members of the archive file are optimized.
-map	Print a map of basic blocks and static variables with their respective old -> new addresses into a suffixed **.mapper** file.
-disasm	Prints the disassembled text section of the output optimized and instrumented program into a suffixed **.dis_text** file.
-disasm_data	Prints the disassembled data section of the output optimized and instrumented program into a suffixed **.dis_data** file.
-disasm_bss	Prints the disassembled bss section of the output optimized and instrumented program into a suffixed **.dis_bss** file.
-profcount	Prints the profiling counters into a suffixed **.ncounts** file.
-quiet	Quiet output mode.
-v	Verbose output.
-x *WorkloadCommand*	Specifies the command used for invoking the instrumented program. All the arguments after the **-x** flag are used for the invocation. Therefore, the **-x** flag must appear last in the command line. The **-x** flag is required when the **-2** flag is used.

Optimization Flags

Optimization

The **fdpr** command performs, by default, the highest possible level of code reordering optimization together with the optimizations of branch prediction bit setting, branch folding, code alignment and removal of redundant NOOP instructions. The **-pc** flag reorders the entire code while preserving csects' boundaries and therefore, may result in less performance improvement than the default code reordering. Similarly, the **-pp** flag reorders the entire code while preserving procedures' boundaries.

Additional optimizations performed on the entire executable program file are available by the optimization flags above.

Executables built with the **-qfdpr** IBM xl compiler flag contain information to assist **fdpr** in producing reordered programs. Modules which are not compiled with the **-qfdpr** option, are reordered based on the compiler signatures in the symbol table.

Additional performance enhancements may be realized by using static linking when building the program to be reordered. Since the **fdpr** program only reorders the instructions within the executable program specified, any dynamically linked shared library routines called by the program are not optimized. Statically linking these library routines to the executable allows for optimizing both the instructions in the program and all library routines used by the program. There are other advantages as well as disadvantages to building a statically linked program.

Output Files

All files created by the **fdpr** command are stored in the current directory with the exception of any files which may be created by running the workload command specified in the **-x** flag. During the optimization process, the original program is saved by renaming the program, and is only restored to the original program name upon successful completion of the final phase.

The profile file created by the **fdpr** command explicitly uses the full name of the current directory since scripts used to run the program may change the working directory before executing the program.

The files created and/or used by the **fdpr** command are:

Item	Description
program	Name of the unstripped executable to be optimized.
program.**save**	Saved version of the original executable program.
program.**nprof**	Name of the profile file.
program.**instr**	Name of the instrumented version of program.
program.**fdpr**	Default name of optimized executable output file.
program.**instr.dis_text**	Default disassembly file in ASCII format produced by **-disasm** flag after instrumentation phase.
program.**fdpr.dis_text**	Default disassembly file in ASCII format produced by **-disasm** flag after optimization phase.
program.**instr.dis_data**	Default disassembly file in ASCII format produced by **-disasm_data** flag after instrumentation phase.
program.**fdpr.dis_data**	Default disassembly file in ASCII format produced by **-disasm_data** flag after optimization phase.
program.**instr.dis_bss**	Default disassembly file in ASCII format produced by **-disasm_bss** flag after instrumentation phase.
program.**fdpr.dis_bss**	Default disassembly file in ASCII format produced by **-disasm_bss** flag after optimization phase.
program.**instr.mapper**	Default mapping file in ASCII format produced by **-map** flag after instrumentation phase.
program.**fdpr.mapper**	Default mapping file in ASCII format produced by **-map** flag after optimization phase.
program.**ncounts**	Default profile counters file in ASCII format produced by **-profcount** flag.

Enhanced Debugging Capabilities

In order to enable a certain degree of debugging capability for optimized programs, **FDPR** updates the Symbol Table to reflect the changes that were made in the **.text** section.

Entry fields in the Symbol Table that specify addresses of symbols that were relocated during the reordering of **FDPR**, are modified to point to their new addresses in the **.text** section.

In addition, in the case where functions or files are split during reordering, **FDPR** creates new entries in the Symbol Table for each new part of the split function/file. These new parts of the same function are given new symbol names in the Symbol Table according to the following naming convention:

```
<original function name>__fdpr_<function's part number>
```

After code reordering all the new entries are suffixed with the `__fdpr_` string.

Example: Originally, function "main" had the following entry in the Symbol Table:

```
   [Index] m   Value       Scn     Aux   Sclass    Type    Name
    [456]  m  0x00000230    2       1     0x02    0x0000   .main
```

If after code reordering, function `main` was split into 3 parts, then it would have 3 entries in the Symbol Table; one for each part as follows:

```
   [Index] m   Value       Scn     Aux   Sclass    Type    Name
    [456]  m  0x00000304    2       1     0x02    0x0000   .main
   [1447]  m  0x00003328    2       1     0x02    0x0000   .main__fdpr_1
   [1453]  m  0x000033b4    2       1     0x02    0x0000   .main__fdpr_2
```

Examples

The following are typical usage examples of the **fdpr** command.

1. This example allows the user to run all three phases. In this example, `test1` is the unstripped executable and `test2` is a shell script that invokes `test1`. The current working directory is **/tmp/fdpr**.

   ```
   test2 script file:

   # code to exercise test1
   test1 -expand 100 -root $PATH file.jpg -quit
   # the end of test2
   ```

   Execute the **fdpr** command (using the default optimization):

   ```
   fdpr -p test1 -x test2
   ```

   This results in the new reordered executable **test1.fdpr**.

2. To run one phase at a time, execute phase one of **fdpr**.

   ```
   fdpr -1 -p test1
   ```

   This command string creates an instrumented version with the name `test1.instr` and the empty template profile file `test1.nprof`.

   To execute phase two:

   ```
   fdpr -2 -p test1 -x test2
   ```

   This command string executes the script file `test2` that runs the instrumented version of `test1` to collect the profile data.

   To execute phase three:

   ```
   fdpr -3 -p test1
   ```

   Again, this results in the new reordered executable **test1.fdpr**.

3. To run the first two phases followed by phase three, execute phase one and two.

   ```
   fdpr -12 -p test1 -x test2
   ```

Execute phase three using optimization level three.

```
fdpr -3 -O3 -p test1
```

4. If an error occurs while running an **fdpr** optimized program, the **dbx** command can be used to determine what procedure the error occurred in as follows:

   ```
   dbx program.fdpr
   ```

   which produces the output similar to the following:

   ```
   Type 'help' for help.
   reading symbolic information ...warning: no source compiled with -g

   [using memory image in core]

   Segmentation fault in proc_d at 0x10000634
   0x10000634 (???) 98640000        stb   r3,0x0(r4)
   (dbx)
   ```

   A stack traceback, which is used to determine how the program arrived at the current location, is produced as follows:

   ```
   (dbx) where
   ```

   which produces the following output:

   ```
   proc_d(0x0) at 0x10000634
   proc_c(0x0) at 0x10000604
   proc_b(0x0) at 0x100005d0
   proc_a(0x0) at 0x1000059c
   main(0x2, 0x2ff7fba4) at 0x1000055c
   (dbx)
   ```

5. The **dbx** subcommand **stepi** may also be used to single step through the instructions of a reordered executable program as follows:

   ```
   (dbx) stepi
   ```

   which produces the following output:

   ```
   stopped in proc_d at 0x1000061c
   0x1000061c (???) 9421ffc0       stwu   r1,-64(r1)
   (dbx)
   ```

   In this example, **dbx** indicates that the program stopped in routine `proc_d` at address `0x1000061c` in the reordered text section.

Implementation Specifics

Software Product/Option: *AIX Performance Aide/ Local Performance Analysis & Control Commands*.

Standards Compliance: None.

Files

Item	Description
/usr/bin/fdpr	Contains the **fdpr** command.
program	Name of the unstripped executable to be optimized.
*program***.save**	Saved version of the original executable program.
*program***.nprof**	Name of the profile file.
*program***.instr**	Name of the instrumented version of program.

Item	Description
program.**fdpr**	Default name of optimized executable output file.
program.**instr.dis_text**	Default disassembly file in ASCII format produced by **-disasm** flag after instrumentation phase.
program.**fdpr.dis_text**	Default disassembly file in ASCII format produced by **-disasm** flag after optimization phase.
program.**instr.dis_data**	Default disassembly file in ASCII format produced by **-disasm_data** flag after instrumentation phase.
program.**fdpr.dis_data**	Default disassembly file in ASCII format produced by **-disasm_data** flag after optimization phase.
program.**instr.dis_bss**	Default disassembly file in ASCII format produced by **-disasm_bss** flag after instrumentation phase.
program.**fdpr.dis_bss**	Default disassembly file in ASCII format produced by **-disasm_bss** flag after optimization phase.
program.**instr.mapper**	Default mapping file in ASCII format produced by **-map** flag after instrumentation phase.
program.**fdpr.mapper**	Default mapping file in ASCII format produced by **-map** flag after optimization phase.
program.**ncounts**	Default profile counters file in ASCII format produced by **-profcount** flag.

fencevsd Command

Purpose

Prevents an application running on a node or group of nodes from accessing a virtual shared disk or group of virtual shared disks.

Syntax

`fencevsd` {`-a` | `-v` *vsd_name_list*} `-n` *node_list*

Description

Under some circumstances, the system may believe a node has stopped functioning and begin recovery procedures, when the node is actually operational, but cut off from communication with other nodes running the same application. In this case, the problem node must not be allowed to serve requests for the virtual shared disks it normally serves until recovery is complete and the other nodes running the application recognize the problem node as operational. The `fencevsd` command prevents the problem node from filling requests for its virtual shared disks.

This command can be run from any node in the RSCT peer domain where the recoverable virtual shared disk subsystem is running.

Flags

-a
Specifies all virtual shared disks.

-v *vsd_name_list*
Specifies one or more virtual shared disk names, separated by commas.

-n ***node_list***
Specifies one or more node numbers, separated by commas.

Parameters

logical_volume_name
Is the name of the logical volume you want to specify as a virtual shared disk. This logical volume must reside on the global volume group indicated. The length of the name must be less than or equal to 15 characters.

global_group_name
Is the name of the globally-accessible volume group previously defined by the **vsdvg** command where you want to specify a virtual shared disk. The length of the name must be less than or equal to 31 characters.

vsd_name
Specifies a unique name for the new virtual shared disk. This name must be unique within the RSCT peer domain, and, in order to avoid possible future naming conflicts, should also be unique across the overall cluster. The suggested naming convention is **vsdnn***gvg_name*. The length of the name must be less than or equal to 31 characters.

Note: If you specify a *vsd_name* that is already the name of another device, the **cfgvsd** command will be unsuccessful for that virtual shared disk. This error ensures that the special device files created for the name do not overlay and destroy files of the same name representing some other device type (such as a logical volume).

Security

You must have `root` authority to run this command.

Restrictions

You must issue this command from a node in the peer domain that has an active recoverable virtual shared disk subsystem.

Examples

To fence the virtual shared disks vsd1 and vsd2 from node 5, enter:

```
fencevsd -v vsd1,vsd2 -n 5
```

Location

/opt/rsct/vsd/bin/fencevsd

ff Command

Purpose

Lists the file names and statistics for a file system.

Syntax

ff [**-a** *Number*] [**-c** *Number*] [**-I**] [**-l**] [**-m** *Number*] [**-n** *File*] [**-o** *Options*] [**-p** *Prefix*] [**-s**] [**-u**] [**-V** *VFSName*] [**-i** *I-Number* [**,***I-Number ...*]] [*FileSystem* | *DeviceName*]

Description

The **ff** command reads the i-nodes in the file system specified by the *FileSystem* parameter and then writes information about them to standard output. It assumes the *FileSystem* is a file system, which is referenced in the **/etc/filesystems** file, and saves i-node data for files specified by flags.

The output from the **ff** command consists of the path name for each requested i-node number, in addition to other file information that you can request using the flags. The output is listed in order by i-node number, with tabs between all fields. The default line produced by the **ff** command includes the path name and i-node number fields. With all flags enabled, the output fields include path name, i-node number, size, and UID (user ID).

The *Number* parameter is a decimal number that specifies a number of days. It is prefixed by a + or - (plus or minus sign). Therefore, +3 means more than 3 days, -3 means less than 3 days, and 3 means 3 days, where a day is defined as a 24-hour period.

The **ff** command lists only a single path name out of many possible ones for an i-node with more than one link, unless you specify the **-l** flag. With the **-l** flag, the **ff** command lists all links.

Flags

Item	Description
-a *Number*	Displays the file if it has been accessed within the number of days specified by the *Number* parameter.
-c *Number*	Displays the file if its i-node has been changed within the number of days specified by the *Number* parameter.
-i *I-Number*	Displays the files corresponding to the i-node numbers specified by the *I-Number* parameter. The i-node numbers listed must be separated by a comma.
-I	(This flag is an uppercase i.) Does not display the i-node after each path name.

Item	Description
-l	(This flag is a lowercase L.) Additionally displays a list of pathnames for files with more than one link.
-m *Number*	Displays the file if it has been modified within the number of days specified by the *Number* parameter.
-n *File*	Displays the file if it has been modified more recently than the file specified by the *File* parameter.
-o *Options*	Specifies a comma-separated list of implementation-specific options for a virtual file system. The following options are specific to the enhanced journaled file system (JFS2): **-o snapshot=***snapName* Specifies the name of the internal snapshot subject to the **ff** command. The file system owning the snapshot must be mounted.
-p *Prefix*	Adds the prefix specified by the *Prefix* parameter to each path name. The default prefix is **.** (dot).
-s	Writes the file size, in bytes, after each path name.
-u	Writes the owner's login name after each path name.
-V *VFSName*	Instructs the **ff** command to assume the file system is of type *VFSName*, overriding the value in the **/etc/filesystems** file.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To list the path names of all files in a given file system, enter:

   ```
   ff    -I    /dev/hd0
   ```

   This displays the path names of the files on the /dev/hd0 device. If you do not specify the **-I** flag, the **ff** command also displays the i-node number of each file.
2. To list files that have been modified recently, enter:

   ```
   ff    -m    -2    -u    /dev/hd0
   ```

   This displays the path name, i-node number, and owner's user name (the -u flag) of each file on the /dev/hd0 device that has been modified within the last two days (-m -2).
3. To list files that have *not* been used recently, enter:

   ```
   ff    -a    +30    /dev/hd0
   ```

   This displays the path name and i-node of each file that was last accessed more than 30 days ago (-a +30).
4. To find out the paths corresponding to certain i-node numbers, enter:

   ```
   ff    -l    -i    451,76    /dev/hd0
   ```

   This displays all the path names (-l) associated with i-nodes 451 and 76.

Files

Item	Description
/etc/vfs	Contains descriptions of virtual file system types.
/etc/filesystems	Lists the known file systems and defines their characteristics.

fg Command

Purpose

Runs jobs in the foreground.

Syntax

fg [*JobID*]

Description

If job control is enabled, the **fg** command moves a background job in the current environment into the foreground. Use the *JobID* parameter to indicate a specific job to be run in the foreground. If this parameter is not supplied, the **fg** command uses the job most recently suspended, placed in the background, or run as a background job.

The *JobID* parameter can be a process ID number, or you can use one of the following symbol combinations:

Item	Description
%*Number*	Refers to a job by the job number.
%*String*	Refers to a job whose name begins with the specified string.
%?*String*	Refers to a job whose name contains the specified string.
%+ OR **%%**	Refers to the current job.
%-	Refers to the previous job.

Using the **fg** command to place a job into the foreground removes the job's process ID from the list of those known by the current shell environment.

The **/usr/bin/fg** command does not work when operating in its own command execution environment, because that environment does not have applicable jobs to manipulate. For this reason, the **fg** command is implemented as a Korn shell or POSIX shell regular built-in command.

Exit Status

The following exit values are returned:

Item	Description
0	Successful completion.
>0	An error occurred.

If job control is disabled, the **fg** command exits with an error, and no job is placed in the foreground.

Examples

If the output of the **jobs -l** command shows the following job running in the background:

```
[1] + 16477RunningSleep 100 &
```

use the process ID to run the `sleep 100 &` command in the foreground by entering:

```
fg 16477
```

The screen displays:

```
sleep
```

Files

Item	Description
/usr/bin/ksh	Contains the Korn shell **fg** built-in command.
/usr/bin/fg	Contains the **fg** command.

fgrep Command

Purpose

Searches a file for a literal string.

Syntax

fgrep [**-h**] [**-i**] [**-s**] [**-u**] [**-v**] [**-w**] [**-x**] [**-y**] [[**-b**] [**-n**] | [**-c** | **-l** | **-q**]] [**-p** *Separator*] {*Pattern* | **-e** *Pattern* | **-f** *StringFile*} [*File...*]

Description

The **fgrep** command searches the input files specified by the *File* parameter (standard input by default) for lines that match a pattern. The **fgrep** command searches specifically for *Pattern* parameters that are fixed strings. The **fgrep** command displays the file that contains the matched line if you specify more than one file in the *File* parameter.

The **fgrep** command differs from the **grep** and **egrep** commands because it searches for a string instead of searching for a pattern that matches an expression. The **fgrep** command uses a fast and compact algorithm. The $, *, [, |, (,), and \ characters are interpreted literally by the **fgrep** command. These characters are not interpreted as parts of a regular expression, as they are interpreted in the **grep** and **egrep** command. Since these characters have special meaning to the shell, the entire string must be enclosed in single quotation mark ('...'). If no files are specified, the **fgrep** command assumes standard input. Normally, each line found is copied to the standard output. The file name is printed before each line found if there is more than one input file.

Notes:

1. The **fgrep** command is the same as the **grep** command with the **-F** flag, except that error and usage messages are different and the **-s** flag functions differently.
2. Lines are limited to 2048 bytes.
3. Paragraphs (under the **-p** flag) are currently limited to a length of 5000 characters.
4. Do not run the **grep** command on a special file because it produces unpredictable results.
5. Input lines must not contain the NULL character.
6. Input files must end with the new line character.
7. Although some flags can be specified simultaneously, some flags override others. For example, if you specify **-l** and **-n** together, only file names are written to standard output.

Flags

Flag	Description
-b	Precedes each line by the block number on which it was found. Use this flag to help find disk block numbers by context. The **-b** flag cannot be used with input from stdin or pipes.
-c	Displays only a count of matching lines.
-e *Pattern*	Specifies a pattern. It works like a simple pattern but is useful when the pattern begins with a **-** (minus sign).
-f *StringFile*	Specifies a file that contains strings. **Note:** To enhance the performance of the **fgrep** (or **grep -F**) command with input as a file that contains search patterns, export the **ENABLE_FGREP_AC** environment variable before you run the **fgrep** command. For example, you can run the following command to export this environment variable: `export ENABLE_FGREP_AC=""`
-h	Suppresses file names when multiple files are processed.
-i	Ignores the case of letters when comparing.
-l	Lists just the names of files (once) with matching lines. Each file name is separated by a new line character.

Flag	Description
-n	Precedes each line with its relative line number in the file.
-p *Separator*	Displays the entire paragraph that contains matched lines. Paragraphs are delimited by paragraph separators, as specified by the *Separator* parameter, which are patterns in the same form as the search pattern. Lines containing the paragraph separators are used only as separators; they are never included in the output. The default paragraph separator is a blank line.
-q	Suppresses all writing to standard output, regardless of matching lines. Exits with a 0 status if an input line is selected.
-s	Displays only error messages. It is useful for checking status.
-u	Causes output to be unbuffered.
-v	Displays all lines except those lines that match the specified pattern.
-w	Searches a word.
-x	Displays lines that match the pattern exactly with no additional characters.
-y	Ignores the case of letters when comparing.

Exit Status

This command returns the following exit values:

Item	Description
0	A match was found.
1	No match was found.
>1	A syntax error was found or a file was inaccessible (even if matches were found).

Examples

1. To search several files for a simple string of characters:

   ```
   fgrep strcpy *.c
   ```

   This searches for the string `strcpy` in all files in the current directory with names that end in the `.c` character string.

2. To count the number of lines that match a pattern:

   ```
   fgrep -c "{" pgm.c
   fgrep -c "}" pgm.c
   ```

   It displays the number of lines in `pgm.c` that contain left and right braces.

   If you do not put more than one { (left brace) or one } (right brace) on a line in your C programs, and if the braces are properly balanced, the two numbers displayed are usually the same if the proper conditions are met. If the numbers are not the same, you can display the lines that contain braces in the order that they occur in the file with:

   ```
   egrep {\|} pgm.c
   ```

3. To display the names of files that contain a pattern:

   ```
   fgrep -l strcpy *.c
   ```

   It searches the files in the current directory that end with `.c` and displays the names of those files that contain the `strcpy` string.

Files

File	Description
/usr/bin/fgrep	Contains the **fgrep** command.
/bin/fgrep	Symbolic link to the **fgrep** command.

file Command

Purpose

Determines the file type.

Syntax

To Classify the File Type

file [**-m** *MagicFile*] [**-d**] [**-h**] [**-i**] [**-M** *MagicFile*] [**-f** *FileList*] [*File...*]

To Check the Magic File for Format Errors

file -c [**-m** *MagicFile*]

Description

The **file** command reads the files specified by the *File* parameter or the *FileList* variable, performs a series of tests on each file, and attempts to classify them by type. The command then writes the file types to standard output. The file can be regular file, directory, FIFO(named pipe), block special, character special, symbolic link or sockets type.

- If it is a regular file and of zero length, it is identified as an empty file.
- If the file is a symbolic link, by default, the link is followed by file the symbolic link refers to.

If a file appears to be in ASCII format, the **file** command examines the first 1024 bytes and determines the file type. If a file does not appear to be in ASCII format, the **file** command further attempts to distinguish a binary data file from a text file that contains extended characters.

If the *File* parameter specifies an executable or object module file and the version number is greater than 0, the **file** command displays the version stamp. The **ld** command explains the use of **a.out** files.

If the language environment is the C programming language, the **file** command uses the **/etc/magic** file to identify files that have some sort of a magic number; that is, any file containing a numeric or string constant that indicates type.

However, if the language environment is some language other than the C programming language, the **file** command uses the **/usr/lib/nls/msg/<*language_env.*>/magic.cat** file to identify files with a magic number.

If the file does not exist, cannot be read or its file status could not be determined then, it is not considered as an error that affects the exit status. The output indicates that the file was processed but the type could not be determined.

When the **-i** flag is used, the following format shall be used to identify each operand, *file* specified:

```
"%s: %s\n", file, type
```

The values for *type* are unspecified except that in the POSIX locale, if *file* is identified as one of the types listed in the following table, *type* shall contain (but is not limited to) the corresponding string. Each space shown in the strings shall be exactly one *space*.

Table 5. File Utility Output Strings	
If *file* is a:	***type* shall contain the string:**
Directoy	directory
FIFO	fifo
Socket	socket
Block special	block special
Character special	character special
Executable binary	executable
Empty regular file	empty
Symbolic link	symbolic link to
ar archive library	archive
Extended *cpio* format	cpio archive
Extended *tar* format	tar archive
Shell script	commands text
C-language source	c program text
FORTRAN source	fortran program text

If *file* is identified as a symbolic link, the following alternative output format shall be used:

```
"%s: %s %s\n", file, type, contents of link"
```

If the file named by the *file* operand does not exist or cannot be read, the string `cannot open` shall be included as part of the *type* field, but this shall not be considered an error that affects the exit status. If the type of the file named by the *file* operand cannot be determined, the string `data` shall be included as part of the *type* field, but this shall not be considered an error that affects the exit status.

Flags

Item	Description
-c	Checks the specified magic file (the **/etc/magic** file, by default) for format errors. This validation is not normally done. File typing is not done under this flag.
-d	Applies any default system tests to the file.
-f *FileList*	Reads the specified file list. The file must list one file per line and must not contain leading or trailing spaces.
-h	When a symbolic link is encountered, identifies the file as a symbolic link. If the **-h** flag is not specified and *file* is a symbolic link that refers to a nonexistent file, *file* shall identify the file as a symbolic link, as if the **-h** flag had been specified.
-i	If a file is a regular file, does not attempt to classify the type of the file further, but identifies the file as specified in “Description” on page 1372.
-m *MagicFile*	Specifies the file name of the magic file (the **/etc/magic** file, by default).
-M *MagicFile*	Specifies the name of a file containing tests that shall be applied to a file in order to classify it. No default system tests shall be applied.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To display the type of information a file contains, enter:

   ```
   file myfile
   ```

   This displays the file type of *myfile* (such as directory, data, ASCII text, C-program source, and archive).
2. To display the type of each file named in a list of file names, enter:

   ```
   file -f filenames
   ```

   This displays the type of each file named in the `filenames` list. Each file name must appear alone on a line.

Note: To get customized messages from the **file** command, use a separate magic file with the **-m** option. It is not advisable to edit the read-only **/etc/magic** file.

Files

Item	Description
/usr/bin/file	Contains the **file** command.
/etc/magic	Contains the file type database.

filemon Command

Purpose

Monitors the performance of the file system, and reports the I/O activity on behalf of logical files, virtual memory segments, logical volumes, and physical volumes.

Syntax

filemon [**-d**] [**-i** *Trace_File* **-n** *Gensyms_File*] [**-o** *File*] [**-O** ***Levels***] [**-w**] [**-I** ***count:interval***] [**-P**] [**-T** *n*] [**-u**] [**-v**] [**-@** [*WparList* | **ALL**] [**-r** *RootString*] [**-A** **-x** *User_Command*]

Description

The **filemon** command monitors a trace of file system and I/O system events, and reports on the file and I/O access performance during that period.

In its normal mode, the **filemon** command runs in the background while one or more application programs or system commands are being run and monitored. The **filemon** command automatically starts and monitors a trace of the program file system and I/O events in real time. By default, the trace is started immediately; optionally, tracing might be deferred until you issue a **trcon** command. You can issue the **trcoff** and **trcon** commands while the **filemon** command is running to turn the monitoring off and on, as required. When tracing is stopped by a **trcstop** command, the **filemon** command generates an I/O activity report and exits.

The **filemon** command can also process a trace file that is previously recorded by the trace facility. The file and I/O activity report are based on the events recorded in that file.

To provide a complete understanding of file system performance for an application, the **filemon** command monitors file and I/O activity at four levels:

Item	Description
Logical file system	The **filemon** command monitors logical I/O operations on logical files. The monitored operations include all **read**, **write**, **open**, and **lseek** system calls, which might or might not result in actual physical I/O, depending on whether the files are already buffered in memory. I/O statistics are kept on a per-file basis. Calls to Asynchronous I/O system calls are not monitored by the `filemon` command, so the `filemon` logical file report does not include asynchronous I/O (AIO) requests.
Virtual memory system	The **filemon** command monitors physical I/O operations (that is, paging) between segments and their images on disk. I/O statistics are kept on a per-segment basis.
Logical volumes	The **filemon** command monitors I/O operations on logical volumes. I/O statistics are kept on a per-logical-volume basis.
Physical volumes	The **filemon** command monitors I/O operations on physical volumes. At this level, physical resource utilizations are obtained. I/O statistics are kept on a per-physical-volume basis.

Any combination of the four levels can be monitored, as specified by the command-line flags. By default, the **filemon** command only monitors I/O operations at the virtual memory, logical volume, and physical volume levels. These levels are all concerned with requests for real disk I/O.

The **filemon** command also generates a hotness report on the files, logical volumes, and physical volumes. The hotness report can be generated by using **–O** hot option. This report is supported only in automated offline and manual offline modes. Hotness report contains statistics of I/O operations of files, logical volumes, and physical volumes. This report helps you decide which files or logical volumes to move to any drive, with a different I/O characteristic based on the hotness of the file/logical volume. The hotness is determined based on number of read operations, average number of bytes read per read operation, number of read sequences and the average sequence length.

The **filemon** command writes its report to standard output or to a specified file. By default the report contains a summary of the I/O activity for each of the levels being monitored. Detailed report is printed only if the **-O detailed** flag is enabled. The summary and detailed report contents are described in the Reports section.

Notes:

1. The reports produced by the **filemon** command can be long. Consequently, the **-o** option is to be used to write the report to an output file. When a physical device is opened and accessed directly by an application, only reads and writes of complete 512-byte blocks are reflected in the report. “Short” reads and writes, used by the device driver to issue device commands and read device status, are ignored. CD-ROMs do not have concentric “tracks” or “cylinders,” as in hard files. (There is one spiral track.) Consequently, it is not possible to report distance statistics for CD-ROMs in terms of cylinders.
2. The **-u** flag is used to generate reports on files opened before the start of the **trace** daemon. Some of this data can be useful, but much of it applies to daemons and other unrelated activity. This background information can be overwhelming, especially on large systems. If the **/unix** file and the running kernel are not the same, then the kernel addresses are incorrect, causing the **filemon** command to exit. When using the **filemon** command from within a shell script, view the contents of the **filemon** output file after a slight delay. The **filemon** command might take a few seconds to produce this report.
3. When you specify relative paths in an I/O process program to read or write a file, the **filemon** command interprets this relative path as the directory from where the **filemon** command was run.

In such cases, the I/O activity report might not display the correct volume information (i-node) for that file. To avoid this problem, use the complete path in all the I/O process programs.

4. The **filemon** command does not support the solid state drive (SSD) disks. Hence, the **filemon** command does not report statistics of the SSD disks.

System Trace Facility

The **filemon** command obtains raw I/O performance data using the system trace facility. Currently, the trace facility only supports one output stream. Consequently, only one **filemon** or trace process can be active at a time. If another **filemon** or trace process is already running, the **filemon** command responds with the message:

```
/dev/systrace: Device busy
```

While monitoring the I/O-intensive applications, the **filemon** command might not be able to consume trace events as fast as they are produced in real time. When that happens, the error message:

```
Trace kernel buffers overflowed, N missed entries
```

is displayed on `stderr`, indicating how many trace events were lost while the trace buffers were full. The **filemon** command continues monitoring the I/O activity, but the accuracy of the report is diminished to some unknown degree. One way to prevent overflow is to monitor fewer levels of the file and I/O subsystems: the number of trace events generated is proportional to the number of levels monitored. Additionally, the trace buffer size can be increased using the **-T** option, to accommodate larger bursts of trace events before overflow. Remember that increasing the trace buffer size results in more pinned memory, and therefore might affect I/O and paging behavior.

In memory-constrained environments (where demand for memory exceeds supply), the **-P** option can be used to pin the text and data pages of the real-time **filemon** process in memory so the pages cannot be swapped out. If the **-P** option is not used, letting the **filemon** process to be swapped out, the progress of the **filemon** command might be delayed to the point where it cannot process trace events fast enough. This situation leads to trace buffer overflow as described previously. Consequently, pinning this process takes memory away from the application (although the **filemon** command is not a large program, its process image can consume up to 500KB).

The **-i** *Trace_File* and **-n** *Gensyms_File* flags let offline processing by **filemon** of trace data files created by the **trace** command. Both flags must be supplied if either is present. These flags are useful when it is necessary to postprocess a trace file from a remote machine or perform the trace data collection at one time and postprocess it at another time. The flags are also useful when system load is high and trace hooks are being missed by **filemon**. You can use these flags for automated offline mode.

The **-r** *RootString* flag deprecates the **-i** *Trace_File* flag and the **-n** *Gensyms_File* flag. Apart from using the **-r** *RootString* flag for offline processing, the same can be used along with the **-A** flag which enables automated offline mode.

The **gensyms** file (containing file system information) must be used from the machine that the trace came from. Also, it is wise to run **gensyms** at close to the same time that the system trace file is created, so that the system configuration is the same for both.

Trace hooks relevant to **filemon** must be collected by the **trace** command and are specified by the **trace -j** flag. The relevant trace hooks are listed when **filemon** is started with the **-v** flag. The **gensyms** command with **-F** option is then run, with its output saved in *Gensyms_File* to collect additional information for **filemon**. The **-F** option is used with the gensyms command to collect the device information for physical and logical volumes. It is also used to get the virtual file system information used by offline **filemon**. Then this file and the *Gensyms_File* might be provided to **filemon**.

Reports

Each report generated by the **filemon** command has a header that identifies the date, the machine ID, and the length of the monitoring period, in seconds. The processor utilization during the monitoring period is also reported.

Next, summary reports are generated for each of the file system levels being monitored. By default, the logical file and virtual memory reports are limited to the 20 most active files and segments, as measured by the total amount of data transferred. If the **-v** flag is specified, activity for all files and segments is reported. There is one row for each reported file, segment, or volume. The columns in each row for the four summary reports are described in the following lists:

Most Active Files Report

Column	Description
#MBS	Total number of megabytes transferred to or from file. The rows are sorted by this field, in decreasing order.
#opns	Number of times the file was opened during measurement period.
#rds	Number of read system calls made against file.
#wrs	Number of write system calls made against file.
file	Name of file (full path name is in detailed report).
volume:inode	Name of volume that contains the file, and the i-node number of the file. This field can be used to associate a file with its corresponding persistent segment, shown in the virtual memory I/O reports. This field might be blank; for example, for temporary files created and deleted during execution.

Most Active Segments Report

Item	Description
Column	**Description**
#MBS	Total number of megabytes transferred to/from segment. The rows are sorted by this field, in decreasing order.
#rpgs	Number of 4096-byte pages read into segment from disk (that is, page).
#wpgs	Number of 4096-byte pages written from segment to disk (page out).
segid	Internal ID of segment.
segtype	Type of segment: working segment, persistent segment (local file), client segment (remote file), page table segment, system segment, or special persistent segments containing file system data (log, root directory, .inode, .inodemap, .inodex, .inodexmap, .indirect, .diskmap).
volume:inode	For persistent segments, name of volume that contains the associated file, and the i-node number of the file. This field can be used to associate a persistent segment with its corresponding file, shown in the file I/O reports. This field is blank for non-persistent segments. **Note:** The virtual memory analysis tool, **svmon** can be used to display more information about a segment, given its segment ID (segid), as follows: `svmon -S <segid>`

Most Active Logical Volumes Report

Item	Description
Column	**Description**
util	Utilization of the volume (fraction of time busy). The rows are sorted by this field, in decreasing order.
#rblk	Number of 512-byte blocks read from the volume.
#wblk	Number of 512-byte blocks written to the volume.
KB/sec	Total transfer throughput, in Kilobytes per second.
volume	Name of volume.
description	Contents of volume: either a file system name, or logical volume type (paging, jfslog, boot, or sysdump). Also, indicates whether the file system is fragmented or compressed.

Most Active Physical Volumes Report

Item	Description
Column	**Description**
util	Utilization of the volume (fraction of time busy). The rows are sorted by this field, in decreasing order.
#rblk	Number of 512-byte blocks read from the volume.
#wblk	Number of 512-byte blocks written to the volume.
KB/sec	Total volume throughput, in Kilobytes per second.
volume	Name of volume.
description	Type of volume, for example, 120MB disk, 355MB SCSI, or CDROM SCSI. **Note:** Logical volume I/O requests start before, and end after, physical volume I/O requests. For that reason, total logical volume utilization appears to be higher than total physical volume utilization.

Most Active Files Process-Wise Report

Item	Description
Column	**Description**
#MBS	Total number of megabytes transferred to or from the file. The rows are sorted by this field, in decreasing order.
#opns	Number of times the file was opened during measurement period.
#rds	Number of read system calls made against file.
#wrs	Number of write system calls made against file.
file	Name of file (full path name is in detailed report).
PID	ID of the process which opened the file.
Process	Name of the process which opened the file.
TID	ID of the thread which opened the file.

Most Active Files Thread-Wise Report

Item	Description
Column	**Description**

Item	Description
#MBS	Total number of megabytes transferred to or from the file. The rows are sorted by this field, in decreasing order.
#opns	Number of times the file was opened during measurement period.
#rds	Number of read system calls made against file.
#wrs	Number of write system calls made against file.
file	Name of file (full path name is in detailed report).
TID	ID of the thread which opened the file.
Process	Name of the process which opened the file.
PID	ID of the process which opened the file.

Finally, detailed reports are generated for each of the file system levels being monitored. By default, the logical file and virtual memory reports are limited to the 20 most active files and segments, as measured by the total amount of data transferred. If the **-v** flag is specified, activity for all files and segments is reported. There is one entry for each reported file, segment, or volume.

Some of the fields report a single value, others report statistics that characterize a distribution of many values. For example, response time statistics are kept for all read or write requests that were monitored. The average, minimum, and maximum response times and the standard deviation of the response times are reported. The standard deviation is used to show how much the individual response times deviated from the average. Roughly two-thirds of the sampled response times are between `average - standard deviation` and `average + standard deviation`. If the distribution of response times is scattered over a large range, the standard deviation will be large compared to the average response time. The four detailed reports are described in the following lists:

Detailed File Statistics Report

Item	Description
Column	**Description**
FILE	Name of the file. The full path name is given, if possible.
volume	Name of the logical volume/file system containing the file.
inode	I-node number for the file within its file system.
opens	Number of times the file was opened while monitored.
total bytes xfrd	Total number of bytes read/written to/from the file.
reads	Number of read calls against the file.
read sizes (bytes)	The read transfer-size statistics (avg/min/max/sdev), in bytes.
read times (msec)	The read response-time statistics (avg/min/max/sdev), in milliseconds.
writes	Number of write calls against the file.
write sizes (bytes)	The write transfer-size statistics.
write times (msec)	The write response-time statistics.
seeks	Number of **lseek** subroutine calls.

Detailed VM Segment Statistics Report

Item	Description
Column	**Description**

Item	Description
SEGMENT	Internal segment ID.
segtype	Type of segment contents.
segment flags	Various segment attributes.
volume	For persistent segments, the name of the logical volume containing the corresponding file.
inode	For persistent segments, the i-node number for the corresponding file.
reads	Number of 4096-byte pages read into the segment (that is, paged in).
read times (msec)	The read response-time statistics (avg/min/max/sdev), in milliseconds.
read sequences	Number of read sequences. A sequence is a string of pages that are read (paged in) consecutively. The number of read sequences is an indicator of the amount of sequential access.
read seq. lengths	Statistics describing the lengths of the read sequences, in pages.
writes	Number of pages written from the segment (that is, paged out).
write times (msec)	Write response time statistics.
write sequences	Number of write sequences. A sequence is a string of pages that are written (paged out) consecutively.
write seq.lengths	Statistics describing the lengths of the write sequences, in pages.

Detailed Logical/Physical Volume Statistics Reports

Item	Description
Column	**Description**
VOLUME	Name of the volume.
description	Description of the volume. (Describes contents, if dealing with a logical volume; describes type, if dealing with a physical volume.)
reads	Number of read requests made against the volume.
read sizes (blks)	The read transfer-size statistics (avg/min/max/sdev), in units of 512-byte blocks.
read times (msec)	The read response-time statistics (avg/min/max/sdev), in milliseconds.
read sequences	Number of read sequences. A sequence is a string of 512-byte blocks that are read consecutively and indicate the amount of sequential access.
read seq. lengths	Statistics describing the lengths of the read sequences, in blocks.
writes	Number of write requests made against the volume.
write sizes (blks)	The write transfer-size statistics.
write times (msec)	The write-response time statistics.
write sequences	Number of write sequences. A sequence is a string of 512-byte blocks that are written consecutively.
write seq. lengths	Statistics describing the lengths of the write sequences, in blocks.
seeks	Number of seeks that preceded a read or write request; also expressed as a percentage of the total reads and writes that required seeks.

Item	Description
seek dist (blks)	Seek distance statistics, in units of 512-byte blocks. In addition to the usual statistics (avg/min/max/sdev), the distance of the initial seek operation (assuming block 0 was the starting position) is reported separately. This seek distance is sometimes large, so it is reported separately to avoid skewing the other statistics.
seek dist (cyls)	(Hard files only.) Seek distance statistics, in units of disk cylinders.
time to next req	Statistics (avg/min/max/sdev) describing the length of time, in milliseconds, between consecutive read or write requests to the volume. This column indicates the rate at which the volume is being accessed.
throughput	Total volume throughput, in Kilobytes per second.
utilization	Fraction of time the volume was busy. The entries in this report are sorted by this field, in decreasing order.

Detailed Process-wise Statistics Report

Item	Description
Column	**Description**
Process Id	ID of the process which opened the file.
Name	Name of the file opened including the path.
Thread Id	ID of the thread which opened the file.
Total Bytes	Total number of bytes read or written.
# of seeks	Number of seeks.
# of reads	Number of read operations.
read errors	Number of read errors.
# of writes	Number of write operations.
Bytes Read	Number of bytes read. **min** Minimum number of bytes read at a time. **avr** Average number of bytes read at a time. **max** Maximum number of bytes read at a time.
Bytes Written	Number of bytes written. **min** Minimum number of bytes written at a time. **avr** Average number of bytes written at a time. **max** Maximum number of bytes written at a time.
Read Time	Time spent in read operations.
Write Time	Time spent in write operations.

Detailed Thread-wise Statistics Report

Item	Description
Column	**Description**
Thread Id	ID of the thread which opened the file.
Name	Name of the file opened including the path.
Process Id	ID of the thread which opened the file.
Total Bytes	Total number of bytes read or written.
# of seeks	Number of seeks.
# of reads	Number of read operations.
read errors	Number of read errors.
# of writes	Number of write operations.
Bytes Read	Number of bytes read. **min** Minimum number of bytes read at a time. **avr** Average number of bytes read at a time. **max** Maximum number of bytes read at a time.
Bytes Written	Number of bytes written. **min** Minimum number of bytes written at a time. **avr** Average number of bytes written at a time. **max** Maximum number of bytes written at a time.
Read Time	Time spent in read operations.
Write Time	Time spent in write operations.

Collated Report Format

Item	Description
ID	**process** ID of the process which did read or write operation. **thread** ID of the thread which did read or write operation. **CPU** ID of the CPU in which read or write operation was performed.
transaction type	Type of transaction: SCSI, SSA, and so on.
time	**bstart event** Time at which the **bstart** event was started. **iodone event** Time at which the I/O operation was completed. **duration** Total time duration of the I/O operation.

Item	Description
read/write	Type of operation: read or write.
physical block address	Physical block address.
access pattern	Type of access: pattern, sequential, or random.
physical block size	Physical block size.
volume name or address	**physical** Physical volume name or address. **logical** Logical volume name or address.
Transaction index	Unique ID to identify the transaction.
time	**event** Time at which the event started. **extend** Time at which the event extended.
ID	**process** ID of the process which performed the transaction. **thread** ID of the thread which performed the transaction. **CPU** ID of the CPU in which the transaction was performed.
protocol stage	Displays the breakup of the events.
name	Name of device, buffer, or block; or byte count.
address/count	Address or byte count of device, buffer, or block.
access pattern	Type of access pattern: sequential or random.
label	Volume types or transfer flags.
values	Volume names or flag values.

Hotness Report

The hotness report consists of three sections: information section, summary section, and hotness reports section. The information section contains the system model, the **filemon** command used, and the **trace** command used. The summary section contains: total number of read or write operations, total time taken, total data read or written, and the CPU utilization.

Hot files report

Item	Description
Column	**Description**
Name	Name of the file.
Size	Size of the file. The default unit is MB. The default unit is overridden by the unit specified by **–O** unit option.

Item	Description
CAP_ACC	Capacity accessed. This value is the unique data accessed in the file. The default unit is MB. The default unit is overridden by the unit specified by **–O** unit option.
IOP/#	Number of I/O operations per unit of data accessed. The unit of data is taken from **–O** unit option. The default is MB. Examples of value for this column are 2560/T, 256/G, 0.256/M, 0.000/K. The letters K, M, G and T stand for KB, MB, GB, and TB.
LV	Name of logical volume the file belongs to. If this information cannot be obtained, a **"-"** is reported.
#ROP	Total number of read operations happened on the file.
#WOP	Total number of write operations happened on that file.
B/ROP	<minimum, average, maximum> number of bytes read per read operation.
B/WOP	<minimum, average, maximum> number of bytes read per write operation.
RTIME	<minimum, average, maximum> time taken per read operation in milliseconds.
WTIME	<minimum, average, maximum> time taken per write operation in milliseconds.
Seqlen	<minimum, average, maximum> length of read sequences.
#Seq	Number of read sequences. A sequence is a string of 4K pages that are read (paged in) consecutively. The number of read sequences is an indicator of the amount of sequential access.

Hot Logical Volumes Report

Item	Description
Column	**Description**
Name	Name of the logical file.
Size	Size of the logical volume. The default unit is MB. The default unit is overridden by the unit specified by –O unit option. If this value cannot be obtained, a “-“ is reported.
CAP_ACC	Capacity accessed. This value is the unique data accessed in the file. The default unit is MB. The default unit is overridden by the unit specified by **–O** unit option.
IOP/#	Number of I/O operations per unit of data accessed. The unit of data is taken from **–O** unit option. The default is MB. Examples of value for this column are 2560/T, 256/G, 0.256/M, 0.000/K. The letters K, M, G and T stand for KB, MB, GB, and TB respectively.
#Files	Number of files accessed in this logical volume.
#ROP	Total number of read operations happened on the logical volume.
#WOP	Total number of write operations happened on that logical volume.
B/ROP	<minimum, average, maximum> number of bytes read per read operation.
B/WOP	<minimum, average, maximum> number of bytes read per write operation.
RTIME	<minimum, average, maximum> time taken per read operation in milliseconds.
WTIME	<minimum, average, maximum> time taken per write operation in milliseconds.
Seqlen	<minimum, average, maximum> length of read sequences.
#Seq	Number of read sequences. A sequence is a string of 4K pages that are read (paged in) consecutively. The number of read sequences is an indicator of the amount of sequential access.

Hot Physical Volumes Report

Item	Description
Column	**Description**
Name	Name of the physical volume.
Size	Size of the physical volume. The default unit is MB. The default unit is overridden by the unit specified by **–O** unit option.
CAP_ACC	Capacity accessed. This value is the unique data accessed in the file. The default unit is MB. The default unit is overridden by the unit specified by **–O** unit option.
IOP/#	Number of I/O operations per unit of data accessed. The unit of data is taken from **–O** unit option. The default is MB. Examples of value for this column are 2560/T, 256/G, 0.256/M, 0.000/K. The letters K, M, G and T stand for KB, MB, GB, and TB respectively.
#ROP	Total number of read operations happened on the physical volume.
#WOP	Total number of write operations happened on that physical volume.
B/ROP	<minimum, average, maximum> number of bytes read per read operation.
B/WOP	<minimum, average, maximum> number of bytes read per write operation.
RTIME	<minimum, average, maximum> time taken per read operation in milliseconds.
WTIME	<minimum, average, maximum> time taken per write operation in milliseconds.
Seqlen	<minimum, average, maximum> length of read sequences.
#Seq	Number of read sequences. A sequence is a string of 512-byte blocks that are read consecutively. The number of read sequences is an indicator of the amount of sequential access.

Each of the described hotness reports is repeated multiple times based on the sort field.

The different hotness reports based on different sort fields are:

1. hotness report sorted on key factor
2. hotness report sorted on CAP_ACC
3. hotness report sorted on IOP/#
4. hotness report sorted on #ROP
5. hotness report sorted on #WOP
6. hotness report sorted on RTIME
7. hotness report sorted on WTIME

Each of the reports is sorted in descending order of the corresponding sort field.

If you specify the **–O hot=r** option then only read operations-based reports and report based on key factor are generated, that is, report number 1, 4, and 6 are generated.

If the user specifies **–O hot=w** option then only write operations-based reports and report based on key factor are generated, that is, report number 1, 5, and 7 are generated.

The key factor is determined by the values of following columns: **#ROP**, **B/ROP**, **Seqlen** and **#Seq**.

Flags

Item	Description
-i *Trace_File*	Reads the I/O trace data from the specified *Trace_File*, instead of from the real-time trace process. The **filemon** report summarizes the I/O activity for the system and period represented by the trace file. This option is deprecated. Use the **-r** *RootString* flag instead. For the report to be accurate, the trace file must contain all the hooks required by the **filemon** command. The **-n** option must also be specified.
-n *Gensyms_File*	Specifies a *Gensyms_File* for offline trace processing. This file is created by running the gensyms command with **-f** option and redirecting the output to a file, as follows: `gensyms -F > file` The **-i** option must also be specified. The **-n** flag is depredated. Use the **-r** *RootString* flag instead.
-o *File*	Writes the I/O activity report to the specified *File*, instead of to the **stdout** file.
-d	Starts the **filemon** command, but defers tracing until the **trcon** command is run by the user. By default, tracing is started immediately.
-T *n*	Sets the trace buffer size of the kernel to *n* bytes. The default size is 64 000 bytes per CPU. The buffer size can be increased to accommodate larger bursts of events, if any. (A typical event record size is 30 bytes.) **Note:** The trace driver in the kernel uses double buffering, so in fact there are two buffers allocated of size *n* bytes. Also, note that these buffers are pinned in memory, so they are not subject to paging. Large buffers might affect the performance of paging and other I/O.
-P	Pins monitor process in memory. The **-P** flag causes the **filemon** command text and data pages to be pinned in memory for the duration of the monitoring period. This flag can be used to ensure that the real-time **filemon** process is not paged out when running in a memory-constrained environment.
-v	Prints extra information in the report. The most significant effect of the **-v** flag is that all logical files and all segments that were accessed are included in the I/O activity report, instead of only the 20 most active files and segments.
-A -x *User_Command*	Turns on automated offline mode. You must use the **-x** flag along with the **-A** flag where the trace is collected until the specified user command finishes its execution. The typical example of user command is `sleep 10`.
-r *RootString*	If you combine this flag with the **-A** flag, the **filemon** command stores the trace data in the **RootString.trc** file and generates a **gensyms** file and stores it in the **RootString.syms** file. When this option is enabled in the absence of the **-A** flag, the **filemon** command posts processing the **RootString.trc** file and the **RootString.syms** file to generate offline report. This option deprecates the existing **-n** and **-i** flags. The **filemon** command continues to support the **-i** flag and the **-n** flag for binary compatibility.

Item	Description
-O *Levels*	Monitors only the specified file system levels. Valid comma-separated options are: **abbreviated** Produces a list of transactions in abbreviated format, one line per transaction (replaces old "subpar" tool). This option is supported only in offline mode and cannot be combined with any other **-O** options. **collated** Produces a list of transactions in collated format: events are collected together per transaction. This option is supported only in offline mode and cannot be combined with any other **-O** options. **detailed** Detailed report is generated along with statistical summary mode and cannot be combined with the **abbreviated** option or the **collated** option. **lf=num** Displays only the specified number of logical file entries and cannot be combined with **-O abbreviated** flag or the **-O collated** flag. If the *num* argument is not specified, it displays all the entries. **vm=num** Displays only the specified number of virtual memory entries and cannot be combined with the **-O abbreviated** flag or the **-O collated** flag. If the *num* argument is not specified, it displays all the entries. **lv=num** Displays only the specified number of logical volume entries and cannot be combined with the **-O abbreviated** flag or the **-O collated** flag. If the *num* argument is not specified, it displays all the entries. **pv=num** Displays only the specified number of physical volume entries and cannot be combined with the **-O abbreviated** flag or the **-O collated** flag. If the *num* argument is not specified, it displays all the entries. **hot=r|w** Generates the hotness report. If **hot=r** specified then hotness reports based on read operations only are generated. If **hot=w** specified the hotness reports based on write operations only are generated. **sz=num** Specifies the maximum size of the files accessed to be reported in the hotness report. Unit for this value is specified by **–O** unit option. The default unit is MB. **unit={KB|MB|GB|TB}** Specifies the unit to be used with **sz** option and the unit to be used with **CAP_ACC** and Size fields in hotness report. **th=num** Displays only the specified number of thread statistics entries and cannot be combined with the **-O abbreviated** flag or the **-O collated** flag. If the *num* argument is not specified, it displays all the entries. **pr=num** Displays only the specified number of process statistics entries and cannot be combined with the **-O abbreviated** flag or the **-O collated** flag. If the *num* argument is not specified, it displays all the entries. **all=num** Sets **lf=num**, **vm=num**, **lv=num**, **pv=num**, **ts=num** and overwrites the old values for the options of **lf**, **vm**, **lv**, **pv**, **th**, and **pr**. This option cannot be combined with the **-O abbreviated** flag or the **-O collated** flag. If the *num* argument is not specified, it displays all the entries and this is the default option.

Item	Description
	The **vm**, **lv**, and **pv** levels are implied by default when you run the **filemon -O** command in the global WPAR without the **-@** flag. The **lf** level is implied by default when you run the **filemon -O** command in a WPAR or when you use the **-@** flag. If the *num* argument is not specified, the default is to display all the entries of that section. The *num* argument is not supported in **abbreviated** and **collated** formats and it is supported only in statistical summary. If the **-O detailed** flag is specified, the report is in statistical summary format along with detailed report in both online and offline mode. The default mode of operation for the **filemon** command is changed from Summary and Detailed Statistical report to Summary only Statistical Report. If the **filemon** command is called without any option or just with the **-O** flag with any combination of the **lf**, **vm**, **lv**, **pv**, **pr**, **th**, or **all** option, only summary report is displayed unless otherwise the **-O detailed** flag is specified.
-u	Reports on files that were opened before the start of the **trace** daemon. The process ID (PID) and the file descriptor (FD) are substituted for the file name. **Note:** Since PIDs and FDs are reusable, it is possible to see different files reported with the same name field.

Item	Description
-w	Prints the hotness report in wide format. This option is valid only if the **–O** hot option is specified.
-I *count:interval*	Specifies the count and interval to be used for multi-snapshot tracing. If this option is specified, **count** number of snapshots of trace is collected with a gap of **interval** seconds between two snapshots. This option is valid only in automated offline mode with **–O** hot option specified.
-@ [*WparList* | **ALL**]	Reports are limited to the list of WPARs passed by the argument.

Examples

1. To monitor the physical I/O activity of the virtual memory, logical volume, and physical volume levels of the file system, enter:

   ```
   filemon
   ```

   The **filemon** command automatically starts the system trace and puts itself in the background. After this command, enter the application programs and system commands to be run at this time, then enter:

   ```
   trcstop
   ```

   After the **trcstop** command is issued, the I/O activity report is displayed on standard output (but probably scrolls off the screen). The virtual memory I/O report is limited to the 20 segments that incurred the most I/O.
2. To monitor the activity at all file system levels, and write the report to the `fmon.out` file, enter:

   ```
   filemon -o fmon.out -O all
   ```

   The **filemon** command automatically starts the system trace and puts itself in the background. After this command, enter the application programs and system commands to be run at this time, then enter:

   ```
   trcstop
   ```

   After the **trcstop** command is issued, the I/O activity report is written to the `fmon.out file`. All four levels of the file and I/O system (the logical file, virtual memory, logical volume, and physical volume levels) are monitored. The logical file and virtual memory I/O reports are limited to the 20 files and segments (respectively) that incurred the most I/O.
3. To monitor the activity at all file system levels and write a verbose report to the `fmon.out` file, enter:

   ```
   filemon -v -o fmon.out -O all
   ```

   The **filemon** command automatically starts the system trace and puts itself in the background. After this command, enter the application programs and system commands to be run at this time, then enter:

   ```
   trcstop
   ```

   This example is similar to the previous example, except a verbose report is generated on the `fmon.out` file. The primary difference is that the **filemon** command indicates the steps that it is taking to start the trace, and the summary and detailed reports include all files and segments that incurred any I/O (there might be many), instead of just the top 20.
4. To report on I/O activity captured by a previously recorded trace session, enter:

   ```
   filemon -i trcfile | pg
   ```

In this example, the **filemon** command reads file system trace events from the input file `trcfile`. Since the trace data is already captured on a file, the **filemon** command does not put itself in the background to let application programs run. After the entire file is read, an I/O activity report for the virtual memory, logical volume, and physical volume levels will be displayed on standard output (which, in this example, is piped to pg).

5. To monitor the I/O activity for logical and physical volumes only, while controlling the monitored intervals using the **trcon** and **trcoff** commands, enter:

```
filemon -d -o fmon.out -O pv,lv
```

The **filemon** command automatically starts the system trace and puts itself in the background. After this command, you can enter the unmonitored application programs and system commands to be run at this time, then enter:

```
trcon
```

After this command, you can enter the monitored application programs and system commands to be run at this time, then enter:

```
trcoff
```

After this command, you can enter the unmonitored application programs and system commands to be run at this time, then enter:

```
trcon
```

After this command, you can enter the monitored application programs and system commands to be run at this time, then enter:

```
trcstop
```

In this example, the **-O** flag is used to restrict monitoring to logical and physical volumes only. Only those trace events that are relevant to logical and physical volumes are enabled. Also, as a result of using the **-d** flag, monitoring is initially deferred until the **trcon** command is issued. System tracing can be intermittently disabled and reenabled using the **trcoff** and **trcon** commands, so that only specific intervals are monitored.

6. To run **filemon** in offline mode, run the **trace** and **gensyms** commands separately, then use the output from those commands as input to the **filemon** command, as follows:

```
trace -a -T 768000 -L 10000000 -o trace.out -j
000,000,001,002,003,005,006,139,102,10C,106,00A,107,
101,104,10D,15B,12E,130,163,19C,154,3D3,1BA,1BE,1BC,10B,221,1C9,222,228,232,45B
```

Run the monitored application programs and system commands, then enter:

```
trcstop
```

Create the **gensyms** file:

```
gensyms -F > gensyms.out
```

Then run **filemon** with both **-i** and **-n** flags:

```
filemon -i trace.out -n gensyms.out -O all
```

7. To generate hotness report in automated offline mode, with unit of data as megabytes, use the following command:

```
filemon -O hot,unit=MB -r <rootstring> -A-x "<user command>"
```

8. To generate hotness report with three snapshots of trace in 5-seconds interval, run the following command:

```
filemon -O hot -r <rootstring> -A-x "<user command>" -I 3:5
```

9. To generate hotness report in offline mode:

```
filemon -r <rootstring> -O hot
```

fileplace Command

Purpose

Displays the placement of file blocks within logical or physical volumes.

Syntax

fileplace [{ **-l** | **-p** [**-o** *FragOffset*] [**-n** *FragNumber*] }[**-i**] [**-v**][**-a**]] *File* | [**-m** *LogicalVolumeName*]

Description

The **fileplace** command displays the placement of a specified file within the logical or physical volumes containing the file.

By default, the **fileplace** command lists to standard output the ranges of logical volume fragments allocated to the specified file. The order in which the logical volume fragments are listed corresponds directly to their order in the file. A short header indicates the file size (in bytes), the name of the logical volume in which the file lies, the block size (in bytes) for that volume, the fragment size in bytes, and the compression, indicating if the file system is compressed or not.

Occasionally, portions of a file may not be mapped to any fragments in the volume. These areas, whose size is an integral number of fragments, are implicitly zero-filled by the file system. The **fileplace** command indicates which areas in a file have no allocated fragments.

Optionally, the **fileplace** command also displays:

- Statistics indicating the degree to which the file is spread within the volume.
- The indirect block addresses for the file.
- The file's placement on physical (as opposed to logical) volume, for each of the physical copies of the file.

Notes:

1. The **fileplace** command is not able to display the placement of remote Network File System (NFS) files. If a remote file is specified, the **fileplace** command returns an error message. However, the placement of the remote file can be displayed if the **fileplace** command is run directly on the file server.
2. The **fileplace** command reads the file's list of blocks directly from the logical volume on disk. If the file is newly created, extended, or truncated, the file system information may not yet be on the disk when the **fileplace** command is run. Use the **sync** command to flush the file information to the logical volume.
3. There is no Indirect/Double Indirect blocks concept in JFS2 filesystem. The file is represented in terms of extents. Therefore the size of the maximum extent depends on the aggregate block size. With a 512 byte aggregate block size (the smallest allowable), the maximum extent is 512*(2^ 24-1) bytes long (slightly under 8G). With a 4096 byte aggregate block size (the largest allowable), the maximum extent is 4096*(2^ 24-1) bytes long (slightly under 64G).

   These limits apply only to a single extent; in no way do they have any limiting effects on overall file sizes.

Flags

Item	Description
-i	Displays the indirect blocks for the file, if any. The indirect blocks are displayed in terms of either their logical or physical volume block addresses, depending on whether the **-l** or **-p** flag is specified.
-l	Displays file placement in terms of logical volume fragments, for the logical volume containing the file. The **-l** and **-p** flags are mutually exclusive. **Note:** If neither the **-l** flag nor the**-p** flag is specified, the **-l** flag is implied by default. If both flags are specified, the **-p** flag is used.
-m *LogicalVolumeName*	Displays the logical to physical map for a logical volume.
-n *FragNumber*	Displays the logical or physical file blocks ranging from the first block to the block corresponding to *FragNumber*.
-o *FragOffset*	Displays the logical or physical file blocks ranging from the block corresponding to *fragoffset* + 1 to the last block. The **fileplace** command displays the address of the specific fragment when both the **-n** flag and the **-o** flag is specified.
-p	Displays file placement in terms of underlying physical volume, for the physical volumes that contain the file. If the logical volume containing the file is mirrored, the physical placement is displayed for each mirror copy. The **-l** and **-p** flags are mutually exclusive.

Item	Description
-v	Displays more information about the file and its placement, including statistics on how widely the file is spread across the volume and the degree of fragmentation in the volume. The statistics are expressed in terms of either the logical or physical volume fragment numbers, depending on whether the **-l** or **-p** flag is specified. *File space efficiency* is calculated as the number of nonnull fragments (*N*) divided by the range of fragments (*R*) assigned to the file and multiplied by 100, or (*N* /*R*) x 100. Range is calculated as the highest assigned address minus the lowest assigned address plus 1, or *MaxBlk*-*MinBlk*+1. For example, the logical blocks written for the file are 01550 through 01557, so *N* equals 8. The range, *R*, (01557 - 01550 +1) also equals 8. Space efficiency for this file is 100% or 8/8 x 100. The **-v** flag message prints the results of the (*N*/*R*)+100 equation. According to this method of calculating efficiency, files greater than 32KB are never 100% efficient because of their use of the indirect block. *Sequential efficiency* is defined as 1 minus the number of gaps (*nG*) divided by number of possible gaps (*nPG*) or 1 - (*nG*/*nPG*). The number of possible gaps equals *N* minus 1 (*nPG=N* - 1). If the file is written to 9 blocks (greater than 32KB), and the logical fragment column shows: `01550-01557` `01600` The file is stored in 2 fragments out of a possible 9 fragments. The sequential efficiency calculation for this file is: *nG*=1 *nPG*=9-1=8 (1-1/8) x 100=87.5%
-a	Marks Allocated But Not Recorded (ABNR) blocks with an asterisk (*) at the beginning of the line. ABNR is a feature provided by the J2 filesystem.

Examples

1. To display the placement of a file in its logical volume, enter:

   ```
   fileplace data1
   ```

   This example displays the list of fragments and the logical volume that contains the file `data1`.
2. To display the indirect blocks for a file, enter:

   ```
   fileplace -i data1
   ```

   In addition to the default list of logical volume fragments, the indirect blocks (if any) used to store the file block addresses in the file system are enumerated.
3. To display more placement information for a file, enter:

   ```
   fileplace -v data1
   ```

In addition to the default list of logical volume fragments, statistics about the placement efficiency are displayed.

4. To display all information about the placement of a file on its physical volumes, enter:

```
fileplace -piv data1
```

This example displays the list of file and indirect blocks in terms of the underlying physical volumes, and includes statistics about the efficiency of the placement.

5. To display the locations of the underlying physical volume for the first 18 blocks in the **/usr/lib/boot/unix_mp** file, enter:

```
fileplace -n 18 -p /usr/lib/boot/unix_mp
```

6. To display the locations of the underlying physical volume from the 18th block to the last block in the **/usr/lib/boot/unix_mp** file, enter:

```
fileplace  -p -o 17 /usr/lib/boot/unix_mp
```

7. To display the location of the underlying physical volume of the 18th block in the **/usr/lib/boot/unix_mp** file, enter:

```
fileplace -o 17 -n 1 -p /usr/lib/boot/unix_mp
```

Files

Item	Description
/dev/hd0, /dev/hd1, .../dev/hd*n*	Specifies the logical volume.

find Command

Purpose

Finds files with a matching expression.

Syntax

`find` [**-H** | **-L**] *Path ...* [*Expression*]

Description

The **find** command recursively searches the directory tree for each specified *Path* parameter, seeking files that match a Boolean expression. The Boolean expression is written by using the terms that are provided in the following text. When the **find** command is recursively descending directory structures, it does not descend into directories that are symbolically linked into the current hierarchy. The output from the **find** command depends on the terms that are specified by the *Expression* parameter.

The **find** command does not support the 4.3 BSD fast-find syntax.

Flags

Item	Description
-H	Causes the file information and file type that are evaluated for each symbolic link that is encountered on the command line to be those of the file that is referenced by the link, and not the link itself. If the referenced file does not exist, the file information and type are for the link itself. File information for all symbolic links not on the command line is that of the link itself.

Item	Description
-L	Causes the file information and file type that are evaluated for each symbolic link to be those of the file that is referenced by the link, and not the link itself.

Expression Terms

These Boolean expressions and variables describe the search boundaries of the **find** command as defined in the *Path* and *Expression* parameters.

Note: In the following definitions, the *n* variable specifies a decimal integer that can be expressed as +*n* (more than *n*), -*n* (less than *n*), or *n* (exactly *n*) and the *Number* variable specifies a decimal integer that can be expressed as +*Number* (more than *Number*), -*Number* (less than Number), or *Number* (*Number*-1 to *Number*).

Item	Description
\(*Expression* \)	Evaluates to the value True if the expression in parentheses is true.
-amin *n*	The value of *n* can be one of the following values: ***n*** Evaluates as True if the file access time subtracted from the initialization time, divided by 60 seconds (with any remainder discarded), is *n*. ***-n*** Evaluates as True if the file access time subtracted from the initialization time, divided by 60 seconds (with any remainder discarded), is less than *n*. ***+n*** Evaluates as True if the file access time subtracted from the initialization time, divided by 60 seconds (with any remainder discarded), is greater than *n* (in case of UNIX03, greater than *n*+1). For example, `-amin 2` is true if the file is accessed within 1 to 2 minutes. **Note:** Files that are accessed after the **find** command start time are not taken into account. However, when the **find** command is used within the unary NOT operator for non-UNIX03 behavior, the files that are modified after the command start time are displayed until the value of *n*.

Item	Description
-atime *n*	The value of *n* can be one of the following values: ***n*** Evaluates as True if the file access time subtracted from the initialization time, divided by 86400 seconds (with any remainder discarded), is *n*. ***-n*** Evaluates as True if the file access time subtracted from the initialization time, divided by 86400 seconds (with any remainder discarded), is less than *n*. ***+n*** Evaluates as True if the file access time subtracted from the initialization time, divided by 86400 seconds (with any remainder discarded), is greater than *n* (in case of UNIX03, greater than *n*+1). **Note:** The definition of `-atime` is changed to comply with the Single UNIX Specification, Version 3. The previous behavior of `-atime` evaluated as True if the file was accessed in *n*-1 to *n* multiples of 24 hours. By default, `find -atime` works like it did before UNIX03. The UNIX03 behavior can be obtained by setting the environment variables `XPG_SUS_ENV` to `ON` and `XPG_UNIX98` to `OFF`. The previous behavior for this option can be obtained by setting the `XPG_UNIX98` variable to `ON`. Files that are accessed after the **find** command start time is not taken into account. However, when the **find** command is used within the unary `NOT` operator for non-UNIX03 behavior, the files that are modified after the command start time are displayed until the value of *n*.
-cmin *n*	The value of *n* can be one of the following values: ***n*** Evaluates as True if the file i-node modification time subtracted from the initialization time, divided by 60 seconds (with any remainder discarded), is *n*. ***-n*** Evaluates as True if the file i-node modification time subtracted from the initialization time, divided by 60 seconds (with any remainder discarded), is less than *n*. ***+n*** Evaluates as True if the file i-node modification time subtracted from the initialization time, divided by 60 seconds (with any remainder discarded), is greater than *n* (in case of UNIX03, greater than *n*+1). **Note:** Files with i-nodes that are modified after the **find** command start time are not taken into account. However, when the **find** command is used within the unary `NOT` operator for non-UNIX03 behavior, files with i-nodes modified after the command start time are displayed until the value of *n*.
-cpio *Device*	Writes the current file to the specified device in the **cpio** command format.

Item	Description
-ctime *n*	The value of *n* can be one of the following values: ***n*** Evaluates as True if the file i-node modification time subtracted from the initialization time, divided by 86400 seconds (with any remainder discarded), is *n*. ***-n*** Evaluates as True if the file i-node modification time subtracted from the initialization time, divided by 86400 seconds (with any remainder discarded), is less than *n*. ***+n*** Evaluates as True if the file i-node modification time subtracted from the initialization time, divided by 86400 seconds (with any remainder discarded), is greater than *n* (in case of UNIX03, greater than *n*+1). **Note:** The definition of **-ctime** is changed to comply with the Single UNIX Specification, Version 3. The previous behavior of **-ctime** evaluated as True if the file was accessed in *n*-1 to *n* multiples of 24 hours. By default, `find -ctime` works like it did before UNIX03. The UNIX03 behavior can be obtained by setting the environment variables `XPG_SUS_ENV` to `ON` and `XPG_UNIX98` to `OFF`. The previous behavior for this option can be obtained by setting the `XPG_UNIX98` variable to `ON`. Files with i-nodes modified after the **find** command start time is not taken into account. However, when the **find** command is used within the unary `NOT` operator for non-UNIX03 behavior, files with i-nodes modified after the command start time is displayed until the value of *n*.
-depth	Always evaluates to the value True. Causes the descent of the directory hierarchy to be done so that all entries in a directory are affected before the directory itself is affected. It can be useful when the **find** command is used with the **cpio** command to transfer files that are contained in directories without write permission.
-ea	Evaluates to the value True if file has either access control information (ACL) or Extended attributes (EA) set.
-exec *Command*	Evaluates to the value True if the specified command runs and returns a 0 value as exit status. The end of the specified command must be punctuated by a semicolon in quotation marks, an escaped semicolon, or a plus sign. An argument that contains the two characters `{}` (braces) must be followed by a plus sign that punctuates the end of the specified command. A command parameter `{}` (braces) is replaced by the current path name.
-follow	Causes symbolic and hard links to be followed.
-fstype *Type*	Evaluates to the value True if the file system to which the file belongs is of the specified type. The *Type* variable has a value of `jfs` (journaled file system), `nfs` (network file system), `jfs2` (enhanced journaled file system), `procfs` (proc file system), or `namefs` (name file system).
-group *Group*	Evaluates to the value True if the file belongs to the specified group. If the value of the *Group* variable is numeric and does not appear in the `/etc/group` file, it is interpreted as a group ID.

Item	Description
-inum *n*	Evaluates to the value True if file has an i-node matching the value of the *n* variable.
-links *n*	Evaluates to the value True if the file has the specified number of links. See the **ln** command for a description of links.
-iregex *regular_expression*	Evaluates to the value True if the entire path name of the file matches the regular expression. This option is similar to the **-regex** option, except that the match is case-insensitive.
-long	Prints all available characters of each user/group name instead of truncating to the first 8 when used in combination with `-ls`.
-ls	Always evaluates to the value True. Causes the current path name to be printed together with its associated statistics. These statistics include the following values: • I-node number • Size in KB (1024 bytes) • Protection mode • Number of hard links • User • Group • Size in bytes • Modification time If the file is a special file, the size field contains the major and minor device numbers. If the file is a symbolic link, the path name of the linked-to file is printed preceded by the -> (hyphen, greater than) symbols. Formatting is similar to that of the **ls -filds** command, however formatting is done internally without running the **ls** command. Therefore, differences in output with the **ls** command might exist, such as with the protection mode.
-mmin *n*	The value of *n* can be one of the following values: ***n*** Evaluates as True if the file modification time subtracted from the initialization time, divided by 60 seconds (with any remainder discarded), is *n*. ***-n*** Evaluates as True if the file modification time subtracted from the initialization time, divided by 60 seconds (with any remainder discarded), is less than *n*. ***+n*** Evaluates as True if the file modification time subtracted from the initialization time, divided by 60 seconds (with any remainder discarded), is greater than *n* (in case of UNIX03, greater than *n*+1). **Note:** Files that are modified after the **find** command start time are not taken into account. However, when the **find** command is used within the unary NOT operator for non-UNIX03 behavior, the files that are modified after the command start time are displayed until the value of *n*.

Item	Description
-mtime *n*	The value of *n* can be one of the following values: ***n*** Evaluates as True if the file modification time subtracted from the initialization time, divided by 86400 seconds (with any remainder discarded), is *n*. 86400 seconds is 24 hours. ***-n*** Evaluates as True if the file modification time subtracted from the initialization time, divided by 86400 seconds (with any remainder discarded), is less than *n*. ***+n*** Evaluates as True if the file modification time subtracted from the initialization time, divided by 86400 seconds (with any remainder discarded), is greater than *n* (in case of UNIX03, greater than *n*+1). **Note:** The definition of **-mtime** is changed to comply with the Single UNIX Specification, Version 3. The previous behavior of **-mtime** evaluated as True if the file is modified in *n*-1 to *n* multiples of 24 hours. By default, `find -mtime` works like it did before UNIX03. The UNIX03 behavior can be obtained by setting the environment variables `XPG_SUS_ENV` to `ON` and `XPG_UNIX98` to `OFF`. The previous behavior for this option can be obtained by setting the `XPG_UNIX98` variable to `ON`. Files that are modified after the **find** command start time are not taken into account. However, when the **find** command is used within the unary `NOT` operator for non-UNIX03 behavior, the files modified after the command start time are displayed until the value of *n*.
-name *File*	Evaluates to the value True if the value of the *File* variable matches the file name. The typical shell file name generation characters (see the **sh** command) can be used. The pattern must be enclosed in either quotation marks or the escape characters. The escape character is used when the **find** command is used from the shell. A backslash (\) is used as an escape character within the pattern. You can use wildcard (pattern-matching) characters, provided they are in quotation marks. In an expression such as [a-z], the hyphen means through according to the current collating sequence. A collating sequence might define equivalence classes for use in character ranges. For more information about collating sequences and equivalence classes, see "National Language Support Overview" in the *Globalization Guide and Reference*.
-newer *File*	Evaluates to the value True if the current file is modified more recently than the file indicated by the *File* variable.
-nogroup	Evaluates to the value True if the file belongs to a group not in the `/etc/group` database.
-nouser	Evaluates to the value True if the file belongs to a user not in the `/etc/passwd` database.

Item	Description
-ok *Command*	The same as the **-exec** expression, except that the **find** command verifies whether it must start the specified command. An affirmative response starts the command. The end of the specified command must be punctuated by a semicolon that is enclosed in quotation marks or the \; (backslash-escape semicolon).
-perm [**-**] *OctalNumber*	Evaluates to the value True if the permission code of the file exactly matches the *OctalNumber* parameter. For details about file permissions, refer to the **chmod** command. If the optional **-** (hyphen) is present, this expression evaluates to the value true if at least these permissions are set. The *OctalNumber* parameter can be up to 9 octal digits. **Note:** For files that are a part of TCB environment, additional security bits are added to the permission of the files. These files have the S_ITCB bit set and the security bit set is defined as 0x010000000. Therefore, the octal permissions value of a TCB enabled file must include the bit setting of 100000000 along with its other permission bits. Example: To list a file, which is a part of the TCB environment, find -perm 100000600 -print. It lists the names of the files that have only owner-read and owner-write permission and are a part of the TCB environment. See the **chmod** command for an explanation of permission codes.
-perm [**-**] *Mode*	The mode argument is used to represent file mode bits. It is identical in format to the <symbolicmode> operand described in **chmod**, and is interpreted as follows: Initially, a template is assumed with all file mode bits cleared. Op (-) symbols have the following function: **+** Sets the appropriate mode bits in the template **-** Clears the appropriate bits **=** Sets the appropriate mode bits, without regard to the contents of the process' file mode creation mask The op symbol - cannot be the first character of mode. It avoids ambiguity with the optional leading hyphen. Because the initial mode is all bits off, there are no symbolic modes that must use - as the first character. If the hyphen is omitted, the primary evaluates as True when the file permission bits exactly match the value of the resulting template. Otherwise, if mode is prefixed by a hyphen, the primary evaluates as True if at least all bits in the resulting template are set in the file permission bits. The *Mode* parameter is identical to the **chmod** command syntax. This expression evaluates to the value True if the file has exactly these permissions. If the optional **-** (hyphen) is present, this expression evaluates to the value True if at least these permissions are set.

Item	Description
-print	Always evaluates to the value True. Displays the current path name. The **find** command assumes a **-print** expression, unless the **-exec, - ls**, or **-ok** expressions are present.
-prune	Always evaluates to the value True. Stops the descent of the current path name if it is a directory. If the **-depth** flag is specified, the **-prune** flag is ignored.
-size *n*	Evaluates to the value True if the file is the specified *n* of blocks long (512 bytes per block). The file size is rounded up to the nearest block for comparison.
-regex *regular_expression*	Evaluates to the value True if the entire path name of the file matches the regular expression. This option does not search for the regular expression but matches the regular expression with the complete path name of the file. For example, to match a file named `./test`, you can use the regular expression `.*test.*` or `.*t.*t`, but not `t.*t`.
-regextype *Type*	Always evaluates to the value True. This option specifies the type of regular expression syntax for the **-regex** and **-iregex** options. It also affects regular expressions that occur later in the command line. The *Type* variable can have one of the following values: **Basic** For basic regular expression syntax. **Extended** For extended regular expression syntax. **Note:** If the **-regextype** option is not used, the regular expressions are interpreted as `basic`.
-size *n***c**	Evaluates to the value True if the file is exactly the specified *n* of bytes long. Adding **c** to the end of the *n* variable indicates that the size of the file is measured in individual bytes not blocks.
-type *Type*	Evaluates to the value True if the *Type* variable specifies one of the following values: **b** Block special file **c** Character special file **d** Directory **f** Plain file **l** Symbolic link **p** FIFO (a named pipe) **s** Socket

Item	Description
-user *User*	Evaluates to the value True if the file belongs to the specified user. If the value of the *User* variable is numeric and does not appear as a login name in the `/etc/passwd` file, it is interpreted as a user ID.
-xdev	Always evaluates to the value True. Prevents the **find** command from traversing a file system different from the one specified by the *Path* parameter.

These expressions can be combined by using the following operators in the order of decreasing precedence:

1. **(** *Expression* **)** - A parenthetic group of expressions and operators (parentheses are special to the shell and require the backslash-escape sequence).
2. **!** *Expression* - The negation of an expression (**'!'** is the unary NOT operator).
3. *Expression* [**-a**] *Expression* - Concatenation of expressions (the AND operation is implied by the juxtaposition of two primaries or might be explicitly stated as **-a**).
4. *Expression* **-o** *Expression* - Alternation of primaries; **-o** is the OR operator. The second expression is not evaluated if the first expression is true.

Note: When you use the **find** and **cpio** commands together, you must use the `-follow` option and the `-L` option with the **cpio** command. Not using these two options together produces undesirable results. If expression is not present, `-print` as used in the default expression. For example, if the specified expression does not contain any of the primaries `-exec`, `-ok`, or `-print`, the expression is replaced by (*given_expression*) `-print`. The `-user`, `-group`, and `-newer` primaries each evaluate their respective arguments only once. Using a command that is specified by `-exec` or `-ok` does not affect subsequent primaries on the same file.

Exit Status

This command returns the following exit values:

Item	Description
0	All *Path* parameters were traversed successfully.
>0	An error occurred.

Examples

1. To list all files in the file system with a specified base file name, type:

   ```
   find /  -name .profile -print
   ```

   This command searches the entire file system and writes the complete path names of all files named `.profile`. The / (slash) instructs the **find** command to search the root directory and all of its subdirectories. In order not to waste time, it is best to limit the search by specifying the directories where you think the files might be.

2. To list files that have a specific permission code in the current directory tree, type:

   ```
   find . -perm 0600  -print
   ```

   This command lists the names of the files that have only owner-read and owner-write permission. The . (dot) instructs the **find** command to search the current directory and its subdirectories. See the **chmod** command for an explanation of permission codes.

3. To search several directories for files with certain permission codes, type:

```
find manual clients proposals -perm -0600  -print
```

This command lists the names of the files that have owner-read and owner-write permissions and possibly other permissions. The `manual`, `clients`, and `proposals` directories and their subdirectories are searched. In the previous example, `-perm 0600` selects only files with permission codes that match `0600` exactly. In this example, `-perm -0600` selects files with permission codes that allow the accesses that are indicated by `0600` and other accesses above the `0600` level. It also matches the permission codes 0622 and 0744.

4. To list all files in the current directory that are changed during the current 24-hour period, type:

```
find .  -ctime 1  -print
```

5. To search for regular files with multiple links, type:

```
find .  -type f  -links +1  -print
```

This command lists the names of the ordinary files (`-type f`) that have more than one link (`-links +1`).

Note: Every directory has at least two links: the entry in its parent directory and its own `.` (dot) entry. The **ln** command explains multiple file links.

6. To find all accessible files whose path name contains **find**, type:

```
find .  -name '*find*' -print
```

7. To remove all files named `a.out` or `*.o` that are not accessed for a week and that are not mounted by using `nfs`, type:

```
find / \( -name a.out -o -name '*.o' \) -atime +7 ! -fstype nfs -exec rm {} \;
```

Note: The number that is used within the **-atime** expression is +7. It is the correct entry if you want the command to act on files that are not accessed for more than a week (seven 24-hour periods).

8. To print the path names of all files in or below the current directory, except the directories named SCCS or files in the SCCS directories, type:

```
find .  -name SCCS  -prune -o -print
```

To print the path names of all files in or below the current directory, including the names of SCCS directories, type:

```
find . -print -name SCCS -prune
```

9. To search for all files that are exactly 414 bytes long, type:

```
find . -size 414c -print
```

10. To find and remove every file in your home directory with the `.c` suffix, type:

```
find /u/arnold -name "*.c" -exec rm {} \;
```

Every time the **find** command identifies a file with the `.c` suffix, the **rm** command deletes that file. The **rm** command is the only parameter that is specified for the **-exec** expression. The {} (braces) represent the current path name.

11. In this example, `dirlink` is a symbolic link to the directory `dir`. To list the files in `dir` by referring to the symbolic link `dirlink` on the command line, type:

```
find -H dirlink -print
```

12. In this example, `dirlink` is a symbolic link to the directory `dir`. To list the files in `dirlink`, traversing the file hierarchy under `dir` including any symbolic links, type:

```
find -L dirlink -print
```

13. To determine whether the file `dir1` referred by the symbolic link `dirlink` is newer than `dir2`, type:

```
find -H dirlink -newer dir2
```

Note: Because the **-H** flag is used, time data is collected not from `dirlink` but instead from `dir1`, which is found by traversing the symbolic link.

14. To produce a listing of files in the current directory in `ls` format with expanded user and group name, type:

```
find . -ls -long
```

15. To list the files with ACL/EA set in current directory, type:

```
find . -ea
```

16. To list the files that are modified within 60 minutes, type:

```
find . -mmin -60
```

17. To find all path names in the `/home` directory that contain a pattern `afile` in the path name, type the following command:

```
find /home -regextype basic -regex ".*afile.*"
```

18. To find all path names in the `/home` directory that contain a pattern `afile` or `cap` in the path name, type the following command:

```
find /home -regextype extended -regex ".*afile.*|.*cap.*"
```

19. To find all path names in the `/home` directory that contain a pattern `afile`, `AFILE`, `cap`, or `CAp` in the path name, type the following command:

```
find /home -regextype extended -iregex ".*afile.*|.*cap.*"
```

Files

Item	Description
`/usr/bin/find`	Contains the **find** command.
`/bin/find`	Symbolic link to the **find** command.
`/etc/group`	Contains a list of all known groups.
`/etc/passwd`	Contains a list of all known users.

finger Command

Purpose

Shows user information. This command is the same as the **f** command.

Syntax

{ **finger** | **f** }[[**-b**][**-h**] [**-l**][**-p**]]|[**-i**][**-q**][**-s**][**-w**]]

[**-f**][**-m**][*User*| *User* **@***Host*| **@***Host*]

Description

The **/usr/bin/finger** command displays information about the users currently logged in to a host. The format of the output varies with the options for the information presented.

Default Format

The default format includes the following items:

- Login name
- Full user name
- Terminal name
- Write status (an * (asterisk) before the terminal name indicates that write permission is denied)

For each user on the host, the default information list also includes, if known, the following items:

- Idle time (Idle time is minutes if it is a single integer, hours and minutes if a : (colon) is present, or days and hours if a "d" is present.)
- Login time
- Site-specific information

The site-specific information is retrieved from the gecos field in the **/etc/passwd** file. The gecos field may contain the Full user name followed by a comma or / (slash character). All information that follows the comma or slash character is displayed by the finger command with the Site-specific information.

Longer Format

A longer format is used by the **finger** command whenever a list of user's names is given. (Account names as well as first and last names of users are accepted.) This format is multiline, and includes all the information described above along with the following:

- User's **$HOME** directory
- User's login shell
- Contents of the **.plan** file in the user's **$HOME** directory
- Contents of the **.project** file in the user's **$HOME** directory

The **finger** command may also be used to look up users on a remote system. The format is to specify the user as *User@Host*. If you omit the user name, the **finger** command provides the standard format listing on the remote system.

Create the **.plan** and **.project** files using your favorite text editor and place the files in your **$HOME** directory. The **finger** command uses the **toascii** subroutine to convert characters outside the normal ASCII character range when displaying the contents of the **.plan** and **.project** files. The **finger** command displays a `M-` before each converted character.

When you specify users with the *User* parameter, you can specify either the user's first name, last name, or account name. When you specify users, the **finger** command, at the specified host, returns information about those users only in long format.

For other information about the **finger** command, see "Installation of TCP/IP" in *Networks and communication management*.

Flags

Item	Description
-b	Gives a brief, long-form listing.
-f	Suppresses printing of header line on output (the first line that defines the fields that are being displayed).
-h	Suppresses printing of **.project** files on long and brief long formats.

Item	Description
-i	Gives a quick listing with idle times.
-l	Gives a long-form listing.
-m	Assumes that the *User* parameter specifies a user ID (used for discretionary access control), *not* a user login name.
-p	Suppresses printing of **.plan** files on long-form and brief long-form formats.
-q	Gives a quick listing.
-s	Gives a short format list.
-w	Gives a narrow, short-format list.

Parameters

Item	Description
@Host	Specifies all logged-in users on the remote host.
User	Specifies a local user ID (used for discretionary access control) or local user login name, as specified in the **/etc/passwd** file.
User@Host	Specifies a user ID on the remote host, displayed in long format.

Examples

1. To get information about all users logged in to host `alcatraz`, enter:

   ```
   finger @alcatraz
   ```

   Information similar to the following is displayed:

   ```
   [alcatraz.austin.ibm.com]
   Login     Name         TTY Idle          When      Site Info
   brown    Bob Brown   console   2d   Mar 15 13:19
   smith    Susan Smith    pts0  11:   Mar 15 13:01
   jones    Joe Jones      tty0    3   Mar 15 13:01
   ```

   User `brown` is logged in at the `console`, user `smith` is logged in from pseudo teletype line `pts0`, and user `jones` is logged in from `tty0`.

2. To get information about user `brown` at `alcatraz`, enter:

   ```
   finger brown@alcatraz
   ```

   Information similar to the following is displayed:

   ```
   Login name: brown
   Directory: /home/brown    Shell: /home/bin/xinit -L -n Startup
   On since May 8 07:13:49 on console
   No Plan.
   ```

3. To get information about user `brown` at a local host in short form, enter:

   ```
   finger -q brown
   ```

   Information similar to the following is displayed:

   ```
   Login           TTY             When
   brown           pts/6           Mon Dec1710:58
   ```

Files

Item	Description
/usr/bin/finger	Contains the **finger** command.
/etc/utmp	Contains list of users currently logged in.
/etc/passwd	Defines user accounts, names, and home directories.
/etc/security/passwd	Defines user passwords.
/var/adm/lastlog	Contains last login times.
$HOME/.plan	Optional file that contains a one-line description of a user's plan.
$HOME/.project	Optional file that contains a user's project assignment.

fingerd Daemon

Purpose

Provides server function for the **finger** command.

Syntax

Note: The **fingerd** daemon is usually started by the **inetd** daemon. It can also be controlled from the command line, using System Resource Controller (SRC) commands.

/usr/sbin/fingerd [**-s**] [**-f**]

Description

The **/usr/sbin/fingerd** daemon is a simple protocol that provides an interface to the **finger** command at several network sites. The **finger** command returns a status report on either the current system or a user. The **fingerd** daemon listens for Transmission Control Protocol (TCP) requests at port 79 as listed in the **/etc/services** file and the /**etc**/**inetd.conf** file.

For individual site security concern the **fingerd** daemon, by default, will not forward any **finger** request to any other system. If it receives a **finger** forward request, the **fingerd** daemon replies with the message `Finger forwarding service denied` to the **finger** command. The system administractor has the option to turn on finger forwarding as the default when running the **fingerd** daemon by using the **-f** flag.

Changes to the **fingerd** daemon can be made using the System Management Interface Tool (SMIT) or SRC or by editing the **/etc/inetd.conf** file or /**etc**/**services** file. Entering `fingerd` at the command line is not recommended. The **fingerd** daemon is started by default when it is uncommented in the **/etc/inetd.conf** file.

The **inetd** daemon get its information from the /**etc**/**inetd.conf** file and the /**etc**/**services** file.

After changing the /**etc**/**inetd.conf** or /**etc**/**services** file, run the **refresh -s inetd** or **kill-1***InetdPID* command to inform the **inetd** daemon of the changes to its configuration file.

The **fingerd** daemon should have a user ID with the least privileges possible. The **nobody** ID allows the least permissions. Giving the **fingerd** daemon the **nobody** user ID allows the daemon to be used on your host. Change the /**etc**/**services** file to the reflect the user ID you want to use.

Manipulating the fingerd Daemon with the System Resource Controller

The **fingerd** daemon is a subserver of the **inetd** daemon. The **fingerd** daemon is a member of the **tcpip** SRC subsystem group. This daemon is enabled when it is uncommented in the **/etc/inetd.conf** file and can be manipulated by the following SRC commands:

Item	Description
startsrc	Starts a subsystem, group of subsystems, or a subserver.
stopsrc	Stops a subsystem, group of subsystems, or a subserver.
lssrc	Gets the status or a subsystem, group or subsystems, or a subserver.

Flags

Item	Description
-s	Turns on socket-level debugging.

Item	Description
-f	Turns on finger forwarding service for this **fingerd** daemon.

Examples

Note: The arguments for the **fingerd** daemon can be specified by using SMIT or by editing the **/etc/inetd.conf** file.

1. To start the **fingerd** daemon type:

   ```
   startsrc -t finger
   ```

   This command starts the **fingerd** subserver.
2. To stop the **fingerd** daemon usually, type:

   ```
   stopsrc -t finger
   ```

   This command allows all pending connections to start and existing connections to complete but prevents new connections from starting.
3. To force stop the **fingerd** daemon and all **fingerd** connections type:

   ```
   stopsrc -f -t finger
   ```

   This command terminates all pending connections and existing connections immediately.
4. To display a short status report about the **fingerd** daemon type:

   ```
   lssrc -t finger
   ```

   This command returns the daemon's name, process ID, and state (active or inactive).

fish Command

Purpose

Plays the go fish card game.

Syntax

fish

Description

The object of the go fish game is to accumulate books of four cards with the same face value. You and the program (your opponent) take turns asking for cards from one another's hand. If your opponent has one or more cards of the value requested, your opponent must hand them over. If not, your opponent prompts `GO FISH!`, and you draw a card from the pool of undealt cards. If you draw the card you asked for, you draw again. As books are made, they are laid down on the table. Play continues until there are no cards left. The player with the most books wins the game. The **fish** command tells you the winner and exits.

The **fish** command prompts with `instructions?` before play begins. To see the instructions, enter Y (yes).

Entering a p as your first move gives you the professional-level game. The default is an amateur-level game.

When playing go fish, you enter the card you want when your opponent prompts:

```
you ask me for:
```

If you press only the Enter key when prompted, you receive information about the number of cards in your opponent's hand and in the pool.

The game displays:

- your current hand, including the books you have accumulated
- `GO FISH!` when either you or your opponent ask for a card the other does not have
- the card drawn after the `GO FISH!` prompt
- the card your opponent asks you for
- completed books (yours or your opponent's)
- the requested card when you or your opponent get another guess.

Examples

The following is a sample of a **fish** screen display:

```
your hand is: A 5 5 7 10 J Q
you ask me for: 5
I say "GO FISH!"
You draw A
I ask you for: 5
Made a book of 5's
I get another guess
I ask you for 6
You say "GO FISH!"
your hand is: A A 7 10 J Q
you ask me for:
```

To exit the game before play is completed, press the Interrupt (Ctrl-C) key sequence.

Files

Item	Description
/usr/games	Location of the system's games.

flcopy Command

Purpose

Copies to and from diskettes.

Syntax

flcopy [**-f** *Device*] [**-h** | **-r**] [**-t** *Number*]

Description

The **flcopy** command copies a diskette (opened as **/dev/rfd0**) to a file named **floppy** created in the current directory, then prints the message: `Change floppy, hit return when done`. The **flcopy** command then copies the **floppy** file to the diskette. You can specify the **-f**, **-h**, **-r**, or **-t***Number* flag to modify the behavior of the **flcopy** command.

Note: You cannot use the **flcopy** command to copy data from one diskette to another diskette of different size.

Flags

Item	Description
-f *Device*	Allows you to specify a drive other than **/dev/rfd0**.
-h	Causes the **flcopy** command to open the **floppy** file in the current directory and copy it to **/dev/rfd0**.
-r	Tells the **flcopy** command to exit after copying the diskette to the **floppy** file in the current directory.
-t *Number*	Causes only the specified *Number* of tracks to be copied. The tracks copied always begin with the first tracks on the diskette.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To copy **/dev/rfd1** to the **floppy** file in the current directory, enter:

   ```
   flcopy -f/dev/rfd1 -r
   ```

2. To copy the first 100 tracks of the diskette, enter:

   ```
   flcopy -f/dev/rfd1 -t100
   ```

Files

Item	Description
/usr/sbin/flcopy	Contains the **flcopy** command.

flush-secldapclntd Command

Purpose

The **flush-secldapclntd** command flushes the cache for the **secldapclntd** daemon process.

Syntax

/**/usr/sbin/flush-secldapclntd**

Description

The **flush-secldapclntd** command clears the cache for the **secldapclntd** daemon process.

Example

1. To flush the **secldapclntd** daemon cache, type:

```
/usr/sbin/flush-secldapclntd
```

Files

Item	Description
/etc/security/ldap/ldap.cfg	Contains information needed by the **secldapclntd** daemon to connect to the server.

fmt Command

Purpose

Formats mail messages prior to sending.

Syntax

/usr/bin/fmt [**-***Width*] [*File* ...]

Description

The **fmt** command starts a text formatter that reads the concatenation of input *Files* (or standard input if no *Files* are specified), then produces on standard output a version of the input with the line lengths set to the value of **-***Width*. If no value is specified with the **-***Width* flag, the default value of 72 characters is used. The spacing at the beginning of the input lines is preserved in the output, as are blank lines and spacing between words.

The **fmt** command is generally used to format mail messages to improve their appearance before they are sent. However, the **fmt** command may also be useful for simple formatting tasks. For example, within visual mode of a text editing program such as the vi editor, the command **!}fmt** formats a paragraph so that all lines are set to the value specified with the **-***Width* flag. If no value is specified with the -*Width* flag, the default value of 72 characters is used. Standard text editing programs are more appropriate than **fmt** for complex formatting operations.

Note: Do not use the **fmt** command if the message contains embedded messages or preformatted information from other files. This command formats the heading information in embedded messages and may change the format of preformatted information.

Flags

Item	Description
File	Specifies the name of the file to be formatted.
-*Width*	Specifies the line length. The default value for *Width* is 72 characters.

Examples

1. To format a message you have created with the mail editor, enter:

   ```
   ~| fmt
   ```

   The ~| is entered at the left margin of the message. After you issue the ~| `fmt` command, the message is formatted. The word `(continue)` is displayed to indicate that you can enter more information or send the message.
2. To format a file and display the output on your screen, enter:

   ```
   fmt file1
   ```

   In this example, the file `file1` is formatted and displayed on your screen.

Files

Item	Description
/usr/bin/fmt	Contains the **fmt** command.

fold Command

Purpose

Folds long lines for fixed-width output devices.

Syntax

fold [**-b**] [**-s**] [**-w** *Width*] [*File*...]

Description

The **fold** command is a filter that folds long lines for a finite-width output device. By default, the command folds the contents of standard input, breaking the lines to a line width of 80 (eighty). You can also specify one or more files as input to the command. The standard input is used if you do not specify any file parameters or if you specify the '-' parameter.

The **fold** command inserts a new-line character in the input lines so that each output line is as wide as possible without exceeding the value specified by the *Width* parameter. If the **-b** flag is specified, line width is counted in bytes. If the **-b** flag is not specified:

- *Width* is counted in columns as determined by the **LC_CTYPE** environment variable.
- A backspace character decreases the length of an output line by 1.
- A tab character advances to the next column where the column position is 1 plus a multiple of 8.

The **fold** command accepts **-w** *Width* values in multiples of 8 if the file contains tabs. To use other width values when the file contains tabs, use the **expand** command before using the **fold** command.

Notes:

1. The **fold** command may affect any underlining that is present.
2. The **fold** command does not insert new-line characters in the middle of multibyte characters even when the **-b** flag is used.

Flags

Item	Description
-b	Counts *Width* in bytes. The default is to count in columns.
-s	Breaks the line after the rightmost blank within the *Width* limit, if an output line segment contains any blank characters. The default is to break lines so each output line segment is as wide as possible.
-w *Width*	Specifies the maximum line width as the value of the *Width* variable. The default is 80.

Parameters

The **fold** command supports the following parameters:

Item	Description
File	The path name of a text file that must be folded. If you do not specify any file parameters, the standard input is used.
INPUT FILES	If you specify the **-b** flag, the input files are text files and the width of the lines of the text files can exceed {LINE_MAX} bytes in length. **Note:** If the **-b** flag is not specified, the input files are text files and the width of the lines of the text files can not exceed {LINE_MAX} bytes in length.

Exit Status

This command returns the following exit values:

Item	Description
0	All input files processed successfully.
>0	An error occurred.

Examples

To fold the lines of a file named `longlines` into width 72 (seventy-two), enter:

```
fold -w 72 longlines
```

Files

Item	Description
/usr/bin/fold	Contains the **fold** command.

folder Command

Purpose

Selects and lists folders and messages.

Syntax

folder [**+** *Folder*] [*Message*] [**-all**] [**-nopack** | **-pack**] [**-nofast** | **-fast**] [**-norecurse** | **-recurse**] [**-print** | **-noprint**] [**-header** | **-noheader**] [**-nototal** | **-total**] [**-push** | **-pop**] [**-list** | **-nolist**]

Description

The **folder** command sets the current folder and the current message for that folder, and lists information about your folders. By default, the **folder** command lists the current folder name, the number of messages, the range of the message numbers, and the current message.

The folder specified by the **+***Folder* flag becomes the current folder. The message specified by the *Message* parameter becomes the current message for the folder. Use the **-pack** flag to renumber the messages in a folder.

Flags

Item	Description
-all	Displays a line of information about each folder in your mail directory.
-fast	Displays only the names of the folders.
+*Folder*	Specifies the folder information to display.
-header	Displays column headings for the folder information.
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For Message Handler (MH), the name of this flag must be fully spelled out.
-list	Displays the current folder followed by the contents of the folder stack.
Message	Sets the specified message as the current message. Unless you specify the **+***Folder* flag, the command sets the specified message for the current folder. Use the following references to specify a message: ***Number*** Number of the message. **cur or . (period)** Current message. This is the default. **first** First message in a folder. **last** Last message in a folder. **next** Message following the current message. **new** The new message that is created. **prev** Message preceding the current message.
-nofast	Displays information about each folder. This flag is the default.
-noheader	Suppresses column headings for the folder information. This flag is the default.
-nolist	Suppresses the display of the folder-stack contents. This flag is the default.
-nopack	Prevents renumbering of the messages in the folder. This flag is the default.
-noprint	Prevents display of folder information. If the **-push**, **-pop**, or **-list** flag is specified, the **-noprint** flag is the default.
-norecurse	Displays information about the top-level folders in your current folder only. Information about subfolders is not displayed. This flag is the default.

Item	Description
-nototal	Prevents display of the total of all messages and folders in your mail directory structure. When the **-all** flag is specified, the default is the **-total** flag; otherwise, the **-nototal** flag is the default.
-pack	Renumbers the messages in the specified folder. Renumbering eliminates gaps in the message numbering after messages have been deleted.
-pop	Removes the folder from the top of the folder stack and makes it the current folder. The **+***Folder* flag cannot be specified with the **-pop** flag.
-print	Displays information about the folders. If the **-push**, **-pop**, or **-list** flag is specified, the **-noprint** flag is the default; otherwise, the **-print** flag is the default.
-push	Moves the current folder to the top of the folder stack and sets the specified folder as the current folder. If no folder is specified, the **-push** flag swaps the current folder for the folder on top of the folder stack.
-recurse	Displays information about all folders and subfolders in your current folder.
-total	Displays all messages and folders in your mail directory structure. The **-total** flag does not display information for subfolders unless you specify the **-recurse** flag. The **-total** flag is the default if the **-all** flag is specified.

Profile Entries

The following entries are entered in the *UserMhDirectory***/.mh_profile** file:

Item	Description
`Current-Folder:`	Sets the default current folder.
`Folder-Protect:`	Sets the protection level for the new folder directories.
`Folder-Stack:`	Specifies the folder stack.
`lsproc:`	Specifies the program used to list the contents of a folder.
`Path:`	Specifies the user's MH directory.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To display information about the current folder, enter:

   ```
   folder
   ```

   The system responds with a message similar to the following:

   ```
   inbox+ has 80 messages (1-82); cur = 7; (others).
   ```

   In this example, the current folder is `inbox`.The folder contains `80 messages`, ranging from message 1 to message 82. The current message number is 7.

2. To display information about all folders, enter:

   ```
   folder -all
   ```

The system responds with a message similar to the following:

```
Folder    #  of  messages  (range);  cur  msg    (other  files)
inbox+  has  80  messages  (1-82);  cur=  7;  (others).
test    has    5  messages  (1-5);    cur=  5;  (others).

        Total=  85  messages  in  2  folders
```

In this example, there are 2 folders containing a total of 85 messages. The current folder is `inbox`, indicated by the + (plus sign) that follows it.

3. To make the `test` folder the current folder and display information about `test`, enter:

   ```
   folder   +test
   ```

   The system responds with a message similar to the following:

   ```
   test+  has  5  messages  (1-5);  cur  =  5;  (others)
   ```

4. To make message 2 the current message in the current folder, enter:

   ```
   folder  2
   ```

   The system responds with a message similar to the following:

   ```
   test+  has  5  messages  (1-5);  cur  =  2;  (others)
   ```

5. To create a folder called `group` and make it the current folder, enter:

   ```
   folder   +group
   ```

   The system responds with a message similar to the following:

   ```
   Create  folder  "/home/dawn/Mail/group"?  _
   ```

   Enter:

   ```
   yes
   ```

   The system responds with a message similar to the following:

   ```
   group+  has  no  messages.
   ```

6. To renumber the messages in the current folder, enter:

   ```
   folder   -pack
   ```

   The system responds with a message similar to the following:

   ```
   inbox+  has  80  messages  (1-80);  cur=  7;  (others).
   ```

   In this example, the messages are renumbered to eliminate gaps in the message numbering after messages have been deleted.

Files

Item	Description
$HOME/.mh_profile	Contains the MH user profile.
/usr/bin/folder	Contains the **folder** command.

folders Command

Purpose

Lists all folders and messages in mail directory.

Syntax

folders [**+***Folder*] [*Message*] [**-all**] [**-pack** | **-nopack**] [**-fast** | **-nofast**] [**-recurse** | **-norecurse**] [**-print** | **-noprint**] [**-header** | **-noheader**] [**-total** | **-nototal**] [**-push** | **-pop**] [**-list** | **-nolist**]

Description

The **folders** command lists all folders and messages in your mail directory. This command is equivalent to the **folder** command specified with the **-all** flag.

Flags

Item	Description
-all	Displays a line of information about each folder in your mail directory.
-fast	Displays only the names of the folders.
+*Folder*	Specifies the folder information to display.
-header	Displays column headings for the folder information. This flag is the default.
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For Message Handler (MH), the name of this flag must be fully spelled out.
-list	Displays the current folder followed by the contents of the folder stack.
Message	Sets the specified message as the current message. Unless you specify the **+***Folder* flag, the command sets the specified message for the current folder. Use the following references to specify a message: ***Number*** Number of the message. **cur or . (period)** Current message. This is the default. **first** First message in a folder. **last** Last message in a folder. **next** Message following the current message. **new** The new message that is created. **prev** Message preceding the current message.
-nofast	Displays information about each folder. This flag is the default.
-noheader	Suppresses column headings for the folder information.
-nolist	Suppresses the display of the folder-stack contents. This flag is the default.
-nopack	Prevents renumbering of the messages in the folder. This flag is the default.

Item	Description
-noprint	Prevents display of folder information. If the **-push**, **-pop**, or **-list** flag is specified, the **-noprint** flag is the default.
-norecurse	Displays information about the folders in your mail directory. Information about subfolders is not displayed. This flag is the default.
-nototal	Prevents display all messages and folders in your mail directory structure.
-pack	Renumbers the messages in the folders. Renumbering eliminates gaps in message numbering after messages have been deleted.
-pop	Removes the folder from the top of the folder stack and makes it the current folder.
-print	Displays the number of messages in each folder, the current message for each folder, and the current folder. If the **-push**, **-pop**, or **-list** flag is specified, the **-noprint** flag is the default; otherwise, the **-print** flag is the default.
-push	Moves the current folder to the top of the folder stack and sets the specified folder as the current folder. If no folder is specified, the **-push** flag swaps the current folder for the folder on top of the folder stack.
-recurse	Displays information about all folders and subfolders in your mail directory structure.
-total	Displays all messages and folders in your mail directory structure. The **-total** flag does not display information for subfolders unless you specify the **-recurse** flag. The **-total** flag is the default.

Profile Entries

The following entries are entered in the *UserMhDirectory***/.mh_profile** file:

Item	Description
`Current-Folder:`	Sets the default current folder.
`Folder-Protect:`	Sets the protection level for the new folder directories.
`Folder-Stack:`	Specifies the folder stack.
`lsproc:`	Specifies the program used to list the contents of a folder.
`Path:`	Specifies the user's MH directory.

Examples

1. To display information about all folders, enter:

   ```
   folders
   ```

   The system responds with a message similar to the following:

   ```
   Folder  # of messages (range); cur msg  (other files)
   inbox+ has 80 messages (1-82); cur= 7; (others).
   test has 5 messages (1-6);   cur=  5; (others).

      Total= 85 messages in 2 folders.
   ```

   In this example, there are 2 folders containing a total of 85 messages. The current folder is `inbox`, indicated by the + (plus sign) following it.

2. To list only the names of all folders, enter:

   ```
   folders    -fast
   ```

   The system responds with a message similar to the following:

```
inbox
test
```

3. To renumber the messages in all folders, enter:

   ```
   folders    -pack
   ```

   The system responds with a message similar to the following:

   ```
   inbox+ has 80 messages (1-80); cur= 7; (others).
   test has 5 messages (1-5);  cur= 5; (others).
   ```

   In this example, the messages in the `inbox` folder and in the `test` folder have been renumbered to eliminate gaps in message numbering after messages were deleted.

Files

Item	Description
$HOME/.mh_profile	Contains the MH user profile.
/usr/bin/folders	Contains the **folders** command.

forcerpoffline Command

Purpose

Forces a peer domain to be offline.

Syntax

`forcerpoffline` [`-h`] *domain_name*

Description

Attention: Use this command with extreme caution.

The `forcerpoffline` command must be used only if a node is in a pending online state and you are unable to bring it online using the `startrpdomain` command. This scenario can occur if you try to bring the node online while the domain is operating under quorum. If you are not sure why the node is stuck in the pending online state, run the `ctsnap` command before using the `forcerpoffline` command. As a result of running the `forcerpoffline` command, the configuration resource manager subsystem (`IBM.ConfigRM`) and the RMC subsystem (`ctrmc`) are recycled.

Parameters

domain_name
Specifies the name of a previously defined peer domain that is to be forced offline.

Flags

-h
Writes the command usage statement to standard output.

Files

The `/var/ct/cfg/current_cluster` file and the `/var/ct/cfg/default_cluster` file are modified.

Standard output

When the `-h` flag is specified, this command usage statement is written to standard output.

Exit status

0
The command ran successfully.

1
The command terminated due to an underlying RMC error.

2
The command terminated due to an underlying error in the command script.

3
The command terminated because the user specified a non-valid flag.

4
The command terminated because the user specified a non-valid parameter.

5
The command terminated due to a user error (specifying a domain name that does not exist, for example).

Security

You must have `root` authority to run this command.

Implementation specifics

This command is part of the `rsct.basic.rte` fileset for AIX and `rsct.basic-3.1.0.0-0.`*platform*`.rpm` package for Linux, Solaris, and Windows, where *platform* is `i386`, `ppc`, `ppc64`, `s390`, or `x86_64`.

Location

/opt/rsct/bin/forcerpoffline

format Command

Purpose

Formats either diskettes or read/write optical media disks.

Syntax

format [**-d** *Device*] [**-f**] [**-l**]

Description

Attention: Formatting a diskette or read/write optical disk destroys any existing data on it.

The **format** command formats diskettes in the diskette drive specified by the *Device* parameter. The **format** command determines the device type, which may be one of the following:

- 5.25-inch low-density diskette (360KB) containing 40x2 tracks, each with 9 sectors
- 5.25-inch high-capacity diskette (1.2MB) containing 80x2 tracks, each with 15 sectors
- 3.5-inch low-density diskette (720KB) containing 80x2 tracks, each with 9 sectors
- 3.5-inch high-capacity diskette (1.44MB) containing 80x2 tracks, each with 18 sectors

- 3.5-inch high-capacity diskette (2.88MB) containing 80x2 tracks, each with 36 sectors

The sector size is 512 bytes for all diskette types.

The **format** command formats a diskette with the highest capacity supported by the diskette drive, unless the *Device* parameter specifies a different density.

The **format** command formats a read/write optical disk, provided that the drive supports setting the Format Options Valid (FOV) bit of the defect list header to 0. To format a read/write optical disk, use the name of the read/write optical drive (such as **/dev/romd0**) after the **-d** flag.

Before formatting a diskette or read/write optical disk, the **format** command prompts for verification. This allows you to end the operation cleanly.

Flags

Item	Description
-d *Device*	Specifies the device used to format the diskette. If the device name ends with the letter **h**, the drive formats the diskette for high density. If the device name ends with the letter **l**, the drive formats the diskette for low density. Refer to the **fd** special file for information about valid device types. This flag is used only with the **format** command. **Attention:** If the diskette drive supports a higher capacity than the highest capacity for which the diskette was manufactured, the capacity of the diskette should be explicitly stated in the *Device* parameter (**-d** *Device* flag) of the **format** command. For example, to format a 1MB diskette on a 4MB diskette drive, specify the diskette capacity in the **-d** flag as follows: `-d /dev/fd0.9 for a 1MB diskette` Failure to do this may cause read and write errors.
-f	Formats the diskette without checking for bad tracks, thus formatting the diskette more quickly. This flag applies to diskettes only, not to read/write optical disks. It is used only with the **format** command.
-l	(Lowercase L) Formats a 360KB diskette in a 5.25-inch, 1.2MB diskette drive. Formats a 720KB diskette in a 3.5-inch 1.4MB diskette drive. This flag applies to diskettes only, not to read/write optical disks. It is used only with the **format** command. **Attention:** A 360KB diskette drive may not be able to read a 360KB diskette that has been formatted in a 1.2MB drive.

Parameters

Item	Description
Device	Specifies the device containing the diskette to be formatted. The default is the **/dev/rfd0** device for drive 0.

Examples

1. To format a diskette in the **/dev/rfd0** device, enter:

```
format   -d   /dev/rfd0
```

2. To format a diskette without checking for bad tracks, enter:

```
format   -f
```

3. To format a 360KB diskette in a 5.25-inch, 1.2MB diskette drive in the **/dev/rfd1** device, enter:

```
format   -l   -d   /dev/rfd1
```

4. To format a 3.5-inch, low-density (720KB) diskette, enter:

```
format -d /dev/fd0.9
```

5. To format a 3.5-inch, high-capacity (1.44MB) diskette, enter:

```
format -d /dev/fd0.18
```

6. To format a read/write optical disk in the **/dev/romd0** device, enter:

```
format -d /dev/romd0
```

Files

Item	Description
/usr/sbin/format	Contains the **format** command.
/dev/rfd*	Specifies the device parameters.
/dev/fd*	Specifies the device parameters.
/dev/romd*	Specifies the device parameters.
/dev/omd*	Specifies the device parameters.

fortune Command

Purpose

Displays a random fortune from a database of fortunes.

Syntax

fortune [**-**] [**-s** | **-l** | **-a** [**-w**]] [*File*]

Description

The **fortune** command displays a fortune from either the **fortunes.dat** file or the file specified by the *File* parameter. After displaying the fortune, the **fortune** command exits.

Flags

Item	Description
-	Displays the usage summary.
-a	Displays either type of fortune.
-l	Displays long fortunes only.
-s	Displays short fortunes only.
-w	Waits after displaying a fortune to allow the user time to read the fortune.

Files

Item	Description
/usr/games	Location of the system's games.
/usr/games/lib/fortune/fortunes.dat	Location of the default **fortune** database.

forw Command

Purpose

Forwards messages.

Syntax

forw [**+** *Folder*] [**-draftfolder** **+***Folder* | **-nodraftfolder**] [*Message*] [**-draftmessage** *Message*] [**-digest** *Name* [**-issue** *Number*] [**-volume** *Number*]] [**-form** *FormFile*] [**-editor** *Editor* | **-noedit**] [**-whatnowproc** *Program* | **-nowhatnowproc**] [**-filter***File*] [**-annotate** [**-inplace** | **-noinplace**] | **-noannotate**] [**-format** | **-noformat**] [**-help**]

Description

The **forw** command starts an interface for forwarding messages. By default, the **forw** command interface:

- Opens for editing a *UserMhDirectory***/draft** file.
- Prompts the user to enter forwarding information based on the template defined in the **/etc/mh/mhl.forward** file.
- Prompts the user to enter any additional text that should accompany the forwarded message.

To complete editing of the *UserMhDirectory***/draft** file, press the Ctrl-D sequence. The **forw** command appends the current message from the current folder to the **draft** file. If you want to append more than one message, use the *Messages* parameter.

Note: A line of dashes or a blank line must be left between the header and the body of the message for the message to be identified when it is sent.

Upon exiting the editor, the **forw** command starts the `What Now?` prompt. Press the Enter key to see a list of the available **whatnow** subcommands. These subcommands enable you to continue to edit the message, list the message, direct the disposition of the message, or end the processing of the **forw** command.

The **forw** command allows you to change the format of the forwarded message with the **-form** flag. By default, the command uses the default message format located in your *UserMhDirectory***/forwcomps** file. If you have not defined your own **forwcomps** file, the **/etc/mh/forwcomps** file is used.

Use the **-annotate** flag to annotate the original message with forwarding information. To ensure annotation, send the forwarded note before exiting the **forw** command interface.

Note: The **-annotate** flag is not preserved over multiple executions of the **forw** command on the same draft.

Flags

Item	Description
-annotate	Annotates the forwarded messages with the lines: `Forwarded: Date` `Forwarded: Addresses` Use the **-inplace** flag to force annotation in place. This preserves links to the annotated message.
-digest *Name*	Uses the digest facility to create a new issue for the digest specified by the *Name* variable. The **forw** command expands the format strings in the **components** file (using the same format string mechanism used by the **repl** command) and composes the draft using the standard digest encapsulation algorithm. After the draft has been composed, the **forw** command writes out the volume and issue entries for the digest and starts the editor. Unless you specify the **-form** flag, the **forw** command uses the format in the *UserMhDirectory***/digestcomps** file. If this file does not exist, the command uses the default specified in the **/etc/mh/digestcomps** file.
-draftfolder +*Folder*	Places the draft message in the specified folder. If you do not specify this flag, the **forw** command selects a default draft folder according to the information supplied in the Message Handler (MH) profiles. If **+***Folder* is not specified, the `Current-Folder` is assumed. You can define a default draft folder in the **$HOME/.mh_profile** file. **Note:** If **-draftfolder +***Folder* is followed by a *Message* parameter, it is the same as specifying the **-draftmessage** flag.
-draftmessage *Message*	Identifies a draft message. If you specify **-draftfolder** without the **-draftmessage** flag, then the default message is `new`.
-editor *Editor*	Specifies the initial editor for preparing the message.
-filter *File*	Reformats each message being forwarded and places the reformatted message in the draft message. The **-filter** flag accepts formats used by the **mhl** command.
+*Folder*	Specifies the folder that contains the messages you want to forward. If a folder is not specified, `Current-Folder` is assumed.
-form *FormFile*	Displays the **forw** command output in the format specified by the *FormFile* variable. The **forw** command treats each line in the specified file as a format string. If the **-digest** flag is also specified, the **forw** command uses the form specified by the *File* variable as the format of the digest. If the **-form** flag is not specified when the **-digest** flag is used, the digest filter file becomes the form default.
-format	Using the **mhl** command and a default format file, reformats each message being forwarded and places the reformatted message in the draft message. If the *UserMhDirectory***/mhl.forward** file exists, it contains the default format. Otherwise, the **/etc/mh/mhl.forward** file contains the default format.

Item	Description
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For MH, the name of this flag must be fully spelled out.
-inplace	Forces annotation to be done in place to preserve links to the annotated message.
-issue *Number*	Specifies the issue number of the digest. The default issue number is one greater than the current value of the `DigestName-issue-list` entry in the *UserMhDirectory***/context** file.
Message	Specifies a message. You can specify several messages, a range of messages, or a single message. Use the following references when specifying messages: ***Number*** Number of the message. ***Sequence*** A group of messages specified by the user. Recognized values include: **all** All messages in the folder. **cur or . (period)** Current message. This is the default. **first** First message in a folder. **last** Last message in a folder. **new** New message that is created. **next** Message following the current message. **prev** Message preceding the current message The default message is the current message in the current folder. When you specify several messages, the first message forwarded becomes the current message. When you specify a folder, that folder becomes the current folder.
-noannotate	Prevents annotation of the original message. This flag is the default.
-nodraftfolder	Places the draft in the *UserMhDirectory***/draft** file.
-noedit	Suppresses the initial edit.
-noformat	Prevents reformatting of the messages being forwarded. This flag is the default.
-noinplace	Prevents annotation in place. This flag is the default.
-nowhatnowproc	Prevents interactive processing of the **forw** command. With this flag, no editing occurs.

Item	Description
-volume *Number*	Specifies the volume number of the digest. The default volume number is the current value of the `DigestName-volume-list` entry in the *UserMhDirectory***/context** file.
-whatnowproc *Program*	Starts the specified program to guide you through the forwarding tasks. **Note:** If you specify the **whatnow** command for *Program*, the **forw** command starts an internal **whatnow** procedure instead of a program with the file name **whatnow**.

Profile Entries

The following entries are entered in the *UserMhDirectory***/.mh_profile** file:

Item	Description
`Current-Folder:`	Sets the default current folder.
`Draft-Folder:`	Sets the default folder for drafts.
`Editor:`	Sets the default editor.
`fileproc:`	Specifies the program used to refile messages.
`mhlproc:`	Specifies the program used to filter messages being forwarded.
`Msg-Protect:`	Sets the protection level for the new message files.
`Path:`	Specifies the *UserMhDirectory*.
`whatnowproc:`	Specifies the program used to prompt `What now?` questions.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To forward the current message to another person, enter:

   ```
   forw
   ```

   The system prompts you to enter information in the header fields. To skip a field, press the Enter key. You must enter information in the `To:` field. The system responds with:

   ```
   ---------Enter initial text
   ```

   Enter the text you want displayed before the text of the forwarded message, and press the Ctrl-D key sequence. The text of the forwarded message is displayed, and you are prompted with `What now?` Enter `send` after the `What now?` prompt to forward the message.

2. To forward message 5 from the `inbox` folder, enter:

   ```
   forw    +inbox   5
   ```

Files

Item	Description
/etc/mh/digestcomps	Defines the MH default message form when the **-digest** flag is specified.
/etc/mh/mhl.forward	Contains the default MH message filter.
UserMhDirectory/**digestcomps**	Specifies a user's default message form when the **-digest** flag is specified. (If it exists, it overrides the MH default message filter.)
UserMhDirectory/**forwcomps**	Contains a user's default message form.
UserMhDirectory/**mhl.forward**	Contains a user's default message filter. (If it exists, it overrides the MH default message filter.)
/usr/bin/forw	Contains the executable form of the **forw** command.
$HOME/.mh_profile	Contains the file that customizes MH for an individual user.
UserMhDirectory/**draft**	Contains the draft created for editing messages.
/etc/mh/forwcomps	Defines components for the messages created by the **forw** command.

fpm Command

Purpose

Manages the permissions on commands and daemons owned by privileged users with setuid or setgid permissions.

Syntax

fpm [**-l** *level* [**-f** *file*] [[**-c**] [**-p**]] [**-v**]] | [**-s**] | [**-q**] | [**-?**]

Description

The **fpm** command allows administrators to harden their system by disabling the setuid and setgid bits on many commands in the operating system. This command is intended to remove the setuid permissions from commands and daemons owned by privileged users, but you can also customize it to address the specific needs of unique computer environments.

The setuid programs on the base AIX operating system have been grouped to allow for levels of hardening. This grouping allows administrators to choose the level of hardening according to their system environment. Additionally, you can use the **fpm** command to customize the list of programs that need to be disabled in your environment. You must review the levels of disablement and choose the right level for your environment.

Changing execution permissions of commands and daemons with the **fpm** command affects non-privileged users, denying their access to these commands and daemons or functions of the commands and daemons. Additionally, other commands that call or depend on these commands and daemons can be affected. Any user-created scripts that depend on commands and daemons with permissions that were altered by the **fpm** command cannot operate as expected when run by non-privileged users. Give full consideration to the effect and potential impact of modifying default permissions of commands and daemons.

You must perform appropriate testing before using this command to change the execution permissions of commands and daemons in any critical computer environment. If you encounter problems in an environment where execution permissions have been modified, restore the default permissions and

recreate the problem in this default environment to ensure the issue is not due to lack of appropriate execution permissions.

The **fpm** command provides the capability to restore the original AIX installation default permissions using the **-l default** flag.

Additionally, the **fpm** command logs the permission state of the files prior to changing them. The **fpm** log files are created in the **/var/security/fpm/log/*date_time*** file. If necessary, you can use these log files to restore the system's file permissions recorded in a previously saved log file.

When the **fpm** command is used on files that have extended permissions, it disables the extended permissions, though any extended permission data that existed prior to the **fpm** invocation is retained in the extended ACL.

Customized configuration files can be created and enacted as part of the high, medium, low, and default settings. File lists can be specified in the **/usr/lib/security/fpm/custom/high/*** directory, the **/usr/lib/security/fpm/custom/medium/*** directory, and the **/usr/lib/security/fpm/custom/default/*** directory. To take advantage of this feature, create a file containing a list of files that you want to be automatically processed in addition to the **fpm** commands internal list. When the **fpm** command is run, it also processes the lists in the corresponding customized directories. To see an example of the format for a customized file, view the **/usr/lib/security/fpm/data/high_fpm_list** file. The default format can be viewed in the **/usr/lib/security/fpm/data/default_fpm_list.example** file. For the customization of the **-l low** flag, the **fpm** command reads the same files in the **/usr/lib/security/fpm/custom/medium** directory, but only removes the setgid permissions, whereas the **-l medium** flag removes both the setuid and setgid permissions.

The **fpm** command cannot run on TCB-enabled hosts.

Flags

Item	Description
-l *level*	Specifies that the file permissions are changed according to the level specified. **-l high** High-level security. This flag removes the setuid and setgid permissions for computer systems that fall into the category of high-level security. This flag uses the list of files in the **/usr/lib/security/fpm/data/high_fpm_list** file and the **/usr/lib/security/fpm/custom/high/*.*** file as input by default, but an alternate input file can be selected with the **-f** flag. **-l medium** Medium-level security. This flag removes the setuid and setgid permissions for computer systems that fall into the category of medium-level security. This flag uses the list of files in the **/usr/lib/security/fpm/data/med_fpm_list** file and the **/usr/lib/security/fpm/custom/med/*.*** file as input by default. An alternate input file can be selected with the **-f** flag. **-l low** Low-level security. This flag removes only the setuid permission for computer systems that fall into the category of low-level security. This flag uses the list of files in the **/usr/lib/security/fpm/data/med_fpm_list** file and the **/usr/lib/security/fpm/custom/med/*.*** file as input by default. An alternate input file can be selected with the **-f** flag. **-l default** Returns the system commands previously modified by the **fpm** command to their default out-of-the-box permissions, if the commands were previously altered using the level of high, medium or low. This option reads the **/usr/lib/security/fpm/custom/default/*.*** file and sets the permissions defined in the file.
-s	Displays the status of the changes last made by the **fpm** command. The status is written in the **/usr/lib/security/fpm/data/status_fpm** file. The security level is represented as a whole integer from 1-5 (inclusive).
-f *file*	Allows the specification of a file list to override the default input file, where the *file* parameter is a file name containing the list of files to be used as input. This flag must be used along with the **-l high|medium|low|default** or the **-c** flag. When using a level of high, medium or low, the input file format is as follows: *full_path*/*filename* For example, `/usr/sbin/foo`. When used with the **-l default** flag, the input file format is as follows: *octet_permissions full_path*/*filename* There must be a space between the *octet_permissions* variable and the *full_path* variable. For example, `0750 /usr/sbin/foo`. The **-f** format allows for the specific control of the list of files being affected.

Item	Description
-c	Checks the files permissions, but takes no action. The **fpm** command returns 0 if no files were found out of compliance. If one or more files contain non-compliant permissions, this option lists the non-compliant file(s) and returns 1. This flag must be used with the **-l *level*** option. For example, if the **-c** and the **-l high** flags are used together, the **fpm** command checks the files listed in the **/usr/lib/security/fpm/data/high_fpm_list** file and removes their setuid and setgid permissions. The **-f *file*** flag can also be used with the **-c** option.
-v	Verbose output.
-p	Previews the changes the **fpm** command is to make, but takes no action. This flag must be used in conjunction with the **-l *level*** flag.
-q	Quit mode, which minimizes output and suppresses warnings.
-?	Prints the usage statement.

Exit Status

Item	Description
0	Success.
Non-zero	Failure or partial failure. Use the **-v** flag for more details.

Security

The **fpm** command reduces the number of commands with setuid and setgid permissions.

Examples

1. To apply the **fpm** command's low level security settings, enter:

   ```
   fpm –l low
   ```

   This command also processes any file list in the **/usr/lib/security/fpm/custom/med/** directory.
2. To check if the system commands are presently set to **fpm** low-level permissions, enter:

   ```
   fpm –c –l low
   ```

   This command reports any file with permissions out of conformance.
3. To restore the traditional out-of-the-box default permissions, enter:

   ```
   fpm –l default
   ```

   This command also processes any file list in the **/usr/lib/security/fpm/custom/default/** directory.
4. To list, or give a preview of what permission changes are to be done to make the system compliant with the **fpm** command's high-level security without changing any file permissions, enter:

   ```
   fpm -l high –p
   ```

   This command also previews any file list in the **/usr/lib/security/fpm/custom/high/** directory.
5. To apply the **fpm** command's high level security settings, enter:

   ```
   fpm –l high
   ```

   This command also processes any file list in the **/usr/lib/security/fpm/custom/high/** directory.

6. To list the current status of the system as changed through the **fpm** command, enter:

```
fpm -s
```

7. If the **fpm -l *level*** command was run on 7 January 2007 at 8:00 a.m., then the permission state of the affected files was captured by the **fpm** command before it made any changes. To restore the file permissions to their state of 7 January 2007 at 8:00 a.m., enter:

```
fpm -l default -f /var/security/fpm/log/01072007_08:00:00
```

Files

Item	Description
/usr/lib/security/fpm/data/default_list_example	Contains the default out-of-the-box permissions and files.
/usr/lib/security/fpm/data/high_fpm_list	Contains the list of files whose permissions can be changed with the **-l high** flag.
/usr/lib/security/fpm/data/med_fpm_list	Contains the list of files whose permissions can be changed with the **-l medium** or **-l low** flag.
/usr/lib/security/fpm/custom/high/*	Files in this directory can be used as user-configured input when the **-l high** level is selected. These files must contain a list of files, from which the **fpm** command removes setuid and setgid permissions.
/usr/lib/security/fpm/custom/medium/*	Files in this directory serve the same function as the high-level directory, but are used with the **-l medium** flag and the **-l low** flag.
/usr/lib/security/fpm/custom/default/*	Files in this directory serve the same function as the high-level directory, but are used with the **-l default** flag. **Note:** These files must be in the same format as the **/usr/lib/security/fpm/data/default_list_example** file.
/usr/lib/security/fpm/data/status_fpm	Contains the status of the file permissions changed from the last run of the **fpm** command.
/var/security/fpm/log/*date_time*	Contains the list of files changed by the **fpm** command corresponding to the data and the time at which the command was run. This file can be used as the input file of the **-f** flag to restore permissions to this instance.

frcactrl Command

Purpose

Controls and configures FRCA.

Syntax

frcactrl { **load** | **unload** }**frcactrl open** *Ip_Address Port* [*Virtual_Host*] *Server_Name Virtual_Root Log_File***frcactrl close** *Ip_Address Port* [*Virtual_Host*]**frcactrl loadfile** *Ip_Address Port* [*Virtual_Host*] *Document_Root File ...***frcactrl stats** [reset] [*Interval*]**frcactrl logging** *Ip_Address Port* [*Virtual_Host*] { on | off } [*Format*] [*CPU_Id*] **frcactrl** { **start** | **stop** } *Ip_Address Port* [*Virtual_Host*] **frcactrl revaltimeout** *Ip_Address Port* [*Virtual_Host*] [*Seconds*] **frcactrl pctonintr** [*Percentage*]**frcactrl set** { option=*value* }**frcactrl getfrcactrl default** [*option*]

Description

The **frcactrl** command controls and configures the FRCA kernel extension. The kernel extension must be loaded before starting any Web servers that want to use FRCA.

Subcommands

load
Loads the FRCA kernel extension if not loaded.

unload
Unloads the FRCA kernel extension if loaded.

open *Ip_Address Port* [*Virtual_Host*] *Server_Name Virtual_Root Log_File*
Opens and configures an FRCA instance under the name *Server_Name* for IP address *Ip_Address* on port *Port*. The *Virtual_Root* parameter specifies the directory where the Web data starts. The requests will be logged in the file specified by *Log_File*. This filename must be fully qualified.

Note: FRCA only supports one log file. When running more than one Web server on a system with FRCA, all requests will be logged to the same file.

close *Ip_Address Port* [*Virtual_Host*]
Closes the FRCA instance associated with the specified IP address and port.

loadfile *Ip_Address Port* [*Virtual_Host*] *Document_Root File ...*
Loads the specified file(s) into the FRCA / Network Buffer Cache. The IP and Port number at which the FRCA instance has been opened earlier must be specified here along with the document root and the file(s) to be loaded.

stats [reset] [*Interval*]
Displays FRCA statistics. The optional **reset** subcommand clears (zeros) the statistics. You can display the statistics at a regular interval by specifying the duration of the interval in seconds with the *Interval* parameter.

logging *Ip_Address Port* [*Virtual_Host*] { on | off } [*Format*] [*CPU_Id*]
Turns logging of request served by an FRCA instance bound to the specified *Ip_Address* and *Port* on or off. The format can be one of CLF, V-CLF, or ECLF (Common Log Format, Virtual Host & CLF, Extended CLF). The FRCA logging thread can also be bound to a particular CPU by specifying the optional *CPU_Id* parameter on multiprocessor machines.

start *Ip_Address Port* [*Virtual_Host*]
Enables the kernel get engine to serve requests sent to the specified IP and port.

stop *Ip_Address Port* [*Virtual_Host*]
Disables the kernel get engine for the specified IP and port.

revaltimeout *Ip_Address Port* [*Virtual_Host*] [*Seconds*]
Changes the revalidation timeout value for an FRCA instance at the specified address and port. The timeout value must be specified in seconds.

pctonintr [*Percentage*]
Controls the percentage of CPU time that can be spent in interrupt context. If this value is too low then FRCA will send requests up to Web server more often since it always executes in interrupt context. Any value >= 100 will result in FRCA serving every request that is cached in the FRCA cache.

set {option=*value*}
Sets the specified FRCA option to the value. The only option currently available is **frca_hashsz** which sets the number of slots in the FRCA hash table to the specified value. The default value of **frca_hashsz** is 12841. If changed, the value used must be prime as this results in a more even distribution of hash table entries.

get
Displays all FRCA options available along with their current values. Only one option called **frca_hashsz** currently exists.

default [*option*]
Sets the value of all options to their default values when used without specifying an option name. If an option name is specified it sets only the value of the specified option to its default.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. The following are examples of using the **open** subcommand:

   ```
   frcactrl open 9.1.1.1 80 ici imgcache01 /htdocs /logs/frca.log bin
   ```

   ```
   frcactrl open 9.1.1.2 80 ici imgcache02 /htdocs /logs/frca.log bin
   ```

   In the above examples "ici" is the virtual host name which could be used to access one of the mirrors imgcache01 or imgcache02. The IP address may be 0.0.0.0 if the Web server is not bound to a specific IP address.
2. To close the FRCA instance associated with IP address 9.1.1.1 and port 80, type:

   ```
   frcactrl close 9.1.1.1 80
   ```
3. To load the content of files /a/b/c/d and /a/b/c/e with URLs /d and /e, type:

   ```
   frcactrl loadfile /a/b/c /a/b/c/d e
   ```
4. To display the FRCA statistics, type:

   ```
   frcactrl stats
   ```

   This will cause the FRCA statistics to be displayed. They will look similar to this:

   ```
          Total    Deferred       Cache       Cache    Resource
       Requests    Requests        Hits      Misses      Errors
    ------------------------------------------------------------
     1024065396         227  1024065168           1           0
   ```
5. This examples shows how to use the **start** subcommand for virtual host "ici":

   ```
   frcactrl start 9.1.1.1 80 ici
   ```

   Note: The virtual host parameter is optional.
6. To disable the kernel get engine for port 80 on IP address 9.1.1.1 on virtual host "ici", type:

   ```
   frcactrl stop 9.1.1.1 80 ici
   ```
7. The following example sets the revalidation timeout value for the FRCA instance at port 80 of IP address 9.1.1.1 to 100 seconds:

```
frcactrl revaltimeout 9.1.1.1 80 100
```

8. To allow the CPU to spend 98 percent of its time in interrupt context, type:

```
frcactrl pctonintr 98
```

9. To set the value of the **frca_hashsz** option to 24499, type:

```
frcactrl set frca_hashsz=24499
```

10. To set the value of **frca_hashsz** to its default, type:

```
frcactrl default frca_hashsz
```

Files

/usr/bin/frcactrl

from Command

Purpose

To determine whom mail is from.

Syntax

from [**-d** *Directory*] [**-s** *Sender*] [*user*]

Description

The **from** command displays the message headings in your mailbox file to show you whom mail is from. If you specify *user*, the *user* mailbox is examined instead of your own (provided that you have read permission to user's mailbox).

Flags

Item	Description
-d *Directory*	Specifies the system mailbox directory.
-s *Sender*	Prints message headers only for mail sent by *Sender*.

Parameters

Item	Description
user	Specifies the *user* mailbox that is examined instead of your own (provided that you have read permission to the user's mailbox).

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To display the message headings in your mailbox, enter:

```
from
```

The names of the senders and message dates are displayed.

2. To display the message headings for mail sent by a specific user, enter:

   ```
   from -s dale
   ```

   In this example, only the message headings of the messages sent from user `dale` are displayed.

3. To display the message headings in a specific user's mailbox, enter:

   ```
   from   dawn
   ```

   In this example, the message headings from user `dawn ' s` mailbox are displayed (provided that you have read permission to `dawn ' s` mailbox).

4. To view all messages bob received from `jane`, enter:

   ```
   from -d /var/spool/mail -s jane bob
   ```

   This allows you to see all messages that bob received from `jane`, provided you have the permissions (such as root).

Files

Item	Description
/var/spool/mail/*	System mailboxes for all users.
/usr/bin/from	User mailbox files.

fsck Command

Purpose

Checks file system consistency and interactively repairs the file system.

Syntax

fsck [**-n**] [**-p**] [**-y**] [**-d***BlockNumber*] [**-f**] [**-i***i-NodeNumber*] [**-o** *Options*] [**-t***File*] [**-V** *VfsName*] [*FileSystem1 - FileSystem2 ...*]

Description

Attention: Always run the **fsck** command on file systems after a system malfunction. Corrective actions may result in some loss of data. The default action for each consistency correction is to wait for the operator to enter `yes` or `no`. If you do not have write permission for an affected file system, the **fsck** command defaults to a no response in spite of your actual response.

Notes:

1. The **fsck** command does not make corrections to a mounted file system.
2. The **fsck** command can be run on a mounted file system for reasons other than repairs. However, inaccurate error messages may be returned when the file system is mounted.

The **fsck** command checks and interactively repairs inconsistent file systems. You should run this command before mounting any file system. You must be able to read the device file on which the file system resides (for example, the **/dev/hd0** device). Normally, the file system is consistent, and the **fsck** command merely reports on the number of files, used blocks, and free blocks in the file system. If the file system is inconsistent, the **fsck** command displays information about the inconsistencies found and prompts you for permission to repair them.

The **fsck** command is conservative in its repair efforts and tries to avoid actions that might result in the loss of valid data. In certain cases, however, the **fsck** command recommends the destruction of a damaged file. If you do not allow the **fsck** command to perform the necessary repairs, an inconsistent file system may result. Mounting an inconsistent file system may result in a system crash.

If a JFS2 file system has snapshots, the `fsck` command will attempt to preserve them. If this action fails, the snapshots cannot be guaranteed to contain all of the before-images from the snapped file system. The `fsck` command will delete the snapshots and the snapshot logical volumes. Internal snapshots are deleted if the **fsck** command modifies the file system.

If you do not specify a file system with the *FileSystem* parameter, the **fsck** command checks all file systems listed in the **/etc/filesystems** file for which the **check** attribute is set to True. You can enable this type of checking by adding a line in the stanza, as follows:

```
check=true
```

You can also perform checks on multiple file systems by grouping the file systems in the **/etc/filesystems** file. To do so, change the check attribute in the **/etc/filesystems** file as follows:

```
check=Number
```

The *Number* parameter tells the **fsck** command which group contains a particular file system. File systems that use a common log device should be placed in the same group. File systems are checked, one at a time, in group order, and then in the order that they are listed in the **/etc/filesystems** file. All `check=true` file systems are in group 1. The **fsck** command attempts to check the root file system before any other file system regardless of the order specified on the command line or in the **/etc/filesystems** file.

The **fsck** command checks for the following inconsistencies:

- Blocks or fragments allocated to multiple files.
- i-nodes containing block or fragment numbers that overlap.
- i-nodes containing block or fragment numbers out of range.
- Discrepancies between the number of directory references to a file and the link count of the file.
- Illegally allocated blocks or fragments.
- i-nodes containing block or fragment numbers that are marked free in the disk map.
- i-nodes containing corrupt block or fragment numbers.
- A fragment that is not the last disk address in an i-node. This check does not apply to compressed file systems.
- Files larger than 32KB containing a fragment. This check does not apply to compressed file systems.
- Size checks:
  - Incorrect number of blocks.
  - Directory size not a multiple of 512 bytes.

  These checks do not apply to compressed file systems.
- Directory checks:
  - Directory entry containing an i-node number marked free in the i-node map.
  - i-node number out of range.
  - Dot (.) link missing or not pointing to itself.
  - Dot dot (..) link missing or not pointing to the parent directory.
  - Files that are not referenced or directories that are not reachable.
- Inconsistent disk map.
- Inconsistent i-node map.

Orphaned files and directories (those that cannot be reached) are, if you allow it, reconnected by placing them in the **lost+found** subdirectory in the root directory of the file system. The name assigned is the i-node number. If you do not allow the **fsck** command to reattach an orphaned file, it requests permission to destroy the file.

In addition to its messages, the **fsck** command records the outcome of its checks and repairs through its exit value. This exit value can be any sum of the following conditions:

Item	Description
0	All checked file systems are now okay.
2	The **fsck** command was interrupted before it could complete checks or repairs.
4	The **fsck** command changed the file system; the user must restart the system immediately.
8	The file system contains unrepaired damage.

The **fsck** command requires exclusive access to the underlying logical volume device of the file system. If fsck fails because the underlying device is unavailable, then fsck should be retried after the device is free to be opened.

When the system is booted from a disk, the boot process explicitly runs the **fsck** command, specified with the **-f** and **-p** flags on the **/**, **/usr**, **/var**, and **/tmp** file systems. If the **fsck** command is unsuccessful on any of these file systems, the system does not boot. Booting from removable media and performing maintenance work will then be required before such a system will boot.

If the **fsck** command successfully runs on **/**, **/usr**, **/var**, and **/tmp**, normal system initialization continues. During normal system initialization, the **fsck** command specified with the **-f** and **-p** flags runs from the **/etc/rc** file. This command sequence checks all file systems in which the **check** attribute is set to True (`check=true`). If the **fsck** command executed from the **/etc/rc** file is unable to guarantee the consistency of any file system, system initialization continues. However, the mount of any inconsistent file systems may fail. A mount failure may cause incomplete system initialization.

Note: By default, the **/**, **/usr**, **/var**, and **/tmp** file systems have the **check** attribute set to False (`check=false`) in their **/etc/filesystem** stanzas. The attribute is set to False for the following reasons:

1. The boot process explicitly runs the **fsck** command on the **/**, **/usr**, **/var**, and **/tmp** file systems.
2. The **/**, **/usr**, **/var**, and **/tmp** file systems are mounted when the **/etc/rc** file is executed. The **fsck** command will not modify a mounted file system. Furthermore, the **fsck** command run on a mounted file system produces unreliable results.

You can use the System Management Interface Tool (SMIT) **`smit fsck`** fast path to run this command.

Flags

Item	Description
-d*BlockNumber*	Searches for references to a specified disk block. Whenever the **fsck** command encounters a file that contains a specified block, it displays the i-node number and all path names that refer to it. For JFS2 filesystems, the i-node numbers referencing the specified block will be displayed but not their path names."

Item	Description
-f	Performs a fast check. Under normal circumstances, the only file systems likely to be affected by halting the system without shutting down properly are those that are mounted when the system stops. The **-f** flag prompts the **fsck** command not to check file systems that were unmounted successfully. The **fsck** command determines this by inspecting the **s_fmod** flag in the file system superblock. This flag is set whenever a file system is mounted and cleared when it is unmounted successfully. If a file system is unmounted successfully, it is unlikely to have any problems. Because most file systems are unmounted successfully, not checking those file systems can reduce the checking time.
-i*i-NodeNumber*	Searches for references to a specified i-node. Whenever the **fsck** command encounters a directory reference to a specified i-node, it displays the full path name of the reference.
-n	Assumes a no response to all questions asked by the **fsck** command; does not open the specified file system for writing.
-o *Options*	Passes comma-separated options to the **fsck** command. The following options are currently supported for JFS (these options are obsolete for newer file systems and can be ignored): **mountable** Causes the **fsck** command to exit with success, returning a value of 0, if the file system in question is mountable (clean). If the file system is not mountable, the **fsck** command exits returning with a value of 8. **mytype** Causes the **fsck** command to exit with success (0) if the file system in question is of the same type as either specified in the **/etc/filesystems** file or by the **-V** flag on the command line. Otherwise, 8 is returned. For example, `fsck -o mytype -V jfs /` exits with a value of 0 if **/** (the root file system) is a journaled file system.
-p	Does not display messages about minor problems but fixes them automatically. This flag does not grant the wholesale license that the **-y** flag does and is useful for performing automatic checks when the system is started normally. You should use this flag as part of the system startup procedures, whenever the system is being run automatically. If the primary superblock is corrupt, the secondary superblock is verified and copied to the primary superblock.
-t*File*	Specifies a *File* parameter as a scratch file on a file system other than the one being checked, if the **fsck** command cannot obtain enough memory to keep its tables. If you do not specify the **-t** flag and the **fsck** command needs a scratch file, it prompts you for the name of the scratch file. However, if you have specified the **-p** flag, the **fsck** command is unsuccessful. If the scratch file is not a special file, it is removed when the **fsck** command ends.
-V *VfsName*	Uses the description of the virtual file system specified by the *VFSName* variable for the file system instead of using the **/etc/filesystems** file to determine the description. If the **-V** *VfsName* flag is not specified on the command line, the **/etc/filesystems** file is checked and the **vfs=***Attribute* of the matching stanza is assumed to be the correct file system type.
-y	Assumes a yes response to all questions asked by the **fsck** command. This flag lets the **fsck** command take any action it considers necessary. Use this flag only on severely damaged file systems.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To check all the default file systems, enter:

   ```
   fsck
   ```

   This command checks all the file systems marked `check=true` in the **/etc/filesystems** file. This form of the **fsck** command asks you for permission before making any changes to a file system.
2. To fix minor problems with the default file systems automatically, enter:

   ```
   fsck -p
   ```

3. To check a specific file system, enter:

   ```
   fsck /dev/hd1
   ```

   This command checks the unmounted file system located on the **/dev/hd1** device.

Files

Item	Description
/usr/sbin/fsck	Contains the **fsck** command.
/etc/filesystems	Lists the known file systems and defines their characteristics.
/etc/vfs	Contains descriptions of virtual file system types.
/etc/rc	Contains commands (including the **fsck** command) that are run when the system is started.

fsck_cachefs Command

Purpose

Checks the integrity of data cached with CacheFS.

Syntax

fsck_cachefs [**-m**] [**-o noclean**] *cache_directory*

Description

The CacheFS version of the **fsck** command checks the integrity of a cache directory. By default it corrects any CacheFS problems it finds. There is no interactive mode. The most likely invocation of **fsck_cachefs** for CacheFS filesystems is at boot time from an entry in **/etc/rc.nfs**.

Flags

Item	Description
-m	Check, but do not repair.

Item	Description
-o noclean	Force a check on the cache even if there is no reason to suspect there is a problem.

Examples

To force a check on the cache directory, enter:

```
fsck_cachefs -o noclean /cache3
```

fsdb Command

Purpose

Debugs file systems.

Syntax

fsdb *FileSystem* [**-**]

Description

The **fsdb** command enables you to examine, alter, and debug a file system, specified by the *FileSystem* parameter. The command provides access to file system objects, such as blocks, i-nodes, or directories. You can use the **fsdb** command to examine and patch damaged file systems. Key components of a file system can be referenced symbolically. This feature simplifies the procedures for correcting control-block entries and for descending the file system tree.

To examine a file system, specify it by a block device name, a raw device name, or a mounted file system name. In the last case, the **fsdb** command determines the associated file system name by reading the **/etc/filesystems** file. Mounted file systems cannot be modified.

The **fsdb** command has a different interface for a JFS file system and a JFS2 file system. The following explains how to use **fsdb** with a JFS file system. See JFS2 Subcommands for information about JFS2 subcommands.

If the file system specified is a JFS2 snapshot, the **fsdb** command enables examination and modification of the snapshot superblock, snapshot map, block map xtree copy, and segment headers. See JFS2 Snapshot Subcommands for information about JFS2 snapshot subcommands.

The subcommands for the **fsbd** command allow you to access, view, or change the information in a file system. Any number you enter in the subcommand is considered decimal by default, unless you prefix it with either 0 to indicate an octal number or 0x to indicate a hexadecimal number. All addresses are printed in hexadecimal.

Because the **fsdb** command reads and writes one block at a time, it works with raw as well as with block I/O.

Flag

Item	Description
-	Disables the error checking routines used to verify i-nodes and block addresses. The **O** subcommand switches these routines on and off. When these routines are running, the **fsdb** command reads critical file system data from the superblock. The obtained information allows the **fsdb** command to access the various file system objects successfully and to perform various error checks.

Subcommands

The **fsdb** subcommands are requests to locate and display or modify information in the file system. The main categories of subcommands are:

Item	Description
Category	**Function**
Location	Access the information in the file system.
Display	View the information in the file system.
Modification	Change the information in the file system.

In addition, there are a few miscellaneous subcommands.

Location Subcommands

There are two types of location subcommands:

```
Number[ I | M | i | b ]
```

```
OR
```

```
dDirectorySlot
```

The first type consists of a number, optionally followed by an address specification. The address specification defines how the preceding number is to be interpreted. There are four address specifications corresponding to four different interpretations of the *Number* variable:

Item	Description
I	I-node map block number
M	Disk map block number
i	I-node number
b	Fragment number

Depending on the address specification (or absence of it), this type of location subcommand accesses information as follows:

Item	Description
Number	Accesses data at the absolute byte offset specified by the *Number* variable.
*MapBlockNumber***I**	Accesses the i-node map block indicated by the *MapBlockNumber* variable.
*MapBlockNumber***M**	Accesses the disk map block indicated by the *MapBlockNumber* variable.
*InodeNumber***i**	Accesses the i-node indicated by the *InodeNumber* variable.
*FragmentNumber***b**	Accesses the file system block indicated by the *FragmentNumber* variable. A fragment number consists of a block address and an encoded length. A complete fragment address is 32 bits in length. The low-order 28 bits are the beginning fragment address. The fragment length is encoded in the remaining 4 bits; it is encoded as the number of fragments less than a full block. For example, on a file system consisting of 1024-byte fragments, the address `0x2000010f` references a block that begins at 1KB block number `0x10f` and is 2KB in length. In contrast, on a file system of 512-byte fragments, the address `0x2000010f` references a block that begins at 512-byte block `0x10f` and is 3072 (512 * 6) bytes in length.

The second type of location subcommand is used to access directory entries. The subcommand consists of the character **d** followed by a directory-slot number. Directory-slot numbers start at 0 for each block of the associated i-node.

This type of location subcommand accesses information as follows:

Item	Description
d*DirectorySlot*	Accesses the directory entry indexed by the *DirectorySlot* variable for the current i-node. Only allocated directory entries can be manipulated using this location subcommand.

Display Subcommands

To view information relative to the address specification, use a display subcommand comprised of one of the display facilities in conjunction with one of the display formats, as follows:

p[*Number*]{ **i** | **d** | **o** | **e** | **c** | **b** | **y** | **M** | **I** | **x** | **s** | **D** }

OR

f[*Number*]{ **i** | **d** | **o** | **e** | **c** | **b** | **y** | **M** | **I** | **x** | **s** | **D** }

The display facilities are:

Item	Description
p	Indicates a general facility. Use the general display subcommand to display data relative to the current address. If you enter a number after the **p** symbol, the **fsdb** command displays that number of entries. A check is made to detect block boundary overflows. If you enter 0 or * (asterisk), the **fsdb** command displays all entries to the end of the current fragment.
f	Indicates a file facility. Use the file display subcommand to display data blocks associated with the current i-node. If you enter a number after the **f** symbol, the **fsdb** command displays that block of the file. Block numbering begins at 0. The display format follows the block number. If you enter **f** without a block number, the **fsdb** command defaults to displaying block 0 of the current i-node.

The display formats for either facility are:

Item	Description
i	Displays as i-nodes.
d	Displays as directories.
o	Displays as octal words.
e	Displays as decimal words.
c	Displays as characters.
b	Displays as octal bytes.
y	Displays as hexadecimal bytes.
M	Displays as disk map entries.
I	Displays as i-node map entries.
x	Displays as hexadecimal words.
S	Displays as single indirect blocks.
D	Displays as double indirect blocks.

The chosen display facility and display format remain in effect during the processing of the **fsdb** command until explicitly changed. You may receive an error message indicating improper alignment if the address you specify does not fall on an appropriate boundary.

If you use the *Number*, *MapBlockNumber***I**, or *FragmentNumber***b** location subcommands to access i-node information, you can step through the data, examining each byte, word, or double word. Select the desired display mode by entering one of the following subcommands:

Item	Description
B	Begins displaying in byte mode.
D	Begins displaying in double-word mode.
W	Begins displaying in word mode.

You can move forward or backward through the information. The boundary advances with the display screen and is left at the address of the last item displayed. The output can be ended at any time by pressing the INTERRUPT key. The following symbols allow movement through the information:

Item	Description
+ *Number*	Moves forward the specified number of units currently in effect.
-*Number*	Moves backward the specified number of units currently in effect.

The following symbols allow you to store the current address and return to it conveniently:

Item	Description
>	Stores the current address.
<	Returns to the previously stored address.

You can use dots, tabs, and spaces as subcommand delimiters, but they are only necessary to delimit a hexadecimal number from a subcommand that could be interpreted as a hexadecimal digit. Pressing the Enter key (entering a blank line) increments the current address by the size of the data type last displayed. That is, the address is set to the next byte, word, double word, directory entry, or i-node, allowing you to step through a region of a file system.

The **fsdb** command displays information in a format appropriate to the data type. Bytes, words, and double words are displayed as a hexadecimal address followed by the hexadecimal representation of the data at that address and the decimal equivalent enclosed in parentheses. The **fsdb** command adds a **.B** or **.D** suffix to the end of the address to indicate a display of byte or double word values. It displays directories as a directory slot offset followed by the decimal i-node number and the character representation of the entry name. It displays i-nodes with labeled fields describing each element. The environment variables control the formats of the date and time fields.

Modification Subcommands

You can modify information relative to the address specification by using a field specification (for fields in the i-node and fields in the directory). The general form for assigning new values is: *mnemonic operator new-value*, where the *mnemonic* parameter represents one of the fields described in the following list:

The following mnemonics are used for the names of the fields of an i-node and refer to the current working i-node:

Item	Description
`md`	Permission mode
`ln`	Link count
`uid`	User number

Item	Description
`gid`	Group number
`sz`	File size
a*Number*	Data block numbers (0 to 8) where the *Number* parameter can be a location subcommand
`at`	Access time
`mt`	Modification time
`maj`	Major device number
`min`	Minor device number

The following mnemonics refer to the i-node and disk maps:

Item	Description
`mf`	Map free count
`ms`	Map size
`mp`	Permanent allocation bit map
`mw`	Working allocation bit map

The following mnemonics are used for the names of the fields in directories:

Item	Description
`rl`	Length of directory entry record
`nl`	Length of directory name
`nm`	Directory name

Valid values of the *Operator* parameter include:

Note: A file system must be unmounted before attempting to modify it.

Item	Description
=	Assigns the *New-Value* parameter to the specified *Mnemonic* parameter.
=+	Increment the *Mnemonic* parameter by the specified *New-Value* parameter. The default *New-Value* parameter is a value of one.
=-	Decrease the *Mnemonic* by the specified *New-Value*. The default *New-Value* is a value of one.
="	Assigns the character string specified by the *New-Value* parameter to the specified *Mnemonic* parameter. If the current display format is the **d** address specification for directory and a mnemonic is not specified, the directory name is changed. The new directory name cannot be longer than the previous directory name.

Miscellaneous Subcommands

Miscellaneous subcommands are:

Item	Description
q	Quits.

Item	Description
x*n*	Expands a directory by *n* bytes where *n* plus the current size of the directory is not greater than the current directory's fragment in bytes.
!	Escapes to the shell.
O	Toggles error checking.

JFS2 Subcommands

These subcommands can be entered by their entire name or by using a subset of the name. At least the bold letters must be entered.

Item	Description
a[lter] <block> <offset> <hex string>	Alters disk data.
b[map] [<block number>]	Displays block allocation map.
dir[ectory] <inode number> [<fileset>] [R]	Displays directory entries.
d[isplay] [<block> [<offset> [<format> [<count>]]]]	Displays data.
dt[ree] {<block number> |<inode number>{a | f } }	Displays dtree nodes.
h[elp] [<command>]	Provides help on subcommands.
ia[g] [<IAG number>] [a | <fileset>]	Displays IAG pages.
im[ap] [a | <fileset>]	Displays inode allocation map.
i[node] [<inode number>] [a | <fileset>]	Displays inodes.
q[uit]	Exits fsdb.
su[perblock] [p | s]	Displays superblock.
x[tree] {<block number> | <inode number>{a | f}}	Displays xtree nodes.

a[lter] <block> <offset> <hex string>

where:

Item	Description
<block>	block number (decimal)
<offset>	offset within block (hex)
<hex string>	string of hex digits

Alters disk data. <hex string> should contain an even number of digits.

b[map] [<block numbers>]

Display Block Allocation Map.

<block number> Display the **dmap** page which describes this block number

Subcommands:

Item	Description
m	modify current node
u	visit upper level **bmap** page
l	visit left sibling
r	visit right sibling
w	display wmap
p	display pmap
s	display stree
x	exit subcommand mode

dir[ectory] <inode number> [<fileset>][R]

Item	Description
<inode number>	inode number of directory (decimal)
<fileset>	number, currently must be zero
R	recursively lists all subdirectories

Displays directory entries.

d[isplay] [<block> [<offset> [<format>[<count>]]]]

Item	Description
<block>	block number (decimal)
<offset>	offset within block (hex)
<format>	format in which to display data (see below)
<count>	number of objects to display (decimal)

Displays data in a variety of formats.

Format may be one of the following:

Item	Description
a	ascii

Item	Description	
i	inode	struct dinode
I	inode allocation map	iag_t
s	superblock	struct superblock
x	hexadecimal	

dt[ree] {<block number> | <inode number>{a | f}}

Item	Description
<block number>	block number containing a dtree page
<inode number>	inode number of directory (decimal)
{a | f}	'a' indicates inode number is an aggregate inode. 'f' indicates inode number is a fileset inode.

Displays root of the directory btree and enters a subcommand mode in which to navigate the btree.

Subcommands:

Item	Description
m	Modifies current node
f	Walks freelist entries
s	Displays specified slot entry
[0-9]+	Displays specified stbl entry
t	Displays formatted stbl
u	Visits parent node (not parent directory)
d	Visits child node
x	Exits subcommand mode

h[elp] [<command>]

Item	Description
<command>	command name

Prints help text. Lists all commands if no parameter.

ia[g] [<IAG number>] [a | <fileset>]

Item	Description
<IAG number>	IAG number (decimal)
a	use aggregate inode table
<fileset>	fileset number (currently must be zero)

Displays iag information and enters subcommand mode.

Subcommands:

Item	Description
e	Displays/modifies inode extents map
m	Modifies iag
p	Displays/modifies persistent map
w	Displays/modifies working map

im[ap] [a | <fileset>]

Item	Description
a	use aggregate inode table
<fileset>	fileset number (currently must be zero)

Display specified inode map and enters subcommand mode.

Subcommands:

Item	Description
e	Displays/modifies inode extents map
m	Modifies iag
p	Displays/modifies persistent map

i[node] [<inode number>] [a | <fileset>]

Item	Description
<inode number>	Inode number (decimal)
a	Use aggregate inode table
fileset	Fileset number (currently must be zero)

Displays inode information and enters subcommand mode.

Subcommands:

Item	Description
m	Modifies inode
t	Displays/modifies inode's b-tree
e	display/modify inode's EAs

Note: The **fsdb** command understands both the **v1** and the **v2** extended attribute formats. The behavior when viewing EAs is dependent on the format for the inode being viewed.

For **v1**, after displaying the inode's EAs you can modify its `pxdTable` or `eaDirectory` entries. Specify modify option and then the `pxdTable` or `eaDirectory` indicator and the offset into the table.

For **v2** the EAs are displayed using the **dtree** subcommand format. All of the **dtree** subcommands are then available for further action on the EAs.

q[uit]
Exits fsdb.

su[perblock] [p | s]

Item	Description
p	Displays primary superblock
s	Displays secondary superblock

Displays superblock data.

x[tree] {<block number> | <inode number>{a | f} }

Item	Description
<block number>	block number (decimal)
<inode number>	inode number
{a | f}	'a' indicates inode number is an aggregate inode. 'f' indicates inode number is a fileset inode.

Displays one node of a xtree and enters a subcommand mode in which to navigate the xtree.

Subcommands:

Item	Description
m	Modifies current node
u	Visits parent node
d	Visits child node
n	Visits right sibling
p	Visits left sibling
s	Selects xad entry to view
x	Exits subcommand mode

JFS2 Snapshot Subcommands

These subcommands can be entered by their entire name or by using a subset of the name. At least the bold letters must be entered.

Item	Description
a[lter] <block> <offset> <hex string>	Alters disk data.
b[map]	Displays block map xtree copy.
d[isplay] [<block> [<offset> [<format> [<count>]]]]	Displays data.
h[elp] [<command>]	Provides help on subcommands.
q[uit]	Exits fsdb.
st[able] [<block number>]	Displays summary snapshot table.
s[map] <block number>	Displays snapshot bit map.
su[perblock]	Displays superblock.

a[lter] <block> <offset> <hex string>

where:

Item	Description
<block>	block number (decimal)
<offset>	offset within block (hex)
<hex string>	string of hex digits

Alters disk data. <hex string> should contain an even number of digits.

b[map]

Displays block map xtree copy.

d[isplay] [<block> [<offset> [<format>[<count>]]]]

Item	Description
<block>	block number (decimal)
<offset>	offset within block (hex)
<format>	format in which to display data (see below)
<count>	number of objects to display (decimal)

Displays data in a variety of formats.

Format may be one of the following:

Item	Description
a	ascii
s	snapshot segment header
t	snapshot table page
x	xtree page

h[elp] [<command>]

Item	Description
<command>	command name

Provides help on subcommands.

q[uit]
Exits fsdb.

st[able] [<block number>]
where:

Item	Description
<block number>	block number (decimal)

Displays summary snapshot table.

s[map] [<block number>]
where:

Item	Description
<block number>	block number (decimal)

Displays snapshot bit map.

su[perblock]

Displays superblock.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

The following examples show subcommands you can use after starting the **fsdb** command on a JFS file system.

1. To display an i-node, enter:

   ```
   386i
   ```

   This command displays i-node 386 in i-node format. It now becomes the current i-node.
2. To change the link count for the current i-node to a value of 4, enter:

   ```
   ln=4
   ```
3. To increase the link count of the current i-node by a value of 1, enter:

   ```
   ln=+1
   ```
4. To display part of the file associated with the current i-node, enter:

   ```
   fc
   ```

   This command displays block 0 of the file associated with the current i-node in ASCII bytes.
5. To display entries of a directory, enter:

   ```
   2i.fd
   ```

   This changes the current i-node to the root i-node (i-node 2) and then displays the directory entries in the first block associated with that i-node. One or more of the last entries displayed may have an i-node number of 0 (zero). These are unused directory blocks; such entries cannot be manipulated as in the next example.
6. To go down a level of the directory tree, enter:

   ```
   d5i.fc
   ```

This command changes the current i-node to the one associated with directory entry 5. Then it displays the first block of the file as ASCII text (`fc`). Directory entries are numbered starting from 0.

7. To display a block when you know its block number, enter:

```
1b.p0o
```

This command displays the superblock (block 1) of file system in octal.

8. To change the i-node of a directory entry, enter:

```
2i.a0b.d7=3
```

This command changes the i-node of directory entry 7 in the root directory (`2i`) to 3. This example also shows how several operations can be combined on one line.

9. To change the file name of a directory entry, enter:

```
d7.nm="chap1.rec"
```

This command changes the name field of directory entry 7 to `chap1.rec`.

10. To display a given block of the file associated with the current i-node, enter:

```
a2b.p0d
```

This command displays block 2 of the current i-node as directory entries.

11. To display the content of a single indirect block at block 7, enter:

```
7b. p0S
```

This command displays the block numbers allocated to the i-node that has a single indirect block at block 7.

12. To display the first page of the disk map, enter:

```
OM
```

13. To display the first 10 words of permanent block allocation map in hexadecimal, enter:

```
mp1.p10x
```

This command shows the allocation bit map at the current address; for example, at 0M.

The following examples show some subcommands you can use on a JFS2 file system.

Attention: Do not use JFS2 subcommands to modify a file system.

1. To display an i-node, enter:

```
inode 2
```

This command displays i-node 2 in i-node format.

2. To display entries of a directory, enter:

```
dir 2
```

This command displays the directory entries associated with i-node 2.

3. To display a block whose block number is 0x1000, enter:

```
display 0x1000
```

This command displays the block at file system in hexadecimal format.

Files

Item	Description
/usr/sbin	Contains the **fsdb** command.
/etc/filesystems	Contains information on the file systems.

fsplit Command

Purpose

Splits FORTRAN source code into separate routine files.

Syntax

fsplit [**-e** *SubprogramUnit*] ... [*File*]

Description

The **fsplit** command takes as input either a file or standard input containing FORTRAN source code and splits the input into separate routine files of the form *name***.f**, where *name* is the name of the program unit (for example, function, subroutine, block data or program).

The name for unnamed block data subprograms has the form *blkdtaNNN***.f**, where NNN is three digits and a file of this name does not already exist. For unnamed main programs the name has the form *mainNNN***.f**. If there is an error in classifying a program unit, or if *name***.f** already exists, the program unit is put in a file of the form *zzzNNN***.f**, where *zzzNNN***.f** does not already exist.

Note: The **fsplit** command assumes that the subprogram name is on the first non-comment line of the subprogram unit. Non-standard source formats can confuse the command and produce unpredictable results.

Flags

Item	Description
-e *SubprogramUnit*	Causes only the specified subprogram units to be split into separate files. Normally each subprogram unit is split into a separate file. The **-e** flag can be used only for named main programs and block data subprograms. If names specified via the **-e** option are not found, a diagnostic is written to standard error.

Example

The following **fsplit** command splits the subprograms `readit` and `doit` into separate files:

```
fsplit -e readit -e doit prog.f
```

Files

Item	Description
/usr/bin/fsplit	Contains the **fsplit** command.

ftp Command

Purpose

Transfers files between a local and a remote host.

Syntax

ftp [**-d**] [**-D** *DataConnTimeOut*] [**-g**] [**-i**] [**-n**] [**-v**] [**-f**] [**-K**] [**-k** *realm*] [**-q**] [**-C**] [**-s**] [**-M**] [*HostName* [*Port*]] [**-H**]

Description

The **ftp** command uses the File Transfer Protocol (FTP) to transfer files between the local host and a remote host or between two remote hosts. Remote execution of the **ftp** command is not recommended.

The FTP protocol allows data transfer between hosts that use dissimilar file systems. Although the protocol provides a high degree of flexibility in transferring data, it does not attempt to preserve file attributes (such as the protection mode or modification times of a file) that are specific to a particular file system. Moreover, the FTP protocol makes few assumptions about the overall structure of a file system and does not provide or allow such functions as recursively copying subdirectories.

Note: If you are transferring files between systems and need to preserve file attributes or recursively copy subdirectories, use the **rcp** command.

Issuing Subcommands

At the `ftp>` prompt, you can enter subcommands to perform tasks such as listing remote directories, changing the current local and remote directory, transferring multiple files in a single request, creating and removing directories, and escaping to the local shell to perform shell commands. See the Subcommands section for a description of each subcommand.

If you execute the **ftp** command and do not specify the *HostName* parameter for a remote host, the **ftp** command immediately displays the `ftp>` prompt and waits for an **ftp** subcommand. To connect to a remote host, execute the **open** subcommand**.** When the **ftp** command connects to the remote host, the **ftp** command then prompts for the login name and password before displaying the `ftp>` prompt again. The **ftp** command is unsuccessful if no password is defined at the remote host for the login name.

The **ftp** command interpreter, which handles all subcommands entered at the `ftp>` prompt, provides facilities that are not available with most file-transfer programs, such as:

- Handling file-name parameters to **ftp** subcommands
- Collecting a group of subcommands into a single subcommand macro
- Loading macros from a **$HOME/.netrc** file

These facilities help simplify repetitive tasks and allow you to use the **ftp** command in unattended mode.

The command interpreter handles file-name parameters according to the following rules:

- If a - (hyphen) is specified for the parameter, standard input (stdin) is used for read operations and standard output (stdout) is used for write operations.
- If the preceding check does not apply and file-name expansion is enabled (see the **-g** flag or the **glob** subcommand), the interpreter expands the file name according to the rules of the C shell. When globbing is enabled and a pattern-matching character is used in a subcommand that expects a single file name, results may be different than expected.

  For example, the **append** and **put** subcommands perform file-name expansion and then use only the first file name generated. Other **ftp** subcommands, such as **cd**, **delete**, **get**, **mkdir**, **rename**, and **rmdir**, do not perform file-name expansion and take the pattern-matching characters literally.
- For the **get**, **put**, **mget**, and **mput** subcommands, the interpreter has the ability to translate and map between different local and remote file-name syntax styles (see the **case**, **ntrans**, and **nmap**

subcommands) and the ability to modify a local file name if it is not unique (see the **runique** subcommand). Additionally, the **ftp** command can send instructions to a remote **ftpd** server to modify a remote file name if it is not unique (see the **sunique** subcommand).

- Use double quotes (" ") to specify parameters that include blank characters.

  Note: The **ftp** command interpreter does not support pipes. It also does not necessarily support all multibyte-character file names.

To end an **ftp** session when you are running interactively, use the **quit** or **bye** subcommand or the End of File (Ctrl-D) key sequence at the `ftp>` prompt. To end a file transfer before it has completed, press the Interrupt key sequence. The default Interrupt key sequence is Ctrl-C. The **stty** command can be used to redefine this key sequence.

The **ftp** command normally halts transfers being sent (from the local host to the remote host) immediately. The **ftp** command halts transfers being received (from the remote host to the local host) by sending an FTP ABOR instruction to the remote FTP server and discarding all incoming file transfer packets until the remote server stops sending them. If the remote server does not support the ABOR instruction, the **ftp** command does not display the `ftp>` prompt until the remote server has sent all of the requested file. Additionally, if the remote server does something unexpected, you may need to end the local **ftp** process.

Security and Automatic Login

If Standard is the current authentication method:

The **ftp** command also handles security by sending passwords to the remote host and permits automatic login, file transfers, and logoff.

If you execute the **ftp** command and specify the host name (*HostName*) of a remote host, the **ftp** command tries to establish a connection to the specified host. If the **ftp** command connects successfully, the **ftp** command searches for a local **$HOME/.netrc** file in your current directory or home directory. If the file exists, the **ftp** command searches the file for an entry initiating the login process and command macro definitions for the remote host. If the **$HOME/.netrc** file or automatic login entry does not exist or if your system has been secured with the **securetcpip** command, the **ftp** command prompts the user for a user name and password. The command displays the prompt whether or not the *HostName* parameter is specified on the command line.

Note: The queuing system does not support multibyte host names.

If the **ftp** command finds a **$HOME/.netrc** automatic login entry for the specified host, the **ftp** command attempts to use the information in that entry to log in to the remote host. The **ftp** command also loads any command macros defined in the entry. In some cases (for example, when the required password is not listed in an automatic login entry), the **ftp** command prompts for the password before displaying the `ftp>` prompt.

Once the **ftp** command completes the automatic login, the **ftp** command executes the **init** macro if the macro is defined in the automatic login entry. If the **init** macro does not exist or does not contain a **quit** or **bye** subcommand, the **ftp** command then displays the `ftp>` prompt and waits for a subcommand.

Note: The remote user name specified either at the prompt or in a **$HOME/.netrc** file must exist and have a password defined at the remote host. Otherwise, the **ftp** command fails.

If Kerberos 5 is the current authentication method

The **ftp** command will use the extensions to ftp specifications as defined in IETF draft document "draft-ietf-cat-ftpsec-09.txt". The FTP security extensions will be implemented using the Generic Security Service API (GSSAPI) security mechanism. The GSSAPI provides services independent to the underlying security and communication mechanism. The GSSAPI is defined in rfc 1508 and 1509.

The **ftp** command will use the AUTH and ADAT commands to authenticate with the **ftpd** daemon. If both support Kerberos authentication, then they will use the local users DCE credentials to authenticate the user on the remote system. If this fails and Standard authentication is configured on both systems, the process described above will be used.

The *HostName* parameter is the name of the host machine to which files are transferred. The optional *Port* parameter specifies the ID of the port through which to transmit. (The **/etc/services** file specifies the default port.)

Note: If the value of the registry is correctly set to the current authentication scheme, the FTP authentication works with the active directory password. If the value of registry is set to null, then the default value of files (local user authentication) is used.

Transport Layer Security support

The **ftp** command supports Transport Layer Security (TLS) as defined in RFC 4217. TLS is a cryptographic protocol that provides secure communications between clients and servers.

The **ftp** command uses the **AUTH TLS** and **PROT P** commands to secure the communication with the **ftpd** daemon. If both the **AUTH TLS** and **PROT P** commands support the TLS protocol, then a secure channel is established. Only the Standard Authentication method is supported.

If the **-s** flag is specified when you run the **ftp** command, then the **ftp** command searches for a local **$HOME/.ftpcnf** file in the your home directory. If the file is found, the **ftp** command uses the following configuration parameters to set up a TLS session with the server. If the file is not found or the configuration parameters are missing, the **ftp** command attempts to connect to the server without using the configuration parameters.

CRL_PATH
The CRL_PATH parameter provides the path to the certificate revocation list file, which must be in privacy enhanced mail (PEM) format. If specified, the digital certificate that is provided by the server is verified against the certificate revocation list. If the certificate was revoked, the TLS session fails. If not specified, the digital certificate is not verified against a certificate revocation list.

CA_PATH
The CA_PATH parameter provides the path to the certificate authority file, which must be in PEM format. If specified, the server certificate is verified against the certificate authority. If the digital certificate that is provided by the server was not signed by the security authority, the TLS session fails. If not specified, the digital certificate that is provided by the server is not verified against a certificate revocation list.

CIPHER_LIST
If the CIPHER_LIST parameter is specified, the list is used during the TLS session. If not, a default cipher list is used.

DEPTH
If the CA_PATH configuration parameter is specified, the DEPTH value is used to verify the certificate that is provided by the **ftpd** server in the digital certificate hierarchy. If not provided, a default value of 9 is used.

CERTIFICATE
The CERTIFICATE parameter provides a path to the chain file of a valid digital certificate in PEM format. This file is used in the TLS session.

CERTIFICATE_PRIVATE_KEY
The CERTIFICATE_PRIVATE_KEY parameter contains the path to the certificate private key, in PEM format, which is used during the TLS session. To support TLS, you must install the latest version of the OpenSSL tool from the AIX Web Download Pack Programs website.

For Trusted AIX system

The user is assigned a default login Sensitivity Label (SL) and Integrity Label (TL), which is the effective SL and effective TL of the user's process after a successful login. If the user does not want to log in at the default login SL, the user can choose to supply a different SL at the login time by using the **-e** option. The SL supplied by the user must be dominated by the user's clearance and contained in the system accreditation range. The TL cannot be specified by the user at login time. The default login SL and TL are defined in the **/etc/security/user** file along with the user name and the clearance for each user. To use the **-e** option, the server side's kernel trusted network bit must be turned off.

Note: Any user with user ID less than or equal to 128 cannot log in to the remote Trusted AIX system.

Flags

Item	Description
-C	Allows the user to specify that the outgoing file sent using the **send_file** command must be cached in the Network Buffer Cache (NBC). This flag cannot be used unless the **-q** flag is specified. This flag is only applicable when a file is being sent out in the binary mode with no protection.
-d	Sends debugging information about **ftp** command operations to the **syslogd** daemon. If you specify the **-d** flag, you must edit the **/etc/syslog.conf** file and add one of the following entries: `user.info FileName` OR `user.debug FileName` **Note:** The **syslogd** daemon debug level includes info level messages. If you do not edit the **/etc/syslog.conf** file, no messages are produced. After changing the **/etc/syslog.conf** file, run the **refresh -s syslogd** or **kill -1** *SyslogdPID* command to inform the **syslogd** daemon of the changes to its configuration file. For more information about debug levels, refer to the **/etc/syslog.conf** file. Also, refer to the **debug** subcommand**.**
-D *DataConnTimeOut*	Specifies the maximum number of seconds that the **ftp** command holds a data connection. The default value is 300 seconds and can range from 300 seconds to 3600 seconds.
-f	Causes the credentials to be forwarded. This flag will be ignored if Kerberos 5 is not the current authentication method.
-g	Disables the expansion of metacharacters in file names. Interpreting metacharacters can be referred to as expanding (sometimes called globbing) a file name. See the **glob** subcommand.
-H	Turns on audit logging for the `FILE_Unlink` event if the event is enabled for the user.
-i	Turns off interactive prompting during multiple file transfers. See the **prompt**, **mget**, **mput**, and **mdelete** subcommands for descriptions of prompting during multiple file transfers.
-K	Disables the SO_KEEPALIVE option defined in the `sys/socket.h` file on both the control and data connection.
-k *realm*	Allows the user to specify the realm of the remote station if it is different from the local systems realm. For these purposes, a realm is synonymous with a DCE cell. This flag will be ignored if Kerberos 5 is not the current authentication method.
-M	Prevents the **ftp** command from being blocked after a file is transferred between a local and a remote host.
-n	Prevents an automatic login on the initial connection. Otherwise, the **ftp** command searches for a **$HOME/.netrc** entry that describes the login and initialization process for the remote host. See the **user** subcommand.
-q	Allows the user to specify that the **send_file** subroutine must be used for sending the file on the network. This flag is only applicable when a file is being sent out in the binary mode with no protection.

Item	Description
-v	Displays all the responses from the remote server and provides data transfer statistics. This display mode is the default when the output of the **ftp** command is to a terminal, such as the console or a display. If stdin is not a terminal, the **ftp** command disables verbose mode unless the user invoked the **ftp** command with the **-v** flag or issued the **verbose** subcommand.
-s	Starts a TLS session with the server by sending an **AUTH TLS** command and a **PROT P** command to the **ftpd** daemon. If the TLS session is established, and you are authenticated by using the Standard Authentication method, the transfer of the data and commands is encrypted.

Subcommands

The following **ftp** subcommands can be entered at the `ftp>` prompt. Use double quotes (" ") to specify parameters that include blank characters.

Item	Description
![*Command* [*Parameters*]]	Invokes an interactive shell on the local host. An optional command, with one or more optional parameters, can be given with the shell command.
$*Macro* [*Parameters*]	Executes the specified macro, previously defined with the **macdef** subcommand. Parameters are not expanded.
?[*Subcommand*]	Displays a help message describing the subcommand. If you do not specify a *Subcommand* parameter, the **ftp** command displays a list of known subcommands.
account [*Password*]	Sends a supplemental password that a remote host may require before granting access to its resources. If the password is not supplied with the command, the user is prompted for the password. The password is not displayed on the screen.
append *LocalFile* [*RemoteFile*]	Appends a local file to a file on the remote host. If the remote file name is not specified, the local file name is used, altered by any setting made with the **ntrans** subcommand or the **nmap** subcommand. The **append** subcommand uses the current values for **form**, **mode**, **struct**, and **type** subcommands while appending the file.
ascii	Synonym for the **type ascii** subcommand.
bell	Sounds a bell after the completion of each file transfer.
binary	Synonym for the **type binary** subcommand.
block	Synonym for the **mode block** subcommand.
bye	Ends the file-transfer session and exits the **ftp** command. Same as the **quit** subcommand.
carriage-control	Synonym for the **form carriage-control** subcommand.
case	Sets a toggle for the case of file names. When the **case** subcommand is On, the **ftp** command changes remote file names displayed in all capital letters from uppercase to lowercase when writing them in the local directory. The default is Off (so the **ftp** command writes uppercase remote file names in uppercase in the local directory).
cd *RemoteDirectory*	Changes the working directory on the remote host to the specified directory.
cdup	Changes the working directory on the remote host to the parent of the current directory.

Item	Description
close	Ends the file-transfer session, but does not exit the **ftp** command. Defined macros are erased. Same as the **disconnect** subcommand.
copylocal	Toggles local copy. **copylocal** defaults to off. An effort is made by ftp to make sure you do not zero out a file by ftp'ing it to itself (eg. same hostname, same pathname). Turning **copylocal** ON bypasses this check.
cr	Strips the carriage return character from a carriage return and line-feed sequence when receiving records during ASCII-type file transfers. (The **ftp** command terminates each ASCII-type record with a carriage return and line feed during file transfers.) Records on remote hosts with operating systems other than the one you are running can have single line feeds embedded in records. To distinguish these embedded line feeds from record delimiters, set the **cr** subcommand to Off. The **cr** subcommand toggles between On and Off.
debug [**0** | **1**]	Toggles debug record keeping On and Off. Specify **debug** or **debug 1** to print each command sent to the remote host and save the restart control file. Specify **debug** again, or **debug 0**, to stop the debug record keeping. The Ctrl-C key sequence also saves the restart control file. Specifying the **debug** subcommand sends debugging information about **ftp** command operations to the **syslogd** daemon. If you specify the **debug** subcommand, you must edit the **/etc/syslog.conf** file and add one of the following entries: `user.info FileName` OR `user.debug FileName` **Note:** The **syslogd** daemon debug level includes info level messages. If you do not edit the **/etc/syslog.conf** file, no messages are produced. After changing the **/etc/syslog.conf** file, run the **refresh -s syslogd** or **kill -1** *SyslogdPID* command to inform the **syslogd** daemon of the changes to its configuration file. For more information about debug levels, refer to the **/etc/syslog.conf** file. Also, refer to the **ftp -d** flag.
delete *RemoteFile*	Deletes the specified remote file.
dir [*RemoteDirectory*] [*LocalFile*]	Writes a listing of the contents of the specified remote directory (*RemoteDirectory*) to the specified local file (*LocalFile*). If the *RemoteDirectory* parameter is not specified, the **dir** subcommand lists the contents of the current remote directory. If the *LocalFile* parameter is not specified or is a - (hyphen), the **dir** subcommand displays the listing on the local terminal.
disconnect	Ends the file-transfer session but does not exit the **ftp** command. Defined macros are erased. Same as the **close** subcommand.
ebcdic	Synonym for the **type ebcdic** subcommand.
exp_cmd	Toggles between conventional and experimental protocol commands. The default is off.
file	Synonym for the **struct file** subcommand.

Item	Description
form [**carriage-control** | **non-print** | **telnet**]	Specifies the form of the file transfer. The **form** subcommand modifies the **type** subcommand to send the file transfer in the indicated form. Valid arguments are **carriage-control**, **non-print**, and **telnet**. **carriage-control** Sets the form of the file transfer to carriage-control. **non-print** Sets the form of the file transfer to non-print. **telnet** Sets the form of the file transfer to Telnet. Telnet is a Transmission Control Protocol/Internet Protocol (TCP/IP) protocol that opens connections to a system.
get *RemoteFile* [*LocalFile*]	Copies the remote file to the local host. If the *LocalFile* parameter is not specified, the remote file name is used locally and is altered by any settings made by the **case**, **ntrans**, and **nmap** subcommands**.** The **ftp** command uses the current settings for the **type**, **form**, **mode**, and **struct** subcommands while transferring the file.
glob	Toggles file-name expansion (globbing) for the **mdelete**, **mget**, and **mput** subcommands. If globbing is disabled, file-name parameters for these subcommands are not expanded. When globbing is enabled and a pattern-matching character is used in a subcommand that expects a single file name, results may be different than expected. For example, the **append** and **put** subcommands perform file-name expansion and then use only the first file name generated. Other **ftp** subcommands, such as **cd**, **delete**, **get**, **mkdir**, **rename**, and **rmdir**, do not perform file-name expansion and take the pattern-matching characters literally. Globbing for the **mput** subcommand is done locally in the same way as for the **csh** command. For the **mdelete** and **mget** subcommands, each file name is expanded separately at the remote machine and the lists are not merged. The expansion of a directory name can be different from the expansion of a file name, depending on the remote host and the **ftp** server. To preview the expansion of a directory name, use the **mls** subcommand: `mls RemoteFile` To transfer an entire directory subtree of files, transfer a **tar** archive of the subtree in binary form, rather than using the **mget** or **mput** subcommand.
hash	Toggles hash sign (#) printing. When the **hash** subcommand is on, the **ftp** command displays one hash sign for each data block (1024 bytes) transferred.
help [*Subcommand*]	Displays help information. See the **?** subcommand.
image	Synonym for the **type image** subcommand.
lcd [*Directory*]	Changes the working directory on the local host. If you do not specify a directory, the **ftp** command uses your home directory.
local *M*	Synonym for the **type local** *M* subcommand.
ls [*RemoteDirectory*] [*LocalFile*]	Writes an abbreviated file listing of a remote directory to a local file. If the *RemoteDirectory* parameter is not specified, the **ftp** command lists the current remote directory. If the *LocalFile* parameter is not specified or is a - (hyphen), the **ftp** command displays the listing on the local terminal.

Item	Description
macdef *Macro*	Defines a subcommand macro. Subsequent lines up to a null line (two consecutive line feeds) are saved as the text of the macro. Up to 16 macros, containing at most 4096 characters for all macros, can be defined. Macros remain defined until either redefined or a **close** subcommand is executed. The $ (dollar sign) and \ (backslash) are special characters in **ftp** macros. A $ symbol followed by one or more numbers is replaced by the corresponding macro parameter on the invocation line (see the **$** subcommand). A $ symbol followed by the letter i indicates that the macro is to loop, with the $i character combination being replaced by consecutive parameters on each pass. The first macro parameter is used on the first pass, the second parameter is used on the second pass, and so on. A \ symbol prevents special treatment of the next character. Use the \ symbol to turn off the special meanings of the $ and \. (backslash period) symbols.
mdelete *RemoteFiles*	Expands the files specified by the *RemoteFiles* parameter at the remote host and deletes the remote files.
mdir [*RemoteDirectories LocalFile*]	Expands the directories specified by the *RemoteDirectories* parameter at the remote host and writes a listing of the contents of those directories to the file specified in the *LocalFile* parameter. If the *RemoteDirectories* parameter contains a pattern-matching character, the **mdir** subcommand prompts for a local file if none is specified. If the *RemoteDirectories* parameter is a list of remote directories separated by blanks, the last argument in the list must be either a local file name or a - (hyphen). If the *LocalFile* parameter is - (hyphen), the **mdir** subcommand displays the listing on the local terminal. If interactive prompting is on (see the **prompt** subcommand), the **ftp** command prompts the user to verify that the last parameter is a local file and not a remote directory.
mget *RemoteFiles*	Expands the *RemoteFiles* parameter at the remote host and copies the indicated remote files to the current directory on the local host. See the **glob** subcommand for more information on file-name expansion. The remote file names are used locally and are altered by any settings made by the **case**, **ntrans**, and **nmap** subcommands. The **ftp** command uses the current settings for the **form**, **mode**, **struct**, and **type** subcommands while transferring the files.
mkdir [*RemoteDirectory*]	Creates the directory specified in the *RemoteDirectory* parameter on the remote host.
mls [*RemoteDirectories LocalFile*]	Expands the directories specified in the *RemoteDirectories* parameter at the remote host and writes an abbreviated file listing of the indicated remote directories to a local file. If the *RemoteDirectories* parameter contains a pattern-matching character, the **mls** subcommand prompts for a local file if none is specified. If the *RemoteDirectories* parameter is a list of remote directories separated by blanks, the last argument in the list must be either a local file name or a - (hyphen). If the *LocalFile* parameter is - (hyphen), the **mls** subcommand displays the listing on the local terminal. If interactive prompting is on (see the **prompt** subcommand), the **ftp** command prompts the user to verify that the last parameter is a local file and not a remote directory.

Item	Description
mode [**stream** | **block**]	Sets file-transfer mode. If an argument is not supplied, the default is **stream**. **block** Sets the file-transfer mode to block. **stream** Sets the file-transfer mode to stream.

Item	Description
modtime	Shows the last modification time of the specified file on the remote machine. If the **ftp** command is not connected to a host prior to execution, the **modtime** subcommand terminates with an error message. The **ftp** command ignores parameter beyond the first parameter. If the *FileName* parameter is not specified, the **ftp** command prompts for a file name. If no file name is given, the **ftp** command sends a usage message to standard output and terminates the subcommand. If the name specified by the *FileName* parameter exists on the remote host, and the name specifies a file, then the **ftp** command sends a message containing the last modification time of the file to standard output and terminates the subcommand. If *FileName* specifies a directory, the **ftp** command sends an error message to standard output and terminates the subcommand. **Note:** The **modtime** subcommand interprets metacharacters when allowed.
mput [*LocalFiles*]	Expands the files specified in the *LocalFiles* parameter at the local host and copies the indicated local files to the remote host. See the **glob** subcommand for more information on file-name expansion. The local file names are used at the remote host and are altered by any settings made by the **ntrans** and **nmap** subcommands. The **ftp** command uses the current settings for the **type**, **form**, **mode**, and **struct** subcommands while transferring the files.
nlist [*RemoteDirectory*] [*LocalFile*]	Writes a listing of the contents of the specified remote directory (*RemoteDirectory*) to the specified local file (*LocalFile*). If the *RemoteDirectory* parameter is not specified, the **nlist** subcommand lists the contents of the current remote directory. If the *LocalFile* parameter is not specified or is a **-** (hyphen), the **nlist** subcommand displays the listing on the local terminal.

Item	Description
nmap [*InPattern OutPattern*]	Turns the file-name mapping mechanism On or Off. If no parameters are specified, file-name mapping is turned off. If parameters are specified, source file names are mapped for the **mget** and **mput** subcommands and for the **get** and **put** subcommands when the destination file name is not specified. This subcommand is useful when the local and remote hosts use different file-naming conventions or practices. Mapping follows the pattern set by the *InPattern* and *OutPattern* parameters. The *InPattern* parameter specifies the template for incoming file names, which may have already been processed according to the **case** and **ntrans** settings. The template variables $1 through $9 can be included in the *InPattern* parameter. All characters in the *InPattern* parameter, other than the $ (dollar sign) and the \$ (backslash, dollar sign), are treated literally and are used as delimiters between *InPattern* variables. For example, if the *InPattern* parameter is `$1.$2` and the remote file name is `mydata.dat`, the value of $1 is `mydata` and the value of $2 is `dat`. The *OutPattern* parameter determines the resulting file name. The variables $1 through $9 are replaced by their values as derived from the *InPattern* parameter, and the variable $0 is replaced by the original file name. Additionally, the sequence [*Sequence1*,*Sequence2*] is replaced by the value of *Sequence1*, if *Sequence1* is not null; otherwise, it is replaced by the value of *Sequence2*. For example, the subcommand: `nmap $1.$2.$3 [$1,$2].[$2,file]` would yield `myfile.data` from `myfile.data` or `myfile.data.old`, `myfile.file` from `myfile`, and `myfile.myfile` from `.myfile`. Use the \ (backslash) symbol to prevent the special meanings of the $ (dollar sign), [(left bracket),] (right bracket), and , (comma) in the *OutPattern* parameter.
non-print	Synonym for the **form non-print** subcommand.
ntrans [*InCharacters* [*OutCharacters*]]	Turns the file-name character translation mechanism On and Off. If no parameters are specified, character translation is turned off. If parameters are specified, characters in source file names are translated for **mget** and **mput** subcommands and for **get** and **put** subcommands when the destination file name is not specified. This subcommand is useful when the local and remote hosts use different file-naming conventions or practices. Character translation follows the pattern set by the *InCharacters* and *OutCharacters* parameter. Characters in a source file name matching characters in the *InCharacters* parameter are replaced by the corresponding characters in the *OutCharacters* parameter. If the string specified by the *InCharacters* parameter is longer than the string specified by the *OutCharacters* parameter, the characters in the *InCharacters* parameter are deleted if they have no corresponding character in the *OutCharacters* parameter.
open *HostName* [*Port*]	Establishes a connection to the FTP server at the host specified by the *HostName* parameter. If the optional port number is specified, the **ftp** command attempts to connect to a server at that port. If the automatic login feature is set (that is, the **-n** flag was not specified on the command line), the **ftp** command attempts to log in the user to the FTP server. You must also have a **$HOME/.netrc** file with the correct information in it and the correct permissions set. The **.netrc** file must be in your home directory.

Item	Description
passive	Toggles passive mode for file transfers. When a file transfer command (such as **get**, **mget**, **put**, or **mput**) is invoked with passive mode off, the **ftp** server opens a data connection back to the client. In passive mode, the client opens data connections to the server when sending or receiving data.
private	Sets the protection level to private only when the authentication method is set. At this level, data integrity and confidentiality are protected.
prompt	Toggles interactive prompting. If interactive prompting is on (the default), the **ftp** command prompts for verification before retrieving, sending, or deleting multiple files during the **mget**, **mput**, and **mdelete** subcommands. Otherwise, the **ftp** command acts accordingly on all files specified.
protect	This command returns the current level of protection.
proxy [*Subcommand*]	Executes an **ftp** command on a secondary control connection. This subcommand allows the **ftp** command to connect simultaneously to two remote FTP servers for transferring files between the two servers. The first **proxy** subcommand should be an **open** subcommand to establish the secondary control connection. Enter the **proxy ?** subcommand to see the other **ftp** subcommands that are executable on the secondary connection. The following subcommands behave differently when prefaced by the **proxy** subcommand: • The **open** subcommand does not define new macros during the automatic login process. • The **close** subcommand does not erase existing macro definitions. • The **get** and **mget** subcommands transfer files from the host on the primary connection to the host on the secondary connection. • The **put**, **mput**, and **append** subcommands transfer files from the host on the secondary connection to the host on the primary connection. • The **restart** subcommand can be handled by the **proxy** command. • The **status** subcommand displays accurate information. File transfers require that the FTP server on the secondary connection must support the PASV (passive) instruction.
put *LocalFile* [*RemoteFile*]	Stores a local file on the remote host. If you do not specify the *RemoteFile* parameter, the **ftp** command uses the local file name to name the remote file, and the remote file name is altered by any settings made by the **ntrans** and **nmap** subcommands. The **ftp** command uses the current settings for the **type**, **form**, **mode**, and **struct** subcommands while transferring the files.
pwd	Displays the name of the current directory on the remote host.
quit	Closes the connection and exits the **ftp** command. Same as the **bye** subcommand.
quote *String*	Sends the string specified by the *String* parameter verbatim to the remote host. Execute the **remotehelp** or **quote help** subcommand to display a list of valid values for the *String* parameter. **Note:** "Quoting" commands that involve data transfers can produce unpredictable results.
record	Synonym for the **struct record** subcommand.
recv *RemoteFile* [*LocalFile*]	Copies the remote file to the local host. Same as the **get** subcommand.

Item	Description
reinitialize	Reinitializes an FTP session by flushing all I/O and allowing transfers to complete. Resets all defaults as if a user had just started an FTP session without logging in to a remote host.
remotehelp [*Subcommand*]	Requests help from the remote FTP server.
rename *FromName ToName*	Renames a file on the remote host.
reset	Clears the reply queue. This subcommand resynchronizes the command parsing.
restart get | **put** | **append**	Restarts a file transfer at the point where the last checkpoint was made. To run successfully, the subcommand must be the same as the aborted subcommand, including structure, type, and form. Valid arguments are **get**, **put**, and **append**.
rmdir *RemoteDirectory*	Removes the remote directory specified by the *RemoteDirectory* parameter at the remote host.
runique	(ReceiveUnique) Toggles the facility for creating unique file names for local destination files during **get** and **mget** subcommands. If this facility is Off (the default), the **ftp** command overwrites local files. Otherwise, if a local file has the same name as that specified for a local destination file, the **ftp** command modifies the specified name of the local destination file with `.1`. If a local file is already using the new name, the **ftp** command appends the postfix .2 to the specified name. If a local file is already using this second name, the **ftp** command continues incrementing the postfix until it either finds a unique file name or reaches .99 without finding a unique file name. If the **ftp** command cannot find a unique file name, the **ftp** command reports an error and the transfer does not take place. Note that the **runique** subcommand does not affect local file names generated from a shell command.
safe	Sets the protection level to "safe." At this level, data is integrity protected.
send *LocalFile* [*RemoteFile*]	Stores a local file on the remote host. Same as the **put** subcommand.
sendport	Toggles the use of FTP PORT instructions. By default, the **ftp** command uses a PORT instruction when establishing a connection for each data transfer. When the use of PORT instructions is disabled, the **ftp** command does not use PORT instructions for data transfers. The PORT instruction is useful when dealing with FTP servers that ignore PORT instructions while incorrectly indicating the instructions have been accepted.
site *Args*	Displays or sets the idle time-out period, displays or sets the file-creation umask, or changes the permissions of a file, using the **chmod** command. Possible values for the *Args* parameter are **umask** and **chmod**.
size *RemoteFile*	Displays the size in bytes of the remote file specified by the *RemoteFile* parameter.
status	Displays the current status of the **ftp** command as well as the status of the subcommands.
stream	Synonym for the **mode stream** subcommand.

Item	Description
struct [**file** | **record**]	Sets the data transfer structure type. Valid arguments are **file** and **record**. **file** Sets the data-transfer structure type to file. **record** Sets the data-transfer structure type to record.
sunique	(Send/Store Unique) Toggles the facility for creating unique file names for remote destination files during **put** and **mput** subcommands. If this facility is off (the default), the **ftp** command overwrites remote files. Otherwise, if a remote file has the same name as that specified for a remote destination file, the remote FTP server modifies the name of the remote destination file. Note that the remote server must support the STOU instruction.
system	Shows the type of operating system running on the remote machine.
telnet	Synonym for the **form telnet** subcommand.
tenex	Synonym for the **type tenex** subcommand.
trace	Toggles packet tracing.
type [**ascii** | **binary** | **ebcdic** | **image** | **local** *M* | **tenex**]	Sets the file-transfer type. Valid arguments are **ascii**, **binary**, **ebcdic**, **image**, **local** *M*, and **tenex**. If an argument is not specified, the current type is printed. The default type is **ascii**; the **binary** type can be more efficient than **ascii**. **ascii** Sets the file-transfer type to network ASCII. This type is the default. File transfer may be more efficient with binary-image transfer. See the **binary** argument for further information. **binary** Sets the file-transfer type to binary image. This type can be more efficient than an ASCII transfer. **ebcdic** Sets the file-transfer type to EBCDIC. **image** Sets the file-transfer type to binary image. This type can be more efficient than an ASCII transfer. **local *M*** Sets the file-transfer type to local. The *M* parameter defines the decimal number of bits per machine word. This parameter does not have a default. **tenex** Sets the file-transfer type to that needed for TENEX machines.
user *User* [*Password*] [*Account*]	Identifies the local user (*User*) to the remote FTP server. If the *Password* or *Account* parameter is not specified and the remote server requires it, the **ftp** command prompts for the password or account locally. If the *Account* parameter is required, the **ftp** command sends it to the remote server after the remote login process completes. **Note:** Unless automatic login is disabled by specifying the **-n** flag on the command line, the **ftp** command sends the *User*, *Password*, and *Account* parameters automatically for the initial connection to the remote server. You also need a **.netrc** file in your home directory in order to issue an automatic login.

Item	Description
verbose	Toggles verbose mode. When the verbose mode is on (the default), the **ftp** command displays all responses from the remote FTP server. Additionally, the **ftp** command displays statistics on all file transfers when the transfers complete.

Examples

1. To invoke the **ftp** command, log in to the system canopus, display local help information, display remote help information, display status, toggle the **bell**, **prompt**, **runique**, **trace**, and **verbose** subcommands, and then quit, enter:

```
$ ftp canopus
Connected to canopus.austin.century.com.
220 canopus.austin.century.com FTP server (Version 4.1 Sat Nov 23 12:52:09 CST 1991) ready.
Name (canopus:eric): dee
331 Password required for dee.
Password:
230 User dee logged in.
ftp> help
Commands may be abbreviated. Commands are:
!          delete          mdelete          proxy          runique
$          debug           mdir             sendport       send
account    dir             mget             put            size
append     disconnect      mkdir            pwd            status
ascii      form            mls              quit           struct
bell       get             mode             quote          sunique
binary     glob            modtime          recv           system
bye        hash            mput             remotehelp     tenex
case       help            nmap             rstatus        trace
cd         image           nlist            rhelp          type
cdup       lcd             ntrans           rename         user
close      ls              open             reset          verbose

Files

Item	Description
/usr/samples/tcpip/netrc	Contains the sample **.netrc** file.
/etc/syslog.conf	Contains configuration information for the **syslogd** daemon.

ftpd Daemon

Purpose

Provides the server function for the Internet FTP protocol.

Syntax

Note: The **ftpd** daemon is usually started by the **inetd** daemon. It can also be controlled from the command line, using SRC commands.

/usr/sbin/ftpd [**-d**] [**-D** *DataConnTimeOut*] [**-e**][**-f**] [**-ff**] [**-k**] [**-l**] [**-U**] [**-t** *TimeOut*] [**-T** *MaxTimeOut*] [**-s**] [**-u** *OctalVal*] [**-q** [**-C**]] [**-c**] [**-H**]

Description

The **/usr/sbin/ftpd** daemon is the DARPA Internet File Transfer Protocol (FTP) server process. The **ftpd** daemon uses the Transmission Control Protocol (TCP) to listen at the port specified with the **ftp** command service specification in the **/etc/services** file.

Changes to the **ftpd** daemon can be made using the System Management Interface Tool (SMIT) or System Resource Controller (SRC), by editing the **/etc/inetd.conf** or /**etc**/**services** file. Typing `ftpd` at the command line is not recommended. The **ftpd** daemon is started by default when it is uncommented in the **/etc/inetd.conf** file.

The **inetd** daemon gets its information from the /**etc**/**inetd.conf** file and the /**etc**/**services** file.

If you change the **/etc/inetd.conf** or /**etc**/**services** file, run the **refresh -s inetd** or **kill -1** *InetdPID* command to inform the **inetd** daemon of the changes to its configuration files.

The **ftpd** daemon expands file names according to the conventions of the **csh** command. This command allows you to use such metacharacters as the * (asterisk), the ? (question mark), [ ] (left and right brackets), { } (left and right braces), and the ~ (tilde).

ftpaccess.ctl File

The **/etc/ftpaccess.ctl** file is searched for lines that start with **allow:**, **deny:**, **readonly:**, **writeonly:**, **readwrite:**, **useronly:**, **grouponly:**, **herald:** and/or **motd:**. Other lines are ignored. If the file doesn't exist, then ftp access is allowed for all hosts. The **allow:** and **deny:** lines are for restricting host access. The **readonly:**, **writeonly:** and **readwrite:** lines are for restricting ftp reads (get) and writes (put). The **useronly:** and **grouponly:** lines are for defining anonymous users. The **herald:** and **motd:** lines are for multiline messages before and after login.

The syntax for all lines in **/etc/ftpaccess.ctl** is in the form:

```
keyword: value, value, ...
```

where you can specify one or more values for every keyword. You can have multiple lines with the same keyword. The lines in **/etc/ftpaccess.ctl** are limited to 1024 characters, anything more than 1024 characters will be ignored.

The syntax for the **allow:** and **deny:** lines are:

```
allow: host, host, ...
deny: host, host, ...
```

If an **allow:** line is specified, then only the hosts listed in all the **allow:** lines are allowed ftp access. All other hosts will be refused ftp access. If there is no **allow:** line, then all hosts will be given ftp access except those hosts specified in the **deny:** line(s). The host can be specified as either a hostname or IP address.

The syntax for the `readonly:`, `writeonly:` and `readwrite:` lines is:

```
readonly: dirname, dirname, ...
writeonly: dirname, dirname, ...
readwrite: dirname, dirname, ...
```

The **readonly:** lines list the read-only directories and the **writeonly:** lines list the write-only directories. Read access is denied in a write-only directory and write access is denied in a read-only directory. All other directories are granted access except when a **readwrite:** line is specified. If a **readwrite:** line is specified, only directories listed in the **readwrite:** line and/or listed in the **readonly:** line are granted access for reading, AND only directories listed in the **readwrite:** line and/or listed in the **writeonly:** line are granted access for writing. Also, these lines can have a value of "ALL" or "NONE".

The syntax for the **useronly:**, `puseronly:`, `grouponly:`, and **pgrouponly:** lines is:

```
useronly: username, username, ...
puseronly: username, username, ...
grouponly: groupname, groupname, ...
pgrouponly: groupname, groupname, ...
```

The username is from **/etc/passwd** and the groupname is from **/etc/group**. The **useronly:** and `puseronly:` lines define an anonymous user. The **grouponly:** and `pgrouponly:` lines define a group of anonymous users. These anonymous users are similar to the user anonymous in that ftp activity is restricted to their home directories. The `useronly:` and `grouponly:` lines define anonymous users similar to the user anonymous in that they are not password protected. The `puseronly:` and `pgrouponly:` lines define anonymous users that are password protected.

Note: For `puseronly:` and `pgrouponly:` users, passwords must be created and login must be disabled.

The syntax for the **herald:** and **motd:** lines are:

```
herald: path
motd: on|off
```

The path is the full path name of the file that contains the multiline herald that displays before login. When the **motd:** line has a value of 'on', then the **$HOME/motd** file contains the multiline message that displays after login. If the user is a defined anonymous user, then the **/etc/motd** file contains the multiline message that displays after login. (Note that **/etc/motd** is in the anonymous user's chroot'ed home directory). The default for the **motd:** line is off.

If the Standard Operating system authentication method is the current authentication method :

Before the **ftpd** daemon can transfer files for a client process, it must authenticate the client process. The **ftpd** daemon authenticates client processes according to these rules:

- The user must have a password in the password database, **/etc/security/passwd**. (If the user's password is not null, the client process must provide that password.)
- The user name must not appear in the **/etc/ftpusers** file.
- The user's login shell must appear in the shells attribute of the **/etc/security/login.cfg** file.
- If the user name is `anonymous`, `ftp` or is a defined anonymous user in the **/etc/ftpaccess.ctl** file, an anonymous FTP account must be defined in the password file. In this case, the client process is allowed to log in using any password. By convention, the password is the name of the client host. The **ftpd** daemon takes special measures to restrict access by the client process to the anonymous account.

If Kerberos 5 is the current authentication method:

The **ftpd** daemon allows access only if all of the following conditions are satisfied:

- The local user of the ftp client has current DCE credentials.
- The local and remote systems both support the **AUTH** command.
- The remote system accepts the DCE credentials as sufficient for access to the remote account. See the **kvalid_user** function for additional information.

Transport Layer Security support

The **ftpd** daemon supports Transport Layer Security (TLS) as defined in RFC 4217. TLS is a cryptographic protocol that provides secure communication between clients and servers.

The main purpose of the implementation is to secure the control and data connection using encryption. The client needs to be authenticated by other means. The only supported method is the Standard Authentication method.

Upon receiving a request to start a TLS session, the **ftpd** daemon proceeds to read the **/etc/ftpd.cnf** file, loading the following configuration parameters that will be used to set up the TLS session:

Item	Description
CRL_PATH	The *CRL_PATH* parameter provides the path to the certificate revocation list file, which must be in PEM format. If specified, the digital certificate provided by the client will be verified against the certificate revocation list. If the ftp client is not using a digital certificate, the connection will fail. If the client provides a digital certificate, but the certificate has been revoked, the TLS session will fail. If this parameter is not specified, the client does not have to provide a digital certificate.
CA_PATH	The *CA_PATH* parameter provides the path to the certificate authority file, which must be in PEM format. If specified, the client certificate will be verified against the certificate authority. If the client does not provide a digital certificate, the connection will fail. If the client provides a digital certificate, but the certificate has not been signed by the security authority, the TLS session will fail. If this parameter is not specified, the client does not have to provide a digital certificate.
CIPHER_LIST	If the *CIPHER_LIST* parameter is specified, the list is used during the TLS session. If not, a default cipher list is used.
DEPTH	If the *CA_PATH* configuration parameter has been specified, the *DEPTH* value is used to verify the certificate provided by the ftp client in the digital certificate hierarchy. If not provided, a default value of 9 is used.
CERTIFICATE	The *CERTIFICATE* parameter provides a path to a valid digital certificate chain file in PEM format. This file is used in the TLS session. This parameter needs to be specified to start a TLS session. If this parameter is not specified, the ftpd server rejects all TLS requests.
CERTIFICATE_PRIVATE_KEY	The *CERTIFICATE_PRIVATE_KEY* parameter provides the path to the certificate private key, which is in PEM format, and is used during the TLS session. This parameter needs to be specified to start a TLS session. If this parameter is not specified, the ftpd server rejects all TLS requests.
DH_PARAMETERS_DIR	The *DH_PARAMETERS_DIR* parameter provides the path to a directory containing *Diffie Helman* parameters in PEM format. More than one file containing *Diffie Helman* parameters in PEM format can be included in this directory. The **ftpd** daemon searches for the appropriate parameter to use if required.

To support TLS, you must install the latest version of the OpenSSL tool from the AIX Web Download Pack Programs website.

File Transfer Protocol Subtree Guidelines

When handling an anonymous FTP user, the server performs the **chroot** command in the home directory of the FTP user account. For greater security, implement the following rules when you construct the FTP subtree:

Item	Description
~ftp	Make the home directory owned by root and mode r-xr-xr-x (555).
~ftp/bin	Make this directory owned by the root user and not writable by anyone. The **ls** program must be present in this directory to support the list command. This program must have mode 111.
~ftp/etc	Make this directory owned by the root user and not writable by anyone.
~ftp/pub	Make this directory mode 777 and owned by FTP. Users must then place files that are to be accessible through the anonymous account in this directory.

Note: The shell script **/usr/samples/tcpip/anon.ftp** uses the above rules to set up the anonymous FTP account for you.

When handling an anonymous FTP user defined in **/etc/ftpaccess.ctl**, the server performs the **chroot** command in the home directory of the user account. For greater security, implement the following rules when you construct the user's subtree:

~user
Make the home directory owned by root and mode `r-xr-xr-x` (555).

~user/bin
Make this directory owned by the root user and unwritable by anyone. The **ls** program must be present in this directory to support the list command. This program must have mode 111.

~user/etc
Make this directory owned by the root user and unwritable by anyone.

~user/pub
Make this directory mode 777 and owned by user. Users must then place files that are to be accessible through the `anonymous` account in this directory.

Note: The shell script **/usr/samples/tcpip/anon.users.ftp** uses the above rules to set up the anonymous FTP account for you.

The server must run as the root user to create sockets with privileged port numbers. The server maintains an effective user ID of the logged-in user, reverting to the root user only when binding addresses to sockets.

Supported File Transfer Protocol Requests

The **ftpd** daemon currently supports the following FTP requests:

Item	Description
ABOR	Terminates previous command.
ACCT	Specifies account (ignored).
ADAT	Specifies the Authentication/Security Data.
ALLO	Allocates storage (vacuously).
APPE	Appends to a file.
AUTH	Specifies the Authentication/Security Mechanism.
CCC	Specifies the Clear Command Channel.
CDUP	Changes to the parent directory of the current working directory.
CWD	Changes working directory.

Item	Description
DELE	Deletes a file.
ENC	Specifies the Privacy Protected Command.
HELP	Gives help information.

Item	Description
LIST	Gives list files in a directory (this FTP request is the same as the **ls -lA** command).
MKD	Makes a directory.
MDTM	Shows last modification time of file.
MIC	Specifies the Integrity Protected Command.
MODE	Specifies data transfer mode.
NLST	Gives a name list of files in directory (this FTP request is the same as the **ls** command).
NOOP	Does nothing.
PASS	Specifies a password.
PASV	Prepares for server-to-server transfers.
PBSZ	Specifies the Protection Buffer Size.
PORT	Specifies a data connection port.
PROT	Specifies the Data Channel Protection Level.
PWD	Prints the current working directory.
QUIT	Terminates session.
RETR	Retrieves a file.
RMD	Removes a directory.
RNFR	Specifies rename-from file name.
RNTO	Specifies rename-to file name.
SITE	The following nonstandard or UNIX-specific commands are supported by the **SITE** request: **UMASK** Changes umask (**SITE UMASK 002**). **IDLE** Sets idler time (**SITE IDLE 60**). **CHMOD** Changes mode of a file (**SITE CHMOD 755** *FileName*). **HELP** Gives help information (**SITE HELP**).
SIZE	Returns size of current file.
STAT	Returns the status of the server.
STOR	Stores a file.
STOU	Stores a file using a unique file name.
STRU	Specifies the structure of data transfer as a file structure.
SYST	Shows operating system type of server system.

Item	Description
TYPE	Specifies data transfer type with the *Type* parameter.
USER	Specifies user name.
XCUP	Changes the parent directory of the current working directory (not usually used).
XCWD	Changes current directory (not usually used).
XMKD	Creates a directory (not usually used).
XPWD	Prints the current working directory (not usually used).
XRMD	Removes a directory (not usually used).

The remaining FTP requests defined in Internet RFC 959 are recognized, but not implemented. The **MDTM** and **SIZE** requests are not specified by RFC 959, but are scheduled to appear in the next updated FTP RFC.

If a **STAT** request is received during a data transfer and preceded by both a Telnet **IP** signal and **SYNCH** signal, transfer status is returned.

The **ftpd** daemon must be controlled using the System Management Interface Tool (SMIT) or by changing the **/etc/inetd.conf** file. Typing `ftpd` at the command line is not recommended.

Manipulating the ftpd Daemon with the System Resource Controller

The **ftpd** daemon is a subserver of the **inetd** daemon. The **ftpd** daemon is a member of the **tcpip** SRC subsystem group. This daemon is enabled by default in the **/etc/inetd.conf** file and can be manipulated by the following SRC commands:

Item	Description
startsrc	Starts a subsystem, group of subsystems, or a subserver.
stopsrc	Stops a subsystem, group of subsystems, or a subserver.
lssrc	Gets the status of a subsystem, group of subsystems, or a subserver.

Flags

Item	Description
-C	Allows the user to specify that the outgoing file sent using the **send_file** command must be cached in the Network Buffer Cache (NBC). This flag cannot be used unless the **-q** flag is specified. This flag is only applicable when a file is being sent out in the binary mode with no protection.
-c	Suppresses the reverse host name lookup.
-d	Sends debugging information about **ftpd** daemon operations to the **syslogd** daemon. If you specify the **-d** flag, you must edit the **/etc/syslog.conf** file and add the following entry: `daemon.debug FileName` **Note:** The **syslogd** daemon's `debug` level includes `info` level messages. If you do not edit the **/etc/syslog.conf** file, no messages are produced. After changing the **/etc/syslog.conf** file, run the **refresh -s syslogd** command or **kill -1** *SyslogdPID* command to inform the **syslogd** daemon of the changes to its configuration file. For more information about debug levels, refer to the **/etc/syslog.conf** file.

Item	Description
-D *DataConnTimeOut*	Specifies the maximum number of seconds that the **ftpd** daemon holds a data connection. The default value is 300 seconds and a value of 0 specifies an indefinite wait. The value for the *DataConnTimeOut* parameter can range from 0 to *MAXINT*.
-e	Enables only TLS enabled clients to establish connection with the server.
-f	Disables checking for a privileged port when the client requests the server to connect back to a specific port. By default, **ftpd** does not allow the client to request a connection to a privileged port as a security precaution.
-ff	Disables checking for both a privileged port and an IP address that matches the one used for the control connection when the client requests the server to connect back to a specific client port. Using this flag enables the client to request that the server send data to an alternate host or interface. By default, **ftpd** does not allow this action as a security precaution.
-H	Turns on audit logging for the `FILE_Rename`, `FS_Rmdir`, and `FILE_Unlink` events if these events are enabled for the root user.
-k	Sets the **SO_KEEPALIVE** option defined in the **sys/socket.h** file on the data transfer socket to enable the data transfer to time out in the event TCP/IP hangs. The idle interval time is based on system-wide values designated by the `tcp_keepidle` and `tcp_keepintvl` options of the **no** command. Without the flag, **ftpd** data transfer will not time out.
-l	Sends logging information about **ftpd** daemon operations to the **syslogd** daemon. If you specify the **-l** flag, you must edit the **/etc/syslog.conf** file and add the following entry: `daemon.info FileName` If you do not edit the **/etc/syslog.conf** file, no messages are produced. After changing the **/etc/syslog.conf** file, run the **refresh -s syslogd** command or **kill -1** *SyslogdPID* command to inform the **syslogd** daemon of the changes to its configuration file. For more information about debug levels, refer to the **/etc/syslog.conf** file.
-q	Allows the user to specify that the **send_file** subroutine must be used for sending the file on the network. This flag is only applicable when a file is being sent out in the binary mode with no protection.
-t *TimeOut*	Logs out inactive sessions after the number of seconds specified by the *TimeOut* variable. The default limit is 15 minutes (900 seconds). The timeout applies to both the data and the control connections.
-T *MaxTimeOut*	Logs out inactive client sessions after a maximum number of seconds specified by the *MaxTimeOut* variable. The default limit is 2 hours (7200 seconds).
-s	Turns on socket-level debugging.
-u *OctalVal*	Sets the **ftpd** daemon's umask. The *OctalVal* variable must be specified as an octal value to define the umask. The default umask is an octal value of 027, which results in file permissions of rw-r---.
-U	Keep files unlocked while in transfer. If this flag is specified with **/usr/sbin/ftpd**, then the file can be opened while still in transfer.

Security

The **ftpd** daemon is a PAM-enabled application with a service name of *ftp*. System-wide configuration to use PAM for authentication is set by modifying the value of the **auth_type** attribute, in the **usw** stanza of **/etc/security/login.cfg**, to PAM_AUTH as the root user.

The authentication mechanisms used when PAM is enabled depend on the configuration for the **ftp** service in **/etc/pam.conf**. The **ftpd** daemon requires **/etc/pam.conf** entries for the **auth**, **account**, and **session** module types. Listed below is a recommended configuration in **/etc/pam.conf** for the **ftp** service:

```
#
# AIX ftp configuration
#
ftp auth      required     /usr/lib/security/pam_aix

ftp account   required     /usr/lib/security/pam_aix

ftp session   required     /usr/lib/security/pam_aix
```

Examples

Note: The arguments for the **ftpd** daemon can be specified by using SMIT or by editing the **/etc/inetd.conf** file.

1. To start the **ftpd** daemon, type the following:

   ```
   startsrc -t ftp
   ```

   The **startsrc** command with the **-t** flag starts the **ftpd** subserver. You must use the **-t** flag to specify a subserver. Otherwise, the command does not execute properly.
2. To stop the **ftpd** daemon, usually type the following:

   ```
   stopsrc -t ftp
   ```

   The **stopsrc** command with the **-t** flag stops the **ftpd** subserver. The **stopsrc** command allows all pending connections to start and all existing connections to complete, but prevents new connections from starting. You must use the **-t** flag to specify a subserver. Otherwise, the command does not execute properly.
3. To force the **ftpd** daemon and all **ftpd** connections to stop, type the following:

   ```
   stopsrc -f -t ftp
   ```

   The **stopsrc** command with the **-t** and **-f** flags forces the **ftpd** subserver to stop. It terminates all pending connections and existing connections immediately.
4. To display a short status report about the **ftpd** daemon, type the following:

   ```
   lssrc -t ftp
   ```

   The **lssrc** command with the **-t** flag returns the daemon's name, process ID, and state (active or inactive). You must use the **-t** flag to specify a subserver. Otherwise, the command does not execute properly.

Files

Item	Description
/etc/locks/ftpd	Contains interlock and process ID (PID) storage.
/etc/group	Contains passwords for groups.
/etc/passwd	Contains passwords for users.
/etc/security/login.cfg	Contains configuration information for login and user authentication.
/etc/security/passwd	Contains encrypted passwords.
/etc/syslog.conf	Contains configuration information for the **syslogd** daemon.
/usr/samples/tcpip/anon.ftp	Contains the example shell script with which to set up an anonymous FTP account. This file also contains directions for its use.

Item	Description
/etc/ftpd.cnf	Contains the configuration parameters for TLS support.

fuser Command

Purpose

Identifies processes using a file or file structure.

Syntax

fuser [[**-c** | **-C** | **-f**] [**-x**] |**-d**] [**-k** | -K { *SignalNumber* | *SignalName* }] [**-u**] [**-V**]*File* ...

Description

The **fuser** command lists the process numbers of local processes that use the local or remote files specified by the *File* parameter. For block special devices, the command lists the processes that use any file on that device.

Each process number is followed by a letter indicating how the process uses the file:

Item	Description
c	Uses the file as the current directory.
e	Uses the file as a program's executable object.
r	Uses the file as the root directory.
s	Uses the file as a shared library (or other loadable object).

The process numbers are written to standard output in a line with spaces between process numbers. A new line character is written to standard error after the last output for each file operand. All other output is written to standard error.

The **fuser** command will not detect processes that have mmap regions where that associated file descriptor has since been closed. Also, processes using FIFOs (named pipes) will not be detected until the FIFO is fully opened. For example, a process waiting for an open system call to complete will not be seen by the **fuser** command.

The **`fuser`** command is used to determine the processes that are using a file system. If the file system is a network file system (NFS) and the NFS server is not responding, the **`fuser`** command might hang. To avoid such a situation, you can set the `FUSER_VERSION` environment variable to 1.

Flags

Item	Description
-c	Reports on any open files in the file system containing *File*.
-C	Reports on any open files in the file system that is mounted at the directory specified by the **`File`** parameter. If the **`File`** parameter is not a mount point, the command reports an error.
-d	Reports on any open files which have been unlinked (deleted) from the file system containing *File*. When used in conjunction with the **-V** flag, it also reports the inode number and size of the deleted file.
-f	Reports on open instances of *File* only.

Item	Description
-K *SignalNumber* | *SignalName*	Sends the specified signal to each local process. Only the root user can kill a process of another user. Signal can be specified as either a *SignalName*, such as KILL for the SIGKILL signal or a *SignalNumber*, such as 9. Valid values for *SignalName* are those which are displayed by the `kill -l` command.
-k	Sends the **SIGKILL** signal to each local process. Only the root user can kill a process of another user. **Note:** `fuser -k` or **-K** might not be able to detect and kill new processes that are created immediately after the program starts to run.
-u	Provides the login name for local processes in parentheses after the process number.
-V	Provides verbose output.
-x	Used in conjunction with **-c** or **-f**, reports on executable and loadable objects in addition to the standard fuser output.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To list the process numbers of local processes using the **/etc/passwd** file, enter:

   ```
   fuser /etc/passwd
   ```

2. To list the process numbers and user login names of processes using the **/etc/filesystems** file, enter:

   ```
   fuser -u /etc/filesystems
   ```

3. To terminate all of the processes using a given file system, enter:

   ```
   fuser -k -x -u -c /dev/hd1
   ```

   or

   ```
   fuser -kxuc /home
   ```

   Either command lists the process number and user name, and then terminates each process that is using the **/dev/hd1 (/home)** file system. Only the root user can terminate processes that belong to another user. You might want to use this command if you are trying to unmount the **/dev/hd1** file system and a process that is accessing the **/dev/hd1** file system prevents this.

4. To list all processes that are using a file which has been deleted from a given file system, enter:

   ```
   fuser -d /usr
   ```

Files

Item	Description
/dev/kmem	Used for the system image.
/dev/mem	Also used for the system image.

fwtmp Command

Purpose

Manipulates connect-time accounting records by reading binary records in **wtmp** format from standard input and converting them to formatted ASCII records. You can use the ASCII version to edit bad records.

Syntax

/usr/sbin/acct/fwtmp [**-i**] [**-c**] [-X] [-L]

Description

The `fwtmp` command manipulates the accounting records by reading binary records in `wtmp` format from standard input and converting them to formatted ASCII records.

Flags

Item	Description
-i	Accepts ASCII records in the **utmp** format as input.
-c	Converts output to **utmp** formatted binary records.
-ic	Converts ASCII **utmp** formatted input records to binary output records.
-X	Prints all available characters of each user name instead of truncating to the first 8 characters.
-L	Prints all available characters of each host name instead of truncating to the first 32 characters.

Security

Access Control: These commands should grant execute (x) access only to members of the **adm** group.

Examples

1. To convert a binary record in **wtmp** format to an ASCII record called `dummy.file`, enter:

   ```
   /usr/sbin/acct/fwtmp < /var/adm/wtmp > dummy.file
   ```

   The content of a binary **wtmp** file is redirected to a dummy ASCII file.
2. To convert an ASCII `dummy.file` to a binary file in **wtmp** format called `/var/adm/wtmp`, enter the `fwtmp` command with the `-ic` switch:

   ```
   /usr/sbin/acct/fwtmp  -ic < dummy.file  > /var/adm/wtmp
   ```

   The dummy ASCII file is redirected to a binary **wtmp** file.

Files

Item	Description
/usr/sbin/acct/fwtmp	Contains the **fwtmp** command.
/var/adm/wtmp	Contains records of date changes that include an old date and a new date.
/usr/include/utmp.h	Contains history records that include a reason, date, and time.

fxfer Command

Purpose

Transfers files between a local system and a host computer connected by HCON.

Syntax

To Restart an Interrupted File Transfer

fxfer **-R** [**-n** *SessionName*]

To Download a File from the Host

fxfer [**-n** *SessionName*] [**-a** | **-r**] [**-d**] [**-c** | **-C**] [**-J**] [**-f** *FileName*] [**-F**] [**-H** *HostType*][**-I** *InputField*] [**-q**] [**-t** [[**-l**] [**-s**] [**-b**]] | **-T** [[**-l**] [**-s**] [**-b**]]]

[**-v**] [**-x** *HostLogin*] [**-e**] [**-X** *CodeSet*] *SourceFile DestFile*

To Upload a File to the Host

fxfer [**-n** *SessionName*] [**-a** | **-r**] [**-u**] [**-c** | **-C**] [**-J**] [**-f** *FileName*] [**-H** *HostType*] [**-q**] [**-t** [[**-l**] [**-s**]] | **-T** [[**-l**] [**-s**]]] [**-l**] [**-s**] [**-v**] [**-x** *HostLogin*] [**-X** *CodeSet*] [**-F** | **-V** | **-U**] [**-B** *BlockSize*] [**-L** *LoglRecLength*] [**-I** *InputField*] [**-S** *NumberUnits* [**,***IncreaseUnits* | **,***IncreaseUnits***,***UnitType* | **,,***UnitType*]] [**-M** *Volume*] [**-N** *Unit*] [**-k**] *SourceFile DestFile*

To Display the Help Screen

fxfer **-h**

Description

The **fxfer** command transfers files between local system and mainframe hosts connected by the Host Connection Program (HCON). Files may transfer from a local system to the host (uploading) or from the host to a local system (downloading). The **fxfer** command transfers the file named by the *SourceFile* parameter to the file named by the *DestFile* parameter. The transfer occurs over an HCON session requiring a specific session profile or an existing session.

The host operating system may be VM/CMS, MVS/TSO, CICS/VS (for CICS/MVS or CICS/VSE), VSE/ESA, or VSE/SP, with the corresponding version of the 3270 File Transfer Program (**IND$FILE** or its equivalent) installed. The version of the host file transfer program is determined by the File Transfer Program value in the session profile. The **fxfer** command supports transfer of either text or binary data. Files will transfer to or from the host with or without ASCII or EBCDIC translation.

Security mechanisms prevent unauthorized access, the destruction of existing files, or the loss of data. If a non-HCON user issues the **fxfer** command, the command fails. If the **fxfer** command is interrupted before completion, the state of the transfer is saved in a RESTART file.

If the **fxfer** command is issued with the **-h** flag, it displays a help screen. If the command is issued with the **-R** flag, it searches the **$HOME** directory for a restart file. If a restart file exists, the restart menu displays, enabling a restart of the file transfer. If the **-h** and **-R** flags are not specified, the command attempts to perform the specified file transfer.

The **fxfer** command information includes:

- Flags
- Flags for Host File Characteristics
- Examples
- Files

This command requires:

- One or more adapters used to connect to a mainframe host.

- One of the following mainframe operating systems be installed on the host:
  - VM/SP CMS
  - VM/XA CMS
  - MVS/SP TSO/E
  - MVS/XA TSO/E
  - CICS/VS (for CICS/MVS or CICS/VSE)
  - VSE/ESA
- The mainframe Host-Supported File Transfer Program (**IND$FILE** or equivalent) be installed on the mainframe.

Session Profiles for Using the fxfer Command

The **fxfer** command communicates with an HCON session and may require a specific session profile. The session profile defines:

- Communication path to the host
- Host type
- Default file transfer direction (down or up)
- Recovery time
- File transfer wait period

When the **fxfer** command is performing an automatic logon, the profile can also define:

- Host logon ID
- AUTOLOG node ID
- Whether the AUTOLOG trace is on
- AUTOLOG time out value

The user usually specifies a session profile when invoking the **fxfer** command. The exception occurs when the command is run from a subshell of an existing session. In this case, if the user does not specify a session profile, the **fxfer** command uses the existing session. If the appropriate session is not running, the **fxfer** command attempts to invoke a new session.

The **fxfer** command searches for an HCON session as follows:

- When issued without the **-n** *SessionName* flag:
  - If the **fxfer** command is issued from a subshell of an existing session, the command uses the session associated with the subshell (defined by the **$SNAME** environment variable).
  - If *not* issued from a subshell of an emulator session, the **fxfer** command issues an error message and terminates.
- When issued with the **-n** *SessionName* flag, the file transfer performs over the specified session. If the specified session does not exist, the command searches for a session profile for that session. If the specified session profile cannot be found, the **fxfer** command issues an error message and terminates. If the specified profile exists, the **fxfer** command attempts an automatic logon to the host using either the AUTOLOG values defined in the session profile, the values defined with the **-x** flag, or by prompting the user for the necessary logon information.

Interrupted and Restarted File Transfers

The **fxfer** command can be interrupted by the operator or an unrecoverable communication error, before completion. If interrupted, the command saves the state of the transfer in a RESTART file. The transfer can be restarted from the beginning without loss of data.

If you run a new file transfer after an interrupted transfer, the **fxfer** command signals that a RESTART file has been created and displays these choices:

- Restart the interrupted file transfer.

- Save the RESTART file and exit the file transfer program.
- Delete the RESTART file and exit the file transfer program.
- Delete the RESTART file and continue the present transfer.

The **fxfer** command with the **-R** flag also restarts an interrupted file transfer.

If the host communication is lost or disconnected during a file transfer started with an automatic logon, the file transfer attempts to recover by reconnecting and logging back on to the host. The recovery time for this attempt is determined by the File Transfer Recovery Time value in the session profile. Once the host connection is re-established, the file transfer resumes from the start. If communication cannot be re-established, the file transfer program generates a RESTART file.

When an explicit file transfer loses communication with the host, the user must restart the emulator session and log back in to the host before attempting to restart the file transfer.

Source and Destination Files

The **fxfer** command *SourceFile* and *DestFile* parameters are required. The *SourceFile* parameter specifies the source file for a file transfer. The *DestFile* parameter specifies the destination file for a file transfer. The local system file names are in the normal format. The host file names conform to the host naming convention, which is one of the following formats:

Host Type	File Name Format
VM/CMS	**"***FileName FileType FileMode***"** **Note:** The " " (double quotation marks) are required for all VM/CMS file names to ensure proper file transfer.
MVS/TSO	**"**[**'**]*DataSetName* [**(***MemberName***)**] [**/***Password*][**'**]**"** where: ***DataSetName*** Indicates either a physical sequential data set or a partitioned data set. **(*MemberName*)** Indicates the name of one of the members in the directory of an existing partitioned data set. The **()** (parentheses) enclosing the *MemberName* are required. **/*Password*** Required if password protection is specified for the MVS/TSO data set. The **/** (slash) preceding the *Password* is required. **Notes:** 1. The **" "** (double quotation marks) are required for all MVS/TSO file names to ensure proper file transfer. 2. When specifying a complete path name for MVS/TSO file names, use **'** (single quotation marks) within the **"** (double quotation marks). Do not put spaces between the double and single quotation marks or between the quotation marks and the file names.
CICS/VS	**"***FileName***"**
VSE/ESA	**"***FileName FileType***"** **Notes:** 1. The **" "** (double quotation marks) are required for all CICS/VS, VSE/ESA, and VSE/SP file names to ensure proper file transfer. 2. CICS/VS, VSE/ESA, and VSE/SP file name conventions allow for a file name up to 8 characters long. 3. In a DBCS environment, HCON does not support a VSE host.

Flags

Note: For Double-Byte Character Set (DBCS) support that includes either Japanese-English, Japanese Katakana, Korean, or Traditional Chinese, these considerations apply:

- If the DBCS **-l** or **-s** flag is specified, one of the translate flags (**-t**, **-T**, or **-J**) must also be specified or the DBCS flags are ignored.
- The **-M**, **-N**, and **-k** flags are used only with MVS/TSO hosts.
- The **-e** flag is valid only with the CICS® program for downloading.
- The **-b** flag is valid only for downloading.

Item	Description
-a	Appends the file designated by *SourceFile* to the file designated by *DestFile*, if the destination file exists. This flag is ignored and the destination file is created if the file designated by *DestFile* does not exist. **Note:** The **-a** flag is not valid when uploading a file to a CICS/VS host. For VSE/ESA, the **-a** flag is valid only for uploading to CICS temporary storage (FILE=TS).
-b	Retains the blanks at the end of each record when used with the **-t**, **-T**, **-c**, or **-C** flags. The **-b** flag is only supported in the DBCS environment.
-c	In a DBCS environment, the **-c** flag changes LF (line-feed) code of a file to CRLF (carriage return line-feed) code if the file transfer is an upload. For a downloading file transfer, the **-c** flag changes the CRLF code of a file to LF code.
-C	In a DBCS environment, the **-C** flag inhibits the sending of the EOF (end-of-file) code of a PC-DOS file if the file transfer is an upload. For a downloading file transfer, the **-C** flag appends an EOF code: x ' 1A at the end of a PC-DOS file.
-d	Downloads the file by transferring it from the host to the local system. If neither this flag nor the **-u** flag is specified, the File Transfer Direction characteristic in the session profile determines the direction of the transfer. **Note:** When downloading a translated file from a VSE/ESA host file transfer (FILE=HTF) the file is deleted from the host system unless you specify the **-I** "KEEP" flag.
-e	Deletes the temporary storage queue at the completion of the file transfer. Use this flag only with the CICS host for downloading. The **-e** flag is only supported in the DBCS environment.
-f *FileName*	Places the file transfer process diagnostic output (or file transfer status) in the file specified by the *FileName* variable. If the **-f** flag is not specified for an asynchronous transfer, messages are placed in the **$HOME/hconerrors** file. If the **-f** flag is not specified for a synchronous transfer, messages are sent to standard output. Messages due to errors in specifying file transfer parameters or file names, or failures in the file transfer process, are directed to standard output (if it is a local system screen) or to the **$HOME/hconerrors** file (if standard output is not a local system screen).

Item	Description
-h	Displays a help screen for the **fxfer** command. This screen summarizes each available command flag and command operation. When this flag is specified all other flags are ignored and no files are transferred. **Notes:** 1. If the **-h** flag is used, all other flags are ignored. No files transfer. 2. If the **fxfer** command is not initiated from a subshell of an existing HCON session, either the **-h** flag or the **-n** flag is required.
-H *HostType*	Specifies the type of host. The *HostType* variable may have any of these values: **CMS** VM/SP CMS or VM/XA CMS **TSO** MVS/SP TSO or MVS/XA TSO **CICS** CICS/VS (The CICS host type includes CICS/VSE, CICS/MVS, CICS/ESA, and CICS/MVS/ESA.) **VSE** VSE/ESA (Not supported in a DBCS environment.) If the **-H** flag is omitted, the value specified by the Host Type characteristic in the session profile is used. The user must specify the correct host operating system. **Notes:** 1. If you specified the **CICS** or **VSE** value and the system returns an error, retry the command with the alternate value. The CICS and VSE **IND$FILE** programs are functionally interchangeable; however, there is a 6-byte header-size discrepancy that makes the versions operationally incompatible. The destination host may be using the alternate version of the program. 2. To transfer files to an MVS/TSO host, you may need to leave session manager mode before initiating the file transfer.
-I *InputField*	Specifies host file transfer options placed directly within the **IND$FILE** command. Also allows comments within the **IND$FILE** command placed after a) (right parentheses). The value specified by the *InputField* variable is placed in quotation marks, as follows: `-I "FILE=TS) This is a comment"` **Note:** The **-I** field is not supported in a DBCS environment.
-J	Allows data conversion between EBCDIC and ASCII, and normalization of SI/SO characters. The translation depends on the direction of the transfer: **Upload** Translates 1-byte characters of a file to EBCDIC code. For DBCS countries, the extended code is translated to the appropriate DBCS code. SO/SI characters are inserted into DBCS fields containing DBCS characters. If the file contains control codes 0x1E or 0x1F, they are replaced with SO and SI characters respectively. **Download** Translates EBCDIC code to 1-byte characters of a file; For DBCD, the DBCS code is translated to extended code. Deletes SO/SI characters from DBCS fields. **Note:** The **-J** field is only supported in a DBCS environment.

Item	Description
-k	Releases unused records in the data set at the completion of file transfer. Use this flag only in the MVS/TSO environment. The **-k** flag is only supported in the DBCS environment.
-l	Specifies the host language in the DBCS environment. This option must be used with one of the translate flags (**-t**, **-T**, or **-J**). If **-t**, **-T**, or **-J** is omitted, the **-l** flag is ignored. If the **-l** flag is not specified, the host language defined in the session profile is used. If the **-l** flag is specified, the host language used is the alternate language of the language defined in the session profile. For example, if the Language characteristic in the session profile is JPK (Japanese Katakana), the host language used for file transfer will be Japanese-English. The **-l** flag is only supported in the DBCS environment.
-M *Volume*	Specifies the volume serial number of the host disk for data set allocation. Use this flag only in the MVS/TSO environment. The **-M** flag is only supported in the DBCS environment.
-n *SessionName*	Specifies the name of a previously defined session whose characteristics control the file transfer. The session name is a single character in the range of a to z. Capital letters are interpreted as lowercase letters. The **-n** *SessionName* flag is required except when the user is initiating the **fxfer** command from a subshell of an existing session. In this case, if the **-n** flag is not used the **fxfer** command defaults to the existing session. **Notes:** 1. The specified session must have been previously defined by using the **smit hcon** fast path command or the **mkhcons** command. 2. If the **fxfer** command is not initiated from a subshell of an existing HCON session, either the **-h** flag or the **-n** flag is required.
-N *Unit*	Specifies the unit type of the host disk for data set allocation. Use this flag only in the MVS/TSO environment. The **-N** flag is only supported in the DBCS environment.
-q	Runs the file transfer asynchronously as a background process. If any file transfers are not completed, the current transfer request is queued. If the **-q** flag is not specified, the file transfer operation is synchronous. If the **-f** flag is not specified, diagnostic output and status is placed in the **$HOME/hconerrors** file. **Note:** The system limits the number of bytes allowed in one Interprocess Communication (IPC) message queue. As a result, the maximum number of file transfers that can be queued at any one time is approximately 580.

Item	Description
-r	Specifies replacement of an existing file on the host (upload) or an existing file on the local system (download). On downloads, the replacement is done only when the transfer is successful. This ensures the existing file is not lost or destroyed if the transfer does not complete for any reason. If the **-r** flag is specified and the file does not exist, it is created during the file transfer. If the **-r** flag is *not* specified and the destination file exists, an error message is produced. For uploading, the **-r** flag must be specified when using a version of the host file transfer program below PTF UR20455 for MVS/TSO or PTF UR90118 for VM/CMS. For VSE and CICS the **-r** flag is ignored. **Note:** The host file transfer program usually defaults to replace for a file. If it does not, add `-I "replace"` to the **fxfer** command to specify replace. **Attention:** When replacing a file on the host, you must specify a logical record length (**-L** flag) and a record format (**-F** or **-V** flag) equal to the logical record length and record format of the existing file. If you do not do this, data corruption may result. This does not apply to VSE/ESA.
-R	Restarts a previous file transfer (which was interrupted by the user or an unsuccessful recovery attempt) using the information saved in one of the RESTART files: the **$HOME/x_fxfer.r** file or the **$HOME/i_fxfer.r** file. If the file transfer is not invoked from the subshell of an existing session, the **-n** *SessionName* flag must be included to specify the session to be used. If the **-R** flag is specified in conjunction with any other file transfer flags, those flags are ignored and the RESTART file transfer menu is displayed. **Note:** With the **-R** flag, all other flags except the **-n** *SessionName* flag are ignored. The RESTART file transfer menu displays.
-s	Specifies the SO/SI handling in the DBCS environment. The **-s** flag must be used with one of the translate flags (**-t**, **-T**, or **-J**). If **-t**, **-T**, or **-J** is omitted, the **-s** flag is ignored. When the **-s** flag is specified, the following functions are performed for file transfer: **Upload** SO/SI characters are not inserted in DBCS fields. **Download** SO/SI characters are replaced with control characters (0x1E/0x1F) in DBCS fields. The **-s** flag is only supported in the DBCS environment.
-t	Performs ASCII-EBCDIC translation for a file. If downloading, the **fxfer** command translates EBCDIC to ASCII. If uploading, the **fxfer** command translates ASCII to EBCDIC. The language is specified by the Language characteristic in the session profile. The **-t** flag assumes the file is a text file. The new-line character is the line delimiter. When the **-t** flag is used in a DBCS environment with other DBCS supported flags, the behavior of the **-t** flag changes as follows: **Upload** Translates JISCII (Japan) or ASCII (Korean, Traditional Chinese) to EBCDIC. Inserts SO/SI characters in DBCS fields. **Download** Translates EBCDIC to JISCII (Japan) or ASCII (Korean, Traditional Chinese). Deletes SO/SI characters from DBCS fields.

Item	Description
-T	Performs ASCII-EBCDIC translation for a disk operating system file. The character sequence, CRLF, used as the line delimiter, and a disk operating system EOF (end-of-file) character are inserted at the end of the downloaded file. The language to be used for EBCDIC to ASCII translation is specified by the Language characteristic in the session profile. The **-T** flag is used to translate disk operating system files. **Note:** If neither the **-T**, **-t**, nor the **-J** flag is specified, the file transfer assumes no translation and transfers the information in binary form.
-u	Uploads the file by transferring the file from the local system to the host. If neither this flag nor the **-d** flag is specified, the File Transfer Direction characteristic in the session profile determines the direction of the transfer.
-v	Periodically writes the current status of the file transfer to the screen or to the status file specified by the **-f** flag. The status includes the number of bytes transferred and the elapsed time since the file transfer process began transferring data.
-x *HostLogin*	Uses the login ID specified by the *HostLogin* variable to log in to the host. The user is prompted to enter the password. The *HostLogin* string consists of the host login ID, the AUTOLOG node ID, and other optional AUTOLOG values. The string cannot contain any blanks and must contain the AUTOLOG node ID. Format the AUTOLOG string as: `UserID,AutologNodeID[,Trace,Time . . .]` If the **-x** flag is not specified, the information for the *HostLogin* string is taken from the session profile as follows: • If the host login ID is set in the session profile, you are prompted for the password. The remaining parameters are retrieved from the profile. • If the host login ID is not set in the profile, you are prompted for both the host login string and the password. • Your response to a prompt always overrides a profile parameter. For example, if the AUTOLOG time is set in the profile but you enter a different value at the prompt, the value entered at the prompt is used. If you omit certain parameters from the host login string, they are retrieved from the profile, if defined there. For example, if the you set the AUTOLOG Node ID, AUTOLOG Trace, and AUTOLOG Time parameters in the profile, only the host login ID must be entered at the prompt. The file transfer process logs in to the host and establishes an emulation session using the session profile specified with the **-n** flag. Once the process is successfully logged in, the file transfer begins. The File Transfer Wait Period parameter in the session profile determines how long the login session is maintained. Using this parameter, the host login session is maintained for subsequent file transfers. The need to log in again is eliminated.

Item	Description
-X *CodeSet*	Specifies an alternate code set to use for ASCII-EBCDIC translation. If the **-X** flag is omitted, the code set specified by the system locale is used. The following code sets are supported: **Default** Uses current system ASCII code page. **IBM-932** Uses IBM code page 932 for translation in a DBCS environment. **ISO8859-1** Uses ISO 8859-1 Latin alphabet number 1 code page. **ISO8859-7** Uses ISO 8859-7 Greek alphabet. **ISO8859-9** Uses ISO 8859-9 Turkish alphabet. **IBM-eucJP** Uses IBM Extended UNIX Code for translation in the Japanese Language environment. **IBM-eucKR** Uses IBM Extended UNIX Code for translation in Korean Language environment. **IBM-eucTW** UsesIBM Extended UNIX Code for translation in Traditional Chinese Language environment.

Flags for Host File Characteristics

The following flags specify host file characteristics and can be used only to upload files (with the exception of the **-F** flag, which can be used when downloading from a VSE host):

Item	Description
-B *BlockSize*	Specifies the block size of the host data set. The **-B** flag can only be used in the MVS/TSO environment and only for sequential data sets. The *BlockSize* variable cannot exceed the capacity of a single track. The **-B** flag is ignored if the file is being appended. A block size value of 0 causes an error.
-F	Specifies fixed-length records. This is the default if neither the **-V**, **-t**, **-T**, **-c**, nor **-C** flag is specified. The **-F** flag is ignored if the file is being appended. On a CICS or VSE host, one of the translate flags (**-t** or **-T**) or one of the CRLF flags (**-c** or **-C**) must be specified along with the **-F** flag, since the CICS and VSE host file transfer programs do not support fixed record lengths. The combination of the **-F** flag and the translate flag causes the transfer program to pad the records with blanks to the end of the logical record length. The default is 80. **Note:** Use the **-F** flag when downloading from a VSE host to prevent the deletion of trailing blanks from the translated file.

Item	Description
-L *LoglRecLength*	Specifies the logical record length in bytes of the host file. For new files, the default is 80. For variable-length records, *LoglRecLength* is the maximum size of the record. The **-L** flag is ignored if the file is being appended. A *LoglRecLength* value of 0 causes an error. Because of MVS™ overhead, the actual number of bytes stored in the variable length records on an MVS/TSO host is four bytes less than the value specified by the *LoglRecLength* variable. The CICS and VSE host file transfer programs do not support logical record lengths. For transfers to or from a CICS or VSE host the **-L** flag must be accompanied by the **-F** flag. The combination of the **-F** and **-L** flags causes the transfer program to pad the records with blanks to the end of the logical record length. The default is 80. **Note:** The **-L** flag is required if a record length is greater than the default record length of 80.
-S *NumberUnits* [**,***IncreaseUnits* | **,***IncreaseUnits*,*UnitType* | **,,***UnitType*]	Specifies the amount of space to be allocated for a new sequential data set on TSO. For large MVS files, the maximum block size permissible on the host is used to ensure that the whole disk track is filled. The **-S** flag can be used only with MVS/TSO hosts. The following variables can be used with the **-S** flag. If used, they must be specified in the order given and separated by commas. If a variable preceding another variable is omitted, a comma must be included as a placeholder. A space is required between the **-S** flag and the *NumberUnits* variable. However, no spaces can appear in the variable string. ***NumberUnits*** Specifies the number of units of space to be added initially. A value of 0 or a negative value cannot be specified for the *NumberUnits* variable. ***IncreaseUnits*** Specifies the number of units of space to be added to the data set each time the previously allocated space is filled (optional). ***UnitType*** Defines the unit of space and may be T for tracks, C for cylinders, or a number specifying the average block size (in bytes) of the records written to the data set. If the *UnitType* variable is not specified, the default is the value specified by the **-B** flag. If the **-B** *BlockSize* flag is not specified, the default value is 80. Following are the possible combinations of variables used with the **-S** flag: `-S NumberUnits,IncreaseUnits,UnitType` `-S NumberUnits,IncreaseUnits` `-S NumberUnits` `-S NumberUnits,,UnitType`
-U	Specifies records of undefined length. The **-U** flag can only be used in the MVS/TSO environment. The **-U** flag is ignored if the file is being appended.
-V	Specifies records of variable length. This is the default if the **-F** flag is not specified, and either the **-t**, **-T**, **-c**, or **-C** flag is specified. The **-V** flag is ignored if the file is being appended. The **-V** flag is not supported by the CICS or VSE host file transfer programs, since variable record lengths are the default.

Examples

The following examples assume the session profile for session a is:

```
Session   type         DFT
Communication   device         3270c0
Language         English   (U.S.A.)
Host   type         CMS
File   transfer   direction         up
File   transfer   wait   period         10
File   transfer   recovery   time         30
```

where:

- The host type is VM/CMS.
- The connection is made using the DFT 3270 connection device.
- The file transfer default direction is upload (to use session profile a for downloading files, the user must specify the **-d** flag with the **fxfer** command).
- The file transfer process stays logged in for 10 minutes.
- If a transfer is interrupted, the process attempts recovery for 30 minutes before saving information in the RESTART file for later transfer.
- The translation language is U.S.A. ASCII-EBCDIC.

1. To upload the `samplefile` file (in the current directory) to the host and translate it to EBCDIC using the U.S.A. translation table, enter:

   ```
   fxfer   -n   a   -t   samplefile   "test   file   a"
   ```

   – **-n** instructs the **fxfer** command to use session a to transfer the file.
   – **-t** instructs the command to translate using the new-line character.

   The translated data is placed in the `test file a` on the host. Because the host file name contains spaces, quotation marks around the file name are required.

2. To upload the `file2` file to the VM/CMS host `test file b`, enter:

   ```
   fxfer   -urv   -L   132   -V   -H   CMS   file2   "test   file   b"
   ```

   – **-u** instructs the **fxfer** command to upload the file.
   – **-H** indicates that the host type is a VM/CMS host. If the destination file exists, it is replaced (since the **-r** flag is specified) by the transferred file.
   – **-v** causes **fxfer** to display the number of bytes transferred and elapsed time. The status or diagnostic output is displayed on the terminal.
   – If the host file does not exist, the host file maximum logical record length is set to 132 bytes (**-L** flag).
   – The host file record format is variable (**-V** flag). No translation is performed.

3. To upload, from a subshell of emulator session a, the local system **/etc/motd** file to the CICS motdfile host file with translation and padding of blanks, enter:

   ```
   fxfer   -utFH   CICS   -I   ")This   is   a   comment"   /etc/motd   "motdfile"
   ```

   – **-u** instructs the command to upload the file.
   – **-t** causes translation from ASCII to EBCDIC.
   – **-F** causes the transfer program to pad the uploaded file with blanks to column 80 (the default record length). To change the default column, use the **-L** flag with a different record length (column).
   – **-H** specifies the host as type CICS.
   – **-I** specifies that the *InputField* value be added to the **IND$FILE** command.

In this example, "This is a comment" is a host comment field.

To upload or download files with the **fxfer** command, to or from a TSO environment other than your current environment, you must have authorization for the other environment. You must completely qualify the file (or data set) within single quotes ('), then double quotes (" ").

4. For example, to upload the file newfile to a TSO environment where the complete qualified name is sys4.parmlib.samplefile, enter:

```
fxfer   -urtvH   TSO   'newfile'   "sys4.parmlib.samplefile"
```

   - **-u** instructs the command to upload the file.
   - If the sys4.parmlib.samplefile file exists, it is replaced (**-r** flag) with the translated contents of the newfile file (**-t** flag).
   - **-v** instructs the **fxfer** command to write the file transfer status to the local screen every few seconds.
   - **-H** instructs the **fxfer** command that the host is a MVS/TSO host.

     Note: This example assumes that the **fxfer** command is issued from a subshell of an established session (use the **e789** command to establish a session).

5. To download the file spfuser.test from the MVS/TSO host to the local system, enter:

```
fxfer   -n   a   -d   -r   -H   TSO   spfuser.test   samplefile1
```

   - **-n** instructs the **fxfer** command to use session a to transfer the file. If session a has not already been established, the command attempts an automatic login. Since no host login ID is specified, the **fxfer** command checks the session profile for a login ID. If one is not specified there, the user is prompted for the login ID and password.
   - **-d** overrides the default file transfer direction of upload.
   - If the samplefile1 file already exists, it is replaced (**-r** flag) with the downloaded file from the host.
   - **-H** instructs the **fxfer** command that the host is an MVS/TSO host instead of VM/CMS (the default from the session profile).

   The transferred file is placed in the samplefile1 file on the local system. The file transfer is performed synchronously.

6. To download the VM/CMS host test file a and append it to the local system mydir/samplefile file, using session profile a and automatic login, enter:

```
fxfer   -n   a   -dat   -q   -f   status.out
-x   laura,vm1,trace   "test   file   a"   mydir/samplefile
```

   - **-n** instructs the **fxfer** command to use session profile a to transfer the file.
   - **-x** provides the host login ID. The **fxfer** command first checks to see if session is established on the local system. If so, the command transfers the file over the existing session. If session a is not established, the **fxfer** command performs an automatic login using the host logon ID laura and the AUTOLOG script vm1, and traces the login activity. The user is prompted for the password. The command transfers the file.
   - **-dat** instruct the **fxfer** command to download the file (**-d** flag), translate the data from EBCDIC to ASCII (**-t** flag) using the U.S.A. translation table (defined in the session profile), and append (**-a** flag) the translated file to the mydir/samplefile file on the local system. If the mydir/samplefile file does not already exist, the **fxfer** command ignores the **-a** flag and creates the file.
   - The status or diagnostic output is placed in the status.out file in the current local directory (**-f** flag).
   - **-q** instructs the **fxfer** command to transfer the file asynchronously.

When the user enters the password, the prompt is returned and the file transfer is performed in the background.

To queue another file transfer to be performed by the same file transfer process, enter:

```
fxfer   -n   a   -daq   -f   status.out   "test   file   b"
mydir/samplefile
```

- **-n** instructs the **fxfer** command to use session a to transfer the file. Since session a has been established by the previous command, the **fxfer** command does not need to log in to the host again.
- **-d** instructs the command to download a file from the host.
- **-a** instructs the command to append the `test file b` host file to the `mydir/samplefile` file on the local system.
- **-q** instructs the **fxfer** command to transfer the file asynchronously.

The **fxfer** command continues to send status information to the `status.out` file on the local system (**-f** flag).

Notes:

a. If the text for the **fxfer** command extends beyond the limit of the screen, the text wraps automatically to the next line. Pressing the Enter key to wrap the text causes an error.

b. Attempting to start a synchronous file transfer when there is an asynchronous transfer in the queue causes an error.

c. The user will not be prompted for a login ID or a password as long as the session remains running and the **dfxfer** process remains logged in to the host. The amount of time the process remains logged in is determined by the File Transfer Wait Period in the session profile.

7. To restart an interrupted file transfer from an emulator subshell, enter:

```
fxfer   -R
```

-R instructs the **fxfer** command to use the information saved in one of the RESTART files to execute a file transfer. The RESTART file is the **$HOME/x_fxfer.r** explicit restart file or **$HOME/i_fxfer.r** implicit restart file. If the **-R** flag is specified in conjunction with other file transfer flags, the other flags are ignored. The RESTART file transfer menu is displayed. Using this menu, instruct the **fxfer** command to transfer the interrupted file.

8. To restart the file transfer from the command line instead of from an emulator subshell, enter:

```
fxfer   -R   -n   a
```

The **-n** flag instructs the **fxfer** command to use session a to perform the restarted transfer.

Files

Item	Description
/usr/bin/fxfer	Contains the **fxfer** command.
/usr/bin/dfxfer	Contains the **dfxfer** process.
$HOME/i_fxfer.r	Contains RESTART information for automatic login queues. Temporary file created by the **fxfer** command.
$HOME/x_fxfer.r	Contains RESTART information for manual login queues. Temporary file created by the **fxfer** command.
$HOME/hconerrors	Contains HCON diagnostic output and file transfer status. Temporary file created by any HCON command.
/usr/lib/libfxfer.a	Contains the library for programmatic file transfers.

g

The following AIX commands begin with the letter g.

gated Daemon

Purpose

Provides gateway routing functions for the RIP, RIPng, EGP, BGP, BGP4+, HELLO, IS-IS, ICMP, ICMPv6, and SNMP protocols.

Note: Use SRC commands to control the **gated** daemon from the command line. Use the **rc.tcpip** file to start the daemon with each system startup.

Syntax

/usr/sbin/gated [**-c**] [**-C**] [**-n**] [**-N**] [**-t** *TraceOptions*] [**-f** *ConfigFile*] [*TraceFile*]

Description

The **/usr/sbin/gated** daemon handles multiple routing protocols and replaces **routed** and any routing daemon that speaks the (HELLO) routing protocol. The **/usr/sbin/gated** daemon currently handles the Routing Information Protocol (RIP), Routing Information Protocol Next Generation (RIPng), Exterior Gateway Protocol (EGP), Border Gateway Protocol (BGP) and BGP4+, Defense Communications Network Local-Network Protocol (HELLO), and Open Shortest Path First (OSPF), Intermediate System to Intermediate System (IS-IS), and Internet Control Message Protocol (ICMP)/Router Discovery routing protocols. In addition, the **gated** daemon supports the Simple Network Management Protocol (SNMP). The **gated** process can be configured to perform all of these protocols or any combination of them. The default configuration file for the **gated** daemon is the **/etc/gated.conf** file. The **gated** daemon stores its process ID in the **/etc/gated.pid** file.

Note: Unpredictable results may occur when the **gated** and **routed** daemons are run together on the same host.

If on the command line a trace file is specified, or no trace flags are specified, the **gated** daemon detaches from the terminal and runs in the background. If trace flags are specified without specifying a trace file, **gated** assumes that tracing is desired to **stderr** and remains in the foreground.

Note: IS-IS routing protocol cannot be run on 64-bit kernel.

Signals

The **gated** server performs the following actions when you use the **kill** command to send it signals.

Item	Description
SIGHUP	Re-read configuration. A **SIGHUP** causes gated to reread the configuration file. The **gated** daemon first performs a clean-up of all allocated policy structures. All BGP and EGP peers are flagged for deletion and the configuration file is reparsed. If the reparse is successful, any BGP and EGP peers that are no longer in the configuration are shut down, and new peers are started. The **gated** daemon attempts to determine if changes to existing peers require a shutdown and restart. **Note:** Reconfiguration is disable when OSPF (Open Shortest Path First) is enabled.

Item	Description
SIGINT	Snapshot of current state. The current state of all gated tasks, timers, protocols and tables are written to **/var/tmp/gated_dump**. This is done by forking a subprocess to dump the table information so as not to impact the **gated** daemon's routing functions.
SIGTERM	Graceful shutdown. Upon receiving a **SIGTERM** signal, the **gated** daemon attempts a graceful shutdown. All tasks and protocols are asked to shutdown. Most will terminate immediately, the exception being EGP peers which wait for confirmation. It may be necessary to repeat the **SIGTERM** once or twice if this process takes too long. All protocol routes are removed from the kernel's routing table on receipt of a **SIGTERM**. Interface routes, routes with **RTF_STATIC** set (from the **route** command where supported) and static routes specifying **retain** will remain. To terminate the **gated** daemon with the exterior routes intact, use the **SIGKILL** or **SIGQUIT** signals (which causes a core dump).
SIGUSR1	Toggle tracing. Upon receiving a **SIGUSR1** signal, the **gated** daemon will close the trace file. A subsequent **SIGUSR1** will cause it to be reopened. This will allow the file to be moved regularly. **Note:** It is not possible to use the **SIGUSR1** signal if a trace file has not been specified, or tracing is being performed to **stderr**.
SIGUSR2	Check for interface changes. Upon receiving a **SIGUSR2** signal, the **gated** daemon rescans the kernel interface list looking for changes.

The gated and snmpd Daemons

The **gated** daemon is internally configured to be an SNMP multiplexing (SMUX) protocol peer, or proxy agent, of the **snmpd** daemon. For more information, refer to "SNMP daemon processing" in *Networks and communication management*.

Manipulating the gated Daemon with the System Resource Controller

The **gated** daemon can be controlled by the System Resource Controller (SRC). The **gated** daemon is a member of the SRC **tcpip** system group. This daemon is disabled by default and can be manipulated by the following SRC commands:

Item	Description
startsrc	Starts a subsystem, group of subsystems, or a subserver.
stopsrc	Stops a subsystem, group of subsystems, or a subserver.
refresh	Causes the subsystem or group of subsystems to reread the appropriate configuration file.
lssrc	Gets the status of a subsystem, group of subsystems, or a subserver.

Note: On initial startup from the **startsrc** command, the **gated** daemon does not start responding to other SRC commands until all **gated** initialization is completed. A very large **/etc/gated.conf** file can require a minute or more to parse completely.

Flags

Item	Description
-c	Specifies parsing of the configuration file for syntax errors after which the **gated** daemon exits. If no errors occur, the **gated** daemon puts a dump file into the **/var/tmp/gated_dump** file. The **-c** flag implies the **-tgeneral,kernel,nostamp** flag. If the **-c** flag is specified, the **gated** daemon ignores all **traceoption** and **tracefile** clauses in the configuration file.
-C	Specifies that the configuration file is parsed only for syntax errors. The **gated** daemon exists with a status of **1** if it finds any errors and with a status of **0** if it does not. The **-C** flag implies the **-tnostamp** flag.
-f *ConfigFile*	Specifies an alternate configuration file. By default, the **gated** daemon uses the **/etc/gated.conf** file.
-n	Specifies that the **gated** daemon will not modify the kernel's routing table. This is used for testing **gated** configurations with actual routing data.
-N	Specifies that the **gated** daemon does not daemonize. Normally, if tracing to **stderr** is not specified and the parent process ID is not 1, the **gated** daemon daemonizes. This flag allows the use of a method similar to **/etc/inittab** of invoking the **gated** daemon that does not have a process ID of 1.
-t*TraceOptions*	Specifies which trace options are enabled at system startup. When used without the *TraceOptions* variable, this flag starts the **general** trace options. Separate each trace option from another with a comma. Do not insert a space between the flag and the first trace option. The **-t** flag must be used to trace events that take place before the **/etc/gated.conf** file is parsed, such as determining the interface configuration and reading routes from the kernel. The **gated.conf** file article describes the available trace options.

Examples

1. To start the **gated** daemon, enter a command similar to the following:

   ```
   startsrc -s gated -a "-tall /var/tmp/gated.log"
   ```

   This command starts the **gated** daemon and logs messages. Messages are sent to the **/var/tmp/gated.log** file.
2. To stop the **gated** daemon normally, enter:

   ```
   stopsrc -s gated
   ```

   This command stops the daemon. The **-s** flag specifies that the subsystem that follows is to be stopped.
3. To get short status from the **gated** daemon, enter:

   ```
   lssrc -s gated
   ```

   This command returns the name of the daemon, the process ID of the daemon, and the state of the daemon (active or inactive).

Files

Item	Description
/etc/gated.pid	Contains the **gated** process ID.

Item	Description
/var/tmp/gated_dump	Specifies the memory dump file.
/var/tmp/gated.log	Specifies the log file for error messages.

gdc Command

Purpose

Provides an operational user interface for **gated**.

Syntax

gdc [**-q**] [**-n**] [**-c** *coresize*] [**-f** *filesize*] [**-m** *datasize*] [**-s** *stacksize*] [**-t** *seconds*] *Subcommands*

Description

The **gdc** command provides a user-oriented interface for the operation of the **gated** routing daemon. It provides support for:

- starting and stopping the daemon
- the delivery of signals to manipulate the daemon when it is operating
- the maintenance and syntax checking of configuration files
- for the production and removal of state dumps and core dumps.

The **gdc** command can reliably determine **gated**'s running state and produces a reliable exit status when errors occur, making it advantageous for use in shell scripts which manipulate **gated**. Commands executed using **gdc** and, optionally, error messages produced by the execution of those commands, are logged via the same **syslogd** facility which **gated** itself uses, providing an audit trail of operations performed on the daemon.

Flags

Item	Description
-n	Runs without changing the kernel forwarding table. This is useful for testing, and when operating as a route server which does no forwarding.
-q	Runs quietly. With this flag informational messages which are normally printed to the standard output are suppressed and error messages are logged with **syslogd** instead of being printed to the standard error output. This is convenient when running **gdc** from a shell script.
-t *seconds*	Specifies the time in seconds that **gdc** waits for **gated** to complete certain operations, in particular at termination and startup. By default this value is set to 10 seconds.
-c *coresize*	Sets the maximum size of a core dump a **gated** started with **gdc** produces. This is useful on systems where the default maximum core dump size is too small for **gated** to produce a full core dump on errors.
-f *filesize*	Sets the maximum file size a **gated** started with **gdc** will produce. Useful on systems where the default maximum file dump size is too small for **gated** to produce a full state dump when requested.
-m *datasize*	Sets the maximum size of the data segment of a **gated** started with **gdc**. Useful on systems where the default data segment size is too small for **gated** to run.
-s *stacksize*	Sets the maximum size of stack of a **gated** started with **gdc**. Useful on systems where the default maximum stack size is too small for **gated** to run.

Subcommands

The following subcommands cause signals to be delivered to **gated** for various purpose:

Item	Description
COREDUMP	Sends an abort signal to **gated**, causing it to terminate with a core dump.
dump	Signals **gated** to dump its current state into the file **/var/tmp/gated_dump**.
interface	Signals **gated** to recheck the interface configuration. **gated** normally does this periodically in any event, but the facility can be used to force the daemon to check interface status immediately when changes are known to have occurred.
KILL	Causes **gated** to terminate ungracefully.
reconfig	Signals **gated** to reread its configuration file, reconfiguring its current state as appropriate.
term	Signals **gated** to terminate after shutting down all operating routing protocols gracefully. Executing this command a second time causes **gated** to terminate even if some protocols have not yet fully shut down.
toggletrace	Causes tracing to be suspended, and if **gated** is currently tracing to a file, closes the trace file. If **gated** tracing is current suspended, this subcommand causes the trace file to be reopened and tracing initiated. This is useful for moving trace files.

The following subcommands perform operations related to configuration files:

Item	Description
checkconf	Check **/etc/gated.conf** for syntax errors. This is usefully done after changes to the configuration file but before sending a **reconfig** signal to the currently running **gated**, to ensure that there are no errors in the configuration which would cause the running **gated** to terminate on reconfiguration. When this command is used, **gdc** issues an informational message indicating whether there were parse errors or not, and if so saves the error output in a file for inspection.
checknew	Like **checkconf** except that the **new** configuration file, **/etc/gated.conf+**, is checked instead.
newconf	Move the **/etc/gated.conf+** file into place as **/etc/gated.conf**, retaining the older versions of the file as described above. **gdc** will decline to do anything when given this command if the **new** configuration file doesn't exist or otherwise looks suspect.
backout	Rotate the configuration files in the **newer** direction, in effect moving the **old** configuration file to **/etc/gated.conf**. The command will decline to perform the operation if **/etc/gated.conf-** doesn't exist or is zero length, or if the operation would delete an existing, non-zero length **/etc/gated.conf+** file.
BACKOUT	Perform a **backout** operation even if **/etc/gated.conf+** exists and is of non-zero length.
modeconf	Set all configuration files to mode 664, owner root, group system.
createconf	If **/etc/gated.conf+** does not exist, create a zero length file with the file mode set to 664, owner root, group system.

The following subcommands provide support for starting and stopping **gated**, and for determining its running state:

Item	Description
running	Determine if **gated** is currently running. This is done by checking to see if **gated** has a lock on the file containing its pid, if the pid in the file is sensible and if there is a running process with that pid. Exits with zero status if **gated** is running, non-zero otherwise.
start	Start **gated**. The command returns an error if **gated** is already running. Otherwise it executes the **gated** binary and waits for up to the delay interval (10 seconds by default, as set with the **-t** option otherwise) until the newly started process obtains a lock on the pid file. A non-zero exit status is returned if an error is detected while executing the binary, or if a lock is not obtained on the pid file within the specified wait time.
stop	Stop **gated**, gracefully if possible, ungracefully if not. The command returns an error (with non-zero exit status) if **gated** is not currently running. Otherwise it sends a terminate signal to **gated** and waits for up to the delay interval (10 seconds by default, as specified with the **-t** option otherwise) for the process to exit. Should **gated** fail to exit within the delay interval it is then signaled again with a second terminate signal. Should it fail to exit by the end of the second delay interval it is signaled for a third time with a kill signal. This should force immediate termination unless something is very broken. The command terminates with zero exit status when it detects that **gated** has terminated, non-zero otherwise.
restart	If **gated** is running it is terminated via the same procedure as is used for the **stop** command above. When the previous **gated** terminates, or if it was not running prior to command execution, a new **gated** process is executed using the procedures described for the **start** command above. A non-zero exit status is returned if any step in this procedure appears to have failed.

The following subcommands allow the removal of files created by the execution of some of the commands above:

Item	Description
rmcore	Removes any existing **gated** core dump file.
rmdump	Removes any existing **gated** state dump file.
rmparse	Removes the parse error file generated when a **checkconf** or **checknew** command is executed and syntax errors are encountered in the configuration file being checked.

By default **gated** obtains its configuration from a file normally named **/etc/gated.conf**. The **gdc** program also maintains several other versions of the configuration file, in particular named:

Item	Description
/etc/gated.conf+	The new configuration file. When **gdc** is requested to install a new configuration file, this file is renamed **/etc/gated.conf**.
/etc/gated.conf-	The old configuration file. When **gdc** is requested to install a new configuration file, the previous **/etc/gated.conf** is renamed to this name.
/etc/gated.conf—	The really old configuration file. **gdc** retains the previous **old** configuration file under this name.

Files

Item	Description
/usr/sbin/gated	The **gated** binary.

Item	Description
/etc/gated.conf	Current **gated** configuration file.
/etc/gated.conf+	Newer configuration file.
/etc/gated.conf-	Older configuration file
/etc/gated.conf—	Much older configuration file
/etc/gated.pid	Where **gated** stores its pid.
/var/tmp/gated_dump	**gated**'s state dump file
/var/tmp/gated.log	Where config file parse errors go.

gencat Command

Purpose

Creates and modifies a message catalog.

Syntax

gencat *CatalogFile SourceFile ...*

Description

The **gencat** command creates a message catalog file (usually ***.cat**) from message text source files (usually ***.msg**). The **gencat** command merges the message text source files, specified by the *SourceFile* parameter, into a formatted message catalog, specified by the *CatalogFile* parameter. After entering messages into a source file, use the **gencat** command to process the source file to create a message catalog. The **gencat** command creates a catalog file if one does not already exist. If the catalog file does exist, the **gencat** command includes the new messages in the catalog file.

You can specify any number of message text source files. The **gencat** command processes multiple source files, one after another, in the sequence specified. Each successive source file modifies the catalog. If the set and message numbers collide, the new message text defined in the *SourceFile* parameter replaces the old message text currently contained in the *CatalogFile* parameter. Message numbers must be in the range of 1 through **NL_MSGMAX**. The set number must be in the range of 1 through **NL_SETMAX**.

The **gencat** command does not accept symbolic message identifiers. You must run the **mkcatdefs** command if you want to use symbolic message identifiers.

Note: Standard output is used if the **-** (dash) character is specified as the *CatalogFile* parameter. Standard input is used if the **-** (dash) character is specified as the *SourceFile* parameter.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

To generate a `test.cat` catalog from the source file `test.msg`, enter:

```
gencat test.cat test.msg
```

The `test.msg` file does not contain symbolic identifiers.

Files

Item	Description
/usr/bin/gencat	Contains the **gencat** command.

gencopy Command

Purpose

Allows software products of various packaging formats (installp, RPM, ISMP) to be copied.

Syntax

To Copy Software from Media to Target Location

gencopy **-d** *Media* [**-t** *TargetLocation*] [**-D**] [**-b** *bffcreateFlags*] [**-U**] [**-X**] **-f** *File* | *CopyList...* | all

To List Software Products and Packages on Media

gencopy **-L** **-d** *Media* [**-D**]

Description

The **gencopy** command is the wrapper to the **bffcreate** command. It determines what images must be copied and calls the appropriate command. For RPM, ISMP, or other types of images where the list of required files is unknown, all the files in the subdirectory are copied to the target location.

Flags

Item	Description
-b *bffcreateFlags*	Specifies the following flags that are valid: **l**, **q**, **v**, **w**, and **S**.
-d *Media*	Specifies the device or directory where the install images exist. Media can be a device (**/dev/cd0**, **/dev/rmt0**) or directory.
-D	Specifies debug mode. This flag is for debugging this script. It produces a large quantity of output and should not be used for normal operations.
-f *File*	Specifies a file that contains a list of images to copy to the target location. The `installp`, RPM, and ISMP images should be prefixed with `I:`, `R:`, and `J:`, respectively. Prefix the interim fix packages with an `E:`.
-L	Lists the install packages on the media. This listing is colon separated and contains the following information: file_name:package_name:fileset:V.R.M.F:type:platform:Description bos.sysmgt:bos.sysmgt:bos.sysmgt.nim.client:4.3.4.0:I:R:Network Install Manager - Client Tools bos.sysmgt:bos.sysmgt:bos.sysmgt.smit:4.3.4.0:I:R:System Management Interface Tool (SMIT)
-t *TargetLocation*	Specifies the directory where the installation image files are stored. If the **-t** flag is not specified, the files are saved in the **/usr/sys/inst.images** directory.

Item	Description
-U	Upgrades the directory structure of the destination repository to the current standard, if necessary. The current standard requires images to be organized into subdirectories according to package type and architecture. For example, installp images reside in the ***SaveDir*/installp/ppc** directory. When copying from a source containing this structure, the destination is required to conform. Specifying the **-U** flag permits the **gencopy** command to create the appropriate subdirectory structure in your repository and move any existing images into the appropriate locations. Unless invalid manual copying is performed thereafter, this flag should only need to be used once.
-X	Extends the file system automatically if space is needed.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Example

To copy all of the image from a CD (**/dev/cd0**) to an **LPP_SOURCE** (**/export/lpp_source/500**) use, type:

```
gencopy -d  /dev/cd0 -t  /export/lpp_source/500 all
```

Files

Item	Description
/usr/sbin/gencopy	
/usr/sys/inst.data/sys_bundles	
/usr/sys/inst.data/user_bundles	

gencore Command

Purpose

Generates a core file for a running process.

Syntax

gencore *ProcessID FileName*

Description

The **gencore** command creates a core file of the process specified by the process ID *ProcessID* without terminating the process. The created core file contains the memory image of the process, which can be used with the **dbx** command for debugging purposes. The core file generated will be named as specified by *FileName* parameter.

The `gencore` command does not create the core file in the location set by the `chcore` or `syscorepath` commands. The core file is placed in the path specified by the *FileName* parameter. If *FileName* specifies only the name of the file, the core file is placed in the current working directory.

Parameters

Item	Description
FileName	Specifies the file name of the core file the **gencore** command creates.
ProcessID	Specifies the process ID of the process from which **gencore** will create a core file.

Exit Status

0
The core file was created successfully.

>0
An Error occurred. A partial core file may be created.

Examples

1. To generate a core file named "core.1095" for the process with process ID 1095, enter:

```
gencore 1095 core.1095
```

   The creates the core file without terminating the process.

Files

Item	Description
/usr/bin/gencore	Contains the **gencore** command.

genfilt Command

Purpose

Adds a filter rule.

Syntax

genfilt -v 4|**6** [**-n** *fid*] [**-a** D|P|I|L|E|H|S] **-s** *s_addr* **-m** *s_mask* **[-d** *d_addr*] [**-M** *d_mask*] [**-g Y**|**N**] [**-c** *protocol*] [**-o** *s_opr*] [**-p** *s_port*] [**-O** *d_opr*] [**-P** *d_port*] [**-r R**|**L**|**B**] [**-w I**|**O**|**B**] [**-l Y**|**N**] [**-f Y**|**N**|**O**|**H**] [**-t** *tid*] [**-i** *interface*] [**-D** *description*] [-e *expiration_time*] [-x *quoted_pattern*] [-X *pattern_filename*] [-C *antivirus_filename*]

Description

Use the **genfilt** command to add a filter rule to the filter rule table. The filter rules generated by this command are called manual filter rules. IPsec filter rules can be configured by using the **genfilt** command or the IPsec smit (IP version 4 or IP version 6).

Flags

Item	Description
-a *Action*	The following *Action* values are allowed: • D (Deny) blocks traffic. • P (Permit) allows traffic. • I makes this an IF filter rule. • L makes this an ELSE filter rule. • E makes this an ENDIF filter rule. • H makes this a SHUN_HOST filter rule. • S makes this a SHUN_PORT filter rule. All IF rules most be close with an associated ENDIF rule. These conditional rules can be nested, but correct nesting and scope must be adhered to or the rules will not load correctly with the `mkfilt` command.
-C *antivirus_filename*	Specifies the antivirus file name. The -C flag understands some versions of ClamAV Virus Database (http://www.clamav.net).
-c *protocol*	The valid values are: **udp**, **icmp**, **icmpv6**, **tcp**, **tcp/ack**, **ospf**, **ipip**, **esp**, **ah**, and **all**. Value **all** indicates that the filter rule will apply to all the protocols. The protocol can also be specified numerically (between 1 and 252). The default value is **all**. Value **tcp/ack** implies checking for TCP packets with the ACK flag set.
-D *description*	A short description text for the filter rule. This is an optional flag for static filter rules, it's not applicable to dynamic filter rules.
-d *d_addr*	Specifies the destination address. It can be an IP address or a host name. If a host name is specified, the first IP address returned by the name server for that host will be used. This value along with the destination subnet mask will be compared against the destination address of the IP packets.
-e *expiration_time*	Specifies the expiration time. The expiration time is the amount of time the rule should remain active in seconds. The *expiration_time* does not remove the filter rule from the database. The *expiration_time* relates to the amount of time the filter rule is active while processing network traffic. If no *expiration_time* is specified, then the live time of the filter rule is infinite. If the *expiration_time* is specified in conjunction with a SHUN_PORT (-a S) or SHUN_HOST (-a H) filter rule, then this is the amount of time the remote port or remote host is denied or shunned once the filter rule parameters are met. If this *expiration_time* is specified independent of a shun rule, then this is the amount of time the filter rule will remain active once the filter rules are loaded into the kernel and start processing network traffic.
-f	Specifies the fragmentation control. This flag specifies that this rule will apply to either all packets (**Y**), fragment headers and unfragmented packets only (**H**), fragments and fragment headers only (**O**), or unfragmented packets only (**N**). The default value is **Y**.
-g	Apply to source routing? Must be specified as **Y** (yes) or **N** (No). If **Y** is specified, this filter rule can apply to IP packets that use source routing. The default value is yes (**Y**). This field only applies to permit rules.
-i *interface*	Specifies the name of IP interface(s) to which the filter rule applies. The examples of the name are: **all**, **tr0**, **en0**, **lo0**, and **pp0**. The default value is **all**.

Item	Description
-l	Specifies the log control. Must be specified as **Y**(yes) or **N** (No). If specified as **Y**, packets that match this filter rule will be included in the filter log. The default value is **N** (no).
-M	Specifies the destination subnet mask. This is used in the comparison of the IP packet's destination address with the destination address of the filter rule.
-m	Specifies the source subnet mask. This is used in the comparison of the IP packet's source address with the source address of the filter rule.
-n	Specifies the filter rule ID. The new rule will be added BEFORE the filter rule you specify. For IP version 4, the ID must be greater than 1 because the first filter rule is a system generated rule and cannot be moved. If this flag is not used, the new rule will be added to the end of the filter rule table.
-O	Specifies the destination port or ICMP code operation. This is the operation that will be used in the comparison between the destination port/ICMP code of the packet with the destination port or ICMP code (**-P** flag). The valid values are: **lt**, **le**, **gt**, **ge**, **eq**, **neq**, and **any**. The default value is **any**. This value must be **any** when the **-c** flag is **ospf**.
-o	Specifies the source port or ICMP type operation. This is the operation that will be used in the comparison between the source port/ICMP type of the packet with the source port or ICMP type(**-p** flag) specified in this filter rule. The valid values are: **lt**, **le**, **gt**, **ge**, **eq**, **neq**, and **any**. The default value is **any**. This value must be **any** when the **-c** flag is **ospf**.
-p	Specifies the source port or ICMP type. This is the value/type that will be compared to the source port (or ICMP type) of the IP packet.
-P	Specifies the destination port/ICMP code. This is the value/code that will be compared to the destination port (or ICMP code) of the IP packet.
-r	Routing. This specifies whether the rule will apply to forwarded packets (**R**), packets destined or originated from the local host (**L**), or both (**B**). The default value is **B**.
-s *s_addr*	Specifies the source address. It can be an IP address or a host name. If a host name is specified, the first IP address returned by the name server for that host will be used. This value along with the source subnet mask will be compared against the source address of the IP packets.
-t	Specifies the ID of the tunnel related to this filter rule. All the packets that match this filter rule must go through the specified tunnel. If this flag is not specified, this rule will only apply to non-tunnel traffic.
-v	Specifies the IP version of the filter rule. Valid values are **4** and **6**.
-w *Direction*	Specifies whether the rule applys to incoming packets (I), outgoing packets (O), or both (B). The default value is B. It is not valid to use the (O) outgoing direction with the `-x`, `-X`, or `-C` pattern options. It is valid to specify the (B) both directions with the pattern options, but only the incoming packets are checked against the packets.
`-X` *pattern_filename*	Specifies the pattern file name. If more than one patterns are associated with this filter rule, then a pattern file name must be used. The pattern file name must be in the format of one pattern per line. A pattern is an unquoted character string. This file is read once when the filter rules are activated. For more information, see the `mkfilt` command.

Item	Description
-x *pattern*	Specifies the quoted character string or pattern. This string specified is interpreted as an ASCII string unless it is preceded by a `0x`, in which case it is interpreted as a hexadecimal string. The -x *pattern* is compared against network traffic.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

geninstall Command

Purpose

A generic installer that installs software products of various packaging formats. For example, installp, RPM, SI, and ISMP.

Syntax

geninstall -d *Media* [**-I** *installpFlags*] [**-E** | **-T**] [**-t** *ResponseFileLocation*] [**-e** *LogFile*] [**-p**] [**-F**] [**-Y**] [**-Z**] [-D] { **-f** *File* | *Install_List*] | all}

OR

geninstall -k [**-d** *Media*] [**-p**] [**-Y**] [**-f** *File* | *install_list* | `all` | `update_all`]

OR

geninstall -u [**-e** *LogFile*] [**-E** | **-T**] [**-t** *ResponseFileLocation*] [-D] {**-f** *File* | *Uninstall_List*...}

OR

geninstall -L -d *Media* [**-e** *LogFile*] [-D]

Description

Accepts all current **installp** flags and passes them on to **installp**. Some flags (for example, **-L**) are overloaded to mean list all products on the media. Flags that don't make sense for ISMP packaged products are ignored. This allows programs (like NIM) to continue to always send in **installp** flags to **geninstall**, but only the flags that make sense are used.

The `geninstall` command provides an easy way to see what modifications have been made to the configuration files listed in `/etc/check_config.files`. When these files have been changed during a `geninstall` installation or update operation, the differences between the old and new files will be recorded in the `/var/adm/ras/config.diff`. If `/etc/check_config.files` requests that the old file be saved, the old file can be found in the `/var/adm/config` directory.

The `/etc/check_config.files` file can be edited and can be used to specify whether old configuration files that have been changed should be saved (indicated by s) or deleted (indicated by d), and has the following format:

```
d /etc/inittab
```

A summary of the **geninstall** command's install activity is kept at **/var/adm/sw/geninstall.summary**. This file contains colon-separated lists of filesets installed by **installp** and components installed by ISMP. This is used mainly to provide summary information for silent installs.

Note: Refer to the **README.ISMP** file in the **/usr/lpp/bos** directory to learn more about ISMP-packaged installations and using response files. Also, the **geninstall** command is capable of installing interim fix files containing concurrent updates. Any interim fixes containing concurrent updates must be placed inside a subdirectory called **cupdates** in the directory containing installation images, and the **geninstall** command will install them appropriately.

Flags

Item	Description
-d *Device or Directory*	Specifies the device or directory that contains the images to install. The **geninstall** command searches for the images in the following paths: • /*mount_point*/installp/ppc (installp package) • /*mount_point*/RPMS/ppc (RPM package) • /*mount_point*/emgr/ppc (Interim fix packages for AIX) • /*mount_point*/ISMP/ppc (ISMP packages for AIX) If the paths do not exist, the **geninstall** command searches for the images in the base directory of the specific device. If the image names are not preceded by a prefix that indicates the image type, the **geninstall** command identifies a type for the image. If the paths exist and the image is not found in any path, and if the image does not contain any prefix, the image is treated as an RPM-formatted image.
-D	Specifies debug mode. This flag is for debugging this script. It produces a large quantity of output and should not be used for normal operations.
-e *LogFile*	Enables event logging. The **-e** flag enables the user to append certain parts of the **geninstall** command output to the file specified by the *LogFile* variable. The *LogFile* variable must specify an existing, writable file, and the file system in which the file resides must have enough space to store the log. The log file does not wrap.
-E	Creates an ISMP response file recording in the default location, which is the directory containing the product installation files. This option requires running the ISMP installation or uninstallation interactively and completely. The resulting response file will be used to provide the same options on future installations or uninstallations of the same product. Creation of the response file recording will also result in installation or uninstallation of the product.
-f *File*	Specifies a file that contains a list of images to copy to the target location. The installp, RPM, and ISMP images should be prefixed with I:, R:, and J:, respectively. Prefix the interim fix packages with an E:.
-F	Allows the user to reinstall a package that is already installed, or to install a package that is older than the currently installed version.
-I *installpFlags*	Specifies the **installp** flags to use when calling the **installp** command. The flags that are used during an install operation for **installp** are the **a**, **b**, **c**, **D**, **e**, **E**, **F**, **g**, **I**, **J**, **M**, **N**, **O**, **p**, **Q**, **q**, **S**, **t**, **v**, **V**, **w**, and **X** flags. The **installp** flags that are not used during install are the **C**, **i**, **r** , **z**, **A**, and **l** flags. The **installp** command should be called directly to perform these functions. The **-u**, **-d**, **-L**, and **-f** flags should be given outside the **-I** flag.

Item	Description
-k	You can use this flag in IBM AIX 7.2 Technology Level 1, or later, to use the AIX Live Update operation to upgrade Service Packs (SPs), Technology levels (TLs), group or individual updates, and interim fixes that are marked as LU CAPABLE. To determine if an interim fix is LU CAPABLE, you can perform a preview installation. Before you begin the Live Update operation, you must commit any existing updates on the system. The Live Update operation always commits all updates that are applied during the process, expands any necessary file systems, and installs any requisite software. All other installation processes are prevented from starting during the Live Update operation. **Note:** If your Live Update operation includes the installation of updates, you must take a viable system backup before proceeding with the Live Update operation. The Live Update operation will not create a backup image. The Live Update operation fails if you are performing the following tasks in your environment: • Installing the interim fix in a special environment such as a workload partition (wpar), multibos, or alternate disk environment. • Installing an operating system. • The logical volume names for the required operating system logical volumes (/, /var, /opt, /usr, /etc) and the boot logical volume are not used as the default logical volume names. The Live Update operation requires additional input that is specified in the /var/adm/ras/liveupdate/lvupdate.data file. For more information about this file, see the /var/adm/ras/liveupdate/lvupdate.template. If the updates are successfully applied and committed and if the Live Update process fails, you can rerun the Live Update process by running the **geninstall** command with only the **-k** flag. In this scenario, you do not need to include the device and software in the command. In AIX 7200-01, or later, you can apply and commit any updates or interim fix by using SMIT or any method that you prefer and perform the Live Update operation without using the **-d** flag so that you do not have to restart the system. The **geninstall -k** operation does not update RPM packages. RPM packages should be updated before performing an LKU operation. The all option installs all the software that is available in the device or directory specified by the **-d** flag. This process installs all the software in the software source specified by the **-d** flag even if the software was not previously installed on the system. The update_all option installs only a higher version of the specified software that is already installed on the system. The update_all option installs new software only if the newer versions of the existing software have requisites to the new software. **Note:** The bos.liveupdate.rte fileset must be installed to perform the Live Update operation.
-L	Lists the contents of the media. The output format is the same as the **installp -Lc** format, with additional fields at the end for ISMP and RPM formatted products.

Item	Description
-p	Performs a preview of an action by running all preinstallation checks for the specified action.
-t *ResponseFileLocation*	Allows specifying an alternate location for response files or response file templates. The default location is the directory containing the product installation files. This flag can be used to create a response file recording or template in a different location. The *ResponseFileLocation* can either be a file or directory name. If the *ResponseFileLocation* is a directory, it must already exist. If the *ResponseFileLocation* is not an existing directory, it will be assumed that a file name is specified.
-T	Creates an ISMP response file template in the default location, which is the directory containing the product installation files. The resulting template can be used to create a response file for future installations or uninstallations of the same product with the desired options. Creation of the response file template will not result in installation or uninstallation of the product.
-u	Performs an uninstall of the specified software. For ISMP products, the uninstaller listed in the vendor database is called, prefixed by a "J:".
-Y	Agrees to required software license agreements for software to be installed. This flag is also accepted as an **installp** flag with the **-I** option.
-Z	Tells **geninstall** to invoke the installation in silent mode.

Examples

1. To install all the products on a CD media that is in the drive `cd0`, type:

   ```
   geninstall -d /dev/cd0 all
   ```

   If ISMP images are present on the media, a graphical interface is presented. Any **installp**, SI, or RPM images are installed without prompting, unless the **installp** images are spread out over multiple CDs.
2. To install an interim fix, named `IV12345.160101.epkg.Z`, that is located in the `/images/emgr/ppc` directory, enter the following command:

   ```
   geninstall -d /images IV12345.160101.epkg.Z
   ```

   Note: If the `/images/emgr/ppc` directory exists, but the package is in the `/images` directory (`/images/IV12345.160101.epkg.Z`), the **geninstall** command does not consider the package as an interim fix, and tries to install it as an RPM-formatted image. Fore more information, see the **-d** flag.

Files

- `/usr/sbin/gencopy`
- `/usr/sys/inst.data/sys_bundles`
- `/usr/sys/inst.data/user_bundles`

genkex Command

Purpose

The **genkex** command extracts the list of kernel extensions currently loaded onto the system and displays the address, size, and path name for each kernel extension in the list.

Syntax

genkex [-**dh**]

Description

For kernel extensions loaded onto the system, the kernel maintains a linked list consisting of data structures called loader entries. A loader entry contains the name of the extension, its starting address, and its size. This information is gathered and reported by the **genkex** command.

Flags

Item	Description
-d	Shows the address and size of the Data section, in addition to the address and size of the Text section.
-h	Displays usage statement.

Examples

To generate the list of loaded kernel extensions, enter:

```
genkex
```

genkld Command

Purpose

The **genkld** command extracts the list of shared objects currently loaded onto the system and displays the address, size, and path name for each object on the list.

Syntax

genkld [-**dh**]

Description

For shared objects loaded onto the system, the kernel maintains a linked list consisting of data structures called loader entries. A loader entry contains the name of the object, its starting address, and its size. This information is gathered and reported by the **genkld** command.

Flags

Item	Description
-d	Shows the address and size of the Data section, in addition to the address and size of the Text section.
-h	Displays usage statement.

Examples

To obtain a list of loaded shared objects, enter:

```
genkld
```

genld Command

Purpose

The **genld** command collects the list of all processes currently running on the system, and optionally reports the list of loaded objects corresponding to each process.

Syntax

genld [**-h** | **-l** [**-d**]] [-a *Area*] [**-u**]

Description

For each process currently running, the **genld** command prints a report consisting of the process ID and name, optionally followed by the list of objects loaded for that process. The object's address and path name are displayed. Members of libraries are shown between brackets. For example, `/usr/lib/libc.a[shr.o]` means `shr.o` is a loaded member of the **libc.a** library.

You can filter the output of the **genld** command by using the **-u** flag to display processes that have old versions of loaded objects. An object is considered as an old object if the object image is different from the image that is currently installed on the file system. The **-u** flag is used after applying an update to list the processes that require a restart operation to use the new binaries and libraries.

Notes:

- Unprivileged users can see loaded objects only for their processes.
- If the full path name to a loaded object cannot be determined, the **genld** command might not report updates to this object if it is located on a file system other than journaled file system (JFS2). The object might also be reported as `updated` if the object is replaced by an identical copy.

Flags

Item	Description
-a *Area*	Lists only processes using the shared library area specified by the *Area* parameter.
-d	Shows the address and size of the Data section, in addition to the address and size of the Text section. This option has no effect without the **-l** flag.
-h	Displays the usage statement.
-l	Reports the lists of loaded objects for each process running on the system.
-u	Lists only processes that have old versions of loaded objects.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **`lssecattr`** command or the **`getcmdattr`** subcommand.

Examples

- To obtain the list of loaded objects for each running process, enter the following command:

```
genld -l
```

- To obtain the list of processes that have old versions of loaded objects, enter the following command:

```
genld -u
```

- To obtain the list of processes that have an old version of the **libcrypt.a** library loaded, enter the following command:

```
genld -lu | grep -p libcrypt.a
```

gennames Command

Purpose

Gathers all the information necessary to run the **filemon** and **netpmon** commands in off-line mode.

Syntax

gennames[**-f**]

Description

The **gennames** command gathers name to address mapping information necessary for the **filemon** and **netpmon** commands to work in off-line mode. The information gathered includes:

- the list of all the loaded kernel extension, similar to what the **genkex** command reports,
- the list of all the loaded shared libraries, similar to what the **genkld** command reports
- the list of all the loaded processes, similar to what the **genld** command reports
- for **/unix** and all kernel extensions and libraries, the output of the **stripnm -z** command is collected

Flags

Item	Description
-f	Collects the device information for physical and logical volumes. It also prints out the virtual file system information used by offline **filemon**.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

To collect information needed for the **filemon** command in off-line mode, type:

```
gennames -f > gen.out
```

gensyms Command

Purpose

Gathers all the necessary information to run the **curt**, **splat**, and **tprof** commands in offline mode.

Syntax

gensyms [**-o**] [**-f**] [**-F**] [**-h**] [**-s**] [**-g**] [**I**] [**-N**] [**-k** *kernel*] [**-i** *file*] [**-b** *binary*[,*binary*[,...]]] [**-P** *pid*[,*pid*[,...]]] [**-S** *path*]

Description

The **gensyms** command gathers name to address mapping information necessary for the **curt**, **splat**, and **tprof** commands to work in offline mode. The information that is gathered includes the following items:

- The list of all the loaded kernel extension.
- The list of all the loaded shared libraries.
- The list of all the loaded processes.
- For **/unix**, all kernel extensions, libraries, and all object files corresponding to processes, the output of the **stripnm** command is collected.

Flags

Item	Description
-b *binary*	Specifies an optional list of binaries for which to find symbols.
-f	Suppresses printing of source file names.
-F	Collects the device information for physical and logical volumes.
-g	Decodes symbol names.
-h	Prints help message.
-i *file*	Reads symbols from specified file.
-I	Prints binary instructions of symbols.
-k *kernel*	Specifies the name of the kernel image (default **/unix**).
-N	Prints the source line number of symbols.
-o	Prints offset instead of addresses
-P *pid*[,*pid*[,...]]	Prints the symbols of dependent modules that are loaded by the specified processes. This flag is optional.
-s	Finds symbols only for files specified by the **-k** and **-b** flags.
-S *path*	Specifies the search path list; it is used to find binaries.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To collect information that is required for the **tprof** command in offline mode with the profiling of user program test, enter the following command:

   ```
   gensyms > test.syms
   ```

2. To collect information about the specified process ID and its dependent processes, enter the following command:

   ```
   gensyms -P pid > test.syms
   ```

gentun Command

Purpose

Creates a tunnel definition in the tunnel database.

Syntax

gentun -s *src_host_IP_address* **-d** *dst_host_IP_address* **-v 4**|**6** [**-t** *tun_type*] [**-m** *pkt_mode*] [**-t** *IBM*] [**-t** *manual*] [**-m** *tunnel*] [**-m** *transport*] [**-f** *fw_address*] [**-x** dst_mask]] [**-e** [*src_esp_algo*]] [**-a** [*src_ah_algo*]] [**-p** *src_policy*] [**-A** [*dst_ah_algo]*] [**-P** *dst_policy*] [**-k** *src_esp_key*] [**-h** *src_ah_key*] [**-K** *dst_esp_key*] [**-H** *dst_ah_key*] [**-n** *src_esp_spi*] [**-u** *src_ah_spi*] [**-N** *dst_esp_spi*] [**-U** *dst_ah_spi*] [**-b** *src_enc_mac_algo*] [**-c** *src_enc_mac_key*] [**-B** *dst_enc_mac_algo*] [**-C** *dst_enc_mac_key*] [**-g**] [**-z**] [**-E**]

Description

The **gentun** command creates a definition of a tunnel between a local host and a tunnel partner host. The associated auto-generated filter rules for the tunnel can be optionally generated by this command.

Flags

Item	Description
-a	Authentication algorithm, used by source for IP packet authentication. The valid values for **-a** depend on which authentication algorithms have been installed on the host. The list of all the authentication algorithms can be displayed by issuing the **ipsecstat -A** command. The default value is HMAC_MD5 for **manual** tunnels.
-A	(**manual** tunnel only) Authentication algorithm, used by destination for IP packet authentication. The valid values for **-A** depend on which authentication algorithms have been installed on the host. The list of all the authentication algorithms can be displayed by issuing the **ipsecstat -A** command. If this flag is not used, the value used by the **-a** flag is used.
-b	(**manual** tunnel only) Source ESP Authentication Algorithm (New header format only). The valid values for **-b** depend on which authentication algorithms have been installed on the host. The list of all the authentication algorithms can be displayed by issuing the **ipsecstat -A** command.
-B	(**manual** tunnel only) Destination ESP Authentication Algorithm (New header format only). The valid values for **-B** depend on which authentication algorithms have been installed on the host. The list of all the authentication algorithms can be displayed by issuing the **ipsecstat -A** command. If this flag is not used, it is set to the same value as the **-b** flag.
-c	(**manual** tunnel only) Source ESP Authentication Key (New header format only). It must be a hexdecimal string started with "0x". If this flag is not used, the system will generate one for you.
-C	(**manual** tunnel only) Destination ESP Authentication Key (New header format only). It must be a hexdecimal string started with "0x". If this flag is not used, it is set to the same value as the **-c** flag.
-d	Destination Host IP address. In host-host case, this is the IP address of the destination host interface to be used by the tunnel. In host-firewall-host case, this is the IP address of the destination host behind the firewall. A host name is also valid and the first IP address returned by name server for the host name will be used.
-e	Encryption algorithm, used by source for IP packet encryption. The valid values for **-e** depend on which encryption algorithms have been installed on the host. The list of all the encryption algorithms can be displayed by issuing the **ipsecstat -E** command.

Item	Description
-E	(**manual** tunnel only) Encryption algorithm, used by destination for IP packet encryption. The valid values for **-E** depend on which encryption algorithms have been installed on the host. The list of all the encryption algorithms can be displayed by issuing the **ipsecstat -E** command. If this flag is not used, the value used by the **-e** flag is used.
-f	IP address of the firewall that is between the source and destination hosts. A tunnel will be established between this host and the firewall. Therefore the corresponding tunnel definition must be made on the firewall host. A host name may also be used for this flag and the first IP address returned by the name server for that host name will be used.
-g	System auto-generated filter rule flag. If this flag is not used, the command will generate two filter rules for the tunnel automatically. The auto-generated filter rules will allow IP traffic between the two end points of the tunnel to go through the tunnel. If the **-g** flag is specified, the command will only create the tunnel definition, and the user will have to add user defined filter rules to let the tunnel work.
-h	This is the AH Key String for a **manual** tunnel. The input must be a hexdecimal string started with "0x". If this flag is not used, the system will generate a key using a random number generator.
-H	(**manual** tunnel only) The Key String for destination AH. The input must be a hexdecimal string started with "0x". If this flag is not used, the system will generate a key using a random number generator.
-k	This is the ESP Key String for a **manual** tunnel. It is used by the source to create the tunnel. The input must be a hexdecimal string started with "0x". If this flag is not used, the system will generate a key using a random number generator.
-K	(**manual** tunnel only) The Key String for destination ESP. The input must be a hexdecimal string started with "0x". If this flag is not used, the system will generate a key using a random number generator.
-l	Key Lifetime, specified in minutes. For **manual** tunnels, this value indicates the time of operability before the tunnel expires. The valid values for **manual** tunnels are 0 - 44640. Value 0 indicates that the **manual** tunnel will never expire. The default value for **manual** tunnels is 480.
-m	Secure Packet Mode. This value must be specified as **tunnel** or **transport**. The default value is **tunnel**. Tunnel mode will encapsulate the entire IP packet, while the transport mode only encapsulates the data portion of the IP packet. When generating a host-firewall-host tunnel (for host behind a firewall), the value of **tunnel** must be used for this flag. The -m flag is forced to use default value (**tunnel**) if the **-f** flag is specified.
-n	(**manual** tunnel only) Security Parameter Index for source ESP. This is a numeric value that, along with the destination IP address, identifies which security association to use for packets using ESP. If this flag is not used, the system will generate an SPI for you.
-N	(**manual** tunnel only) Security Parameter Index for the destination ESP. It must be entered for a **manual** tunnel if the policy specified in the **-P** flag includes ESP. This flag does not apply to **IBM** tunnels.
-p	Source policy, identifies how the IP packet authentication and/or encryption is to be used by this host. If specified as **ea**, the IP packet gets encrypted before authentication. If specified as **ae**, it gets encrypted after authentication, whereas specifying **e** alone or **a** alone corresponds to the IP packet being encrypted only or authenticated only. The default value for this flag will depend on if the **-e** and **-a** flags are supplied. The default policy will be **ea** if either both or neither the **-e** and **-a** flags are supplied. Otherwise the policy will reflect which of the **-e** and **-a** flags were supplied.

Item	Description
-P	(**manual** tunnel only) Destination policy, identifies how the IP packet authentication and/or encryption is to be used by destination. If specified as **ea**, the IP packet gets encrypted before authentication. If specified as **ae**, it gets encrypted after authentication, whereas specifying **e** or **a** corresponds to the IP packet being encrypted only or authenticated only. The default policy will be **ea** if either both or neither the **-E** and **-A** flags are supplied. Otherwise, the policy will reflect which of the **-E** and **-A** flags were specified.
-s	Source Host IP address, IP address of the local host interface to be used by the tunnel. A host name is also valid and the first IP address returned by name server for the host name will be used.
-t	Type of the tunnel. Must be specified as **manual**. The initial tunnel key and any subsequent key updates need to be performed manually when using the **manual** tunnel. Once a key is installed manually, that same key is used for all tunnel operations until it is changed manually. The **manual** tunnel value should be selected when you want to construct a tunnel with a non-IBM IP Security host or any IP version 6 end-point, where the end-point either supports RFCs 1825-1829 or the IETF drafts for the new IP Security encapsulation formats for IP tunnels.
-u	(**manual** tunnel only) Security Parameter Index for source AH. Use SPI and the destination IP address to determine which security association to use for AH. If this flag is not used, the value of the -n SPI will be used.
-U	(**manual** tunnel only) Security Parameter Index for the destination AH. If this flag is not used, the -N spi will be used.
-v	The IP version for which the tunnel is created. For IP version 4 tunnels, use the value of **4**. For IP version 6 tunnels, use the value of **6**.
-x	Network mask for the secure network behind a firewall. The Destination host is a member of the secure network. The combination of **-d** and **-x** allows the source host to communicate with multiple hosts in the secure network through the source-firewall tunnel, which must be in tunnel mode. This flag is valid only when the **-f** flag is used.
-y	(**manual** tunnel only) Replay prevention flag. Replay prevention is valid only when the ESP or AH header is using the new header format (see the **-z** flag). The valid values for the **-y** flag are Y (yes) and N (no). All encapsulations that are used in this tunnel (AH, ESP, sending, and receiving) will use the replay field if the value of this flag is Y. The default value is N.
-z	(**manual** tunnel only) New header format flag. The new header format preserves a field in the ESP and AH headers for replay prevention and also allows ESP authentication. The replay field will only be used when the replay flag (**-y**) is set to Y. The valid values for the **-z** flag are Y (yes) and N (no). The default value when the **-z** flag is not used depends on the algorithms you've chosen for the tunnel. It will default to N unless either an algorithm other than KEYED_MD5 is used for either the **-a** or **-A** flags, or if the **-b** or **-B** flags are used.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

genxlt Command

Purpose

Generates a code set conversion table for use by the **lconv** library.

Syntax

genxlt [OutputFile]

Description

The **genxlt** command reads a source code set conversion table file from standard input and writes the compiled version to the file specified by the *OutputFile* parameter. If a value is not specified for the *OutputFile* parameter, standard output is used. The source code set conversion table file contains directives that are acted upon by the **genxlt** command to produce the compiled version.

The format of a code set conversion table source file is:

- Lines whose initial nonwhite space character is the # (pound sign) are treated as comment lines.
- Null lines and lines consisting only of white-space characters are treated as comment lines.
- Non-comment lines have to be of the following form:

```
%token <blank>   # <tab> and <space>
%token <hex>     # <zero>, <one>, <two>, <three>, <four>,
                 # <five>, <six>, <seven>, <eight>, <nine>,
                 # <a>, <b>, <c>, <d>, <e>, <f>,
                 #  <A>, <B>, <C>, <D>, <E>, <F>,
%token <any>     # any character but '\n'
line    :  offset  blank  value  blank  comment  '\n'
        | 'SUB'  blank  value  blank  comment  '\n'
        ;

blank    : <blank>
        | blank <blank>
        ;

offset   :  '0x'  <hex>
        |  offset  <hex>
        ;

value    :  offset
        |  'invalid'
        |  'substitution'
        ;

comment  :  '#'  <any>
        |  comment  <any>
        ;
```

A line where the offset is `'SUB'` is used to specify the default substitution character.

If the table is set to `'substitution'`, the **iconv** converter using this table uses the SUB value for this offset.

If the value is set to `'invalid'`, the **iconv** converter using this table returns error for its offset.

If the offset is found in the source code set conversion table file multiple times, the last entry is used in the compilation of the translation table.

The offset and value must be in the range of 0x00 through 0xff, inclusive.

The following is an excerpt of a code set conversion table:

```
SUB     0x1a     substitute character
0x80    0xc7     C  cedilla
0x81    0xfc     u  diaeresis
```

```
0x82    0xe9     e  acute
0x83    0xe2     a  circumflex
0x84    0xe4     a  diaeresis
0x85    0x40     a  grave
0x9F            substitution
0xff            invalid
```

If successful, the **genxlt** command exits with a value of 0. If the output file cannot be opened, the **genxlt** command is unsuccessful and exits with a value of 1. If a syntax error is detected in the input stream, the **genxlt** command will exit immediately with a value of 2, and write to standard error the line numbers where the syntax error occurred.

The name of the file generated by the **genxlt** command must follow the naming convention below in order for the **iconv** subsystem to recognize it as a conversion file:

```
fromcode: "IBM-850"
tocode: "ISO8859-1"
conversion table file: "IBM-850_ISO8859-1"
```

The conversion table file name is formed by concatenating the `tocode` file name onto the `fromcode` file name, with an underscore between the two.

Example

To generate a non-English, user-defined code set conversion table, enter:

```
cp  /usr/lib/nls/loc/iconvTable/ISO8859-1_IBM-850_src  $HOME
vi  $HOME/ISO8859-1_IBM-850_src
genxlt  <  $HOME/ISO8859-1_IBM-850_src  >  cs1_cs2
```

get Command

Purpose

Creates a specified version of a SCCS file.

Syntax

To Get Read-Only Versions of SCCS Files

get [**-g**] [**-m**] [**-n**] [**-p**] [**-s**] [**-c** *Cutoff*] [**-i** *List*] [**-r** *SID*] [**-t**] [**-x** *List*] [**-w** *String*] [**-l** [**p**]] [**-L**] *File* ...

To Get Editable Versions of SCCS Files

get [**-e**] [**-k**] [**-b**] [**-s**] [**-c** *Cutoff*] [**-i** *List*] [**-r** *SID*] [**-t**] [**-x** *List*] [**-l** [**p**]] [**-L**] *File* ...

Description

The **get** command reads a specified version of the Source Code Control System (SCCS) file and creates an ASCII text file according to the specified flags. The **get** command then writes each text file to a file having the same name as the original SCCS file but without the **s.** prefix (the **g-file**).

Flags and files can be specified in any order, and all flags apply to all named files. If you specify a directory for the *File* parameter, the **get** command performs the requested actions on all files in the directory that begin with the **s.** prefix. If you specify a **-** (minus sign) for the *File* parameter, the **get** command reads standard input and interprets each line as the name of an SCCS file. The **get** command continues to read input until it reads an end-of-file character.

If the effective user has write permission in the directory containing the SCCS files but the real user does not, then only one file can be named when the **-e** flag is used.

Note: The **get** command supports the Multibyte Character Set (MBCS) for the file name and string data specified with the **w** flag.

Getting Read-Only File Versions

The **get** command creates both read-only versions and editable versions of a file. Read-only versions of files should be used if the application does not require changes to the file contents. Read-only versions of source code files can be compiled. Text files can be displayed or printed from read-only versions.

The difference between an editable and a read-only version is important when using identification keywords. *Identification keywords* are symbols expanded to some text value when the **get** command retrieves the file as read-only. In editable versions, keywords are not expanded. Identification keywords can appear anywhere in an SCCS file. See the **prs** command for further information on identification keywords.

SCCS Files

In addition to the file with the **s.** prefix (the **s-file**), the **get** command creates several auxiliary files: the **g-file**, **l-file**, **p-file**, and **z-file**. These files are identified by their tag, which is the letter before the hyphen. The **get** program names auxiliary files by replacing the leading **s.** in the SCCS file name with the appropriate tag, except for the **g-file**, which is named by removing the **s.** prefix. So, for a file named **s.sample**, the auxiliary file names would be **sample**, **l.sample**, **p.sample**, and **z.sample**.

These files serve the following purposes:

Item	Description
s-file	Contains the original file text and all the changes (deltas) made to the file. It also includes information about who can change the file contents, who has made changes, when those changes were made, and the nature of changes made. You cannot edit this file directly because it is read-only. However, it contains the information needed by the SCCS commands to build the **g-file**, which you can edit.
g-file	An ASCII text file that contains the text of the SCCS file version that you specify with the **-r** flag (or the latest trunk version by default). You can edit this file directly. When you have made all your changes and want to make a new delta to the file, you can then run the **delta** command on the file. The **get** command creates the **g-file** in the current directory. Whenever it runs the **get** command creates a g-file, unless the **-g** flag or the **-p** flag is specified. The real user owns it (not the effective user). If you do not specify the **-k** or **-e** flag, the file is read-only. If the **-k** or **-e** flag is specified, the owner has write permission for the **g-file**. You must have write permission in the current directory to create a **g-file**.

Item	Description
l-file	The **get** command creates the **l-file** when the **-l** flag is specified. The **l-file** is a read-only file. It contains a table showing which deltas were applied in generating the **g-file**. You must have write permission in the current directory to create an **l-file**. Lines in the **l-file** have the following format: • A blank character if the delta was applied; otherwise, an asterisk. • A blank character if the delta was applied, or was not applied and ignored. An asterisk appears if the delta was not applied and not ignored. • A code indicating a special reason why the delta was or was not applied: ***Blankspace*** Included or excluded usually **I** Included using the **-i** flag **X** Excluded using the **-x** flag **C** Cut off using the **-c** flag • The SID. • The date and time the file was created. • The login name of person who created the delta. Comments and Modification Requests (MR) data follow on subsequent lines, indented one horizontal tab character. A blank line ends each entry. For example, for a delta cutoff with the **-c** flag, the entry in the l-file might be: `**C 1.3 85/03/13 12:44:16 pat` and the entry for the initial delta might be: `1.1 85/02/27 15:42:20 pat` `date and time created 85/02/27 15:42:20 by pat`
p-file	The **get** command creates the **p-file** when the **-e** or **-k** flag is specified. The **p-file** passes information resulting from a **get -e** command to a **delta** command. The **p-file** also prevents a subsequent execution of a **get -e** command for the same SID until a **delta** command is run or the joint edit key letter (**j**) is set in the SCCS file. The **j** key letter allows several **get** commands to be run on the same SID. The **p-file** is created in the directory containing the SCCS *File*. To create a **p-file** in the SCCS directory, you must have write permission in that directory. The permission code of the **p-file** is read-only to all but its owner, and it is owned by the effective user. The **p-file** should not be directly edited by the owner. The **p-file** contains: • Current SID • SID of new delta to be created • User name • Date and time of the **get** command • **-i** flag, if present • **-x** flag, if present The **p-file** contains an entry with the preceding information for each pending delta for the file. No two lines have the same new delta SID.

Item	Description
z-file	The **z-file** is a lock mechanism against simultaneous updates. The **z-file** contains the binary process number of the **get** command that created it. This file is created in the directory containing the SCCS file and exists only while the **get** command is running.

When you use the **get** command, it displays the SID being accessed and the number of lines created from the SCCS file. If you specify the **-e** flag, the SID of the delta to be made appears after the SID is accessed and before the number of lines created. If you specify more than one file, a directory, or standard input, the **get** command displays the file name before each file is processed. If you specify the **-i** flag, the **get** command lists included deltas below the word `Included`. If you specify the **-x** flag, the **get** command lists excluded deltas below the word `Excluded`.

The following table illustrates how the **get** command determines both the SID of the file it retrieves and the pending SID. The SID Specified column shows various ways the SID can be specified with the **-r** flag. The first column also illustrates various conditions that can exist, including whether or not the **-b** flag is used with the **get -e** command. The SID Retrieved column indicates the SID of the file that makes up the **g-file**. The SID of Delta to Be Created column indicates the SID of the version that will be created when the **delta** command is applied.

SID Determination		
SID Specified	**SID Retrieved**	**SID of Delta to Be Created**
none [1] **-b Used?** no **Other Conditions** R defaults to mR [2]	mR.mL	mR.(mL+1)
none [1] **-b Used?** yes **Other Conditions** R defaults to mR	mR.mL	mR.mL.(mB+1).1
R **-b Used?** no **Other Conditions** R>mR	mR.mL	R.1 [3]
R **-b Used?** no **Other Conditions** R=mR	mR.mL	mR.(mL+1)
R **-b Used?** yes **Other Conditions** R>mR	mR.mL	mR.mL.(mB+1).1

SID Determination *(continued)*		
SID Specified	**SID Retrieved**	**SID of Delta to Be Created**
R **-b Used?** yes **Other Conditions** R=mR	mR.mL	mR.mL.(mB+1).1
R **-b Used?** N/A **Other Conditions** R<mR and R does not exist	hR.mL [4]	hR.mL.(mB+1) .1
R **-b Used?** N/A **Other Conditions** Trunk successor in release > R and R exists	R.mL	R.mL.(mB+1).1
R.L. **-b Used?** no **Other Conditions** No trunk successor	R.L.	R.(L+1)
R.L. **-b Used?** yes **Other Conditions** No trunk successor	R.L.	R.L(mB+1).1
R.L. **-b Used?** N/A **Other Conditions** Trunk successor in release > or = R	R.L.	R.L.(mB+1).1
R.L.B. **-b Used?** no **Other Conditions** No branch successor	R.L.B.mS	R.L.B.(mS+1)
R.L.B. **-b Used?** yes **Other Conditions** No branch successor	R.L.B.mS	R.L.(mB+1).1

SID Determination *(continued)*		
SID Specified	**SID Retrieved**	**SID of Delta to Be Created**
R.L.B.S. **-b Used?** no **Other Conditions** No branch successor	R.L.B.S.	R.L.B.(S+1)
R.L.B.S. **-b Used?** yes **Other Conditions** No branch successor	R.L.B.S.	R.L.(mB+1).1
R.L.B.S. **-b Used?** N/A **Other Conditions** Branch successor	R.L.B.S.	R.L.(mB+1).1

Note: In the SID Determination table, the letters R, L, B, and S are the release, level, branch, and sequence components of the SID. The letter *m* signifies maximum.

[1] Applies only if the **-d** (default SID) flag is not present in the file (see the **admin** command).

[2] The mR indicates the maximum existing release.

[3] Forces creation of the first delta in a new release.

[4] The hR is the highest existing release lower than the specified, nonexistent release R.

Identification Keywords

Identifying information is inserted into the text retrieved from the SCCS file by replacing identification keywords with their value wherever they occur. The following keywords may be used in the text stored in an SCCS file:

Keyword	Value
%M%	Module name: either the value of the **m** flag in the file, or, if absent, the name of the SCCS file with the **s.** removed.
%I%	SCCS identification (SID) (*%R%.%L%* or *%R%.%L%.%B%.%S%*) of the retrieved text.
%R%	Release.
%L%	Level.
%B%	Branch.
%S%	Sequence.
%D%	Current date, formatted as *YY/MM/DD*.
%H%	Current date, formatted as *MM/DD/YY*.
%T%	Current time, formatted as *HH:MM:SS*.
%E%	Date newest applied delta was created, formatted as *YY/MM/DD*.
%G%	Date newest applied delta was created, formatted as *MM/DD/YY*.

Keyword	Value
01:51:20	Time newest applied delta was created, formatted as *HH:MM:SS*.
%Y%	Module type: value of the **t** flag in the SCCS file.
%F%	SCCS file name.
%P%	SCCS absolute path name.
%Q%	The value of the **-q** flag in the file.
%C%	Current line number. This keyword is intended for identifying messages output by the program, such as `this should not have happened` error messages. The **%C%** is not intended to be used on every line to provide sequence numbers.
%Z%	The four-character string `@(#)` recognizable by *what.*
%W%	A shorthand notation for constructing *what* strings: `%W% = %Z%%M%<tab>%I%`
%A%	Another shorthand notation for constructing *what* strings: `%A% = %Z%%Y% %M% %I% %Z%`

Flags

Item	Description
-b	Specifies that the delta to be created should have an SID in a new branch. The new SID is numbered according to the rules given in the SID determination table. You can use the **-b** flag only with the **-e** flag. It is only necessary when you want to branch from a leaf delta (a delta without a successor). Attempting to create a delta at a nonleaf delta automatically results in a branch, even if the **b** header flag is not set. If you do not specify the **b** header flag in the SCCS file, the **get** command ignores the **-b** flag because the file does not allow branching.
-c *Cutoff*	Specifies a cutoff date and time, in the form *YY[MM[DD[HH[MM[SS]]]]]*. The **get** command includes no deltas to the SCCS file created after the specified cutoff in the g-file. The values of any unspecified items in the *Cutoff* variable default to their maximum allowable values. Thus, a cutoff date and time specified with only the year (YY) would specify the last month, day, hour, minute, and second of that year. Any number of nonnumeric characters can separate the two-digit items of the *Cutoff* variable date and time. This allows you to specify a date and time in a number of ways, as follows: `-c85/9/2,9:00:00` `-c"85/9/2 9:00:00"` `"-c85/9/2 9:00:00"`
-e	Indicates that the g-file being created is to be edited by the user applying the **get** command. The changes are recorded later with the **delta** command. The **get -e** command creates a p-file that prevents other users from issuing another **get -e** command and editing a second g-file on the same SID before the **delta** command is run. The owner of the file can override this restriction by allowing joint editing on the same SID through the use of the **admin** command with the **-fj** flag. Other users, with permission, can obtain read-only copies by using the **get** command without the **-e** flag. The **get -e** command enforces SCCS file protection specified with the ceiling, floor, and authorized user list in the SCCS file. See the **admin** command. **Note:** If you accidentally ruin the g-file created using the **get -e** command, you can recreate the file with the **get -k** command.
-g	Suppresses the actual creation of the **g-file**. Use the **-g** flag primarily to create an **l-file** or to verify the existence of a particular SID. Do not use it with the **-e** flag.

Item	Description
-i *List*	Specifies a list of deltas to be included in the creation of a **g-file**. The SID list format consists of a combination of individual SIDs separated by commas and SID ranges indicated by two SIDs separated by a hyphen. You can specify the same SIDs with either of the following command lines: `get -e -i1.4,1.5,1.6 s.file` `get -e -i1.4-1.6 s.file` You can specify the SCCS identification of a delta in any form shown in the SID Specified column of the previous table. The **get** command interprets partial SIDs as shown in the SID Retrieved column.
-k	Suppresses replacement of identification keywords in the **g-file** by their value. The **-k** flag is implied by the **-e** flag. If you accidentally ruin the **g-file** created using the **get -e** command, you can recreate the file by reissuing the **get** command with the **-k** flag instead of the **-e** flag.
-l[**p**]	Writes a delta summary to an l-file. If you specify **-lp**, the delta summary is written to standard output, and the **get** command does not create the **l-file**. Use this flag to determine which deltas were used to create the g-file currently in use. See the **sccsfile** file for the format of the **l-file**. See also the **-L** flag.
-L	Writes a delta summary to standard output. Specifying the **-L** flag is the same as using the **-lp** flag.
-m	Writes before each line of text in the **g-file** the SID of the delta that inserted the line into the SCCS file. The format is: `SID tab line of text`
-n	Writes the value of the **%M%** keyword before each line of text in the **g-file**. The format is the value of **%M%**, followed by a horizontal tab, followed by the text line. When both the **-m** and **-n** flags are used, the format is: `%M% value tab SID tab line of text`
-p	Writes the text created from the SCCS file to standard output and does not create a g-file. All informative output usually sent to standard output is sent to standard error, unless you specify the **-s** flag with the **-p** flag. In this case, output usually sent to standard output does not appear anywhere.
-r *SID*	Specifies the SCCS identification string (SID) of the SCCS file version to be created. The SID determination table shows the version of the created file and the SID of the pending delta as functions of the specified SID.
-s	Suppresses all output usually written to standard output. Error messages (written to standard error output), remain unaffected.
-t	Accesses the most recently created delta in a given release or for a given release and level.
-w *String*	Substitutes the *String* value for the **%W%** keyword in g-files not intended for editing.
-x *List*	Excludes the specified list of deltas in the creation of the **g-file**. See the **-i** flag for the SID list format.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

The following descriptions and examples illustrate the differences between read-only and editable versions of files.

1. To print the current date and SID in a file, put the following symbols in the file:

   ```
   %H% %I%
   ```

   %H% is the symbol for the current date and **%I%** is the symbol for the SID. When the **get** command retrieves a file as editable, it leaves the symbols in the file and does not perform text value substitution.

2. The following example of the **get** command builds the version with the highest SID, because the example does not specify a version of the file:

   ```
   $ ls
   s.test.c
   $ get s.test.c
   3.5
   59 lines
   $ ls
   s.test.c test.c
   ```

3. In the next two examples, the **-r** flag specifies which version to get:

   ```
   $ get -r1.3 s.test.c
   1.3
   67 lines

   $ get -r1.3.1.4 s.test.c
   1.3.1.4
   50 lines
   ```

4. If you specify just the release number of the SID, the **get** command finds the file with the highest level within that release number.

   ```
   $ get -r2 s.test.c
   2.7
   21 lines
   ```

5. If the SID specified is greater than the highest existing SID, the **get** command gets the highest existing SID. If the SID specified is lower than the lowest existing SID, SCCS writes an error message. In the following example, release 7 is the highest existing release:

   ```
   $ get -r9 s.test.c
   7.6
   400 lines
   ```

6. The **-t** flag gets the top version in a given release or level. The top version is the most recently created delta, independent of its location. In the next example, the highest existing delta in release 3 is 3.5, while the most recently created delta is 3.2.1.5.

   ```
   $ get -t -r3 s.test.c
   3.2.1.5
   46 lines
   ```

7. The previous examples use the **get** command to get a read-only file. To create a copy of the file that can be edited and used to create a new delta, use the **get** command with the **-e** flag. Use **unget** to undo the effect of the **get -e** command and discard any changes made to the file before a delta is created. The following example shows how to use the **-e** flag:

```
$ ls
s.test.c
$ get -e s.test.c
1.3
new delta 1.4
67 lines
$ ls
p.test.c s.test.c test.c
```

The working file is `test.c`. If you edit this file and save the changes with the **delta** command, SCCS creates a new delta with an SID of `1.4`. The file `p.test.c` is a temporary file used by SCCS to keep track of file versions.

In the previous example, you could have used the **-r** flag to get a specific version. Assuming release 1 is the highest existing release and that delta `1.3` already exists and is the highest delta in release, the following three uses of the **get** command are equivalent:

```
$ get -e s.test.c
$ get -e -r1 s.test.c
$ get -e -r1.3 s.test.c
```

8. To start using a new (higher in value) release number, get the file with the **-r** flag and specify a release number greater than the highest existing release number. In the next example, release 2 does not yet exist:

```
$ get -e -r2 s.test.c
1.3
new delta 2.1
67 lines
```

Notice that the **get** command indicates the version of the new delta that will be created if the **delta** command stores changes to the SCCS file.

9. To create a branch delta, use the **-r** flag and specify the release and level where the branch occurs. In the next example, deltas `1.3` and `1.4` already exist.

```
$ get -e -r1.3 s.test.c
1.3
new delta 1.3.1.1
67 lines
```

Creates deltas on branches using the same methods.

To edit a file, get the file version using the **get -e** command and save the changes with the **delta** command. Several different editable versions of an SCCS file can exist as long as each one is in a different directory. If you try to put duplicates of an editable file version into a directory (using the **get** command) without using the **delta** command, SCCS writes an error message.

To get the same editable file version more than once, set the **j** header flag in the SCCS file with the **admin** command. Set the **j** option by using the **-f** flag. You can then get the same SID several times from different directories, creating a separate file for each **get** command. Although the files originate from a single SID, SCCS gives each of them a unique new SID.

10. In the following example, the **pwd** command displays the current directory. Then the **j** option is set with the **admin** command:

Note: You must have write access in both directories to issue the commands in this example.

```
$ pwd
/home/marty/sccs
$ admin -fj s.test.c
```

11. Then use the **get** command to retrieve the latest version of the file:

Note: You must have write access in both directories to issue the commands in this example.

```
$ get -e s.test.c
1.1
```

```
new delta 1.2
5 lines
```

12. Change to the /home/new directory, and issue the **get** command again.

    Note: You must have write access in both directories to issue the commands in this example.

    ```
    $ cd /home/new
    $ get -e /home/marty/sccs/s.test.c
    1.2
    new delta 1.1.1.1
    5 lines
    ```

    Notice that SCCS creates two deltas, `1.2` and `1.1.1.1`, from the single original file version of `1.1`. Look at the **p.test.c** file. It shows a separate entry for each version currently in use. The **p.test.c** file remains in the directory until you take care of both file versions with either the **delta** command or the **unget** command.

Files

Item	Description
/usr/bin/get	Contains the **get** command.

getconf Command

Purpose

Writes system configuration variable values to standard output.

Syntax

getconf [**-v** *specification*] [*SystemwideConfiguration* | *PathConfiguration PathName*] [*DeviceVariable DeviceName*]

getconf -a

Description

The **getconf** command, invoked with the *SystemwideConfiguration* parameter, writes the value of the variable, as specified by the *SystemwideConfiguration* parameter, to standard output.

The **getconf** command, invoked with the *PathConfiguration* and *Pathname* parameters, writes the value of the variable, as specified by the *PathConfiguration* parameter for the path specified by the *PathName* parameter, to standard output.

The **getconf** command, invoked with the **-a** flag, writes the values of all system configuration variables to standard output.

The **getconf** command, invoked with the *DeviceVariable* and *DeviceName* parameters, writes the value of the disk device name or location, for the device path specified by the *DeviceName* parameter, to the standard output.

If the specified variable is defined on the system and its value is described to be available from the **confstr** subroutine, the value of the specified variable is written in the following format:

```
"%s\n", <value>
```

Otherwise, if the specified variable is defined on the system, its value is written in the following format:

```
"%d\n", <value>
```

If the specified variable is valid but undefined on the system, the following is written to standard output:

```
"undefined\n"
```

If the variable name is invalid or an error occurs, a diagnostic message is written to the standard error.

Flags

Item	Description
-v *specification*	Indicates a specific specification and version for which configuration variables are to be determined. If this flag is not specified, the values returned will correspond to an implementation default XBS5 conforming compilation environment.
-a	Writes the values of all system configuration variables to standard output.

Parameters

Item	Description
PathName	Specifies a path name for the *PathConfiguration* parameter.
SystemwideConfiguration	Specifies a system configuration variable.
PathConfiguration	Specifies a system path configuration variable.
DeviceName	Specifies the path name of a device.
DeviceVariable	Specifies a device variable.

When the symbol listed in the first column of the following table is used as the **system_var** operand, **getconf** will yield the same value as **confstr** when called with the value in the second column:

Note: The **_CS_AIX_ARCHITECTURE** and **_CS_AIX_BOOTDEV** variables, used as parameters to **confstr**, are available only to the root user.

system_var	confstr Name Value
BOOT_DEVICE	_CS_AIX_BOOTDEV
MACHINE_ARCHITECTURE	_CS_AIX_ARCHITECTURE
MODEL_CODE	_CS_AIX_MODEL_CODE
PATH	_CS_PATH
XBS5_ILP32_OFF32_CFLAGS	_CS_XBS5_ILP32_OFF32_CFLAGS
XBS5_ILP32_OFF32_LDFLAGS	_CS_XBS5_ILP32_OFF32_LDFLAGS
XBS5_ILP32_OFF32_LIBS	_CS_XBS5_ILP32_OFF32_LIBS
XBS5_ILP32_OFF32_LINTFLAGS	_CS_XBS5_ILP32_OFF32_LINTFLAGS
XBS5_ILP32_OFFBIG_CFLAGS	_CS_XBS5_ILP32_OFFBIG_CFLAGS
XBS5_ILP32_OFFBIG_LDFLAGS	_CS_XBS5_ILP32_OFFBIG_LDFLAGS
XBS5_ILP32_OFFBIG_LIBS	_CS_XBS5_ILP32_OFFBIG_LIBS
XBS5_ILP32_OFFBIG_LINTFLAGS	_CS_XBS5_ILPBIG_OFF32_LINTFLAGS
XBS5_LP64_OFF64_CFLAGS	_CS_XBS5_LP64_OFF64_CFLAGS
XBS5_LP64_OFF64_LDFLAGS	_CS_XBS5_LP64_OFF64_LDFLAGS
XBS5_LP64_OFF64_LIBS	_CS_XBS5_LP64_OFF64_LIBS

system_var	confstr Name Value
XBS5_LP64_OFF64_LINTFLAGS	_CS_XBS5_LP64_OFF64_LINTFLAGS
XBS5_LPBIG_OFFBIG_CFLAGS	_CS_XBS5_LPBIG_OFFBIG_CFLAGS
XBS5_LPBIG_OFFBIG_LDFLAGS	_CS_XBS5_LPBIG_OFFBIG_LDFLAGS
XBS5_LPBIG_OFFBIG_LIBS	_CS_XBS5_LPBIG_OFFBIG_LIBS
XBS5_LPBIG_OFFBIG_LINTFLAGS	_CS_XBS5_LPBIG_OFFBIG_LINTFLAGS

Environment Variables

The following environment variables affect the execution of **getconf**:

Item	Description
LANG	Provide a default value for the internationalisation variables that are unset or null. If LANG is unset or null, the corresponding value from the implementation-dependent | default locale will be used. If any of the internationalisation variables contains an invalid setting, the utility will behave as if none of the variables had been defined.
LC_CALL	If set to a non-empty string value, override the values of all the other internationalisation variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single- as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogues for the processing of LC_MESSAGES.

Systemwide Configuration Variables

The *SystemwideConfiguration* parameter specifies system configuration variables whose values are valid throughout the system. There are two kinds of system configuration variables:

- Systemwide configuration variables
- System standards configuration variables

Systemwide Configuration Variables

Systemwide configuration variables contain the minimum values met throughout all portions of the system. The following list defines the systemwide configuration variables used with the **getconf** command:

Item	Description
_CS_PATH	Value for the **PATH** environment variable used to find commands.
ARG_MAX	Maximum length, in bytes, of the arguments for one of the **exec** subroutines, including environment data.
BC_BASE_MAX	Maximum value allowed for the **obase** variable with the **bc** command.
BC_DIM_MAX	Maximum number of elements permitted in an array by the **bc** command.
BC_SCALE_MAX	Maximum value allowed for the **scale** variable with the **bc** command.
BC_STRING_MAX	Maximum length of a string constant accepted by the **bc** command.

Item	Description
CHARCLASS_NAME_MAX	Maximum number of bytes in a character class name.
CHAR_BIT	Number of bits in a type **character**.
CHAR_MAX	Maximum value of a type **character**.
CHAR_MIN	Minimum value of a type **character**.
CHILD_MAX	Maximum number of simultaneous processes for each real user ID.
CLK_TCK	Number of clock ticks per second returned by the **time** subroutine.
COLL_WEIGHTS_MAX	Maximum number of weights that can be assigned to an entry in the **LC_COLLATE** locale stanza in a locale-definition file.
CS_PATH	Value of the **PATH** environment variable used to find commands.
EXPR_NEST_MAX	Maximum number of expressions that can be nested within parentheses by the **expr** command.
INT_MAX	Maximum value of a type **int**.
INT_MIN	Minimum value of a type **int**.
LINE_MAX	Maximum length, in bytes, of a command's input line (either standard input or another file) when the utility is described as processing text files. The length includes room for the trailing new-line character.
LONG_BIT	Number of bits in a type **long int**.
LONG_MAX	Maximum value of a type **long int**.
LONG_MIN	Minimum value of a type **long int**.
MB_LEN_MAX	Maximum number of bytes in a character for any supported locale.
NGROUPS_MAX	Maximum number of simultaneous supplementary group IDs for each process.
NL_ARGMAX	Maximum value of digit in calls to the **printf** and **scanf** subroutines.
NL_LANGMAX	Maximum number of bytes in a LANG name.
NL_MSGMAX	Maximum message number.
NL_NMAX	Maximum number of bytes in an N-to-1 collation mapping.
NL_SETMAX	Maximum set number.
NL_TEXTMAX	Maximum number of bytes in a message string.
NZERO	Default process priority.
OPEN_MAX	Maximum number of files that one process can have open at one time.
PATH	Sequence of colon-separated path prefixes used to find commands.
RE_DUP_MAX	Maximum number of repeated occurrences of a regular expression permitted when using the interval-notation parameters, such as the *m* and *n* parameters with the **ed** command.
SCHAR_MAX	Maximum value of a type **signed char**.
SCHAR_MIN	Minimum value of a type **signed char**.
SHRT_MAX	Maximum value of a type **short**.
SHRT_MIN	Minimum value of a type **short**.
SSIZE_MAX	Maximum value of an object of type **ssize_t**.
STREAM_MAX	Number of streams that one process can have open at one time.

Item	Description
TMP_MAX	Minimum number of unique path names generated by the **tmpnam** subroutine. Maximum number of times an application can reliably call the **tmpnam** subroutine.
TZNAME_MAX	Maximum number of bytes supported for the name of a time zone (not the length of the **TZ** environment variable).
UCHAR_MAX	Maximum value of a type **unsigned char**.
UINT_MAX	Maximum value of a type **unsigned int**.
ULONG_MAX	Maximum value of a type **unsigned long int**.
USHRT_MAX	Maximum value of a type **unsigned short int**.
WORD_BIT	Number of bits in a word or type **int**.
KERNEL_BITMODE	Bit mode of the kernel, 32-bit or 64-bit.
REAL_MEMORY	Real memory size.
HARDWARE_BITMODE	Bit mode of the machine hardware, 32-bit or 64-bit.
MP_CAPABLE	MP-capability of the machine.

System Standards Configuration Variables

System standards configuration variables contain the *minimum* values required by a particular system standard. The **_POSIX_**, **POSIX2_**, and **_XOPEN_** prefixes indicate that the variable contains the minimum value for a system characteristic required by the POSIX 1003.1, POSIX 1003.2, and X/Open system standards, respectively. System standards are systemwide minimums that the system meets to support the particular system standard. Actual Configuration values may exceed these standards. The system standards configuration variables for the **getconf** command are defined as follows:

Item	Description
_POSIX_ARG_MAX	Maximum length, in bytes, of the arguments for one of the **exec** subroutines, including environment data.
_POSIX_CHILD_MAX	Maximum number of simultaneous processes for each real user ID.
_POSIX_JOB_CONTROL	Value of 1 if the system supports job control.
_POSIX_LINK_MAX	Maximum number of links to a single file.
_POSIX_MAX_CANON	Maximum number of bytes in a terminal canonical input queue.
_POSIX_MAX_INPUT	Maximum number of bytes allowed in a terminal input queue.
_POSIX_NAME_MAX	Maximum number of bytes in a file name (not including terminating null).
_POSIX_NGROUPS_MAX	Maximum number of simultaneous supplementary group IDs for each process.
_POSIX_OPEN_MAX	Maximum number of files that one process can have open at one time.
_POSIX_PATH_MAX	Maximum number of bytes in a path name.
_POSIX_PIPE_BUF	Maximum number of bytes guaranteed to be atomic when writing to a pipe.
_POSIX_SAVED_IDS	Value of 1. Each process has a saved set-user-ID and a saved set-group-ID.
_POSIX_SSIZE_MAX	Maximum value that can be stored in an object of type **ssize_t**.

Item	Description
_POSIX_STREAM_MAX	Number of streams that one process can have open at one time.
_POSIX_TIMESTAMP_RESOLUTION	Resolution of all file time stamps in nanoseconds.
_POSIX_TZNAME_MAX	Maximum number of bytes supported for the name of a time zone (not the length of the **TZ** environment variable).
_POSIX_VERSION	Version of the POSIX 1 standard (C Language Binding) to which the operating system conforms.
_XOPEN_CRYPT	Value of 1 if the system supports the X/Open Encryption Feature Group.
_XOPEN_ENH_I18N	Value of 1 if the system supports the X/Open Enhanced Internationalisation Feature Group.
_XOPEN_SHM	Value of 1 if the system supports the X/Open Shared Memory Feature Group.
_XOPEN_VERSION	Version of the X/Open Portability Guide to which the operating system conforms.
_XOPEN_XCU_VERSION	Version of the X/Open Commands and Utilities specification to which the operating system conforms.
_XOPEN_XPG2	Value of 1 if the system supports the X/Open Portability Guide, Volume 2, January 1987, XVS System Calls and Libraries, otherwise undefined.
_XOPEN_XPG3	Value of 1 if the system supports the X/Open Specification, February 1992, System Interfaces and Headers, Issue 3, otherwise undefined.
_XOPEN_XPG4	Value of 1 if the system supports the X/Open CAE Specification, July 1992, System Interfaces and Headers, Issue 4, otherwise undefined.
POSIX2_BC_BASE_MAX	Maximum value allowed for the **obase** variable with the **bc** command.
POSIX2_BC_DIM_MAX	Maximum number of elements permitted in an array by the **bc** command.
POSIX2_BC_SCALE_MAX	Maximum value allowed for the **scale** variable with the **bc** command.
POSIX2_BC_STRING_MAX	Maximum length of a string constant accepted by the **bc** command.
POSIX2_CHAR_TERM	Value of 1 if the system supports at least one terminal type; otherwise it has the value -1.
POSIX2_COLL_WEIGHTS_MAX	Maximum number of weights that can be assigned to an entry of the **LC_COLLATE** locale variable in a locale-definition file.
POSIX2_C_BIND	Value of 1 if the system supports the C Language Binding Option from POSIX 2; otherwise, it has the value -1.
POSIX2_C_DEV	Value of 1 if the system supports the C Language Development Utilities from POSIX 2; otherwise, it has the value -1.
POSIX2_C_VERSION	Version of the POSIX 2 standard (C Language Binding) to which the operating system conforms.
POSIX2_EXPR_NEST_MAX	Maximum number of expressions that can be nested within parentheses by the **expr** command.

Item	Description
POSIX2_FORT_DEV	Value of 1 if the system supports the FORTRAN Development Utilities Option from POSIX 2; otherwise, it has the value -1.
POSIX2_FORT_RUN	Value of 1 if the system supports the FORTRAN Runtime Utilities Option from POSIX 2; otherwise, it has the value -1.
POSIX2_LINE_MAX	The maximum length, in bytes, of a command's input line (either standard input or another file) when the command is described as processing text files. The length includes room for the trailing new-line character.
POSIX2_LOCALEDEF	Value of 1 if the system supports the creation of the locales by the **localedef** command; otherwise, it is undefined.
POSIX2_RE_DUP_MAX	Maximum number of repeated occurrences of a regular expression permitted when using the interval-notation parameters, such as the *m* and *n* parameters with the **ed** command.
POSIX2_SW_DEV	Value of 1 if the system supports the Software Development Utilities Option; otherwise, it has the value -1.
POSIX2_UPE	Value of 1 if the system supports the User Portability Utilities Option from POSIX 2; otherwise, it as the value -1.
POSIX2_VERSION	Date of approval of the most current version of the POSIX 2 standard that the system supports. The date is a six-digit number, with the first four digits signifying the year and the last two digits the month. Different versions of the POSIX 2 standard are periodically approved by the IEEE Standards Board, and the date of approval is used to distinguish between different versions.

System Path Configuration Variables

The *PathConfiguration* parameter specifies system path configuration variables whose values contain information about paths and path structures in the system. The following list defines these variables:

Item	Description
_POSIX_CHOWN_RESTRICTED	The **chown**() subroutine is restricted to a process with appropriate privileges, and to changing the group ID of a file only to the effective group ID of the process or to one of its supplementary group IDs. If the *PathName* parameter refers to a directory, the value returned applies to any files except directories that exist or can be created within the directory.
_POSIX_NO_TRUNC	Path names longer than the limit specified by the *NAME_MAX* variable will generate an error. If the *PathName* parameter refers to a directory, the value returned applies to file names within the directory.
_POSIX_VDISABLE	Terminal special characters, defined in the **termios.h** file, can be disabled using this character value.
LINK_MAX	Maximum number of links to a single file. If the *PathName* parameter refers to a directory, the value returned applies to the directory.
MAX_CANON	Maximum number of bytes in a terminal canonical input line.

Item	Description
MAX_INPUT	Maximum number of bytes for which space is available in a terminal input queue.
NAME_MAX	Maximum number of bytes in a file name (not including terminating null). If the *PathName* parameter refers to a directory, the value returned applies to the file names within the directory.
PATH_MAX	Maximum number of bytes in a path name, including the terminating null character. If the *PathName* parameter refers to a directory, the value returned is the maximum length of a relative path name when the specified directory is the working directory.
PIPE_BUF	Maximum number of bytes guaranteed to be atomic when writing to a pipe. If the *PathName* parameter refers to a FIFO or a pipe, the value returned applies to the referenced object. If the *PathName* parameter refers to a directory, the value returned applies to any FIFO that exists or can be created within the directory.
DISK_PARTITION	Physical partition size of the disk. **Note:** For the **DISK_PARTITION** path configuration variable, the *PathName* parameter must specify the complete path of the disk for which information is being queried.
DISK_SIZE	Disk size in megabytes. **Note:** For the **DISK_SIZE** path configuration variable, the *PathName* parameter must specify the complete path of the disk for which information is being queried.

Device Variables

The *DeviceVariable* parameter indicates that the *DeviceName* parameter is the path of a device, such as **/dev/hdisk0**. Given the path of a disk, the **getconf** command displays the device name or location of the disk.

Item	Description
DISK_DEVNAME	Device name or location of the device.

Exit Status

This command returns the following exit values:

Item	Description
0	The specified variable is valid and information about its current state was successfully written.
>0	An error occurred.

Examples

1. To display the value of the **ARG_MAX** variable, enter the following command:

```
getconf ARG_MAX
```

2. To display the value of the **NAME_MAX** variable for the **/usr** directory, enter the following command:

```
getconf NAME_MAX /usr
```

3. The following sequence of shell commands shows how to handle unspecified results:

```
if value=$(getconf PATH_MAX /usr)
then
     if [ "$value" = "undefined" ]
     then
             echo
                   The value of PATH_MAX in /usr is undefined.
     else
             echo
                   The value of PATH_MAX in /usr is $value.
     fi
else
     echo Error in the getconf command.
fi
```

4. If the command:

```
getconf _XBS5_ILP32_OFF32
```

   does not write -1\n or undefined\n to standard output, then commands of the form:

```
getconf -v XBS5_ILP32_OFF32 ...
```

   determine values for configuration variables corresponding to the XBS5_ILP32_OFF32 compilation environment specified in **c89**, Extended Description.

5. If the command:

```
getconf _XBS5_ILP32_OFFBIG
```

   does not write -1\n or undefined\n to standard output, then commands of the form:

```
getconf -v XBS5_ILP32_OFFBIG ...
```

   determine values for configuration variables corresponding to the XBS5_ILP32_OFFBIG compilation environment specified in **c89**, Extended Description.

6. If the command:

```
getconf _XBS5_LP64_OFF64
```

   does not write -1\n or undefined\n" to standard output, then commands of the | form:

```
getconf -v XBS5_LP64_OFF64 ...
```

   determine values for configuration variables corresponding to the XBS5_LP64_OFF64 compilation environment specified in c89, Extended Description.

7. If the command:

```
getconf _XBS5_LPBIG_OFFBIG
```

   does not write -1\n or undefined\n to standard output, then commands of the form:

```
getconf -v _XBS5_LPBIG_OFFBIG
```

   determine values for configuration variables corresponding to the XBS5_LPBIG_OFFBIG compilation environment specified in c89, Extended Description.

8. To determine the disk size for disk hdisk0, as root user, enter the following command:

```
getconf DISK_SIZE /dev/hdisk0
```

9. To determine the real memory size, enter the following command:

```
getconf REAL_MEMORY
```

10. To determine if the machine hardware is 32-bit or 64-bit, enter the following command:

```
getconf HARDWARE_BITMODE
```

11. To determine if the kernel is 32-bit or 64-bit, enter the following command:

```
getconf KERNEL_BITMODE
```

12. To determine the device name or location of disk `hdisk0`, enter the following command:

```
getconf DISK_DEVNAME hdisk0
```

Files

Item	Description
/usr/bin/getconf	Contains the **getconf** command.
/usr/include/limits.h	Defines system configuration variables.
/usr/include/unistd.h	Defines system configuration variables.

getdev Command

Purpose

Lists devices that match the specified criteria.

Syntax

getdev [**-a**] [**-e**] [*Criteria*] [*DeviceList*]

Description

Lists devices that match the given criteria. The criteria is given in the form of expressions. The **getdev** command can check all devices on the system or a specified list of devices.

Flags

Item	Description
-a	Specifies that a device must match all criteria to be included in the list generated by this command. The **-a** flag has no effect if no criteria are defined.
-e	Specifies that the devices provided in the *devicelist* be excluded from the list generated by the **getdev** command. Without the *-e* flag only devices in the *devicelist* are generated. This flag is ignored if no devices are specified.

Parameters

Item	Description
Criteria	Defines criteria that a device must match before it can be included in the generated list. *Criteria* can be specified as an expression or a list of expressions which a device must meet for it to be included in the list generated by **getdev**. If no criteria are provided, all devices are included in the list. Devices must satisfy at least one of the criteria in the list. However, the **-a** option can be used to specify that a "logical and" operation should be performed. Then, only those devices that match all of the criteria in a list will be included. There are four possible expression types which the criteria specified in the *Criteria* parameter may follow: ***Attribute*=*Value*** Fetches all devices with a member which has*Attribute* defined and is equal to *Value*. ***Attribute*!=*Value*** Fetches all devices with a member which has *Attribute* defined and does not equal *Value*. ***Attribute*:*** Fetches all devices with a member which has *Attribute* defined. ***Attribute*!:*** Fetches all devices with a member which does not have *Attribute* defined. The following are the valid device attributes: **alias** The name by which a device is known. **desc** A description of the device. **type** A token describing the type of the device. The valid set of values for the **type** attribute can be obtained by executing the following command. **`odmget PdDv | grep -w class | awk '{print $3}' | sed 's/"//g' | sort | uniq`** **status** The current state of the device.The list of possible values for status are: 1.Defined 2.Available 3.Stopped 4.Diagnose The values for **status** are not case sensitive.
DeviceList	Specifies a space-separated list of devices to be checked for the *Criteria*.

Exit Status

0
The command completed successfully

> 1
Failure has occurred.

Examples

1. To display all devices, enter:

```
getdev
```

2. To list devices which are of type "logical_volume", enter:

```
getdev type=logical_volume
```

3. To list devices which are not of type "logical_volume", enter:

```
getdev type!=logical_volume
```

4. To list devices which are of type "logical_volume" or whose device alias is "sys0", enter:

```
getdev type=logical_volume alias=sys0
```

The output will look similar to the following:

```
hd1
hd2
hd3
hd4
...
sys0
```

5. To list devices which are of type "logical_volume" and whose device alias is "lv01", enter:

```
getdev -a type=logical_volume alias=lv01
```

6. To display devices for which the **status** attribute is defined , enter:

```
getdev status:*
```

7. To display devices for which the **desc** attribute is not defined , enter:

```
getdev desc!:*
```

Files

Item	Description
/usr/sbin/getdev	Contains the **getdev** command

getdgrp Command

Purpose

Lists device classes that match the specified criteria.

Syntax

getdgrp [**-a**] [**-e**] [**-l**][*Criteria*] [*DeviceClassList*]

Description

Lists device classes that contain devices matching the given criteria. The criteria is given in the form of expressions.

Flags

Item	Description
-a	Indicates that a device must match all criteria of the device class to be included in the report generated by this command. The **-a** flag has no effect if no criteria are defined.
-e	Indicates that thedevices classes specified in the parameter list be excluded from the report generated by this command. The **-e** flag has no effect if no devices are specified.

Item	Description
-l	Indicates that all device classes that are subject to the **-e** option and the **dgroup** list, be listed even if they contain no valid device members. This option has no affect if *Criteria* is specified on the command line.

Parameters

Item	Description
Criteria	Defines criteria that a device must match before a device class to which it belongs can be included in the generated list. *Criteria* can be specified as an expression or a list of expressions which a device must meet for its class to be included in the list generated by **getdgrp**. If no criteria are given, all device classes are included in the list. Devices must satisfy at least one of the criteria in the list. However, the **-a** option can be used to specify that a "logical and" operation should be performed. Then, only those classes containing devices that match all of the criteria in a list will be included. There are four possible expression types which the criteria specified in the *Criteria* parameter may follow: ***Attribute*=*Value*** Fetches all device classes with a member which has*Attribute* defined and is equal to *Value*. ***Attribute*!=*Value*** Fetches all device classes with a member which has *Attribute* defined and does not equal *Value*. ***Attribute*:*** Fetches all device classes with a member which has *Attribute* defined. ***Attribute*!:*** Fetches all device classes with a member which does not have *Attribute* defined. The following are the valid device attributes: **alias** The name by which a device is known. **desc** A description of the device. **type** A token describing the type of the device. **status** The current state of the device.The list of possible values for status are : 1.Defined 2.Available 3.Stopped 4.Diagnose The values for **status** are not case sensitive.
DeviceClassList	Specifies device class name in the Customized Device Configuration database or in the Predefined Device Configuration database.

Exit Status

0
The command completed successfully

1
Command syntax was incorrect, invalid option was used, or an internal error occurred.

2
The Customized Devices object class or the Predefined Devices object class could not be opened for reading.

Examples

1. To display all device classes, enter:

   ```
   getdgrp
   ```

   The output looks similar to the following:

   ```
   adapter
   aio
   bus
   cdrom
   disk
   diskette
   gxme
   if
   keyboard
   lft
   logical_volume
   lvm
   memory
   mouse
   planar
   processor
   pty
   pwrmgt
   rcm
   sys
   tape
   tcpip
   tty
   ```

2. To list device classes whose devices are of type "logical_volume", enter:

   ```
   getdgrp type=logical_volume
   ```

   The output looks like the following:

   ```
   logical_volume
   ```

3. To list device classes whose devices are of type "logical_volume" or whose device alias is "sys0", enter:

   ```
   getdgrp type=logical_volume alias=sys0
   ```

   The output looks like the following:

   ```
   logical_volume
   sys
   ```

4. To list device classes whose devices status attribute is defined , enter:

   ```
   getdgrp status=defined
   ```

   The output looks like the following:

   ```
   logical_volume
   posix_aio
   rcm
   ```

5. To display device classes for whose devices the **status** attribute is defined and belong to the "processor" device class, enter:

   ```
   getdgrp status:* processor
   ```

   The output looks like the following:

   ```
   processor
   ```

6. To display device classes for whose devices the **status** attribute is not defined, enter:

```
getdgrp status!:* processor
```

Files

Item	Description
/usr/sbin/getdgrp	Contains the **getdgrp** command

getea Command

Purpose

Retrieves named extended attributes from a file.

Syntax

getea [**-n** *Name*] [**-l**] [**-e** *RegExp*] [**-s**] *FileName*

Description

The **getea** command reads named extended attributes from a file. If the **-n** *Name* parameter is specified then just extended attributes matching *Name* are retrieved.

Note: To prevent naming collisions, JFS2 has reserved the 8-character prefix `(0xf8)SYSTEM(0xF8)` for system-defined extended attributes. Avoid using this prefix for naming user-defined extended attributes.

If the **-e** *RegExp* parameter is specified then just extended attributes matching the regular expression *RegExp* are retrieved. If neither **-n** or **-e** flags are specified all extended attributes are retrieved.

This command is not used to get ACLs. The **aclget** command is used to get ACLs.

Flags

Item	Description
-e *RegExp*	Specifies a regular expression to retrieve all extended attributes which match. The values are displayed in character format.
-l	Specifies to get the extended attributes from the symbolic link itself rather than the file to which it is pointing.
-n *Name*	Specifies the name of specific extended attributes to retrieve. The values are displayed in character format.
-s	Displays only the names and not the values for the extended attributes.
FileName	Specifies the file from which to read the extended attributes.

Exit Status

Item	Description
0	Successful completion.
Positive integer	An error occurred.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To retrieve all named extended attributes for the file `design.html`, type:

```
getea design.html
```

2. To retrieve the named extended attribute, `Approver`, for the file `design.html`, type:

```
getea -n Approver design.html
```

3. To retrieve just the names of all named extended attributes for the file `design.html`, type:

```
getea -s design.html
```

4. To retrieve all named extended attributes for the symbolic link `design.html`, type:

```
getea -l design.html
```

Location

/usr/sbin

getopt Command

Purpose

Parses command line flags and parameters.

Syntax

getopt *Format Tokens*

Description

The **getopt** command parses a list of tokens using a format that specifies expected flags and arguments. A flag is a single ASCII letter and when followed by a : (colon) is expected to have an argument that may or may not be separated from it by one or more tabs or spaces. You can include multibyte characters in arguments, but not as a flag letter.

The **getopt** command completes processing when it has read all tokens or when it encounters the special token — (double hyphen). The **getopt** command then outputs the processed flags, a — (double hyphen), and any remaining tokens.

If a token fails to match a flag, the **getopt** command writes a message to standard error.

Examples

The **getopt** command can be used in a skeleton shell script to parse options, as in the following example:

```
#!/usr/bin/bsh
# parse command line into arguments
set -- `getopt a:bc $*`
# check result of parsing
if [ $? != 0 ]
then
```

```
        exit 1
fi
while [ $1 != -- ]
do
        case $1 in
        -a)     # set up the -a flag
                AFLG=1
                AARG=$2
                shift;;
        -b)     # set up the -b flag
                BFLG=1;;
        -c)     # set up the -c flag
                CFLG=1;;
        esac
        shift   # next flag
done
shift   # skip --
# now do the work
.
.
.
```

Note: In the C shell, use the following command to run the **getopt** command:

```
set argv=`getopt OptionString $*`
```

In each of the following examples, the **getopt** command would process the flags and arguments in the same way:

- `-a ARG -b -c`
- `-a ARG -bc`
- `-aARG -b -c`
- `-b -c -a ARG`

Files

Item	Description
/usr/bin/getopt	Contains the **getopt** command.

getopts Command

Purpose

Processes command-line arguments and checks for valid options.

Syntax

getopts *OptionString Name* [*Argument* ...]

Description

The **getopts** command is a Korn/POSIX Shell built-in command that retrieves options and option-arguments from a list of parameters. An option begins with a **+** (plus sign) or a **-** (minus sign) followed by a character. An option that does not begin with either a **+** or a **-** ends the *OptionString*. Each time the **getopts** command is invoked, it places the value of the next option in *Name* and the index of the next argument to be processed in the shell variable **OPTIND**. Whenever the shell is invoked, **OPTIND** is initialized to 1. When an option begins with **+**, a **+** is prepended to the value in *Name*.

If a character in *OptionString* is followed by a **:** (colon), that option is expected to have an argument. When an option requires an option-argument, the **getopts** command places it in the variable **OPTARG**.

When an option character not contained in *OptionString* is found, or an option found does not have the required option-argument:

- If *OptionString* does not begin with a **:** (colon),
  - *Name* will be set to a **?** (question mark) character,
  - **OPTARG**. will be unset, and
  - a diagnostic message will be written to standard error.

This condition is considered to be an error detected in the way arguments were presented to the invoking application, but is not an error in the processing of the **getopts** command; a diagnostic message will be written as stated, but the exit status will be zero.

- If *OptionString* begins with a **:** (colon),
  - *Name* will be set to a **?** (question mark) character for an unknown option or to a **:** (colon) character for a missing required option,
  - **OPTARG** will be set to the option character found, and
  - no output will be written to standard error.

Any of the following identifies the end of options: the special option **- -,** finding an argument that does not begin with a **-**, or **+**, or encountering an error.

When the end of options is encountered:

- the **getopts** command will exit with a return value greater than zero,
- **OPTARG** will be set to the index of the first non-option-argument, where the first **- -** argument is considered to be an option-argument if there are no other non-option-arguments appearing before it, or the value $#+1 if there are no non-option-arguments,
- *Name* will be set to a **?** (question mark) character.

Parameters

Item	Description
OptionString	Contains the string of option characters recognized by the **getopts** command. If a character is followed by a colon, that option is expected to have an argument, which should be supplied as a separate argument. The options can be separated from the argument by blanks. The first character in *OptionString* determines how the **getopts** command behaves if an option character is not known or an option-argument is missing. **Note:** The characters question mark and colon must not be used as option characters by an application. The use of other characters that are not alphanumeric produces unspecified results.
Name	Set by the **getopts** command to the option character that was found.
Argument ...	One or more strings separated by white space, checked by the **getopts** command for legal options. If *Argument* is omitted, the positional parameters are used. **Note:** Generally, you won't specify *Argument* as part of the **getopts** command, but it may be helpful when debugging your script.

Exit Status

This command returns the following exit values:

Item	Description
0	An option, specified or unspecified by *OptionString*, was found.

Item	Description
>0	The end of options was encountered or an error occurred.

Examples

1. The following **getopts** command specifies that a, b, and c are valid options, and that options a and c have arguments:

```
getopts a:bc: OPT
```

2. The following **getopts** command specifies that a, b, and c are valid options, that options a and b have arguments, and that **getopts** set the value of 0PT to **?** when it encounters an undefined option on the command line:

```
getopts :a:b:c OPT
```

3. The following script parses and displays it arguments:

```
aflag=
bflag=

while getopts ab: name
do
             case $name in
             a)     aflag=1;;
             b)     bflag=1
                           bval="$OPTARG";;
             ?)     printf "Usage: %s: [-a] [-b value] args\n" $0
                           exit 2;;
            esac
done

if [ ! -z "$aflag" ]; then
            printf "Option -a specified\n"
fi

if [ ! -z "$bflag" ]; then
            printf 'Option -b "%s" specified\n' "$bval"
fi

shift $(($OPTIND -1))
printf "Remaining arguments are: %s\n" "$*"
```

getrunmode Command

Purpose

Displays the mode the system is running in.

Syntax

getrunmode

Description

The **getrunmode** command displays the mode the system is running in. A run mode is either the CONFIGURATION mode or the OPERATIONAL mode.

Examples

To retrieve the run mode, enter:

```
getrunmode
```

Files

Item	Description
/usr/sbin/getrunmode	Contains the **getrunmode** command.

getsecconf Command

Purpose

Displays the system security flags.

Syntax

getsecconf { **-c** | **-o** }

Description

The **getsecconf** command displays the system security flags. When invoked without any options, the **getsecconf** command displays the security flags that pertain to the mode the system is running in.

Flags

Item	Description
-c	Specifies the CONFIGURATION mode.
-o	Specifies the OPERATIONAL mode.

Exit Status

The **getsecconf** command returns the following exit values:

Item	Description
0	Successful execution.
>0	An error occurred.

Examples

1. To display the system security flags in the CONFIGURATION mode, enter:

   ```
   getsecconf –c
   ```

2. To display the system security flags in the OPERATIONAL mode, enter:

   ```
   getsecconf –o
   ```

Files

Item	Description
/usr/sbin/getsecconf	Contains the **getsecconf** command.

getsyslab Command

Purpose

Displays the minimum and maximum labels of the system.

Syntax

getsyslab

Description

The **getsyslab** command is used to display the system minimum and maximum sensitivity label (SL), and minimum and maximum integrity label (TL).

Security

The **getsyslab** command is a privileged command. Successfully running the command requires the following authorization:

Item	Description
aix.mls.system.label.read	Required to list the system labels.

Files Accessed:

Item	Description
Mode	**File**
r	**/etc/security/enc/LabelEncodings**

Example

To display the system labels, enter:

```
getsyslab
```

Files

Item	Description
/usr/sbin/getsyslab	Contains the **getsyslab** command.
/etc/security/enc/LabelEncodings	System default label encodings file.

gettable Command

Purpose

Gets Network Information Center (NIC) format host tables from a host.

Syntax

/usr/sbin/gettable [**-v**] *Host* [*OutFile*]

Description

The **/usr/sbin/gettable** command is used to obtain the NIC standard host tables from a server indicated by the *Host* parameter. The tables, if retrieved, are placed in the file indicated by the *OutFile* parameter.

The **gettable** command opens a Transmission Control Protocol (TCP) connection to the port indicated in the service specification for the *Host* parameter. A request is then made for all names, and the resultant information is placed in the output file.

The **gettable** command is best used in conjunction with the **htable** command, which converts the NIC standard file format to that used by the network library lookup routines.

Flags

Item	Description
-v	Gets just the version number instead of the complete host table and puts the output in *OutFile* or, by default, in a file named **hosts.ver**.

Parameters

Item	Description
Host	Specifies the server that provides the host table information.
OutFile	Specifies the file where you want to place the host table information. If you use the **gettable** command without the **-v** flag, the default file name is **hosts.txt**.

gettrc Command

Purpose

Manages the collection of trace files.

Syntax

gettrc [**-c**] [**-C** *dirname*] [**-m**] [**-M** *dirname*] [**-s**] [**-S** *filename*]

Description

The `gettrc` command is a script that is used in conjunction with the `snap` command. It manages the collection of system trace files, lightweight memory trace (LMT) files, and component trace (CT) files.

Flags

Flag	Description
`-c`	Collects component trace files.
`-C` *dirname*	Collects component trace files from the directory that are specified by *dirname*.
`-m`	Collects memory trace files.
`-M` *dirname*	Collects lightweight memory trace files from the directory that are specified by *dirname*

Flag	Description
`-s`	Collects system trace files.
`-S` *filename*	Collects system trace files from the directory specified by *filename*

Exit Status

Item	Description
`0`	The command completed successfully.
`>0`	An error occurred.

Examples

1. To use `gettrc` in conjunction with the `snap` command to retrieve the different kinds of trace files, enter:

   ```
   snap "gettrc -c -C dirname -m -M dirname -s -S filename"
   ```

   This command returns system trace files, LMT files, and CT files, including those files that are listed in the directory specified by *dirname*.

Location

`/usr/lib/ras/snapscripts/gettrc`

Files

/usr/lib/ras/cpufmt

/etc/trcfmt

getty Command

Purpose

Sets the characteristics of ports.

Syntax

getty [[**-r** | **-u** | **-U**] [**-d**] [**-H** *HeraldString*] [**-M** *motdFile*] [**-N**]] *PortName*

Description

The **getty** command sets and manages terminal lines and ports. The **getty** command is run by the **init** command. The **getty** command is linked to the Terminal State Manager program. The Terminal State Manager program provides combined terminal control and login functions.

You can configure the **getty** command to create your home directory at your login if you do not have a home directory already. The **getty** command calls the **mkuser.sys** command to create the home directory and customize the account. To enable this capability, set the **mkhomeatlogin** attribute of the **usw** stanza in the **/etc/security/login.cfg** file to true.

> **Note:** The **getty** command is not entered on the command line.

When invoked as the **getty** command, the Terminal State Manager program provides the normal port management functions that include:

Item	Description
Bidirectional use	Allows terminal lines to be used to initiate and accept connections.
Line speed	Sets the baud rates for sending and receiving.
Parity	Sets the parity to be even, odd or none.
Delays	Sets the delays for carriage return, tab, new line, and form feed.
Character set mapping	Sets the character set mapping for case, tabs, and carriage control.
Logger Program	Specifies the program used to log the user into the system. If the attribute is set, the Secure Attention Key (SAK) processing is disabled. If the attribute is not set, it defaults to **/usr/sbin/login**. The **logger** attribute is contained within the Object Data Manager (ODM) database.
Character and line erase	Sets the keystroke used for character and line erase.
Echoing mode	Sets the echo to local or remote.

When the **getty** command is invoked, the following steps occur:

1. The port protection is set according to the **owner** and **protection** attributes in the ODM database. If these attributes are not specified, they default to root and 622.
2. The port specified by the *PortName* parameter is opened. If the carrier detection is available on the port, the open does not complete until the carrier is present or another process has lost the carrier with the port.
3. The specified port might be locked. If the **getty** command is run with the **-u** or **-r** flag, it attempts to lock the port. If the port is already locked the command waits until the port is available and then exits. If the **-r** flag was specified, the **getty** command waits for a byte of data to be received on the port before continuing.
4. The terminal attributes are set according to the configuration information for the specified port. Secure Attention Key processing can be enabled at this point depending on the system configuration.
5. The herald message is written to the specified port.
6. The login name is read from the specified port. If a framing error or a break occurs, the **getty** command repeats steps four and five with the next group of configured terminal attributes. This is most commonly used to cycle the baud rates for modems. But any ODM field (except `logmodes` and `runmodes`) may be cycled by entering a list of comma separated values in the ODM database.
7. The terminal modes are reset according to the `runmodes` parameter and the login name. If the login name is terminated by a new line, the **getty** command turns on the carriage-return to new line mapping. If all alphabetic characters are in uppercase, the user is prompted to log in using lowercase characters if possible, and mapping from lowercase to uppercase is turned on.
8. If a program is specified by the logger parameter, it is executed and Secure Attention Key processing is disabled. Otherwise, the Terminal State Manager program performs a standard system login.

   Note: If the Secure Attention Key sequence is typed during a user login, the user is logged into the trusted shell (if the system is configured where that port is trusted and the user is allowed on the trusted path).

Flags

Item	Description
-d	Provides debugging information.

Item	Description
-H *HeraldString*	Specifies an alternate herald message to write on the port to prompt for a login name. The message string must be one word and cannot contain any spaces. This string will take precedence over herald messages defined in the **/etc/security/login.cfg** file. If no string is specified with this option or in the **login.cfg** file, the default herald from the message catalog will be used.
-M *motdFile*	Specifies the path to an alternate message of the day file. If not specified, this value is **/etc/motd** by default.
-N	Causes **getty** to bypass any checking for the process ID in the **/etc/utmp** file. This allows a process other than the lowest login shell to **exec getty**.
-r	Makes the port available for shared (bi-directional) use. If the lock is unsuccessful, the **getty** command waits until the lock is available and then exits. If the lock is successful, the **getty** command waits for a byte of data on the port after locking the port.
-u	Makes the port available for shared (bi-directional) use. If the lock is unsuccessful, the **getty** command waits until the lock is available and then exits.
-U	Same as the **-u** flag, except **getty** does not wait for the lock to be available. It makes the port available regardless of the lock.

Security

Access Control: This program should be installed as a program in the Trusted Computing Base, executable by any user and **setuid** to root.

Example

To enable logging onto tty0, add the following line to the **/etc/inittab** file:

```
tty0:2:respawn: /usr/sbin/getty /dev/tty0
```

This command initializes the port `/dev/tty0` and sets up the characteristics of the port.

Files

Item	Description
/usr/sbin/getty	Contains the **getty** command.
/etc/locks	Contains lock files that prevent multiple uses of communications devices and multiple calls to remote systems.
/usr/sbin/login	The **login** command.
/etc/security/login.cfg	Contains port login configurations.
/etc/motd	Contains the message of the day displayed after login.
/usr/bin/setmaps	The **setmaps** command.
/etc/utmp	Contains information about users logged into the system.

gmvgstat Command

The **gmvgstat** command man page provides reference information for the **gmvgstat** command.

Purpose

Displays GMVG statistics.

Syntax

```
gmvgstat [-h] | [-r] [-t] [-i Interval [-c Count] [-w]]
[gmvg_name . . .]
```

Description

The **gmvgstat** command displays status information for one or more GMVGs including:

- Number of Physical Volumes
- Number of Remote Physical Volumes
- Total Number of Volumes (PVs and RPVs)
- Number of Stale Volumes
- Total Number of Physical Partitions (PPs)
- Number of Stale PPs
- Percentage GMVG is synchronized

The **gmvgstat** command can optionally be invoked in monitor mode by specifying the -i and -c flags.

If one or more GMVG names are supplied on the command line, then the **gmvgstat** command verifies that each listed GMVG name is a valid, available, online GMVG. In monitor mode, the user-supplied list of GMVGs is verified during each loop.

If no GMVG names are supplied on the command line the **gmvgstat** command reports information on all valid, available, online GMVGs. In monitor mode the list of GMVGs to report on is regenerated during each loop.

Flags

Table 6. gmvgstat command flags

Flag	Description
-h	Display command syntax and help.
-r	Include information for each individual RPV Client associated with the displayed GMVGs.
-t	Display header with date and time.

Table 6. gmvgstat command flags (continued)	
Flag	**Description**
-i Interval	Automatically redisplay status every <Interval> seconds. The value of the <Interval> parameter must be an integer greater than zero and less than or equal to 3600. If the <Interval> parameter is not specified, then display the status information once. The -i interval is the time, in seconds, between each successive gathering and display of GMVG statistics in monitor mode. This interval is not a precise measure of the elapsed time between each successive updated display. The gmvgstat command obtains some of the information it displays by calling other commands and has no control over the amount of time these commands take to complete their processing. Larger numbers of GMVGs will result in the gmvgtstat command taking longer to gather information and will elongate the time between successive displays in monitor mode. In some cases, an underlying command may take excessively long to complete and will result in the gmvgstat command taking much longer than the -i interval between displays.
-c Count	Redisplay information at the indicated interval <Count> times. The value of the <Count> parameter must be an integer greater than zero and less than or equal to 999999. If the <Interval> parameter is specified, but the <Count> parameter is not, then redisplay indefinitely.
-w	Clear the screen between each redisplay.

Operands

Table 7. Operand field	
Field	**Value**
gmvg_name	Name of one or more GMVGs for which to display information. If no GMVG names are specified, then information for all valid, available, online GMVGs is displayed.

Exit Status

Table 8. Exit status	
Value	**Description**
0	No errors.
>0	An error occurred.

Examples

1. To display statistical information for all GMVGs, enter:

   ```
   gmvgstat
   ```

2. To display statistical information for the GMVG named red_gmvg7, enter:

   ```
   gmvgstat red_gmvg7
   ```

3. To display statistical information for the GMVG named red_gmvg7 with statistics for all the RPVs associated with that volume group, enter:

   ```
   gmvgstat -r red_gmvg7
   ```

4. To display detailed information for GMVG red_gmvg7 that is automatically redisplayed every 10 seconds, enter:

```
gmvgstat red_gmvg7 -i 10
```

5. To display detailed information for GMVG red_gmvg7 that is automatically redisplayed every 10 seconds for 20 intervals and clears the screen between each redisplay, enter:

```
gmvgstat red_gmvg7 -i 10 -c 20 -w
```

Files

/usr/sbin/gmvgstat contains the gmvgstat command.

gprof Command

Purpose

Displays call graph profile data.

Syntax

/usr/ccs/bin/gprof [**-b**] [**-c** [*filename*]] [**-e** *Name*] [**-E** *Name*] [**-f** *Name*] [**-g** *filename*] [**-i** *filename*] [**-p** *filename*] [**-F** *Name*] [**-L** *PathName*] [**-s**] [**-x** [*filename*]] [**-z**] [**a.out** [**gmon.out** ...]]

Description

The **gprof** command produces an execution profile of C, FORTRAN, or COBOL programs. The effect of called routines is incorporated into the profile of each caller. The **gprof** command is useful in identifying how a program consumes processor resource. To find out which functions (routines) in the program are using the processor, you can profile the program with the **gprof** command.

The profile data is taken from the call graph profile file (**gmon.out** by default) created by programs that are compiled with the **cc** command by using the **-pg** option. The **-pg** option also links in versions of library routines that are compiled for profiling, and reads the symbol table in the named object file (**a.out** by default), correlating it with the call graph profile file. If more than one profile file is specified, the **gprof** command output shows the sum of the profile information in the specified profile files.

The **-pg** option causes the compiler to insert a call to the **mcount** subroutine into the object code that is generated for each recompiled function of your program. During program execution, each time a parent calls a child function the child calls the **mcount** subroutine to increment a distinct counter for that parent-child pair. Programs that are not recompiled with the **-pg** option do not have the **mcount** subroutine, and therefore keep no record of who called them.

Note: Symbols from C++ object file names get changed before they are used.

The GPROF environment variable can be used to set different options for profiling. The syntax of this environment variable is defined as follows:

```
GPROF = profile:<profile-type>,scale:<scaling-factor>,file:<file-type>,filename:<filename>
```

where:

- <profile-type> describes what type of profiling is to be performed; it can be either process or thread. Type 'process' indicates that profiling granularity is at process level, 'thread' indicates that profiling granularity is at thread level.
- <scaling-factor> describes how much memory is required to be allocated for call graph profile, by default the scaling factor is 2 for process level profiling and 8 for thread level profiling. A scaling factor of 2 indicates that a memory of half of the process size is allocated for every process or thread, scaling factor of 8 indicates that a memory of one eighth of the process size is allocated for every process of thread. This memory is the buffer area to store the call graph information.

- <file-type> describes what type of **gmon.out** file is required, a value of **multi** indicates that one **gmon.out** file per process is required, a value of multithread indicates that one **gmon.out** file per thread is required. If an application is profiled with the **-pg** option, and it forks, then specifying the file type as **multi** generates a **gmon.out** file for the parent process and another for the child process. The naming convention for the generated **gmon.out** files is as follows:
  - For multi file type: <prefix>-processname-pid.out
  - For multithread file type: <prefix>-processname-pid-Pthread<threadid>.out

  The <prefix> is by default **gmon**. You can define your own prefix by using the *filename* parameter of the GPROF environment variable.
- <filename> describes the prefix that requires to be used for the generated **gmon.out** files. By default, the prefix is **gmon**.

Note: Specifying `profile:thread` generates a format **gmon.out** file that can be read only by AIX 5.3 **gprof** command. If you want an old format **gmon.out** file and still want to specify **profile:thread**, then you must specify **file:multithread**. It generates an old format **gmon.out** file per thread. Hence, if your application has 2 threads, then 2 **gmon.out** files are generated, one per thread, by using the naming convention. You cannot enable thread level profiling by compiling an application with the **-pg** flag in AIX 5.2 or earlier and running it in AIX 5.3. To enable thread level profiling, you must compile that application with the **-pg** flag in AIX 5.3 and later.

The **gprof** command produces three items:

1. First, a flat profile is produced similar to the profile that is provided by the **prof** command. This listing gives total execution times and call counts for each of the functions in the program, which is sorted by decreasing time. The times are then propagated along the edges of the call graph. Cycles are discovered, and calls into a cycle are made to share the time of the cycle.
2. A second listing shows the functions that are sorted according to the time they represent, including the time of their call-graph descendants. Below each function entry are its (direct) call-graph children, with an indication of how their times are propagated to this function. A similar display above the function shows how the time of the function and the time of its descendants are propagated to its (direct) call-graph parents.
3. Cycles are also shown, with an entry for the cycle as a whole and a listing of the members of the cycle and their contributions to the time and call counts of the cycle.

Note: If the input to the **gprof** command contains thread level profiling data (format **gmon.out** file), then the **gprof** command produces the specified three items for every thread, starting with a cumulative report, followed by per thread reported (sorted in the ascending order of thread IDs).

The **grpof** command can also be used to analyze the execution profile of a program on a remote machine. It can be done by running the **gprof** command with the **-c** option on the call graph profile file (**gmon.out** by default) to generate a file (**gprof.remote** by default), which can then be processed on a remote machine. If a call graph profile file other than **gmon.out** is to be used, the call graph profile file name must be specified after **-c** *Filename* and the executable name. *Filename* must be specified if the **GPROF** environment variable's **file** attribute is set to **multi**; multiple **gmon.out** files are created, with one **gmon.out** file for each PID when the running program forks. The **-x** option can be used on the remote machine to process the **gprof.remote** (by default) file to generate profile reports.

Profiling with the fork and exec subroutines

Profiling by using the **gprof** command is problematic if your program runs the **fork** or **exec** subroutine on multiple, concurrent processes. Profiling is an attribute of the environment of each process, so if you are profiling a process that forks a new process, the child is also profiled. However, both processes write a **gmon.out** file in the directory from which you run the parent process, overwriting one of them. The **tprof** command is recommended for multiple-process profiling. You can use **file:multi** to avoid deleting the **gmon.out** file of the parent process, **file:multi** by using the AIX naming convention to generate the **gmon.out** files, hence the child processes **gmon.out** file does not have the same name as the parent, which avoids overwrites.

Profiling without source code

If you do not have source for your program, you can profile by using the **gprof** command without recompiling. You must, however, be able to relink your program modules with the appropriate compiler command (for example, **cc** for C). If you do not recompile, you do not get call frequency counts, although the flat profile is still useful without them. As an added benefit, your program runs almost as fast as it usually does. The following explains how to profile:

```
cc -c dhry.c         # Create dhry.o without call counting code.
cc -pg dhry.o -L/lib -L/usr/lib -o dhryfast
                     # Re-link (and avoid -pg libraries).
dhryfast             # Create gmon.out without call counts.
gprof >dhryfast.out  # You get an error message about no call counts
                     #  -- ignore it.
```

A result of running without call counts is that some quickly running functions (which you know had to be called) do not appear in the listing. Although nonintuitive, this result is normal for the **gprof** command. The **gprof** command lists only functions that were either called at least once, or which registered at least one clock tick. Even though they ran, quickly running functions often receive no clock ticks. Since call-counting was suspended, these small functions are not listed at all. (You can get call counts for the runtime routines by omitting the **-L** options on the **cc -pg** command line.)

Using less real memory

Profiling with the **gprof** command can cause programs to page excessively since the **-pg** option dedicates pinned real-memory buffer space equal to one-half the size of your program text. Excessive paging does not affect the data that is generated by profiling, since profiled programs do not generate ticks when waiting on I/O but only when using the processor. If the time delay caused by excessive paging is unacceptable, it is recommended to use the**tprof** command.

Flags

Item	Description
-b	Suppresses the printing of a description of each field in the profile.
-c *Filename*	Creates a file that contains the information that is needed for remote processing of profiling information. Do not use the **-c** flag in combination with other flags.
-E *Name*	Suppresses the printing of the graph profile entry for routine *Name* and its descendants, similar to the **-e** flag, but excludes the time that is spent by routine *Name* and its descendants from the total and percentage time computations. (**-E** *MonitorCount* **-E** *MonitorCleanup* is the default.)
-e *Name*	Suppresses the printing of the graph profile entry for routine *Name* and all its descendants (unless they have other ancestors that are not suppressed). More than one **-e** flag can be given. Only one routine can be specified with each **-e** flag.
-F *Name*	Prints the graph profile entry of the routine *Name* and its descendants similar to the **-f** flag, but uses only the times of the printed routines in total time and percentage computations. More than one **-F** flag can be given. Only one routine can be specified with each **-F** flag. The **-F** flag overrides the **-E** flag.
-f *Name*	Prints the graph profile entry of the specified routine *Name* and its descendants. More than one **-f** flag can be given. Only one routine can be specified with each **-f** flag.
-g *Filename*	Writes call graph information to the specified output *filename*. It also suppresses the profile information unless the **-p** flag is used.
-i *Ffilename*	Writes the routine index table to the specified output *filename*. If this flag is not used, the index table goes either at the end of the standard output, or at the bottom of the filename specified with the **-p** and **-g** flags.
-L *PathName*	Uses an alternative path name for locating shared objects.

Item	Description
-p *Filename*	Writes flat profile information to the specified output file name. It also suppresses the call graph information unless the **-g** flag is used.
-s	Produces the **gmon.sum** profile file, which represents the sum of the profile information in all the specified profile files. This summary profile file might be given to subsequent executions of the **gprof** command (by using the **-s** flag) to accumulate profile data across several runs of an **a.out** file.
-x *Filename*	Retrieves information from *Filename* (a file that is created with the **-c** option) to generate profile reports. If *Filename* is not specified, the **gprof** command searches for the default **gprof.remote** file.
-z	Displays routines that have zero usage (as indicated by call counts and accumulated time).

Examples

1. To obtain profiled output, enter the following command:

```
gprof
```

2. To get profiling output from a command run earlier and possibly moved, enter the following command:

```
gprof -L/home/score/lib runfile runfile.gmon
```

   This example uses the **runfile.gmon** file for sample data and the **runfile** file for local symbols, and checks the **/u/score/lib** file for loadable objects.

3. To profile the sample program **dhry.c**:

   a. Recompile the application program with the **cc -pg** command, as follows:

```
cc -pg dhry.c -o dhry # Re-compile to produce gprof output.
```

   b. Run the recompiled program. A file named `gmon.out` is created in the current working directory (not the directory in which the program executable file is located).

```
dhry    # Execute program to generate ./gmon.out file.
```

   c. Run the **gprof** command in the directory with the `gmon.out` file to produce the call graph and flat profile reports.

```
gprof >gprof.out     # Name the report whatever you like
vi gprof.out         # Read flat profile first.
```

   d. To generated thread level profiling granularity, export the GPROF environment variable as follows, and run the application, enter the following command:

```
export GPROF=profile:thread
dhry   # Execute program to generate ./gmon.out file which has thread level granularity
```

   e. To generate per process **gmon.out** file with a prefix of `mygmon`, enter the following command:

```
export GPROF=file:multi,filename:mygom
dhry  # Execute program to generate ./gmon-dhry-2468.out
```

   f. To generate per thread **gmon.out** file, with a scaling factor of 10, with a file name prefixed as `tgmon`, enter the following command:

```
export GPROF=profile:thread,file:multithread,scale:10,filename:tgmon
dhry # Execute program to generate ./tgmon-dhry-2468-Pthread215.out
```

g. To see only flat profile report from the `gmon-dhry-2468.out`, enter the following command:

```
gprof -p fprofile.out ./dhry ./gmon-dhry-2468.out
```

h. To see only call graph profile report from the `gmon-dhry-2468.out`, enter the following command:

```
gprof -g callgraph.out ./dhry ./gmon-dhry-2468.out
```

4. To use the remote processing feature of **gprof** command:

a. Recompile the application program with **cc -pg** command:

```
cc -pg thread.c -o thread  -lpthread
```

b. Enable thread level profiling granularity and use a different name for **gmon.out**:

```
export GPROF=profile:thread,filename:mygmon
```

c. Run the recompiled program. A file named **mygmon.out** is created in the current working directory (not the directory in which the program executable file is located):

```
thread    # Execute program to generate mygmon.out file.
```

d. Use the **-c** flag to generate the **my.remote** file, which can then be taken to a remote machine for processing:

```
gprof -c my.remote thread mygmon.out
```

e. On a remote machine, use the **-x** flag to extract information from the **my.remote** file:

```
gprof -x my.remote
```

Throughout this description of the **gprof** command, most of the examples use the C program **dhry.c**. However, the discussion and examples apply equally to FORTRAN or COBOL modules by substituting the appropriate compiler name in place of the C compiler, **cc**, and the word *subroutine* for the word *function*. For example, the following commands show how to profile a FORTRAN program named `matrix.f`:

```
xlf -pg matrix.f -o matrix # FORTRAN compile of matrix.f program
matrix                     # Execute with gprof profiling,
                           #   generating gmon.out file
gprof > matrix.out         # Generate profile reports in
                           #   matrix.out from gmon.out
vi matrix.out              # Read flat profile first.
```

Files

Item	Description
a.out	Name list and text space
gmon.out	Dynamic call graph and profile
gmon.sum	Summarized dynamic call graph and profile
gprof.remote	File for remote profiling
/usr/ucb/gprof	Contains the **gprof** command.
/usr/ccs/bin/gprof	Contains the **gprof** command

grap Command

Purpose

Typesets graphs to be processed by the **pic** command.

Syntax

grap [**-l**] [**-T** *Name*] [**—**] [*File* ...]

Description

The **grap** command processes grap language input files and generates input to the **pic** command. The grap language is a language for typesetting graphs. A typical command line is:

```
grap  File  |  pic  |  troff  |  Typesetter
```

Graphs are surrounded by the **.G1** and **.G2 troff** command requests. Data enclosed by these requests are scaled and plotted, with tick marks automatically supplied. Commands exist to modify the frame, add labels, override the default ticks, change the plotting style, define coordinate ranges and transformations, and include data from files. In addition, the **grap** command provides the same loops, conditionals, and macroprocessing as the **pic** command.

Grap language files contain grap programs. A grap program is written in the form:

```
.G1
grap Statement
grap Statement
grap Statement
.G2
```

Parameter

Item	Description
File	Specifies grap language files (grap programs) to be processed by the **grap** command for input to the **pic** command.

grap Statements Summary

Following is a summary of the grap statements you can use to create a grap program:

Item	Description
frame	Defines the frame that surrounds the graph. The syntax is: `frame [ht Expression] [wid Expression] [[Side] LineDescription]`

The attributes are defined as follows:

- *Side*: `top`, `bot`, `left`, `right`
- *LineDescription*: `solid`, `invis`, `dotted [Expression]`, `dashed [Expression]`

Height defaults to 2 inches, width defaults to 3 inches, sides default to solid. If `side` is omitted, the *linedesc* applies to the entire frame.

Item	Description
label	Places a label on a specified side of the graph. The syntax is:

```
label Side StringList ... Shift
```

The attributes are defined as follows:

- *Shift*: `left`, `right`, up, or down *expression*
- *StringList*: str ... `rjust`, `ljust`, `above, below [size (+)Expression] ...`
- *String*: `"..."`

Item	Description
coord	Defines an overriding system. The syntax is:

```
coord [Name] [x Expression,Expression] [y  Expression,Expression] [[log x] [log y]
[log log]]
```

ticks	Places tick marks on one side of the frame. The syntax is:

```
ticks side [[in] [out] [Expression]] [Shift] [TickLocations]
```

The attributes are defined as follows:

- *Shift*: `left`, `right`, up, `down Expression`
- *TickLocations*: at [*Name*] *Expression* [*String*], *Expression* [*String*], ... from [*Name*] *Expression* to *Expression* [by [*Operation*] *Expression*] *String*

If no ticks are specified, they will be provided automatically; `ticks off` suppresses automatic ticks.

Item	Description
grid	Produces grid lines along (that is, perpendicular to) the named side. The syntax is:

```
grid Side [LineDescription] [Shift] [TickLocations]
```

Grids are labeled by the same mechanism as ticks.

Item	Description
plot	Places text at a point. The syntax is:

```
StartList at Point plot Expression [Start] at Point
```

The attributes are defined as follows:

- *StringList*: str ... `rjust`, `ljust`, `above, below [size +)Expression] ...`
- *Point*: `[Name] Expression Expression`

Item	Description
line	Draws a line or arrow from one point to another. The syntax is:

```
{line | arrow} from Point to Point [LineDescription]
```

The attributes linedesc are defined as follows:

- *Point*: [*Name*] *Expression Expression*

- *LineDescription*: `solid`, `invis`, `dotted [Expression], dashed Expression]`

Item	Description
circle	Draws a circle. The syntax is: `circle at Point [radius Expression]`

The radius is in inches; the default size is small.

Item	Description
draw	Defines a sequence of lines. The syntax is: `draw [Name] at Point[LineDescription]`
next	Continues a sequence. The syntax is: `next [Name] at Point [LineDescription]`
new	Starts a new sequence. The syntax is: `new [Name] at Point [LineDescription]`
numberlist	Creates a line from a given set of numbers. The numbers are treated as points *x*, *y*1, *y*2, and so on; and plotted at the single *x* value. The syntax is: `number x, y1, y2 ...`
for	Creates a loop. The syntax is: `for Variable {from | =} Expression to Expression \` `[by [arithmetic or multiplicative operator] Expression] do X Anything X` X is any single character that does not appear in the string. If X is a left brace {, then the string may contain internally balanced braces followed by a right brace}. The text `Anything` is repeated as the `Variable` takes on values from the first `Expression` to the second `Expression`.
if	Creates a conditional evaluation. The syntax is: `if Expression then X Anything X [else X Anything X]`
define	Provides the same macroprocessor that Priority Interrupt Controller (PIC) does. The syntax is: `define MacroName X Anything X`
copy	Copies a file; includes the current contents of the file. The syntax is: `copy Filename`
copy-thru	Copies the file through the macro. `copy Filename thru MacroName` Each number or quoted string is treated as an argument. Copying continues until end of file or the next `.G2`. The optional clause `until String` causes copying to stop when a line whose first field is `String` occurs. The following statement copies subsequent lines through the macro: `copy thru MacroName` In all cases, you can specify the macro by inline rather than by name: `copy thru x MacroBody x`
sh	Passes text through to the UNIX shell. The syntax is: `sh x Anything x` The variable `Anything` is scanned for macros. The **pid** macro is built-in. It is a string consisting of the process identification number; you can use it to generate unique file names.

Item	Description
pic	Passes text through to **pic** with the `pic` removed. Variables and macros are not evaluated. Lines beginning with a period (that are not numbers) are passed through literally, under the assumption that they are **troff** commands.
graph	Defines a new graph named *Picname*, and resets all coordinate systems. The syntax is: `graph Picname [pic-text]` If **graph** commands are used in a grap program, the statement after the `.G1` must be a **graph** command. You can use the `pic-text` to position this graph relative to previous graphs by referring to their Frames as in the following example. `graph First` `  ...` `graph Second with .Frames.w at First.Frame.e + [0.1,0]` Macros and expressions in `pic-text` are not evaluated. `Picnames` must begin with a capital letter according to **pic** syntax.
print	Writes on `stderr` as grap processes its input. This statement can be helpful in debugging. The syntax is: `print [Expression | String]`

grap Language Conventions

The following conventions apply:

- The # (pound sign) introduces a comment. The comment ends automatically at the end of a line.
- Statements that continue for more than one line must be preceded by a \ (backslash character) at the beginning of each new line.
- Multiple statements appearing on one line must be separated by semicolons.
- The grap language ignores blank lines.
- Predefined strings include `bullet`, `plus`, `box`, `star`, `dot`, `times`, `htick`, `vtick`, `square`, and `delta`.
- Built-in functions available in grap include `log` (base 10), `exp` (base 10), `int`, `sin`, `cos`, `atan2`, `sqrt`, `min`, `max`, and `rand`.

Flags

Item	Description
-l	Stops the **grap** command from looking for the **/usr/lib/dwb/grap.defines** library file of macro definitions.
-T*Name*	Specifies the value of the *Name* variable as the **grap** command output device. The default value is **-Tibm3816**.
- -	(Double dash) Indicates the end of flags.

File

Item	Description
/usr/lib/dwb/grap.defines	Contains definitions of standard plotting characters.

greek Command

Purpose

Converts English-language output from a Teletype Model 37 workstation to output for other workstations.

Syntax

greek [**-T** *Name*]

Description

The **greek** command reinterprets the Teletype Model 37 character set, including reverse and half-line motions, for display on other workstations. It simulates special characters, when possible, by overstriking. The **greek** command reads standard input and writes to standard output.

Flags

Item	Description
-T*Name*	Uses the specified workstation name. If you omit the **-T** flag, the **greek** command attempts to use the workstation specified in the **$TERM** environment variable. The value of the *Name* variable can be any one of the following:
300	DASI 300
300-12	DASI 300 in 12-pitch
300s	DASI 300s
300s-12	DASI 300s, in 12-pitch
450	DASI 450
450-12	DASI 450, in 12-pitch
2621	Hewlett-Packard 2621, 2640, and 2645
2640	Hewlett-Packard 2621, 2640, and 2645
2645	Hewlett-Packard 2621, 2640, and 2645
4014	Tektronix 4014
hp	Hewlett-Packard 2621, 2640, and 2645
tek	Tektronix 4014.

Environment Variables

Item	Description
$TERM	Specifies a workstation name.

grep Command

Purpose

Searches for a pattern in a file.

Syntax

grep [**-E** | **-F**] [**-i**] [**-h**] [**-H**] [**-L**] [**-r** | **-R**] [**-s**][**-u**] [**-v**] [**-w**] [**-x**] [**-y**] [[[**-b**] [**-n**]] | [**-c** | **-l** | **-q**]] [**-p** [*Separator*]] { [**-e** *PatternList* ...] [**-f** *PatternFile* ...] | *PatternList* ... } [*File* ...]

Description

The **grep** command searches for the pattern specified by the *Pattern* parameter and writes each matching line to standard output. The patterns are limited regular expressions in the style of the **ed** or **egrep** command. The **grep** command uses a compact non-deterministic algorithm.

The **grep** command displays the name of the file containing the matched line if you specify more than one name in the *File* parameter. Characters with special meaning to the shell ($, *, [, |, ^, (,), \ ) must be in quotation marks when they appear in the *Pattern* parameter. When the *Pattern* parameter is not a

simple string, you usually must enclose the entire pattern in single quotation marks. In an expression such as `[a-z]`, the - (minus sign) cml specifies a range, according to the current collating sequence. A collating sequence may define equivalence classes for use in character ranges. If no files are specified, **grep** assumes standard input.

Notes:

1. Do not run the **grep** command on a special file because it produces unpredictable results. Input lines should not contain the NULL character.
2. Input files should end with the newline character.
3. The newline character will not be matched by the regular expressions.
4. Although some flags can be specified simultaneously, some flags override others. For example, the **-l** option takes precedence over all other flags. And if you specify both the **-E** and **-F** flags, the last one specified takes priority.

Flags

Item	Description
-b	Precedes each line by the block number on which it was found. Use this flag to help find disk block numbers by context. The **-b** flag cannot be used with input from stdin or pipes.
-c	Displays only a count of matching lines.
-E	Treats each pattern specified as an extended regular expression (ERE). A NULL value for the ERE matches every line. **Note:** The **grep** command with the **-E** flag is the same as the **egrep** command, except that error and usage messages are different and the **-s** flag functions differently.
-e *PatternList*	Specifies one or more search patterns. This works like a simple pattern but is useful when the pattern begins with a - (minus). Patterns should be separated by a new-line character. A NULL pattern can be specified by two adjacent new-line characters or a quotation mark followed by a new-line character ("\n). Each pattern is treated like a basic regular expression (BRE) unless the **-E** or **-F** flag is also specified. Multiple **-e** and **-f** flags are accepted by **grep**. All of the specified patterns are used when matching lines, but the order of evaluation is unspecified.
-F	Treats each specified pattern as a string instead of a regular expression. A NULL string matches every line. **Note:** The **grep** command with the **-F** flag is the same as the **fgrep** command, except that error and usage messages are different and the **-s** flag functions differently.
-f *PatternFile*	Specifies a file containing search patterns. Each pattern should be separated by a new-line character, and an empty line is considered a NULL pattern. Each pattern is treated like a basic regular expression (BRE), unless the **-E** or **-F** flag is also specified.
-h	Prevents the name of the file containing the matching line from being appended to that line. Suppresses file names when multiple files are specified.
-H	If the **-r** or **-R** option is specified and a symbolic link referencing a file of type directory is specified on the command line, **grep** will search the files of the directory referenced by the symbolic link and all the files in the file hierarchy below it.

Item	Description
-i	Ignores the case (uppercase or lowercase) of letters when making comparisons.

Item	Description
-l	Lists just the names of files (once) which contain matching lines. Each file name is separated by a new-line character. If standard input is searched, a path name of `(StandardInput)` is returned. The **-l** flag with any combination of the **-c** and **-n** flags behaves like the **-l** flag only.
-L	If the **-r** or **-R** option is specified and a symbolic link referencing a file of type directory is specified on the command line or encountered during the traversal of a file hierarchy, **grep** shall search the files of the directory referenced by the symbolic link and all the files in the file hierarchy below it. If both **-H** and **-L** are specified, the last option specified on the command line takes effect.
-n	Precedes each line with the relative line number in the file. Each file starts at line 1, and the line counter is reset for each file processed.
-p[*Separator*]	Displays the entire paragraph containing matched lines. Paragraphs are delimited by paragraph separators, as specified by the *Separator* parameter, which are patterns in the same form as the search pattern. Lines containing the paragraph separators are used only as separators; they are never included in the output. The default paragraph separator is a blank line.
-q	Suppresses all writing to standard output, regardless of matching lines. Exits with a zero status if an input line is selected. The **-q** flag with any combination of the **-c**, **-l** and **-n** flags behaves like the **-q** flag only.
-r	Searches directories recursively. By default, links to directories are followed.
-R	Searches directories recursively. By default, links to directories are not followed.
-s	Suppresses error messages ordinarily written for nonexistent or unreadable files. Other error messages are not suppressed.
-u	Causes output to be unbuffered.
-v	Displays all lines not matching the specified pattern.
-w	Does a word search.
-x	Displays lines that match the specified pattern exactly with no additional characters.
-y	Ignores the case of letters when making comparisons.
PatternList	Specifies one or more patterns to be used during the search. The patterns are treated as if they were specified using the **-e** flag.
File	Specifies a name of a file to be searched for patterns. If no *File* variable is given, the standard input is used.

Exit Status

This command returns the following exit values:

Item	Description
0	A match was found.
1	No match was found.
>1	A syntax error was found or a file was inaccessible (even if matches were found).

Examples

1. To use a pattern that contains some of the pattern-matching characters *, ^, ?, [,], \(, \), \{, and \}, enter:

   ```
   grep  "^[a-zA-Z]"  pgm.s
   ```

   This displays every line in `pgm.s` whose first character is a letter.
2. To display all lines that do not match a pattern, enter:

   ```
   grep   -v   "^#" pgm.s
   ```

   This displays every line in `pgm.s` whose first character is not a # (pound sign).
3. To display all lines in the `file1` file that match either the `abc` or `xyz` string, enter:

   ```
   grep   -E   "abc|xyz"  file1
   ```
4. To search for a $ (dollar sign) in the file named `test2`, enter:

   ```
   grep \\$ test2
   ```

   The \\ (double backslash) characters are necessary in order to force the shell to pass a \$ (single backslash, dollar sign) to the **grep** command. The \ (single backslash) character tells the **grep** command to treat the following character (in this example the $) as a literal character rather than an expression character. Use the **fgrep** command to avoid the necessity of using escape characters such as the backslash.
5. To search recursively through **/tmp** to find files which have the word `IBM` without recursing through links pointing to directories, type:

   ```
   grep –R IBM /tmp
   ```

   OR

   ```
   grep –r -H IBM /tmp
   ```
6. To search recursively through **/tmp** to find files which have the word `IBM` and recurse through links as well, type:

   ```
   grep –r IBM /tmp
   ```

   OR

   ```
   grep -R -L IBM /tmp
   ```

Files

Item	Description
/usr/bin/grep	Contains the **grep** command.

groups Command

Purpose

Displays group membership.

Syntax

groups [*User...*]

Description

By default, the **groups** command writes the group membership information of the current process to the standard output. If multiple users are specified as command parameters, the group membership for each user is displayed from the database.

The **groups** command will continue its operation with the next user in the parameter list after issuing a warning message if the user given is not found in the user database.

Security

Access Control: This program should be installed as a normal user program in the Trusted Computing Base.

Examples

To display the group membership of users listed in the parameter list, enter:

```
$ groups sys root lp adm
sys : sys
root : system bin sys security cron audit lp
lp : lp printq
adm : adm
```

Files

Item	Description
/usr/bin/groups	Contains the **groups** command
/usr/ucb/groups	Symbolic link to the **groups** command
/etc/group	Group file; contains group IDs
/etc/ogroup	Previous version of the group file
/etc/passwd	Password file; contains user IDs
/etc/opasswd	Previous version of the password file.

grpck Command

Purpose

Verifies the correctness of a group definition. This document describes both the AIX **grpck** command and the System V **grpck** command.

Syntax

grpck { **-n** | **-p** | **-t** | **-y** } { **ALL** | *Group* ... }

Description

The **grpck** command verifies the correctness of the group definitions in the user database files by checking the definitions for all the groups or for the groups that are specified by the *Group* parameter. If more than one group is specified, there must be a space between the groups.

Note: This command writes its messages to `stderr`.

You must select a flag to indicate whether the system must try to fix erroneous attributes. The following attributes are checked:

Item	Description
name	Checks the uniqueness and composition of the group name. The group name must be a unique string of 8 bytes or less. It cannot begin with a + (plus sign), a : (colon), a - (minus sign), or a ~ (tilde). It cannot contain a : (colon) in the string and cannot be the `ALL` or `default` keywords. No system fix is possible.
groupID	Checks the uniqueness and composition of the group ID. The ID must not be null and must consist of decimal digits only. No system fix is possible.
users	Checks the existence of the users that are listed in the group database files. If you indicate that the system must fix errors, it deletes all the users that are not found in the user database files.
adms	Checks the existence of the users that are listed as group administrators in the group database files. If you indicate that the system must fix errors, it deletes all the administrators that are not found in the user database files.
admin	Checks for a valid admin attribute for each group in the `/etc/security/group` file. No system fix is available.

Generally, the **sysck** command calls the **grpck** command as part of the verification of a trusted-system installation. In addition, the root user or a member of the security group can enter the command.

The **grpck** command checks to see whether the database management security files (`/etc/passwd.nm.idx`, `/etc/passwd.id.idx`, `/etc/security/passwd.idx`, and `/etc/security/lastlog.idx`) files are up-to-date or newer than the corresponding system security files. It is acceptable for `/etc/security/lastlog.idx` to be not newer than `/etc/security/lastlog`. If the database management security files are out-of-date, a warning message appears indicating that the root user must run the **mkpasswd** command.

Flags

Item	Description
-n	Reports errors but does not fix them.
-p	Fixes errors but does not report them.
-t	Reports errors and asks if they must be fixed.
-y	Fixes errors and reports them.

Security

Access Control: This command must grant execute (x) access to the root user and members of the security group. The **setuid** command for the root user must have the **trusted computing base** attribute.

Files Accessed:

Mode	File
r	`/etc/passwd`

Mode	File
r	/etc/security/user
rw	/etc/security/group
rw	/etc/group

Auditing Events:

Event	Information
GROUP_User	user, groups, attribute | error, status
GROUP_Adms	user, groups, attribute | error, status

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To verify that all the group members and administrators exist in the user database, and to report all the errors but not fix them, enter the following command:

   ```
   grpck -n ALL
   ```

2. To verify that all the group members and administrators exist in the user database, and to fix all the errors but not report them, enter the following command:

   ```
   grpck -p ALL
   ```

3. To verify the uniqueness of the group name and group ID defined for the `install` group, enter the following command:

   ```
   grpck -n install
   ```

   Or,

   ```
   grpck -t install
   ```

   Or,

   ```
   grpck -y install
   ```

   The **grpck** command does not correct the group names and IDs. Therefore, the **-n**, **-t**, and **-y** flags report problems with group names and group IDs, but do not correct them.

Files

Item	Description
/usr/sbin/grpck	Contains the **grpck** command.
/etc/passwd	Contains the basic attributes of users.
/etc/security/user	Contains the extended attributes of users.
/etc/group	Contains the basic attributes of groups.
/etc/security/group	Contains the extended attributes of groups.

System V grpck command

Syntax

/usr/sysv/bin/grpck

Description

The **/usr/sysv/bin/grpck** command verifies the correctness of the group definitions in the user database files by checking the definitions for all the groups. This **/usr/sysv/bin/grpck** command is a System V version of the existing **grpck** command in /usr/sbin/. This command calls the **/usr/sbin/grpck** command with the **-n** flag and **ALL** options.

Exit Status

0
Successful completion.

>0
An error occurred.

Examples

1. To verify that all the group members and administrators exist in the user database, and have any errors that are reported (but not fixed), enter the following command:

```
/usr/sysv/bin/grpck
```

Files

/usr/sysv/bin/grpck
Contains the System V version of the **grpck** command.

grpsvcsctrl Command

Purpose

Starts the group services subsystems.

Syntax

grpsvcsctrl { -a | -s | -k | -d | -c | -u | -t | -o | -h }

Description

The grpsvcsctrl command starts the group services subsystems. This control script controls the operation of the subsystems that are required for group services. These subsystems are under the control of the system resource controller (SRC) and belong to a subsystem group called grpsvcs. A daemon is associated with each subsystem. From an operational point of view, the group services subsystem group is organized as follows:

Subsystem
group services

Subsystem group
grpsvcs

SRC subsystem
grpsvcs — associated with the hagsd daemon. The subsystem name on the nodes is grpsvcs. The grpsvcs subsystem on each node is associated with the cluster to which the node belongs.

Daemon
hagsd — provides the majority of the group services functions.

The grpsvcsctrl script is not normally run from the command line. It is normally called by the startup command during installation of the cluster.

The grpsvcsctrl script provides a variety of controls for operating the group services subsystems:

- Adding, starting, stopping, deleting, and cleaning up the subsystems
- Turning tracing on and off

Before performing any of these functions, the script obtains the current cluster name.

Adding the subsystem: When the -a flag is specified, the control script uses the mkssys command to add the group services subsystems to the SRC. The control script operates as follows:

1. It makes sure the grpsvcs subsystem is stopped.
2. It gets the port number for the grpsvcs subsystem for this cluster from the global object data manager (ODM) and makes sure the port number is set in the /etc/services file. The range of valid port numbers is 10000 to 10100, inclusive.
3. The service name that is entered in the /etc/services file is grpsvcs.*cluster_name*.
4. It removes the grpsvcs subsystem from the SRC (in case it is still there).
5. It adds the grpsvcs subsystem to the SRC. The cluster name is configured as a daemon parameter on the mkssys command.

Starting the subsystem: When the -s flag is specified, the control script uses the startsrc command to start the group services subsystem, grpsvcs.

Stopping the subsystem: When the -k flag is specified, the control script uses the stopsrc command to stop the group services subsystem, grpsvcs.

Deleting the subsystem: When the -d flag is specified, the control script uses the rmssys command to remove the group services subsystem from the SRC. The control script operates as follows:

1. It makes sure the grpsvcs subsystem is stopped.
2. It removes the grpsvcs subsystem from the SRC using the rmssys command.
3. It removes the port number from the /etc/services file.

Cleaning up the subsystems: When the -c flag is specified, the control script stops and removes the group services subsystems for all system partitions from the SRC. The control script operates as follows:

1. It stops all instances of subsystems in the subsystem group in all partitions, using the stopsrc -g grpsvcs command.
2. It removes all instances of subsystems in the subsystem group in all partitions from the SRC using the rmssys command.

Turning tracing on: When the -t flag is specified, the control script turns tracing on for the hagsd daemon, using the traceson command.

Turning tracing off: When the -o flag is specified, the control script turns tracing off (returns it to its default level) for the hagsd daemon, using the tracesoff command.

Logging: While they are running, the group services daemons provide information about their operation and errors by writing entries in a log file in the /var/ha/log directory.

Each daemon limits the log size to a pre-established number of lines. The default is 5000 lines. When the limit is reached, the daemon appends the string .bak to the name of the current log file and begins a new log. If a .bak version already exists, it is removed before the current log is renamed.

Flags

-a
Adds the subsystem.

-s
Starts the subsystems.

-k
Stops the subsystems.

-d
Deletes the subsystems.

-c
Cleans the subsystems (that is, deletes them from all system partitions).

-u
Removes the group services subsystem from all partitions.

-t
Turns tracing on for the subsystems.

-o
Turns tracing off for the subsystems.

-h
Writes the script's usage statement to standard output.

Security

You must be running with an effective user ID of `root`.

Exit Status

0
Indicates the successful completion of the command.

1
Indicates that an error occurred.

Restrictions

This script is valid in an HACMP environment only.

Standard Output

When the `-h` flag is specified, this command's usage statement is written to standard output.

Standard Error

This command writes error messages (as necessary) to standard error.

Examples

1. To add the group services subsystems to the SRC, enter:

   ```
   grpsvcsctrl -a
   ```

2. To start the group services subsystems, enter:

   ```
   grpsvcsctrl -s
   ```

3. To stop the group services subsystems, enter:

   ```
   grpsvcsctrl -k
   ```

4. To delete the group services subsystems from the SRC, enter:

   ```
   grpsvcsctrl -d
   ```

5. To clean up the group services subsystems, enter:

   ```
   grpsvcsctrl -c
   ```

6. To turn tracing on for the group services daemon hagsd, enter:

```
grpsvcsctrl -t
```

7. To turn tracing off for the group services daemon hagsd, enter:

```
grpsvcsctrl -o
```

Location

/opt/rsct/bin/grpsvcsctrl
Contains the grpsvcsctrl script

Files

/var/ha/log/grpsvcs_*nodenum*_*instnum*.*cluster_name*
Contains the log of the hagsd daemons on the nodes

The file name includes these variables:

nodenum
is the node number on which the daemon is running

instnum
is the instance number of the daemon

cluster_name
is the name of the cluster in which the daemon is running

Implementation Specifics

This command is part of the Reliable Scalable Cluster Technology (RSCT) fileset.

gssd Daemon

Purpose

Services kernel requests for GSS operations.

Syntax

/usr/sbin/gssd

Description

Some NFS security methods, such as Kerberos 5, are provided under a more general mechanism called General Security Services, or GSS. In AIX, GSS services are provided by a library in the IBM Network Authentication Service (NAS) fileset. NAS is shipped on the expansion pack. The gssd daemon makes these GSS services available to the NFS server kernel code. If the gssd daemon is not running, then efforts to access files via NFS using GSS security methods such as Kerberos 5 will fail. The gssd daemon registers using RPC program number 400234.

The gssd daemon is started and stopped with the following System Resource Controller (SRC) commands:

```
startsrc -s gssd
stopsrc -s gssd
```

Files

Item	Description
/etc/nfs/hostkey	Specifies keytab file location and host principal in the following format: `path to keytab file` `host principal`
/etc/nfs/princmap	Specifies mappings to host principals in the following format: `principal1 alias1 alias2 alias3` `principal2 alias1` The aliases can be IP addresses or hostnames; the principal must match the host key maintained by kerberos.

h

The following AIX commands begin with the letter h.

ha.vsd Command

Purpose

Queries and controls the activity of the **rvsd** daemon of the recoverable virtual shared disk subsystem.

Syntax

ha.vsd
{**adapter_recovery [on** | **off]** | **debug [off]** | **mksrc** | **query** | **quorum** *n* | **qsrc** | **refresh [noquorum]** | **reset** | **reset_quorum** | **rmsrc** | **start** | **stop** | **trace [off]**}

Description

Use this command to display information about the recoverable virtual shared disk subsystem, to change the number of nodes needed for quorum, and to change the status of the subsystem.

Flags

-a
Specifies all virtual shared disks.

-v *vsd_name_list*
Specifies one or more virtual shared disk names, separated by commas.

-n *node_list*
Specifies one or more node numbers, separated by commas.

Parameters

adapter_recovery [on | off]
Enables or disables communication adapter recovery. The default is on.

The recoverable virtual shared disk subsystem must be restarted for this operand to take effect.

debug [off]
Specify debug to redirect the recoverable virtual shared disk subsystem's standard output and standard error to the console and cause the recoverable virtual shared disk subsystem to not respawn if it exits with an error. (You can use the `lscons` command to determine the current console.)

The recoverable virtual shared disk subsystem must be restarted for this operand to take effect.

Once debugging is turned on and the recoverable virtual shared disk subsystem has been restarted, `ha.vsd trace` should be issued to turn on tracing.

Use this operand under the direction of your IBM service representative.

Note: The default when the node is booted is to have standard output and standard error routed to the console. If debugging is turned off standard output and standard error will be routed to **/dev/null** and all further trace messages will be lost. You can determine if debug has been turned on by issuing `ha.vsd qsrc`. If debug has been turned on the return value will be:

```
action = "2"
```

mksrc
Uses `mkssys` to create the recoverable virtual shared disk subsystem.

query
Displays the current status of the recoverable virtual shared disk subsystem in detail.

quorum *n*
Sets the value of the quorum, which is the total number of nodes that must join the group before the virtual shared disks will be activated. Usually, quorum is defined as a majority of the nodes that are defined as virtual shared disk nodes in an RSCT peer domain, but this command allows you to override that definition.

The Recoverable virtual shared disk subsystem must be in the active state when you issue this command. This is not a persistent change.

qsrc
Displays the System Resource Controller (SRC) configuration of the Recoverable virtual shared disk daemon.

refresh [noquorum]
Uses the `refresh` command to asynchronously start a refresh protocol to all running recoverable virtual shared disk subsystems. The quorum will be reset before the refresh occurs, unless `noquorum` is specified. Use `ha.vsd query` to check for completion. The following items are refreshed in the device driver:

1. Nodes that have been added or deleted
2. Virtual shared disks that have been added or deleted
3. Changed attribute size_in_MB for virtual shared disks

reset
Stops and restarts the recoverable virtual shared disk subsystem.

reset_quorum
Resets the default quorum.

rmsrc
Uses `rmssys` to remove the recoverable virtual shared disk subsystem.

start
Starts the recoverable virtual shared disk subsystem.

stop
Stops the recoverable virtual shared disk subsystem.

trace [off]
Requests or stops tracing of the recoverable virtual shared disk subsystem. The recoverable virtual shared disk subsystem must be in the active state when this command is issued.

This operand is only meaningful after the `debug` operand has been used to send standard output and standard error to the console and the recoverable virtual shared disk subsystem has been restarted.

Security

You must have `root` authority to run this command.

Exit Status

0
Indicates the successful completion of the command.

nonzero
Indicates that an error occurred.

Restrictions

You must issue this command from a node that is online in the peer domain. To bring a peer domain online, use the **startrpdomain** command. To bring a particular node online in an existing peer domain, use the **startrpnode** command. For more information on creating and administering an RSCT peer domain, refer to *RSCT Administration Guide* .

Examples

1. To stop the recoverable virtual shared disk subsystem and restart it, enter:

   ```
   ha.vsd reset
   ```

   The system returns the messages:

   ```
   Waiting for the rvsd subsystem to exit.
   rvsd subsystem exited successfully.
   Starting rvsd subsystem.
   rvsd subsystem started PID=xxx.
   ```

2. To change the quorum to five nodes of the RSCT peer domain, enter:

   ```
   ha.vsd quorum 5
   ```

   The system returns the message:

   ```
   Quorum has been changed from 8 to 5.
   ```

3. To query the rvsd subsystem, enter:

   ```
   ha.vsd query
   ```

   The system displays a message similar to the following:

   ```
   Subsystem         Group            PID     Status
         rvsd              rvsd             18320   active
         rvsd(vsd): quorum= 9/4, active=1, state=idle, isolation=member,
                    NoNodes=10, lastProtocol=nodes_failing,
                    adapter_recovery=on, adapter_status=up,
                    RefreshProtocol has never been issued from this node,
                    Running function level 4.1.0.0.
   ```

   where:

   quorum
   Is the number of total nodes or server nodes that must join the group before virtual shared disks will be activated. In the system output above, `quorum 9/4` indicates the total number of nodes (9) and the number of server nodes (4).

   active
   Indicates the activation status of the group that is being joined:

   0:
   the group is not active (quorum has not been met).

   1:
   the group is active and the shared disks have been activated.

   state
   Indicates the current protocol that is running.

   isolation
   Indicates the group membership status

   isolated:
   a group "join" has not been proposed.

   proposed:
   a group "join" has been proposed.

member:
we are a member (provider) of the group.

NoNodes
Indicates the number of nodes that have joined the group

lastProtocol
Indicates the last protocol that was run across the group.

adapter_recovery
Indicates communication adapter recovery support:

on:
adapter recovery is enabled.

off:
adapter recovery is disabled.

adapter_status
Indicates communication adapter status:

up:
the adapter is up.

down:
the adapter is down.

unknown:
the adapter status is unknown.

RefreshProtocol ...
Indicates whether a refresh protocol has been issued from this node. If so, the date and time of success or error will be displayed.

Running function level
Indicates the function level that the subsystem is running, in version, release, modification, fix level format (vrmf). (Coexistence with lower levels of the subsystem, may restrict us to running at a reduced function level.)

Location

/opt/rsct/vsd/bin/ha.vsd

ha_star Command

Purpose

Processes high availability event.

Syntax

ha_star [**-C**]

Description

The **ha_star** command is the generic high availability handling command. It is automatically invoked by the operating system through **/etc/rc.ha_star** when a CPU predictive failure is reported by the firmware.

If **ha_star** is invoked without flags, only new events are handled. If **ha_star** does not find any new event, it exits.

When running, **ha_star** handles all new events, even those which arrive while **ha_star** is handling already existing events. Only one instance of **ha_star** can be running at any given time. Should a second instance of **ha_star** be launched, it exits.

The operating system invokes **ha_star** when a high availability event is reported. The event handling may fail or it may be cancelled (for example, by signals). Aborted or cancelled events are held in memory within the kernel. When the cause of the abort has been corrected, then the event handling can be retried. This is when **ha_star** is invoked manually by the system administrator.

The **ha_star** command generates error or failure error log entries.

Description by Event Type

The **ha_star** command is invoked by the operating system to deallocate a CPU when a predictive processor failure event is detected. This deallocation may fail because some threads remain bound to the CPU being deallocated. In some cases, system administrators can fix the condition which led to the failure of the deallocation. For example, they may be able to identify and stop applications with threads bound to the last logical CPU.

The **-C** flag indicates that the high availability event to be resumed is a CPU deallocation event.

Flags

Item	Description
-C	Specifies that the event to be restarted is a CPU deallocation.

Files

Item	Description
/**usr**/**sbin**/**ha_star**	Contains the **ha_star** command.

ha_vsd Command

Purpose

Starts and restarts the Recoverable virtual shared disk subsystem. This includes configuring virtual shared disks and activating the recoverability subsystem.

Syntax

ha_vsd [**reset**]

Description

Use this command to start the recoverable virtual shared disk software after you install it, or, with the `reset` option, to stop and restart the program.

Flags

-a
Specifies all virtual shared disks.

-v ***vsd_name_list***
Specifies one or more virtual shared disk names, separated by commas.

-n ***node_list***
Specifies one or more node numbers, separated by commas.

Parameters

reset
Stops and restarts the recoverable virtual shared disk subsystem.

Security

You must have `root` authority to run this command.

Exit Status

0
Indicates the successful completion of the command.

1
Indicates that an error occurred.

Restrictions

You must issue this command from a node that is online in the peer domain. To bring a peer domain online, use the **startrpdomain** command. To bring a particular node online in an existing peer domain, use the **startrpnode** command. For more information on creating and administering an RSCT peer domain, refer to *RSCT Administration Guide* .

Examples

To stop the recoverable virtual shared disk subsystem and restart it, enter:

```
ha_vsd reset
```

Location

/opt/rsct/vsd/bin/ha_vsd

haemd Daemon

Purpose

Observes resource variable instances that are updated by resource monitors and generates and reports events to client programs.

Syntax

haemd

Description

The haemd (event manager) daemon observes resource variable instances that are updated by resource monitors and generates and reports events to client programs.

One instance of the haemd daemon executes on every node of a cluster. The haemd daemon is under system resource controller (SRC) control.

Because the daemon is under SRC control, it cannot be started directly from the command line. It is normally started by the `emsvcsctrl` command. If you must start or stop the daemon directly, use the `emsvcsctrl` command.

When SRC creates the haemd daemon, the actual program started is haemd_HACMP. The haemd_HACMP program, after collecting information needed by the daemon, then runs the haemd program. In other words, the haemd_HACMP program is replaced by the haemd program in the process created by SRC.

For more information about the event manager daemon, see the `emsvcsctrl` command.

Implementation Specifics

This daemon is part of Reliable Scalable Cluster Technology (RSCT) fileset for AIX.

Location

/opt/rsct/bin/haemd
Location of the haemd daemon

haemd_HACMP Command

Purpose

Startup program for the event manager daemon.

Syntax

haemd_HACMP [-d *trace_arg*]

Description

The haemd_HACMP command is the startup program for the haemd daemon. When the event management subsystem is configured in the system resource controller (SRC) by the emsvcsctrl command, haemd_HACMP is specified as the program to be started.

This program can only be invoked by the SRC. To start the event management subsystem, use the emsvcsctrl command.

Flags

-d *trace_arg*
Should only be used under the direction of the IBM Support Center. The possible trace arguments are the same as for the haemtrcon command, except for reg and dinsts. To use this flag, the emsvcs subsystem definition in the SRC must be changed using the chssys command with the -a flag. The daemon must then be stopped and restarted.

Restrictions

This command is valid in an HACMP environment only.

Implementation Specifics

This script is part of the Reliable Scalable Cluster Technology (RSCT) fileset.

Location

/opt/rsct/bin/haemd_HACMP
Location of the haemd_HACMP program

haemqvar Command

Purpose

Queries resource variables.

Syntax

haemqvar [-H *domain* | -S *domain*] [-c | -d | -i] [-f *file*] [-h] [*class var rsrcID* ["]]

Description

The haemqvar command queries the Event Management subsystem for information about resource variables. By default, the command writes to standard output the definitions for all resource variables in the current SP domain, that is, the current SP system partition as defined by the SP_NAME environment variable. If SP_NAME is not set the default system partition is used. The -S flag can be used to specify another SP domain (system partition). To query variables in an HACMP domain, use the -H flag. For an SP domain, the domain flag argument is a system partition name. For an HACMP domain, the domain flag argument is an HACMP cluster name. When the -H flag is specified, the command must be executed on one of the nodes in the HACMP/ES cluster.

The following information is reported for each resource variable definition:

- Variable Name
- Value Type
- Data Type
- SBS Format (if data type is Structured Byte String)
- Initial Value
- Class
- Locator
- Variable Description
- Resource ID and its description
- Default Expression (if defined) and its description

Because the default behavior of this command can produce a large amount of output, standard output should be redirected to a file.

If the -d flag is specified only the resource variable name and a short description are written to standard output, one name and description per line.

If the -c flag is specified the current values of all resource variables instances are written to standard output, one per line. The line of output contains the location of the resource variable instance (node number), the resource variable name, the resource ID of the instance and the resource variable instance value. If the resource variable is a Structured Byte String (SBS) data type, then the value of each SBS field is reported.

The -i flag reports the same information as the -c flag except that the value of the variable instance is the last known value rather than the current value. The -i flag is useful for determining what resource variable instances exist.

For both the -c and the -i flags, if an error is encountered in obtaining information about a resource variable instance, the output line contains an error message, symbolic error codes, the location of where the error originated (if it can be determined), the resource variable name and the resource ID.

To return information about specific resource variables, specify the class, var and rsrcID operands. These operands can be repeated to specify additional resource variables. In addition, the var and rsrcID operands can be wildcarded to match a number of resource variables. Note that null string operands or an asterisk must be quoted in the shells.

If class is not a null string, then all variables in the specified class, as further limited by the var and rsrcID arguments, are targets of the query. If class is a null string, then variables of all classes, as further limited by the var and rsrcID arguments, are targets of the query. The var argument can be wildcarded in one of two ways:

1. Specify the variable name as a null string
2. Truncate the name after any component

When the resource variable name is wildcarded in the first manner, then all resource variables, as further limited by the class and rsrcID arguments, are targets of the query. When the resource variable name is

wildcarded in the second manner, all resource variables whose high-order (leftmost) components match the var argument, as further limited by the class and rsrcID arguments, are targets of the query.

All resource variable instances, or definitions if neither the -c nor the -i flags are specified, of the variables specified by the class and var arguments that match the rsrcID argument are the targets of the query.

If neither the -c nor the -i flags are specified, the rsrcID argument is a semicolon-separated list of resource ID element names. If either the -c or the -i flags is specified, the rsrcID argument is a semicolon-separated list of name/value pairs. A name/value pair consists of a resource ID element name followed by an equal sign followed by a value of the resource ID element. An element value may consist of a single value, a range of values, a comma-separated list of single values or a comma-separated list of ranges. A range takes the form a-b and is valid only for resource ID elements of type integer (the type information can be obtained from the variable definition). There can be no blanks in the resource ID.

A resource ID element is wildcarded by specifying its value as the asterisk character. Only variables that are defined to contain the elements, and only the elements, specified in the rsrcID argument are targets of the query. If any element of the resource ID consists of the asterisk character, rather than a name/value pair (or just a name if querying for definitions), all variables that are defined to contain at least the remaining specified elements are targets of the query. The entire resource ID is wildcarded if it consists of only the asterisk character; all instances of all resource variables, as further limited by the class and var arguments, are targets of the query.

Note that the rsrcID argument must be quoted in the shells if it contains semicolons or asterisks.

The class, var and rsrcID operands can be placed in a file, one set of operands per line, instead of being specified as command arguments. Use the -f flag to specify the name of the file to the command. If the -f flag is used, any operands to the command are ignored. Within the file, null strings are specified as two adjacent double quotation marks. A completely wildcarded resource ID can either be a single asterisk (*) or an asterisk in double quotation marks ("*"). The arguments must be separated by blank spaces or tabs on each line.

Some examples of using wildcards in the rsrcID argument follow. For these examples, assume the class and var arguments are null strings. If either the class or var arguments or both are not null strings, targets for the query are restricted accordingly. In the first three examples, all variables whose resource IDs are defined to contain the elements NodeNum, VG and LV, and only those elements, are matched.

1. In this example, only one instance is matched:

   ```
   NodeNum=5;VG=rootvg;LV=hd4
   ```

2. In this example, one instance from each node is matched:

   ```
   NodeNum=*;VG=rootvg;LV=hd4
   ```

3. In this example, all instances of the matching resource variables are matched:

   ```
   NodeNum=*;VG=*;LV=*
   ```

4. In this example, all variables whose resource IDs are defined to contain only the element NodeNum are matched. The instances matched are associated with node 9:

   ```
   NodeNum=9
   ```

5. In this example, the same set of variables are matched, but all instances of each variable are matched:

   ```
   NodeNum=*
   ```

6. In this example, all variables whose resource IDs are defined to contain elements NodeNum and VG, as well as zero or more additional elements, are matched. The instances matched are associated with node 9:

   ```
   NodeNum=9;VG=*;*
   ```

7. In this example, all variables whose resource IDs are defined to contain the element NodeNum, as well as zero or more additional elements, are matched. All instances of the variables are matched:

```
NodeNum=*;*
```

Given the flexibility in specifying resource variables for query, it is possible that no resource variable instance or resource variable definition will match. If there is no match appropriate error information is reported, either in the form described above or as follows.

If the specification of the class, var or rsrcID arguments are in error, the output line contains an error message, symbolic error codes and the specified class name, resource variable name, and resource ID.

Flags

-H *domain*
Queries resource variables in the HACMP domain specified by *domain*.

-S *domain*
Queries resource variables in the SP domain specified by *domain*.

-c
Queries current resource variable values.

-d
Queries resource variable definitions but produces short form output.

-i
Queries instances of resource variables.

-f *file*
Queries resource variables specified in *file*.

-h
Displays a usage statement.

Parameters

class
Specifies the name of the resource variable class or a null string.

var
Specifies the name of the resource variable or a null string.

rsrcID
Specifies a resource ID or an asterisk.

Security

You must have root privilege and write access to the SDR to run this command.

You should be running on the control workstation. Before running this command, you must set the SP_NAME environment variable to the appropriate system partition name.

Exit Status

0
Indicates the successful completion of the command.

1
Indicates that an error occurred. It is accompanied by one or more error messages that indicate the cause of the error.

Restrictions

This command is valid in a PSSP environment only.

Standard Output

When the command executes successfully, it writes the following informational messages:

```
Reading Event Management data for partition syspar_name
CDB=new_EMCDB_file_name Version=EMCDB_version_string
```

Standard Error

This command writes error messages (as necessary) to standard error.

Examples

1. To obtain the definitions of all resource variables in the current cluster and place the output in a file, enter:

   ```
   haemqvar -H HAcluster > vardefs.out
   ```

2. To obtain a short form list of all resource variables whose resource IDs contain the element VG, in the HACMP cluster named HAcluster, enter:

   ```
   haemqvar -H HAcluster -d "" "" "VG;*"
   ```

3. To obtain resource variables whose resource IDs contain only the elements VG and NodeNum, enter:

   ```
   haemqvar -H HAcluster -d "" "" "VG;NodeNum"
   ```

Location

/opt/rsct/bin/haemqvar
Location of the `haemqvar` command

Files

/opt/rsct/install/config/haemloadlist
Contains the default configuration data for the Event Management subsystem

Implementation Specifics

This command is part of the Reliable Scalable Cluster Technology (RSCT) fileset.

haemtrcoff Command

Purpose

Turns tracing off for the Event Manager daemon.

Syntax

`haemtrcoff -s` *subsys_name* `-a` *trace_list*

Description

The haemtrcoff command is used to turn tracing off for specified activities of the Event Manager daemon. Trace output is placed in an Event Management trace log for the system partition.

Flags

-s *subsys_name*
Specifies the name of the Event Management subsystem. On a node this is emsvcs. This argument must be specified.

-a *trace_list*
Specifies a list of trace arguments. Each argument specifies the type of activity for which tracing is to be turned off. At least one argument must be specified. If more than one argument is specified, the arguments must be separated by commas. The list may not include blanks.

Parameters

The following trace arguments can be specified:

init
Stops tracing the initialization of the Event Manager daemon.

config
Stops dumping information from the configuration file.

insts
Stops tracing resource variable instances that are handled by the daemon.

rmctrl
Stops tracing Resource Monitor control.

cci
Stops tracing the client communication (internal) interface.

emp
Stops tracing the event manager protocol.

obsv
Stops tracing resource variable observations.

evgn
Stops tracing event generation and notification.

reg
Stops tracing event registration and unregistration.

pci
Stops tracing the peer communication (internal) interface.

msgs
Stops tracing all messages that come to and are issued from the daemon.

query
Stops tracing queries that are handled by the daemon.

gsi
Stops tracing the Group Services (internal) interface.

eval
Stops tracing expression evaluation.

rdi
Stops tracing the reliable daemon (internal) interface.

sched
Stops tracing the internal scheduler.

shm
Stops tracing shared memory management activity.

all
Stops tracing all activities.

all_but_msgs
Stops tracing all activities except for messages. Message activity is defined by the msgs argument.

Security

You must have root privilege and write access to the SDR to run this command.

You should be running on the control workstation. Before running this command, you must set the SP_NAME environment variable to the appropriate system partition name.

Exit Status

0
Indicates the successful completion of the command.

1
Indicates that an error occurred. It is accompanied by one or more error messages that indicate the cause of the error.

Restrictions

Do not use this command during normal operation. Use this command only under the direction of the IBM Support Center. It provides information for debugging purposes and may degrade the performance of the event management subsystem or anything else that is running in the system partition.

Standard Output

When the command executes successfully, it writes the following informational messages:

```
Reading Event Management data for partition syspar_name
CDB=new_EMCDB_file_name Version=EMCDB_version_string
```

Standard Error

This command writes error messages (as necessary) to standard error.

Examples

1. To turn off all tracing for the Event Management subsystem on one of the cluster nodes, log in to the node and enter:

   ```
   haemtrcoff -s emsvcs -a all
   ```

2. To turn off all tracing of initialization and configuration for the Event Management subsystem on a cluster node, log in to the node and enter:

   ```
   haemtrcoff -s emsvcs -a init,config
   ```

Location

/opt/rsct/bin/haemtrcoff
Location of the `haemtrcoff` command

Files

/var/ha/log/em.trace.cluster_name
Contains the trace log of the `haemd` daemon on the cluster named *cluster_name*

/var/ha/log/em.msgtrace.cluster_name
Contains message trace output from the Event Manager daemon on the cluster named *cluster_name*

Implementation Specifics

This command is part of the Reliable Scalable Cluster Technology (RSCT) fileset.

haemtrcon Command

Purpose

Turns tracing on for the event manager daemon.

Syntax

`haemtrcon -s` *subsys_name* `-a` *trace_list*

Description

The `haemtrcon` command is used to turn tracing on for specified activities of the event manager daemon. Trace output is placed in an event management trace log for the system partition. When used, the `regs`, `dinsts`, `iolists`, and `olists` parameters perform a one-time trace. The specified information is placed in the trace log, but no further tracing is done.

Flags

-s *cluster_name*
Specifies the name of the event management subsystem. On a node, *cluster_name* is `emsvcs`. This flag and parameter must be specified.

-a *trace_list*
Specifies a list of trace parameters. Each parameter specifies the type of activity for which tracing is to be turned on. At least one parameter must be specified. If more than one parameter is specified, the parameters must be separated by commas. The list may not include blanks.

Parameters

The following trace parameters can be specified:

init
Traces the initialization of the event manager daemon.

config
Dumps information from the configuration file.

insts
Traces resource variable instances that are handled by the daemon.

rmctrl
Traces resource monitor control.

cci
Traces the client communication (internal) interface.

emp
Traces the event manager protocol.

obsv
Traces resource variable observations.

evgn
Traces event generation and notification.

reg
Traces event registration and unregistration.

pci
Traces the peer communication (internal) interface.

msgs
Traces all messages that come to and are issued from the daemon.

query
Traces queries that are handled by the daemon.

gsi
Traces the group services (internal) interface.

eval
Traces expression evaluation.

rdi
Traces the reliable daemon (internal) interface.

sched
Traces the internal scheduler.

shm
Traces shared memory management activity.

all
Traces all activities.

all_but_msgs
Stops tracing all activities except for messages. Message activity is defined by the msgs argument.

regs
Traces currently registered events.

dinsts
Traces all resource variable instances known to the daemon.

iolists
Traces immediate observation lists

olists
Traces observation lists

Restrictions

Do not use this command during normal operation. Use this command only under the direction of the IBM Support Center. It provides information for debugging purposes and may degrade the performance of the event management subsystem or anything else that is running in the system partition.

Implementation Specifics

This command is part of the Reliable Scalable Cluster Technology (RSCT) fileset.

Examples

1. To turn on all tracing for the event management subsystem on one of the cluster nodes, log in to the node and enter:

```
haemtrcon -s emsvcs -a all
```

2. To turn on all tracing of initialization and configuration for the event management subsystem on a cluster node, log in to the node and enter:

```
haemtrcon -s emsvcs -a init,config
```

Location

/opt/rsct/bin/haemtrcon
Location of the `haemtrcon` command

haemunlkrm Command

Purpose

Unlocks and starts a resource monitor.

Syntax

`haemunlkrm -s` *subsys_name* `-a` *resmon_name*

Description

If the event management daemon cannot successfully start a resource monitor after three attempts within a two-hour interval, or if the daemon has successfully connected to the instances of a resource monitor *n* times within a two-hour interval, the resource monitor is "locked" and no further attempts are made to start it or to connect to any of its instances. *n* is 3 in an HACMP/ES cluster. Once the cause of the failure is determined and the problem corrected, the `haemunlkrm` command can be used to unlock the resource monitor and attempt to start it or connect to the resource monitor instances.

The status of the event manager daemon, as displayed by the `lssrc` command, indicates whether a resource monitor is locked.

Flags

-s *subsys_name*
Specifies the name of the event management subsystem. On a node, *subsys_name* is `emsvcs`. This flag and parameter must be specified.

-a *resmon_name*
Specifies the name of the resource monitor to unlock and start.

Parameters

The following trace parameters can be specified:

init
Traces the initialization of the event manager daemon.

config
Dumps information from the configuration file.

insts
Traces resource variable instances that are handled by the daemon.

rmctrl
Traces resource monitor control.

cci
Traces the client communication (internal) interface.

emp
Traces the event manager protocol.

obsv
Traces resource variable observations.

evgn
Traces event generation and notification.

reg
Traces event registration and unregistration.

pci
Traces the peer communication (internal) interface.

msgs
Traces all messages that come to and are issued from the daemon.

query
Traces queries that are handled by the daemon.

gsi
Traces the group services (internal) interface.

eval
Traces expression evaluation.

rdi
Traces the reliable daemon (internal) interface.

sched
Traces the internal scheduler.

shm
Traces shared memory management activity.

all
Traces all activities.

all_but_msgs
Stops tracing all activities except for messages. Message activity is defined by the msgs argument.

regs
Traces currently registered events.

dinsts
Traces all resource variable instances known to the daemon.

iolists
Traces immediate observation lists

olists
Traces observation lists

Security

You must have root privilege and write access to the SDR to run this command.

You should be running on the control workstation. Before running this command, you must set the SP_NAME environment variable to the appropriate system partition name.

Exit Status

0
Indicates the successful completion of the command.

1
Indicates that an error occurred. It is accompanied by one or more error messages that indicate the cause of the error.

Restrictions

Do not use this command during normal operation. Use this command only under the direction of the IBM Support Center. It provides information for debugging purposes and may degrade the performance of the event management subsystem or anything else that is running in the system partition.

Standard Output

When the command executes successfully, it writes the following informational messages:

```
Reading Event Management data for partition syspar_name
CDB=new_EMCDB_file_name Version=EMCDB_version_string
```

Standard Error

This command writes error messages (as necessary) to standard error.

Examples

1. This example applies to unlocking a resource monitor on a node.

   If the output of the `lssrc` command indicates that the program resource monitor `IBM.PSSP.harmpd` is locked, correct the condition that prevented the resource monitor from being started and enter:

   ```
   haemunlkrm -s emsvcs -a IBM.PSSP.harmpd
   ```

Location

/opt/rsct/bin/haemunlkrm
Location of the `haemunlkrm` command

Files

/var/ha/log/em.trace.*cluster_name*
Contains the trace log of the haemd daemon on the cluster named *cluster_name*.

/var/ha/log/em.msgtrace.cluster_name
Contains message trace output from the event manager daemon on the cluster named *cluster_name*.

hagsd Daemon

Purpose

Observes resource variable instances that are updated by resource monitors and generates and reports events to client programs.

Syntax

`hagsd [-a] [-s] [-k] [-d] [-c] [-u] [-t] [-o] [-r] [-h]` *daemon_name*

Description

The `hagsd` daemon is part of the group services subsystem, which provides a general-purpose facility for coordinating and monitoring changes to the state of an application that is running on the nodes of a cluster. This daemon provides most of the services of the subsystem. *daemon_name* specifies the name used by the daemon to name log files and identify its messages in the AIX error log.

One instance of the `hagsd` daemon executes on each cluster node. The `hagsd` daemon is under the control of the system resource controller (SRC).

Because the daemon is under SRC control, it is better not to start it directly from the command line. It is normally called by the `grpsvcsctrl` command, which is in turn called by the cluster startup process. If you must start or stop the daemon directly, use the `startsrc` or `stopsrc` command.

Flags

-a
Adds the subsystems.

-s
Starts the subsystems.

-k
Stops the subsystems.

-d
Deletes the subsystems.

-c
Cleans the subsystems, that is, delete them from all system partitions.

-u
Unconfigures the subsystems from all system partitions.

-t
Turns tracing on for the subsystems.

-o
Turns tracing off for the subsystems.

-r
Refreshes the subsystem.

-h
Displays usage information.

Parameters

daemon_name
Specifies the name used by the daemon to name log files and identify its messages in the AIX error log.

Security

You must have `root` privilege to run this script.

Exit Status

0
Indicates the successful completion of the command.

1
Indicates that an error occurred.

Restrictions

This command is valid in a PSSP environment only.

Standard Output

When the `-h` flag is specified, this command's usage statement is written to standard output.

Standard Error

This command writes error messages (as necessary) to standard error.

Examples

1. To add the group services subsystems to the SRC in the current system partition, set the SP_NAME environment variable to the appropriate system partition name and enter:

   ```
   hagsctrl -a
   ```

2. To start the group services subsystems in the current system partition, set the SP_NAME environment variable to the appropriate system partition name and enter:

   ```
   hagsctrl -s
   ```

3. To stop the group services subsystems in the current system partition, set the SP_NAME environment variable to the appropriate system partition name and enter:

   ```
   hagsctrl -k
   ```

4. To delete the group services subsystems from the SRC in the current system partition, set the SP_NAME environment variable to the appropriate system partition name and enter:

   ```
   hagsctrl -d
   ```

5. To clean up the group services subsystems on all system partitions, enter:

   ```
   hagsctrl -c
   ```

6. To unconfigure the group servicess subsystem from all system partitions, on the control workstation, enter:

   ```
   hagsctrl -u
   ```

7. To turn tracing on for the group services daemon in the current system partition, set the SP_NAME environment variable to the appropriate system partition name and enter:

   ```
   hagsctrl -t
   ```

8. To turn tracing off for the group services daemon in the current system partition, set the SP_NAME environment variable to the appropriate system partition name and enter:

   ```
   hagsctrl -o
   ```

Location

/opt/rsct/bin/hagsd
Contains the hagsd daemon

Files

/var/ha/log/hags_*nodenum_instnum*. *syspar_name*
Contains the log of the hagsd daemons on the nodes.

/var/ha/log/hags.*syspar_name_nodenum_instnum.syspar_name*
Contains the log of each hagsd daemon on the control workstation.

The file names include the following variables:

- *nodenum* is the node number on which the daemon is running
- *instnum* is the instance number of the daemon
- *syspar_name* is the name of the system partition in which the daemon is running.

hagsns Command

Purpose

Gets group services name server information.

Syntax

hagsns [-h *host*] [-c] -g *group_name*

hagsns [-h *host*] [-c] -s *subsystem_name*

hagsns [-h *host*] [-c] -p *subsystem_pid*

Description

Use the hagsns command to query the status of the group services nameserver.

Flags

-c
Forces the output as "English_only." If the -c flag is not specified, the daemon's locale will be used for the output.

-g *group_name*
Specifies a group of subsystems to get status for. The command is unsuccessful if the *group_name* variable is not contained in the subsystem object class.

-h *host*
Specifies the host to obtain name server status for.

-p *subsystem_pid*
Specifies a particular instance of the *subsystem_pid* to obtain name server status for.

-s *subsystem_name*
Specifies a subsystem to get status for. The *subsystem_name* variable can be the actual subsystem name or the synonym name for the subsystem. The command is unsuccessful if the *subsystem_name* variable is not contained in the subsystem object class.

Parameters

daemon_name
Specifies the name used by the daemon to name log files and identify its messages in the AIX error log.

Security

You must have root authority to run this command.

Exit Status

0
Indicates that the command completed successfully.

a non-zero value
Indicates that an error occurred.

Restrictions

This command is valid in a PSSP environment only.

Standard Output

When the -h flag is specified, this command's usage statement is written to standard output.

Standard Error

This command writes error messages, as necessary, to standard error.

Examples

To get domain information from the group services subsystem, enter:

```
hagsns -c -s cthags
```

or

```
hagsns -s cthags
```

The output will look like this:

```
HA GS NameServer Status
NodeID=1.16, pid=14460, domainID=6.14, NS established,CodeLevel=GSLevel(DRL=8)
NS state=kCertain, protocolInProgress=kNoProtocol,outstandingBroadcast=KNoBcast
Process started on Jun 19 18:34:20, (10d 20:19:22) ago, HB connection took (19:14:9).
Initial NS certainty on Jun 20 13:48:45, (10d 1:4:57) ago, taking (0:0:15).
Our current epoch of Jun 23 13:05:19 started on (7d 1:48:23), ago.
Number of UP nodes: 12
List of UP nodes: 0 1 5 6 7 8 9 11 17 19 23 26
```

In this example, domainID=6.14 means that node 6 is the name server (NS) node. The domain ID consists of a node number and an incarnation number. The incarnation number is an integer, incremented whenever the group services daemon is started. NS established means that the name server was established.

Location

/opt/rsct/bin/hagsns
Contains the hagsns command

Files

/var/ha/log/hags_*nodenum_instnum*. *syspar_name*
Contains the log of the hagsd daemons on the nodes.

/var/ha/log/hags.*syspar_name_nodenum_instnum.syspar_name*
Contains the log of each hagsd daemon on the control workstation.

The file names include the following variables:

- *nodenum* is the node number on which the daemon is running.
- *instnum* is the instance number of the daemon.
- *syspar_name* is the name of the system partition in which the daemon is running.

hagsvote Command

Purpose

Gets vote information for group services groups.

Syntax

hagsvote [-h *host*] [-l] [-a *argument*] [-c] -g *group_name*

`hagsvote` [`-h` *host*] [`-l`] [`-a` *argument*] [`-c`] `-s` *subsystem_name*

`hagsvote` [`-h` *host*] [`-l`] [`-a` *argument*] [`-c`] `-p` *subsystem_pid*

Description

Use the `hagsvote` command to query the status of voting protocols for group services.

Flags

-a
Specifies a group services group name. This group name is different from that of the `-g` flag. In this case, the group was created from the client's first call to join the protocol.

-c
Requests the canonical output of the group services voting information. The output is displayed in English regardless of the installed language locale. If `-c` is not specified, the daemon's locale will be used for the output.

-g *group_name*
Specifies a group of subsystems to get status for. The command is unsuccessful if the *group_name* variable is not contained in the subsystem object class.

-h *host*
Specifies the host name which is getting status.

-l
Requests detailed output in "long" form.

-p *subsystem_pid*
Specifies a particular instance of the *subsystem_pid* variable to get the vote for.

-s *subsystem_name*
Specifies a subsystem to vote on. The *subsystem_name* variable can be the actual subsystem name or the synonym name for the subsystem. The command is unsuccessful if the *subsystem_name* variable is not contained in the subsystem object class.

Parameters

daemon_name
Specifies the name used by the daemon to name log files and identify its messages in the AIX error log.

Security

You must have `root` privilege to run this command.

Exit Status

0
Indicates the successful completion of the command.

non-zero
Indicates that an error occurred.

Restrictions

This command is valid in a PSSP environment only.

Standard Output

This command writes error messages (as necessary) to standard error.

Standard Error

This command writes error messages, as necessary, to standard error.

Examples

1. To see information about the status of the voting protocol for the group `theSourceGroup` in long form, enter:

```
hagsvote -ls cthags -a theSourceGroup (locale-dependent)
```

   The output will look like this:

```
Number of groups: 4
Group name [theSourceGroup] GL node [26] voting data:
GL in phase [1] of n-phase protocol of type [Join].
Local voting data:
Number of providers: 1
Number of providers not yet voted: 1 (vote not submitted).
Given vote: [No vote value] Default vote: [No vote value]
ProviderID Voted? Failed? Conditional?
[101/26] No No Yes
Global voting data:
Number providers not yet voted: 1
Given vote: [No vote value] Default vote: [No vote value]
Nodes that have voted: []
Nodes that have not voted: [26]
```

   The first line of the output means that the total number of groups is 4. The second line provides the group name and the group leader node (in this case 26). The remaining lines give the voting data:

   - The group leader is in phase 1 of a n-phase protocol.
   - The protocol is the Join protocol.
   - For the local node, it has 1 provider, the number of providers which have not voted yet is 1.
   - No default vote value is given and no vote value is given.
   - Under the line "ProviderID Voted? Failed? Conditional?," "[101/16] No No Yes," means that the provider ID is 101/26, not voted yet, not failed, but wait for the vote (so it is conditional).

   The output then shows the global voting status:

   - The number of providers that have not voted yet is 1.
   - No vote value given yet, no default vote value.
   - The nodes that have voted is none.
   - The nodes that have not voted is node 26.

2. In the following example, the meaning of each line of output is the same as in the first example except that node 26 is the group leader node.

```
hagsvote -ls cthags -a theSourceGroup -c (canonical form)
```

   The output will look like this:

```
Number of groups: 4
Group Name: theSourceGroup
GL Node: 26 (I am GL)
Current phase number of an n-phase protocol: 1
Protocol name: [Join]
Local voting data:
Number of local providers: 1
Number of local providers not yet voted: 1 (vote not submitted)
Given vote: [No vote value] Default vote: [No vote value]Global voting data:
Number of nodes in group: 1
Number of global providers not yet voted: 1
Given vote: [No vote value] Default vote: [No vote value]
Nodes that have voted: []
Nodes that have not voted: [26]
```

Location

/opt/rsct/bin/hagsvote
Contains the `hagsvote` command

Files

`/var/ha/log/hags_`*nodenum_instnum. syspar_name*
Contains the log of the `hagsd` daemons on the nodes.

`/var/ha/log/hags.`*syspar_name_nodenum_instnum.syspar_name*
Contains the log of each `hagsd` daemon on the control workstation.

The file names include the following variables:

- *nodenum* is the node number on which the daemon is running
- *instnum* is the instance number of the daemon
- *syspar_name* is the name of the system partition in which the daemon is running.

halt or fasthalt Command

Purpose

Stops the processor.

Syntax

{**halt** | **fasthalt**} [**-l**] [**-n**] [**-p**] [**-q**] [**-y**]

Description

The **halt** command writes data to the disk and then stops the processor. The machine does not restart. Only a root user can run this command. Do not use this command if other users are logged in to the system. If no other users are logged in, the **halt** command can be used. Use the **halt** command if you are not going to restart the machine immediately. When the message `....Halt completed....` is displayed, you can turn off the power.

The **halt** command logs the shutdown by using the **syslogd** command and places a record of the shutdown in `/var/adm/wtmp`, the login accounting file. The system also writes an entry into the error log that states that the system was shut down.

The **fasthalt** command stops the system by calling the **halt** command. The **fasthalt** command provides BSD compatibility.

Flags

Item	Description
-l	Does not log the halt in the accounting file. The **-l** flag does not suppress accounting file update. The **-n** and **-q** flags imply the **-l** flag.
-n	Prevents the **sync** before it stops.
-p	Halts the system without a power down. **Note:** The **-p** flag has no effect if used in combination with flags not requiring a permanent halt. Power is still turned off if other operands request a delayed power-on and restart.

Item	Description
-q	Causes a quick halt. **Notes:** • Running the **halt** command with **-q** flag does not issue **sync**, so the system halts immediately. • If you run the **halt** command with the **-q** flag in a workload partition (WPAR), the **halt** command can stop the WPAR and bring it to the D (defined) state. The WPAR might not stop completely and bring the WPAR to the T (transitional) state because of the timeout condition or a delay caused while unmounting the file system.
-y	Halts the system from a dial-up operation.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To halt the system without logging the halt in the accounting file, enter the following command:

```
halt -l
```

2. To halt the system quickly, enter the following command:

```
halt -q
```

3. To halt the system from a dial-up operation, enter the following command:

```
halt -y
```

Files

Item	Description
/etc/rc	Specifies the system startup script.
/var/adm/wtmp	Specifies the login accounting file.

hangman Command

Purpose

Starts the hangman word-guessing game.

Syntax

hangman [*File*]

Description

The **hangman** command chooses a word of at least seven letters from a standard dictionary. The *File* parameter specifies an alternate dictionary. You guess the word by guessing letters one at a time. You are allowed seven mistakes.

When you start hangman, the game displays:

```
guesses: word: ....... errors: 0/7
guess:
```

The `guesses` displays the letters you have used as guesses. Every letter you guess is listed after `guesses`. The `word: .......` displays the number of letters in the mystery word. In this case there are seven `.` (periods) so there are seven letters in the word. As you correctly guess letters, the game replaces the appropriate `.` with the correct letter. The `errors: 0/7` displays the number of incorrect guesses. You enter your letter guess at the `guess:` prompt. For example:

```
guesses: word: .......... errors: 0/7
guess: q
guesses: q word: .......... errors: 1/7
guess: a
guesses: aq word: .a....a... errors: 1/7
guess: b
guesses: abq word: .a....a... errors 2/7
guess: j
guesses: abjq word: .a....a... errors: 3/7
guess: s
guesses: abjqs word: .a....a..s errors: 3/7
guess: z
guesses: abjqsz word: .a....a..s errors: 4/7
guess: y
guesses: abjqsyz word: .a....a..s errors: 5/7
guess: k
guesses: abjkqsyz word: .a....a..s errors: 6/7
guess: x
the answer was calculates, you blew it
```

To quit the game, press the Interrupt (Ctrl-C) or End Of File (Ctrl-D) key sequence.

Files

Item	Description
/usr/games	Location of the system's games.

hash Command

Purpose

Remembers or reports command path names.

Syntax

To Add the Path of a Command to the Path Name List:

hash [*Command* ...]

To Clear Path Name List:

hash -r

Description

The **hash** command affects the way the current shell remembers a command's path name, either by adding a path name to a list or purging the contents of the list.

When no parameter or flag is specified, the **hash** command reports to standard output the contents of the path name list. The report includes the path name of commands in the current shell environment that were found by previous **hash** command invocations. The display may also contain those commands invoked and found through the normal command search process.

Note: Shell built-in commands are not reported by the **hash** command.

You can use the **-r** flag to clear the contents of the command path name list. Path names can also be cleared from the list by resetting the value of the **PATH** environment variable. In the simplest form, this would be achieved by entering:

```
PATH="$PATH"
```

If the *Command* parameter is used, the **hash** command searches for the path name of the specified command and adds this path to the list. Do not use a / (slash) when you specify the command.

Since the **hash** command affects the current shell environment, it is provided as a Korn shell or POSIX shell regular built-in command. If the **hash** command is called in a separate command execution environment, as in the following examples, it will not affect the command search process of the caller's environment:

```
nohup hash -r
find . -type f | xargs hash
```

Using the **hash** command is equivalent to using the **alias -t** command.

Flag

Item	Description
-r	Clears the contents of the path name list.

Parameter

Item	Description
Command	Specifies the *Command* to add to the path name list.

Exit Status

The following exit values are returned:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To find the path name of the **wc** command and add it to the path name list, enter:

   ```
   hash wc
   ```

2. To clear the contents of the path name list, enter:

   ```
   hash -r
   ```

Files

Item	Description
/usr/bin/ksh	Contains the Korn shell **hash** built-in command.
/usr/bin/hash	Contains the **hash** command.

hatsoptions Command

Purpose

Controls topology services options on a node or a control workstation.

Syntax

`hatsoptions [-s] [-d]`

Description

Before this command can be executed, environment variable HB_SERVER_SOCKET must be set to the location of the UNIX domain socket used by the topology services subsystem. The statement below can be used:

```
export HB_SERVER_SOCKET=/var/ha/soc/hats/server_socket.partition name
```

Alternatively, variable HA_SYSPAR_NAME can be set to the partition name.

The topology services daemon must be running in order for this command to be successful.

`hatsoptions` can be used to control a number of options in topology services. Option `-s` instructs the topology services daemon to reject messages that are apparently delayed. This can be used in very large system configurations, where messages are sometimes delayed in the network or in the sender and receiver nodes. Use this option only if the Time-Of-Day clocks are synchronized across all the nodes and the control workstation. Otherwise messages may be incorrectly discarded when the sender's Time-Of-Day clock is behind the receiver's.

Option `-d` instructs the topology services daemon not to reject messages that are apparently delayed. This is the default.

Flags

-s
Instructs the topology services daemon to reject messages that are apparently delayed.

-d
Instructs the topology services daemon not to reject messages that are apparently delayed (this is the default).

Security

You must have `root` privilege to run this command.

Exit Status

0
Indicates the successful completion of the command.

1
Indicates the command was unsuccessful.

Environment Variables

HB_SERVER_SOCKET
This environment variable should be set before this command can be executed. It must be set to the location of the UNIX domain socket used by topology services clients to connect to

the topology services daemon. This environment variable must be set to `/var/ha/soc/hats/server_socket.`*partition name*.

HA_SYSPAR_NAME
If HB_SERVER_SOCKET is not set, then HA_SYSPAR_NAME must be set to the partition name.

Restrictions

This command is valid in a peer domain only.

Standard Output

When the `-h` flag is specified, this command's usage statement is written to standard output. All verbose messages are written to standard output.

Standard Error

This command writes error messages (as necessary) to standard error.

Examples

To instruct the topology services daemon on the local node to start discarding apparently delayed messages, enter:

```
export HA_SYSPAR_NAME=partition1

/opt/rsct/bin/hatsoptions -s
```

Location

/opt/rsct/bin/hatsoptions
Contains the `hatsoptions` command

Files

`/var/ha/soc/hats/server_socket.`*partition name*

head Command

Purpose

Displays the first few lines of a file.

Syntax

head [**-***Count* | **-c** *Number* | **-n** *Number*] [*File* ...]

Description

The **head** command writes to standard output a specified number of lines or bytes of each of the specified files, or of the standard input. If no flag is specified with the **head** command, the first 10 lines are displayed by default. The *File* parameter specifies the names of the input files. An input file must be a text file. When more than one file is specified, the start of each file will look like the following:

`==> `*filename*` <==`

To display a set of short files, identifying each one, enter:

`example% head -9999 `*filename1 filename2...*

Note: The standard input is used if you do not specify any file parameters or if you specify the '-' parameter.

Flags

Item	Description
-*Count*	Specifies the number of lines from the beginning of each specified file to be displayed. The *Count* variable must be a positive decimal integer. This flag is equivalent to the **-n** *Number* flag, but should not be used if portability is a consideration.
-c *Number*	Specifies the number of bytes to display. The *Number* variable must be a positive decimal integer.
-n *Number*	Specifies the number of lines from the beginning of each specified file to be displayed. The *number* variable must be a positive decimal integer. This flag is equivalent to the **-***Count* flag.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

To display the first five lines of the `Test` file, enter:

```
head -5 Test
```

OR

```
head -n 5 Test
```

help Command

Purpose

Provides information for new users.

Syntax

help

Description

The **help** command presents a one-page display of information for new users. Information is available for the following topics:

- Concatenating or displaying files.
- Editing lines interactively.
- Sending and receiving mail.
- Reading system messages.

- Changing password file information.
- Identifying current users of the system.
- Sending messages to the other users on the system.
- Displaying the contents of directories.
- Viewing information on the Source Code Control System.
- Setting terminal modes.

Examples

To obtain help, type `help` at the command line.

hfistat Command

Purpose

Displays the performance statistics of the host fabric interface.

Syntax

hfistat [-O options] [interval [count]]

hfistat [-h]

Description

The **hfistat** command displays performance statistics related to the host fabric interface.

The following information are the descriptions of the column headings in the output table.

Type	Column name with description
HFI	**HFI** Host fabric interface identifier (0, 1, ...) identifies the interface whose statistics are displayed. **packets - sent** Aggregate packet sent count (56-bit counter) is the number of packets sent to the cluster network, irrespective of the window it is sent from. **packets - imm_send** Aggregate immediate send packet sent count (56-bit counter) is the number of packets that must be sent immediately, irrespective of the window it is sent from. **packets - receive** Aggregate packet received count (56-bit counter) is the number of packets successfully received from the cluster network, irrespective of the window it is received from. The **packets - receive** counter increments whenever the packet received counter of any window increments. **sent_packets - fullRDMA** Aggregate full-RDMA packet sent count (56-bit counter) is the number of full-RDMA packets sent, irrespective of the window it is sent from. **sent_packets - halfRDMA** Aggregate half-RDMA packet sent count (56-bit counter) is the number of half-RDMA packets sent, irrespective of the window it is sent from. The **sent_packets - halfRDMA** counter does not increment for notifications.

Type	Column name with description
	sent_packets - smallRDMA Aggregate small-RDMA packet sent count (56-bit counter) is the number of small-RDMA packets sent, irrespective of the window it is sent from. The **sent_packets - smallRDMA** counter does not increment for notifications. **sent_packets - ip** Aggregate IP packet sent count (56-bit counter) is the number of IP packets sent, irrespective of the window it is sent from. **sent_packets - cau** Aggregate CAU packet sent count (56-bit counter) is the number of CAU packets sent, irrespective of the window it is sent from. **sent_packets - gups** Aggregate GUPS packet sent count (56-bit counter) specifies the number of GUPS packets sent, irrespective of the window it is sent from. **dropped_packets – sending** Aggregate packet dropped from sending count (56-bit counter) specifies the number of packets dropped, and not sent by the FIFO meant for sending packets, irrespective of the window. **dropped_packets – receiving** Aggregate packet dropped from received count (56-bit counter) specifies the number of packets from the ISR that are dropped and not received, irrespective of the window it is received from. **xlat – wait** Address xlat wait count (56-bit counter) specifies the number of missed translations and that are pending. The **xlat – wait** register resets when you write anything to this register.
ISR	**HFI** Host fabric interface identifier (0, 1, ...) identifies the interface whose statistics are displayed. **cycBlocked – sending** The cycles blocked from sending (64-bit) counter increments every 2 - 3 GHz chip cycle when the waiting flit cannot be sent over the link. **flits - sent** The flits sent (64-bit counter) is similar to the cycles blocked counter except that this counter increments each time a flit header passes over the corresponding ISR interface. **flits - dropped** The flits dropped (40-bit counter) is the number of flits that are dropped and counted whenever certain events happen such as the following items: 1. A port's link status bit is off. 2. The ISR ID is not valid. **link – retries** The link level retries (24-bit counter) counter increments each time a flit is removed from the link replay buffer and sent over the link again due to an error.
NMMU	**dyn_prot_cache – hits** Nest memory management unit dynamic protection cache hits. **dyn_prot_cache – misses** Nest memory management unit dynamic protection cache misses. **ATLB – hits** Nest memory management unit address translation buffer hits. **ATLB – misses** Nest memory management unit address translation buffer misses.
CAU	**cycles – waiting** Cycles waiting on credit (nonindexed counter).

Type	Column name with description
Window-based	**HFI** Host fabric interface identifier (0, 1, ...) identifies the interface whose statistics are displayed. **Win** Window number (0, 1, 2 ...) identifies the window whose statistics are displayed. **packet_indicated – send** The packet-indicated sent count (56-bit counter) increments whenever a packet is sent that has the Packet-Indicated-Count bit in the header set. **packet_indicated – receive** The packet-indicated received count (56-bit counter) increments whenever a packet is received that has the packet-indicated-count bit in the header set, but before the packet is written to memory. **packets – sent** The packet sent count (56-bit counter) is the number of packets successfully sent to the cluster network and includes packets sent to the same HFI by sending them to the cluster network where they are wrapped back. **packets – received** The packet received count (56-bit counter) is the number of packets successfully received from the cluster network and includes packets received from the same HFI, which were wrapped back by the cluster network. **packet_dropped – sending** The packet dropped from sending count (40-bit counter) is the number of packets from a send FIFO that were dropped and not sent. **packet_dropped – receiving** The packet dropped from receiving count (40-bit counter) is the number of packets from the ISR that were dropped and not received. **immediate – send_pkts** The immediate send packet count (56-bit counter).

Flags

Item	Description
Options	Specifies the content and the presentation of a report. Use the `Options` parameter with the **-O** flag. `-O option1=value1,option2=value2,option3="value3 value4 value5"` The list of options must be comma-separated and the list of values must be enclosed in quotation marks (“ ”) and separated by spaces. Following are the supported options with their values: • *type = [window nonwindow hfi isr nmmu cau all]* The **type** option specifies that the **hfistat** command displays only the specified types of register values to be displayed. `Default value: hfi` You can specify the following values to the type option: **window** Displays the window-based performance statistics. **nonwindow** Displays the nonwindow-based performance statistics. **hfi** Displays the performance counter values for HFI. **isr** Displays the integrated switch router (ISR) register values. **nmmu** Displays the Nest Memory Management Unit (NMMU) register values. **cau** Displays the Collectives Acceleration Unit (CAU) register values. **all** Displays all the register values. • *display = [raw | delta]* The display option is used to dump the register values. *Default value: none* You can specify the following values with the display option: **raw** Dump the raw register values collected. **delta** Dump the delta values of the registers. **Note:** 1. The **hfistat** tool displays formatted output when the display option is not provided. 2. The raw and delta option values are mutually exclusive. • *hfi = [0 1 ...]* The **hfi** option specifies the list of host fabric interfaces for which the register values are reported. *Default value: All available HFIs in the system* **Note:** 1. You can specify a range of host fabric interfaces in one of the following ways: `hfistat –O hfi=”0 1 2 3”` `hfistat –O hfi=0-3` 2. An empty end of the list can be used to signify the last available host fabric interface. This example of the **hfi** option indicates the range from 1 to the last available host fabric interface. `hfistat –O hfi=1-`

Item	Description
	• *window = [0 1 2...]* The **window** option specifies the list of HFI window numbers for which the register values are reported. `Default value: All available HFI windows for the specified HFIs` **Note:** 1. You can specify a range of HFI window numbers in one of the following ways: `hfistat –O window=”210 211 212 213 214 215 216”` `hfistat –O window=210-216` 2. 4. An empty end of the list can be used to signify the last available HFI window number. This example specifies the **window** option that indicates the range from 0 to the last available HFI window. `hfistat –O window=0-` • *output = <filename>* The **output** option specifies the output file to be used instead of stdout. `Default value: None` **Note:** The filename is mandatory.
interval	Specifies the interval in seconds for the **hfistat** command to collect and print statistics. If the **interval** parameter is not specified, the **hfistat** command runs with the 2-second interval.
Count	Specifies the number of repetitions for the **hfistat** command to collect and print statistics. Use the **Count** parameter along with the interval option. If both the **Count** and the **interval** parameters are not specified, the **hfistat** command runs 10 times. If the **interval** parameter is specified and not the **Count** parameter, the **hfistat** command runs indefinitely.

Examples

1. 1. To display the HFI-based performance statistics for all available HFIs by using a 2-second interval for 10 iterations, run the following command:

```
# hfistat
```

2. 2. To display all the performance statistics for available HFIs including window-based performance statistics of all windows in a formatted output, run the following command:

```
# hfistat –O type=all 2 5
```

3. 3. To display only the window-based performance statistics for fewer windows (0-15) in a formatted output, run the following command:

```
# hfistat –O type=window,window=0-15
```

4. 4. To display the CAU register values for the HFI-1 in a formatted output for 10 samples (default) and an interval of 2 seconds (default), run the following command:

```
# hfistat –O type=cau,hfi=1
```

5. 5. To display both CAU and nest memory management unit (NMMU) register values in a formatted output, run the following command:

```
# hfistat –O type=”cau nmmu”
```

6. 6. To dump the raw register values of all the HFIs including window-based performance statistics for the window 0 with an interval of 2 seconds and 5 iterations, run the following command:

```
# hfistat –O display=raw,type=all,window=0 2 5
```

7. 7. To dump delta values for only ISR performance counters with a 2-second interval and 5 iterations, run the following command:

```
# hfistat -O display=delta,type=isr 2 5
```

Files

Item	Description
`/usr/bin/hfistat`	Contains the **hfistat** command.

hdcryptmgr Command

Purpose

Provides the cryptographic management of logical volumes (LV).

Syntax

```
hdcryptmgr action [-h] [flags] devicename
```

Description

Starting from IBM AIX 7.2 with Technology Level 5, you can run the **hdcryptmgr** command by specifying the *action* parameter to perform one of the following operations:

Table 9. hdcryptmgr command operations

Operation	*action* parameter	Description
Display encryption settings	**showvg**	Displays the data encryption status of the volume group
	showlv	Displays the data encryption status of the logical volume
	showmd	Displays encryption metadata for a specific device
	showconv	Displays status of all active and stopped encryption conversions
Control authentication methods	**authinit**	Initializes a primary key for data encryption in the logical volume
	authunlock or **authunl**	Authenticates to the encrypted logical volume to unlock the primary key of the logical volume
	authadd	Adds additional authentication methods
	authcheck or **authchk**	Checks the validity of an authentication method
	authdelete or **authdel**	Removes an authentication method

Table 9. hdcryptmgr command operations (continued)		
Operation	***action* parameter**	**Description**
Manage platform keystore (PKS) keys	**pksimport**	Imports the platform keystore (PKS) keys
	pksexport	Exports the PKS keys
	pksclean	Removes a PKS key
	pksshow	Displays status of the PKS keys
Convert the encryption status of the logical volume	**plain2crypt**	Enables encryption in a logical volume and encrypts the logical volume data
	crypt2plain	Decrypts the logical volume data and disables encryption in a logical volume

Displaying encryption settings

You can run the following actions with the **hdcryptmgr** command to display encryption settings:

showvg

Syntax:

```
hdcryptmgr showvg [-h] [device]
```

Displays the data encryption status of the specified volume groups. If you do not specify a volume group, this command shows the encryption status of all the volume groups.

```
# hdcryptmgr showvg
VG NAME / ID          ENCRYPTION ENABLED
EVG1                      yes
INSTALLVG                 yes
rootvg                    no
```

showlv

Syntax:

```
hdcryptmgr showlv [-h] [-v] device
```

Displays the data encryption status of a logical volume. You must specify the device name of a volume group or a logical volume by using the **-v** flag. When you specify a volume group, this command displays the data encryption status of all the logical volumes in the volume group. When you specify a logical volume, this command displays the data encryption status of the specified logical volume. If the data encryption capability is not enabled for the volume group, a message, which indicates that encryption is not enabled on the volume group, is displayed.

```
# hdcryptmgr showlv vg00
NAME                CRYPTO_STATUS    %ENCRYPTED       NOTE
lv00                unlocked         100
lv01                unlocked         100
lv03                not_enabled      0
lv04                locked           100
lv02                uninitialized    0
lv06                uninitialized    n/a              not_accessible
lv07                locked           100
fslv00              locked           1                encrypting
```

showmd

Syntax:

```
hdcryptmgr showmd [-h] [-v] device
```

Displays encryption metadata for a specific logical volume, volume group, or physical volume. You must specify the device name of a logical volume, volume group, or a physical volume. When you

specify a volume group, only the header and trailer encryption metadata of the specified volume group are displayed. When you specify a physical volume, the metadata of encrypted logical volumes are displayed even if the corresponding volume group is not varied on. When you specify a logical volume, the entire encryption metadata of the specific logical volume is displayed.

```
# hdcryptmgr showmd ELV1
.....
.....    Wed Jun 17 13:25:46 2020
.....    Device type : LV
.....    Device name : ELV1
.....

```

showconv

Syntax:

```
hdcryptmgr showconv [-h]
```

Displays the status of both active and stopped processes of logical volume that are being converted.

```
# hdcryptmgr showconv
NAME          TID/STATUS       %ENCRYPTED       DIRECTION        START_TIME
lv03          29557045         3                plain2crypt      Sun Feb 14 09:43:10 2021
fslv00        stopped/dirty    1                plain2crypt
```

Controlling authentication methods

The encryption function of the logical volume supports the following key-protection methods: passphrase, key file, key server management solution (such as IBM Security Key Lifecycle Manager), and Platform Keystore (PKS). The passphrase and key file protection methods require you to specify a password or a key file location manually. The key server management and PKS protection methods can be used to automatically unlock and activate the encrypted logical volume. For the key server authentication method to qualify as an automatic method, you must either store the client certificate password in PKS or choose no password for the client certificate. You can run the following actions with the **hdcryptmgr** command to control authentication methods:

authinit

Syntax:

```
hdcryptmgr authinit [-h] [-e algo_detail] [-n name] device
```

Initializes the primary key and encryption metadata for an encrypted logical volume. For each encrypted logical volume, the primary key and encrypted metadata must be initialized only once. A

first passphrase that is obtained from the key-protection method is added to the encryption metadata of the LV. You can specify the following flags or values for this *action* parameter:

-e
Specifies the data encryption algorithm, mode, and key length. The valid values of the **-e** flag are as follows:

prompt
Specifies that the encryption algorithm details will be prompted when the command runs.

[algorithm]:[b|B][key_len][:w]
Specifies the encryption algorithm details. The supported algorithms are Advanced Encryption Standard XTS mode (AES-XTS) 128 bits or 256 bits. The character **b** refers to bits (default) of the key, character **B** refers to bytes of the key, and the *key_len* variable refers to the length of the key. The *:w* parameter overwrites the default values of the volume group with the specified values. By default, when a volume group, in which encryption is enabled, is created, the default encryption algorithm is AES-XTS 128 bits.

-n
Specifies a name for the key-protection method.

device
Specifies the device name of the logical volume for which the key-protection method must be initialized.

authadd
Syntax:

```
hdcryptmgr authadd [-h] [-t type [-m method_detail]] [-n name] device
```

Adds an additional key-protection method to an encrypted logical volume in which a key-protection method is already initialized. To activate the authentication method that you added to an encrypted LV, the encrypted LV must be unlocked. This *action* parameter can be specified with the following flags or values:

-t
Specifies the key-protection type. The valid values are pwd, `keyfile`, `keyserv`, and `pks`.

-m
Specifies any additional information about the key-protection method that might include the following details:

- Input path to the authentication key file
- Key server ID in the `KeySvr` Object Data Manager (ODM) class

-n
Specifies a name for the key-protection method.

device
Specifies the device name of the logical volume for which the key-protection method must be added.

If you do not specify the required flags or values when you run the **hdcryptmgr authadd** command, you are prompted to specify the same. For information about registering key server information, see the **keysvrmgr** command.

authdelete or authdel
Syntax:

```
hdcryptmgr authdelete [-h] [-t type [-m method_detail]] [-i index] [-n name] [-f] device
```

Removes an initiated key-protection method. This *action* parameter can be specified with the following flags:

-t
Specifies the key-protection type. The valid values are pwd, `keyfile`, `keyserv`, and `pks`.

-m
Specifies any additional information about the key-protection method that might include the following details:

- Input path to the authentication key file
- Key server ID in the `KeySvr` ODM class

-i
Specifies the index of the key-protection method that must be deleted.

-n
Specifies the name of the key-protection method that must be deleted.

-f
Specifies the force option. This flag bypasses the authentication method checks to remove the key-protection method.

device
Specifies the device name of the logical volume for which the key-protection method must be deleted.

Only one key-protection method can be removed at a time. If you know the correct index or name of the key-protection method, you can specify the key-protection method by using the **-i** or **-n** flags. You can use the **-t** and **-m** flags to filter the list of existing key-protection methods. If multiple entries match the specified criteria, you are prompted to choose the key-protection method that must be removed.

Before the key-protection method is removed, the validity of the key-protection method is checked, unless the **-f** flag is used. You must authenticate to the LV with the selected key-protection method.

Note: Ensure that the logical volume has at least a passphrase key-protection method after performing the **authdelete** operation.

authunlock or authunl
Syntax:

```
hdcryptmgr authunlock [-h] [-t type [-m method_detail]] [-A] device
```

Authenticates to the encrypted LV and unlocks the encrypted logical volumes. This *action* parameter can be specified with the following flags or values:

-A
Authenticates to the encrypted LV by using the automatic key-protection methods that do not require any user inputs. You can use this flag at a volume group (VG) level only if the VG uses automatic key-protection methods, such as a key server management solution or PKS.

-t
Specifies the type of the key-protection method. The valid values are `pwd`, `keyfile`, `keyserv`, and `pks`.

-m
Specifies any additional information about the key-protection method that might include the following details:

- Input path to the authentication key file
- Key server ID in the `KeySvr` ODM class

device
Specifies the device name of the logical volume which must be authenticated and then the key-protection method must be unlocked. You must specify this value with the **-A** flag.

When you specify an LV device name, you can specify the key-protection method by using the **-t** and **-m** flags. If more than one key-protection methods meet the criteria, you are prompted to select a specific key-protection method.

authcheck or authchk

Syntax:

```
hdcryptmgr authcheck [-h] [-t <type> [-m <method_detail>]] [-i <index>] [-n <name>] <device>
```

Checks the validity of an authentication method. This *action* parameter can be specified with the following flags or values:

-h
Displays help information.

-t
Specifies the type of the key-protection method. The valid values are pwd, `keyfile`, `keyserv`, and pks.

-m
Specifies any additional information about the key-protection method that might include the following details:

- Input path to the authentication key file
- Key server ID in the `KeySvr` ODM class

-i
Checks the authentication of only the specified index. Authentication type is automatically forced according to the selected index.

-n
Specifies the name of the key-protection method that must be checked.

device
Specifies the device name of the logical volume that must be checked.

Managing PKS keys

The platform keystore (PKS) is a secure key-protection method that is available in IBM PowerVM® firmware of the IBM Power System E950. You can add the PKS key-protection method to an encrypted LV. You can use the following *action* parameters to manage the PKS keys for authentication.

pksshow

Syntax:

```
hdcryptmgr pksshow [-h]
```

Displays the logical volume IDs that are associated with the PKS keys and the status of the PKS keys. The LV IDs that are stored in both the PKS and in the LV metadata are displayed.

```
# hdcryptmgr pksshow

PKS uses 317 bytes on a maximum of 65536 bytes.
PKS_Label (LVid)                          Status
00fb293100004c0000000174c0a994b7.1        VALID
00fb293100004c0000000174c0a994b7.2        UNKNOWN
00fb293100004c0000000174c0a994b7.3        UNKNOWN

PKS_Label (objects)
ksvr:gpfs-pw-t2
```

pksclean

Syntax:

```
hdcryptmgr pksclean [-h] lvid
```

Removes an invalid key from the PKS. You must specify the logical volume ID that is associated with the invalid key that you want to remove. This command must be used to remove the keys that are listed in the **`hdcryptmgr pksshow`** command output with the status as O.

pksexport
Syntax:

```
hdcryptmgr pksexport [-h] -p ExportFile device
```

Exports the PKS keys into the specified file. If you specify an LV device name, the PKS key that is associated with the specified LV is exported. If you specify a VG device name, all PKS keys that are associated with the logical volumes in the volume group are exported.

pksimport
Syntax:

```
hdcryptmgr pksimport [-h] -p ExportFile [device]
```

Imports the PKS keys into the specified file. If you specify an LV device name, the PKS key that is associated with the specified LV is imported. If you specify a VG device name, all PKS keys that are associated with the logical volumes in the volume group are imported. If you do not specify a device name, all PKS keys are imported.

Converting the encryption status of the logical volume

You can convert a regular logical volume to an encrypted logical volume, and vice versa. You can perform this conversion operation only on the logical volume that is active and online.

Warning: You must back up your data before you run the following conversion commands.

You can use the following *action* parameters:

plain2crypt
Syntax:

```
hdcryptmgr plain2crypt [-h] [-e algo_detail] [-n name] [-f] device
```

Enables encryption in a logical volume, configures the encryption settings, and encrypts the LV data. This *action* parameter can be specified with the following flags and values:

-e
Specifies the data encryption algorithm, mode, and key length. The valid values of the **-e** flag are as follows:

prompt
Specifies that the encryption algorithm details will be prompted when the command runs.

[algorithm]:[b|B][key_len][:w]
Specifies the encryption algorithm details. The supported algorithms are Advanced Encryption Standard XTS mode (AES-XTS) 128 bits or 256 bits. The character **b** refers to bits (default) of the key, character **B** refers to bytes of the key, and the *key_len* variable refers to the length of the key. The *:w* parameter overwrites the default values of the volume group with the specified values. By default, when a volume group, in which encryption is enabled, is created, the default encryption algorithm is AES-XTS 128 bits.

-n
Specifies a name for the key-protection method.

-f
Specifies the force option. If you do not use this flag, the **hdcryptmgr** command prompts you to confirm that data have been backed up. The force option suppresses this prompt.

device
Specifies the device name of the logical volume for which the encryption status must be converted.

crypt2plain
Syntax:

```
hdcryptmgr crypt2plain [-h] [-f] device
```

Decrypts the encrypted data of the specified logical volume and disables the encryption status of the specified logical volume. This *action* parameter can be specified with the following flags and values:

-f
Specifies the force option. If you do not use this flag, the **hdcryptmgr** command prompts you to confirm that data have been backed up. The force option suppresses this prompt.

device
Specifies the device name of the logical volume for which the encryption status must be converted.

Commands and function restrictions for encrypted LV

For more information about the logical volume commands or functions that are not supported when the LV is encrypted, see the Limitations section in Encrypting logical volumes.

Examples

Scenario: Creating an encrypted logical volume with the passphrase key-protection method

1. Create a volume group in which encryption is enabled.

```
# mkvg -k y hdisk1 hdisk2
vg00
```

2. Create an encrypted LV with a size of 32 MB.

```
# mklv -k y vg00 32M
mklv: Please run :
# hdcryptmgr authinit lvname [..] to define LV encryption options.
lv00
```

3. Initialize the encryption configuration on the logical volume by using a primary key and the passphrase key-protection method.

```
# hdcryptmgr authinit -n default lv00
Enter Passphrase:
Confirm Passphrase:
Password authentication method added successfully
```

Scenario: Creating a file system in an encrypted LV

1. Create volume group in which encryption is enabled, and then create a logical volume with a size of 32 MB, and then initialize the encryption configuration for the logical volume.

```
# mkvg -k y hdisk1 hdisk2
vg00
# mklv -t jfs2 -k y vg00 32M
mklv: Please run :
# hdcryptmgr authinit lvname [..] to define LV encryption options.
fslv00
# hdcryptmgr authinit -n default fslv00
Enter Passphrase:
Confirm Passphrase:
Password authentication method added successfully
```

2. Create a file system in the encrypted logical volume similar to creating it in a regular logical volume.

```
# crfs -v jfs2 -d fslv00 -m /mnt/myfs -A no
File system created successfully.
32560 kilobytes total disk space.
New File System size is 65536
```

Scenario: Authenticating to a logical volume in which encryption is enabled

When the volume group is varied off or the system is restarted, the authentication to the encrypted LV expires. You must authenticate to the encrypted LV to access its data. You must use the configured key-protection method for the encrypted LV. To authenticate an encryption-enabled LV, complete the following steps:

1. Vary on the VG.

```
# varyonvg vg00
```

2. Authenticate by using the passphrase key-protection method.

```
# hdcryptmgr authunlock -t pwd fslv00
Enter Passphrase:
Password authentication succeeded
```

Files

/usr/sbin/hdcryptmgr
Contains the **hdcryptmgr** command.

hmcauth Command

Purpose

The **hmcauth** command is used to authenticate with a Hardware Management Console (HMC) and get a token to use the HMC services for a AIX Live Update operation. It can also be used to invalidate a token.

Syntax

To authenticate with an HMC and get a token, use the following syntax:

```
hmcauth [ -u user_name ] [ -p password ] [ -a hmc ] [ -P port ]
```

To invalidate and remove a previously generated token, use the following syntax:

```
hmcauth -r [ -a hmc ] [ -u user_name ]
```

To list all the known HMC authentication tokens, use the following syntax:

```
hmcauth -l
```

To display the command usage statement, use the following syntax:

```
hmcauth -h
```

Description

You can use the **hmcauth** command if you have all object access and appropriate HMC administrative authority. The **hmcauth** command generates a token that can be used by an AIX partition administrator to perform the Live Update operation. If the command succeeds, a token is stored in the kernel so that the **geninstall** interface can perform the Live Update operation.

To use this command, you must have authority to perform the following tasks:

- Power on a managed partition.
- Shut down a managed partition.
- Remove a managed partition (automatic mode only).
- Create a managed partition based on the current profile (automatic mode only).
- Set the boot device of a managed partition.

- Manage the virtual Ethernet adapters.

The `hmcclientliveupdate` HMC role has all the privileges that are required for the Live Update operation. If a user is defined on the HMC with this role, the authentication can be done with this user rather than the `hscroot` user.

The **hmcauth** command can also be used without any flags. If you do not specify any flags, the **hmcauth** command prompts for all the required information such as *user_name*, *hmc*, and *password*.

Note: If the LPAR is restarted, the HMC authentication token is not preserved. Therefore, you must authenticate with the HMC again before attempting a Live Update operation.

Parameters

Item	Description
user_name	A string of up to 64 characters that specifies the HMC user name.
password	A string of up to 64 characters that specifies a password.
hmc	A string of up to 64 characters that specifies either the host name or the IP address of the HMC to authenticate with.
port	A string of up to 16 characters that specifies a port number to contact the HMC.

Flags

Item	Description
-a *hmc*	Specifies the host name or the IP address of the HMC to authenticate with. If the *hmc* variable is not specified, the command prompts for it.
-h	Writes the command usage statement to standard output.
-r	Removes the token that is generated by the HMC.
-P *port*	Specifies a port number to be used to contact the HMC. The **-P** flag is optional. Therefore, if the port number is not specified, the port number is defaulted to the value of 12443. The HMC always uses port 12443, but if any proxy setup is used, you can use the **-P** option to allow the proxy to use a port other than 12443.
-p *password*	Specifies the password for authentication. If the password is not specified on the command line, you are prompted for the password.
-u *user_name*	Specifies the HMC user name to authenticate as. You must have all object access and appropriate task authority on the HMC.

Examples

1. To authenticate with the HMC called `apollo`, enter the following command:

   ```
   # hmcauth -a apollo -u hscroot -p T2x6z42p
   ```

2. To authenticate with an HMC at IP 5.5.55.121 with password prompt, enter the following command:

   ```
   # hmcauth -a 5.5.55.121 -u hscroot
   Enter password for hscroot:
   ```

3. To invalidate a previous authentication with an HMC at IP 5.5.55.121, enter the following command:

```
# hmcauth -r -a 5.5.55.121
```

4. To authenticate with an HMC called `apollo` that has a firewall, where the HMC port 12443 is not accessible, a rebound proxy node can be set up to use a different open port. To use the SSH client with port 14111 on a proxy node that is called `proxy1` to authenticate from a logical partition `mylpar`, enter the following commands:

```
(0) root @ proxy1: /
# ssh -R localhost:14111:apollo:12443 root@mylpar

(0) root @ mylpar: /
# hmcauth -a localhost -u hscroot -P 14111
Enter HMC password:
```

   You can specify `localhost` as the `management_console` attribute in the hmc stanza of the `lvupdate.data` file to initiate the Live Update operation.

host Command

Purpose

Resolves a host name into an Internet Protocol (IP) address or an IP address into a host name.

Syntax

`host` [**-n** [**-a**] [**-c** *Class*] [**-d**] [**-r**] [**-t** *Type*] [**-v**] [**-w**]] *Hostname* | *Address* [*Server*]

`hostnew` [**-a**] [**-c** *Class*] [**-d**] [**-r**] [**-t** *Type*] [**-v**] [**-w**] *Hostname* | *Address* [*Server*]

Description

The `/usr/bin/host` command returns the IP address of a host machine when the *HostName* parameter is specified and the name of the host when the *Address* parameter is specified. Depending on the configuration of name resolution service, the **host** command might also display any aliases that are associated with the *HostName* parameter. Examples of name resolution services include `local`, `nis`, and `bind`.

If the local host is using the Domain Name Protocol, the local or remote name server database is queried before it searches the local **/etc/hosts** file.

Flags

Item	Description
-a	Equivalent to using "`-v -t *`"
-c *Class*	Specifies the class to look in when it searches non-Internet data. Valid classes follow: **IN** Internet class **CHAOS** Chaos class **HESIOD** MIT Althena Hesiod class **ANY** Wildcard (any of the above)
-d	Turns on debugging mode.
-n	Equivalent to issuing the `/usr/bin/hostnew` command. The **hostnew** command performs `bind` resolution service.

Item	Description
-r	Disables recursive processing.
-t *Type*	Specifies the type of record to query for. Valid types follow: **A** Host's IP address **CNAME** Canonical name for an alias **HINFO** Host processor and operating system type **KEY** Security Key Record **MINFO** Mailbox or mail list information **MX** Mail exchanger **NS** Nameserver for the named zone **PTR** Host name if the query is an IP address; otherwise, the pointer to other information **SIG** Signature Record **SOA** Domain's "start-of-authority" information **TXT** Text information **UINFO** User information **WKS** Supported well-known services
-v	Verbose mode.
-w	Waits forever for a reply from the DNS server.

Parameters

Item	Description
Address	Specifies the IP address of the host machine to use in resolving the host name. The *Address* parameter must be a valid IP address in dotted decimal format.
HostName	Specifies the name of the host machine to use in resolving the IP address. The *HostName* parameter can be either a unique host name or a well-known host name (such as *nameserver*, *printserver*, or *timeserver*, if these names exist).
Server	Specifies the nameserver to query.

Examples

1. To display the address of a host machine named `mephisto`, enter the following command:

```
host mephisto
```

   The output is similar to the following information:

```
mephisto is 192.100.13.5, Aliases: engr, sarah
```

2. To display the host whose address is `192.100.13.1`, enter the following command:

```
host 192.100.13.1
```

The output is similar to the following information:

```
mercutio is 192.100.13.1
```

3. To display the MX records for the domain named `test.ibm.com`, enter:

```
host -n -t mx test.ibm.com
```

or

```
hostnew -t mx test.ibm.com
```

The output is similar to the following information:

```
test.ibm.com mail is handled (pri=10) by test1.tt.ibm.com
test.ibm.com mail is handled (pri=10) by test2.aix.ibm.com
```

Files

Item	Description
/etc/hosts	Contains the Internet Protocol (IP) name and addresses of hosts on the local network.

host9 Command

Purpose

Performs DNS lookups.

Syntax

host9 [**-aCdlrsTwv**] [**-c** *class*] [**-N** *ndots*] [**-R** *number*] [**-t** *type*] [**-W** *wait*] [**-m** *flag*] [**-4**] [**-6**] *name* [*server*]

Description

The **host9** command is a simple utility for performing DNS lookups. You can use this command to convert names to IP addresses and vice versa. When you specify no arguments or options, the **host9** command prints a short summary of its command line arguments and options.

Flags

Item	Description
-a	Equivalent to using the flags of **-v -t ***.
-c *class*	Instructs to make a DNS query of the specified class. You can use this flag to look up Hesiod or Chaosnet class resource records. The default class is IN (Internet).
-C	Attempts to display the SOA records for the zone name from all of the listed authoritative name servers for that zone. The NS records found for the zone defines the list of name servers.
-d	Generates the verbose output. This flag is equivalent to the **-v** flag.

Item	Description
-l	Specifies the list mode. This makes the **host9** command perform a zone transfer for the zone name. Transfers the zone printing out the NS, PTR and address records (A/AAAA). If you use the **-l** flag with the **-a** flag, the **host9** command prints all records.
-m *flag*	Sets the memory usage debugging flags record, usage, and trace.
-N *ndots*	Sets the number of dots that have to be in the name for it to be considered absolute. The default value is that defined using the ndots statement in the **/etc/resolv.conf** file, or 1 if no ndots statement is present. Names with fewer dots are interpreted as relative names and will be searched for in the domains listed in the search or domain directive in the **/etc/resolv.conf** file.
-r	Enables the **host9** command to mimic the behavior of a name server by making non-recursive queries and expecting to receive answers to those queries that are usually referrals to other name servers.
-R *number*	Changes the number of UDP retries for a lookup. The *number* value indicates how many times the **host9** command repeats a query that does not get answered. The default number of retries is 1. If the number is negative or zero, the number of retries defaults to 1.
-s	Informs the **host9** command not to send the query to the next name server if any server responds with a SERVFAIL response.
-t *type*	Selects the query type. The type can be any recognized query type: CNAME, NS, SOA, and so on. When no query type is specified, the **host9** command automatically selects an appropriate query type. By default, it looks for A records, but if you specify the **-C** flag, queries are made for SOA records, and if name is a dotted-decimal IPv4 address or colon-delimited IPv6 address, the **host9** command queries for PTR records. If a query type of IXFR is chosen, you can specify the starting serial by appending an equal sign, followed by the starting serial number (for example, **-t** IXFR=12345678).
-T	Uses a TCP connection when querying the name server. TCP is automatically selected for queries that require it, such as zone transfer (AXFR) requests.
-v	Generates the verbose output. This flag is equivalent to the **-d** flag.
-w	Waits forever for a reply. The time to wait for a response is set to the number of seconds given by the hardware's maximum value for an integer quantity.
-W *wait*	Waits for the *wait* seconds. If the *wait* value is less than one, the wait interval is set to 1 second.
-4	Forces the **host9** command to only use IPv4 query transport.
-6	Forces the **host9** command to only use IPv6 query transport.
name	Specifies the domain name that is to be looked up. It can also be a dotted-decimal IPv4 address or a colon-delimited IPv6 address, in which case the **host9** command performs a reverse lookup for that address.
server	Specifies an optional argument, which is either the name or IP address of the name server that the **host9** command queries instead of the server or servers listed in the **/etc/resolv.conf** file.

IDN SUPPORT

If the **host9** command has been built with internationalized domain name (IDN) support, it can accept and display non-ASCII domain names. The **host9** command appropriately converts character encoding of domain names before sending a request to the DNS server or displaying a reply from the server. If you'd like to turn off the IDN support for some reason, define the IDN DISABLE environment variable; the IDN support is disabled if the variable is set when the **host9** command runs.

Files

Item	Description
/etc/resolv.conf	

Examples

1. To display the address of a host machine named `mephisto`, enter the following command:

   ```
   host9 mephisto
   ```

   This command displays information similar to the following:

   ```
   mephisto is 192.100.13.5, Aliases: engr, sarah
   ```

2. To display the host machine with an address of 192.100.13.1, enter the following command:

   ```
   host9 192.100.13.1
   ```

   This command displays information similar to the following:

   ```
   mercutio is 192.100.13.1
   ```

3. To display the MX records for the domain named `test.ibm.com`, enter the following command:

   ```
   host9 -n -t mx test.ibm.com
   ```

   This command displays information similar to the following:

   ```
   test.ibm.com mail is handled (pri=10) by test1.tt.ibm.com
   test.ibm.com mail is handled (pri=10) by test2.aix.ibm.com
   ```

hostent Command

Purpose

Directly manipulates address-mapping entries in the system configuration database.

Syntax

To Add an Address-to-Host Name Mapping

hostent **-a** *IPAddress* **-h** "*HostName...*"

To Delete an Address-to-Host Name Mapping

hostent **-d** *IPAddress*

To Delete All Address-to-Host Name Mappings

hostent **-X**

To Change an Address-to-Host Name Mapping

hostent **-c** *IPAddress* **-h** "*HostName...*" [**-i** *NewIPAddress*]

To Show an Address or Host Name in Colon Format

hostent -s { *IPAddress* | **"***HostName***"** } [**-Z**]

To Show all Address-to-Host Name Mappings in Colon Format

hostent -S [**-Z**]

Description

The **hostent** low-level command adds, deletes, or changes address-mapping entries in the system configuration database. Entries in the database are used to map an Internet Protocol (IP) address (local or remote) to its equivalent host names.

The **hostent** command can show one or all address-to-host name mapping entries in the **/etc/hosts** file. An Internet Protocol (IP) address of a given local or remote host might be associated with one or more host names. Represent an IP address in dotted decimal format. Represent a host name as a string with a maximum length of 255 characters, and use no blank characters. Each entry must be contained on one line. Multiple *HostNames* (or aliases) can be specified.

Note: Valid host names or alias host names must contain at least one alphabetic character. If you choose to specify a host name or alias that begins with an `x` followed by any hexadecimal digit (`0-f`), the host name or alias must also contain at least one additional letter that cannot be expressed as a hexadecimal digit. The system interprets a leading `x` followed by a hexadecimal digit as the base 16 representation of an address unless there is at least one character in the host name or alias that is not a hexadecimal digit. Thus, `xdeer` would be a valid host name, whereas `xdee` would not.

You can use the System Management Interface Tool (SMIT) **`smit hostent`** fast path to run this command.

Flags

Note: The **-a**, **-d**, **-c**, and **-s** flags cannot be used together.

Item	Description
-a *IPAddress*	Adds an IP address-to-host name mapping entry for the Internet Protocol address in the database. Specify the host names with the **-h** flag.
-c *IPAddress*	Changes an IP address-to-host name mapping entry in the database that corresponds to the address that is specified by the *IPAddress* variable. Specify the changed host names with the **-h** flag. If you want to change the current IP address to a new address (*IPAddress*), use the **-i** flag.
-d *IPAddress*	Deletes the IP address-to-host name mapping entry in the database that corresponds to the address that is specified by the *IPAddress* variable.
-h"*HostName...***"**	Specifies a list of host names. Entries in the list are to be separated by blanks. The **-h"***HostName...***"** flag should be used with the **-a** flag. The **-c** flag might also require the **-h"***HostName...***"** flag.
-i *NewIPAddress*	Specifies a new IP address. This flag is required by the **-c** flag if an existing IP address is to be replaced by the *NewIPAddress* variable.
-S	Shows all entries in the database.
-s"*HostName***"**	Shows an IP address-to-host name mapping entry matching the host name specified by the **"***HostName***"** variable.
-s *IPAddress*	Shows an IP address-to-host name mapping entry matching the entry specified by the *IPAddress* variable.
-X	Deletes all IP address-to-host name mapping entries in the database.
-Z	Generates the report of the query in colon format. This flag is used when the **hostent** command is started from the SMIT usability interface.

Note: The **hostent** command does recognize the following addresses: .08, .008, .09, and .009. Addresses with leading zeros are interpreted as octal, and numerals in octal cannot contain 8s or 9s.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To add an entry in the database associating an address with a series of host names, enter the command in the following format:

   ```
   hostent -a 192.100.201.7 -h "alpha bravo charlie"
   ```

   In example 1, the IP address `192.100.201.7` is specified as the address of the host that has a primary host name of `alpha` with synonyms of `bravo` and `charlie`.
2. To show an entry in the database matching a host name, enter the command in the following format:

   ```
   hostent -s alpha
   ```

   In example 2, the entry to be shown matches the host name `alpha`.
3. To change the IP address of an entry to a new IP address, enter the command in the following format:

   ```
   hostent -c 192.100.201.7 -i 192.100.201.8
   ```

   In example 3, the old IP address is `192.100.201.7` and the new address is `192.100.201.8`.

Files

Item	Description
/etc/hosts	Contains host names and addresses for the network.

hostid Command

Purpose

Sets or displays the identifier of the current local host.

Syntax

/usr/sbin/hostid [*HexNumber* | *InternetAddress* | *HostName*]

Description

The **/usr/sbin/hostid** command displays the identifier (either a unique host name or a numeric argument) of the current local host as a hexadecimal number. This numeric value is expected to be unique across all hosts and is commonly set to the address of the host specified by the *InternetAddress* or *HostName* parameter. The root user can set the **hostid** command by specifying a hexadecimal number for the *HexNumber*, *InternetAddress*, or *HostName* parameter. The host identifier is set to the hostname by the **/etc/rc.net** file.

Parameters

Item	Description
HexNumber	Specifies a unique hexadecimal number representing the current local host.
InternetAddress	Specifies an Internet address representing the current local host.
HostName	Specifies a symbolic name that maps to a unique host.

Examples

1. To set the identifier of the local host to the local Internet address with the **hostid** command, enter the command in the following format:

   ```
   hostid   192.9.200.3
   0xc009c803
   ```

   The **hostid** command converts the Internet address `192.9.200.3` into the hexadecimal representation `0xc009c803`, and then sets the local host (your workstation connected to a network) to this address.
2. To display the identifier of the local host, enter:

   ```
   hostid
   0xc009c803
   ```

   The **hostid** command displays the identifier of the host as a hexadecimal number.

hostmibd Daemon

Purpose

Starts the **hostmibd** dpi2 sub-agent daemon as a background process.

Syntax

hostmibd [**-f** *File*] [**-d** [*Level*]] [**-h** *Hostname*] [**-c** *Community*]

Description

The **hostmibd** command starts the **hostmibd** dpi2 sub-agent. This command may only be issued by a user with root privileges or by a member of the system group.

The **hostmibd** daemon complies with the standard Simple Network Management Protocol Distributed Protocl Interface Version 2.0 defined by RFC 1592. It is acting as a dpi2 sub-agent to communicate with the dpi2 agent through dpiPortForTCP.0 (1.3.6.1.4.1.2.2.1.1.1.0) which is defined in RFC1592 section 3.1.

The Management Information Base (MIB) is defined by RFC 1155. The specific MIB variables `hostmibd` is managing are defined by RFC 2790. The actual MIB variables managed by **hostmibd** are the following six subtrees:

- hrSystem (1.3.6.1.2.1.25.1)
- hrStorage (1.3.6.1.2.1.25.2)
- hrDevice (1.3.6.1.2.1.25.3)
- hrSWRun (1.3.6.1.2.1.25.4)
- hrSWRunPerf (1.3.6.1.2.1.25.5)
- hrSWInstalled (1.3.6.1.2.1.25.6)

The **hostmibd** daemon is normally executed during system startup when **/etc/rc.tcpip** shell script is called.

The **hostmibd** daemon should be controlled using the System Resource Controller(SRC). Entering **hostmibd** at the command line is not recommended.

Use the following SRC commands to manipulate the **hostmibd** daemon:

startsrc
Starts a subsystem, group of subsystems, or a subserver.

stopsrc
Stops a subsystem, group of subsystems, or a subserver.

refresh
Causes a subsystem or group of subsystems to reread the appropriate configuration file.

lssrc
Gets the status of a subsystem, group of subsystems, or a subserver. If the user issuing the long status form of the **lssrc** command is not the root user, no community name information is displayed.

Flags

Item	Description
-c *Community*	Use specified community name. If **-c** flag is not specified, the default community name is 'public'.
-d *Level*	Specifies tracing/debug level. The levels are: • 0 = Least level • 8 = DPI level 1 • 16 = DPI level 2 • 32 = Internal level 1 • 64 = Internal level 2 • 128 = Internal level 3 Add the numbers for multiple trace levels. The default level is 56 if the **-d** flag is specified but *Level* is not specified. If the **-d** flag is not specified, the default level is 0.
-f *File*	Specifies a non-default configuration file. If the **-f** flag is not specified, the default configuration file is **/etc/hostmibd.conf**. See **/etc/hostmibd.conf** file for information on this file format.
-h *Host*	Send request to specified host. The *Host* value can be an IPv4 address, an IPv6 address, or a host name. If **-h** flag is not specified, the default destination host is 'loopback' (127.0.0.1).

Examples

1. To start the **hostmibd** daemon, enter a command similar to the following:

   ```
   startsrc -s hostmibd -a "-f /tmp/hostmibd.conf"
   ```

   This command starts the **hostmibd** daemon and reads the configuration file from **/tmp/hostmibd.conf**.
2. To stop the **hostmibd** daemon, normally enter:

   ```
   stopsrc -s hostmibd
   ```

   This command stops the **hostmibd** daemon. The **-s** flag specified the subsystem that follows to be stopped.
3. To get the short status from the **hostmibd**, enter:

   ```
   lssrc -s hostmibd
   ```

This command returns the name of the daemon, the process ID of the daemon, and the state of the daemon (active or inactive).

4. To get long status from the **hostmibd** daemon, enter:

```
lssrc -ls hostmibd
```

If you are the root user, this long form of the status report lists the configuration parameters in **/etc/hostmibd.conf**.

Files

Item	Description
/etc/hostmibd.conf	Defines the configuration parameters for **hostmibd** command.
/etc/mib.defs	Defines the Management Information Base (MIB) variables the SNMP agent and manager should recognize and handle.

hostname Command

Purpose

Sets or displays the name of the current host system.

Syntax

/usr/bin/hostname [*HostName*] [**-s**]

Description

The **/usr/bin/hostname** command displays the name of the current host system. Only users with root user authority can set the host name. The **mkdev** command and the **chdev** commands also set the host name permanently. Use the **mkdev** command when you are defining the TCP/IP instance for the first time.

You can use the System Management Interface Tool (SMIT) **smit mkhostname** fast path to run this command.

Flags

Item	Description
-s	Trims any domain information from the printed name.

Parameters

Item	Description
HostName	Sets the primary name of the host.

Note: You must have root user authority to use the *HostName* parameter.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

hosts2ldif Command

Purpose

Creates an LDAP Data Interchange Format (LDIF) file from a hosts file.

Syntax

hosts2ldif [**-i** *InputFile*] [**-o** *OutputFile*] [**-s** *SearchBase*]

Description

The **/usr/sbin/hosts2ldif** command creates a LDAP Data Interchange Format (LDIF) file from **/etc/hosts** or another file that looks like **/etc/hosts**. With no flags, the **/etc/hosts** file is used to create the **/tmp/hosts.ldif** LDIF file using `cn=hosts` as the baseDN.

The LDIF file created by this command is compliant with SecureWay Directory Schema and is used for setting up the **ldap** mechanism. The **ldap** mechanism is supported, but the use of the **nis_ldap** mechanism rather than the **ldap** mechanism is recommended.

Flags

Item	Description
-i *InputFile*	Specifies the hosts file used for input.
-o *OutputFile*	Specifies the LDIF file used for output.
-s *SearchBase*	Specifies the baseDN of the host table on the LDAP server.

Examples

1. To create **/home/ldifhosts** from the **/etc/hosts** file, type:

   ```
   hosts2ldif -o /home/ldifhosts
   ```

2. To create **/tmp/hosts.ldif** from the **/home/hosts.bak** file, type:

   ```
   hosts2ldif -i /home/hosts.bak
   ```

3. To create **/home/ldifhosts** from the **/etc/hosts** file using `cn=hosttab` as the baseDN, type:

   ```
   hosts2ldif -o /home/ldifhosts -s cn=hosttab
   ```

Files

Item	Description
/etc/hosts	Contains the Internet Protocol (IP) name and addresses of hosts on the local network.

hp Command

Purpose

Handles special functions for the HP2640- and HP2621-series terminals.

Syntax

hp [**-e**] [**-m** ...]

Description

The **hp** command reads standard input (usually output from the **nroff** command), and writes to standard output, which is usually Hewlett-Packard 2640- and 2621-series terminal displays.

If your terminal has the display enhancement feature, you can display subscript characters and superscript characters. With the mathematical-symbol feature, you can display Greek characters and other special characters, with two exceptions. The **hp** command approximates the logical operator NOT with a right arrow and shows only the top half of the integral sign.

Overstrike characters are characters followed by a backspace and another character. They appear underlined or in inverse video (depending on terminal enhancements) if either the overwritten character or the character typed after the backspace is an underscore character.

Note: Some sequences of control characters (reverse line-feeds and backspaces) can make text disappear from the display. Tables with vertical lines generated by the **tbl** command may be missing lines of text containing the bottom of a vertical line. You may be able to avoid these problems by first piping the input through the **col** command and then through the **hp** command.

Flags

Item	Description
-e	Shows overstruck characters underlined, superscript characters in half-bright, and subscript characters in half-bright underlined. Otherwise, all overstruck characters, subscript characters, and superscript characters appear in inverse video (dark-on-light). Use this flag only if your display has the display enhancements feature.
-m	Produces only one blank line for any number of successive blank lines in the text.

hplj Command

Purpose

Postprocesses the **troff** command output for the HP LaserJet Series printers.

Syntax

hplj [**-F** *Directory*] [**-quietly**] [**-landscape**] [*File* ...]

Description

The **hplj** command processes the output of the **troff** command for output to Hewlett-Packard LaserJet Series printers.

If given one or more files as options, the **hplj** command processes those files. If no files are specified, it acts as a filter interpreting standard input. The parameter *File* specifies files the **hplj** command processes to output on an HP Laser Jet Series printer.

Note: The **hplj** command can use the K cartridge or Text-Equations cartridge if installed in the printer. (The Text-Equations cartridge, HP part number C2053A #C07, supersedes the K cartridge.) The default font files assume one of the cartridges is installed. If you do not have a K cartridge, use the downloaded bit-mapped fonts instead. To do this, run the **no_cart** shell script in the font directory for the HP printer (**/usr/lib/font/devhplj**).

Incorrect output can occur if your font files assume either cartridge is mounted when it is not. Incorrect output can also occur if other cartridges or soft fonts are installed, in addition to the K cartridge or Text-Equations cartridge.

The **hplj** command depends on the files with names ending in **.out** in the **/usr/lib/font/devhplj** file. This command does not produce reasonable output unless these files have been properly set up. See the **troff** font file format document for more information.

Flags

Item	Description
-F*Directory*	Identifies the specified directory as the place to find the font file. By default, the **hplj** command looks for font files in the **/usr/lib/font/devhplj** directory.
-quietly	Suppresses all nonfatal error messages.

Item	Description
-landscape	Prints the specified file in landscape format. A landscape page is oriented so that for normal reading, the width of the page is greater than its length. By default, the **hplj** command prints in portrait orientation. **Note:** Landscape is only available in the Courier font on the Hewlett-Packard Jet II printer. Therefore, **troff** documents must be formatted in the Courier font. To accomplish this, insert the following lines at the beginning of the **troff** input file: `.fp 1 C` `.fp 2 C` `.fp 3 CB` The Courier font is loaded onto font positions #1 & #2 and Courier-Bold onto position #3.

Examples

1. To print a **troff** file named `foo` on the printer called hp using the **lp** command, enter:

```
troff -mm -Thplj foo | hplj | lp -dhp -o -dp
```

2. To print a **troff** file named boo on printer called hp using the **qprt** command, enter:

```
troff -mm -Thplj boo | hplj | qprt -dp -Php
```

Note: The **-dp** flag in both examples sends the printer data to the print device in pass-through (unmodified) mode.

File

Item	Description
/usr/lib/font/devhpl/*.out	Contains font files.

hpmcount Command

Purpose

Measures application performance.

Syntax

`hpmcount` [`-a`] [**-b** *time_base*] [`-d`] [**-D** *metrics*] [**-g** *event_groups*] [`-H`] [`-k`] [**-m** *metrics_groups*] [`-o` *file*] [`-s` *set*] [**-x**] *command*

`hpmcount [-h]`

Description

The `hpmcount` command provides the execution wall clock time, hardware performance counters information, derived hardware metrics, and resource utilization statistics (obtained from the `getrusage()` system call) for the application named by *command*.

Event types to be monitored and the associated hardware performance counters are specified by setting the `-s` option, by specifying an event group name, set number, or a comma-separated list of set numbers in the `HPM_EVENT_SET` environment variable, or by specifying counter/event pairs POWER3 / PowerPC 604 RISC Microprocessor) or an event group name (POWER4 and later) in the `libHPM_events` input file (takes precedence over `HPM_EVENT_SET`). Each set can be qualified by a counting mode. An event group number or name can be specified by setting the **-g** option or specifying a comma-separated list of event groups in the **HPM_EVENT_GROUP** environment variable. In the same manner, each event group can be qualified by a counting mode.

Valid event set numbers run from 1 to an upper limit dependent upon the processor type, which can be listed using the `pmlist` command. A comma-separated list of event sets can be specified instead of a set number, in which case the counter multiplexing mode is selected. To select all event sets, set the number value to `0`.

A comma-separated list of derived metrics can be specified by setting the **-D** option. Each derived metric can be qualified by a counting mode.

A list of derived metric groups can be specified by setting the **-m** option or by specifying a comma-separated list of derived metric groups in the **HPM_PMD_GROUP** environment variable. This allows the selection of all of the derived metrics pertaining to the specified groups. Each metric group can be qualified by a counting mode.

System and hypervisor (for processors supporting hypervisor mode) activity can be included in counting by specifying the `-k` and `-H` options.

When counting in the multiplexing mode, the results must be normalized to be used. The default base used for the data normalization is the timebase. The **-b** option allows for the use of the PURR time or the SPURR time (when supported by the processor) for the data normalization. The base for the data normalization can also be defined using the **HPM_NORMALIZE** environment variable.

Results can be output in XML format using the **-x** option.

Flags

Item	Description
`-a`	Aggregates the counters on POE runs.
-b *time_base*	Selects a base for the data normalization. The available bases are as follows: **time** timebase **purr** PURR time (when available) **spurr** SPURR time (when available) The default value is **time**.
`-d`	Adds detailed set counts for counter multiplexing mode.

Item	Description
-D *metrics*	Selects a list of derived metrics to be evaluated. Each derived metric can be qualified by a counting mode as follows: `metric:counting_modes` (See the **-m** option for available counting modes.)
-g *event_groups*	Lists a predefined group of events or a comma-separated list of event group names or numbers. When a comma-separated list of groups is used, the counter multiplexing mode is selected. Each event group can be qualified by a counting mode as follows: `event_group:counting_modes` (See the **-m** option for available counting modes.)
-H	Adds hypervisor activity on behalf of the process.
-h	Displays help message.
-k	Adds system activity on behalf of the process.
-m *metrics_groups*	Selects a list of derived metric groups to be evaluated. The derived metric group refers to all derived metrics that do not belong to a specific derived metric group. Each metric group can be qualified by a counting mode as follows: `metric_group_name:counting_modes` The available counting modes are as follows: **u** user mode **k** kernel mode **h** hypervisor mode **r** runlatch mode **n** nointerrupt mode
-o *file*	Output file name.
-s *set*	Lists a predefined set of events or a comma-separated list of sets (1 to *N*, or `0` to select all. See the `pmlist` command.) When a comma-separated list of sets is used, the counter multiplexing mode is selected. Each set can be qualified by a counting mode as follows: `event_set:counting_modes` (See the **-m** option for available counting modes.)
-x	Displays results in XML format.

Parameters

Item	Description
command	Specifies the executed program for which performance measurements are made.

Environment Variables

The following environment variables directly affect the execution of the hpmcount command (there are additional MP_* environment variables that influence the execution of parallel programs).

Item	Description
HPM_EVENT_SET	Selects one of the event sets. The value can be an integer from 1 to 6 on POWER3 systems, 1 to 4 on PowerPC 604 RISC Microprocessor systems, or 1 to a processor-dependent upper limit on POWER4 and later systems. This environment variable is also used to select an event group name on POWER4 and later systems. A comma-separated list of event sets can be specified. In this case, the counter multiplexing mode is selected. Each event set can be qualified by a counting mode as follows: `event_set_number:counting_modes` The **-g** or **-s** option takes precedence over this variable. The **HPM_EVENT_GROUP** environment variable takes precedence over this variable.
HPM_EVENT_GROUP	Selects the event groups. A comma-separated list of event groups can be specified. In this case, the counter multiplexing mode is selected. Each event group can be qualified by a counting mode as follows: `event_group_number:counting_modes` The **-g** or **-s** option takes precedence over this variable. The **HPM_EVENT_GROUP** environment variable takes precedence over the **HPM_EVENT_SET** variable.
HPM_NORMALIZE	Provides the base to be used for the data normalization. The **-b** option takes precedence over this variable.
HPM_PMD_GROUP	Specifies a comma-separated list of derived metric groups. Each metric group can be qualified by a counting mode. The **-m** option takes precedence over this variable.
HPM_PMD_METRIC	Specifies a comma-separated list of derived metrics. Each derived metric can be qualified by a counting mode. The **-D** option takes precedence over this variable.
HPM_DIV_WEIGHT	Provides a weight (an integer greater than 1) to be used to compute weighted flips on POWER4 systems.
MP_CHILD	Used in a parallel environment when aggregate counts are specified to complement the output results file name (*myID*), synchronize collation of results, and identify verbose/debug diagnostic messages more closely.
MP_PROCS	The number of program tasks.
HPM_AGGREGATE_OUTPUT	Aggregates counts on POE applications (forces the command line argument -a). With this flag, a single file performance file is generated for all tasks. This only works with POE or Load Leveller, and it requires the availability of a parallel file system (such as GPFS) on the system.
HPM_LOG_DIR	When this flag is set, hpmcount writes a hpm_log.*id* file with the performance data in the provided directory. This is in addition to the regular output.

Item	Description
MP_PARTITION	On POE applications, *id* is a POE ID provided by MP_PARTITION. Otherwise, it is the *pid*. Also names internal lock and data files.
HPM_MX_DURATION	When counting in counter multiplexing mode, this flag specifies the duration of each slice of time. It is expressed in ms, and must lie in the range of 10 ms - 30 s. When this flag is not set, the default value used for the time slice duration is 100 ms.

In addition, the following environment variables, supplied by the user, specify estimations of memory, cache, and TLB miss latencies for the computation of derived metrics. These environment variables do not take precedence over the same estimations eventually provided in the file HPM_flags.env, if present.

- HPM_MEM_LATENCY
- HPM_L3_LATENCY
- HPM_L35_LATENCY
- HPM_AVG_L3_LATENCY
- HPM_AVG_L2_LATENCY
- HPM_L2_LATENCY
- HPM_L25_LATENCY
- HPM_L275_LATENCY
- HPM_L1_LATENCY
- HPM_TLB_LATENCY

Exit Status

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Example

1. To run the ls command and write information concerning events in set 5 from hardware counters, enter:

   ```
   hpmcount -s 5 ls
   ```

2. To run the ls command and write information concerning events in sets 5, 2, and 9 from hardware counters using the counter multiplexing mode, enter:

   ```
   hpmcount -s 5,2,9 ls
   ```

3. To run the **ls** command and report derived metrics pertaining to the default and cpi_breakdown metric groups counted respectively in kernel+user+hypervisor mode and user mode, enter:

   ```
   hpmcount -m default:kuh,cpi_breakdown:u ls
   ```

Implementation Specifics

The hpmcount command uses the PMAPI thread-level API.

The hpmcount *command* parameter is not parsed as a command line for an application name with options. Instead, a shell script must be created that contains the command line.

Location

/usr/bin/perf/pmapi/hpmcount

Standard Input

Not used.

Standard Output

Performance monitoring results are written to stdout, unless the -o *file* option is specified on the command line.

Standard Error

Used only for diagnostic messages.

Files

The following input files are used if present.

Item	Description
libHPM_events	User-supplied event set file. This file does not take precedence over the command lines specified with the -s option. The format for a POWER3/PowerPC 604 RISC Microprocessor counter/event pair is *counternumber eventname*. For example: `0 PM_LD_MISS_L2HIT` `1 PM_TAG_BURSTRD_L2MISS` `2 PM_TAG_ST_MISS_L2` `3 PM_FPU0_DENORM` `4 PM_LSU_IDLE` `5 PM_LQ_FULL` `6 PM_FPU_FMA` `7 PM_FPU_IDLE` A comma-separated list of events can also be specified. This turns on the counter multiplexing mode: `0 PM_CYC,PM_FPU_FIN,PM_IC_MISS` `1 PM_LD_CMPL,PM_INST_CMPL,PM_DC_MISS` `2 PM_INST_CMPL,PM_FPU_WT,PM_INST_CMPL` `3 PM_LD_MISS_DC_XU,PM_CYC,PM_CYC` For a POWER4 event group name, the format is *event_group_name*. For example: `pm_hpmcount1` A comma-separated list of events can also be specified. This turns on the counter multiplexing mode: `pm_hpmcount1,pm_hpmcount2,pm_basic`
HPM_flags.env	File containing environment variable/value pairs used for the computation of derived metrics. For example: `HPM_L2_LATENCY 12` `HPM_EVENT_SET  5`
./.hpm_lockfile_*mp_partition*	Lock file. This file is reserved for the hpmcount command's internal use.
./.hpm_datafile_*mp_partition*	Accumulative results file. This file is reserved for the hpmcount command's internal use.

The following output files are used.

Item	Description
file_*myID*.*pid*	File specified with the -o option for hpmcount output results, where *myID* is taken from the MP_CHILD environment variable, with a default value of 0000.
HPM_LOG_DIR/hpm_log.MP_PARTITION or HPM_LOG_DIR/hpm_log.*pid*	Log file specified for aggregate counters on POE runs.
./.hpm_lockfile_*mp_partition*	Lock file. This file is reserved for the hpmcount command's internal use.

Item	Description
./.hpm_datafile_*mp_partition*	Accumulative results file. This file is reserved for the hpmcount command's internal use.

hpmstat Command

Purpose

Provides system-wide hardware performance counter information.

Syntax

hpmstat [**-b** *time_base*] [-d] [**-D** *metrics*] [**-g** *event_groups*] [-H] [-k] [**-m** *metrics_groups*] [-o *file*] [-r] [-s *set*] [-T] [-U] [-u] [**-x**] [**-@ ALL** | *WparName*] *interval count*

hpmstat [-h]

Description

The hpmstat command provides the execution wall clock time, hardware performance counters information, and derived hardware metrics. It can only be used by a user with root privilege.

When specified without command line options, hpmstat counts the default 1 iteration of user, kernel, and hypervisor (for processors supporting hypervisor mode) activity for 1 second for the default set 1 of events. It then writes the raw counter values and derived metrics to standard output. By default, runlatch is disabled so that counts can be performed while executing in idle cycle.

When the -U option is specified, *interval* is in microseconds, the iteration *count* is infinity, and derived metrics are not calculated and written to standard output. This option is ignored if the counter multiplexing mode is specified.

When the -T option is specified, output information is preceded by the time stamp (seconds plus microseconds) and timing information is written as time stamps instead of time in seconds.

Event types to be monitored and the associated hardware performance counters are specified using either the set -s option or by specifying an event group name or set number in the HPM_EVENT_SETone environment variable. Alternatively, specify counter/event pairs (POWER3 / PowerPC 604 RISC Microprocessor) or an event group name (POWER4 and later) in the libHPM_events input file (takes precedence over HPM_EVENT_SET). Each set can be qualified by a counting mode. An event group number or name can be specified by setting the **-g** option or specifying a comma-separated list of event groups in the **HPM_EVENT_GROUP** environment variable. In the same manner, each event group can be qualified by a counting mode.

A comma-separated list of event sets can be specified instead of a set number, in which case the counter multiplexing mode is selected. To select all event sets, set the set number value to 0.

Valid event set numbers run from 1 to an upper limit dependent upon the processor type, which can be listed using the pmlist command.

A comma-separated list of derived metrics can be specified by setting the **-D** option. Each derived metric can be qualified by a counting mode.

A list of derived metric groups can be specified by setting the **-m** option or by specifying a comma-separated list of derived metric groups in the **HPM_PMD_GROUP** environment variable. This allows to select all the derived metrics pertaining to the specified groups. Each metric group can be qualified by a counting mode.

When counting in the multiplexing mode, the results must be normalized to be used. The default base used for the data normalization is the timebase. The **-b** option allows for the use of the PURR time or the SPURR time (when supported by the processor) for the data normalization. The base for the data normalization can also be defined using the **HPM_NORMALIZE** environment variable.

When you run the **hpmstat** command from the global workload partition (WPAR), it is possible to monitor a specific WPAR using the **-@** *WparName* option. You can use the **-@ ALL** option to monitor all active WPARs in the system and to retrieve per-WPAR data.

Results can be output in XML format using the **-x** option.

Flags

Item	Description
-@ ALL | *WparName*	Selects the target WPAR in which the activity is to be measured. The **ALL** value means that the **hpmstat** command measures all active WPARs in the system and reports the activity for each WPAR. This option is only available when you run the **hpmstat** command from the global WPAR; it is ignored otherwise.
-b *time_base*	Selects a base for the data normalization. The available bases are as follows: **time** timebase **purr** PURR time (when available) **spurr** SPURR time (when available) The default value is **time**.
-d	Adds detailed set counts for counter multiplexing mode.
-D *metrics*	Selects a list of derived metrics to be evaluated. Each derived metric can be qualified by a counting mode as follows: `metric:counting_modes` (See the **-m** option for available counting modes.)
-g *event_groups*	Lists a predefined group of events or a comma-separated list of event group names or numbers. When a comma-separated list of groups is used, the counter multiplexing mode is selected. Each event group can be qualified by a counting mode as follows: `event_group:counting_modes` (See the **-m** option for available counting modes.)
-H	Counts hypervisor activity only.
-h	Displays help message.
-k	Counts system activity only.

Item	Description
-m *metrics_groups*	Selects a list of derived metric groups to be evaluated. The default derived metric group refers to all derived metrics that do not belong to a specific derived metric group. Each metric group can be qualified by a counting mode as follows: `metric_group_name:counting_modes` The available counting modes are as follows: **u** user mode **k** kernel mode **h** hypervisor mode **r** runlatch mode **n** nointerrupt mode
`-o` *file*	Output file name.
`-r`	Enables `runlatch` and disables counts while executing in idle cycle.
`-s` *set*	Lists a predefined set of events or a comma-separated list of sets (`1` to *N*, or `0` to select all. See the `pmlist` command.) When a comma-separated list of sets is used, the counter multiplexing mode is selected. Each set can be qualified by a counting mode as follows: `event_set:counting_modes` (See the **-m** option for available counting modes.)
`-T`	Writes time stamps instead of time in seconds.
`-U`	Puts counting time interval in microseconds. This option is ignored if the counter multiplexing mode is specified.
`-u`	Counts user activity only.
-x	Displays results in VPA XML format.

Parameters

Item	Description
interval	Displays the counting time interval in seconds or microseconds, with a default value of `1`.
count	Shows the number of iterations to count. The default is `1` with an interval in seconds, and infinity when the option `-U` is specified.

Environment Variables

The following environment variables directly affect the execution of the `hpmstat` command (there are additional `MP_*` environment variables that influence the execution of parallel programs).

Item	Description
HPM_EVENT_SET	Selects one of the event sets. The value can be an integer from 1 to 6 on POWER3 systems, 1 to 4 on PowerPC 604 RISC Microprocessor systems, or 1 to a processor-dependent upper limit on POWER4 and later systems. This environment variable is also used to select an event group name on POWER4 and later systems. Each event set can be qualified by a counting mode as follows: `event_set_number:counting_modes` The **-g** or **-s** option takes precedence over this variable. The **HPM_EVENT_GROUP** environment variable takes precedence over this variable.
HPM_EVENT_GROUP	Selects the event groups. A comma-separated list of event groups can be specified. In this case, the counter multiplexing mode is selected. Each event group can be qualified by a counting mode as follows: `event_group_number:counting_modes` The **-g** or **-s** option takes precedence over this variable. The **HPM_EVENT_GROUP** environment variable takes precedence over the **HPM_EVENT_SET** variable.
HPM_NORMALIZE	Provides the base to be used for the data normalization. The **-b** option takes precedence over this variable.
HPM_PMD_GROUP	Specifies a comma-separated list of derived metric groups. Each metric group can be qualified by a counting mode. The **-m** option takes precedence over this variable.
HPM_PMD_METRIC	Specifies a comma-separated list of derived metrics. Each derived metric can be qualified by a counting mode. The **-D** option takes precedence over this variable.
HPM_DIV_WEIGHT	Provides a weight (an integer greater than 1) to be used to compute weighted flips on POWER4 systems.
HPM_MX_DURATION	When counting in counter multiplexing mode, this flag specifies the duration of each slice of time. It is expressed in ms, and must lie in the range of 10 ms - 30 s. When this flag is not set, the default value used for the time slice duration is 100 ms.

In addition, the following environment variables, supplied by the user, specify estimations of memory, cache, and TLB miss latencies for the computation of derived metrics. These environment variables do not take precedence over the same estimations eventually provided in the file `HPM_flags.env`, if present.

- HPM_MEM_LATENCY
- HPM_L3_LATENCY
- HPM_L35_LATENCY
- HPM_AVG_L3_LATENCY
- HPM_AVG_L2_LATENCY
- HPM_L2_LATENCY
- HPM_L25_LATENCY
- HPM_L275_LATENCY
- HPM_L1_LATENCY

- HPM_TLB_LATENCY

Exit Status

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To write information for system, user, and hypervisor activity over a 1 second interval concerning events in set 2 from hardware counters, enter the following command:

   ```
   hpmstat -s 2
   ```

2. To write information for the user activity concerning events of group 0 and the system activity concerning events of group 1 for the wpar1 WPAR over a five-second interval, enter the following command:

   ```
   hpmstat -@ wpar1 -g 0:u,1:k 5
   ```

Location

/usr/bin/perf/pmapi/hpmstat

Standard Input

Not used.

Standard Output

Performance monitoring results are written to stdout, unless the -o *file* option is specified on the command line.

Standard Error

Used only for diagnostic messages.

Files

The following input files are used if present.

Item	Description
`libHPM_events`	User-supplied event set file. This file does not take precedence over the command lines specified with the `-s` option. The format for a POWER3/PowerPC 604 RISC Microprocessor counter/event pair is *countername eventname*. For example: `0 PM_LD_MISS_L2HIT` `1 PM_TAG_BURSTRD_L2MISS` `2 PM_TAG_ST_MISS_L2` `3 PM_FPU0_DENORM` `4 PM_LSU_IDLE` `5 PM_LQ_FULL` `6 PM_FPU_FMA` `7 PM_FPU_IDLE` For a POWER4 event group name, the format is *event_group_name*. For example: `pm_hpmcount1`
`HPM_flags.env`	File containing environment variable/value pairs used for the computation of derived metrics. For example: `HPM_L2_LATENCY 12` `HPM_EVENT_SET  5`

The following output files are used.

Item	Description
file	File specified with the `-o` option for `hpmstat` output results.

hps_dump Command

Purpose

Dumps contents of Network Terminal Accelerator (NTX) adapter memory to a host file.

Syntax

hps_dump [**-f** *Name*] [**-d** *Device*]

Description

The **hps_dump** command uses the loader interface to upload all of the memory from the adapter board into a file. It produces a snapshot of a system for later analysis and debugging. The first 1024 bytes of the file contains the following items:

Item	Description
80	Identification string, includes version.
80	Time and date of memory dump from host system.
80	Comments.

Item	Description
268	Log table from the host adapter.
32	System address table.
8	Starting and ending address range of memory dump.
476	Padding to 1024 bytes total.

Flags

Item	Description
-f *Name*	Specifies the name of the memory dump. Use this option to override the default file name **./hpscore**.
-d *Device*	Specifies the raw device file name of the adapter. Use this option to override the default device name **/dev/rhp0**.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Access Control: You must have root authority to run this command.

Auditing Events: Not applicable.

Examples

1. To get a memory dump of the default adapter to the file **hpscore** in the current directory, enter:

   ```
   hps_dump
   ```

2. To get a memory dump of the default adapter to the file hpsdebug in the current directory of the default adapter, enter:

   ```
   hps_dump -f hpsdebug
   ```

3. To get a memory dump of memory of the adapter **/dev/rhp1** to the file **hpsdebug** in the current directory of the default adapter, enter:

   ```
   hps_dump -f hpsdebug -d /dev/rhp1
   ```

Files

Item	Description
/usr/bin/hps_dump	Contains the **hps_dump** command.

Item	Description
/dev/rhp0	Default NTX raw device file name.

htable Command

Purpose

Converts host files to the format used by network library routines.

Syntax

/usr/sbin/htable [**-c** *connected-nets*] [**-l** *local-nets*] *input-file*

Note: Do not put a space on either side of the comma.

Description

The **htable** command converts host files in the format specified in RFC 810 to the format used by the network library routines. The conversion creates three files: the **/etc/hosts** file, the **/etc/networks** file, and the **/etc/gateways** file.

The **gethostbyname** subroutine uses the **hosts** file for mapping host names to addresses when the **named** daemon is not used. The **getnetent** subroutine uses the **networks** file for mapping network names to numbers.

The **gateways** file may be used by the **routed** daemon in identifying passive Internet gateways.

If any local **hosts**, **networks**, or **gateways** files (**localhosts**, **localnetworks**, or **localgateways** respectively) exist in the current directory, that file's contents are added as a prefix to the output file. Of these, the **htable** program only interprets the **gateways** file. Adding the prefix to the contents allows sites to maintain local entries that are not normally present in the master database.

Flags

Item	Description
-c *connected-nets*	Specifies a list of networks to which the host is directly connected if the network routing daemons use the **gateways** file. Separate the networks with commas, and use the network name or standard Internet dot notation (for example, `-c arpanet,128.32,LocalEthernet`). The **htable** command only includes gateways that are directly connected to one of the networks specified or that can be reached from another gateway on a connected network.
-l *local-nets*	Specifies a list of networks for the **htable** command to treat as local. Take information about hosts on local networks only from the **localhosts** file. Separate the networks with commas, and use the network name or standard Internet dot notation (for example, `-l 128.32,local-ether-net`). Entries for local hosts from the main database are omitted so that the **localhosts** file can override entries in the input file (the file you specify on the command line).

Files

Item	Description
/*CurrentDirectory***/localgateways**	Contains local gateway information.
/*CurrentDirectory***/localhosts**	Contains local host name information.

Item	Description
/CurrentDirectory/**localnetworks**	Contains local network information.

hty_load Command

Purpose

Displays or downloads Network Terminal Accelerator (NTX) adapter configurations.

Syntax

hty_load [**-d** *Device*] [**-f** *ConfigFileName*]

Description

The **hty_load** command displays or downloads adapter configurations. If you issue this command without any flags, the system displays the current adapter configuration for the **/dev/rhp0** device file. Given a *Device* parameter, the **hty_load** command loads a configuration file into the tty driver. The tty driver uses the file to configure both the host presentation services (HPS) and the adapters.

Typically, the **hty_load** command is invoked from the **/etc/rc.ntx** file.

The Configuration File

The **hty_load** command uses a single configuration file to configure the adapters. Each entry is on a separate line. Entries are separated by new-line characters. Fields in an entry are separated by tabs or space characters. Entries in the configuration file have the following fields.:

```
MinorNumber Cluster NumberOfPorts
```

These fields have the following values:

Item	Description
MinorNumber	Specifies the board's minor device number.
Cluster	This field is always 1.

Item	Description
NumberOfPorts	Specifies the number of hty devices. The number depends on the model of adapter you are using. The number of available channels is from 1 to 256 for a 2MB board or from 1 to 2048 for an 8MB board.

The configuration file also supports comments. Comment lines begin with a # (pound sign). Everything to the right of the comment character is ignored. Comment lines end with new-line characters.

Flags

Item	Description
-d *Device*	Specifies the raw device file name of the adapter. Use this option to override the default device name **/dev/rhp0**.
-f *ConfigFileName*	Specifies the driver configuration file name. The default configuration file is the **/etc/hty_config** file.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Security

Access Control: You must have root authority to run this command.

Auditing Events: N/A

Examples

To load the system configuration and use the default driver configuration file, enter:

```
hty_load -d /dev/rhp0
```

Files

Item	Description
/usr/bin/hty_load	Contains the **hty_load** command.
/etc/rc.ntx	Invokes the **hty_load** command.
/etc/hty_config	Default NTX driver configuration file name.
/dev/rhp0	Default NTX raw device file name.

hyphen Command

Purpose

Finds hyphenated words.

Syntax

hyphen [*File* ...]

Description

The **hyphen** command reads one or more English-language files, finds all the lines ending with hyphenated words, and writes those words to standard output. The parameter *File* specifies English-language files to be read by the **hyphen** command. The default is standard input. If no file is specified or if the - (hyphen) is specified as the last file name, the **hyphen** command reads standard input. The **hyphen** command can be used as a filter.

Note: The **hyphen** command cannot read hyphenated words that are italic or underlined. The **hyphen** command sometimes gives unnecessary output.

Examples

To check the hyphenation performed by a text-formatting program on a file, enter:

```
mm [Flag...] [File...] | hyphen
```

i

The following AIX commands begin with the letter *i*.

ibm3812 Command

Purpose

Postprocesses the **troff** command output for the IBM 3812 Model 2 Pageprinter.

Syntax

ibm3812 [**-altpaper**] [**-landscape**] [**-quietly**] [**-F***Directory*] [**-i**] [*File*...]

Description

The **ibm3812** command is a postprocessor that can be used on intermediate output produced by the **troff** command.

Note: An entire page is placed in memory before it is printed.

If given one or more file names as options, the **ibm3812** command processes those files. If no file names are specified, this command acts as a filter interpreting standard input.

The **ibm3812** command's font files allow the postprocessor to send characters of more than one byte to the printer. These can be characters that require multiple bytes to represent them, such as code page and point; or, they can be characters that are composed of two or more concatenated glyphs.

For example, the character code for the \(ib (improper subset) special character is:

```
"\001\125\xe2\xff\xe8\xe3%\x00\x16\001\074\xe3\xff\xea"
```

The printer is in Page Map Primitive (PMP) mode when these bytes are sent, so you must use the 001 directive to introduce a character. For single-byte codes, this Generic Font Patterns command is automatically handled by the postprocessor. The % (percent sign) characters escape the bytes containing 0, which would otherwise terminate the code sequence. To obtain a literal % character, escape it with another % character so that a percent sign is displayed as %%. A single-byte % code is assumed to be a literal percent sign, so that the single-byte % character needs no special handling in the font file.

Notes:

1. The **ibm3812** command depends on the files with names ending in **.out** in the **/usr/lib/font/devibm3812** directory. It does not produce usable output unless these files have been properly set up.
2. The postprocessor requires additional font information to be stored in the **/usr/lib/font/devibm3812/fonts** file. If new fonts are added to this file, make sure that the **DESC** file is also updated to reflect the additional fonts and special characters.

The format of the file must be preserved. The file contains the following four fields:

- The one- or two-letter name of the font
- The full name of the font on the printer-font diskette
- The one- or two-letter name of the substitute font
- An array of five available sizes.

Flags

Item	Description
-altpaper	Specifies that the file should be printed from the alternate paper drawer. By default, the **ibm3812** command prints from the primary paper drawer.
-landscape	Specifies that the file should be printed in landscape orientation, so that the wider part of the paper is horizontally oriented. This flag rotates the page to the right by 90 degrees. By default, the **ibm3812** command prints in portrait orientation.
-quietly	Suppresses all non-fatal error messages.
-F*Directory*	Specifies the directory holding the font files. The default file is **devibm3812**. The command looks for font files in the **/usr/lib/font** directory by default.
-i	Suppresses initialization of the printer that runs the PMP.init macro, after the job has printed.

Example

Following is an example of the **troff** command used with the **ibm3812** command:

```
troff file|ibm3812|qprt-dp
```

Files

Item	Description
/usr/lib/font/devibm3812/*.out	Contains font files for the **ibm3812** command.
/usr/lib/font/devibm3812/fonts	Contains information about the available fonts for the **ibm3812** command.

ibm3816 Command

Purpose

Postprocesses the **troff** command output for the IBM 3816 Pageprinter.

Syntax

ibm3816 [**-altpaper**] [**-landscape**] [**-quietly**] [**-F***Directory*] [**-i**] [*File*...]

Description

The **ibm3816** command is a postprocessor that can be used on intermediate output produced by the **troff** command.

Note: An entire page is placed in memory before it is printed.

If given one or more file names as options, the **ibm3816** command processes those files. If no file names are specified, this command acts as a filter interpreting standard input.

The **ibm3816** command's font files allow the postprocessor to send characters of more than one byte to the printer. These can be characters that require multiple bytes to represent them, such as code page and point; or, they can be characters that are composed of two or more concatenated glyphs.

For example, the character code for the \(ib (improper subset) special character is:

```
"\001\125\xe2\xff\xe8\xe3%\x00\x16\001\074\xe3\xff\xea"
```

The printer is in Page Map Primitive (PMP) mode when these bytes are sent, so you must use the 001 directive to introduce a character. For single-byte codes, this Generic Font Patterns command is automatically handled by the postprocessor. The % (percent sign) characters escape the bytes containing 0, which would otherwise terminate the code sequence. To obtain a literal % character, escape it with another % character so that a percent sign is displayed as %%. A single-byte % code is assumed to be a literal percent sign, so that the single-byte % character needs no special handling in the font file.

Notes:

1. The **ibm3816** command depends on the files with names ending in **.out** in the **/usr/lib/font/devibm3816** directory. It does not produce usable output unless these files have been properly set up.
2. The postprocessor requires additional font information to be stored in the **/usr/lib/font/devibm3816/fonts** file. If new fonts are added to this file, make sure that the **DESC** file is also updated to reflect the additional fonts and special characters.

The format of the file must be preserved. The file contains the following four fields:

- The one- or two-letter name of the font
- The full name of the font on the printer-font diskette
- The one- or two-letter name of the substitute font
- An array of five available sizes.

Flags

Item	Description
-altpaper	Specifies that the file should be printed from the alternate paper drawer. By default, the **ibm3816** command prints from the primary paper drawer.
-landscape	Specifies that the file should be printed in landscape orientation, so that the wider part of the paper is horizontally oriented. This flag rotates the page to the right by 90 degrees. By default, the **ibm3816** command prints in portrait orientation.
-quietly	Suppresses all non-fatal error messages.
-F*Directory*	Specifies the directory holding the font files. The default file is **devibm3816**. The command looks for font files in the **/usr/lib/font** directory by default.
-i	Suppresses initialization of the printer that runs the PMP.init macro, after the job has printed.

Example

Following is an example of the **troff** command used with the **ibm3816** command:

```
troff file|ibm3816|qprt-dp
```

Files

Item	Description
/usr/lib/font/devibm3816/*.out	Contains font files for the **ibm3816** command.
/usr/lib/font/devibm3816/fonts	Contains information about the available fonts for the **ibm3816** command.

ibm5585H-T Command

Purpose

Processes **troff** command output for the IBM 5585H-T printer.

Syntax

ibm5585H-T [**-F***Directory*] [*File*]

Description

The **ibm5585H-T** command processes the output of the **troff** command for output to the IBM 5585H-T printer for traditional Chinese language. This command is provided exclusively for traditional Chinese language support.

The **ibm5585H-T** command processes one or more files specified by the *File* parameter. If no file is specified, the **ibm5585H-T** command reads from standard input.

The **ibm5585H-T** command uses font files in the **/usr/lib/font/devibm5585H-T** directory that have command names ending with **.out**. The **ibm5585H-T** command does not produce correct output unless these files are provided.

Flag

Item	Description
-F*Directory*	Specifies a directory name as the place to find font files. By default, the **ibm5585H-T** command looks for font files in the **/usr/lib/font/devibm5585H-T** directory.

Example

To process the `reports` file for the IBM 5585H-T printer, enter:

```
troff reports |ibm5585H-T | qprt -dp
```

The **ibm5585H-T** command first processes the output of the **troff** command, then sends the file to a print queue.

File

Item	Description
/usr/lib/font/devibm5585H-T/*.out	Contains font files.

ibm5587G Command

Purpose

Postprocesses **troff** command output for the IBM 5587-G01, 5584-H02, 5585-H01, 5587-H01, and 5589-H01 printers with the (32x32/24x24) cartridge installed. This command is used exclusively for Japanese Language Support.

Syntax

ibm5587G [**-F***Directory*] [**-quietly**] [*File* ...]

Description

The **ibm5587G** command processes the output of the **troff** command for output to the 5587-G01, 5584-H02, 5585-H01, 5587-H01, and 5589-H01 printers.

If given one or more files as options, the **ibm5587G** command processes those files. If no files are specified, it acts as a filter interpreting standard input.

> **Note:** The **ibm5587G** command assumes that the (32x32/24x24) cartridge is installed in the printer. Incorrect output from the printer may result if the wrong cartridge is installed in the printer.

The **ibm5587G** command depends on the files with names ending in **.out** in the **/usr/lib/font/devibm5587G** directory. It does not produce reasonable output unless these files have been properly set up.

Flags

Item	Description
-F*Directory*	Specifies a directory name as the place to find the font files. By default, the **ibm5587G** command looks for font files in the **/usr/lib/font/devibm5587G** directory.
-quietly	Suppresses all nonfatal error messages.

Files

Item	Description
/usr/lib/font/devibm5587G/*.out	Contains font files.

ibstat Command

Purpose

Displays operational information about one or more InfiniBand network devices.

Syntax

`ibstat` [`-d`, `-h`, `-i`, `-n`, `-p`, `-v`] [*DeviceName*]

Description

This command displays InfiniBand operational information pertaining to a specified Host Channel Adapter Device (HCAD). If an HCAD device name is not entered, status for all available HCADs are displayed. Select a flag to narrow down your search results. You can display specific categories of information, including Node, Port, Interface, and Debug information. You can also choose to display all of the information categories.

Flags

Item	Description
`-d`	Displays current debug setting.
`-h`	Displays `ibstat` command usage.
`-i`	Displays network interface information.
`-n`	Displays only IB node information.

Item	Description
-p	Displays only IB port information.
-v	Displays all IB device information.

The following fields display information for all valid calls:

Device Name
Displays the name of an available HCAD (for example, `iba0`).

Port State
Displays the current state of each HCAD port.

Down
Port is disabled.

Initialized
Port is enabled and issuing training sequences.

Armed
Port is trained and attempting to configure to the active state.

Active
Port is in a normal operational state.

Unknown
Port is in an invalid or unknown state.

Parameters

Item	Description
DeviceName	Specifies the name of the HCAD device (for example, `iba0`) **Tip:** The device name is optional. If you do not specify a device name, all InfiniBand devices are queried for control or information.

Exit Status

When you specify an invalid *DeviceName*, the `ibstat` command produces error messages stating that it could not connect to the device. For example:

```
IBSTAT: No device iba2 configured.
```

or:

```
IBSTAT: Device iba3 is not available.
```

Examples

1. To request node and port information, enter:

   ```
   ibstat -n -p
   ```

   Information similar to the following is displayed:

   ```
   ================================================================================
    INFINIBAND DEVICE INFORMATION (iba0)
   ================================================================================

   --------------------------------------------------------------------------------
    IB NODE INFORMATION (iba0)
   --------------------------------------------------------------------------------
   ```

```
Number of Ports:                         2
Globally Unique ID (GUID):               00.02.55.00.00.00.46.00
Maximum Number of Queue Pairs:           1023
Maximum Outstanding Work Requests:       32768
Maximum Scatter Gather per WQE:          252
Maximum Number of Completion Queues:     1023
Maximum Multicast Groups:                256
Maximum Memory Regions:                  3836
Maximum Memory Windows:                  3836

Current Number of GUID's:                1
Globally Unique ID List:
  GUID[0]:                               00.02.55.00.00.00.46.12

------------------------------------------------------------------------------
 IB PORT 2 INFORMATION (iba0)
------------------------------------------------------------------------------
Global ID Prefix:                        fe.80.00.00.00.00.00.00
Local ID (LID):                          0011
Port State:                              Active
Maximum Transmission Unit Capacity:      2048
Current Number of Partition Keys:        1
Partition Key List:
  P_Key[0]:                              ffff
Current Number of GUID's:                1
Globally Unique ID List:
  GUID[0]:                               00.02.55.00.00.00.46.52
```

Location

`/usr/sbin/ibstat`

iconv Command

Purpose

Converts the encoding of characters from one code page encoding scheme to another.

Syntax

iconv [`-cs`] **-f** *FromCode* **-t** *ToCode* [*FileName*...]

`iconv -l`

Description

The **iconv** command converts the encoding of characters read from either standard input or the specified file from one coded character set to another and then writes the results to standard output. The input and output coded character sets are identified by the *FromCode* and *ToCode* parameters. The input data should consist of characters in the code set specified by the *FromCode* parameter. If the *FileName* parameter is not specified on the command line, the **iconv** command reads from standard input.

You can use the System Management Interface Tool (SMIT) **smit iconv** fast path to run this command. The `iconv` command uses the LOCPATH environment variable to search for code-set converters of the form `iconv/`*FromCodeSet_ToCodeSet*. The default value of LOCPATH is `/usr/lib/nls/loc`.

Flags

Item	Description
-c	Omits characters that cannot be converted in the input file from the output. Characters that cannot be converted include characters that are invalid in the *FromCode* of the input or that have no corresponding character in the *ToCode* of the output. After omitting an unconvertible character, `iconv` advances to the next byte of the input to convert the next character. If `-c` is not used, `iconv` exits upon encountering a character that cannot be converted in the input. The presence or absence of `-c` does not affect the exit status of `iconv`.
-f *FromCode*	Specifies the code set in which the input data is encoded. The space between the **-f** flag and the *FromCode* parameter is optional.
-l	Writes all supported *FromCode* and *ToCode* values to standard output.
-s	Suppresses any messages written to standard error concerning invalid characters. When -s is not used, an error message is written to standard error for each unconvertible or truncated character. The presence or absence of `-s` does not affect the exit status of `iconv`.
-t *ToCode*	Specifies the code set to which the output data is to be converted. The space between the **-t** flag and the *ToCode* parameter is optional.
FileName	Specifies a file to be converted.

Exit Status

This command returns the following exit values:

Item	Description
0	Input data was successfully converted.
1	The specified conversions are not supported; the given input file cannot be opened for read; or there is a usage-syntax error.
2	An unusable character was encountered in the input stream.

Examples

1. To convert the contents of the **mail.x400** file from code set IBM-850 and store the results in the **mail.local** file, enter:

```
iconv -f IBM-850 -t ISO8859-1 mail.x400 > mail.local
```

2. To convert the contents of the **mail.japan** file from the 7-bit interchange (ISO2022) encoding to the Japanese EUC code set (IBM-eucJP), enter:

```
iconv -f fold7 -t IBM-eucJP mail.japan > mail.local
```

3. To convert the contents of a local file to the mail-interchange format and send mail, enter:

```
iconv -f IBM-943 -t fold7 mail.local | mail fxrojas
```

id Command

Purpose

Displays the system identifications of a specified user.

Syntax

id [user]

id **- G** [**-n**] [*User*]

id **-g** [**-n l** | [**-n -r**] [*User*]

id **-u** [**-n l** | [**-n r**] [*User*]

Description

The **id** command writes to standard output a message containing the system identifications (ID) for a specified user. The system IDs are numbers which identify users and user groups to the system. The **id** command writes the following information, when applicable:

- User name and real user ID
- Name of the user's group and real group ID
- Name of user's supplementary groups and supplementary group IDs

  Supplementary group information is written only for systems supporting multiple-user groups and only if the specified user belongs to a supplementary group.

The **id** command also writes effective user and group IDs, but only for the user that invoked the **id** command. (If the *User* parameter is specified with the **id** command, the effective IDs are assumed to be identical to real IDs.) If the effective and real IDs for the invoking user are different, the **id** command writes the following effective ID information, when applicable:

- Effective user name and effective user ID
- Name of effective user's group and effective group ID

The id command, when specified with the -l option, displays login UID. Login ID indicates the system credentials at the time of logging in to the session. Login UID indicates the user ID (numeric value) of the user, who actually logged in. The login UID is equal to the UID for a user who has logged in to the system and whose credentials remain unchanged. For example, when the user runs the su command, the UID for the user changes and the login UID remains the same.

The **id** command will fail if the specified user does not exist or if the command cannot read the user or group information.

Flags

The contents and format of the message written by the **id** command can be altered with the following flags:

Item	Description
-G	Specifies that the **id** command write the effective, real, and supplementary group IDs only. If there are multiple entries for the effective, real, or supplementary IDs, they are separated by a space and placed on the same line.
-g	Specifies that the **id** command write only the effective group ID.
-u	Specifies that the **id** command write only the effective user ID.
-r	Specifies that the **id** command write the real ID instead of the effective ID. This flag can be invoked with either the **-g** flag to write the real group ID, or the **-u** flag to write the real user ID.
-n	Specifies that the **id** command outputs the name, instead of the ID number, when it is specified with the **-G**, **-g**, and **-u** flags.

Item	Description
-l	Specifies that the `id` command write the login ID instead of the real or effective ID. This flag can be invoked with either the `-u` flag to write the login UID or the `-g` flag to write the primary group ID for the login user. When *username* is passed with the `-l` option, the `id` command displays the ID details of the user name instead of the login ID details.
User	Specifies the login name of a user for the **id** command. If no user is specified, the user invoking the **id** command is the default.

Security

Access Control: This program should be installed as a normal user program in the Trusted Computing Base.

Exit Status

This command returns the following exit values:

Item	Description
0	Successful completion.
>0	An error occurred.

Examples

1. To display all system identifications for the current user, enter:

   ```
   id
   ```

   Output for the **id** command is displayed in the following format:

   ```
   uid=1544(sah) gid=300(build) euid=0(root) egid=9(printq) groups=0(system),10(audit)
   ```

   In this example, the user has user name `sah` with an ID number of `1544`; a primary group name of `build` with an ID number of `300`; an effective user name of `root` with an ID number of `0`; an effective group name of `printq` with an ID number of `9`; and two supplementary group names of `system` and `audit`, with ID numbers `0` and `10`, respectively.
2. To display all group ID numbers for the current user, enter:

   ```
   id -G
   ```

   Output is displayed in the following format:

   ```
   0 10 300 9
   ```

   The **-G** flag writes only the group IDs for a user. In this example, user `sah` is a member of the system (`0`), audit (`10`), build (`300`), and printq (`9`) groups.
3. To display all group names for the current user, enter:

   ```
   id -Gn
   ```

   Output is displayed in the following format:

   ```
   system audit build printq
   ```

   The **-n** flag writes only the names instead of the ID numbers.
4. To display the real group name for the current user, enter:

```
id -gnr
```

Output is displayed in the following format:

```
build
```

5. To display the login UID after logging in as root and running the su command to user sah, type:

```
id -lu
```

Output is displayed in the following format:

```
0
```

6. To display the primary group name of the user who actually logged in, type:

```
id -lgn
```

Output is displayed in the following format:

```
system
```

7. To display the primary group ID of the user who actually logged in, type:

```
id -lg
```

Output is displayed in the following format:

```
0
```

Files

Item	Description
/usr/bin/id	Contains the **id** command.

ifconfig Command

Purpose

Configures or displays network interface parameters for a network by using TCP/IP.

Syntax

ifconfig *interface* [*addressfamily* [*address* [*destinationaddress*]] [*parameters*...]]

ifconfig *interface* [*protocolfamily*] *interface protocolfamily*

ifconfig **-a** [**-l**] [**-d**] [**-u**] [*protocolfamily*]

ifconfig *interface* [**tcp_low_rto** *rto* | **-tcp_low_rto**]

Description

You can use the **ifconfig** command to assign an address to a network interface and to configure or display the current network interface configuration information. The **ifconfig** command must be used at system startup to define the network address of each interface present on a system. After system startup, it can also be used to redefine an interfaces address and its other operating parameters. The network interface configuration is held on the running system and must be reset at each system restart. The **ifconfig** command interprets the **IFF_MULTICAST** flag and prints its value if it is set.

An interface can receive transmissions in differing protocols, each of which might require separate naming schemes. It is necessary to specify the *addressfamily* parameter, which might change the interpretation of the remaining parameters. The address families that are currently supported are **inet** and **inet6**.

For the DARPA-Internet family, **inet**, the address is either a host name present in the host name database, that is, the **/etc/hosts** file, or a DARPA-Internet address that is expressed in the Internet standard dotted decimal notation.

While any user can query the status of a network interface, only a user who has administrative authority can modify the configuration of those interfaces.

The **ifconfig** function displays the current configuration for a network interface when no optional parameters are supplied.

If a protocol family is specified, **ifconfig** reports only the details specific to that protocol family.

Only a super user can modify the configuration of a network interface.

Gratuitous ARP is supported for Ethernet, token-ring, and FDDI interfaces. This support means when an IP address is assigned, the host sends an ARP request for its own address (the new address) to inform other systems of its address so that they can update their ARP entry immediately. It also lets hosts detect duplicate IP address. If you get a response to the ARP request, an error is logged in **/var/adm/ras/errlog**, which can be viewed by using **errpt** command (or by using SMIT interface) for the error ID **AIXIF_ARP_DUP_ADDR**.

The **ifconfig** command calls the **ifconfig.ib** command. The **ifconfig.ib** command displays the interface information as shown:

```
ib0:flags=e3a0063<UP,BROADCAST,NOTRAILERS,RUNNING,ALLCAST,MULTICAST,GROUPRT>
pmtu 2048 qkey
0x1e qpn 0x48 lid 0x5c hca iba0 port 1 inet 1.2.3.120 netmask 0xffffff00 broadcast
1.2.3.255 inet6
fe80::2:c903:1:1e8d/64 tcp_sendspace 262144 tcp_recvspace 262144 rfc1323 1
```

The interface now displays the path mtu (pmtu), Queue Key (qkey), Queue Pair Number (qpn), Local ID (lid), Host Channel Adapter (hca), and the port number (port). This information is useful during debugging or performing diagnostics.

Note: Any changes that are made to the attributes of an interface by using the **ifconfig** command are lost when the system is rebooted.

When the **detach** command is specified with the **ifconfig** command, all other options are ignored. Specifying the **detach** command prevents the garbage character in the **ipconfig** command from causing any error. For example, the `ifconfig en3 garbage detach` command runs properly even when with the bad option.

Flags

Item	Description
-a	Optionally, the **-a** flag can be used instead of an interface name. This flag instructs **ifconfig** to display information about all interfaces in the system.
-d	The **-d** flag displays interfaces that are down. You can use the flag only with the **-a** or **-l** flag.
-l	This flag can be used to list all available interfaces on the system, with no other additional information. Use of this flag is mutually exclusive with all other flags and commands, except for **-d** and **-u**.
-u	The **-u** flag displays interfaces that are up. You can use the flag only with the **-a** or **-l** flag.
protocolfamily	This flag specifies protocols such as **tcp**, **udp**, **tcp6**, **udp6**, **icmp**, and **icmp6**.

Parameters

Item	Description
address	Specifies the network address for the network interface. For the **inet** family, the *address* parameter is either a host name or an IP address in the standard dotted decimal notation.
addressfamily	Specifies which network address family to change. The **inet** and **inet6** address families are currently supported. This parameter defaults to the **inet** address family.
destinationaddress	Specifies the address of the correspondent on the remote end of a point-to-point link.
interface	Specifies the network interface configuration values to show or change. You must specify an interface with the *interface* parameter when you use the **ifconfig** command. Abbreviations for the interfaces include: • at for asynchronous transfer mode (ATM) • en for Standard Ethernet (inet) • et for IEEE 802.3 Ethernet (inet) • gre for generic routing encapsulation tunnel pseudointerface (inet) • gif for IPv4-over-IPv6 tunnel pseudointerface (inet) • tr for token-ring (inet) • xt for X.25 (inet) • sl for serial line IP (inet) • lo for loopback (inet) • op for serial (inet) • vi for virtual IP address (inet) • ib for IP over InfiniBand (inet) • tap for TAP pseudo-Ethernet Include a numeral after the abbreviation to identify the specific interface (for example, `tr0`). If *interface* is not yet loaded, **ifconfig** *interface* loads that interface and **netstat -in** lists it. In processing a status query for *interface*, that interface is loaded (if not already loaded) to complete the query processing.
parameter	Allows the following parameter values: **alias** Establishes an additional network address for the interface. When changing network numbers, this parameter is useful for accepting packets that are addressed to the old interface. **allcast** Sets the token-ring interface to broadcast to all rings on the network. **-allcast** Confines the token-ring interface to broadcast only to the local ring. **anycast** (inet6 only) Adds the specified anycast address.

Item	Description
	-anycast (inet6 only) Deletes the specified anycast address.
	arp Enables the **ifconfig** command to use the Address Resolution Protocol in mapping between network-level addresses and link-level addresses. The **arp** value is the default.
	-arp Disables the use of the address resolution protocol.
	authority Reserved for future use.
	bridge Reserved for future use.
	-bridge Reserved for future use.
	broadcast *Address* (**inet** only) Specifies the address to use to broadcast to the network. The default broadcast address has a host part of all 1's.
	checksum_offload Enables the flag to indicate that the transmit TCP checksum will be offloaded to the adapter. The command also resets the per-interface counter that determines whether TCP must dynamically enable or disable offloading of checksum computation.
	-checksum_offload Disables transmit TCP checksum offloading.
	create (TAP only) Creates a network interface. You can either create a specific interface, such as **tap0** or specify the **tap** option to create the next available TAP interface, such as **ifconfig tap create**.
	-dad (inet6 only) Does not perform duplicate IPv6 address detection.
	-debug Disables driver-dependent debug code.
	delete Removes the specified network address. This command is used when an alias is incorrectly specified or when it is no longer needed. Incorrectly setting an **ns** address has the side effect of specifying the host portion of the network address. Removing all **ns** addresses lets you specify the host portion again.
	destroy (TAP only) Destroys a network interface. The **ifconfig** command removes the specified network interface from the list of interfaces. It also removes the interface and any associated TAP network device from the Object Data Manager (ODM).

Item	Description
device *dev_name*	(ATM network interface only). Specifies the device name that this interface is associated with. Unlike token ring or Ethernet, in case of ATM, there is not a one-to-one correspondence between an interface and a device. In the case of ATM, there can be more than one interface for every device.
detach	Removes an interface from the network interface list. If the last interface is detached, the network interface driver code is unloaded. For the interface route of an attached interface to be changed, that interface must be detached and added again with **ifconfig**.
down	Marks an interface as inactive (**down**), which keeps the system from trying to transmit messages through that interface. If possible, the **ifconfig** command also resets the interface to disable the reception of messages. Routes that use the interface, however, are not automatically disabled.
eui64	(inet6 only) Computes real IPv6 address by replacing the last 64 bytes of the specified address with the Interface Identifier.
first	Puts an IPv6 address at the first place on an interface to select it as the source for unbound sockets. The syntax for using this parameter is as follows: `ifconfig interface inet6 first address`
firstalias	Same as alias, but sets the address in front of the interface address list to select it as the source for unbound sockets.
group *ID*	Adds a group ID to the group ID list for the interface. This list is used in determining the route to use when forwarding packets that arrived on the interface.
-group *ID*	Removes a group ID from the group ID list for the interface. This list is used in determining the route to use when forwarding packets that arrived on the interface.
hwloop	Enables hardware loopback. The hardware loopback specifies that locally addressed packets that are handled by an interface are sent out by using the associated adapter.
-hwloop	Disables hardware loop-back. The hardware loop-back specifies that locally addressed packets that are handled by an interface must be sent out using the associated adapter.

Item	Description
	ipdst Specifies an Internet host that can receive IP packets encapsulating **ns** packets that are bound for a remote network. An apparent point-to-point link is constructed, and the specified address is taken as the **ns** address and network of the destination.
	ipv6dst Used to specify an IPv6 node that can receive IPv6 packets encapsulating IPv6 or IPv4 packets through a tunnel. The apparent destination of the point-to-point tunnel interface might not be the real destination of the packets. At the tunnel endpoint, the decapsulated packets might then be forwarded to their final destination.
	largesend Enables one LPAR to send large data in a single packet to another LPAR. It works similarly to `largesend` over real adapters except in this case no TCP segmentation is done. If the SEA on VIOS supports `largesend`, the LPAR can transmit large data, which gets segmented by the real adapter on SEA. Use the `chdev` command to enable the `largesend` attribute on SEA.
	-largesend Disables `largesend` over virtual Ethernet. This value is the default.
	link [0-2] Enables special processing of the link level of the interface. These 3 options are interface-specific. In actual effect, however, they are used to select special modes of operation. An example of the usage is to enable Serial Line Internet Protocol (SLIP) compression, or to select the connector type for some Ethernet cards. For more information, see the manual page of the specific driver.
	-link [0-2] Disables special processing at the link level with the specified interface.
	metric *Number* Sets the routing metric of the interface to the value specified by the *Number* variable. The default is 0. The routing metric is used by the routing protocol (the **routed** daemon). Higher metrics have the effect of making a route less favorable. Metrics are counted as additional hops to the destination network or host.
	monitor Enables the underlying adapter to notify the interface layer of link status changes. The adapter must support link status callback notification. If multipath routing is used, alternative routes are selected when a link goes down.
	-monitor Disables monitoring of the adapter link status.

Item	Description
mtu ***Value***	Sets the maximum IP packet size for this system. The *Value* variable can be a number in the range 60 - 65535, but is media-dependent. See Automatic configuration of network interfaces in *Networks and communication management* for the maximum transmission unit (MTU) values by interface.
netmask ***Mask***	Specifies how much of the address must be reserved for subdividing networks into subnetworks. This parameter can be used only with the **inet** address family. The *Mask* variable includes both the network part and the subnet part of the local address, which is taken from the host field of the address. The mask can be specified as a single hexadecimal number that begins with 0x, in standard Internet dotted decimal notation, or begins with a name or alias that is listed in the **/etc/networks** file. In the 32-bit address, the *Mask* variable contains 1s for the bit positions that are reserved for the network and subnet parts, and *Mask* variable contains 0s for the bit positions that specify the host. The *Mask* variable contains at least the standard network portion. The subnet segment is contiguous with the network segment. If the **netmask** parameter is used without specifying the IP address, the netmask value of the first IP address of the specified interface is updated.
pvc	(ATM network interface only). Specifies that this interface supports Permanent Virtual Circuit (PVC) types of virtual connections only.
pktchain	Enables the flag to indicate that this interface can handle multiple packets chained together on the output path.
-pktchain	Disables the flag that indicates that this interface can handle multiple packets chained together on the output path.
svc_c ***server_addr***	(ATM Network interface only). Specifies that this interface supports both switched virtual circuit (SVC) and PVC types of virtual connections. It further specifies that this interface is an ARP client. The *server_addr* is the list of 20-byte ATM addresses of the ARP servers that this client uses. The addresses are specified in the form of xx.xx....xx. The first entry is considered the primary ARP server and the rest are considered secondary ARP servers. The list of 20-byte ARP server addresses must be separated by a comma.
site6	Sets the IPv6 site number (default is 0). This command must be used only with site-local addresses on a multiple-site node.

Item	Description
	svc_s (ATM network interface only). Specifies that this interface supports both SVC and PVC types of virtual connections. It further specifies that this interface is the ARP server for this logical IP subnetwork (LIS). **security** Reserved for future use. **snap** Reserved for future use. **-snap** Reserved for future use. **tcp_low_rto** Enables the use of lower retransmission timeouts (RTO) for TCP connections on a low latency, fast network, such as gigabit ethernet and 10-gigabit ethernet). If the networks experience packet drops, the respective TCP connections use the *rto* value for RTO. The *rto* values are in the range of 0 - 3000 ms. This runtime option must be set in the **if_isno** flags field. The **use_isno** option must also be set for this flag to be effective. **tcp_nocksum** Disables verification of the checksum of TCP data for local traffic to the subnet attached to the interface. Checksum verification of TCP, UDP, and IP headers continues. Checksum verification of TCP data that is read or written from this interface, from or to remote networks also continues. **-tcp_nocksum** Enables verification of the checksum of TCP data for local traffic to the subnet attached to the interface. This value is the default. **thread** (**inet** only) Configures dedicated kernel threads for an interface. This parameter can be used only SMP systems that have multiple CPU. This parameter causes input packets to be queued to a kernel thread after processing by the device driver and input demuxer. The input packet is processed in IP and TCP, or UDP by the thread instead of directly on the interrupt level. Setting this parameter can improve throughput when high-speed adapters bottleneck on a single CPU during interrupt processing by allowing the input packets to be processed on other CPUs running the kernel threads (improved pipelining). For some workloads, this parameter increases the per packet load, due to the thread scheduling load, resulting in higher CPU utilization, and possibly lower throughput. **-thread** (**inet** only) Disables kernel thread support that has been configured with the *thread* parameter.

Item	Description
	tunnel Configures a dedicated tunnel for the trusted communication. A tunnel establishes a virtual link between two trusted nodes for transmitting data packets as payloads of other packet headers. A tunnel can be one of the following types: **Generic routing encapsulation (GRE) tunnel** Expects the source and destination IPv4 addresses of the tunnel endpoint as arguments that are followed by the **tunnel** parameter value. A tunnel is created between the 2 endpoints. **IPv4 over IPv6 tunnel (GIF tunnel)** Expects the source IPv6 address of the tunnel. The address is followed by a destination IPv4 address and a destination IPv6 address that are separated by a comma. For one-to-many tunnels, each target is separated by a comma. **transfer *tointerface*** Transfers an address and its related static routes from *interface* to *tointerface*. For IPv6, this command works only for addresses added by using the **ifconfig** command. `ifconfig interface addressfamily address transfer tointerface` **Note:** If you want to transfer an IP address from one interface to another, and if the destination interface is not part of the virtual LAN (VLAN) to which the IP address belongs, you must add the VLAN to the adapter on which the destination interface is configured. **up** Marks an interface as active (**up**). This parameter is used automatically when you set the first address for an interface. It can also be used to enable an interface after you issue an **ifconfig down** command. **vipa_iflist** Adds the interfaces to the list of interfaces that must use this **vipa** parameter as the source address in the outgoing packets. **-vipa_iflist** Removes the interfaces from the list of interfaces that are configured to use this **vipa** as the source address in the outgoing packets. **scope addrscope zone zoneid** Moves the interface into the topological zone that is specified by *zoneid* at the address scope that is specified by the *addrscope*. IPv6 zones are defined in RFC 4007. The parameter is applicable to only inet6.
rto	Specifies the retransmission timeout in milliseconds. The range for this value is 0 - 3000. **Requirement:** You must set the **timer_wheel_tick** value of the **no** command before you set the *rto* value by using the **ifconfig** command. The *rto* value that you specify must be equal to or a multiple of 10 times the **timer_wheel_tick** value that is set.

The following network options, commonly known as Interface Specific Network Options (ISNO), can be configured on a per interface basis:

rfc1323 [0 | 1]
Enables or disables TCP enhancements as specified by RFC 1323, *TCP Extensions for High Performance*. A value of 1 specifies that all TCP connections by using this interface will attempt to negotiate the RFC enhancements. A value of 0 disables **rfc1323** for all connections by using this interface. The SOCKETS application can override this ISNO and global behavior on individual TCP connections with the **setsockopt** subroutine.

-rfc1323
Removes the use of ISNO for **rfc1323** for this network. A SOCKETS application can override the global behavior on individual TCP connections by using the **setsockopt** subroutine.

tcp_mssdflt *Number*
Sets the default maximum segment size that is used in communicating with remote networks. If you communicate over this interface, a socket uses *Number* as the value of the default maximum segment size.

-tcp_mssdflt
Removes the use of ISNO for the **tcp_mssdflt** option. The global value, which is manipulated through **/usr/sbin/no**, is used instead.

tcp_recvspace *Size*
Specifies the default socket buffer size for interface sockets that are receiving data. The buffer size affects the window size that is used by TCP. (For more information, see the **no** command.)

-tcp_recvspace
Removes the use of ISNO for the **tcp_recvspace** option. The global value is used instead.

tcp_sendspace *Size*
Specifies the default socket buffer size for interface sockets that are sending data. The buffer size affects the window size that is used by TCP. (For more information, see the **no** command.)

-tcp_sendspace
Removes the use of ISNO for the **tcp_sendspace** option. The global value is used instead.

tcp_nodelay [0 | 1]
Specifies that sockets by using TCP over this interface follow the Nagle algorithm when you send data. By default, TCP follows the Nagle algorithm.

-tcp_nodelay
Removes the use of ISNO for the **tcp_nodelay** option.

Tip: Parameters that you set by using the **ifconfig** command are lost the next time that you restart your system. Use the **chdev** command to change the Object Data Manager (ODM) database for each interface to make parameter changes permanent. Use the **lsattr -E -l** [*interface*] command to view the interface attributes and use the **chdev -l** [*interface*] **-a** [*attribute=value*] command to change the attribute. For example:

```
lsattr -E -l en0
chdev -l en0 -a tcp_sendspace=65536
```

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To query the status of a serial line IP interface, enter the following command:

```
ifconfig  sl1
```

In this example, the interface to be queried is `sl1`. The result of the command looks similar to the following result:

```
sl1:  flags=51<UP,POINTOPOINT,RUNNING>
            inet  192.9.201.3  -->  192.9.354.7  netmask  ffffff00
```

2. To configure the local loop-back interface, enter the following command:

```
ifconfig  lo0  inet  127.0.0.1  up
```

3. To mark the local token-ring interface as down, enter the following command:

```
ifconfig  tr0  inet  down
```

In this example, the interface to be marked is `token0`.

> **Note:** Only a user with root user authority can modify the configuration of a network interface.

4. To turn **rfc1323** off for all connections over `en5` (assuming that the global value is 1), enter the following command:

```
ifconfig en0 rfc1323 0
```

5. To configure a list of interfaces to use a vipa, enter the following command:

```
ifconfig vi0 vipa_iflist en0,en1,tr0
```

6. To remove interfaces that are configured to use vipa, enter the following command:

```
ifconfig vi0 -vipa_iflist en1,tr0
```

7. To find out which interfaces are configured to use a vipa, say vi0, enter the following command:

```
ifconfig vi0
```

8. To enable link status monitoring, enter the following command:

```
ifconfig en0 monitor
```

If the link status on adapter `ent0` changes to down, the adapter notifies the interface layer, which causes the interface to also be marked as down.

9. To configure a Generic Routing Encapsulation (GRE) tunnel between the interfaces of two nodes, enter the following command:

```
ifconfig gre0 tunnel 9.3.149.70 9.3.149.121
```

This creates a GRE tunnel between the local interface `9.3.149.70` and the remote interface `9.3.149.121`. The local end of the tunnel is identified by `gre0`.

10. To associate an IP address with the newly created interface, enter the following command:

```
ifconfig gre0 10.10.10.1
```

11. To configure NAT on a GRE tunnel, enter the following command:

```
ifconfig gre0 nat toaddr 127.0.0.1 fromport 80 toport 8080
```

In this example, the original destination port of the GRE packet is 80 and the command changes the destination port to 8080 and the destination address to `127.0.0.1`.

12. To configure a GIF tunnel between one-to-many endpoints (one-to-many tunnel), enter the following command:

```
ifconfig gif0 10.10.10.1 netmask 255.255.255.0 tunnel  2000::4612:6995:6c4a:fa6e
10.10.10.10,2000::4612:6995:6c4a:fa6a 10.10.10.11,2000::4612:6995:6c4a:
fa6b 15.15.15.1,2000::4612:6995:6c4a:f777
```

The command creates a one-to-many tunnel between the source (2000::4612:6995:6c4a:fa6e) and the following 3 targets:

- 2000::4612:6995:6c4a:fa6a
- 2000::4612:6995:6c4a:fa6b
- 2000::4612:6995:6c4a:f777

The command also configures the 10.10.10.1 IP address to the GIF interface.

13. To configure a one-to-one GIF tunnel between two endpoints, enter the following command:

```
ifconfig gif0 10.10.10.1 netmask 255.255.255.0 tunnel  2000::4612:6995:6c4a:fa6e
10.10.10.10,2000::4612:6995:6c4a:fa66
```

The command creates a GIF tunnel between the source (2000::4612:6995:6c4a:fa6e) and the target (2000::4612:6995:6c4a:fa66).

14. The command also configures the 10.10.10.1 IP address to a GIF interface.

Item	Description
/etc/host	Contains the host name database.
/etc/networks	Contains network names.

ike Command

Purpose

Starts, stops, and monitors IP Security dynamic tunnels which use the Internet Key Exchange Protocol (ISAKMP/Oakley).

Syntax

ike cmd=Subcommand [*parameter* ...]

Description

The **ike** is used to start, stop, and monitor IP Security dynamic tunnels using the Internet Key Exchange (IKE) protocol. IP Security tunnels protect IP traffic by authenticating and/or encrypting IP data. The **ike** command performs several functions. It can activate, remove, or list IKE and IP Security tunnels.

Note: You must have root access to use the **ike** command.

The IKE negotiation occurs in two phases. The first phase authenticates the two parties and sets up a **Key Management** (also known as phase 1) **Security Association** for protecting the data that is passed during the negotiation. In this phase the key management policy is used to secure the negotiation messages. The second phase negotiates **Data Management** (also known as the phase 2) **Security Association**, which uses the data management policy to set up IP Security tunnels in the kernel for encapsulating and decapsulating data packets. The secure channel established in phase 1 can be used to protect multiple data management negotiations between 2 hosts.

The **ike** command is used to activate tunnels with identification and policy information which has already been entered using the **ikedb** command. The parameters to be used during the negotiation are entered by the user and stored in a database. The **ike** command allows the activation, removal and listing of tunnels that have been started using the security parameters stored in the database.

In most uses of the **ike** command, activation and deletion occurs for both phases, however the command allows these operations to be done separately.

Subcommands

activate

activate command

Item	Description
Purpose	Start the negotiation of an IKE tunnel. If phase is not specified, both a phase 1 and phase 2 tunnel are started. If IP addresses are supplied, the tunnel is setup using those IP addresses. If the IDs used during the negotiation are not IP addresses, the local and remote host IDs must be entered using the **ikedb** command. A unique tunnel number is created. The tunnel can then be referenced by the tunnel number in the **ike** command to indicate the particular tunnel to be started.
Syntax	**ike cmd=activate** [**phase=1**|**2**] [**numlist=***tunnel_num_list*] [**namelist=tunnel_name_list**] [**remid=***remote_id*] [**ipaddr=***src_addr*,*dst_addr*] [**autostart**]
Description	The **activate** subcommand works using a two phase paradigm. A phase 1 tunnel must be established before a phase 2 tunnel can be started. If a phase 1 tunnel is specified, then only the phase 1 tunnel negotiation takes place. If a phase 2 tunnel is specified, the system checks for the existence of the corresponding phase 1 tunnel before creating the phase 2 tunnel. If the phase 1 negotiation has not been started, it is started automatically. Upon successful completion of a phase 2 tunnel, the tunnel definition and corresponding filter rules are inserted into the IP Security kernel, and the new tunnel is activated. Traffic described by the tunnel definition passing between the designated endpoints is protected by the encryption and authentication algorithms indicated by the associated IKE security policy. Multiple phase 2 tunnels can be started under the same phase 1 tunnel. A situation where this may be desired is if different types of traffic between two endpoints need different levels of security protection. The Security Association used for the phase 1 tunnel can be shared by multiple phase 2 tunnels. The phase 2 tunnels would specify the type of traffic (by protocol and port, or subnet mask, for instance) and could have different security policies protecting them. The **ike** command returns if either a negotiation has been initiated, an error returns, or the tunnel already exists. Since the remote host must be contacted during the negotiation and the amount of time needed to complete the negotiation is uncertain, the **list** subcommand should be used to determine if the negotiation was successful. Errors that are detected during the negotiation process can be captured by using **syslog**.

Item	Description
Flags	**phase** Specifies the type of negotiation desired. If omitted, the **activate** subcommand activates both a phase 1 and phase 2 tunnel. The **phase** flag is an optional flag. **numlist** Initiates the **ike** tunnel number which corresponds to the desired phase 1 or phase 2 tunnel(s) to be started. The **,** (comma) and **-** (dash) characters can be used to delimit values and indicate ranges. The **list** subcommand with the database option **db** can be used to determine the tunnel number for a particular tunnel. An example using tunnel numbers is shown below: `ike cmd=activate numlist=1,3,5-7` This would start tunnels 1, 3, 5, 6 and 7. **remid** Starts phase 1 or phase 2 tunnel(s) from the local ID to the specified remote ID. **remid** could be a phase 1 ID (such as IP address, FQDN, user FQDN and X500DN), a phase 2 ID (such as IP address, subnet and IP address range) or a group ID. The **,** (comma) is used to delimit the subnet id and subnet mask, and the starting and ending IP address. If **remid** is a group name, a tunnel is initiated for each group member. **remid** is an optional flag and can only be used with the **activate** subcommand. It cannot be used in conjunction with the **ipaddr**, **numlist** or **namelist** flags. 1. To activate a phase 1 tunnel to remote IP address 9.3.97.100, type: `ike cmd=activate phase=1 remid=9.3.97.100` 2. To activate a phase 2 tunnel to remote subnet ID 9.3.97.100,255.255.255.0, type: `ike cmd=activate phase=2 remid=9.3.97.100,255.255.255.0` **ipaddr** Starts a phase 1 or phase 2 tunnel between the specified IP Addresses. **autostart** Causes the activation of all phase 1 and phase 2 tunnel database entries which were created with the **autostart** parameter set. The **autostart** flag does not work in conjunction with any other flags pertaining to the **activate** subcommand. **namelist** Specifies a tunnel name or comma-separated list of tunnel names to be activated. This flag requires the use of the **phase** flag.

activate command *(continued)*

Item	Description
Examples	1. To activate a phase 2 tunnel between source IP address x.x.x.x and destination IP address y.y.y.y, enter: `ike cmd=activate phase=2 ipaddr=x.x.x.x,y.y.y.y` The security policy indicated in the database for the IP addresses x.x.x.x and y.y.y.y is used for activating the tunnel. 2. To activate phase 1 tunnels for tunnels 1 and 2, enter: `ike cmd=activate phase=1 numlist=1,2` 3. To activate phase 2 tunnels for inactive tunnels named AIXFW1_DM and remote_office in the database enter: `ike cmd=activate phase=2 namelist=AIXFW1_DM,remote_office` **Note:** Because each phase 2 tunnel must have an associated phase 1 tunnel, a phase 1 tunnel is automatically activated before the phase 2 tunnel is activated.

list

list command

Item	Description
Purpose	Monitors the status of IP Security tunnels by phase. It is also used to view tunnel entries defined in the IKE database.
Syntax	**ike cmd=list** [**phase=1**|**1+**|**2**] [**numlist=** *tunnel_num_list*] [**db** | **role=i**|**r**] [**verbose**]
Description	The **list** subcommand queries the Tunnel Manager and lists phase 1 and phase 2 tunnel status and information according to the result of the query. This command can also be used to view information in the Tunnel Definition database. The default behavior is to list the tunnels currently active. To list the tunnels in the database, the **db** option must be used.

Item	Description
Flags	**phase** Indicates the type and order of the tunnel(s) to be listed. A phase value of 1 results in only the requested phase 1 tunnel information being displayed. A phase value of 2 results in the information for the requested phase 2 tunnel(s) and their associated phase 1 tunnel(s) should be displayed. A phase value of 1+ means that the requested phase 1 tunnel and all associated phase 2 tunnels should be displayed. The default phase value is 1+. **numlist** Lists of the tunnel numbers which you would like to view. If omitted, the information from all tunnels is displayed. The **,** (comma) and **-** (dash) characters can be used to delimit values and indicate ranges. For example: `ike cmd=list numlist=1,3,5-7` When used in conjunction with **db**, tunnels from the IKE Security Policy database are shown. **Note:** Active tunnel numbers and tunnel numbers from the IKE Tunnel Definitions database do not necessarily match up. This is because a single tunnel entry in the database can correspond to multiple active tunnels. **db** Shows the entries in the database. If this flag is omitted, only active tunnels are displayed. This cannot be used in conjunction with **role**. Supply the list of tunnel numbers which you would like to view. **role** Allows the display of tunnels by the point of initiation. If **i** is specified, then the tunnels that were initiated by the local host are displayed. If **r** is specified, then the tunnels where the local host acted as a responder are displayed. If this flag is omitted, both initiator and responder tunnels are shown. This flag cannot be used in conjunction with **db**. **verbose** Shows extended information about the specified tunnels. If this flag is not specified, then only a concise entry for each tunnel is shown.

list command *(continued)*

Item	Description
Examples	**Note:** Tunnel numbers from the database and tunnel numbers from the tunnel manager do not necessarily reflect the same tunnel. 1. To perform a concise (short form) listing of phase 1 tunnels with entries in the tunnel manger, enter: `ike cmd=list phase=1 numlist=1,2,3` These tunnels are either being negotiated, in the active state , or have expired. Only tunnels 1, 2, and 3 are listed. Tunnels can be either initiator or responder role. 2. To perform a concise (short form) listing of of the specified phase 2 tunnels in the database with each preceded by the associated phase 1 tunnel, enter: `ike cmd=list phase=2 numlist=1-3 db` These are tunnels defined in the database which may or may not be currently active in the tunnel manager. All tunnels in the database are used in the initiator role only. 3. To perform a verbose (long form) listing of a phase 1 tunnel followed by all of its associated phase 2 tunnels from the tunnel manager, enter: `ike cmd=list phase=1+ role=r verbose` Only tunnels which were activated in the responder role are listed. All available tunnel numbers are listed since no **numlist** was specified.

remove

remove command

Item	Description
Purpose	Deactivates specified phase 1 or phase 2 tunnel(s).
Syntax	**ike cmd=remove** [**phase=1**|**2**] [**numlist=** *tunnel_num_list*] [**all**]
Description	The **remove** subcommand requests the deactivation of phase 1 or phase 2 tunnel(s). Because phase 2 tunnels are associated with a phase 1 tunnel, if a phase 1 tunnel is deactivated, all phase 2 tunnels under the phase 1 tunnel are not refreshed when the phase 2 tunnel lifetime expires.
Flags	**phase** Indicates the phase of the tunnel to be deactivated and must be specified. A phase value of 1 refers to a phase 1 tunnel and a phase value of 2 refers to a phase 2 tunnel. **numlist** Lists the tunnel numbers you would like to deactivate. The **,** (comma) and **-** (dash) characters can be used to delimit values and indicate ranges. For example: `ike cmd=remove phase=1 numlist=1,3,5-7` When **numlist** is omitted, all tunnels are deactivated. **all** Deactivates all active tunnels. This parameter does not work in conjunction with **numlist**.

remove command *(continued)*

Item	Description
Examples	1. To deactivate phase 1 tunnels numbered 1, 2, and 3, enter: `ike cmd=remove phase=1 numlist=1-3` 2. To deactivate all phase 1 and phase 2 tunnels, enter: `ike cmd=remove all` 3. To deactivate all phase 2 tunnels but keep all phase 1 tunnels active, enter: `ike cmd=remove phase=2 all` 4. To deactivate all phase 1 tunnels (corresponding phase 2 tunnels will not be refreshed), enter: `ike cmd=remove phase=1 all`

log

Table 10. log

Item	Description
Purpose	Read the ISAKMP daemon log level from **/etc/isakmpd.conf** and start logging at that level.
Syntax	**ike cmd=log**
Description	The **log** subcommand causes the ISAKMP daemon to read the log level from **/etc/isakmpd.conf**, and a filename from **/etc/syslog.conf**. The logging level specified is set and the log output, along with other **syslog** output, is placed in the file specified.

Notes:

- If the log level or the output file name in the `/etc/syslog.conf` file is changed, you can refresh the `syslogd` subsystem by running the **`refresh -s syslogd`** command or by refreshing the IKE daemons. You can refresh the IKE daemons by running the **`refresh -s ike`** command.
- There are four valid logging levels for the ISAKMP daemon. They are **none**, **errors**, **events**, and **information**. **none** means no logging, **errors** means logging of only ISAKMP daemon errors will occur, **events** means errors and other ISAKMP daemon events will be logged, and **information** is the highest level of logging which is all inclusive.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **`lssecattr`** command or the **`getcmdattr`** subcommand.

Files

Files

Item	Description
/usr/sbin/ike	Location of the **ike** admin commands.
/etc/isakmpd.conf	Configuration file for the **iksakmpd** daemon.
/etc/syslog.conf	Provides configuration information for the **syslogd** daemon.

ikedb Command

Purpose

Retrieves, updates, deletes, imports, and exports information in the IKE database.

Syntax

ikedb **-p**[**F** **s**] [**-e** *entity-file*] [*XML-file*]

ikedb **-g**[**r**] [**-t** *type* [**-n** *name* | **-i** *ID* **-y** *ID-type*]]

ikedb **-d** **-t** *type* [**-n** *name* | **-i** *ID* **-y** *ID-type*]

ikedb **-c**[**F**] [**-l** *linux-file*] [**-k** *secrets-file*] [**-f** *XML-file*]

ikedb **-x**

ikedb **-o**

LDAP supported operations

ikedb –R LDAP **-p** [**-F**]

ikedb –R LDAP **-g** [*policy-name*]

ikedb –R LDAP **-o**

ikedb –R LDAP **-A** <*policy-name*> [-f <xml file name>] [-h ip/host] -C <Dn Name>

ikedb –R LDAP -D <*policy-name*> [-h ip/host] [-F]

Description

The **ikedb** command allows the user to write to (**put**) or read from (**get**) the IKE database. The input and output format is an Extensible Markup Language (XML) file. The format of an XML file is specified by its Document Type Definition (DTD). The **ikedb** command allows the user to see the DTD that is used to validate the XML file when doing a put. While entity declarations can be added to the DTD using the **-e** flag, this is the only modification to the DTD that can be made.

Any external DOCTYPE declaration in the input XML file will be ignored and any internal DOCTYPE declaration might result in an error. The rules followed to parse the XML file using the DTD are specified in the XML standard. **/usr/samples/ipsec** has a sample of what a typical XML file that defines common tunnel scenarios looks like.

Flags

To use LDAP supported operations, configure the host as an LDAP client.

Item	Description
-p	Performs a put, which writes to the database, based on the given *XML-file*. **-F** Forces a put, even if a specified tunnel, protection, proposal, group, or preshared key would overwrite one that exists in the database. The default is for such put attempts to fail. When an **-R** switch is present, the local entities are overwritten in case the name is a duplicate of a name specified as part of applicable policy on the host in the configuration. **-s** Swaps the local and remote IDs of all tunnels. This flag facilitates importing a tunnel that is generated by a peer system. This flag affects only tunnels. This option is illegal if the remote ID of any tunnel is a group. **-e *entity-file*** Specifies the name of the file that contains the <!ENTITY ...> lines as defined by *entity-file*. These lines are added to the internal DTD and allow the user to include XML files in other XML files. ***XML-file*** Specifies the **XML-file** to be used and must be the last argument to be displayed in the command line. The *XML-file* determines whether the write is to a tunnel, protection, proposal, group, pre-shared key, or all of these. If no *XML-file* is specified, input is read from **stdin**. A - (hyphen) can also be used to specify **stdin**. **-R LDAP** The valid value is **LDAP**. When **-p** is used in conjunction with the **-R** switch, the put operation is done by importing the XML configuration file that is associated with the applicable IPSec configuration policy from the LDAP server.
-h	Specifies host name or IP address along with the **-A** flag or the **-D** flag. The IP address can be IPv4 or IPv6.

Item	Description
-g	Performs a **get**, which displays what is stored in the IKE database. Output is sent to **stdout** and is in XML format, which is suitable for processing with **ikedb -p**. **-r** Recursive. If this flag is specified for a phase 1 tunnel, information is also returned for all associated phase 2 tunnels and all protections and proposals associated with both sets of tunnels. **-t *type*** Specifies the *type* of output requested. *Type* can have the value of any of the XML elements under AIX_VPN, such as **IKETunnel**, **IPSecProtection**, and so on. If omitted, the entire database is output. **-n *name*** Specifies the *name* of the requested object. *Name* can be the name of a proposal, protection, tunnel, or group, depending on the value of the **-t** flag. The **-n** flag is valid with all values specified by the **-t** flag, except **IKEPresharedKey**. If omitted, all objects of the specified *type* will be output. **-i *ID*** Specifies the *ID* associated with a pre-shared key. The **-i** flag is only valid with the **IKEPresharedKey** value of the **-t** flag. If omitted, all objects of the specified *type* will be output. The **-i** flag must be used in conjunction with the **-y** flag. **-y *ID-type*** Specifies the *ID-type* defined by the **-i** flag. ID-type can be any of the legal types allowed in the XML file, such as **User_FQDN**, **IPV4_Address**, and so on. The **-y** flag must be used in conjunction with the **-i** flag. **-R LDAP** The valid value is **LDAP**. When the **-g** flag is used in conjunction with the**-R** switch, the get operation is done by displaying XML configuration file stored on the LDAP server for the policy that is associated with the local host. If a policy name is also provided, the xml file stored as part of the policy is displayed on stdout.
-d	Performs a **delete** on the specified item from the database. The flags are the same as for the **-g** flag, except that **-r** is not supported.
-C	Used to provide the IPSec certificate used in the associated clients.
-c	Performs a conversion from a Linux IPSec configuration file to an AIX IPSec configuration file in XML format. It requires as input one or two files from the Linux environment, a configuration file, and possibly a secrets file with pre-shared keys. **-F** Forces a **put**, even if a specified tunnel, protection, proposal, group, or pre-shared key would overwrite one that already exists in the database. The default is for such **put** attempts to fail. The **-F** flag has no effect if the **-f** flag is also used. **-l *linux-file*** Specifies the Linux configuration file as define by *linux-file*. If no file is specified, the system looks for the **ipsec.conf** file in the current directory. **-k *secrets-file*** Specifies the Linux pre-shared keys file as defined by the *secrets-file* parameter. If no file is specified, the system looks for the **ipsec.secrets** file in the current directory. **-f *XML-file*** Specifies the XML configuration file to which the Linux configuration files are converted. The default behavior is to do a put operation directly to the IKE database. If the filename has a hyphen (-), the results are sent to stdout. This flag is invalid if the -R switch is also present on the command line.

Item	Description
-x	Performs an **expunge** operation on the database. This flag empties the database. This flag is invalid if the **-R** flag is also present on the command line.
-o	Performs an **output** of the DTD that specifies all elements and attributes for an XML file that is used by the **ikedb** command. The DTD is sent to **stdout**. When **-R** switch is present, DTD that specifies all the elements and attribute for the XML file allowed to be stored as part of configuration policy on LDAP is sent to **stdout**.
-A	Associates the IP addresses provided with the policy name. If no IP addresses are provided, the first local IPV6 address for the local host is selected and associated with the policy. Policy configuration is enforced by downloading the XML file from LDAP and putting it into the database. The tunnels thus defined are activated. **-f < -path to XML file >** If an XML file is provided, it is stored on the LDAP server as the new XML applicable for the defined policy. If the policy does not exist, this flag is required. **-R LDAP** The valid value is LDAP. This switch must be provided on the command line.
-D	Performs disassociation of configuration policy and IP on LDAP server. This flag is invalid without the **-R** switch. The only valid value for the **R** switch is LDAP. **- F** If the last IP address associated with the specified policy is removed, this switch causes the corresponding policy data (XML configuration file) to be deleted from LDAP server. If this flag is not used, the policy is not deleted from the LDAP server.

Files

Item	Description
/usr/samples/ipsec	Examples of an XML file that sets up various tunnel configurations.

Examples

1. To **put** definitions to the IKE database from an XML file that has been generated on a peer machine and overwrite any existing objects in the database with the same name, type:

   ```
   ikedb -pFs peer_tunnel_conf.xml
   ```

   `peer_tunnel_conf.xml` is the XML file generated on a peer machine.
2. To **get** the definition of the phase 1 tunnel named `tunnel_sys1_and_sys2` and all dependent phase 2 tunnels with respective proposals and protections, type:

   ```
   ikedb -gr -t IKETunnel -n tunnel_sys1_and_sys2
   ```
3. To **delete** all preshared keys from the database, type:

   ```
   ikedb -d -t IKEPresharedKey
   ```
4. To **associate** the host that has the IP address 10.10.10.1 with the configuration policy named Poll with certificate */C=US/O=IBM/CN=test01.austin.ibm.com* with xml file ldap.xml, type:

   ```
   ikedb -R LDAP -A Pol1  -f  ldap.xml  -h 10.10.10.1 -C /C=US/O=IBM/CN=test01.austin.ibm.com
   ```

imake Command

Purpose

C preprocessor interface to the **make** command.

Syntax

imake [**-D***Define*] [**-I***Directory*] [**-T***Template*] [**-f** *FileName*] [**-C** *FileName*] [**-s** *FileName*] [**-e**] [**-v**]

Description

The **imake** command generates **Makefiles** from a template, a set of cpp macro functions, and a per-directory input file called **Imakefile**. This command keeps machine dependencies (such as compiler options, alternate command names, and special **make** command rules) separate from the descriptions of the items to build.

imake invokes cpp with any **-I** or **-D** flags passed on the command line and passes to it the following three lines:

```
#define IMAKE_TEMPLATE "Imake.tmpl"
#define INCLUDE_MAKEFILE "Imakefile"
#include IMAKE_TEMPLATE
```

Override **Imake.tmpl** and **Imakefile** by using the **-T** and **-f** flags, respectively.

The IMAKE_TEMPLATE typically reads the following files:

- A machine-dependent parameters file in which the parameters are specified as cpp symbols
- A site-specific parameters file
- A file that defines variables
- A file containing cpp macro functions for generating **make** command rules
- The **Imakefile** (specified by INCLUDE_IMAKEFILE) in the current directory.

The **Imakefile** file uses the macro functions to indicate what targets to build and the **imake** command generates the appropriate rules.

Imake configuration files contain two types of variables, imake variables and make variables. The imake variables are interpreted by cpp when the **imake** command is run. By convention, they are not case-sensitive. The make variables are written into the **Makefile** for later interpretation by the **make** command. By convention, make variables are uppercase.

The rules file (usually named **Imake.rules** in the configuration directory) contains a variety of cpp macro functions that are configured according to the current platform. The **imake** command replaces any occurrences of the string ``@@'' with a newline character (carriage return) to support macros that generate more than one line of make rules. For example, the macro:

```
#define   program_target(program, objlist)        @@\
program:  objlist                                 @@\
          $(CC)  -o  $@  objlist  $(LDFLAGS)
```

when called with `program_target(foo,foo1.o foo2.o)` will expand to:

```
foo:      foo1.o  foo2.o
          $(CC)  -o  $@  foo1.o  foo2.o  $(LDFLAGS)
```

On systems whose cpp reduces multiple tabs and spaces to a single space, the **imake** command attempts to put back any necessary tabs (the **make** command distinguishes between tabs and spaces). For this reason, precede all colons (:) in command lines by a backslash (\).

Use with

AIXwindows uses the **imake** command extensively for both full builds within the source tree and builds of external software. Two special variables, TOPDIR and CURDIR, are set to make referencing files using relative path names easier. For example, the following command is generated automatically to build the **Makefile** in the **lib/X** directory (relative to the top of the sources):

```
%  ../.././config/imake  -I../.././config  \
            -DTOPDIR=../../.  -DCURDIR=./lib/X
```

To build AIXwindows programs outside the source tree, a special symbol, UseInstalled, is defined and the TOPDIR and CURDIR variables are omitted. If the configuration files are properly installed, you can use the **xmkmf** command.

The **imake** command reads the following files as used by AIXwindows.

Note: The indented format indicates files that include other files.

```
Imake.tmpl                  generic variables
   site.def                 site-specific, BeforeVendorCF defined
         *.cf               machine-specific
             *Lib.rules     shared library
   site.def                 site-specific, AfterVendorCF defined
   Imake.rules              rules
   Project.tmpl             X-specific variables
         *Lib.tmpl          shared library variables
Imakefile
   Library.tmpl             library rules
   Server.tmpl              server rules
   Threads.tmpl              multi-thread rules
```

Note: The **site.def** file is included twice, both before and after the ***.cf** file. Although most site customizations are specified after the ***.cf** file, some, such as the choice of compiler, need to be specified before, because other variable settings may depend on them.

The first time the **site.def** file is included, the **BeforeVendorCF** variable is defined, and the second time, the **AfterVendorCF** variable is defined. All code in the **site.def** file should be placed inside a **#ifdef** macro for one of these symbols.

Flags

Item	Description
-D*Define*	Passed directly to cpp to set directory-specific variables. For example, X-windows uses this flag to set the TOPDIR variable to the name of the directory containing the top of the core distribution, and the CURDIR variable to the name of the current directory, relative to the top.
-e	Indicates that the **imake** command should execute the generated **Makefile**. The default is to leave this to the user.
-f *FileName*	Specifies the name of the per-directory input file. The default is the **Imakefile** file.
-I*Directory*	(Uppercase i) Passed directly to cpp to indicate the directory in which the imake template and configuration files are located.
-C *FileName*	Specifies the name of the **.c** file that is constructed in the current directory. The default is **Imakefile.c**.
-s *FileName*	Specifies the name of the **make** description file to be generated, without invoking the **make** command. If the *FileName* variable is a **-** (dash), the output is written to **stdout**. The default is to generate, but not execute, a **Makefile**.
-T*Template*	Specifies the name of the master template file (which is usually located in the directory specified with **-I**) used by the **cpp** command. The default is the **Imake.tmpl**.
-v	Indicates that **imake** should print the **cpp** command line that it is using to generate the **Makefile**.

Environment Variables

Note: The following environment variables may be set, but their use is not recommended because they introduce dependencies that are not readily apparent when the **imake** command is run.

Item	Description
IMAKEINCLUDE	If defined, specifies an include argument for the C preprocessor. For example: `-I/usr/include/local`
IMAKECPP	If defined, specifies a valid path to a preprocessor program. For example: `/usr/local/cpp` The default is the **/lib/cpp** program.
IMAKEMAKE	Specifies a valid path to a **make** program such as **/usr/local/make**. By default, **imake** uses whatever **make** program is found using the **execvp** subroutine. This variable is only used if the **-e** flag is specified.

Example

```
imake -I/usr/lib/X11/config -DTOPDIR=/usr/lpp/X11/Xamples
```

Files

Item	Description
/usr/tmp/tmp-imake.*nnnnnn*	Specifies the temporary input file for the cpp preprocessor.
/usr/tmp/tmp-make.*nnnnnn*	Specifies the temporary input file for make.
/lib/cpp	The default C preprocessor.

imapd Daemon

Purpose

Starts the Internet Message Access Protocol (IMAP) server process.

Syntax

imapd [**-c**]

Description

The **imapd** command is an IMAP4 server. It supports the IMAP4 remote mail access protocol. Also, it accepts commands on its standard input and responds on its standard output. You normally invoke the **imapd** command with the **inetd** daemon with those descriptors attached to a remote client connection.

The **imapd** command works with the existing mail infrastructure consisting of **sendmail** and **bellmail**.

Flags

Item	Description
-c	Suppresses the reverse host name lookup.

Exit Status

All error and status information is written to a logfile if **syslogd** is configured for logging.

Security

The **imapd** daemon is a PAM-enabled application with a service name of *imap*. System-wide configuration to use PAM for authentication is set by modifying the value of the **auth_type** attribute, in the **usw** stanza of **/etc/security/login.cfg**, to PAM_AUTH as the root user.

The authentication mechanisms used when PAM is enabled depend on the configuration for the **imap** service in **/etc/pam.conf**. The **imapd** daemon requires **/etc/pam.conf** entries for the **auth** and **session** module types. Listed below is a recommended configuration in **/etc/pam.conf** for the **imap** service:

```
#
# AIX imap configuration
#
imap auth      required     /usr/lib/security/pam_aix

imap session   required     /usr/lib/security/pam_aix
```

Files

Item	Description
/usr/sbin/imapd	Contains the **imapd** command.
/etc/services	Specifies the file with port assignments for required services. The following entry must be in this file: `imap2  143/tcp  # Internet Mail Access Protocol`

imapds Daemon

Purpose

Starts the Internet Message Access Protocol (IMAP) server process over TSL/SSL.

Syntax

imapds [**-c**]

Description

The **imapds** command is an IMAP4 server. It supports the IMAP4 remote mail access protocol. Also, it accepts commands on its standard input and responds on its standard output. You normally invoke the **imapds** command with the **inetd** daemon with those descriptors attached to a remote client connection.

The **imapds** command works with the existing mail infrastructure consisting of **sendmail** and **bellmail**.

Flags

Item	Description
-c	Suppresses the reverse host name lookup.

Exit Status

All error and status information is written to a logfile if **syslogd** is configured for logging.

Security

The **imapds** daemon is a PAM-enabled application with a service name of *imap*. System-wide configuration to use PAM for authentication is set by modifying the value of the **auth_type** attribute, in the **usw** stanza of **/etc/security/login.cfg**, to PAM_AUTH as the root user.

The authentication mechanisms used when PAM is enabled depend on the configuration for the **imap** service in **/etc/pam.conf**. The **imapds** daemon requires **/etc/pam.conf** entries for the **auth** and **session** module types. Listed below is a recommended configuration in **/etc/pam.conf** for the **imap** service:

```
#
# AIX imap configuration
#
imap auth      required     /usr/lib/security/pam_aix

imap session   required     /usr/lib/security/pam_aix
```

Files

Item	Description
/usr/sbin/imapds	Contains the **imapds** command.
/etc/services	Specifies the file with port assignments for required services. The following entry must be in this file: `imaps  993/tcp  # imap4 protocol over TLS/SSL`

impfilt Command

Purpose

Imports filter rules from an export file.

Syntax

impfilt [**-v** **4**|**6**] **-f** *directory* [**-l** *filt_id_list*]

Description

Use the **impfilt** command to import filter rules from text export file(s) that are generated by the **expfilt** command. IPsec filter rules for this command can be configured using the `genfilt` command or IPsec smit (IP version 4 or IP version 6).

Flags

Item	Description
-v	IP version of the rules to be imported. The value of **4** specifies IP version 4 and the value of **6** specifies IP version 6. When this flag is not used, both IP version 4 and IP version 6 are imported.
-f	Specifies the directory where the imported text files are to be read.
-l	Lists the IDs of the filter rules to be imported. The filter rule IDs can be separated by "**,**". If this flag is not used, all filter rules for the applicable IP version(s) in the text export files will be imported.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

importvg Command

Purpose

Imports a new volume group definition from a set of physical volumes.

Syntax

importvg [**-V** *MajorNumber*] [**-y** *VolumeGroup*] [**-f**] [**-c**] [**-x**] **|** [**-L** *VolumeGroup*] [**-n**] [**-F**] [**-R**] [**-I**] [**-O**] [**-r** *file_name*] *PhysicalVolume*

Description

The **importvg** command makes the previously exported volume group known to the system. The *PhysicalVolume* parameter specifies only one physical volume to identify the volume group; any remaining physical volumes (those belonging to the same volume group) are found by the **importvg** command and included in the import. An imported volume group is automatically varied unless the volume group is Concurrent Capable. You must use the **varyonvg** command to activate Concurrent Capable volume groups before you access them.

When a volume group with file systems is imported, the **/etc/filesystems** file is updated with values for the new logical volumes and mount points. After importing the volume group and activating it with the **varyonvg** command, you must run the **fsck** command before the file systems can be mounted. However, the mount point information would be missing from the LVCB (logical volume control block) if it is longer than 128 characters. In this case, the **importvg** command will not be able to update the **/etc/filesystems** file with the stanza for the newly imported logical volume. You should manually edit the **/etc/filesystems** file to add a new stanza for this logical volume.

The **importvg** command changes the name of a logical volume if the name already exists in the system. It prints a message and the new name to standard error, and updates the **/etc/filesystems** file to include the new logical volume name. If the **importvg** command renames any filesystem log logical volumes, you must manually update any file systems using that log device to know about the renamed device.

Notes:

1. To use this command, you must either have root user authority or be a member of the **system** group.
2. As part of the **importvg** process, the volume group is automatically varied on by the system after it is imported. However, if the volume group is Concurrent Capable then the **importvg** command prompts you to **varyonvg** the imported volume group manually.
3. A volume group with a mirrored striped logical volume cannot be back ported into a version older than AIX 4.3.3.

You can use the System Management Interface Tool (SMIT) **smit importvg** fast path to run this command.

Flags

Item	Description
-c	This flag is ignored. Only Enhanced Concurrent Capable volume groups will be created.
-f	Forces the volume group to be varied online.

Item	Description
-L*VolumeGroup*	Takes a volume group and learns about possible changes performed to that volume group. Any new logical volumes created as a result of this command emulate the ownership, group identification, and permissions of the **/dev** special file for the volume group listed in the **-y** flag. The **-L** flag performs the functional equivalent of the **-F** and **-n** flags during execution. **Restrictions:** • The volume group must not be in an active state on the system executing the **-L** flag. • The volume group's disks must be unlocked on all systems that have the volume group varied on and operational. Volume groups and their disks may be unlocked, remain active and used via the **varyonvg -b -u** command. • The physical volume name provided must be of a good and known state, the disk named may not be in the missing or removed state. • If a logical volume name clash is detected, the command will fail. Unlike the basic **importvg** actions, clashing logical volume names will not be renamed.
-F	Provides a fast version of **importvg** that checks the Volume Group Descriptor Areas of only the disks that are members of the same volume group. As a result, if a user exercises this flag, they must ensure that all physical volumes in the volume group are in a good and known state. If this flag is used on a volume group where a disk may be in missing or removed state, the command may fail or the results may be inconsistent.
-I	Causes the **importvg** command to fail if imfs fails.
-n	Causes the volume not to be varied at the completion of the volume group import into the system.
-O	Forces varyon the volume group even if it is varied on in some other node. **Note:** In AIX 61 TL8 and later releases, **varyonvg** command updates the LVM metadata and ODM with varyon state of the volume group. During varyon time, **varyonvg** command reads this data and fails if the volume group is already varied in another node. **Varyoffvg** command resets the varyon state of the volume group during varyoff time. If system crashes before varying off the volume group or the volume group is forced off, then **varyonvg** command will fail after reboot. In this scenario, use **–O** flag to force varyon the volume group.
-R	Restores the ownership, group ID, and permissions of the logical volume special device files. These values will be restored only if they were set using **U**, **G** and **P** flags of **mklv** and **chlv** commands. This flag is applicable only for volume groups of the types big and scalable.
-r *file_name*	Restores the performance tunable parameters of the volume group. To use this flag, you must specify the file name that was backed up when you ran the **exportvg -b** command.
-V *MajorNumber*	Specifies the major number of the imported volume group.
-x	This flag is ignored. Only Enhanced Concurrent Capable volume groups will be created.

Attention: This entry must be added after the entry used to initiate **srcmstr**.

Item	Description
-y *VolumeGroup*	Specifies the name to use for the new volume group. If this flag is not used, the system automatically generates a new name. The volume group name can only contain the following characters: "A" through "Z," "a" through "z," "0" through "9," or "_" (the underscore), "-" (the minus sign), or "." (the period). All other characters are considered invalid.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To import the volume group bkvg from physical volume hdisk7, enter:

   ```
   importvg  -y bkvg hdisk7
   ```

   The volume group bkvg is made known to the system.
2. To use the -L on a multi-tailed system:

   ```
   Node A has the volume group datavg varied on.
   Node B is aware of datavg, but it is not varied on.
   Node A: varyonvg -b -u datavg
   Node B: importvg -L datavg hdisk7
   Node A: varyonvg datavg
   ```

Files

Item	Description
/usr/sbin	Directory where the **importvg** command resides.
/tmp	Directory where the temporary files are stored while the command is running.

imptun Command

Purpose

Adds the exported tunnel definitions and optional user-defined filter rules associated with the tunnels to the local host.

Syntax

imptun -f *directory* [**-t** *tunnel_id_list*] [**-v 4** | **6**] [**-n**] [**-r**] [**-g**] [**-l manual**]

Description

Use the **imptun** command to add exported tunnel definitions and optional user-defined filter rules associated with the exported tunnels (files generated by the tunnel owner by using the **exptun** command) to the local host. This command can also import tunnel definitions from the exported files generated by the IBM firewall (SNG) product export command.

A new tunnel ID is generated by the local host when a tunnel is imported to the local tunnel table. The auto-generated filter rules associated with the tunnel also is generated automatically. Importing the exported user-defined filter rules is optional.

If the exported files are transmitted by diskette, it is assumed they will be loaded to a local file directory using a command such as **tar**, depending on the tunnel owner's instructions.

Flags

Item	Description
-f	Specifies the directory from where the exported files will be read.
-g	The suppress system auto-generated filter rule flag. If the **-g** flag is not used, the **imptun** command generates two filter rules for each imported tunnel automatically. The auto-generated filter rules allow all traffic between the two end points of the tunnel to go through the tunnel. If the **-g** flag is specified, the command only imports the tunnel IBM definitions, and the user must add user-defined filter rules to use the tunnel.
-l	Specifies the type of the tunnel(s) you want to import. If **manual** is specified, only manual tunnel(s) are imported. **-n** and **-l** flags are mutually exclusive.
-n	Specifies that the export files were generated by the IBM firewall (version 2.2) tunnel export command. This flag cannot be specified with the **-v** flag. The **-n** flag is also mutually exclusive with the **-r** flag.
-r	Imports the user-defined filter rules associated with the tunnels that are being imported. To use the **-r** flag, it must have been specified with the **exptun** command when the exported files were generated. The **-r** flag is mutually exclusive with the **-n** flag.
-t	Lists the set of tunnel IDs to be imported from the export files. The tunnel definitions identified by these tunnel IDs are added to the local host. If this flag is not used, all the tunnel definitions in the export files are added to the local host.
-v	Specifies the IP version of the tunnel definitions from the exported files that you wish to import. If the **-v** flag is not given, then all IP version 4 and IP version 6 tunnel definitions that exist in the export files are imported.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

inc Command

Purpose

Files new mail in a folder.

Syntax

inc [**+** *Folder*] [**-noaudit** | **-audit** *File*] [**-changecur** | **-nochangecur**] [**-form** *FormFile* | **-format** *String*] [**-help**] [**-file** *File*] [**-truncate** | **-notruncate**] [**-nosilent** | **-silent**] [**-width** *Number*]

Description

The **inc** command files incoming mail in a specified folder and outputs a list of the messages filed. A folder is a system directory. By default, the **inc** command removes the new messages from your mail drop and places them in the specified folder. To file new mail without deleting the mail drop, use the **-notruncate** flag.

If the specified folder does not exist, the **inc** command prompts you for permission to create it. The system creates the folder as a subdirectory of the user's Message Handler (MH) directory. The default folder is **inbox**.

> **Note:** If you do not have a `Path:` entry specified in your **.mh_profile** file, the **inc** command creates the folder as a subdirectory of the current directory.

Filed messages are assigned consecutive message numbers starting with the next highest number in the folder. Each new message receives the protection code specified in the `Msg-Protect:` entry in your **.mh_profile** file. If the `Msg-Protect:` entry does not exist, a protection code of 644 is assigned. If the `Unseen-Sequence:` entry exists, new messages are added to each sequence specified by the entry.

Flags

Item	Description
-audit *File*	Copies the current date to the specified file and appends the output of the **inc** command to the file.
-changecur	Sets the first new message as the current message for the specified folder. This flag is the default.
-file *File*	Files messages from the specified file instead of the user's maildrop.
+*Folder*	Specifies the folder in which to place new messages. By default, the system creates a subdirectory called **inbox** in the user's MH directory.
-form *FormFile*	Identifies a file that contains an alternate output format for the **inc** command.
-format *String*	Specifies a string that defines an alternate output format for the **inc** command.
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For MH, the name of this flag must be fully spelled out.
-noaudit	Suppresses recording of information about any new messages filed. This is the default.
-nochangecur	Prevents alteration of the current message for the specified folder.
-nosilent	Prompts the user for any necessary information. This flag is the default.
-notruncate	Prevents clearing of the mailbox or file from which the **inc** command is taking new messages. If the **-file** flag is specified, the **-notruncate** flag is the default.
-silent	Prevents prompting by the **inc** command for information. This flag is useful when running the **inc** command in the background.
-truncate	Clears the mailbox or file from which the **inc** command is taking new messages. If the **-file** flag is not specified, the **-truncate** flag is the default.
-width *Number*	Sets the number of columns in the command output. The default is the width of the display.

Profile Entries

The following entries are entered in the *UserMhDirectory***/.mh_profile** file:

Item	Description
`Alternate-Mailboxes:`	Specifies alternate mailboxes.
`Folder-Protect:`	Sets the protection level for new folder directories.
`Msg-Protect:`	Sets the protection level for new message files.

Item	Description
`Path:`	Specifies the user's MH directory.
`Unseen-Sequence:`	Specifies the sequences used to keep track of unseen messages.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To incorporate new mail into the default mail folder, **inbox**, enter:

   ```
   inc
   ```

   If the **inbox** folder exists, the system displays a message similar to the following:

   ```
   Incorporating new mail into inbox...
   65+        04/08    jim@athena.a         Meeting                                 <<The
   meeting will
   66         04/08    jim@athena.a         Schedule                                <<Schedule
   change
   ```

   In this example, two messages are filed in the `inbox` folder. The subject of the first message is `Meeting`, and the first line starts with the words `The meeting will`. The subject of the second message is `Schedule`, and the first line starts with the words `Schedule change`.

2. To incorporate new mail into a new folder called **test cases**, enter:

   ```
   inc     +test cases
   ```

   The system prompts you as follows:

   ```
   Create folder "/home/mary/test cases"?
   ```

   If you wish to create the folder, enter:

   ```
   yes
   ```

   A message similar to the following is displayed:

   ```
   Incorporating new mail into test cases...
   67+        04/08    jim@athena.a            Meeting                                 <<We will
   begin
   68         04/08    jim@athena.a            Schedule
   <<Schedule change
   ```

Files

Item	Description
$HOME/.mh_profile	Customizes the MH user profile.
/etc/mh/mtstailor	Tailors the MH environment to the local environment.
/var/spool/mail/$USER	Specifies the location of the mail drop.
/usr/bin/inc	Contains the **inc** command.

indent Command

Purpose

Reformats a C language program.

Syntax

indent *InputFile* [*OutputFile*] [**-nbad** | **-bad**] [**-nbap** | **-bap**] [**-nbbb** | **-bbb**] [**-nbc** | **-bc**] [**-br** | **-bl**] [**-c***n*] [**-cd***n*] [**-ncdb** | **-cdb**] [**-nce** | **-ce**] [**-ci***n*] [**-cli***n*] [**-d***n*] [**-di***n*] [**-ndj** | **-dj**] [**-nei** | **-ei**] [**-fa**] [**-nfa**] [**-nfc1** | **-fc1**] [**-i***n*] [**-nip** | **-ip**] [**-l***n*] [**-lc***n*] [**-nlp** | **-lp**] [**-npro**] [**-npcs** | **-pcs**] [**-nps** | **-ps**] [**-npsl** | **-psl**] [**-nsc** | **-sc**] [**-nsob** | **-sob**] [**-nslb** | **-slb**] [**-st**] [**-troff**] [**-nv** | **-v**] [**-T***Type*] ...

Description

The **indent** command reformats a C program as specified by flags entered with the command.

If you only specify the *InputFile* parameter, the reformatted file is written back into the *InputFile* parameter and a backup copy of the *InputFile* parameter is written in the current directory with a **.BAK** filename suffix.

If you specify the *OutputFile* parameter, the **indent** command checks to make sure its name is different from the *InputFile* parameter.

To set up your own profile of defaults for the **indent** command, create a file called **.indent.pro** in your login directory or the current directory. In this file, include as many flags as desired, separated by spaces, tabs, or new lines.

Flags in the **.indent.pro** file in the current directory override those in your login directory (with the exception of **-T***Type* flags, which accumulate). If the **indent** command is run and a profile file exists, the profile file is read to set up the defaults of the program. Flags on the command line, however, override profile flags.

Comment Handling

The **indent** command assumes that any comment with a **-** (dash) or ***** (asterisk) immediately after the start of a comment marker (**/*-** or **/****) is a comment surrounded by asterisks. Each line of the comment is left unchanged, except for its indentation. This indentation can be adjusted to account for the change in indentation of the first line of the comment.

All other comments are treated as text. The **indent** command fits as many words (separated by blanks, tabs, or new-lines) on a line as possible. Blank lines break paragraphs.

A block comment is a comment that is not to the right of the code, and extends for more than one line.

If a comment is on a line with code, it is started in the comment column set by the **-c***n* flag. Otherwise, the comment is started at *n* indentation levels less than where code is currently being placed, where *n* is specified by the **-d***n* flag. If the code on a line extends past the comment column, the comment starts further to the right. The right margin can be extended automatically in extreme cases.

Preprocessor Lines Handling

In general, the **indent** command leaves preprocessor lines alone. The only reformatting it does is to straighten up trailing comments. It leaves embedded comments alone. Conditional compilation (code between **#ifdef** and **#endif** lines) is recognized and the **indent** command attempts to compensate correctly for the syntactic peculiarities introduced.

C Syntax Handling

The parser built into the **indent** command attempts to cope with incomplete and misformed syntax. In particular, the use of macros like:

```
#define forever for(;;)
```

is handled properly. For best results, use the **indent** command on source that is syntactically correct.

Flags

Note: Flags can appear before or after file names.

Item	Description
-bad	Forces a blank line after every block of declarations.
-nbad	Suppresses a blank line after every block of declarations; active unless turned off with the **-bad** flag.
-bap	Forces a blank line after every procedure body.
-nbap	Suppresses a blank line after every procedure body; active unless turned off with the **-bap** flag.
-bbb	Forces a blank line before every block comment.
-nbbb	Suppresses a blank line before every block comment; active unless turned off with the **-bbb** flag.
-bc	Forces a new line after each comma in a declaration.
-nbc	Suppresses a new line after each comma in a declaration; active unless turned off with the **-bc** flag.
-bl	Formats compound statements, structure initializations, and enum initializations, as follows: `if (...)` `{` `  code` `}`
-br	Formats compound statements, structure initializations, and enum initializations, as follows: `if (...) {` `  code` `}` This flag is active unless turned off with the **-bl** flag.
-c*n*	Sets the initial tab position for comments on code to the *n* variable. The default value is 33.
-cd*n*	Sets the initial tab position for comments on declarations to the *n* variable. By default, this flag uses the value defined with the **-c** flag.
-cdb	Enables placing comment delimiters on blank lines; active unless turned off with the **-ncdb** flag. The **-cdb** flag affects only block comments, not comments to the right of code. Resulting comments look like the following: `/*` ` * this is a comment` ` */`
-ncdb	Disables placing comment delimiters on blank lines. The **-ncdb** flag affects only block comments, not comments to the right of code. Resulting comments look like the following: `/* this is a comment */`
-ce	Enables forcing **else** statements to follow the immediately preceding **}** (left bracket); active unless turned off with the **-nce** flag.
-nce	Disables forcing **else** statements to follow the immediately preceding **}** (left bracket).

Item	Description
-ci*n*	Indents the continuation lines *n* positions from the beginning of the first line of the statement. Expressions in parentheses have extra indentation added to indicate the nesting, unless the **-lp** flag is in effect. By default, this flag uses the value defined by the **-i** flag.
-cli*n*	Indents the case labels *n* positions to the right of the containing flag statement. Entering **-cli0.5** causes case labels to be indented half a tab stop. This option is the only one that takes a fractional argument. By default, the value is **-cli0**.
-d*n*	Controls the placement of comments that are not to the right of code with the *n* variable. Specifying the **-d1** flag causes such comments to appear one indention level to the left of code. By default, this flag uses **-d0** and comments are aligned with code. The location of comment lines relative to program code affects the comment indention.
-di*n*	Specifies the number of positions to indent an identifier from a preceding declaration keyword with the *n* variable. By default, this flag uses **-di16**.
-dj	Left-justifies declarations.
-ndj	Indents declarations; active unless turned off with the **-dj** flag.
-ei	Enables special **else**-**if** processing; active unless turned off with the **-nei** flag. The **-ei** flag causes **if** statements following **else** statements to have the same indentation as the preceding **if** statement.
-nei	Disables special **else**-**if** processing.
-fa	Flips assign operators from old style C code to the ANSI format. This flag remains active unless turned off with the **-nfa** flag. **Attention:** The possibility of changing the meaning of the code exists if the code was meant for the ANSI compiler. For example, A=-B becomes A-=B. **Note:** Use no spaces between operators. If the user means subtraction, then the flipping is necessary; on the other hand, if the user means A equals the negative of B, the flipping alters the meaning.
-nfa	Suppresses flipping the operators. Use this flag if the code is written for an ANSI compiler.
-fc1	Enables formatting comments that start in column 1; active unless turned off with the **-nfc1** flag.
-nfc1	Disables formatting comments that start in column 1.
-i*n*	Sets the indentation level size. By default, the level size is 8 positions.
-ip	Enables indenting parameter declarations; active unless turned off with the **-nip** flag.
-nip	Disables indenting parameter declarations.

Item	Description
-l*n*	Sets the maximum column position of comments that are to the right of the code. If the comment does not fit on a line, a maximum of 25 characters are printed.
-lc*n*	Sets the maximum line length for block comments to the *n* variable. By default, this flag uses the length specified with the **-l** flag.

Item	Description
-lp	Aligns code surrounded by parentheses in continuation lines; active unless turned off with the **-nlp** flag. If a line has a left parenthesis with no matching right parenthesis on that line, continuation lines start at the position following the left parenthesis. With the **-lp** flag in effect, such lines appear as follows: `p1 = first_procedure(second_procedure(p2,p3),` `third_procedure(p4,p5));` Inserting two more new lines yields the following: `p1 = first_procedure(second_procedure(p2,` `p3),` `third_procedure(p4,` `p5));`
-nlp	Leaves code surrounded by parentheses in continuation lines unaligned. With the **-nlp** flag in effect, such lines appear as follows: `p1 = first_procedure(second_procedure(p2,p3),` `third_procedure(p4, p5));`
-npro	Causes the profile files **./.indent.pro** and **$HOME/.indent.pro** to be ignored.
-pcs	Inserts a space between each procedure call name and the following **(** (left parenthesis).
-npcs	Suppresses a space between each procedure call name and the following **(** (left parenthesis); active unless turned off with the **-pcs** flag.
-ps	Inserts spaces on both sides of the pointer following the **->** operator.
-nps	Suppresses spaces on both sides of the pointer following the **->** operator; active unless turned off with the **-ps** flag.
-psl	Left-justifies the names of procedures being defined; active unless turned off with the **-npsl** flag. The procedure types, if any, remain on the previous lines.
-npsl	Disables left-justification of names of defined procedures.
-sc	Enables the placement of ***** (asterisks) to the left of comments; active unless turned off with the **-nsc** flag.
-nsc	Disables the placement of ***** (asterisks) to the left of comments.
-slb	Treats any single-line comment that is not to the right of the code as a block comment.
-nslb	Disables treating any single-line comment that is not to the right of the code as a block comment; active unless turned off with the **-slb** flag.
-sob	Removes optional blank lines. Works in combination with any of the following flags: **-nbad**, **-nbap**, or **-nbbb**. Removes only blank lines that were inserted by the **-bad**, **-bap**, or **-bbb** flags.
-nsob	Retains optional blank lines; active unless turned off with the **-sob** flag.
-st	Causes the **indent** command to take its input from stdin and output to stdout.
-T*Type*	Adds the *Type* variable to the list of type keywords. Names accumulate so **-T** can be specified more than once. You should specify all the types appearing in your program defined by **typedef** statements to produce the best output from the **indent** command.
-troff	Formats the C program for processing by **troff**. Produces a listing similar to listings produced by the **vgrind** command. If no output file is specified, the default is standard output, rather than formatting in place.

Item	Description
-v	Turns on verbose mode, which reports when one line of input is split into two or more lines of output and gives size statistics at completion.
-nv	Turns off verbose mode; active unless turned off with the **-v** flag.

Examples

1. To format the `test.c` file using the default settings of the **indent** command and place the output into the `newtest.c` file, enter:

```
indent test.c newtest.c
```

2. To format the `test.c` file so that a blank line is forced after every block of declarations and procedure body, use all other default settings, and store the output in the `newtest.c` file, enter:

```
indent test.c newtest.c -bad -bap
```

3. To format the `test.c` file using the default settings of the **indent** command and to define `uint` as a type keyword recognizable to the **indent** command, enter:

```
indent test.c newtest.c -Tuint
```

Files

Item	Description
./.indent.pro	Contains the profile file.
$HOME/.indent.pro	Contains the profile file.
/usr/ccs/bin/indent	Contains the **indent** command.

indxbib Command

Purpose

Builds an inverted index for a bibliography.

Syntax

indxbib *Database* ...

Description

The **indxbib** command makes an inverted index to the named database (or files) for use by the **lookbib** and **refer** commands. These files contain bibliographic references (or other kinds of information) separated by blank lines.

Note: The **indxbib** command expects the database to exist in the current working directory.

A bibliographic reference is a set of lines, constituting fields of bibliographic information. Each field starts on a line beginning with a **%** (percent sign), followed by a key letter, then a space character, and finally the contents of the field, which can continue until the next line starting with a **%** (percent sign). All key letters are ASCII characters.

The **indxbib** command is a shell script that calls the **/usr/lib/refer/mkey** and **/usr/lib/refer/inv** files. The first program, **mkey**, performs the following operations:

1. Truncates words (delimited by blanks or tabs) to six characters.
2. Maps uppercase to lowercase characters.
3. Discards words shorter than three characters.
4. Discards the most commonly used words according to an existing **ign** file. An English language file, **/usr/lib/eign**, has been provided with a list of common English words. It is suggested, but not necessary, that users create their own files, named **ign**, consisting of language-specific common words. This file, if created, should exist in the **/usr/lib/nls/msg/$LANG** directory.
5. Discards numbers (dates) less than 1900 or greater than 2099.

   Note: All dates should be indexed because many disciplines refer to literature written in the 1800s or earlier.

The second program, **inv**, creates in the working directory an entry file (**.ia**), a posting file (**.ib**), and a tag file (**.ic**).

Files

Item	Description
/usr/lib/eign	Contains the default list of common words the **indxbib** command discards while processing.
Database.**ia**	Contains the entry file.
Database.**ib**	Contains the posting file.
Database.**ic**	Contains the tag file.

Environment Variables

Item	Description
NLSPATH	Refers to a list of directory names where the message catalog files can be found.

inetd Daemon

Purpose

Provides Internet service management for a network.

Syntax

Note: Use SRC commands to control the **inetd** daemon from the command line. Use the **rc.tcpip** file to start the daemon with each system restart.

/usr/sbin/inetd [**-d**] [**-t** *SecondsToWait*] [*ConfigurationFile*]

Description

The **/usr/sbin/inetd** daemon provides Internet service management for a network. This daemon reduces system load by invoking other daemons only when they are needed and by providing several simple Internet services internally without invoking other daemons.

The **inetd** daemon starts by default each time you start your system. When the daemon starts, it reads its configuration information from the file specified in the *ConfigurationFile* parameter. If the parameter is not specified, the **inetd** daemon reads its configuration information from the **/etc/inetd.conf** file.

Once started, the **inetd** daemon listens for connections on certain Internet sockets in the **/etc/inetd.conf**. The **/etc/inetd.conf** file describes to the **inetd** daemon how Internet service requests on Internet sockets should be handled. When the **inetd** daemon receives a request on one of these sockets, it determines

which service corresponds to that socket and then either handles the service request itself or invokes the appropriate server.

Subservers of the inetd Daemon

The **inetd** daemon (a subsystem) controls the following daemons (subservers):

- **comsat** daemon
- **ftpd** daemon
- **fingerd** daemon
- **rlogind** daemon
- **rexecd** daemon
- **rshd** daemon
- **talkd** daemon
- **telnetd** daemon
- **tftpd** daemon
- **uucpd** daemon.

The **ftpd**, **rlogind**, **rexecd**, **rshd**, **talkd**, **telnetd**, and **uucpd** daemons are started by default. The **tftpd**, **fingerd**, and **comsat** daemons are not started by default unless they are uncommented in the **/etc/inetd.conf** file.

Inetd Configuration File

The **/etc/inetd.conf** file can be updated by using the System Management Interface Tool (SMIT), the System Resource Controller (SRC), or by editing the **/etc/inetd.conf**.

If you change the `/etc/inetd.conf` file, using SMIT, then the **inetd** daemon will be refreshed automatically and will read the new `/etc/inetd.conf` file. If you change the `/etc/inetd.conf` file using any other editor, run the **refresh -s inetd** or **kill -1** *InetdPID* command to inform the **inetd** daemon of the changes to its configuration file. If you run the **refresh -s inetd** command, the running services continue to run with old configuration until the services terminate and the new services are created.

The entries in the `/etc/inetd.conf` file include the following information:

Item	Description
Service Name	Specifies the name of a valid Internet service.
Socket Type	Specifies the type of Internet socket used for the Internet service. (Only stream and datagram sockets are implemented.) Valid values are: stream dgram sunrpc_udp sunrpc_tcp
Protocol	Specifies the Internet Protocol used for the Internet service. Valid values are: tcp tcp6 udp udp6
Wait/Nowait	Specifies whether the **inetd** daemon should wait for the service to complete before continuing to listen for this type of service request.

Item	Description
Wait/Nowait	Specifies whether the **inetd** daemon should wait for the service to complete before continuing to listen for this type of service request. SRC works like wait, but instead of forking and waiting for the child to die, it does a **startsrc** on the subsystem and store information about the starting of the service. When the service is removed from the **inetd.conf** file and **inetd** is restarted, the service has a **stopsrc** issued to the service to stop it.
User	Specifies the user name that **inetd** should use to start the subserver.
Path	Specifies the fully qualified path name that inetd should execute to provide the service. For services that **inetd** provides internally, this entry should be internal.
Command	Specifies the name of the service to start and its parameters. This field is empty for internal services.

The **inetd** daemon can be run with or without the SRC. In addition, the inetd daemon can be controlled by issuing signals using the kill command.

Flags

Item	Description
-d	Sends debugging messages to the syslogd daemon.
-t *SecondsToWait*	Specifies the number of seconds to wait in the select() system call before looping. The *SecondsToWait* can be a number from 1 to 999999. Without this flag the **inetd** daemon will block until one of the active services is requested by a network connection. This flag should only be used when a machine is servicing many wait services like **tftp** and is not being used for other services. Since timing out the select() system call will cause the **inetd** daemon to use more CPU cycles, this flag is not recomended for most situations.

Service Requests

The Internet service requests that are supported internally by the **inetd** daemon are generally used for debugging. They include the following internal services:

Item	Description
ECHO	Returns data packets to a client host.
DISCARD	Discards received data packets.
CHARGEN	Discards received data packets and sends predefined or random data.
DAYTIME	Sends the current date and time in user-readable form.
TIME	Sends the current date and time in machine-readable form.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

infocmp Command

Purpose

Manages **terminfo** descriptions.

Syntax

infocmp [**-d**] [**-c**] [**-n**] [**-I**] [**-L**] [**-C**] [**-r**] [**-u**] [**-s** { **d**| **i**| **l**| **c**}] [**-v**] [**-V**] [**-1**] [**-w** *Width*] [**-A** *Directory*] [**-B** *Directory*] [*TermName...*]

Description

The **infocmp** command manages **terminfo** descriptions. You can use this command to:

- Compare a binary **terminfo** entry with other **terminfo** entries.
- Print a **terminfo** description from the binary file.
- Rewrite a **terminfo** description to take advantage of the **use** attribute.

The **infocmp** command prints the Boolean attributes first, the numeric attributes second, and the string attributes last.

Comparing Entries

Use the **-d**, **-c**, and **-n** flags to compare entries. The **-d** flag returns the differences between entries. The **-c** flag produces a list of the capabilities that are set and in common between two entries. The **-n** flag returns a list of the capabilities that neither entry has.

To compare **terminfo** entries, you specify two or more *TermName* parameters. The **infocmp** command compares the **terminfo** description of the first *TermName* parameter with each of the descriptions for the subsequent *TermName*s specified. If a capability is defined for only one of the terminal descriptions, the value returned will depend on the type of capability. For Boolean capabilities the **infocmp** command returns an F, the command returns a -1 for integer capabilities, and null for string capabilities.

Producing a Source Listing

Use the **-I** (uppercase i), **-L**, **-C**, and **-r** flags to produce a source listing for one or more terminals. If you do not specify a *TermName* parameter, the system uses the **TERM** environment variable. You can use these source options to produce a source file for a terminfo binary when one is not available.

The **I** (uppercase i) flag produces a listing with the terminfo names. The **-L** flag produces a listing using the long **C** variable names listed in **/usr/include/term.h**.

The **-C** flag uses **termcap** names instead of terminfo capability names when producing the source listing. The **infocmp** commands translates and outputs only those **terminfo** capabilities that have a corresponding **termcap** code name. To remove this restriction, specifying the **-r** flag. This flag causes the command to output **terminfo** capabilities that cannot be translated into **termcap** format.

When using the **-C** and **-r** flags, the **infocmp** command notes any string parameters it was unable to convert to the **termcap** format. You must edit these parameters manually. The command collects all padding information for strings together and places it at the beginning of the string where **termcap** expects it. Mandatory padding is optional after translation. Mandatory padding is padding information with a trailing **/** (slash).

> **Note:** The **-C** and **-r** flags cannot always convert a **terminfo** string into its equivalent **termcap** form. Similarly, a conversion from the **termcap** file format back into the **terminfo** file format does not necessarily reproduce the original source.

Definitions with the use Attribute

Given a list of terminal menus and the **-u** flag, the **infocmp** command compares the first terminal's description against the other terminal descriptions. The **infocmp** command then creates a new description for the first terminal using as much of the subsequent terminal descriptions as possible.

When you specify the **-u** flag and a list of terminal names, the **infocmp** command does the following:

- Compares subsequent terminal descriptions against the first.
- Creates a description of the first terminal you specified relative to the description of the other terminals.

The new description for the first terminal will have the following:

- Capabilities that exist in the subsequent terminals but do not exist for the first terminal will appear with an @ in the resulting description.

  Note: The @ implies that the capability does not exist.
- Capabilities defined in a subsequent terminal with the same value are replaced with *use=<subsequent terminal>*.
- Any capabilities in the first terminal not found in any of the other terminals are printed along with the corresponding values.
- If the first terminal has a capability whose value differs from the value found in at least one of the other terminals, the capability is printed.

You can change a description and specify a capability after the **use** attribute. If this capability is also found in the terminal referenced by the **use** attribute, the second capability takes precedence over the one referenced by the **use** attribute.

Changing Databases

By default, terminal descriptions appear in the system **terminfo** database directory, **/usr/share/lib/terminfo**. You can specify a different database location with the **TERMINFO** environment variable. The **infocmp** command first checks to see if this variable exists. If the variable does not exist, the command uses the system **terminfo** database.

You can use the **-A** and **-B** flag with the **infocmp** command to override the system database. The **-A** flag identifies the **terminfo** database for the first *TermName* parameter. The **-B** flag identifies the database to use for any subsequent terminals you name. Together, these flags make it possible to compare descriptions for two terminals with the same name located in two different databases.

Flags

Item	Description
-A *Directory*	Identifies the **terminfo** database for the first *TermName* parameter.
-B *Directory*	Identifies the **terminfo** database for every *TermName* parameter except the first.
-C	Uses the **termcap** code names to produce the source listing. Will not list **terminfo** capabilities that cannot be translated to **termcap** format.
-c	Lists the capabilities that are common between the two entries. Capabilities that are not set are ignored. This flag can be used as a quick check to see if it is desirable to use the **-u** flag.
-d	Lists the capabilities that are different between terminals. You can use this flag to pinpoint the differences between similar terminal entries.
-I (uppercase i)	Uses the **terminfo** capability names when producing the source listing.
-1 (numeral)	Prints the capabilities one to a line. by default, the fields are printed several to a line to a maximum width of 60 characters.
-L	Uses the long C variable name listed in **/usr/include/term.h** file to produce the source listing.

Item	Description
-n	Compares two entries and lists the capabilities that do not exist in either. If you do not specify a *TermName* parameter, the system uses the **TERM** environment variable for both *TermName* parameters. You can use this as a quick check to see if anything was left out of the description.
-r	Instructs the **infocmp** command to output **terminfo** capabilities that cannot be translated to **termcap** format. This flag is valid only with the **-C** flag.
-s	Sorts the output from the **infocmp** command within each capability type (Boolean, numeric, and string) and according to the argument below: **d** Sort in the order specified in the **terminfo** database. **i** Sort by **terminfo** name. **l** Sort by the long C variable name. **c** Sort by the **termcap** name. If you do not specify an option with the **-s** flag, the command sorts each capability alphabetically by the **terminfo** name within each type. If you specify the **-C** or the **-L** flags with the **-s** flag, the capabilities are sorted by the **termcap** name or the long C variable name, respectively.
-u	Compares two or more terminal descriptions and produces new descriptions using the **use** attribute.
-v	Prints out tracing information on standard error.
-V	Prints out the version of the program in use on standard error and exits.
-w *Width*	Changes the output to the specified number of characters per line. The output includes as many fields as possible that can fit within the specified number of characters. **Note:** Fields are not truncated.

Examples

1. To list the common capabilities between the aixterm and lft terminals, enter:

```
infocmp -c aixterm lft
```

2. To list all of the capabilities that are possible but do not currently exist for the current terminal, enter:

```
infocmp -n
```

3. To produce a source listing for the lft terminal in **terminfo** format, enter:

```
infocmp -I lft
```

4. To produce a source listing for the terminal description my_term that is located in **/tmp** using as much of the lft description as possible, enter:

```
infocmp -A /tmp -u my_term lft
```

File

Item	Description
/usr/share/lib/terminfo	Contains the compiled terminal description database.

telinit or init Command

Purpose

Initializes and controls processes.

Syntax

{ **telinit** | **init** } { **0** | **1** | **2** | **3** | **4** | **5** | **6** | **7** | **8** | **9** | **a** | **b** | **c** | **h** | **Q** | **q** | **S** | **s** | **M** | **m** | **N** }

Description

The **init** command initializes and controls processes. Its primary role is to start processes based on records read from the **/etc/inittab** file. The **/etc/inittab** file usually requests that the **init** command run the **getty** command for each line on which a user can log in. The **init** command controls autonomous processes required by the system.

The process that constitutes the majority of the **init** command's process dispatching activities is **/usr/sbin/getty**. The **/usr/sbin/getty** process initiates individual terminal lines. Other processes typically dispatched by the **init** command are daemons and the shell.

The **telinit** command, which is linked to the **init** command, directs the actions of the **init** command. The **telinit** command takes a one-character argument and signals the **init** command by way of the **kill** subroutine to perform the appropriate action.

The **telinit** command sets the system at a specific run level. A run level is a software configuration that allows only a selected group of processes to exist. The system can be at one of the following run levels:

Item	Description
0-9	Tells the **init** command to place the system in one of the run levels **0-9**. When the **init** command requests a change to run levels **0-9**, it kills all processes at the current run levels and then restarts any processes associated with the new run levels.
0-1	Reserved for the future use of the operating system.
2	Contains all of the terminal processes and daemons that are run in the multiuser environment. In the multiuser environment, the **/etc/inittab** file is set up so that the **init** command creates a process for each terminal on the system. The console device driver is also set to run at all run levels so the system can be operated with only the console active.
3-9	Can be defined according to the user's preferences.
S,s,M,m	Tells the **init** command to enter the maintenance mode. When the system enters maintenance mode from another run level, only the system console is used as the terminal.

The following arguments also serve as directives to the **init** command:

Item	Description
a,b,c,h	Tells the **init** command to process only those records in the **/etc/inittab** file with **a**, **b**, **c**, or **h** in the run level field. These four arguements, **a**, **b**, **c**, and **h**, are not true run levels. They differ from run levels in that the **init** command cannot request the entire system to enter run levels **a, b, c**, or **h**. When the **init** command finds a record in the **/etc/inittab** file with a value of **a**, **b**, **c**, or **h** in the run level field, it starts the process. However, it does not kill any processes at the current run level; processes with a value of **a**, **b**, **c**, or **h** in the run level field are started in addition to the processes already running at the current system run level. Another difference between true run levels and **a**, **b**, **c**, or **h** is that processes started with **a**, **b**, **c**, or **h** are not stopped when the **init** command changes run levels. Three ways stop **a**, **b**, **c**, or **h** processes: • Type **off** in the *Action* field. • Delete the objects entirely. • Use the **init** command to enter maintenance state.
Q,q	Tells the **init** command to re-examine the **/etc/inittab** file.
N	Sends a signal that stops processes from being respawned.

During system startup, after the root file system has been mounted in the pre-initialization process, the following sequence of events occurs:

1. The **init** command is run as the last step of the startup process.
2. The **init** command attempts to read the **/etc/inittab** file.
3. If the **/etc/inittab** file exists, the **init** command attempts to locate an `initdefault` entry in the **/etc/inittab** file.
   a. If the `initdefault` entry exists, the **init** command uses the specified run level as the initial system run level.
   b. If the `initdefault` entry does not exist, the **init** command requests that the user enter a run level from the system console (**/dev/console**).
   c. If the user enters an **S**, **s**, **M** or **m** run level, the **init** command enters maintenance run level. These are the only run levels that do not require a properly formatted **/etc/inittab** file.
4. If the **/etc/inittab** file does not exist, the **init** command places the system in the maintenance run level by default.
5. The **init** command rereads the **/etc/inittab** file every 60 seconds. If the **/etc/inittab** file has changed since the last time the **init** command read it, the new commands in the **/etc/inittab** file are executed during system startup.

When you request the **init** command to change the run level, the **init** command reads the **/etc/inittab** file to identify what processes should exist at the new run level. Then, the **init** command cancels all processes that should not be running at the new level and starts any processes that should be running at the new level.

The processes run by the **init** command for each of these run levels are defined in the **/etc/inittab** file. The run level is changed by having a root user run the **telinit** command, which is linked to the **init** command. This user-run **init** command sends appropriate signals to the original **init** command initiated by the system during startup. The default run level can be changed by modifying the run level for the `initdefault` entry in the **/etc/inittab** file.

In the maintenance run level, the **/dev/console** console terminal is opened for reading and writing. The password for root is prompted. When the root password is entered successfully, the **su** command is invoked. Two ways exist to exit from the maintenance run level:

- If the shell is terminated, the **init** command requests a new run level.

  OR

- The **init** (or **telinit**) command can signal the **init** command and force it to change the run level of the system.

During a system startup attempt, apparent failure of the **init** command to prompt for a new run level (when **initdefault** is maintenance) may be due to the fact that the terminal console device (**/dev/console**) has been switched to a device other than the physical console. If this occurs and you wish to work at the physical console rather than the **/dev/console**, you can force the **init** command to switch to the physical console by pressing the DEL (delete) key at the physical console device.

When the **init** command prompts for a new run level, enter one of the digits **0** through **9** or any of the letters **S**, **s**, **M**, or **m**. If you enter **S**, **s**, **M**, or **m**, the **init** command operates in maintenance mode with the additional result that if control had previously been forced to switch to the physical console, the **/dev/console** file is switched to this device as well. The **init** command generates a message to this effect on the device to which the **/dev/console** file was previously connected.

If you enter a **0** through **9** run level, the **init** command enters the corresponding run level. The **init** command rejects any other input and re-prompts you for the correct input. If this is the first time the **init** command enters any run level other than maintenance, it searches the **/etc/inittab** file for entries with the **boot** or **bootwait** keywords. If the **init** command finds these keywords, it performs the corresponding task, provided the run level entered matches that of the entry. For example, if the **init** command finds the **boot** keyword, it boots the machine. Any special initialization of the system, such as checking and mounting file systems, takes place before any users are allowed on the system. The **init** command then scans the **/etc/inittab** file to find all entries that are processes for that level. It then resumes normal processing of the **/etc/inittab** file.

Run level **2** is defined by default to contain all of the terminal processes and daemons that are run in the multiuser environment. In the multiuser environment, the **/etc/inittab** file is set up so that the **init** command creates a process for each terminal on the system.

For terminal processes, the shell terminates either as a result of an end of file character (EOF) typed explicitly or as the result of disconnection. When the **init** command receives a signal telling it that a process has terminated, it records the fact and the reason it stopped in **/etc/utmp** file and /**var**/**adm**/**wtmp** file. The /**var**/**adm**/**wtmp** file keeps a history of the processes started.

To start each process in the **/etc/inittab** file, the **init** command waits for one of its descendant processes to stop, for a power fail signal **SIGPWR**, or until the **init** command is signaled by the **init** or **telinit** commands to change the system's run level. When one of the above three conditions occurs, the **init** command re-examines the **/etc/inittab** file. Even if new entries have been added to the **/etc/inittab** file, the **init** command still waits for one of the three conditions to occur. To provide for instantaneous response, re-examine the **/etc/inittab** file by running the **telinit -q** command.

If the **init** command finds that it is continuously running an entry in the **/etc/inittab** file (more than five times in 225 seconds), it assumes that an error in the entry command string exists. It then prints an error message to the console and logs an error in the system error log. After the message is sent, the entry does not run for 60 seconds. If the error continues to occur, the command will respawn the entry only five times every 240 seconds. The **init** command continues to assume an error occurred until the command does not respond five times in the interval, or until it receives a signal from a user. The **init** command logs an error for only the first occurrence of the error.

When the **init** command is requested to change run levels by the **telinit** command, the **init** command sends a **SIGTERM** signal to all processes that are undefined in the current run level. The **init** command waits 20 seconds before stopping these processes with the **SIGKILL** signal.

If the **init** command receives a **SIGPWR** signal and is not in maintenance mode, it scans the **/etc/inittab** file for special power fail entries. The **init** command invokes the tasks associated with these entries (if the run levels permit) before any further processing takes place. In this way, the **init** command can perform cleanup and recording functions whenever the system experiences a power failure. It is important to note that these power fail entries should not use devices that need to be initialized first.

Environments

Because the **init** command is the ultimate ancestor of every process on the system, every other process on the system inherits the **init** command's environment variables. As part of its initialization sequence,

the **init** command reads the **/etc/environment** file and copies any assignments found in that file into the environment passed to all of its subprocesses. Because **init** subprocesses do not run from within a login session, they do not inherit a umask setting from **init**. These processes may set the umask to whatever value they require. A command that is executed by **init** from the **/etc/inittab** file uses **init**'s ulimit values and not the default values as given in **/etc/security/limits**. The result is that a command that is successfully executed from the command line may not execute correctly when invoked by **init**. Any command that has specific **ulimit** requirements should include specific actions to set the **ulimit** values as required.

Security

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To request the **init** command to reexamine the **/etc/inittab** file, enter:

   ```
   telinit  q
   ```

2. To request the **init** command to enter maintenance mode, enter:

   ```
   telinit  s
   ```

Files

Item	Description
/etc/inittab	Specifies the **init** command control file.
/etc/utmp	Specifies the record of logged-in users.
/var/adm/wtmp	Specifies the permanent login accounting file.
/sbin/rc.boot	Specifies the pre-initialization command file.
/etc/rc	Specifies the initialization command file.
/etc/environment	Specifies system environment variables.
/dev/console	Specifies the console device driver.

install Command

Purpose

Installs a command.

Syntax

/usr/bin/install [**- c** *DirectoryA*] [**- f** *DirectoryB*] [**- i**] [**- m**] [**- M** *Mode*] [**- O** *Owner*] [**- G** *Group*] [**- S**] [**- n** *DirectoryC*] [**- o**] [**- s**] *File* [*Directory ...*]

Description

The **install** command installs a specified file in a specific place within a file system. It is most often used in makefiles. When replacing files, the **install** command copies (or moves) each file into the appropriate directory, thereby retaining the original owner and permissions based on the behavior of the **cp** and **mv** commands. An attempt is made to change the destination to owner **bin** and group **bin**. The **-O** *Owner* and

-G *Group* flags can be used to specify a different owner or group. The **install** command writes a message telling you exactly which files it is replacing or creating and where they are going.

You must be a super-user if you want to specify the ownership of the installed file with the **-O** or **-G** flags.

If you do not specify the *Directory* parameter, the **install** command searches a set of default directories (**/usr/bin**, **/etc**, and **/usr/lib**, in that order) for a file with the same name as the *File* parameter. The first time it finds one, it overwrites it with *File* and issues a message indicating that it has done so. If a match is not found, the **install** command issues a message telling you there was no match and exits with no further action. If the *File* parameter does not exist in the current directory, the **install** command displays an error message and exits with a nonzero value.

If any directories are specified on the command line, the **install** command searches them before it searches the default directories.

Flags

Item	Description
-c *DirectoryA*	Installs a new command file in the *DirectoryA* variable only if that file does not already exist there. If it finds a copy of *File* there, it issues a message and exits without overwriting the file. This flag can be used alone or with the **-s**, **-M**, **-O**, **-G**, or **-S** flag.
-f *DirectoryB*	Forces installation of *File* in *DirectoryB* whether or not *File* already exists. If the file being installed does not already exist, the command sets the permission code and owner of the new file to **755** and **bin**, respectively. This flag can be used alone or with the **-o**,**-s, -M, -O, -G,** or **-S** flag.
-G *Group*	Specifies a different group for the destination file. The default group is **bin**.
-i	Ignores the default directory list and searches only those directories specified on the command line. This flag cannot be used with the **-c, -f,** or **-m** flags.
-m	Moves the *File* parameter to the directory instead of being copied. Cannot be used with the **-c**, **-f**, **-i**, or **-n** flag.
-M *Mode*	Specifies the mode of the destination file.
-n *DirectoryC*	Installs the *File* parameter in the *DirectoryC* variable if it is not in any of the searched directories, and sets the permissions and owner of the file to **755** and **bin**, respectively. This flag cannot be used with the **-c**, **-f**, or **-m** flag.
-o	Saves the old copy of the *File* parameter by copying it into a file called **OLD***File* in the same directory. This flag cannot be used with the **-c** flag.
-O *Owner*	Specifies a different owner of the destination file. The default owner is **bin**.
-s	Suppresses the display of all but error messages.
-S	Causes the binary to be stripped after installation.

Examples

1. To replace a command that already exists in one of the default directories, enter:

   ```
   install fixit
   ```

   This replaces the **fixit** file if it is found in the **/usr/bin**, **/etc**, or **/usr/lib** directory. Otherwise, the **fixit** file is not installed. For example, if **/usr/bin/fixit** exists, then this file is replaced by a copy of the file **fixit** in the current directory.
2. To replace a command that already exists in a specified or default directory and to preserve the old version, enter:

```
install  -o fixit /etc /usr/games
```

This replaces the **fixit** file if it is found in the **/etc** or **/usr/games** directory or in one of the default directories. Otherwise the **fixit** file is not installed. If the file is replaced, the old version is preserved by renaming it **OLDfixit** in the directory in which it was found.

3. To replace a command that already exists in a specified directory, enter:

```
install  -i fixit /home/jim/bin /home/joan/bin /usr/games
```

This replaces the **fixit** file if it is found in the **/home/jim/bin**, **/home/joan/bin**, or **/usr/games** directory. Otherwise, the file is not installed.

4. To replace a command found in a default directory or install it in a specified directory if it is not found, enter:

```
install  -n /usr/bin fixit
```

This replaces the **fixit** file if it is found in one of the default directories. If the file is not found, it is installed as **/usr/bin/fixit**.

5. To install a new command, enter:

```
install  -c /usr/bin fixit
```

This creates a new command by installing a copy of the **fixit** file as **/usr/bin/fixit**, but only if this file does not already exist.

6. To install a command in a specified directory whether or not it already exists, enter:

```
install  -f /usr/bin  -o  -s fixit
```

This forces the **fixit** file to be installed as **/usr/bin/fixit** whether or not it already exists. The old version, if any, is preserved by moving it to **/usr/bin/OLDfixit** (a result of the **-o** flag). The messages that tell where the new command is installed are suppressed (a result of the **-s** flag).

Compatibility

For compatibility with Berkeley Software Distribution (BSD), two **install** commands exist. See the **installbsd** command.

Files

Item	Description
/usr/bin/install	Contains the **install** command.

install_all_updates Command

Purpose

Updates installed software to the latest level on media and verifies the current recommended maintenance or technology level.

Syntax

install_all_updates **-d** *Device* [**-p**] [**-i**] [**-c**] [**-r**] [**-n**] [**-s**] [**-x**] [**-v**] [**-N**] [**-S**] [**-Y**] [**-V**] [**-D**]

Description

install_all_updates examines currently installed software and attempts to update it to the latest level that is available on the media. **install_all_updates** will not install any filesets that are present on the media, but not installed on the system except in the following situations:

- the new filesets are installed as requisites of other filesets.
- the **/var/adm/ras/bosinst.data** filesets ALL_DEVICES_KERNELS to yes.

For installp images, all installp requisites are enforced.

Note:

1. Currently, **install_all_updates** processes installp images and rpm images. Because the **rpm** utility does not support automatic installation of requisites, some rpm software may not be installable with **install_all_updates**.
2. **install_all_updates** verifies the current recommended maintenance or technology level by using the "**oslevel**" utility and checking with the latest recommended maintenance or technology level known to this version of **install_all_updates**.
3. If **install_all_updates** locates an update to the install utilities (the **bos.rte.install** fileset), it first installs the update and then reinvokes itself to process the remaining updates. The "**-i**" flag can be used to update the install utilities only, this is useful when attempting to view an accurate preview.
4. **install_all_updates applies** all installp updates unless the **COMMIT** flag (**-c**) is specified. For more information of **APPLY** vs. **COMMIT** please see the **installp** man page.
5. **install_all_updates** will by default instruct **installp** to automatically install requisites and to do any necessary file system expansions. The "**-n**" will override the install requisite default, and "**-x**" will override the file system expansion default.
6. The following flags apply to installp updates *only*: **-c**, **-n**, **-x**, **-v**, **-S**, and **-V**.
7. Any library or executable program updated by an interim fix or service update which is in use by an active process will not be reflected in that process unless it is restarted. For example, an update that changes the ksh will not have the changes reflected in any ksh processes that are already running. Likewise, an update to the **libc.a** library will not be reflected in any process that is already running. In addition, any process that is using a library and does a **dlopen** operation of the same library after the library has been updated could experience inconsistencies if it is not restarted.
8. If an attempt is made to update a fileset that is locked by the interim fix manager (the **emgr** command), a notice will be displayed indicating which filesets are locked. The **lslpp** command shows that any locked filesets are in the EFIXLOCKED state.
9. If an attempt is made to update a file set that has an installed build date more recent than the build date of the selected fileset, a message will be displayed to indicate this.

Some installed software must ship new installation images instead of service updates in new technology levels or service packs of the AIX operating system. For instance, a new installation image is required if the requisites of the installation image changes. When filesets are updated by using the **smitty update_all** or **install_all_updates** command, the most current version of the fileset is installed irrespective of whether filesets are updated by using the installation image or service update in the software source.

When a new installation image is installed, the history of the fileset in the system, which is the output of the **lslpp -ah <fileset>** command, is reset. The output of the **lslpp -ah <fileset>** command lists the new level of the fileset instead of original installation that was installed and all changes after that installation. . The following examples show the history of the **bos.ecc_client.rte** file before and after the installation image is installed.

- Before a new installation image for the **bos.ecc_client.rte** file is shipped, the following output is displayed:

```
# lslpp -ah bos.ecc_client.rte
       Fileset         Level       Action       Status       Date       Time
       ----------------------------------------------------------------------------
       Path: /usr/lib/objrepos  bos.ecc_client.rte
                       6.1.9.0     COMMIT       COMPLETE     04/26/17     16:49:31
                       6.1.9.0     APPLY        COMPLETE     04/26/17     16:49:31
                       6.1.9.15    APPLY        COMPLETE     04/26/17     21:02:55
                       6.1.9.45    APPLY        COMPLETE     04/27/17     08:11:05
       Path: /etc/objrepos  bos.ecc_client.rte
                       6.1.9.0     COMMIT       COMPLETE     04/26/17     16:49:42
                       6.1.9.0     APPLY        COMPLETE     04/26/17     16:49:42
```

```
                        6.1.9.15    APPLY        COMPLETE     04/26/17     21:03:07
                        6.1.9.45    APPLY        COMPLETE     04/27/17     08:11:19
```

- After a new installation image for the **bos.ecc_client.rte** file is shipped and installed on the system, the following output is displayed:

```
# lslpp -ah bos.ecc_client.rte
       Fileset         Level        Action       Status       Date         Time
       ----------------------------------------------------------------------------
Path: /usr/lib/objreposbos.ecc_client.rte
                        6.1.9.100    COMMIT       COMPLETE     04/27/17     09:19:12
                        6.1.9.100    APPLY        COMPLETE     04/27/17     09:19:12

Path: /etc/objreposbos.ecc_client.rte
                        6.1.9.100    COMMIT       COMPLETE     04/27/17     09:19:22
                        6.1.9.100    APPLY        COMPLETE     04/27/17     09:19:22
```

Flags

Item	Description
-c	Instructs **installp** to commit all newly installed updates. Updates are applied by default (Please see the **installp** man page for more explanation on applying vs. committing updates).
-d *Device*	Specifies where the installation media can be found. This can be a hardware device such as tape or cdrom or it can be a directory that contains installation images. When installation media is a tape device it should be specified as no-rewind-on-close and no-retension-on-open.
-D	Turns on **install_all_updates** debug output. This flag is for debugging the **install_all_updates** utility and should not be used for normal operations.
-i	Update install utilities only.
-n	Instructs **installp** to not automatically install requisites. Automatic installation of requisites is the default behavior.
-N	Skip updating install utilities first. **Note:** This flag is not recommended unless you are debugging a related problem.
-p	Performs a preview of an action by running all preinstallation checks for the specified action. No software changes are made.
-r	Update rpm images (if possible). This flag is not set by default.
-s	Skip recommended maintenance or technology level verification. The verification is performed by default.
-S	Instructs **installp** to suppress multi-volume processing of cdrom media.
-v	Instructs **installp** to verify that all installed files in the fileset have the correct checksum value after the installation. This operation may require more time to complete the installation.
-V	Instructs **installp** to run in verbose output mode.
-x	Instructs **installp** to not automatically expand file systems. Automatic expansion of file systems is the default.
-Y	Agrees to all software license agreements which are required for software installation.

Exit Status

0

All **lppmgr** related operations completed successfully.

>0
An error occurred.

Security

Only the root user can execute **install_all_updates**.

Attention RBAC users and Trusted AIX users: This command can perform privileged operations. Only privileged users can run privileged operations. For more information about authorizations and privileges, see Privileged Command Database in *Security*. For a list of privileges and the authorizations associated with this command, see the **lssecattr** command or the **getcmdattr** subcommand.

Examples

1. To install all installp updates on device **/dev/cd0** and to verify the current recommended maintenance or technology level, enter:

```
install_all_updates -d /dev/cd0
```

2. To update any rpm images on your system, with newer technology levels from the **/images** directory, enter:

```
install_all_updates -d /images -r
```

3. To install the latest level of install utilities on device **/dev/cd0** (**bos.rte.install** update), enter:

```
install_all_updates -d /dev/cd0 -i
```

Files

Item	Description
/usr/sbin/install_all_updates	Contains the **install_all_updates** command.

install_assist Command

Purpose

Starts the Installation Assistant application.

Syntax

install_assist

Description

The **install_assist** command starts Installation Assistant, an application designed to simplify the customization of your system after a Base Operating System (BOS) installation. The Installation Assistant guides you through post-installation tasks and, in some cases, automatically installs software packages for you. The Installation Assistant has two interfaces, ASCII and graphical. The interface that displays is based on your terminal type (defined in the **TERM** environment variable).

If your terminal type is not set, the first menu displayed by the ASCII Installation Assistant requires you to enter your terminal type (tty). If you enter a terminal type that is not valid, this menu redisplays until a valid type is entered. If you enter a valid terminal type that does not match your terminal, the next screen displayed could be unreadable. In this case, press the break key sequence to return to the Set Terminal Type screen. For most terminal types, the break key sequence is Ctrl-C.

On a system with an ASCII interface, the newly installed BOS reboots and starts the Installation Assistant to guide you through completing configuration tasks. You must have root user authority to use the

Installation Assistant. To access the Installation Assistant later, type **install_assist** on the command line. You can also access it from a graphics system through the SMIT **smit assist** fast path. If there are outstanding software license agreements that must be accepted before you can continue to use the machine, the Installation Assistant prompts you to view and accept these agreements.

On a system with a graphical interface, the newly installed BOS reboots and the Configuration Assistant starts to guide you through the configuration tasks. If there are outstanding software license agreements that must be accepted before you can continue to use the machine, the Configuration Assistant prompts you to view and accept these agreements. To access the Configuration Assistant later, type **configassist** on the command line.

Most Installation Assistant tasks create or add to the **smit.log** and **smit.script** files in your home directory. (These are the same files appended when you run a SMIT session.) The commands built and run by the Installation Assistant tasks are added to the end of the **smit.log** file along with the command output. The time, name of the task, and the command (flags and parameters included) are added to the end of the **smit.script** file in a format that can easily be used to create executable shell scripts.

Example

1. To start the Installation Assistant, type:

   ```
   install_assist
   ```

2. To access the Configuration Assistant, type:

   ```
   configassist
   ```

3. Access the Installation Assistant from a graphical interface, use the SMIT `smit assist` fast path.

Files

Item	Description
smit.log	Specifies detailed information on your session, with time stamps.
smit.script	Specifies the task commands run during your session, with time stamps.

install_mh Command

Purpose

Sets up mailbox directories.

Syntax

install_mh [**-auto**] [**-help**]

Description

The **install_mh** command sets up mailbox directories. The **install_mh** command is not started by the user. The **install_mh** command is called by other programs only.

The **install_mh** command starts automatically the first time you run any Message Handler (MH) command. The **install_mh** command prompts you for the name of your mail directory. If the directory does not exist, the **install_mh** command queries you if it should be created. Upon receiving a positive response, the **install_mh** command creates the **$HOME/.mh_profile** file and places the `Path:` profile entry in it. This entry identifies the location of your mailbox by specifying the directory path for your MH directory, *UserMHDirectory*.

Flags

Item	Description
-auto	Creates the standard MH path without prompting.
-help	Lists the command syntax, available switches (toggles), and version information. **Note:** For MH, the name of this flag must be fully spelled out.

Files

Item	Description
$HOME/.mh_profile	Contains the MH user profile.

installbsd Command

Purpose

Installs a command (BSD version of the **install** command).

Syntax

/usr/bin/installbsd [**-c**] [**-g** *Group*] [**-m** *Mode*] [**-o** *Owner*] [**-s**] *BinaryFileDestination*

Description

The **installbsd** command installs the file specified by the *BinaryFile* parameter by moving it to a file or directory specified by the *Destination* parameter. Use of the **-c** flag copies the *BinaryFile* rather than moving it. If the specified *Destination* parameter is a directory, the *BinaryFile* is moved into the directory. If the specified *Destination* parameter already exists as a file, the **installbsd** command removes that file before the *BinaryFile* is moved. The **installbsd** command does not move a file onto itself.

Installing the file /**dev**/**null** creates an empty file.

Flags

Item	Description
-c	Copies the file specified by the *BinaryFile* parameter to the file or directory specified by the *Destination* parameter.
-g *Group*	Specifies a group for the file specified by the *Destination* parameter. The default group is staff.
-m *Mode*	Specifies a mode for the file specified by the *Destination* parameter. The default mode is 755. The specified mode can be an octal number or a symbolic value.
-o *Owner*	Specifies the owner for the file specified by the *Destination* parameter. The default owner is the root user.
-s	Causes the file specified by the *BinaryFile* parameter to be stripped after installation.

Examples

To install a new command called **fixit**, enter:

```
installbsd  -c o mike fixit /usr/bin
```

This command sequence installs a new command by copying the program `fixit` to `/usr/bin/fixit`, with user `mike` as the owner.

Files

Item	Description
/usr/ucb/install	Hard-link to the **/usr/bin/installbsd** file.
/usr/bin/installbsd	Contains the **installbsd** command.

installios Command

Purpose

Sets up the environment and creates NIM resources from the Virtual I/O Server DVD to install the Virtual I/O logical partition and the Integrated Virtualization Manager.

Syntax

To set up the environment and create NIM resources for installing a Virtual I/O logical partition or Integrated Virtualization Manager:

`installios` [`-p` *partition_name* `-i` *ipaddrorhostname* `-S` *subnet_mask* `-g` *gateway* `-d` *path* `-s` *system_name* `-r` *profile* [`-n`] [`-P` *speed*] [`-D` *duplex*] [`-l` *language*] [`-L` *location*] [`-V` *vlan_tag*] [**-Y** *vlan_priority*]]

To clean up tasks from the setup process:

`installios -u` [`-f` | `-U`]

Description

The `installios` command creates NIM resources from the Virtual I/O Server DVD to install a Virtual I/O logical partition and Integrated Virtualization Manager. When invoked on a NIM client, the `-L` flag must be specified with the location of the bos.sysmgt.nim.master fileset. The `installios` command configures the client as a NIM master and creates the resources from the Virtual I/O Server DVD to install the ioserver logical partition or the Integrated Virtualization Manager. After the logical partition or Integrated Virtualization Manager have been installed, the `installios` command can return the NIM master back to its original state by removing the created resources from the DVD or by unconfiguring the NIM master. All of the flags are optional. If no flags are specified, the `installios` wizard runs and the user is prompted to interactively enter the flag information.

Flags

Item	Description
`-d` *path*	Specifies the path to the installation images (`/dev/cd0` or the path to a system backup of the Virtual I/O Server created by the `backupios` command. The path may also specify a remote NFS-mountable location such as *hostname*`:`*/path_to_backup*.

Item	Description
-D *duplex*	Specifies duplex (optional). This is the duplex setting with which to configure the network interface of a client. The network interface of the client must support the value of the *duplex* parameter. This value can be `full`, `half`, or `auto`. The default value is `full` if you do not specify this flag.
-f	Forces a cleanup to deallocate and remove resources which are not yet installed on a Virtual I/O logical partition or Integrated Virtualization Manager.
-g *gateway*	Specifies the client gateway (the default gateway that the client will use during network installation of the Virtual I/O Server operating system).
-i *ipaddrorhostname*	Specifies the client IP address or hostname (the IP address or hostname with which the network interface of a client will be configured for network installation of the Virtual I/O Server operating system).
-l *language*	Specifies the language (optional). This is the language in which the license agreement will be displayed before the installation. When the license is viewed, a prompt displays asking if the license is to be accepted. If the prompt is answered with y, then the installation will proceed and the Virtual I/O Server license is automatically accepted after installation. If the prompt is answered with n, the `installios` command exits and the installation does not proceed. If this flag is not specified, the installation proceeds, but the Virtual I/O Server will not be usable until the license is manually accepted after installation.
-L *location*	Specifies the location of the bos.sysmgt.nim.master fileset to configure a client to become a NIM master.
-n	Specifies that the network interface of a client should not be configured. If this flag is specified, the network interface of a client will not be configured with the IP settings that were specified in the flags given to the `installios` command after the installation has completed.
-p *partition_name*	Specifies the partition name. This is the name of the LPAR that will be installed with Virtual I/O Server operating system. This partition must be of type Virtual I/O Server and the partition name must match the name shown on the HMC; the name is not a host name.

Item	Description
-P *speed*	Specifies speed (optional). This is the communication speed to use when configuring the network interface of a client. The network interface of the client must support the value of the *speed* parameter. This value can be `10`, `100`, `1000`, or `auto`. The default value is `100` if you do not specify this flag.
-r *profile*	Specifies the profile name. This is the name of the profile that will contain the hardware resources that will be installed.
-s *system_name*	Specifies the managed system (the name of the managed system maintained by the HMC). This name must match the name shown on the HMC; the name is not a host name.
-S *subnet_mask*	Specifies the client subnet mask (the subnet mask with which the network interface of a client will be configured for network installation of the Virtual I/O Server operating system).
-u	Cleans up the environment to return the NIM master back to its original state.
-U	Unconfigures the NIM master.
-V *vlan_tag*	Specifies the virtual local area network (VLAN) tag identifier (0 to 4094) that is used for tagging Ethernet frames during the network installation for virtual network communication.
-Y *vlan_priority*	Specifies the virtual local area network (VLAN) tag priority (0 to 7) that is used for tagging Ethernet frames during the network installation for virtual network communication.

Exit Status

Item	Description
0	The **installios** command was successful.

Security

You must have root authority to run the **installios** command

Examples

1. To create Virtual I/O resources on a NIM master for installing client 9.3.6.234, type:

```
installios -d /dev/cd0 -i 9.3.6.234 -g 9.3.6.1 -S 255.255.255.0
```

2. To create Virtual I/O resources on a NIM client for installing client 9.3.6.234 where /tmp contains the bos.sysmgt.nim.master fileset, type:

```
installios -d /dev/cd0 -i 9.3.6.234 -g 9.3.6.1 -S 255.255.255.0 -L /tmp
```

3. To clean up tasks performed while creating Virtual I/O resources, type:

```
installios -u
```

4. To clean up tasks performed during the creation of Virtual I/O resources on a logical partition which has not yet been installed, type:

```
installios -u -f
```

5. To clean up tasks and unconfigure NIM after creating Virtual I/O resources , type:

```
installios -u -U
```

Location

/usr/sbin/installios

Files

Item	Description
/usr/sbin/installios	Contains the **installios** command
/etc/niminfo	Contains variables used by NIM

installp Command

Purpose

Installs available software products in a compatible installation package.

Syntax

To Install with Apply Only or with Apply and Commit

installp [**-R** *path*] [**-a** | **-a** **-c** [**-N**]] [**-e** *LogFile*] [**-V** *Number*] [**-d** *Device*] [**-E**] [**-Y**] [**-b**] [**-S**] [**-B**] [**-D**] [**-I**] [**-p**] [**-Q**] [**-q**] [**-v**] [**-X**] [**-F** | **-g**] [**-O** { [**r**] [**s**] [**u**] }] [**-t** *SaveDirectory*] [**-w**] [**-z** *BlockSize*] { *FilesetName* [*Level*]... | **-f** *ListFile* | **all** }

To Commit Applied Updates

installp [**-R** *path*] **-c** [**-e** *LogFile*] [**-V** *Number*] [**-b**] [**-g**] [**-p**] [**-v**] [**-X**] [**-O** { [**r**] [**s**] [**u**] }] [**-w**] { *FilesetName* [*Level*]... | **-f** *ListFile* | **all** }

To Reject Applied Updates

installp [**-R** *path*] **-r** [**-e** *LogFile*] [**-V** *Number*] [**-b**] [**-g**] [**-p**] [**-v**] [**-X**] [**-O** { [**r**] [**s**] [**u**] }] [**-w**] { *FilesetName* [*Level*]... | **-f** *ListFile* }

To Deinstall (Remove) Installed Software

installp [**-R** *path*] **-u** [**-e** *LogFile*] [**-V** *Number*] [**-b**] [**-g**] [**-p**] [**-v**] [**-X**] [**-O** { [**r**] [**s**] [**u**] }] [**-w**] { *FilesetName* [*Level*]... | **-f** *ListFile* }

To Clean Up a Failed Installation:

installp [**-R** *path*] **-C** [**-b**] [**-e** *LogFile*]

To List All Installable Software on Media

installp { **-l** | **-L** } [**-e** *LogFile*] [**-d** *Device*] [**-B**] [**-I**] [**-q**] [**-E**] [**-z** *BlockSize*] [**-O** { [**s**] [**u**] }]

To List All Customer-Reported Problems Fixed with Software or Display All Supplemental Information

installp { **-A**| **-i** } [**-e** *LogFile*] [**-d** *Device*] [**-B**] [**-I**] [**-q**] [**-z** *BlockSize*] [**-O** { [**s**] [**u**] }] { *FilesetName* [*Level*]... | **-f** *ListFile* | **all** }

To List Installed Updates That Are Applied But Not Committed

installp -s [**-e** *LogFile*] [**-O** { [**r**] [**s**] [**u**] }] [**-w**] { *FilesetName* [*Level*]... | **-f** *ListFile* | **all** }

To List Platform Specific Installable Software on Media

installp { **-l** | **-L** } { **-M** *Platform* } [**-e** *LogFile*] [**-d** *Device*] [**-B**] [**-I**] [**-q**] [**-z** *BlockSize*] [**-O** { [**s**] [**u**] }]

Description

Notes:

1. The **noclobber** option of the Korn or C shell must be unset in the environment from which an installation is performed.
2. Update all can be accomplished with smitty or with `install_all_updates`.

The **installp** command installs and updates software.

A fileset is the lowest installable base unit. For example, **bos.net.tcp.client 4.1.0.0** is a fileset. A fileset update is an image with a different modification level or a different fix level. For example, **bos.net.tcp.client 4.1.0.2** and **bos.net.tcp.client 4.1.1.0** are both fileset updates for **bos.net.tcp.client 4.1.0.0**.

When a base level (fileset) is installed on the system, it is automatically committed. You can remove a fileset regardless of the state (such as committed, broken, committed with applied updates, and committed with committed updates).

When a fileset update is applied to the system, the update is installed. The current version of that software, during installation, is saved in a special save directory on the disk so that later you can return to that version if desired. After a new version of a software product has been applied to the system, that version becomes the currently active version of the software.

Updates that have been applied to the system can be either committed or *rejected* at a later time. The **installp -s** command can be used to get a list of applied updates that can be committed or rejected.

When updates are committed with the **-c** flag, the user is making a commitment to that version of the software product. The saved files from all previous versions of the software product are removed from the system, making it impossible to return to a previous version of the software product. Software can be committed at the time of installation by using the **-ac** flags.

Notes:

- Committing the already applied updates does not change the currently active version of a software product. It merely removes saved files for previous versions of the software product.
- The signature verification is performed during the package installation. The verification is based on the level of digital signature verification policy.

When a base level is removed with the **-u** flag, the files that are part of the software product and all its updates are removed from the system. Most cleanup of system configuration information pertaining to the product is also done, but this is dependent on the product and may not always be complete.

When a software product update is rejected with the **-r** flag, the current version of the software product is changed to the immediate previous version of the update. Files saved for the rejected update and any updates that were applied after it are removed from the system.

A software product that is to be removed from the system can be in any state. Product updates can be in either the applied or committed state, and they will also be removed.

If a previously interrupted installation leaves any software in a state of either applying or committing, it is necessary to perform cleanup with the **-C** flag before any further installations are allowed. Although the **installp -C** command accepts software product names on the command line without returning an error, an attempt is always made to clean up all products when the **-C** flag is used. An attempt is made to clean

up any incomplete installations by removing those parts that were previously completed. An attempt is also made to return to the previous version of the software product, if one exists, as the currently active version. If this cannot be done, the software product is marked as *broken*, and unpredictable results can occur if the user attempts to use it. Therefore, it is advisable for the user to reinstall any broken software products or updates.

The **-t** flag specifies an alternate location for a save directory that holds files being replaced by an update. This option is primarily useful in the following two circumstances.

- You have enough local disk space for saving replaced files but you do not want to permanently expand the root and **/usr** file systems.

  In this case, you can choose to create a separate file system for the alternate save directory. When you are satisfied with the updated system and have committed all applied updates, disk space can be retrieved by deleting the save file system.
- You do not have enough local disk space for saving replaced files but you have access to ample disk space on a remote system. In this case, you can specify a directory that is mounted from a remote file system.

  If a remote file system is used, commit the updates *as soon as possible*. You may want to initiate the installation action as an `apply` and `commit` operation with the **-ac** flags. If you want to `apply` only to be able to reject unwanted updates, then test the newly installed updates *as soon as possible* and then commit or reject them.

  Take into account the following considerations when using an alternate save directory:
- It is recommended that you use the same alternate save location on each invocation of the **installp** command.
- If an alternate save directory is used for an apply operation, make sure that the file system containing that directory remains mounted. It is highly recommended that any necessary mounts be done automatically on a reboot.
- If an alternate save directory is missing on a commit operation, the commit takes place, a warning is given stating that the save directory could not be deleted. In this case, you must delete the save directories that are no longer used in order to retrieve that disk space.
- If an alternate save directory is missing on reject, the reject operation cannot be done because the saved files are missing. An error is given, and the entire reject operation is canceled. If the missing save directory is not caused by a temporary situation (for example, the inability to contact a remote directory on the network) your only options are to commit the updates or leave them in an applied state permanently.
- When doing a system backup, ensure that you back up any alternate save directories that do not reside in the root volume group.
- The installation process safeguards users with a remote save directory from the possibility of two different systems using the same remote directory. However, use directory path names that easily and uniquely identify each user's system. For example, you can add the system's host name in the path name.
- Do not create a **mksysb** backup of a system with a remote save directory and then try to restore the **mksysb** image onto a system other than the original. In this case, using a **mksysb** image to install several like systems causes multiple ownership of the same remote save directory.

The **installp -A** command can be used to obtain a list of the Authorized Program Analysis Report (APAR) numbers and summaries for all customer-reported problems that are fixed in the specified software package. The **installp -i** command can be used to display supplemental information contained in files that can be a part of the specified software package.

To list all the software products and updates on the specified installation media, use the **installp -l** command. The output of the **installp** command with the **-l** flag resembles the following:

```
# Fileset Name             Level                   I/U Q Content
#=============================================================
  X11.adt.include          4.1.0.0                 I  N usr
#   AIX windows Application Development Toolkit Include F
```

```
  X11.adt.lib              4.1.0.0                  I  N usr
#   AIX windows Application Development Toolkit Libraries
#
  X11.adt.motif            4.1.0.0                  I  N usr
#    AIX windows Application Development Toolkit Motif

#
  X11.adt.bitmaps          4.1.0.0                  I  N usr
#    AIX windows Application Development Toolkit Bitmap Fi

#
  X11.adt.ext              4.1.0.0                  I  N usr
#    AIX windows Application Development Toolkit for X Ext
#
  X11.adt.imake            4.1.0.0                  I  N usr
#    AIX windows Application Development Toolkit imake
#
  X11.apps.rte             4.1.0.0                  I  N usr
#    AIX windows Runtime Configuration Applications
#
  X11.apps.msmit           4.1.0.0                  I  N usr
#    AIX windows msmit Application
```

The field descriptions are as follows:

Item	Description
`Fileset Name`	Name of the fileset to be installed.
`Level`	Level of the fileset to be installed.
`I/U`	The type of package to which the fileset belongs. The fileset can belong to an installation package or to one of several types of update packages. The package types are as follows: **I** Indicates an installation package. **S** Indicates a single update. **SR** Indicates a required update. Whenever the **installp** command encounters a required update, the update is automatically included in the input list. **SF** Indicates a required update. Whenever the **installp** command encounters a required update, the update is automatically included in the input list. Reserved for updates to the **installp** fileset. **M** Indicates a maintenance or technology package. This is a packaging update that contains only a list of other updates to be applied. This package delivers no files. **ML** Indicates an update package that identifies a new maintenance or technology level for the product. This is a cumulative set of all updates since the previous product level.
`Q`	Quiescent (quiet) column. A **Y** indicates that running processes can be affected by the installation of this fileset. Refer to the documentation supplied with the software product. An **N** indicates that running processes are not affected by the installation of this fileset. A **B** indicates **bosboot** and quiescent. A **b** indicates **bosboot** and not quiescent.

Item	Description
Content	Content column: **usr,root** **/usr** and root file systems (AIX 3.2 and later) **usr** **/usr** file system only (AIX 3.2 and later) **share** **/usr/share** file system only (AIX 3.2 and later)

Output from the **installp -s** command, which is used to get a list of applied software fileset updates and updates that are available to be either committed or rejected, resembles the following:

```
Installp Status
---------------
Name                        Part    Level                     State
-------------------------------------------------------------------
bos.net.tcp.client          USR     4.1.0.2                   APPLIED
bos.net.tcp.client          ROOT    4.1.0.2                   APPLIED
bos.rte.commands            USR     4.1.0.1                   APPLIED
bos.rte.misc_cmds           USR     4.1.0.1                   APPLIED
bos.rte.tty                 USR     4.1.0.1                   APPLIED
```

The field descriptions are as follows:

Item	Description
Name	Name of the installed software product fileset.
Part	The part of the fileset where:
ROOT	root file system
SHARE	**/usr/share** file system
USR	**/usr** file system.
Level	The level of the installed software product option.
State	The state of the installed software product option.

The software products and updates to be installed can be identified in one of following ways:

- by the keyword **all**, which indicates that all software contained on the specified installation media is to be installed
- by a list of software product names (each of which can optionally be followed by a level) that indicates the software to be installed
- by the **-f** flag followed by a file name, where each line in the file is an entry containing a software product name, optionally followed by a level, or is a comment line that begins with a # and is ignored

  Note: The **installp** program uses the **sysck** command to verify files after restoring them. The **sysck** command does not recognize the following special characters in file names: ~, ` , ', \, ", $, ^, &, ( ), |, {}, [], <>, and ?. If a file name contains any of these characters, installation fails.

The *FilesetName* parameter can be used to specify an entire software product or any separately installable filesets within the software package. For example, **bos.net** is the name of a software package, and the separately installable filesets within that software package are **bos.net.ncs.client**, **bos.net.nfs.client**, and **bos.net.tcp.client**. If the user specifies **bos.net** for the *FilesetName* parameter, then all of the separately installable filesets listed are installed. If the user specifies **bos.net.tcp.client** for the *FilesetName* parameter, then only that fileset is installed.

The *Level* parameter indicates the level of the software product or update that is to be installed. The *Level* parameter is of the form *vv.rr.mmmm.ffff* where:

Item	Description
vv	is a numeric field of 1 to 2 digits that represents the version number.
rr	is a numeric field of 1 to 2 digits that represents the release number.
mmmm	is a numeric field of 1 to 4 digits that represents the modification level. Modification level is also called maintenance level or technology level.
ffff	is a numeric field of 1 to 4 digits that represents the fix level.

If a user is installing an installation package from installation media that contains only installation packages it is not necessary to specify the level. More than one software product installation package with different levels does not often exist on the same installation medium. However, when this does occur **installp** installs the specified software product at the latest software product level when *Level* is not specified with *FilesetName*. For installation media that contain either update packages only or contain both installation and update packages, all applicable update packages that are present on the installation media for the specified *FilesetName* are also installed when *Level* is not specified. For installation media that contain both installation and update packages the user can request the installation of only installation packages or only update packages by specifying the **-I** or **-B** flags, respectively. If the user wants to install only some of the updates on the installation medium for a specific software product both *FilesetName* and *Level* for each of the updates to be installed for that software product must be specified.

You can use the following example to install TCP/IP and one of its updates that are both contained in the **/usr/sys/inst.images** directory.

```
installp -a -d/usr/sys/inst.images bos.net.tcp.client 4.1.0.0
bos.net.tcp.client 4.1.0.2
```

Note: If there are duplicate filesets at the same level, **installp** uses the first one that it finds in the install table of contents (**.toc**). This situation can occur when **bffcreate** is used to extract images from different media to the same installation directory. For this reason, make sure that update images are not extracted to the same directory as base level images for the same fileset at the same level.

A summary report is given at the end of the **installp** output that lists the status of each of the software products that were to be installed. An example summary report for the previous **installp** command is as follows:

```
Installp Summary
----------------
Name                    Level        Part        Event        Result
-------------------------------------------------------------------------
bos.net.tcp.client      4.1.0.0      USR        APPLY        SUCCESS
bos.net.tcp.client      4.1.0.0      ROOT       APPLY        SUCCESS
bos.net.tcp.client      4.1.0.2      USR        APPLY        SUCCESS
```

Note:

1. If a previously installed level of a fileset update is in the broken state, the **-acgN** flags must be used when that fileset update is installed again.
2. The **installp** command cannot install a mkinstallp package or bff image that is larger than 2 GB in size. An alternative is to break the bff image into multiple packages that are less than 2 GB in size.
3. If an attempt is made to update a fileset that is locked by the interim fix manager (the **emgr** command), a notice is displayed indicating the filesets that are locked. The **lslpp** command shows that any locked filesets are in the EFIXLOCKED state.
4. If an attempt is made to update a fileset that has an installed build date more recent than the build date of the selected fileset, a message is displayed to indicate this.

Summary Report Values

The summary report identifies the name of the product option and the part of the product. Other information given includes the requested action (event) and the result of that action.

Event Values

The Event column of the summary report identifies the action that has been requested of the **installp** command. The following values are displayed in this column:

Event	Definition
APPLY	An attempt was made to apply the specified fileset.
COMMIT	An attempt was made to commit the specified fileset update.
REJECT	An attempt was made to reject the specified fileset update.
CLEANUP	An attempt was made to perform cleanup for the specified fileset.
DEINSTALL	An attempt was made to remove the specified fileset.

Result Values

The Result column of the summary report gives the result of **installp** performing the requested action. It can have the following values:

Result	Definition
SUCCESS	The specified action succeeded.
FAILED	The specified action failed.
CANCELLED	Although preinstallation checking passed for the specified option, it was necessary to cancel the specified action before it was begun. Interrupting the installation process with Ctrl+c can sometimes cause a canceled action, although, in general, a Ctrl+c interrupt causes unpredictable results.

Flags

Item	Description
-A	Displays the APAR number and summary of all customer-reported problems that are fixed in the specified software package. No installation is attempted.
-a	Applies one or more software products or updates. This is the default action. This flag can be used with the **-c** flag to apply and commit a software product update when installed.
-b	Prevents the system from performing a bosboot in the event that one is needed.
-B	Indicates that the requested action should be limited to software updates.
-C	Cleans up after an interrupted installation and attempts to remove all incomplete pieces of the previous installation. Cleanup must be performed whenever any software product or update is in a state of either *applying* or *committing* and can be run manually as needed. For backward compatibility, other flags and parameters can be accepted with **installp -C**, but are ignored because all necessary cleanup is attempted.

Item	Description
-c	Commits all specified updates that are currently applied but not committed. When an update is committed all other software products it is dependent on must also be committed (unless they are already in the committed state). The specified software product is dependent on any software product that is a prerequisite or corequisite of the specified product. If the requisite software products are not in the committed state, the commit fails and error messages are displayed. The **-g** flag can be used to automatically commit requisite software product updates.
-D	Deletes the installation image file after the software product or update has been successfully installed. When the **-g** flag is specified, the installation image files for any products that are automatically included are also deleted. This flag is valid only with the **-a** or **-ac** flags and is not valid with the **-Or** flag. This flag is also only valid when the device is a directory and an installation image file on the system where the installation is taking place.
-d *Device*	Specifies where the installation media can be found. This can be a hardware device such as tape or diskette, it can be a directory that contains installation images, or it can be the installation image file itself. When the installation media is a product tape or Corrective Service tape, specified the tape device as no-rewind-on-close and no-retension-on-open. Examples of this would be **/dev/rmt0.1** for a high density tape, or **/dev/rmt0.5** for a low density tape. Use the options specified by the tape supplier. The default device is **/dev/rfd0**.
-e *LogFile*	Enables event logging. The **-e** flag enables the user to append certain parts of the **installp** command output to the file specified by the *LogFile* variable. By default the output of the **installp** command goes to **stdout** and **stderr**, unless SMIT or VSM is used, in which case the output goes to the **smit.log**. The *LogFile* variable must specify an existing, writable file, and the file system in which the file resides must have enough space to store the log. The log file does not wrap. Not all output is appended. Copyright information is still displayed to the user. Error messages are displayed on the screen and are sent to the file specified by the *LogFile* variable. A results summary of the **installp** command invocation is also displayed on the screen and sent to the *LogFile*. This flag is primarily used by NIM and BOS install to limit the output shown to the user, but keep useful information for later retrieval.
-E	Displays software license agreements. This flag is only valid with the **-a** or **-l** flags. If the **-E** flag is specified with the **-a** flag, a new section is displayed showing the pending license agreements associated with the selected filesets. If the **-E** flag is specified with the **-l** flag, output is displayed showing the license agreements associated with all filesets on the media.
-F	This option can be used to force the installation of a software product even if there exists a previously installed version of the software product that is the same as or newer than the version currently being installed. The **-F** flag is not valid with update packages or the **-g** flag. When you use the **-F** flag, the **-I** flag is implicit.
-f *ListFile*	Reads the names of the software products from *ListFile*. If *ListFile* is a - (dash), it reads the list of names from the standard input. Software fileset names, optionally followed by a level, should be one per line of text, and any text following the second set of white spaces or tabs on a line is ignored. Output from the **installp -l** command is suitable for input to this flag.

Item	Description
-g	When used to install or commit, this flag automatically installs or commits, respectively, any software products or updates that are requisites of the specified software product. When used to remove or reject software, this flag automatically removes or rejects dependents of the specified software. The **-g** flag is not valid when used with the **-F** flag. **Note:** This flag also automatically pulls in a superseding update present on the media if the specified update is not present. This flag causes the newest update to be installed for a given fileset, when there are multiple superseding updates for the same fileset on the installation media.
-I	(uppercase i) Indicates that the requested action must be limited to base level filesets.
-i	Displays on standard output the **lpp.instr**, **lpp.doc**, **lpp.README**, and **README** files on the installation media for the software product, if they exist. This flag can take a significant amount of time for a large number of filesets.
-J	This flag is used when the **installp** command is executed from the System Management Interface Tool (SMIT) menus.
-l	(lowercase L) Lists all the software products and their separately installable options contained on the installation media to standard output. No installation occurs. The **-l** flag is not valid with the **-Or** flag.
-L	Displays the contents of the media by looking at the table of contents (TOC) and displaying the information in colon-separated output. This flag is used by smit and vsm to list content of the media. The format provided: **package:fileset:v.r.m.f:PTF:type:state:supersede:\ sup_ptf:sup_state:latest_sup:quiesce:Descr:\ netls_vendor_id:netls_prod_id:netls_prod_ver:relocatable:build date**
-M*Platform*	Specifies the *Platform* value. Any of the following values can be used to list the installable software packages: **R** Specifies POWER processor-based platform packages only. **N** Specifies neutral packages, that is, packages that are not restricted to the POWER processor-based platform. **A** Specifies all packages.
-N	Overrides saving of existing files that are replaced when installing or updating. This flag is valid only with the **-ac** flags. If there is a failure in the system during the installation, there is no recovery of replaced files when this flag is used.
-O{[**r**][**s**][**u**]}	Installs the specified part of the software product. The **r** indicates the **/** (root) part is to be installed, the **s** indicates the **/usr/share** part is to be installed, and the **u** indicates the **/usr** part is to be installed. The **-O** flag is not needed with standard systems because without this flag all parts are installed by default. This flag is needed for use with the installation of diskless or dataless workstations and is designed for use by the **nim** command. The **-Or** option is not valid with the **-d** or **-l** flags.

Item	Description
-p	Performs a preview of an action by running all preinstallation checks for the specified action. This flag is only valid with apply, commit, reject, and remove (**-a**, **-c**, **-r**, and **-u**) flags.
-Q	Suppresses errors and warnings concerning products failing to install due to instrequisites.
-q	Specifies quiet mode, which suppresses the prompt for the device, except for media volume change.
-r	Rejects all specified software updates that are currently applied but not committed. When a software update is rejected any other software product that is dependent on it (that is, those software products that have the specified software product as a requisite) must also be rejected. The **-g** flag can be used to reject automatically dependent software updates. The keyword **all** is not valid with the reject flag (**-r**).
-R *path*	Indicates a user-specified installation location.
-s	Lists information about all software products and updates that have been applied but not committed. This list comprises the software that is available to be either committed or rejected.
-S	Suppresses multiple volume processing when the installation device is a CD-ROM. Installation from a CD_ROM is always treated as a single volume, even if the CD-ROM contains information for a multiple volume CD set. This same suppression of multiple volume processing is performed if the **INU_SINGLE_CD** environment is set.
-t *SaveDirectory*	Specifies an alternate save directory location for files being replaced by an update. The **-t** flag is only valid with an apply or an apply/commit operation for updates. This flag is not valid with the **-N** flag. The **-t** flag is useful when there is insufficient space in the default file systems (**/** and **/usr**) or when it is undesirable to permanently expand these file systems. It may be desirable for the specified directory to be a remote file system. A remote file system must have ample space, because the **installp** command cannot expand remote file systems.
