AIX Version 7.2

Technical Reference

Kernel Services and Subsystem Operations

IBM

Note

Before using this information and the product it supports, read the information in "Notices" on page 955.

This edition applies to AIX Version 7.2 and to all subsequent releases and modifications until otherwise indicated in new editions.

Contents

iv

About this document

This topic collection is part of the six-volume technical reference set that provides information about system calls, kernel extension calls, and subroutines.

Highlighting

The following highlighting conventions are used in this document:

Bold	Identifies commands, subroutines, keywords, files, structures, directories, and other items whose names are predefined by the system. Bold highlighting also identifies graphical objects, such as buttons, labels, and icons that the you select.
Italics	Identifies parameters for actual names or values that you supply.
`Monospace`	Identifies examples of specific data values, examples of text similar to what you might see displayed, examples of portions of program code similar to what you might write as a programmer, messages from the system, or text that you must type.

Case sensitivity in AIX

Everything in the AIX® operating system is case sensitive, which means that it distinguishes between uppercase and lowercase letters. For example, you can use the **ls** command to list files. If you type LS, the system responds that the command `is not found`. Likewise, **FILEA**, **FiLea**, and **filea** are three distinct file names, even if they reside in the same directory. To avoid causing undesirable actions to be performed, always ensure that you use the correct case.

ISO 9000

ISO 9000 registered quality systems were used in the development and manufacturing of this product.

Kernel Services and Subsystem Operations

This topic collection provides information about kernel services, device driver operations, virtual file system operations, configuration subsystem, SCSI subsystem, NVMe Subsystem, and USB subsystem.

The AIX operating system is designed to support The Open Group's Single UNIX Specification Version 3 (UNIX 03) for portability of operating systems based on the UNIX operating system. Many new interfaces, and some current ones, have been added or enhanced to meet this specification. To determine the correct way to develop a UNIX 03 portable application, see The Open Group's UNIX 03 specification on The UNIX System website (http://www.unix.org).

What's new in Technical Reference: Kernel and Subsystems

Read about new or significantly changed information for the Technical Reference: Kernel and Subsystems topic collection.

How to see what's new or changed

To help you see where technical changes have been made, the information center uses:

- The >| image to mark where new or changed information begins.
- The |< image to mark where new or changed information ends.

November 2019

The following information is a summary of the updates that are made to this topic collection:

- Added information about the "facility_enable Kernel Service" on page 144 and the "facility_disable Kernel Service" on page 146. These kernel services are used to enable or disable a specified facility.

Kernel Services

The following kernel services begin with the with the letter a - x.

a

The following kernel services begin with the with the letter a.

acct_add_LL or acct_zero_LL Kernel Service

Purpose

Increments counters for advanced accounting.

Syntax

```
unsigned long long acct_add_LL(ptr, incr)
unsigned long long *ptr;
unsigned int incr;

unsigned long long acct_zero_LL(ptr)
unsigned long long *ptr;
```

Parameters

Item	Description
ptr	Address of statistic to be incremented.
incr	Increment to be applied.

Description

These kernel services are special atomic increment and clear services that are designed to allow machine-independent updating of **unsigned long long** values. The increment service only performs an increment if advanced accounting is enabled.

The **acct_add_LL** kernel service adds the value associated with the *incr* parameter to the 64-bit counter at the address designated by the *ptr* parameter. The **acct_zero_LL** kernel service atomically zeroes the 64-bit counter.

Both routines return the previous value of the 64-bit counter. This way, the **acct_zero_LL** kernel service can be used to atomically get the most recent value and set the counter to NULL. Because only delta statistics are reported each interval, this capability is required by interval accounting when the accounting record is being built for a report.

Execution Environment

These kernel services can be called from either the interrupt environment or the process environment.

Return Values

These subroutines return the previous value of the location designated by the *ptr* parameter.

Related reference
acct_interval_register or acct_interval_unregister Kernel Service
acct_put Kernel Service

acct_get_projid Kernel Service

Purpose

Gets the project identifier for the current process.

Syntax

```
projid_t acct_get_projid(void)
```

Description

The **acct_get_projid** kernel service returns the project identifier for the current process.

Execution Environment

The **acct_get_projid** kernel service can be called from the process environment only.

Return Values

The **acct_get_projid** kernel service returns the current project identifier.

acct_get_usage Kernel Service

Purpose

Allows kernel extensions to measure the resource utilization of transactions.

Syntax

```
#include <sys/types.h>
#include <sys/aacct.h>

unsigned long long acct_get_usage(usage)
struct tusage *usage;
```

Parameters

Item	Description
usage	Resource utilization structure.

Description

This routine is used to measure the resource utilization of a client transaction, so that the cost of the transaction can be included within the accounting record that identifies the client transaction. This accounting record is then used for chargeback purposes.

The **acct_get_usage** kernel service is designed to be called twice: once at the start of a transaction and a second time at the end of a transaction. Each time that the routine is called, it returns the resource utilization for the calling thread from creation using the *usage* parameter. Therefore, this routine can be called multiple times to determine the resource utilization of a code fragment by subtracting start and end values.

The following macros are provided for manipulating the usage parameter:

TUSAGE_ZERO(TU)
   Initializes the **tusage** structure

TUSAGE_ADD(TU1, TU2)
   Adds **tusage** structures (T1 = T1 + T2)

TUSAGE_SUB(TU1, TU2)
   Subtracts **tusage** structures (T1 = T1 − T2)

The *usage* parameter provides thread-specific information, so the caller must ensure that this routine is called from the same thread context when measuring the utilization of a transaction. The return value identifies the calling thread context.

The **acct_get_usage** kernel service returns a token that identifies the calling context. This token can be logically compared with other tokens returned by this routine to ensure that start and stop invocations were made from the same thread. The scope of the token depends on the context of the calling program. If this routine is called under a pthread, then it returns a token representing the currently executing pthread. Otherwise, the **acct_get_usage** kernel service returns a token representing the currently executing kernel thread. In the former case, the token has process-wide scope; in the latter case, the token has system-wide scope.

Execution Environment

The **acct_get_usage** kernel service can only be called from the process environment.

Return Values

Upon successful completion, the **acct_get_usage** kernel service returns a token that identifies the calling thread context.

acct_interval_register or acct_interval_unregister Kernel Service

Purpose

Registers or unregisters an advanced accounting handler.

Syntax

```
#include <sys/aacct.h>

int acct_interval_register(trid, cmds, handler, arg, reg_token, reg_name)
int trid;
int cmds;
int (*handler)(int trid, int cmds, void *arg);
void *arg;
unsigned long *reg_token;
char *reg_name;

int acct_interval_unregister(reg_token)
unsigned long reg_token;
```

Parameters

Item	Description
trid	Transaction identifier
cmds	Invocations supported by the advanced accounting handler
handler	Function descriptor for the handler
arg	Identifies the instance of the kernel extension
reg_token	Token that is returned to caller naming the instance of the registration
reg_name	Identifies the transaction using a string

Description

The **acct_interval_register** kernel service registers accounting records that are produced by the kernel extension with the advanced accounting subsystem. These accounting records are named through accounting transaction identifiers, which are provided by the caller. Transaction identifiers are persistent in nature, because they are used by report and analysis utilities to interpret transaction-specific accounting data. The transaction identifier is implicitly mapped to a template.

Transaction identifiers (and associated templates) used by AIX are defined in the **sys/aacct.h** file. Identifiers in the range of 0 – 127 are reserved for AIX. Vendors can choose any value in the range 128 – 256 for their accounting records. If two vendors choose the same value, report and analysis programs must reference other fields in the accounting record header to uniquely identify the source of the transaction; that way, they can apply the appropriate template. The *subproject* field (which specifies the command name of the logger) and *length* field can be used to identify the source of the transaction. Collisions are very unlikely to occur. The transaction identifier and the transaction name, which is provided by the *reg_name* field, are presented to the system administrator. Vendors should choose representative names for their transactions. The maximum length of a transaction name is 15 bytes.

Administrators can enable and disable transactions, and thereby drive callouts to the kernel extension. A function descriptor for the advanced accounting handler is provided through the *handler* parameter. The interface of this handler is:

```
int handler(int trid, int cmd, void *arg);
```

The *trid* parameter is the transaction being acted on. The *cmd* parameter describes the action. The *arg* parameter is a value that was specified at registration for this particular instance of the handler. The *arg* parameter is specific to the kernel extension.

The following *cmd* values are supported:

Item	Description
ACCT_CMD_ENABLE	The transaction is being enabled; start collecting.
ACCT_CMD_DISABLE	The transaction is being disabled; stop collecting.
ACCT_CMD_INTERVAL	The system interval has expired; provide accounting data.
ACCT_CMD_FSWITCH	The active accounting file has changed; provide meta data.

The handler is invoked in the process environment from a dedicated kernel-only thread that is part of the advanced accounting subsystem. The kernel extension registers for the callouts that should be made by logically ORing *cmd* values. The *cmds* parameter to the **acct_interval_register** kernel service is provided for this purpose.

When a transaction is enabled, the kernel extension should allocate accounting structures and start collecting statistics. When a transaction is disabled, the kernel extension should quit collecting statistics and free accounting structures. If a transaction is not enabled, the kernel subsystem should not collect statistics for the transaction. The kernel extension relies on the callout mechanism to provide notification when a transaction is enabled. This way, accounting records that are not required for the report are not collected and the accounting overhead is minimized.

If the kernel extension registers for interval accounting, the extension is called when the system interval expires. The handler should record its data using the **acct_put** kernel service and should reset its counters so that only delta statistics are produced in the next interval. The **acct_zero_LL** and **acct_add_LL** kernel services are provided so that statistics can be reported and zeroed atomically. When the system interval is disabled, the system automatically generates an interval callout to collect the last round of statistics.

The file switch callout is provided, so that subsystems can record accounting data in each accounting file. Most subsystems are not expected to use this option.

Execution Environment

The **acct_interval_register** kernel service can be called from the process environment only.

The **acct_interval_unregister** kernel service can be called from either the interrupt environment or the process environment.

Return Values

Upon successful completion, 0 is returned. If unsuccessful, **errno** is set to a value that explains the error.

Related reference
acct_add_LL or acct_zero_LL Kernel Service
acct_put Kernel Service

acct_put Kernel Service

Purpose

Writes an accounting record.

Syntax

```
#include <sys/aacct.h>

void acct_put(trid, flags, projid, usage, trdata, tr_len);
int trid;
int flags;
projid_t projid;
struct tusage *usage;
void *trdata;
int tr_len;
```

Parameters

Item	Description
trid	Transaction identifier.
flags	Flags associated with the transaction or the production of the transaction. The following value is defined: **ACCT_PUT_DIRECT** Overrides aggregate transaction
projid	Project identifier, associated with the transaction, that identifies the billable entity. The following values are defined: **PROJID_SYSTEM** This identifier is typically associated with system overhead and is often used for shared devices, such as disks and network adapters. **PROJID_UNKNOWN** This identifier is used when the billable entity is unknown to the caller. In this case, the system calculates the project identifier using the project assignment policy specified by the system administrator. ***project identifier*** If the project identifier is known, it should be specified.
usage	Identifies the resource usage values associated with the transaction.
trdata	Transaction-specific information.
tr_len	Size of the transaction-specific data in bytes.

Description

The **acct_put** kernel service provides accounting data to the advanced accounting subsystem. This service builds the accounting record header from its parameters and values associated with the calling context. The transaction-specific data specified by the caller is copied after the header. This data is internally buffered so that it can be written efficiently to the accounting data file some time later.

The *trid* parameter identifies the type of transaction that is being provided and implicitly identifies the format of the transaction-specific data. This identifier is included within the accounting header and is used by report and analysis commands to infer the right template that can interpret transaction-specific data. Vendors are encouraged to document their transaction identifiers and record templates so that report and analysis tools can be produced to interpret this data.

Accounting transaction identifiers are defined in the following range:

Item	Description
0-127	AIX accounting transaction identifiers
128-255	Vendor accounting transaction identifiers

The **ACCT_PUT_DIRECT** flag is provided as an override to the aggregation of accounting records, which is an optional feature of the advanced accounting subsystem. By default, the system does not aggregate accounting data. Aggregation is designed to reduce the volume of data that is written to the accounting file. It is transparent to applications and middleware. When aggregation is enabled, the system throws out the transaction-specific data and produces statistics about the occurrence of the transaction and the aggregate resource utilization. The data is produced along project boundaries, so the ability to perform chargeback is not lost, although the data that is produced is different. Statistical information about the transaction is captured in the accounting file in lieu of the transaction.

Because aggregation might not be desirable in some cases, the **ACCT_PUT_DIRECT** flag is provided to override this feature. For example, because the significance of a transaction that describes the shared use of a disk is bound up in the transaction-specific data, the transaction cannot be effectively aggregated. The significance of the transaction is thrown out in the course of aggregation. In effect, the statistic has already been aggregated by the producer, so it should be written directly to the file instead of being aggregated again by the accounting subsystem.

The usage values pointed to by the *usage* parameter is calculated using the **acct_get_usage** kernel service. The *usage* parameter is optional. A value of NULL can be specified to signify no usage information. Aggregation uses this field to accumulate resource utilization. If this information is calculated for the transaction, it should be passed as a parameter to this routine, instead of just including it within the transaction-specific data section. The advanced accounting subsystem does not know the format of this section and cannot aggregate it. In such a case, this section would be thrown out when aggregation is enabled.

The *trdata* parameter contains the address of a buffer containing transaction-specific data, and the *tr_len* parameter identifies the number of bytes in this buffer that should be copied to the accounting file. A maximum of 16 KB of data can be written.

Execution Environment

The **acct_put** kernel service can be started from either the process or interrupt environment. However, aggregation of the transaction is only supported when the **acct_put** service is started from the process environment.

Return Values

The **acct_put** kernel service does not return a value.

acctctl Command

add_domain_af Kernel Service

Purpose

Adds an address family to the Address Family domain switch table.

Syntax

#include <sys/types.h> #include <sys/errno.h> #include <sys/domain.h> int add_domain_af (_domain_) struct domain * _domain_**;**

Parameter

Item	Description
domain	Specifies the domain of the address family.

Description

The **add_domain_af** kernel service adds an address family domain to the Address Family domain switch table.

Execution Environment

The **add_domain_af** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates that the address family was successfully added.
EEXIST	Indicates that the address family was already added.
EINVAL	Indicates that the address family number to be added is out of range.

Example

To add an address family to the Address Family domain switch table, invoke the **add_domain_af** kernel service as follows:

```
add_domain_af(&inetdomain);
```

In this example, the family to be added is `inetdomain`.

Related reference
del_domain_af Kernel Service
Related information
Network Kernel Services

add_input_type Kernel Service

Purpose

Adds a new input type to the Network Input table.

Syntax

#include <sys/types.h> #include <sys/errno.h> #include <net/if.h> #include <net/netisr.h> int add_input_type (_type_**,** _service_level_**,** _isr_**,** _ifq_**,** _af_**) u_short** _type_**; u_short** _service_level_**; int (*** _isr_**) (); struct ifqueue *** _ifq_**; u_short** _af_**;**

Parameters

Item	Description
type	Specifies which type of protocol a packet contains. A value of x'FFFF' indicates that this input type is a wildcard type and matches all input packets.
service_level	Determines the processing level at which the protocol input handler is called. If the *service_level* parameter is set to **NET_OFF_LEVEL**, the input handler specified by the *isr* parameter is called directly. Setting the *service_level* parameter to **NET_KPROC** schedules a network dispatcher. This dispatcher calls the subroutine identified by the *isr* parameter.
isr	Identifies the routine that serves as the input handler for an input packet type.
ifq	Specifies an input queue for holding input buffers. If this parameter has a non-null value, an input buffer (**mbuf**) is enqueued. The *ifq* parameter must be specified if the processing level specified by the *service_level* parameter is **NET_KPROC.** Specifying null for this parameter generates a call to the input handler specified by the *isr* parameter, as in the following:
af	Specifies the address family of the calling protocol. The *af* parameter must be specified if the *ifq* parameter is not a null character. This parameter must be greater than or equal to 0 and less than **NETISR_MAX**. Refer to `netisr.h` for the range of values of *af* that are already in use. Also, other kernel extensions that are not AIX and that use network ISRs currently running on the system can make use of additional values not mentioned in `netisr.h`.

```
(*isr)(CommonPortion,Buffer);
```

In this example, `CommonPortion` points to the network common portion (the **arpcom** structure) of a network interface and `Buffer` is a pointer to a buffer (**mbuf**) containing an input packet.

Description

To enable the reception of packets, an address family calls the **add_input_type** kernel service to register a packet type in the Network Input table. Multiple packet types require multiple calls to *Kernel Extensions and Device Support Programming Concepts* the **add_input_type** kernel service.

Execution Environment

The **add_input_type** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates that the type was successfully added.
EEXIST	Indicates that the type was previously added to the Network Input table.
ENOSPC	Indicates that no free slots are left in the table.
EINVAL	Indicates that an error occurred in the input parameters.

Examples

1. To register an Internet packet type (**TYPE_IP**), invoke the **add_input_type** service as follows:

```
add_input_type(TYPE_IP, NET_KPROC, ipintr, &ipintrq, AF_INET);
```

This packet is processed through the network `kproc`. The input handler is `ipintr`. The input queue is `ipintrq`.

2. To specify the input handler for ARP packets, invoke the **add_input_type** service as follows:

```
add_input_type(TYPE_ARP,  NET_OFF_LEVEL,  arpinput,  NULL,  NULL);
```

Packets are not queued and the `arpinput` subroutine is called directly.

Network Kernel Services

add_netisr Kernel Service

Purpose

Adds a network software interrupt service to the Network Interrupt table.

Syntax

#include <sys/types.h> #include <sys/errno.h> #include <net/netisr.h> int add_netisr (*soft_intr_level*, *service_level*, *isr*) u_short *soft_intr_level*; u_short *service_level*; int (**isr***) ();**

Parameters

Item	Description
soft_intr_level	Specifies the software interrupt level to add. This parameter must be greater than or equal to 0 and less than **NETISR_MAX**. Refer to `netisr.h` for the range of values of *soft_intr_level* that are already in use. Also, other kernel extensions that are not AIX and that use network ISRs currently running on the system can make use of additional values not mentioned in `netisr.h`.
service_level	Specifies the processing level of the network software interrupt.
isr	Specifies the interrupt service routine to add.

Description

The **add_netisr** kernel service adds the software-interrupt level specified by the *soft_intr_level* parameter to the Network Software Interrupt table.

The processing level of a network software interrupt is specified by the *service_level* parameter. If the interrupt level specified by the *service_level* parameter equals **NET_KPROC**, a network interrupt scheduler calls the function specified by the *isr* parameter. If you set the *service_level* parameter to **NET_OFF_LEVEL**, the **schednetisr** service calls the interrupt service routine directly.

Execution Environment

The **add_netisr** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates that the interrupt service routine was successfully added.

Item	Description
EEXIST	Indicates that the interrupt service routine was previously added to the table.
EINVAL	Indicates that the value specified for the *soft_intr_level* parameter is out of range or at a service level that is not valid.

Network Kernel Services

add_netopt Macro

Purpose

Adds a network option structure to the list of network options.

Syntax

**#include <sys/types.h> #include <sys/errno.h> #include <net/netopt.h> add_netopt
(** *option_name_symbol***,** *print_format***)** *option_name_symbol***; char ****print_format***;**

Parameters

Item	Description
option_name_symbol	Specifies the symbol name used to construct the **netopt** structure and default names.
print_format	Specifies the string representing the print format for the network option.

Description

The **add_netopt** macro adds a network option to the linked list of network options. The **no** command can then be used to show or alter the variable's value.

The **add_netopt** macro has no return values.

Execution Environment

The **add_netopt** macro can be called from either the process or interrupt environment.

Related reference
del_netopt Macro

no Command
Network Kernel Services

as_att64 Kernel Service

Purpose

Allocates and maps a specified region in the current user address space.

Syntax

**#include <sys/types.h> #include <sys/errno.h> #include <sys/vmuser.h> #include <sys/adspace.h>
unsigned long long as_att64 (***vmhandle, offset***) vmhandle_t** *vmhandle*; **int** *offset*;

Parameters

Item	Description
vmhandle	Describes the virtual memory object being made addressable in the address space.
offset	Specifies the offset in the virtual memory object. The upper 4-bits of this offset are ignored.

Description

Item	Description
The **as_att64** kernel service:	Selects an unallocated region within the current user address space.
	Allocates the region.
	Maps the virtual memory object selected by the vmhandle parameter with the access permission specified in the handle.
	Constructs the address of the offset specified by the offset parameter within the user-address space.

The **as_att64** kernel service assumes an address space model of fixed-size virtual memory objects.

This service will operate correctly for both 32-bit and 64-bit user address spaces. It will also work for kernel processes (*kprocs*).

Note: This service only operates on the current process's address space. It is not allowed to operate on another address space.

Execution Environment

The **as_att64** kernel service can be called from the process environment only.

Return Values

On successful completion, this service returns the base address plus the input offset (offset) into the allocated region.

Item	Description
NULL	An error occurred and ernno indicates the cause:
EINVAL	Address specified is out of range, or
ENOMEM	Could not allocate due to insufficient resources.

Related reference
as_seth64 Kernel Service
as_geth64 Kernel Service
as_getsrval64 Kernel Service

as_det64 Kernel Service

Purpose

Unmaps and deallocates a region in the current user address space that was mapped with the **as_att64** kernel service.

Syntax

#include <sys/errno.h> #include <sys/adspace.h> int as_det64 (*addr64***) unsigned long long** *addr64*;

Parameters

Item	Description
addr64	Specifies an effective address within the region to be deallocated.

Description

The **as_det64** kernel service unmaps the virtual memory object from the region containing the specified effective address (specified by the **addr64** parameter).

The **as_det64** kernel service assumes an address space model of fixed-size virtual memory objects.

This service should not be used to deallocate a base kernel region, process text, process private or an unallocated region. An **EINVAL** return code will result.

This service will operate correctly for both 32-bit and 64-bit user address spaces. It will also work for kernel processes *(kprocs)*.

Note: This service only operates on the current process's address space. It is not allowed to operate on another address space.

Execution Environment

The **as_det64** kernel service can be called from the process environment only.

Return Values

Item	Description
0	The region was successfully unmapped and deallocated.
EINVAL	An attempt was made to deallocate a region that should not have been deallocated (that is, a base kernel region, process text region, process private region, or unallocated region).
EINVAL	Input address out of range.

Related reference
as_seth64 Kernel Service
as_geth64 Kernel Service
as_getsrval64 Kernel Service

as_geth Kernel Service

Purpose

Obtains a handle to the virtual memory object for the specified address given in the specified address space.

Syntax

#include <sys/types.h> #include <sys/errno.h> #include <sys/vmuser.h> #include <sys/adspace.h>
vmhandle_t as_geth (*Adspacep*, *Addr***) adspace_t ****Adspacep*; **caddr_t** *Addr*;

Parameters

Item	Description
Adspacep	Points to the address space structure to obtain the virtual memory object handle from.
Addr	Specifies the virtual memory address that should be used to determine the virtual memory object handle for the specified address space.

Description

The **as_geth** kernel service is used to obtain a handle to the virtual memory object corresponding to a virtual memory address in a particular address space. This handle can then be used with the **vm_att** kernel service to make the object addressable in another address space.

This service can also be called from the interrupt environment.

Execution Environment

The **as_geth** kernel service can be called from the process environment only.

Return Values

The **as_geth** kernel service always succeeds and returns the appropriate handle.

as_geth64 Kernel Service

Purpose

Obtains a handle to the virtual memory object for the specified address.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
#include <sys/adspace.h>

vmhandle_t as_geth64 (addr64)
unsigned   long long addr64;
```

Parameter

Item	Description
addr64	Specifies the virtual memory address for which the corresponding handle should be returned.

Description

The **as_geth64** kernel service is used to obtain a handle to the virtual memory object corresponding to the input address (addr64). This handle can then be used with the **as_att64** or **vm_att** kernel service to make the object addressable at a different location.

After the last use of the handle and after it is detached accordingly, the **as_puth64** kernel service must be used to indicate this fact. Failure to call the **as_puth64** service may result in resources being permanently unavailable for re-use.

If the handle returned refers to a virtual memory segment, then that segment is protected from deletion until the **as_puth64** kernel service is called.

If, for some reason, it is known that the virtual memory object cannot be deleted, then the **as_getsrval64** kernel service may be used instead of the **as_geth64** service.

The **as_geth64** kernel service assumes an address space model of fixed-size virtual memory objects.

This service will operate correctly for both 32-bit and 64-bit user address spaces. It will also work for kernel processes (*kprocs*).

Note: This service only operates on the current process's address space. It is not allowed to operate on another address space.

Execution Environment

The **as_geth64** kernel service can be called from the process environment only.

Return Values

On successful completion, this routine returns the appropriate handle.

On error, this routine returns the value INVLSID defined in **sys/seg.h**. This is caused by an address out of range.

Errors include: Input address out of range.

Related reference
as_seth64 Kernel Service
as_getsrval64 Kernel Service
as_puth64 Kernel Service

as_getsrval64 Kernel Service

Purpose

Obtains a handle to the virtual memory object for the specified address.

Syntax

#include <sys/types.h> #include <sys/errno.h> #include <sys/vmuser.h> #include <sys/adspace.h>
vmhandle_t as_getsrval64 (*addr64***) unsigned long long** *addr64***;**

Parameters

Item	Description
addr64	Specifies the virtual memory address for which the corresponding handle should be returned.

Description

The **as_getsrval64** kernel service is used to obtain a handle to the virtual memory object corresponding to the input address(addr64). This handle can then be used with the **as_att64** or **vm_att** kernel services to make the object addressable at a different location.

This service should only be used when it is known that the virtual memory object cannot be deleted, otherwise the **as_geth64** kernel service must be used.

The **as_puth64** kernel service must not be called for handles returned by the **as_getsrval64** kernel service.

The **as_getsrval64** kernel service assumes an address space model of fixed-size virtual memory objects.

This service will operate correctly for both 32-bit and 64-bit user address spaces. It will also work for kernel processes (*kprocs*).

Note: This service only operates on the current process's address space. It is not allowed to operate on another address space.

Execution Environment

The **as_getsrval64** kernel service can be called from the process environment only when the current user address space is 64-bits. If the current user address space is 32-bits, or is a *kproc*, then **as_getsrval64** may be called from an interrupt environment.

Return Values

On successful completion this routine returns the appropriate handle.

On error, this routine returns the value INVLSID defined in **sys/seg.h**. This is caused by an address out of range.

Errors include: Input address out of range.

Related reference
as_geth64 Kernel Service
as_puth64 Kernel Service
as_seth64 Kernel Service

as_lw_att64 Kernel Service

Purpose

Allocates and maps a specified region in the current user address space. Part of the lightweight kernel service subsystem, which must be initialized with the **as_lw_pool_init** kernel service before it can be used.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sysvmuser.h>
#include <sys/adspace.h>
#include <sys/mem.h>

int as_lw_att64 (dp, offset, length, addr)
xmem* dp;
size_t offset;
size_t length;
ptr64* addr;
```

Parameters

Item	Description
dp	Pointer to a cross memory descriptor that describes the virtual memory object that is being made addressable in the address space.
offset	Specifies the byte offset in the virtual memory object.
length	Specifies the number of bytes to map in the virtual memory object.

Item	Description
addr	Pointer to the location where the address will be returned.

Description

The **as_lw_att64** kernel service does the following:

- Allocates a region from the process' address space for the mapping.
- Maps the virtual memory object selected by the *dp* parameter.
- Constructs the address of the offset specified by the *offset* parameter within the user-address space.

Note: The **as_lw_att64** kernel service should be used with caution. Be sure to read the documentation for this and the other lightweight services (**as_lw_det64** and **as_lw_pool_init**) carefully before doing so. There is a risk of illegal data access and cross-process data corruption if these services are not used correctly.

In order to use this service, the cross memory descriptor pointed to by the *dp* parameter must be initialized by using the **xmattach** kernel service with the **LW_XMATTACH** flag set. The **lw_pool_init** kernel service must also have been successfully called by the current process.

The service will map an area length *bytes* long into the caller's address space from the memory represented by the descriptor, starting at the number of bytes specified in the *offset* parameter. It is illegal for any thread other than the caller of this service to address the attached region.

This service will operate correctly only in 64-bit user address spaces. It will not work for kernel processes (kprocs).

Note: This service only operates on the current process's address space. It is not allowed to operate on another address space.

Execution Environment

The **as_lw_att64** kernel service can be called from the process environment only.

Return Values

On successful completion, this service sets the value of *addr* to the address of the allocated region and returns 0.

Item	Description
NULL	An error occurred and errno indicates the cause.
EINVAL	Cross memory descriptor is in an invalid state, length is zero or offset plus length goes past the end of the virtual memory object.
ENODEV	The **as_lw_pool_init** kernel service has not been called to initialize the pool settings for this process.
ENOSYS	Called by a 32-bit process.
ENOSPC	Resources allocated to do lightweight services for this thread expended. Either the region to be attached is too large (the **as_lw_pool_init** kernel service was called with too small a *pool_size*) or there are outstanding attaches which need to release their lightweight resources using the **as_lw_det64** kernel service before this attach can be completed.
EIO	Indicates a failure of the lightweight subsystem, process should discontinue use of lightweight kernel services.
EPERM	Called by a user thread that is not 1:1 with a kernel thread.
ENOMEM	Could not allocate system resources for lightweight services for this thread.

Implementation Specifics

The **as_lw_att64** kernel service is part of Base Operating System (BOS) Runtime.

Related reference
as_lw_det64 Kernel Service
as_lw_pool_init Kernel Service

as_lw_det64 Kernel Service

Purpose

Unmaps and deallocates a region in the current user address space that was mapped using the **as_lw_att64** kernel service.

Syntax

```
#include <sys/errno.h>
#include <sys/adspace.h>
#include <sys/xmem.h>
int as_lw_det64 (dp, addr, length)
xmem* dp;
void* addr;
size_t length;
```

Parameters

Item	Description
dp	The cross memory descriptor describing the attached virtual memory.
addr	Specifies the first effective address of the region to be deallocated.
length	Specifies the length of the region to be deallocated.

Description

Note: The **as_lw_det64** kernel service should be used with caution. Read the documentation for this and the other lightweight services (**as_lw_att64** and **as_lw_pool_init**) carefully before doing so. There is a risk that illegal data accesses will be allowed if these services are not used correctly.

The **as_lw_det64** kernel service unmaps the virtual memory from the region starting at the specified effective address, which is specified by the *addr* parameter. This service (and only this service) must be used to unmap regions mapped by the **as_lw_att64** kernel service. It must be called by the same thread that called the **as_lw_att64** kernel service. The *addr* parameter must be the value returned by the **as_lw_att64** kernel service, and the *dp* parameter and the *length* parameter must be the same *dp* and *length* passed to it. The *xmdetach* kernel service must not be called to release the *dp* parameter until any outstanding attaches of the *dp* parameter using the **as_lw_att64** kernel service have been detached using the **as_lw_det64** kernel service.

The **as_lw_det64** kernel service cannot be used to detach a region not mapped by the **as_lw_att64** kernel service.

The **as_lw_det64** kernel service will operate correctly only for 64-bit user address spaces. It will not work for kernel processes (kprocs).

Note: This service only operates on the current process's address space. It is not allowed to operate on another address space.

Execution Environment

The **as_lw_det64** kernel service can be called from the process environment only.

Return Values

Item	Description
0	The region was successfully unmapped and deallocated.
EINVAL	An attempt was made to deallocate a region that should not have been deallocated.
ENOSYS	The service was called by a 32-bit process.
ENOMEM	No lightweight resources allocated to this thread.
EIO	Indicates a failure of the lightweight subsystem, process should discontinue use of lightweight kernel services.
EPERM	Called by a user thread that is not 1:1 with a kernel thread.

Implementation Specifics

The **as_lw_det64** kernel service is part of Base Operating System (BOS) Runtime.

Related reference
as_lw_att64 Kernel Service
as_lw_pool_init Kernel Service

as_lw_pool_init Kernel Service

Purpose

Initializes lightweight attach and detach subsystem for the current process with the given settings.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
#include <sys/adspace.h>

int as_lw_pool_init (pool_size, flags)
size_t pool_size;
uint flags;
```

Parameters

Item	Description
pool_size	Specifies the maximum number of bytes that can be attached by lightweight services at one time by each thread of this process.
flags	Specifies flag options for this kernel service. Valid values are 0 and LW_DEBUG.

Description

Note: The **as_lw_pool_init** kernel service should be used with caution. Read the documentation for this and the other lightweight services (**as_lw_att64** and **as_lw_det64**) carefully before doing so. There is a risk that illegal data accesses will be allowed if these services are not used correctly.

The **as_lw_pool_init** kernel service initializes the lightweight pool size and flag settings for the current process. Once it has been called, these settings are fixed and cannot be changed for the process.

If **LW_DEBUG** is set in the *flags* parameter, the risk of illegal data access will be removed from calls to the **as_lw_att64** kernel service and the **as_lw_det64** kernel service. This setting allows users to debug problems that are caused by incorrect use of these services.

Processes that have called the **as_lw_pool_init** kernel service can use the other lightweight kernel services (**as_lw_att64** and **as_lw_det64**) to attach and detach virtual memory regions represented by a cross memory descriptor. These kernel services are used on a per-thread basis, that is if one thread uses the **as_lw_att64** kernel service to attach virtual memory to a region of its address space, that region cannot be addressed by any other thread, and it must be detached by the same thread by using the **as_lw_det64** kernel service.

This service will operate correctly only for 64-bit user address spaces. It will not work for kernel processes (kprocs).

Execution Environment

The **as_lw_pool_init** kernel service can be called from a 64-bit process environment only.

Return Values

On successful completion, this service returns 0.

Item	Description
ENOSYS	The service was called by a 32-bit process.
EEXIST	The **as_lw_pool_init** kernel service has already been successfully completed for this process.
EINVAL	Invalid flag settings or the *pool_size* parameter is 0.
EPERM	Called by a user thread that is not 1:1 with a kernel thread.

Implementation Specifics

The **as_lw_pool_init** kernel service is part of Base Operating System (BOS) Runtime.

Related reference
as_lw_att64 Kernel Service
as_lw_det64 Kernel Service

as_puth64 Kernel Service

Purpose

Indicates that no more references will be made to a virtual memory object obtained using the **as_geth64** kernel service.

Syntax

**#include <sys/types.h> #include <sys/errno.h> #include <sys/vmuser.h> #include <sys/adspace.h>
int as_puth64 (** *addr64, vmhandle* **) unsigned long long** *addr64***; vmhandle_t** *vmhandle***;**

Parameters

Item	Description
addr64	Specifies the virtual memory address that the virtual memory object handle was obtained from. This must be the same address that was given to the **as_geth64** kernel service previously.
vmhandle	Describes the virtual memory object that will no longer be referenced. This handle must have been returned by the **as_geth64** kernel service.

Description

The **as_puth64** kernel service is used to indicate that no more references will be made to the virtual memory object returned by a call to the **as_geth64** kernel service. The virtual memory object must be detached from the address space already, using either **as_det64** or **vm_det** service.

Failure to call the **as_puth64** kernel service may result in resources being permanently unavailable for re-use.

If, for some reason, it is known that the virtual memory object cannot be deleted, the **as_getsrval64** kernel service may be used instead of the **as_geth64** kernel service. This kernel service does not require that the **as_puth64** kernel service be used.

The **as_puth64** kernel service assumes an address space model of fixed-size virtual memory objects.

This service will operate correctly for both 32-bit and 64-bit user address spaces. It will also work for kernel processes (*kprocs*).

Note: This service only operates on the current process's address space. It is not allowed to operate on another address space.

Execution Environment

The **as_puth64** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Successful completion.
EINVAL	Input address out of range.

Related reference
as_getsrval64 Kernel Service
as_geth64 Kernel Service
as_seth64 Kernel Service

as_seth64 Kernel Service

Purpose

Maps a specified region for the specified virtual memory object.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
#include <sys/adspace.h>

int as_seth64 (addr64,vmhandle)
unsigned long long addr64;
vmhandle_t vmhandle;
```

Parameters

Item	Description
addr64	The region covering this input virtual memory address will be mapped.

Item	Description
vmhandle	Describes the virtual memory object being made addressable within a region of the address space.

Description

The **as_seth64** kernel service maps the region covering the input **addr64** parameter. Any virtual memory object previously mapped within this region is unmapped.

The virtual memory object specified with the **vmhandle** parameter is then mapped with the access permission specified in the handle.

The **as_seth64** kernel service should only be used when it is necessary to map a virtual memory object at a fixed address. The **as_att64** kernel service should be used when it is not absolutely necessary to map the virtual memory object at a fixed address.

The **as_seth64** kernel service assumes an address space model of fixed-size virtual memory objects.

This service will operate correctly for both 32-bit and 64-bit user address spaces. It will also work for kernel processes (*kprocs*).

Note: This service only operates on the current process's address space. It is not allowed to operate on another address space.

Execution Environment

The **as_seth64** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Successful completion.
EINVAL	Input address out of range.

Related reference
as_det64 Kernel Service
as_geth64 Kernel Service
as_puth64 Kernel Service

attach Device Queue Management Routine

Purpose

Provides a means for performing device-specific processing when the **attchq** kernel service is called.

Syntax

#include <sys/types.h> #include <sys/errno.h> #include <sys/deviceq.h> int attach (*dev_parms*, *path_id***) caddr_t** *dev_parms***; cba_id** *path_id***;**

Parameters

Item	Description
dev_parms	Passed to the **creatd** kernel service when the **attach** routine is defined.
path_id	Specifies the path identifier for the queue being attached to.

Description

The **attach** routine is part of the Device Queue Management kernel extension. Each device queue can have an **attach** routine. This routine is optional and must be specified when the **creatd** kernel service defines the device queue. The **attchq** service calls the **attach** routine each time a new path is created to the owning device queue. The processing performed by this routine is dependent on the server function.

The **attach** routine executes under the process under which the **attchq** kernel service is called. The kernel does not serialize the execution of this service with the execution of any other server routines.

Execution Environment

The **attach-device** routine can be called from the process environment only.

Return Values

Item	Description
RC_GOOD	Indicates a successful completion.
RC_NONE	Indicates that resources such as pinned memory are unavailable.
RC_MAX	Indicates that the server already has the maximum number of users that it supports.
Greater than or equal to **RC_DEVICE**	Indicates device-specific errors.

audit_svcbcopy Kernel Service

Purpose

Appends event information to the current audit event buffer.

Syntax

#include <sys/types.h> #include <sys/errno.h> int audit_svcbcopy (*buf*, *len***) char ****buf***; int** *len***;**

Parameters

Item	Description
buf	Specifies the information to append to the current audit event record buffer.
len	Specifies the number of bytes in the buffer.

Description

The **audit_svcbcopy** kernel service appends the specified buffer to the event-specific information for the current switched virtual circuit (SVC). System calls should initialize auditing with the **audit_svcstart** kernel service, which creates a record buffer for the named event.

The **audit_svcbcopy** kernel service can then be used to add additional information to that buffer. This information usually consists of system call parameters passed by reference.

If auditing is enabled, the information is written by the **audit_svcfinis** kernel service after the record buffer is complete.

Execution Environment

The **audit_svcbcopy** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
ENOMEM	Indicates that the kernel service is unable to allocate space for the new buffer.

Related reference
audit_svcfinis Kernel Service
audit_svcstart Kernel Service
Related information
Security Kernel Services

audit_svcfinis Kernel Service

Purpose

Writes an audit record for a kernel service.

Syntax

#include <sys/types.h> #include <sys/errno.h> #include <sys/audit.h> int audit_svcfinis ( )

Description

The **audit_svcfinis** kernel service completes an audit record begun earlier by the **audit_svcstart** kernel service and writes it to the kernel audit logger. Any space allocated for the record and associated buffers is freed.

If the system call terminates without calling the **audit_svcfinis** service, the switched virtual circuit (SVC) handler exit routine writes the records. This exit routine calls the **audit_svcfinis** kernel service to complete the records.

Execution Environment

The **audit_svcfinis** kernel service can be called from the process environment only.

Return Values

The **audit_svcfinis** kernel service always returns a value of 0.

Related reference
audit_svcbcopy Kernel Service
audit_svcstart Kernel Service
Related information
Security Kernel Services

audit_svcstart Kernel Service

Purpose

Initiates an audit record for a system call.

Syntax

**#include <sys/types.h> #include <sys/errno.h> #include <sys/audit.h>
int audit_svcstart (***eventnam** , *eventnum*, *numargs*, *arg1*, *arg2*, ...***) char *** *eventnam*; **int *** *eventnum*;
int *numargs*; **int** *arg1*; **int** *arg2*; **...**

Parameters

Item	Description
eventnam	Specifies the name of the event. In the current implementation, event names must be less than 17 characters, including the trailing null character. Longer names are truncated.
eventnum	Specifies the number of the event. This is an internal table index meaningful only to the kernel audit logger. The system call should initialize this parameter to 0. The first time the **audit_svcstart** kernel service is called, this parameter is set to the actual table index. The system call should not reset the parameter. The parameter should be declared a static.
numargs	Specifies the number of parameters to be included in the buffer for this record. These parameters are normally zero or more of the system call parameters, although this is not a requirement.
arg1, *arg2*, ...	Specifies the parameters to be included in the buffer.

Description

The **audit_svcstart** kernel service initiates auditing for a system call event. It dynamically allocates a buffer to contain event information. The arguments to the system call (which should be specified as parameters to this kernel service) are automatically added to the buffer, as is the internal number of the event. You can use the **audit_svcbcopy** service to add additional information that cannot be passed by value.

The system call commits this record with the **audit_svcfinis** kernel service. The system call should call the **audit_svcfinis** kernel service before calling another system call.

Execution Environment

The **audit_svcstart** kernel service can be called from the process environment only.

Return Values

Item	Description
Nonzero	Indicates that auditing is on for this routine.
0	Indicates that auditing is off for this routine.

Example

```
svccrash(int x, int y, int z)
{
        static int eventnum;
        if (audit_svcstart("crashed", &eventnum, 2, x, y))
                {
                audit_svcfinis();
                }
        body of svccrash
}
```

The preceding example allocates an audit event record buffer for the `crashed` event and copies the first and second arguments into it. The third argument is unnecessary and not copied.

b

The following kernel services begin with the with the letter b.

bawrite Kernel Service

Purpose

Writes the specified buffer data without waiting for I/O to complete.

Syntax

#include <sys/types.h> #include <sys/errno.h> #include <sys/buf.h> int bawrite (*bp***) struct buf ****bp***;**

Parameter

Item	Description
bp	Specifies the address of the buffer structure.
	On a platform that supports storage keys, the passed in *bp* parameter must be in the **KKEY_PUBLIC** or **KKEY_BLOCK_DEV** protection domain.

Description

The **bawrite** kernel service sets the asynchronous flag in the specified buffer and calls the **bwrite** kernel service to write the buffer.

Execution Environment

The **bawrite** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
ERRNO	Returns an error number from the **/usr/include/sys/errno.h** file on error.

Related reference
bwrite Kernel Service
Related information
Block I/O buffer cache kernel services overview
I/O Kernel Services

bdwrite Kernel Service

Purpose

Releases the specified buffer after marking it for delayed write.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
```

void bdwrite (_bp_**)**
struct buf *****_bp_**;**

Parameter

Item	Description
_bp_	Specifies the address of the buffer structure for the buffer to be written.
	On a platform that supports storage keys, the passed in _bp_ parameter must be in the **KKEY_PUBLIC** or **KKEY_BLOCK_DEV** protection domain.

Description

The **bdwrite** kernel service marks the specified buffer so that the block is written to the device when the buffer is stolen. The **bdwrite** service marks the specified buffer as delayed write and then releases it (that is, puts the buffer on the free list). When this buffer is reassigned or reclaimed, it is written to the device.

Execution Environment

The **bdwrite** kernel service can be called from the process environment only.

Return Values

The **bdwrite** kernel service has no return values.

Related reference
brelse Kernel Service
Related information
Block I/O Buffer Cache Kernel Services: Overview
I/O Kernel Services

bflush Kernel Service

Purpose

Flushes all write-behind blocks on the specified device from the buffer cache.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
```

void bflush (_dev_**)**
dev_t _dev_**;**

Parameter

Item	Description
dev	Specifies which device to flush. A value of **NODEVICE** flushes all devices.

Description

The **bflush** kernel service runs the free list of buffers. It notes as busy or writing any dirty buffer whose block is on the specified device. When a value of **NODEVICE** is specified, the **bflush** service flushes all write-behind blocks for all devices. The **bflush** service has no return values.

Execution Environment

The **bflush** kernel service can be called from the process environment only.

Related reference
bwrite Kernel Service
Related information
Block I/O Buffer Cache Kernel Services: Overview
I/O Kernel Services

bindprocessor Kernel Service

Purpose

Binds or unbinds kernel threads to a processor.

Syntax

```
#include <sys/processor.h>
```

```
int bindprocessor ( What,  Who,  Where)
int What;
int Who;
cpu_t Where;
```

Parameters

Item	Description
What	Specifies whether a process or a kernel thread is being bound to a processor. The *What* parameter can take one of the following values: **BINDPROCESS** A process is being bound to a processor. **BINDTHREAD** A kernel thread is being bound to a processor.
Who	Indicates a process or kernel thread identifier, as appropriate for the *What* parameter, specifying the process or kernel thread which is to be bound to a processor.
Where	If the *Where* parameter is in the range 0-*n* (where *n* is the number of online processors in the system), it represents a bind CPU identifier to which the process or kernel thread is to be bound. Otherwise, it represents a processor class, from which a processor will be selected. A value of **PROCESSOR_CLASS_ANY** unbinds the specified process or kernel thread, which will then be able to run on any processor.

Description

The **bindprocessor** kernel service binds a single kernel thread, or all kernel threads in a process, to a processor, forcing the bound threads to be scheduled to run on that processor only. It is important to understand that a process itself is not bound, but rather its kernel threads are bound. Once kernel threads are bound, they are always scheduled to run on the chosen processor, unless they are later unbound. When a new thread is created using the **thread_create** kernel service, it has the same bind properties as its creator.

Programs that use processor bindings must be aware of Dynamic Logical Partitioning (DLPAR).

Return Values

On successful completion, the **bindprocessor** kernel service returns 0. Otherwise, a value of -1 is returned and the error code can be checked by calling the **getuerror** kernel service.

Error Codes

The **bindprocessor** kernel service is unsuccessful if one of the following is true:

Item	Description
EINVAL	The *What* parameter is invalid, or the *Where* parameter indicates an invalid processor number or a processor class which is not currently available.
ESRCH	The specified process or thread does not exist.
EPERM	The caller does not have root user authority, and the *Who* parameter specifies either a process, or a thread belonging to a process, having a real or effective user ID different from that of the calling process.

Execution Environment

The **bindprocessor** kernel service can be called from the process environment only.

Related information

bindprocessor command
fork subroutine
sysconf subroutine
Dynamic Logical Partitioning

binval Kernel Service

Purpose

Makes nonreclaimable all blocks in the buffer cache of a specified device.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
```

void binval (*dev*)
dev_t *dev;*

Parameter

Item	Description
dev	Specifies the device to be purged.

Description

The **binval** kernel service makes nonreclaimable all blocks in the buffer cache of a specified device. Before removing the device from the system, use the **binval** service to remove the blocks.

All of blocks of the device to be removed need to be flushed before you call the **binval** service. Typically, these blocks are flushed after the last close of the device.

Execution Environment

The **binval** kernel service can be called from the process environment only.

Return Values

The **binval** service has no return values.

Related reference
bflush Kernel Service
Related information
Block I/O Buffer Cache Kernel Services Overview
I/O Kernel Services

blkflush Kernel Service

Purpose

Flushes the specified block if it is in the buffer cache.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
```

int blkflush (** *dev,* *blkno* **)
dev_t *dev;*
daddr_t *blkno;*

Parameters

Item	Description
dev	Specifies the device containing the block to be flushed.
blkno	Specifies the block to be flushed.

Description

The **blkflush** kernel service checks to see if the specified buffer is in the buffer cache. If the buffer is not in the cache, then the **blkflush** service returns a value of 0. If the buffer is in the cache, but is busy, the

blkflush service calls the **e_sleep** service to wait until the buffer is no longer in use. Upon waking, the **blkflush** service tries again to access the buffer.

If the buffer is in the cache and is not busy, but is dirty, then it is removed from the free list. The buffer is then marked as busy and synchronously written to the device. If the buffer is in the cache and is neither busy nor dirty (that is, the buffer is already clean and therefore does not need to be flushed), the **blkflush** service returns a value of 0.

Execution Environment

The **blkflush** kernel service can be called from the process environment only.

Return Values

Item	Description
1	Indicates that the block was successfully flushed.
0	Indicates that the block was not flushed. The specified buffer is either not in the buffer cache or is in the buffer cache but neither busy nor dirty.

Related reference
bwrite Kernel Service
Related information
Block I/O Buffer Cache Kernel Services: Overview
I/O Kernel Services

bread Kernel Service

Purpose

Reads the specified block data into a buffer.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
```

struct buf *bread (*dev,* *blkno***)**
dev_t *dev;*
daddr_t *blkno;*

Parameters

Item	Description
dev	Specifies the device containing the block to be read.
blkno	Specifies the block to be read.

Description

The **bread** kernel service assigns a buffer to the given block. If the specified block is already in the buffer cache, then the block buffer header is returned. Otherwise, a free buffer is assigned to the specified block and the data is read into the buffer. The **bread** service waits for I/O to complete to return the buffer header.

The buffer is allocated to the caller and marked as busy.

Execution Environment

The **bread** kernel service can be called from the process environment only.

Return Values

The **bread** service returns the address of the selected buffer's header. A nonzero value for **B_ERROR** in the b_flags field of the buffer's header (**buf** structure) indicates an error. If this occurs, the caller should release the buffer associated with the block using the **brelse** kernel service.

On a platform that supports storage keys, the buffer header is allocated from the storage protected by the **KKEY_BLOCK_DEV** kernel key.

Related reference
iowait Kernel Service
Related information
Block I/O Buffer Cache Kernel Services: Overview
I/O Kernel Services

breada Kernel Service

Purpose

Reads in the specified block and then starts I/O on the read-ahead block.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
```

struct buf *breada (*dev*, *blkno*, *rablkno***)**
dev_t *dev*;
daddr_t *blkno*;
daddr_t *rablkno*;

Parameters

Item	Description
dev	Specifies the device containing the block to be read.
blkno	Specifies the block to be read.
rablkno	Specifies the read-ahead block to be read.

Description

The **breada** kernel service assigns a buffer to the given block. If the specified block is already in the buffer cache, then the **bread** service is called to:

- Obtain the block.
- Return the buffer header.

Otherwise, the **getblk** service is called to assign a free buffer to the specified block and to read the data into the buffer. The **breada** service waits for I/O to complete and then returns the buffer header.

I/O is also started on the specified read-ahead block if the free list is not empty and the block is not already in the cache. However, the **breada** service does not wait for I/O to complete on this read-ahead block.

Execution Environment

The **breada** kernel service can be called from the process environment only.

Return Values

The **breada** service returns the address of the selected buffer's header. A nonzero value for B_ERROR in the b_flags field of the buffer header (**buf** structure) indicates an error. If this occurs, the caller should release the buffer associated with the block using the **brelse** kernel service.

On a platform that supports storage keys, the buffer header is allocated from the storage protected by the **KKEY_BLOCK_DEV** kernel key.

Related information
Block I/O Buffer Cache Kernel Services: Overview

brelse Kernel Service

Purpose

Frees the specified buffer.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
```

void brelse (*bp*)
struct buf *bp;**

Parameter

Item	Description
bp	Specifies the address of the **buf** structure to be freed. On a platform that supports storage keys, the passed in *bp* parameter must be in the **KKEY_PUBLIC** or **KKEY_BLOCK_DEV** protection domain.

Description

The **brelse** kernel service frees the buffer to which the *bp* parameter points.

The **brelse** kernel service awakens any processes waiting for this buffer or for another free buffer. The buffer is then put on the list of available buffers. The buffer is also marked as not busy so that it can either be reclaimed or reallocated.

The **brelse** service has no return values.

Execution Environment

The **brelse** kernel service can be called from either the process or interrupt environment.

I/O Kernel Services

bsr_alloc Kernel Service

Purpose

Allocates a Barrier Synchronization Register (BSR) resource, and retrieves mapping information.

Syntax

```
#include <sys/adspace.h>

int bsr_alloc (
    int bsr_bytes,
    struct io_map * bsr_map,
    int *bsr_stride,
    int *bsr_id)
```

Parameters

Item	Description
bsr_bytes	Number of BSR bytes wanted.
bsr_map	Mapping information for the BSR facility
bsr_stride	Stride at which the BSR bytes repeat within the mapping
bsr_id	An opaque identifier for the allocated BSR resource

Description

The `bsr_alloc` service can be used to allocate and reserve all or a portion of the BSR facility. The requested number of BSR bytes to allocate is communicated through the *bsr_bytes* parameter. The requested number of bytes must correspond to a supported window size, as communicated by the *supported_window_mask* parameter of the `bsr_query` service. If the requested number of bytes is available, the bytes are reserved and the I/O mapping information for accessing the allocated facility is written to the *bsr_map* structure. In addition, the stride within the mapping that the allocated BSR bytes repeat is recorded in the *bsr_stride* field. The *bsr_id* field is written with a unique identifier to be used with the `bsr_free` call.

If multiple granules or windows are to be used, they must be allocated with independent calls to `bsr_alloc`. this is because I/O mappings for multiple granules might not be contiguous, and strides are only applicable within the granule.

The resulting *bsr_map* information can then be used as input to `rmmap_create` for establishing addressability to the BSR resource within the current process address space.

Execution Environment

The `bsr_alloc` service can only be called from the process environment.

Return Values

If successful, `bsr_alloc` returns 0 and modifies the *bsr_map* structure so that it contains the mapping information for the newly allocated resource, modifies the *bsr_stride* field displays the stride on which the BSR bytes repeat within the mapping, and modifies the *bsr_id* field so that it displays a unique identifier for the newly allocated BSR resource. If unsuccessful, one of the following values is returned:

Item	Description
ENODEV	The BSR facility does not exist.
EINVAL	Unsupported number of bytes requested.
EBUSY	Requested BSR bytes or mappable BSR windows are currently in use.

Related reference
bsr_free Kernel Service
bsr_query Kernel Service
rmmap_create Kernel Service

bsr_free Kernel Service

Purpose

Frees a Barrier Synchronization Register (BSR) resource previously allocated with the `bsr_alloc` kernel service.

Syntax

```
#include <sys/adspace.h>

int bsr_free (
    int bsr_id,
```

Parameters

Item	Description
bsr_id	BSR resource identifier as returned in the *bsr_id* field of the `bsr_alloc` call.

Description

The `bsr_free` service releases a BSR allocation. The specific BSR resource being freed is identified by the unique identifier *bsr_id* from the corresponding `bsr_alloc` call.

It is the caller's responsibility to ensure that all prior attachments to the BSR resource, through `rmmap_create` calls, have been detached with corresponding `rmmap_remove` calls prior to freeing the BSR resource.

Execution Environment

The `bsr_free` service can only be called from the process environment.

Return Values

Item	Description
0	A successful operation.

Item	Description
ENODEV	The BSR facility is not present.
EINVAL	BSR resource corresponding to *bsr_id* is invalid or not currently allocated.

Related reference
bsr_alloc Kernel Service
bsr_query Kernel Service
rmmap_remove Kernel Service

bsr_query Kernel Service

Purpose

Queries the existence of the Barrier Synchronization Register facility, and, if it exists, its size and allocation granule.

Syntax

```
#include <sys/adspace.h>

int bsr_query (
    int *total_bytes,
    uint * supported_window_mask,
    int *free_bytes,
    uint *free_window_mask)
```

Parameters

Item	Description
total_bytes	Total bytes of the BSR facility currently present within the system or logical partition
supported_window_mask	Bit mask representing supported power-of-2-sized windows that can be allocated
free_bytes	Number of BSR bytes currently available (not allocated)
free_window_mask	Bit mask representing available (not allocated) power-of-2-sized windows

Description

The `bsr_query` service can be used to detect the presence and capabilities of the Barrier Synchronization Register (BSR) facility on a given system or logical partition. If the BSR facility is present on a system or within a logical partition, a value of 0 is returned, and the parameters, passed by reference, are written with the appropriate information.

The *total_bytes* field is written with the total number of BSR bytes currently present in the system or logical partition. The *supported_window_mask* field is written with a bitmask, where each bit set indicates the various power-of-2 window sizes that the *total_bytes* can be allocated and accessed. For example, a mask of 0x58 would indicate that windows of size 64 (0x40), 16 (0x10), and 8 (0x8) bytes were supported.

The *free_bytes* field is written with the number of BSR bytes within the system or logical partition that are currently unallocated. The *free_window_mask* field is written with a bitmask, where each bit set indicates the power-of-2 window sizes that are available for allocating and accessing the remaining *free_bytes*.

Note: Due to dynamic reconfiguration, the information returned by this query service might become stale.

Execution Environment

The `bsr_query` service can only be called from the process environment.

Return Values

Item	Description
0	The BSR facility exists and information is provided.
ENODEV	The BSR facility does not exist.

Related reference

bsr_free Kernel Service

bwrite Kernel Service

Purpose

Writes the specified buffer data.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
```

int bwrite (*bp***)**
struct buf ******bp***;**

Parameter

Item	Description
bp	Specifies the address of the buffer structure for the buffer to be written.
	On a platform that supports storage keys, the passed in *bp* parameter must be in the **KKEY_PUBLIC** or **KKEY_BLOCK_DEV** protection domain.

Description

The **bwrite** kernel service writes the specified buffer data. If this is a synchronous request, the **bwrite** service waits for the I/O to complete.

"Block I/O Buffer Cache Kernel Services: Overview" in *Kernel Extensions and Device Support Programming Concepts* describes how the three buffer-cache write routines work.

Execution Environment

The **bwrite** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.

Item	Description
ERRNO	Returns an error number from the **/usr/include/sys/errno.h** file on error.

Related reference
brelse Kernel Service
iowait Kernel Service

I/O Kernel Services

c

The following kernel services begin with the with the letter c.

cancel Device Queue Management Routine

Purpose

Provides a means for cleaning up queue element-related resources when a pending queue element is eliminated from the queue.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/deviceq.h>
```

void cancel (*ptr*)
struct req_qe *ptr;**

Parameter

Item	Description
ptr	Specifies the address of the queue element.

Description

The kernel calls the **cancel** routine to clean up resources associated with a queue element. Each device queue can have a **cancel** routine. This routine is optional and must be specified when the device queue is created with the **creatq** service.

The **cancel** routine is called when a pending queue element is eliminated from the queue. This occurs when the path is destroyed or when the **canclq** service is called. The device manager should unpin any data and detach any cross-memory descriptor.

Any operations started as a result of examining the queue with the **peekq** service must be stopped.

The **cancel** routine is also called when a queue is destroyed to get rid of any pending or active queue elements.

Execution Environment

The **cancel-queue-element** routine can be called from the process environment only.

cfgnadd Kernel Service

Purpose

Registers a notification routine to be called when system-configurable variables are changed.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/sysconfig.h>
```

```
void cfgnadd
( cbp)
struct cfgncb *cbp;
```

Parameter

Item	Description
cbp	Points to a **cfgncb** configuration notification control block. On a platform that supports storage keys, the passed in *cbp* parameter must only be in the **KKEY_PUBLIC** domain.

Description

The **cfgnadd** kernel service adds a **cfgncb** control block to the list of **cfgncb** structures that the kernel maintains. A **cfgncb** control block contains the address of a notification routine (in its `cfgncb.func` field) to be called when a configurable variable is being changed.

The **SYS_SETPARMS sysconfig** operation allows a user with sufficient authority to change the values of configurable system parameters. The **cfgnadd** service allows kernel routines and extensions to register the notification routine that is called whenever these configurable system variables have been changed.

This notification routine is called in a two-pass process. The first pass performs validity checks on the proposed changes to the system parameters. During the second pass invocation, the notification routine performs whatever processing is needed to make these changes to the parameters. This two-pass procedure ensures that variables used by more than one kernel extension are correctly handled.

To use the **cfgnadd** service, the caller must define a **cfgncb** control block using the structure found in the **/usr/include/sys/sysconfig.h** file.

Execution Environment

The **cfgnadd** kernel service can be called from the process environment only.

The **cfgncb.func** notification routine is called in a process environment only.

Related reference
cfgndel Kernel Service
Related information
sysconfig subroutine
Kernel Extension and Device Driver Management Kernel Services

cfgncb Configuration Notification Control Block

Purpose

Contains the address of a notification routine that is invoked each time the **sysconfig** subroutine is called with the **SYS_SETPARMS** command.

Syntax

```
int func (cmd, cur, new)
int cmd;
struct var *cur;
struct var *new;
```

Parameters

Item	Description
cmd	Indicates the current operation type. Possible values are **CFGV_PREPARE** and **CFGV_COMMIT**, as defined in the **/usr/include/sys/sysconfig.h** file.
cur	Points to a **var** structure representing the current values of system-configurable variables.
new	Points to a **var** structure representing the new or proposed values of system-configurable variables.

The *cur* and *new* **var** structures are both in the system address space.

Description

The configuration notification control block contains the address of a notification routine. This structure is intended to be used as a list element in a list of similar control blocks maintained by the kernel.

Each control block has the following definition:

```
struct cfgncb {
    struct cfgncb    *cbnext;     /* next block on chain         */
    struct cfgncb    *cbprev;     /* prev control block on chain */
    int    (*func)();             /* notification function       */
    };
```

The **cfgndel** or **cfgnadd** kernel service can be used to add or delete a **cfgncb** control block from the **cfgncb** list. To use either of these kernel services, the calling routine must define the **cfgncb** control block. This definition can be done using the **/usr/include/sys/sysconfig.h** file.

Every time a **SYS_SETPARMS sysconfig** command is issued, the **sysconfig** subroutine iterates through the kernel list of **cfgncb** blocks, invoking each notification routine with a **CFGV_PREPARE** command. This call represents the first pass of what is for the notification routine a two-pass process.

On a **CFGV_PREPARE** command, the **cfgncb.func** notification routine should determine if any values of interest have changed. All changed values should be checked for validity. If the values are valid, a return code of 0 should be returned. Otherwise, a return value indicating the byte offset of the first field in error in the *new* **var** structure should be returned.

If all registered notification routines create a return code of 0, then no value errors have been detected during validity checking. In this case, the **sysconfig** subroutine issues its second pass call to the **cfgncb.func** routine and sends the same parameters, although the *cmd* parameter contains a value of **CFGV_COMMIT**. This indicates that the new values go into effect at the earliest opportunity.

An example of notification routine processing might be the following. Suppose the user wishes to increase the size of the block I/O buffer cache. On a **CFGV_PREPARE** command, the block I/O notification routine would verify that the proposed new size for the cache is legal. On a **CFGV_COMMIT** command, the notification routine would then make the additional buffers available to the user by chaining more buffers onto the existing list of buffers.

cfgndel Kernel Service

cfgndel Kernel Service

Purpose

Removes a notification routine for receiving broadcasts of changes to configurable system variables.

Syntax

#include <sys/types.h> #include <sys/errno.h> #include <sys/sysconfig.h> void cfgndel (*cbp***) struct cfgncb ****cbp***;**

Parameter

Item	Description
cbp	Points to a **cfgncb** configuration notification control block. On a platform that supports storage keys, the passed in *cbp* parameter must only be in the **KKEY_PUBLIC** domain.

Description

The **cfgndel** kernel service removes a previously registered **cfgncb** configuration notification control block from the list of **cfgncb** structures maintained by the kernel. This service thus allows kernel routines and extensions to remove their notification routines from the list of those called when a configurable system variable has been changed.

The address of the **cfgncb** structure passed to the **cfgndel** kernel service must be the same address used to call the **cfgnadd** service when the structure was originally added to the list. The **/usr/include/sys/ sysconfig.h** file contains a definition of the **cfgncb** structure.

Execution Environment

The **cfgndel** kernel service can be called from the process environment only.

Return Values

The **cfgndel** service has no return values.

Related reference
cfgnadd Kernel Service
Related information
sysconfig subroutine

check Device Queue Management Routine

Purpose

Provides a means for performing device-specific validity checking for parameters included in request queue elements.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/deviceq.h>
```

int check (*type, ptr, length*)
int *type;*
**struct req_qe ***ptr;*
int *length;*

Parameters

Item	Description
type	Specifies the type of call. The following values are used when the kernel calls the **check** routine:

CHECK_PARMS + SEND_CMD
> Send command queue element.

CHECK_PARMS + START_IO
> Start I/O CCB queue element.

CHECK_PARMS + GEN_PURPOSE
> General purpose queue element.

Item	Description
ptr	Specifies the address of the queue element.
length	Specifies the length of the queue element.

Description

The **check** routine is part of the Device Queue Management Kernel extension. Each device queue can have a **check** routine. This routine is optional and must be specified when the device queue is created with the **creatq** service. The **enque** service calls the **check** routine before a request queue element is put on the device queue. The kernel uses the routine's return value to determine whether to put the queue element on the device queue or to stop the request.

The kernel does not call the **check** routine when an acknowledgment or control queue element is sent. Therefore, the **check** routine is only called while executing within a process.

The address of the actual queue element is passed to this routine. In the **check** routine, take care to alter only the fields that were meant to be altered. This routine does not need to be serialized with the rest of the server's routines, because it is only checking the parameters in the queue element.

The **check** routine can check the request before the request queue element is placed on the device queue. The advantage of using this routine is that you can filter out unacceptable commands before they are put on the device queue.

The routine looks at the queue element and returns **RC_GOOD** if the request is acceptable. If the return code is not **RC_GOOD**, the kernel does not place the queue element in a device queue.

Execution Environment

The **check** routine executes under the process environment of the requester. Therefore, access to data areas must be handled as if the routine were in an interrupt handler environment. There is, however, no requirement to pin the code and data as in a normal interrupt handler environment.

Return Values

Item	Description
RC_GOOD	Indicates successful completion.

All other return values are device-specific.

clrbuf Kernel Service

Purpose

Sets the memory for the specified buffer structure's buffer to all zeros.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
void clrbuf ( bp)
struct buf   *bp;
```

Parameter

Item	Description
bp	Specifies the address of the buffer structure for the buffer to be cleared.
	On a platform that supports storage keys, the passed in *bp* parameter must be in the **KKEY_PUBLIC** or **KKEY_BLOCK_DEV** protection domain.

Description

The **clrbuf** kernel service clears the buffer associated with the specified buffer structure. The **clrbuf** service does this by setting to 0 the memory for the buffer that contains the specified buffer structure.

Execution Environment

The **clrbuf** kernel service can be called from either the process or interrupt environment.

Return Values

The **clrbuf** service has no return values.

Related information

Block I/O Buffer Cache Kernel Services: Overview

I/O Kernel Services

clrjmpx Kernel Service

Purpose

Removes a saved context by popping the last saved jump buffer from the list of saved contexts.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

void clrjmpx (*jump_buffer***)**
label_t **jump_buffer***;**

Parameter

Item	Description
jump_buffer	Specifies the address of the caller-supplied jump buffer that was specified on the call to the **setjmpx** service.

Description

The **clrjmpx** kernel service pops the most recent context saved by a call to the **setjmpx** kernel service. Since each **longjmpx** call automatically pops the jump buffer for the context to resume, the **clrjmpx** kernel service should be called only following:

- A normal return from the **setjmpx** service when the saved context is no longer needed
- Any code to be run that requires the saved context to be correct

The **clrjmpx** service takes the address of the jump buffer passed in the corresponding **setjmpx** service.

Execution Environment

The **clrjmpx** kernel service can be called from either the process or interrupt environment.

Return Values

The **clrjmpx** service has no return values.

Understanding Exception Handling

common_reclock Kernel Service

Purpose

Implements a generic interface to the record locking functions.

Syntax

```
#include <sys/types.h>
#include <sys/flock.h>
```

```
common_reclock( gp, size, offset,
lckdat, cmd, retray_fcn, retry_id, lock_fcn,
rele_fcn)
struct gnode *gp;
offset_t size;
offset_t offset;
struct eflock *lckdat;
int cmd;
int (*retry_fcn)();
```

```
ulong *retry_id;
int (*lock_fcn)();
int (*rele_fcn)();
```

Parameters

Item	Description
gp	Points to the gnode that represents the file to lock.
size	Identifies the current size of the file in bytes.
offset	Specifies the current file offset. The system uses the *offset* parameter to establish where the lock region is to begin.
lckdat	Points to an **eflock** structure that describes the lock operation to perform.
cmd	Defines the type of operation the kernel service performs. This parameter is a bit mask consisting of the following bits:

<div style="margin-left:2em">

SETFLCK
If set, the system sets or clears a lock. If not set, the lock information is returned.

SLPFLCK
If the lock cannot be granted immediately, wait for it. This is only valid when **SETFLCK** flag is set.

INOFLCK
The caller is holding a lock on the object referred to by the gnode. The **common_reclock** kernel service calls the release function before sleeping, and the lock function on return from sleep.

When the *cmd* parameter is set to **SLPFLCK**, it indicates that if the lock cannot be granted immediately, the service should wait for it. If the *retry_fcn* parameter contains a valid pointer, the **common_reclock** kernel service does not sleep, regardless of the **SLPFLCK** flag.

</div>

Item	Description
retry_fcn	Points to a retry function. This function is called when the lock is retried. The retry function is not used if the lock is granted immediately. When the requested lock is blocked by an existing lock, a sleeping lock is established with the retry function address stored in it. The **common_reclock** kernel service then returns a correlating ID (see the *retry_id* parameter) to the calling routine, along with an exit value of **EAGAIN**. When the sleeping lock is awakened, the retry function is called with the correlating ID as its ID argument.
	If this argument is not NULL, then the **common_ reclock** kernel service does not sleep, regardless of the **SLPFLCK** command flag.
retry_id	Points to location to store the correlating ID. This ID is used to correlate a retry operation with a specific lock or set of locks. This parameter is used only in conjunction with retry function. The value stored in this location is an opaque value. The caller should not use this value for any purpose other than lock correlation.
lock_fcn	Points to a lock function. This function is invoked by the **common_ reclock** kernel service to lock a data structure used by the caller. Typically this is the data structure containing the gnode to lock. This function is necessary to serialize access to the object to lock. When the **common_reclock** kernel service invokes the lock function, it is passed the private data pointer from the gnode as its only argument.
rele_fcn	Points to a release function. This function releases the lock acquired with the lock function. When the release function is invoked, it is passed the private data pointer from the gnode as its only argument.

Description

The **common_reclock** routine implements a generic interface to the record-locking functions. This service allows distributed file systems to use byte-range locking. The kernel service does the following when a requested lock is blocked by an existing lock:

- Establishes a sleeping lock with the retry function in the **lock** structure. The address of the retry function is specified by the *retry_fcn* parameter.
- Returns a correlating ID value to the caller along with an exit value of **EAGAIN**. The ID is stored in the *retry_id* parameter.
- Calls the retry function when the sleeping lock is later awakened, the retry function is called with the *retry_id* parameter as its argument.

    Note: Before a call to the **common_ reclock** subroutine, the **eflock** structure must be completely filled in. The *lckdat* parameter points to the **eflock** structure.

The caller can hold a serialization lock on the data object pointed to by the gnode. However, if the caller expects to sleep for a blocking-file lock and is holding the object lock, the caller must specify a lock function with the *lock_fcn* parameter and a release function with the *rele_fcn* parameter.

The lock is described by a **eflock** structure. This structure is identified by the *lckdat* parameter. If a read lock (**F_RDLCK**) or write lock (**F_WRLCK**) is set with a length of 0, the entire file is locked. Similarly, if unlock (**F_UNLCK**) is set starting at 0 for 0 length, all locks on this file are unlocked. This method is how locks are removed when a file is closed.

To allow the **common_reclock** kernel service to update the per-gnode lock list, the service takes a **GN_RECLK_LOCK** lock during processing.

Execution Environment

The **common_reclock** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
EAGAIN	Indicates a lock cannot be granted because of a blocking lock and the caller did not request that the operation sleep.
ERRNO	Indicates an error. Refer to the **fcntl** system call for the list of possible values.

Related information
fcntl subroutine
flock.h subroutine

compare_and_swap Kernel Services

Purpose

Conditionally updates or returns a variable atomically.

Syntax

```
#include <sys/atomic_op.h>
```

boolean_t compare_and_swap (*addr,*   *old_val_addr,*   *new_val***)**
atomic_p *addr;*

```
int * old_val_addr;
int new_val;

boolean_t compare_and_swaplp ( addr,  old_val_addr,  new_val)
atomic_l addr;
long * old_val_addr;
long new_val;
```

Parameters

Item	Description
addr	Specifies the address of the variable.
old_val_addr	Specifies the address of the old value to be checked against (and conditionally updated with) the value of the variable.
new_val	Specifies the new value to be conditionally assigned to the variable.

Description

The **compare_and_swap** kernel services performs an atomic (uninterruptible) operation which compares the contents of a variable with a stored old value; if equal, a new value is stored in the variable, and **TRUE** is returned, otherwise the old value is set to the current value of the variable, and **FALSE** is returned.

The **compare_and_swap** kernel service operates on a single word (32 bit) variable while the **compare_and_swaplp** kernel service operates on a double word (64 bit) variable.

The **compare_and_swap** kernel services are particularly useful in operations on singly linked lists, where a list pointer must not be updated if it has been changed by another thread since it was read.

Note:

- The single word variable passed to the **compare_and_swap** kernel service must be aligned on a full word (32 bit) boundary.
- The double word variable passed to the **compare_and_swaplp** kernel service must be aligned on a double word (64 bit) boundary.

Execution Environment

The **compare_and_swap** kernel services can be called from either the process or interrupt environment.

Return Values

Item	Description
TRUE	Indicates that the variable was equal to the old value, and has been set to the new value.
FALSE	Indicates that the variable was not equal to the old value, and that its current value has been returned in the location where the old value was stored.

Locking Kernel Services

coprocessor_user_register Kernel Service

Purpose

Registers the current process as a coprocessor user.

Syntax

```
#include <sys/coprocessor.h>
kerrno_t coprocessor_user_register ( int coprocessor_type, unsigned int * phandle )
```

Parameters

Item	Description
coprocessor_type	Numeric value in the [0..63] range
phandle	Pointer to an unsigned 32 bit integer where a handle identifying this process is returned.

Description

This kernel service allows a kernel extension to register the current process as a user of the coprocessor type passed as the first argument. When successful, the service sets up values in the process context that allow the current process to access coprocessors of the specified type in user mode.

Execution Environment

This kernel service can be called in the process environment only.

Return Values

When the call is successful, the kernel service returns a value of zero. Otherwise, a negative value is returned to indicate an error.

Error Values

Possible errors are:

- Coprocessors not supported (supported only on POWER7® and newer processors)
- Invalid coprocessor type (must be in the range 0-63).
- Bad address passed as the second argument.
- The current process is already registered for this coprocessor type.
- The service is being called in interrupt context.
- The service could not allocate a value for the handle.

coprocessor_user_unregister Kernel Service

Purpose

Unregisters the current process as a coprocessor user.

Syntax

```
#include <sys/coprocessor.h>
kerrno_t coprocessor_user_unregister ( int coprocessor_type )
```

Parameters

Item	Description
coprocessor_type	Numeric value in the range [0..63] which identifies a coprocessor type.

Description

This kernel service allows a kernel extension to unregister the current process that was previously registered as a coprocessor user. When successful, further accesses by the process to the coprocessor type passed as an argument in user mode will fail with a privileged operation exception.

Execution Environment

This kernel service can be called in the process environment only.

Return Values

When the call is successful, the kernel service returns a value of zero. Otherwise, a negative value is returned to indicate an error.

Error Values

Possible errors are:

- Coprocessors not supported (supported only on POWER7 and newer processors).
- Invalid coprocessor type (must be in the range 0-63).
- The current process is not registered for this coprocessor type.
- The service is being called in interrupt context.

copyin Kernel Service

Purpose

Copies data between user and kernel memory.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

int copyin (*uaddr,* *kaddr,* *count***)**
char **uaddr***;**
char **kaddr***;**
int *count***;**

Parameters

Item	Description
uaddr	Specifies the address of user data.
kaddr	Specifies the address of kernel data.
count	Specifies the number of bytes to copy.

Description

The **copyin** kernel service copies the specified number of bytes from user memory to kernel memory. This service is provided so that system calls and device driver top half routines can safely access user data. The **copyin** service ensures that the user has the appropriate authority to access the data. It also provides recovery from paging I/O errors that would otherwise cause the system to crash.

The **copyin** service should be called only while executing in kernel mode in the user process.

Execution Environment

The **copyin** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
EFAULT	Indicates that the user has insufficient authority to access the data, or the address specified in the *uaddr* parameter is not valid.
EIO	Indicates that a permanent I/O error occurred while referencing data.
ENOMEM	Indicates insufficient memory for the required paging operation.
ENOSPC	Indicates insufficient file system or paging space.

copyinstr Kernel Service

Purpose

Copies a character string (including the terminating null character) from user to kernel space.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/uio.h>
```

On the 32-bit kernel, the syntax for the **copyinstr** Kernel Service is:

```
int copyinstr (from, to, max, actual)
caddr_t from;
caddr_t to;
uint max;
uint *actual;
```

On the 64-bit kernel, the syntax for the **copyinstr** subroutine is:

```
int copyinstr (from, to, max, actual)
void *from;
void *to;
size_t max;
size_t *actual;
```

Parameters

Item	Description
from	Specifies the address of the character string to copy.
to	Specifies the address to which the character string is to be copied.
max	Specifies the number of characters to be copied.
actual	Specifies a parameter, passed by reference, that is updated by the **copyinstr** service with the actual number of characters copied.

Description

The **copyinstr** kernel service permits a user to copy character data from one location to another. The source location must be in user space or can be in kernel space if the caller is a kernel process. The destination is in kernel space.

Execution Environment

The **copyinstr** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
E2BIG	Indicates insufficient space to complete the copy.
EIO	Indicates that a permanent I/O error occurred while referencing data.
ENOSPC	Indicates insufficient file system or paging space.
EFAULT	Indicates that the user has insufficient authority to access the data or the address specified in the *uaddr* parameter is not valid.

Memory Kernel Services

copyout Kernel Service

Purpose

Copies data between user and kernel memory.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

int copyout (*kaddr,* *uaddr,* *count***)**
char **kaddr;*
char **uaddr;*
int *count;*

Parameters

Item	Description
kaddr	Specifies the address of kernel data.
uaddr	Specifies the address of user data.
count	Specifies the number of bytes to copy.

Description

The **copyout** service copies the specified number of bytes from kernel memory to user memory. It is provided so that system calls and device driver top half routines can safely access user data. The **copyout** service ensures that the user has the appropriate authority to access the data. This service also provides recovery from paging I/O errors that would otherwise cause the system to crash.

The **copyout** service should be called only while executing in kernel mode in the user process.

Execution Environment

The **copyout** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
EFAULT	Indicates that the user has insufficient authority to access the data or the address specified in the *uaddr* parameter is not valid.
EIO	Indicates that a permanent I/O error occurred while referencing data.
ENOMEM	Indicates insufficient memory for the required paging operation.
ENOSPC	Indicates insufficient file system or paging space.

cpu_speculation_barrier kernel service

Purpose

Provides protection against speculative execution side-channel attacks.

Syntax

```
#include <sys/processor.h>
```

void cpu_speculation_barrier (void **)**

Description

The `cpu_speculation_barrier` kernel service provides kernel extensions with processor-model-dependent mitigation against known speculative-execution vulnerabilities. The

`cpu_speculation_barrier` kernel service can be used to protect against side-channel attacks within the kernel environment. Kernel extensions should be carefully vetted when the `cpu_speculation_barrier` kernel service is used.

Note: Kernel performance might reduce when the `cpu_speculation_barrier` kernel service is used.

The `cpu_speculation_barrier` kernel service must be called before storage is accessed by using addresses that are computed from an untrusted source. Therefore, only kernel extensions that reference user-mode data directly without using cross-privilege domain access services, such as the `copyin` service, can use the `cpu_speculation_barrier` kernel service.

Execution Environment

The `cpu_speculation_barrier` kernel service can be called from either the process environment or the interrupt environment.

Example

The following example shows an `ioctl` device driver handler that directly references user-mode data:

```
int
dd_ioctl(dev_t devno, int cmd, void *arg, ulong devflag, chan_t chan, int ext)
{
    int         index;
    char         val;
    vector_t    *uvec = NULL;
    extern int     max_kdata_index;
    extern char     kdata[];

    if (cmd == 0xC1C2) {
        /* Select kernel data from user input */
        uvec = (vector_t *)arg;
        index = uvec->index;

        if (index < max_kdata_index) {
            cpu_speculation_barrier();
            val = kdata[index];
            uvec->data[val]++;
        }
    }
}
```

Return Values

The `cpu_speculation_barrier` kernel service does not return any value.

Accessing User-Mode Data While in Kernel Mode

crcopy Kernel Service

Purpose

Copies a credentials structure to a new one and frees the old one.

Syntax

```
#include <sys/cred.h>
```

struct ucred * crcopy (*cr***)**
struct ucred * *cr***;**

Parameter

Item	Description
cr	Pointer to the credentials structure that is to be copied and then freed.

Description

The **crcopy** kernel service allocates a new credentials structure that is initialized from the contents of the *cr* parameter. The reference to *cr* is then freed and a pointer to the new structure returned to the caller.

Note: The *cr* parameter must have been obtained by an earlier call to the **crcopy** kernel service, **crdup** kernel service, **crget** kernel service, or the **crref** kernel service.

Execution Environment

The **crcopy** kernel service can be called from the process environment only.

Return Values

Item	Description
Nonzero value	A pointer to a newly allocated and initialized credentials structure.
Zero value	An error occurred when the kernel service was attempting to allocate pinned memory for the credentials structure.

Related information
Security Kernel Services

crdup Kernel Service

Purpose

Copies a credentials structure to a new one.

Syntax

```
#include <sys/cred.h>
```

```
struct ucred * crdup ( cr)
struct ucred * cr;
```

Parameter

Item	Description
cr	Pointer to the credentials structure that is to be copied.

Description

The **crdup** kernel service allocates a new credentials structure that is initialized from the contents of the *cr* parameter.

Execution Environment

The **crdup** kernel service can be called from the process environment only.

Return Values

Item	Description
Nonzero value	A pointer to a newly allocated and initialized credentials structure.
Zero value	An error occurred when the kernel service was attempting to allocate pinned memory for the credentials structure.

Related information
Security Kernel Services

creatp Kernel Service

Purpose

Creates a new kernel process.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
pid_t creatp()
```

Description

The **creatp** kernel service creates a kernel process. It also allocates and initializes a process block for the new process. Initialization involves these three tasks:

- Assigning an identifier to the kernel process.
- Setting the process state to idle.
- Initializing its parent, child, and sibling relationships.

"Using Kernel Processes" in *Kernel Extensions and Device Support Programming Concepts* has a more detailed discussion of how the **creatp** kernel service creates and initializes kernel processes.

The process calling the **creatp** service must subsequently call the **initp** kernel service to complete the process initialization. The **initp** service also makes the newly created process runnable.

Execution Environment

The **creatp** kernel service can be called from the process environment only.

Return Values

Item	Description
-1	Indicates an error.

Upon successful completion, the **creatp** kernel service returns the process identifier for the new kernel process.

Related reference

Using Kernel Processes

CRED_GETEUID, CRED_GETRUID, CRED_GETSUID, CRED_GETLUID, CRED_GETEGID, CRED_GETRGID, CRED_GETSGID and CRED_GETNGRPS Macros

Purpose

Credentials structure field accessing macros.

Syntax

```
#include <sys/cred.h>

uid_t CRED_GETEUID ( crp )
uid_t CRED_GETRUID ( crp )
uid_t CRED_GETSUID ( crp )
uid_t CRED_GETLUID ( crp )
gid_t CRED_GETEGID ( crp )
gid_t CRED_GETRGID ( crp )
gid_t CRED_GETSGID ( crp )
int CRED_GETNGRPS ( crp )
```

Parameter

Item	Description
crp	Pointer to a credentials structure

Description

These macros provide a means for accessing the user and group identifier fields within a credentials structure. The fields within a **ucred** structure should not be accessed directly as the field names and their locations are subject to change.

The **CRED_GETEUID** macro returns the effective user ID field from the credentials structure referenced by *crp*.

The **CRED_GETRUID** macro returns the real user ID field from the credentials structure referenced by *crp*.

The **CRED_GETSUID** macro returns the saved user ID field from the credentials structure referenced by *crp*.

The **CRED_GETLUID** macro returns the login user ID field from the credentials structure referenced by *crp*.

The **CRED_GETEUID** macro returns the effective group ID field from the credentials structure referenced by *crp*.

The **CRED_GETRUID** macro returns the real group ID field from the credentials structure referenced by *crp*.

The **CRED_GETSUID** macro returns the saved group ID field from the credentials structure referenced by *crp*.

The **CRED_GETNGRPS** macro returns the number of concurrent group ID values stored within the credentials structure referenced by *crp*.

These macros are defined in the system header file *<sys/cred.h>*.

Execution Environment

The credentials macros called with any valid credentials pointer.

Related information
Security Kernel Services

crexport Kernel Service

Purpose

Copies an internal format credentials structure to an external format credentials structure.

Syntax

```
#include <sys/cred.h>

void crexport (src, dst)
struct ucred * src;
struct ucred_ext * dst;
```

Parameter

Item	Description
src	Pointer to the internal credentials structure.
dst	Pointer to the external credentials structure.

Description

The **crexport** kernel service copies from the internal credentials structure referenced by *src* into the external credentials structure referenced by *dst*. The external credentials structure is guaranteed to be compatible between releases. Fields within a **ucred** structure must not be referenced directly as the field names and locations within that structure are subject to change.

Execution Environment

The **crexport** kernel service can be called from the process environment only.

Return Values

This kernel service does not have a return value.

Related information
Security Kernel Services

crfree Kernel Service

Purpose

Releases a reference count on a credentials structure.

Syntax

```
#include <sys/cred.h>
```

```
void crfree ( cr)
struct ucred * cr;
```

Parameter

Item	Description
cr	Pointer to the credentials structure that is to have a reference freed.

Description

The **crfree** kernel service deallocates a reference to a credentials structure. The credentials structure is deallocated when no references remain.

Note: The *cr* parameter must have been obtained by an earlier call to the **crcopy** kernel service, **crdup** kernel service, **crget** kernel service, or the **crref** kernel service.

Execution Environment

The **crfree** kernel service can be called from the process environment only.

Return Values

No value is returned by this kernel service.

Related information

Security Kernel Services

crget Kernel Service

Purpose

Allocates a new, uninitialized credentials structure to a new one and frees the old one.

Syntax

```
#include <sys/cred.h>
```

```
struct ucred * crget ( void )
```

Parameter

This kernel service does not require any parameters.

Description

The **crget** kernel service allocates a new credentials structure. The structure is initialized to all zero values, and the reference count is set to 1.

Execution Environment

The **crget** kernel service can be called from the process environment only.

Return Values

Item	Description
Nonzero value	A pointer to a newly allocated and initialized credentials structure.
Zero value	An error occurred when the kernel service was attempting to allocate pinned memory for the credentials structure.

Related information
Security Kernel Services

crhold Kernel Service

Purpose

Increments the reference count for a credentials structure.

Syntax

```
#include <sys/cred.h>
```

```
void crhold ( cr)
struct ucred * cr;
```

Parameter

Item	Description
cr	Pointer to the credentials structure that will have its reference count incremented.

Description

The **crhold** kernel service increments the reference count of a credentials structure.

Note: Reference counts that are incremented with the **crhold** kernel service must be decremented with the **crfree** kernel service.

Execution Environment

The **crhold** kernel service can be called from the process environment only.

Return Values

No value is returned by this kernel service.

Related information
Security Kernel Services

crref Kernel Service

Purpose

Increments the reference count for the current credentials structure.

Syntax

```
#include <sys/cred.h>
```

```
struct ucred * crref ( void )
```

Parameter

This kernel service does not require any parameters.

Description

The **crref** kernel service increments the reference count of the current credentials structure and returns a pointer to the current credentials structure to the invoker.

Note: References that are allocated with the **crref** kernel service must be released with the **crfree** kernel service.

Execution Environment

The **crref** kernel service can be called from the process environment only.

Return Values

Item	Description
Nonzero value	A pointer to the current credentials structure.

Related information
Security Kernel Services

crset Kernel Service

Purpose

Sets the current security credentials.

Syntax

```
#include <sys/cred.h>
```

void crset (_cr_)
struct ucred * _cr_;

Parameter

Item	Description
_cr_	Pointer to the credentials structure that will become the new, current security credentials.

Description

The **crset** kernel service replaces the current security credentials with the supplied value. The existing structure will be deallocated.

Note: The *cr* parameter must have been obtained by an earlier call to the **crcopy** kernel service, **crdup** kernel service, **crget** kernel service, or the **crref** kernel service.

Execution Environment

The **crset** kernel service can be called from the process environment only.

Return Values

No value is returned by this kernel service.

Related information
Security Kernel Services

curtime Kernel Service

Purpose

Reads the current time into a time structure.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/time.h>
```

void curtime (*timestruct***)**
struct timestruc_t **timestruct***;**

Parameter

Item	Description
timestruct	Points to a **timestruc_t** time structure defined in the **/usr/include/sys/time.h** file. The **curtime** kernel service updates the fields in this structure with the current time.

Description

The **curtime** kernel service reads the current time into a time structure defined in the **/usr/include/sys/time.h** file. This service updates the `tv_sec` and `tv_nsec` fields in the time structure, pointed to by the *timestruct* parameter, from the hardware real-time clock. The kernel also maintains and updates a memory-mapped time **tod** structure. This structure is updated with each clock tick.

The kernel also maintains two other in-memory time values: the **lbolt** and **time** values. The three in-memory time values that the kernel maintains (the **tod**, **lbolt**, and **time** values) are available to kernel extensions. The **lbolt** in-memory time value is the number of timer ticks that have occurred since the system was booted. This value is updated once per timer tick. The **time** in-memory time value is the number of seconds since Epoch. The kernel updates the value once per second.

Note: POSIX 1003.1 defines "seconds since Epoch" as a "value interpreted as the number of seconds between a specified time and the Epoch". It further specifies that a "Coordinated Universal Time name specified in terms of seconds (*tm_sec*), minutes (*tm_min*), hours (*tm_hour*), and days since January 1 of the year (*tm_yday*), and calendar year minus 1900 (*tm_year*) is related to a time represented as seconds since the Epoch, according to the following expression: $tm\_sec + tm\_min * 60\ tm\_hour*3600 + tm\_yday$

* 86400 + (*tm_year* - 70) * 31536000 ((*tm_year* - 69) / 4) * 86400 if the year is greater than or equal to 1970, otherwise it is undefined."

The **curtime** kernel service does not page-fault if a pinned stack and input time structure are used. Also, accessing the **lbolt**, **time**, and **tod** in-memory time values does not cause a page fault since they are in pinned memory.

Execution Environment

The **curtime** kernel service can be called from either the process or interrupt environment.

The **tod**, **time**, and **lbolt** memory-mapped time values can also be read from the process or interrupt handler environment. The *timestruct* parameter and stack must be pinned when the **curtime** service is called in an interrupt handler environment.

Return Values

The **curtime** kernel service has no return values.

Related information
Timer and Time-of-Day Kernel Services

d

The following kernel services begin with the with the letter d.

d_align Kernel Service

Purpose

Provides needed information to align a buffer with a processor cache line.

Library

Kernel Extension Runtime Routines Library (**libsys.a**)

Syntax

```
int  d_align()
```

Description

To maintain cache consistency with system memory, buffers must be aligned. The **d_align** kernel service helps provide that function by returning the maximum processor cache-line size. The cache-line size is returned in log2 form.

Execution Environment

The **d_align** service can be called from either the process or interrupt environment.

Related reference

Understanding Direct Memory Access (DMA) Transfer

d_alloc_dmamem Kernel Service

Purpose

Allocates an area of "dma-able" memory.

Syntax

```
void *
 d_alloc_dmamem(d_handle_t  device_handle, size_t size,int align)
```

Description

Exported, documented kernel service supported on PCI-based systems only. The **d_alloc_dmamem** kernel service allocates an area of "dma-able" memory which satisfies the constraints associated with a DMA handle, specified via the *device_handle* parameter. The constraints (such as need for contiguous physical pages or need for 32-bit physical address) are intended to guarantee that a given adapter will be able to access the physical pages associated with the allocated memory. A driver associates such constraints with a dma handle via the *flags* parameter on its **d_map_init** call.

The area to be allocated is the number of bytes in length specified by the *size* parameter, and is aligned on the byte boundary specified by the *align* parameter. The *align* parameter is actually the log base 2 of the desired address boundary. For example, an *align* value of 12 requests that the allocated area be aligned on a 4096 byte boundary.

d_alloc_dmamem is appropriate to be used for long-term mappings. Depending on the system configuration and the constraints encoded in the *device_handle,* the underlying storage will come from either the real_heap (**rmalloc** service) or pinned_heap (**xmalloc** service).

Note:

1. The **d_free_dmamem** service should be called to free allocation from a previous **d_alloc_dmamem** call.
2. The **d_alloc_dmamem** kernel service can be called from the process environment only.

Parameters

Item	Description
device_handle	Indicates the dma handle.
align	Specifies alignment characteristics.
size_t size	Specifies number of bytes to allocate.

Return Values

Item	Description
Address of allocated area	Indicates that **d_alloc_dmamem** was successful.
NULL	Requested memory could not be allocated.

Related reference
d_free_dmamem Kernel Service
d_map_init Kernel Service
rmalloc Kernel Service

d_cflush Kernel Service

Purpose

Flushes the processor and I/O channel controller (IOCC) data caches when mapping bus device DMA with the long-term **DMA_WRITE_ONLY** option.

Syntax

int d_cflush (*channel_id, baddr, count, daddr*)
int *channel_id*;
caddr_t *baddr*;
size_t *count*;
caddr_t *daddr*;

Parameters

Item	Description
channel_id	Specifies the DMA channel ID returned by the **d_init** kernel service.
baddr	Designates the address of the memory buffer.
count	Specifies the length of the memory buffer transfer in bytes.
daddr	Designates the address of the device corresponding to the transfer.

Description

The **d_cflush** kernel service should be called after data has been modified in a buffer that will undergo direct memory access (DMA) processing. Through DMA processing, this data is sent to a device where the **d_master** kernel service with the **DMA_WRITE_ONLY** option has already mapped the buffer for device DMA. The **d_cflush** kernel service is not required if the **DMA_WRITE_ONLY** option is not used or if the buffer is mapped before each DMA operation by calling the **d_master** kernel service.

The **d_cflush** kernel service flushes the processor cache for the involved cache lines and invalidates any previously retrieved data that may be in the IOCC buffers for the designated channel. This most frequently occurs when using long-term buffer mapping for DMA support to or from a device.

Long-Term DMA Buffer Mapping

The long-term DMA buffer mapping approach is frequently used when a pool of buffers is defined for sending commands and obtaining responses from an adapter using bus master DMA. This approach is also used frequently in the communications field where buffers can come from a common pool such as the **mbuf** pool or a pool used for protocol headers.

When using a fixed pool of buffers, the **d_master** kernel service is used only once to map the pool's address and range. The device driver then modifies the data in the buffers. It must also flush the data from the processor and invalidate the IOCC data cache involved in transfers with the device. The IOCC cache must be invalidated because the data in the IOCC data cache may be stale due to the last DMA operation to or from the buffer area that has just been modified for the next operation.

The **d_cflush** kernel service permits the flushing of the processor cache and making the required IOCC cache not valid. The device driver should use this service after modifying the data in the buffer and before sending the command to the device to start the DMA operation.

Once DMA processing has been completed, the device driver should call the **d_complete** service to check for errors and ensure that any data read from the device has been flushed to memory.

Note: The **d_cflush** kernel service is not supported on the 64-bit kernel.

Execution Environment

The **d_cflush** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates that the transfer was successfully completed.
EINVAL	Indicates the presence of an invalid parameter.

delay Kernel Service

Purpose

Suspends the calling process for the specified number of timer ticks.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

void delay
(*ticks***)**
int *ticks*;

Parameter

Item	Description
ticks	Specifies the number of timer ticks that must occur before the process is reactivated. Many timer ticks can occur per second.

Description

The **delay** kernel service suspends the calling process for the number of timer ticks specified by the *ticks* parameter.

The HZ value in the **/usr/include/sys/m_param.h** file can be used to determine the number of ticks per second.

Execution Environment

The **delay** kernel service can be called from the process environment only.

Return Values

The **delay** service has no return values.

Related information

Timer and Time-of-Day Kernel Services

del_domain_af Kernel Service

Purpose

Deletes an address family from the Address Family domain switch table.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/domain.h>
```

```
int
del_domain_af ( domain)
struct domain *domain;
```

Parameter

Item	Description
domain	Specifies the address family.

Description

The **del_domain_af** kernel service deletes the address family specified by the *domain* parameter from the Address Family domain switch table.

Execution Environment

The **del_domain_af** kernel service can be called from either the process or interrupt environment.

Return Value

Item	Description
EINVAL	Indicates that the specified address is not found in the Address Family domain switch table.

Example

To delete an address family from the Address Family domain switch table, invoke the **del_domain_af** kernel service as follows:

```
del_domain_af(&inetdomain);
```

In this example, the family to be deleted is inetdomain.

del_input_type Kernel Service

Purpose

Deletes an input type from the Network Input table.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/if.h>
```

```
int del_input_type
( type)
u_short type;
```

Parameter

Item	Description
type	Specifies which type of protocol the packet contains. This parameter is a field in a packet.

Description

The **del_input_type** kernel service deletes an input type from the Network Input table to disable the reception of the specified packet type.

Execution Environment

The **del_input_type** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates that the type was successfully deleted.
ENOENT	Indicates that the **del_input_type** service could not find the type in the Network Input table.

Examples

1. To delete an input type from the Network Input table, invoke the **del_input_type** kernel service as follows:

   ```
   del_input_type(ETHERTYPE_IP);
   ```

   In this example, ETHERTYPE_IP specifies that Ethernet IP packets should no longer be processed.

2. To delete an input type from the Network Input table, invoke the **del_input_type** kernel service as follows:

   ```
   del_input_type(ETHERTYPE_ARP);
   ```

   In this example, ETHERTYPE_ARP specifies that Ethernet ARP packets should no longer be processed.

del_netisr Kernel Service

Purpose

Deletes a network software interrupt service routine from the Network Interrupt table.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/netisr.h>
```

int del_netisr (*soft_intr_level*)
u_short *soft_intr_level*;

Parameter

Item	Description
soft_intr_level	Specifies the software interrupt level to delete. This parameter must be greater than or equal to 0 and less than **NETISR_MAX**. Refer to `netisr.h` for the range of values of *soft_intr_level* that are already in use. Also, other kernel extensions that are not AIX and that use network ISRs currently running on the system can make use of additional values not mentioned in `netisr.h`.

Description

The **del_netisr** kernel service deletes the network software interrupt service routine specified by the *soft_intr_level* parameter from the Network Software Interrupt table.

Execution Environment

The **del_netisr** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates that the software interrupt service was successfully deleted.
ENOENT	Indicates that the software interrupt service was not found in the Network Software Interrupt table.

Example

To delete a software interrupt service from the Network Software Interrupt table, invoke the kernel service as follows:

```
del_netisr(NETISR_IP);
```

In this example, the software interrupt routine to be deleted is NETISR_IP.

Related reference

del_netopt Macro

Purpose

Deletes a network option structure from the list of network options.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/netopt.h>
```

del_netopt (*option_name_symbol*)
option_name_symbol;

Parameter

Item	Description
option_name_symbol	Specifies the symbol name used to construct the **netopt** structure and default names.

Description

The **del_netopt** macro deletes a network option from the linked list of network options. After the **del_netopt** service is called, the option is no longer available to the **no** command.

Execution Environment

The **del_netopt** macro can be called from either the process or interrupt environment.

Return Values

The **del_netopt** macro has no return values.

Network Kernel Services

detach Device Queue Management Routine

Purpose

Provides a means for performing device-specific processing when the **detchq** kernel service is called.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/deviceq.h>
```

int detach(*dev_parms*, *path_id*)
caddr_t *dev_parms*;
cba_id *path_id*;

Parameters

Item	Description
dev_parms	Passed to **creatd** service when the **detach** routine is defined.

Item	Description
path_id	Specifies the path identifier for the queue that is being detached from.

Description

The **detach** routine is part of the Device Queue Management kernel extension. Each device queue can have a **detach** routine. This routine is optional and must be specified when the device queue is defined with the **creatd** service. The **detchq** service calls the **detach** routine each time a path to the device queue is removed.

To ensure that the **detach** routine is not called while a queue element from this client is still in the device queue, the kernel puts a detach control queue element at the end of the device queue. The server knows by convention that a detach control queue element signifies completion of all pending queue elements for that path. The kernel calls the **detach** routine after the detach control queue element is processed.

The **detach** routine executes under the process under which the **detchq** service is called. The kernel does not serialize the execution of this service with the execution of any of the other server routines.

Execution Environment

The **detach** routine can be called from the process environment only.

Return Values

Item	Description
RC_GOOD	Indicates successful completion.

A return value other than **RC_GOOD** indicates an irrecoverable condition causing system failure.

devdump Kernel Service

Purpose

Calls a device driver dump-to-device routine.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
int devdump
(devno, uiop, cmd, arg, chan, ext)
dev_t   devno;
struct uio * uiop;
int   cmd,  arg,  ext;
```

Parameters

Item	Description
devno	Specifies the major and minor device numbers.
uiop	Points to the **uio** structure containing write parameters.
cmd	Specifies which dump command to perform.
arg	Specifies a parameter or address to a parameter block for the specified command.

Item	Description
chan	Specifies the channel ID.
ext	Specifies the extended system call parameter.

Description

The kernel or kernel extension calls the **devdump** kernel service to initiate a memory dump to a device when writing dump data and then to terminate the dump to the target device.

The **devdump** service calls the device driver's **dddump** routine, which is found in the device switch table for the device driver associated with the specified device number. If the device number (specified by the *devno* parameter) is not valid or if the associated device driver does not have a **dddump** routine, an **ENODEV** return value is returned.

If the device number is valid and the specified device driver has a **dddump** routine, the routine is called.

If the device driver's **dddump** routine is successfully called, the return value for the **devdump** service is set to the return value provided by the device's **dddump** routine.

Execution Environment

The **devdump** kernel service can be called in either the process or interrupt environment, as described under the conditions described in the **dddump** routine.

Return Values

Item	Description
0	Indicates a successful operation.
ENODEV	Indicates that the device number is not valid or that no **dddump** routine is registered for this device.

The **dddump** device driver routine provides other return values.

Kernel Extension and Device Driver Management Kernel Services

devstrat Kernel Service

Purpose

Calls a block device driver's strategy routine.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

int devstrat (*bp***)**
struct buf **bp***;**

Parameter

Item	Description
bp	Points to the **buf** structure specifying the block transfer parameters.

Description

The kernel or kernel extension calls the **devstrat** kernel service to request a block data transfer to or from the device with the specified device number. This device number is found in the **buf** structure. The **devstrat** service can only be used for the block class of device drivers.

The **devstrat** service calls the device driver's **ddstrategy** routine. This routine is found in the device switch table for the device driver associated with the specified device number found in the b_dev field. The b_dev field is found in the **buf** structure pointed to by the *bp* parameter. The caller of the **devstrat** service must have an **iodone** routine specified in the b_iodone field of the **buf** structure. Following the return from the device driver's **ddstrategy** routine, the **devstrat** service returns without waiting for the I/O to be performed.

On multiprocessor systems, all **iodone** routines run by default on the first processor started when the system was booted. This ensures compatibility with uniprocessor device drivers. If the **iodone** routine has been designed to be multiprocessor-safe, set the **B_MPSAFE** flag in the b_flags field of the **buf** structure passed to the **devstrat** kernel service. The **iodone** routine will then run on any available processor.

If the device major number is not valid or the specified device is not a block device driver, the **devstrat** service returns the **ENODEV** return code. If the device number is valid, the device driver's **ddstrategy** routine is called with the pointer to the **buf** structure (specified by the *bp* parameter).

Execution Environment

The **devstrat** kernel service can be called from either the process or interrupt environment.

Note: The **devstrat** kernel service can be called in the interrupt environment only if its priority level is **INTIODONE** or lower.

Return Values

Item	Description
0	Indicates a successful operation.
ENODEV	Indicates that the device number is not valid or that no **ddstrategy** routine registered. This value is also returned when the specified device is not a block device driver. If this error occurs, the **devstrat** service can cause a page fault.

Kernel Extension and Device Driver Management Kernel Services

devswadd Kernel Service

Purpose

Adds a device entry to the device switch table.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/device.h>
```

int devswadd (*devno*, *dswptr* **)**
dev_t *devno*;
struct devsw * *dswptr*;

Parameters

Item	Description
devno	Specifies the major and minor device numbers to be associated with the specified entry in the device switch table.
dswptr	Points to the device switch structure to be added to the device switch table.

Description

The **devswadd** kernel service is typically called by a device driver's **ddconfig** routine to add or replace the device driver's entry points in the device switch table. The device switch table is a table of device switch (**devsw**) structures indexed by the device driver's major device number. This table of structures is used by the device driver interface services in the kernel to facilitate calling device driver routines.

The major device number portion of the *devno* parameter is used to specify the index in the device switch table where the **devswadd** service must place the specified device switch entry. Before this service copies the device switch structure into the device switch table, it checks the existing entry to determine if any opened device is using it. If an opened device is currently occupying the entry to be replaced, the **devswadd** service does not perform the update. Instead, it returns an **EEXIST** error value. If the update is successful, it returns a value of 0.

Entry points in the device switch structure that are not supported by the device driver must be handled in one of two ways. If a call to an unsupported entry point should result in the return of an error code, then the entry point must be set to the **nodev** routine in the structure. As a result, any call to this entry point automatically invokes the **nodev** routine, which returns an **ENODEV** error code. The kernel provides the **nodev** routine.

Otherwise, a call to an unsupported entry point should be treated as a no-operation function. Then the corresponding entry point should be set to the **nulldev** routine. The **nulldev** routine, which is also provided by the kernel, performs no operation if called and returns a 0 return code.

On multiprocessor systems, all device driver routines run by default on the first processor started when the system was booted. This ensures compatibility with uniprocessor device drivers. If the device driver being added has been designed to be multiprocessor-safe, set the **DEV_MPSAFE** flag in the d_opts field of the **devsw** structure passed to the **devswadd** kernel service. The device driver routines will then run on any available processor.

All other fields within the structure that are not used should be set to 0. Some fields in the structure are for kernel use; the **devswadd** service does not copy these fields into the device switch table. These fields are documented in the **/usr/include/device.h** file.

Execution Environment

The **devswadd** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
EEXIST	Indicates that the specified device switch entry is in use and cannot be replaced.
ENOMEM	Indicates that the entry cannot be pinned due to insufficient real memory.
EINVAL	Indicates that the major device number portion of the *devno* parameter exceeds the maximum permitted number of device switch entries.

Related reference
devswdel Kernel Service
ddconfig Device Driver Entry Point
Related information
Kernel Extension and Device Driver Management Kernel Services

devswchg Kernel Service

Purpose

Alters a device switch entry point in the device switch table.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/device.h>
```

```
int devswchg ( devno,  type,  newfunc,  oldfunc);
dev_t devno;
int type;
int (*newfunc) ();
int (**oldfunc)();
```

Parameters

Item	Description
devno	Specifies the major and minor device numbers of the device to be changed.

Item	Description
type	Specifies the device switch entry point to alter. The *type* parameter can have one of the following values:

DSW_BLOCK
Alters the **ddstrategy** entry point.

DSW_CONFIG
Alters the **ddconfig** entry point.

DSW_CREAD
Alters the **ddread** entry point.

DSW_CWRITE
Alters the **ddwrite** entry point.

DSW_DUMP
Alters the **dddump** entry point.

DSW_MPX
Alters the **ddmpx** entry point.

DSW_SELECT
Alters the **ddselect** entry point.

DSW_TCPATH
Alters the **ddrevoke** entry point.

newfunc	Specifies the new value for the device switch entry point.
oldfunc	Specifies that the old value of the device switch entry point be returned here.

Description

The **devswchg** kernel service alters the value of a device switch entry point (function pointer) after a device switch table entry has been added by the **devswadd** kernel service. The device switch entry point specified by the *type* parameter is set to the value of the *newfunc* parameter. Its previous value is returned in the memory addressed by the *oldfunc* parameter. Only one device switch entry can be altered per call.

If the **devswchg** kernel service is unsuccessful, the value referenced by the *oldfunc* parameter is not defined.

Execution Environment

The **devswchg** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
EINVAL	Indicates the *Type* command was not valid.
ENODEV	Indicates the device switch entry specified by the *devno* parameter is not defined.

List of Kernel Extension and Device Driver Management Kernel Services

devswdel Kernel Service

Purpose

Deletes a device driver entry from the device switch table.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/device.h>
```

int devswdel
(*devno***)**
dev_t *devno***;**

Parameter

Item	Description
devno	Specifies the major and minor device numbers of the device to be deleted.

Description

The **devswdel** kernel service is typically called by a device driver's **ddconfig** routine on termination to remove the device driver's entry points from the device switch table.The device switch table is a table of device switch (**devsw**) structures indexed by the device driver's major device number. The device driver interface services use this table of structures in the kernel to facilitate calling device driver routines.

The major device number portion of the *devno* parameter is used to specify the index into the device switch table for the entry to be removed. Before the device switch structure is removed, the existing entry is checked to determine if any opened device is using it.

If an opened device is currently occupying the entry to be removed, the **devswdel** service does not perform the update. Instead, it returns an **EEXIST** return code. If the removal is successful, a return code of 0 is set.

The **devswdel** service removes a device switch structure entry from the table by marking the entry as undefined and setting all of the entry point fields within the structure to a **nodev** value. As a result, any callers of the removed device driver return an **ENODEV** error code. If the specified entry is already marked undefined, the **devswdel** service returns an **ENODEV** error code.

Execution Environment

The **devswdel** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
EEXIST	Indicates that the specified device switch entry is in use and cannot be removed.
ENODEV	Indicates that the specified device switch entry is not defined.
EINVAL	Indicates that the major device number portion of the *devno* parameter exceeds the maximum permitted number of device switch entries.

Related reference
devswchg Kernel Service
devswqry Kernel Service

devswqry Kernel Service

Purpose

Checks the status of a device switch entry in the device switch table.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/device.h>int devswqry ( devno,  status,  dsdptr)
dev_t devno;
uint *status;
caddr_t *dsdptr;
```

Parameters

Item	Description
devno	Specifies the major and minor device numbers of the device to be queried.
status	Points to the status of the specified device entry in the device switch table. This parameter is passed by reference.
dsdptr	Points to device-dependent information for the specified device entry in the device switch table. This parameter is passed by reference.

Description

The **devswqry** kernel service returns the status of a specified device entry in the device switch table. The entry in the table to query is determined by the major portion of the device number specified in the *devno* parameter. The status of the entry is returned in the *status* parameter that is passed by reference on the call. If this pointer is null on entry to the **devswqry** service, then the status is not returned to the caller.

The **devswqry** service also returns the address of device-dependent information for the specified device entry in the device switch table. This address is taken from the `d_dsdptr` field for the entry and returned in the *dsdptr* parameter, which is passed by reference. If this pointer is null on entry to the **devswqry** service, then the service does not return the address from the `d_dsdptr` field to the caller.

Status Parameter Flags

The *status* parameter comprises a set of flags that can indicate the following conditions:

Item	Description
DSW_BLOCK	Device switch entry is defined by a block device driver. This flag is set when the device driver has a **ddstrategy** entry point.
DSW_CONFIG	Device driver in this device switch entry provides an entry point for configuration.
DSW_CREAD	Device driver in this device switch entry is providing a routine for character reads or raw input. This flag is set when the device driver has a **ddread** entry point.
DSW_CWRITE	Device driver in this device switch entry is providing a routine for character writes or raw output. This flag is set when the device driver has a **ddwrite** entry point.
DSW_DEFINED	Device switch entry is defined.

Item	Description
DSW_DUMP	Device driver defined by this device switch entry provides the capability to support one or more of its devices as targets for a kernel dump. This flag is set when the device driver has provided a **dddump** entry point.
DSW_MPX	Device switch entry is defined by a multiplexed device driver. This flag is set when the device driver has a **ddmpx** entry point.
DSW_OPENED	Device switch entry is in use and the device has outstanding opens. This flag is set when the device driver has at least one outstanding open.
DSW_SELECT	Device driver in this device switch entry provides a routine for handling the **select** or **poll** subroutines. This flag is set when the device driver has provided a **ddselect** entry point.
DSW_TCPATH	Device driver in this device switch entry supports devices that are considered to be in the trusted computing path and provide support for the revoke function. This flag is set when the device driver has provided a **ddrevoke** entry point.
DSW_TTY	Device switch entry is in use by a tty device driver. This flag is set when the pointer to the **d_ttys** structure is not a null character**.**
DSW_UNDEFINED	Device switch entry is not defined.

The *status* parameter is set to the **DSW_UNDEFINED** flag when a device switch entry is not in use. This is the case if either of the following are true:

- The entry has never been used. (No previous call to the **devswadd** service was made.)
- The entry has been used but was later deleted. (A call to the **devswadd** service was issued, followed by a call to the **devswdel** service.)

No other flags are set when the **DSW_UNDEFINED** flag is set.

Note: The *status* parameter must be a null character if called from the interrupt environment.

Execution Environment

The **devswqry** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates a successful operation.
EINVAL	Indicates that the major device number portion of the *devno* parameter exceeds the maximum permitted number of device switch entries.

d_free_dmamem Kernel Service

Purpose

Frees an area of memory.

Syntax

```
int d_free_dmamem(d_handle_t  device_handle, void * addr, size_t size)
```

Description

Exported, documented kernel service supported on PCI-based systems only. The **d_free_dmamem** kernel service frees the area of memory pointed to by the *addr* parameter. This area of memory must be allocated with the **d_alloc_dmamem** kernel service using the same *device_handle*, and the *addr* must be the address returned from the corresponding **d_alloc_dmamem** call. Also, the size must be the same size that was used on the corresponding **d_alloc_dmamem** call.

Note:

1. Any memory allocated in a prior **d_alloc_dmamem** call must be explicitly freed with a **d_free_dmamem** call.

2. This service can be called from the process environment only.

Parameters

Item	Description
device_handle	Indicates the dma handle.
size_t size	Specifies size of area to free.
*void * addr*	Specifies address of area to free.

Return Values

Item	Description
0	Indicates successful completion.
−1	Indicates underlying free service (xmfree or rmalloc) failed.

disable_lock Kernel Service

Purpose

Raises the interrupt priority, and locks a simple lock if necessary.

Syntax

```
#include <sys/lock_def.h>
```

```
int disable_lock ( int_pri,  lock_addr)
int int_pri;
simple_lock_t lock_addr;
```

Parameters

Item	Description
int_pri	Specifies the interrupt priority to set.
lock_addr	Specifies the address of the lock word to lock.

Description

The **disable_lock** kernel service raises the interrupt priority, and locks a simple lock if necessary, in order to provide optimized thread-interrupt critical section protection for the system on which it is executing. On a multiprocessor system, calling the **disable_lock** kernel service is equivalent to calling the **i_disable** and **simple_lock** kernel services. On a uniprocessor system, the call to the **simple_lock** service is not necessary, and is omitted. However, you should still pass a valid lock address to the **disable_lock** kernel service. Never pass a **NULL** lock address.

Execution Environment

The **disable_lock** kernel service can be called from either the process or interrupt environment.

Return Values

The **disable_lock** kernel service returns the previous interrupt priority.

Related reference
i_disable Kernel Service
simple_lock_init Kernel Service
Related information
Understanding Locking

disablement_checking_resume Kernel Service

Purpose

Indicates the end of a disabled code path that was exempted from detection of excessive interrupt disablement.

Syntax

```
#include <sys/intr.h>

void disablement_checking_resume(long prev_state)
```

Parameters

Item	Description
prev_state	Specifies the disablement detection state to be restored. This value is returned by the `disablement_checking_suspend` kernel service.

Description

The `disablement_checking_resume` service restores the disablement detection state to the value passed as *prev_state*. This service must be called after reenabling interrupts at the end of an INTMAX critical section, not within it. This is because, in the case of an INTMAX critical section, the tick counting will have been deferred by the total disablement until the moment of enablement.

This service must be used in conjunction with the `disablement_checking_suspend` kernel service, which temporarily stops disablement detection.

Note: Error checking, including that for excessive interrupt disablement, can be enabled or disabled by the `errctrl` command.

Execution Environment

The `disablement_checking_resume` service can be called from either the process or the interrupt environments.

Related reference
disablement_checking_suspend Kernel Service
Related information
errctrl command

disablement_checking_suspend Kernel Service

Purpose

Indicates the start of a disabled code path that is exempt from detection of excessive interrupt disablement.

Syntax

```
#include <sys/intr.h>

long disablement_checking_suspend(void)
```

Description

A call to the `disablement_checking_suspend` service temporarily disables the detection of excessive disablement for the duration of a portion of a critical section. For base level code, insert this call at the beginning of the exempt critical section immediately after it disables, or as soon as possible within interrupt handling code.

This service must be used in conjunction with the `disablement_checking_resume` kernel service, which resumes the prior disablement checking state.

Note: Error checking, including that for excessive interrupt disablement, can be enabled or disabled by the `errctrl` command.

Execution Environment

The `disablement_checking_suspend` service can be called from either the process or the interrupt environments. Interrupts should be at least partially disabled at the time of the call.

Return Values

The `disablement_checking_suspend` service returns the previous suspension state to the caller. This value must be passed later to the resume function, which restores that state. This enables nesting of exempt critical sections.

Related reference
disablement_checking_resume Kernel Service
Related information
errctrl command

d_map_attr Kernel Service

Purpose

Changes the attributes associated with a DMA handle.

Syntax

```
#include <sys/dma.h>
```

```
kerrno_t d_map_attr (handle, cmd, attr, attr_size)
d_handle_t handle;
ulong cmd;
void * attr;
size_t attr_size;
```

Parameters

Item	Description
handle	Indicates the unique handle returned by the **d_map_init_ext** kernel service.
cmd	Specifies one of the following flags:

D_ATTR_SET_MIN_MAPMEM
Sets the minimum amount of I/O mappable memory. This is the logical memory change and not the DMA bus memory change.

D_ATTR_SET_DES_MAPMEM
Sets the desired amount of I/O mappable memory. This is the logical memory change and not the DMA bus memory change.

Item	Description
attr	You must set this parameter to the value of **size64_t ***. This parameter sets the minimum or the desired amount of I/O mappable memory depending on the specified value of the *cmd* parameter.
attr_size	You must set this parameter to the value of **sizeof(size64_t)**. This parameter sets the minimum or the desired amount of I/O mappable memory depending on the specified value of the *cmd* parameter.

Description

The **d_map_attr** kernel service can change certain attributes of the **d_handle_t** structure in case the needs of a device driver change during runtime. For example, if a device driver needs more DMA space at runtime, it can call the **d_map_attr** kernel service to request an increase in the map space. The **d_map_attr** kernel service is not an exported kernel service, but a bus specific utility routine determined by the **d_map_init_ext** kernel service and provided to the caller through the **d_handle** structure.

Execution Environment

The **d_map_attr** kernel service can be called from the process environment at **INTBASE**. Serialization with other DMA services like the **d_map_page** service and the **d_unmap_page** service is the caller's responsibility.

Return Values

Item	Description
DMA_SUCC	Indicates a successful completion.
EINVAL_D_MAP_ATTR	Indicates that the specified *cmd* parameter is not valid.
ENOMEM_D_MAP_ATTR	Indicates that it is unable to change the minimum or desired I/O mappable memory.

d_map_clear Kernel Service

Purpose

Deallocates resources previously allocated on a **d_map_init** call.

Syntax

```
#include <sys/dma.h>

void d_map_clear (*handle)
struct d_handle *handle
```

Parameters

Item	Description
handle	Indicates the unique handle returned by the **d_map_init** kernel service.

Description

The **d_map_clear** kernel service is a bus-specific utility routine determined by the **d_map_init** service that deallocates resources previously allocated on a **d_map_init** call. This includes freeing the **d_handle** structure that was allocated by **d_map_init**.

Note: You can use the **D_MAP_CLEAR** macro provided in the **/usr/include/sys/dma.h** file to code calls to the **d_map_clear** kernel service.

d_map_disable Kernel Service

Purpose

Disables DMA for the specified handle.

Syntax

```
#include <sys/dma.h>

int d_map_disable(*handle)
struct d_handle *handle;
```

Parameters

Item	Description
handle	Indicates the unique handle returned by **d_map_init**.

Description

The **d_map_disable** kernel service is a bus-specific utility routine determined by the **d_map_init** kernel service that disables DMA for the specified *handle* with respect to the platform.

Note: You can use the **D_MAP_DISABLE** macro provided in the **/usr/include/sys/dma.h** file to code calls to the **d_map_disable** kernel service.

Return Values

Item	Description
DMA_SUCC	Indicates the DMA is successfully disabled.

Item	Description
DMA_FAIL	Indicates the DMA could not be explicitly disabled for this device or bus.

d_map_enable Kernel Service

Purpose

Enables DMA for the specified handle.

Syntax

```
#include <sys/dma.h>
```

```
int d_map_enable(*handle)
struct d_handle *handle;
```

Parameters

Item	Description
handle	Indicates the unique handle returned by **d_map_init**.

Description

The **d_map_enable** kernel service is a bus-specific utility routine determined by the **d_map_init** kernel service that enables DMA for the specified *handle* with respect to the platform.

Note: You can use the **D_MAP_ENABLE** macro provided in the **/usr/include/sys/dma.h** file to code calls to the **d_map_enable** kernel service.

Return Values

Item	Description
DMA_SUCC	Indicates the DMA is successfully enabled.
DMA_FAIL	Indicates the DMA could not be explicitly enabled for this device or bus.

d_map_init Kernel Service

Purpose

Allocates and initializes resources for performing DMA with PCI and ISA devices.

Syntax

```
#include <sys/dma.h>

struct d_handle* d_map_init (bid, flags, bus_flags, channel)
int bid;
int flags;
int bus_flags;
uint channel;
```

Parameters

Item	Description
bid	Specifies the bus identifier.
flags	Describes the mapping.
bus_flags	Specifies the target bus flags.
channel	Indicates the *channel* assignment specific to the bus.

Description

The **d_map_init** kernel service allocates and initializes resources needed for managing DMA operations and returns a unique *handle* to be used on subsequent DMA service calls. The *handle* is a pointer to a **d_handle** structure allocated by **d_map_init** from the pinned heap for the device. The device driver uses the function addresses provided in the *handle* for accessing the DMA services specific to its host bus. The **d_map_init** service returns a **DMA_FAIL** error when resources are unavailable or cannot be allocated.

The *channel* parameter is the assigned channel number for the device, if any. Some devices and or buses might not have the concept of *channels*. For example, an ISA device driver would pass in its assigned DMA channel in the *channel* parameter.

Note: The possible flag values for the *flags* parameter can be found in **/usr/include/sys/dma.h**. These flags can be logically ORed together to reflect the desired characteristics.

Execution Environment

The **d_map_init** kernel service should only be called from the process environment.

Return Values

Item	Description
DMA_FAIL	Indicates that the resources are unavailable. No registration was completed.
struct d_handle *	Indicates successful completion.

Related reference

d_unmap_page Kernel Service
d_map_list Kernel Service
d_map_disable Kernel Service

d_map_init_ext Kernel Service

Purpose

Allocates and initializes resources for performing DMA with PCI and VDEVICE devices.

Syntax

```
#include <sys/types.h>
#include <sys/dma.h>
#include <sys/kerrno.h>
```

```
kerrno_t d_map_init_ext (dma_input, info_size, handle_ptr)
d_info_t * dma_input;
size_t info_size;
d_handle_t * handle_ptr;
```

Parameters

Item	Description
dma_input	Contains information like the bus identifier, flags, and so on.
info_size	Specifies the size of the *dma_input* parameter in bytes.
handle_ptr	Contains the DMA handle returned upon success.

Description

The **d_map_init_ext** kernel service is very similar to the **d_map_init** kernel service. Unlike the **d_map_init** kernel service, the input argument list of the **d_map_init_ext** kernel service is not limited and can be extended without breaking binary compatibility. Also, the **d_map_init_ext** kernel service returns a **kerrno_t** type return code which contains more RAS information rather than just the **DMA_FAIL** value.

The caller of the **d_map_init_ext** kernel service initializes the **d_info_t** structure and passes it into the **d_map_init_ext** kernel service by reference. The size of the **d_info_t** type must match the *info_size* parameter. This allows future expansion of the **d_info_t** type safely. If there is a size mismatch, the **d_map_init_ext** kernel service fails. The **d_map_init_ext** kernel service also creates a new private pool of I/O memory entitlement that can be used for DMA. The private pool is created by carving out a chunk of total I/O memory entitlement for the AIX partition. Thus, in order to create a **d_handle_t** type successfully, there must be sufficient DMA PCI space and I/O memory entitlement.

The following structure is defined in the **sys/dma.h** file:

```
#define DMA_MAX_MAPPER_NAME     32
typedef struct d_info
{
    uint64_t    di_bid;
    uint64_t    di_flags;
    uint64_t    di_bus_flags;
    uint64_t    di_channel;
    uint64_t    di_min_mapmem;
    uint64_t    di_des_mapmem;
    uint64_t    di_max_mapmem;
    char        di_mapper_name[DMA_MAX_MAPPER_NAME];
} d_info_t;
```

Note: The first four fields of the **d_info_t** type match the four arguments of the **d_map_init** kernel service. Therefore, all flags and bus_flags on the **d_map_init** kernel service are honored by the **d_map_init_ext** kernel service except the *DMA_MAXMIN_** flags. The *DMA_MAXMIN_** flags are replaced with the *di_min_mapmem*, *di_des_mapmem*, and *di_max_mapmem* fields. They not only specify the required amount of DMA space, but also the necessary I/O memory entitlement for the device.

The *di_min_mapmem* parameter is the minimum amount of memory that the driver must be able to map for DMA in order to ensure the forward progress. The **d_map_init_ext** kernel service fails if the minimum I/O memory entitlement requirement cannot be satisfied.

The *di_des_mapmem* parameter is the required amount of memory that the driver wants to be able to I/O map in order to have good throughput. In most cases, this is a value that a driver specifies through the *DMA_MAXMIN_** flag.

The *di_max_mapmem* parameter is the maximum amount of memory that the driver can ever map for DMA. This is the amount of DMA space that the **d_map_init_ext** kernel service can allocate.

Note: While the I/O memory entitlement for a **d_handle_t** type can be changed at runtime through the **d_map_attr** kernel service, the DMA space cannot be changed dynamically.

The *di_mapper_name* parameter contains the name of the device instance using the DMA resources (for example, ent0, scsi1, and so on).

Execution Environment

The **d_map_init_ext** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful completion.
struct d_handle *	Indicates a successful completion.
ENOMEM_D_MAP_INIT_EXT_1	Indicates that the memory allocation failed. An AIX error is logged.
ENOMEM_D_MAP_INIT_EXT_2	Cannot reserve I/O memory entitlement with the least amount specified by the *di_min_mapmem* parameter. An AIX error is logged.
ENOMEM_D_MAP_INIT_EXT_3	Cannot allocate enough DMA space. An AIX error is logged.
EINVAL_D_MAP_INIT_EXT_1	Indicates that some input argument is not valid. An AIX error is logged in some cases.
EINVAL_D_MAP_INIT_EXT_2	Indicates that the combination of input arguments and system configuration is not valid. No AIX error is logged.
EINVAL_D_MAP_INIT_EXT_3	Indicates that the RAS initialization failed. No AIX error is logged.

d_map_clear Kernel Service
d_unmap_page Kernel Service
d_map_list Kernel Service

d_map_list Kernel Service

Purpose

Performs platform-specific DMA mapping for a list of virtual addresses.

Syntax

```
#include <sys/dma.h>
```

```
int d_map_list (*handle, flags, minxfer, *virt_list, *bus_list)
struct d_handle *handle;
int flags;
int minxfer;
struct dio *virt_list;
struct dio *bus_list;
```

Note: The following is the interface definition for **d_map_list** when the **DMA_ADDRESS_64** and **DMA_ENABLE_64** flags are set on the **d_map_init** call.

```
int d_map_list (*handle, flags, minxfer, *virt_list, *bus_list)
struct d_handle *handle;
int flags;
int minxfer;
struct dio_64 *virt_list;
struct dio_64 *bus_list;
```

Parameters

Item	Description
handle	Indicates the unique handle returned by the **d_map_init** kernel service.

Item	Description
flags	Specifies one of the following flags:

    DMA_READ
        Transfers from a device to memory.

    BUS_DMA
        Transfers from one device to another device.

    DMA_BYPASS
        Do not check page access.

    DMA_STMAP
        Indicates a short-term mapping.

Item	Description
minxfer	Specifies the minimum transfer size for the device.
virt_list	Specifies a list of virtual buffer addresses and lengths.
bus_list	Specifies a list of bus addresses and lengths.

Description

The **d_map_list** kernel service is a bus-specific utility routine determined by the **d_map_init** kernel service that accepts a list of virtual addresses and sizes and provides the resulting list of bus addresses. This service fills out the corresponding bus address list for use by the device in performing the DMA transfer. This service allows for scatter/gather capability of a device and also allows the device to combine multiple requests that are contiguous with respect to the device. The lists are passed via the **dio** structure. If the **d_map_list** service is unable to complete the mapping due to exhausting the capacity of the provided **dio** structure, the **DMA_DIOFULL** error is returned. If the **d_map_list** service is unable to complete the mapping due to exhausting resources required for the mapping, the **DMA_NORES** error is returned. In both of these cases, the *bytes_done* field of the **dio** virtual list is set to the number of bytes successfully mapped. This byte count is a multiple of the *minxfer* size for the device as provided on the call to **d_map_list**. The *resid_iov* field is set to the index of the remaining *d_iovec* fields in the list. Unless the **DMA_BYPASS** flag is set, this service verifies access permissions to each page. If an access violation is encountered on a page with the list, the **DMA_NOACC** error is returned, and the *bytes_done* field is set to the number of bytes preceding the faulting *iovec*. If the mapping is for short term (that is, it is unmapped as soon as the I/O is complete), you must set the **DMA_STMAP** flag.

Note:

1. When the **DMA_NOACC** return value is received, no mapping is done, and the bus list is undefined. In this case, the *resid_iov* field is set to the index of the *d_iovec* that encountered the access violation.

2. You can use the **D_MAP_LIST** macro provided in the **/usr/include/sys/dma.h** file to code calls to the **d_map_list** kernel service.

Return Values

Item	Description
DMA_NORES	Indicates that resources were exhausted during mapping.

Note: d_map_list possible partial transfer was mapped. Device driver may continue with partial transfer and submit the remainer on a subsequent **d_map_list** call, or call **d_unmap_list** to undo the partial mapping. If a partial transfer is issued, then the driver must call **d_unmap_list** when the I/O is complete.

Item	Description
DMA_DIOFULL	Indicates that the target bus list is full.

Note: d_map_list possible partial transfer was mapped. Device driver may continue with partial transfer and submit the remainder on a subsequent **d_map_list** call, or call **d_unmap_list** to undo the partial mapping. If a partial transfer is issued, then the driver must call **d_unmap_list** when the I/O is complete.

Item	Description
DMA_NOACC	Indicates no access permission to a page in the list.

.

Note: d_map_list no mapping was performed. No need for the device driver to call **d_unmap_list**, but the driver must fail the faulting I/O request, and resubmit any remainder in a subsequent **d_map_list** call.

Item	Description
DMA_SUCC	Indicates that the entire transfer successfully mapped.

Note: d_map_list successful mapping was performed. Device driver must call **d_unmap_list** when the I/O is complete. In the case of a long-term mapping, the driver must call **d_unmap_list** when the long-term mapping is no longer needed.

d_map_init Kernel Service
d_map_init_ext Kernel Service

d_map_page Kernel Service

Purpose

Performs platform-specific DMA mapping for a single page.

Syntax

```
#include <sys/dma.h>
#include <sys/xmem.h>

int d_map_page(*handle, flags, baddr, *busaddr, *xmp)
struct d_handle *handle;
int flags;
caddr_t baddr;
uint *busaddr;
struct xmem *xmp;
```

Note: The following is the interface definition for **d_map_page** when the **DMA_ADDRESS_64** and **DMA_ENABLE_64** flags are set on the **d_map_init** call.

```
int d_map_page(*handle, flags, baddr, *busaddr, *xmp)
struct d_handle *handle;
int flags;
unsigned long long baddr;
unsigned long long *busaddr;
struct xmem *xmp;
```

Parameters

Item	Description
handle	Indicates the unique handle returned by the **d_map_init** kernel service.

Item	Description
flags	Specifies one of the following flags:

DMA_READ
Transfers from a device to memory.

BUS_DMA
Transfers from one device to another device.

DMA_BYPASS
Do not check page access.

DMA_STMAP
Indicates a short-term mapping.

Item	Description
baddr	Specifies the buffer address.
busaddr	Points to the *busaddr* field.
xmp	Cross-memory descriptor for the buffer.

Description

The **d_map_page** kernel service is a bus-specific utility routine determined by the **d_map_init** or **d_map_init_ext** kernel service that performs platform specific mapping of a single 4KB or less transfer for DMA master devices. The **d_map_page** kernel service is a fast-path version of the **d_map_list** service. The entire transfer amount must fit within a single page in order to use this service. This service accepts a virtual address and completes the appropriate bus address for the device to use in the DMA transfer. Unless the **DMA_BYPASS** flag is set, this service also verifies access permissions to the page. If the mapping is for short term (that is, it is unmapped as soon as the I/O is complete), you must set the **DMA_STMAP** flag.

If the buffer is a global kernel space buffer, the cross-memory descriptor can be set to point to the exported **GLOBAL** cross-memory descriptor, *xmem_global*.

If the transfer is unable to be mapped due to resource restrictions, the **d_map_page** service returns **DMA_NORES**. If the transfer is unable to be mapped due to page access violations, this service returns **DMA_NOACC**.

Note: You can use the **D_MAP_PAGE** macro provided in the **/usr/include/sys/dma.h** file to code calls to the **d_map_page** kernel service.

Return Values

Item	Description
DMA_NORES	Indicates that resources are unavailable.

Note: d_map_page no mapping is done, device driver must wait until resources are freed and attempt the **d_map_page** call again.

Item	Description
DMA_NOACC	Indicates no access permission to the page.

Note: d_map_page no mapping is done, device driver must fail the corresponding I/O request.

Item	Description
DMA_SUCC	Indicates that the *busaddr* parameter contains the bus address to use for the device transfer.

Note: d_map_page successful mapping was done, device driver must call **d_unmap_page** when I/O is complete, or when device driver is finished with the mapped area in the case of a long-term mapping.

d_map_query Kernel Service

Purpose

Queries the amount of direct memory access (DMA) space or DMA windows available on the partition end point. To use full 64-bit DMA all device drivers must call the **d_map_query** kernel service before attempting to initialize a new DMA window or before attempting to allocate DMA space within an existing DMA window by using the **d_map_init_ext** kernel service. Device drivers that do not use full 64-bit DMA should not call this service.

Syntax

```
#include <sys/types.h>
#include <sys/dma.h>
#include <sys/kerrno.h>
```

```
kerrno_t d_map_query(bid, slot, flags, cmd, dq_info)
uint64_t  bid;
uint64_t  slot;
uint64_t  flags;
uint64_t  cmd;
void *    dq_info;
```

Parameter

Item	Description
bid	Specifies the bus identifier.
slot	Specifies the slot on the parent bus. This is the same as the **connwhere** property in the **CuDv** object class for the device.
flags	Specifies flags for the **d_map_query** kernel service. For future support, this parameter must be set to 0.
cmd	Specifies the type of query that the **d_map_query** kernel service will execute.
dq_info	Specifies the **dq_ddw_resources_t** or **dq_dma_available_t** structure based on which *cmd* parameter was defined.

Description

The **d_map_query** kernel service allows the device driver to determine the amount of DMA space available within the DMA window or the amount of DMA windows available for a particular partition end point.

The **d_map_query** kernel service Dynamic DMA Windows Query (**DDW_QUERY**) option is supported only on partition end points that support the dynamic DMA windows (**DDW_QUERY**) option. The **d_map_query** kernel service can also be used to determine the dynamic DMA windows capability of a particular partition endpoint. When a slot is initialized on a reboot or power-on operation of the partition or on a DR isolate operation that encompasses the partition endpoint, a default DMA window is always allocated for less than 4 GB. After the first call to the **d_map_query** kernel service with the **DDW_QUERY** option, the default DMA window is removed. This leaves no usable DMA window on the partition endpoint until the **d_map_init_ext** kernel service is called to initialize a new DMA window.

Note: The **DDW_QUERY** option should only be used by device drivers that fully support the 64-bit DMA.

The caller of the **d_map_query** kernel service must pass the desired command to the *cmd* parameter and have the appropriate *dq_info* parameter initialized.

The options available for the *cmd* parameter are defined in the **<sys/dma.h>** header file, and are described as follows:

DDW_QUERY
> Returns the number of additional DMA windows available for a partition endpoint. The **dq_ddw_resources_t** structure must be passed to the *dq_info* parameter for this command. The **dqdr_version** field in the structure should be assigned as **DQDR_VERSION**.

DMA_QUERY
> Returns the maximum amount of contiguous pages available for a given page size in all existing DMA windows. The **dq_dma_available_t** structure must be passed to the **dq_info** parameter for this command. The **dqda_version** field in the structure should be assigned as **DQDA_VERSION** and the corresponding I/O page size for the query must be specified. The supported I/O page size for the DMA operation can be obtained from the **d_map_query** kernel service by running the **DDW_QUERY** command.

The **dq_ddw_resources_t** and **dq_dma_available_t** structures are defined in the **<sys/dma.h>** as follows:

```
typedef struct dq_ddw_resources
    {   /* input by caller */
      uint64_t dqdr_version;
      /* returned to caller */
        uint64_t dqdr_supported_page_sizes;
        uint64_t dqdr_windows_avail;
      /* Amount of dynamic DMA windows available.
         * If DDW_QUERY, is not available
         * 0 will be returned.
      */
        uint64_t dqdr_max_pages; /* Largest number of contiguous pages available.*/
          uint64_t dqdr_rsvd1;                /* reserved for future use */
          uint64_t dqdr_rsvd2;                /* reserved for future use */
          uint64_t dqdr_rsvd3;                /* reserved for future use */
          uint64_t dqdr_rsvd4;                /* reserved for future use */
    } dq_ddw_resources_t;
    /*
     * The dq_dma_available structure is to be used in d_map_querywith the
     * DMA_QUERY cmd specified
     */
    typedef struct dq_dma_available
    {
      /*input by caller */
      uint64_t dqda_version;
      uint64_t dqda_io_page_size;
      /* Page size in bytes, should only be equal to the supported pagesize */
      /* returned to caller for DMA_Query*/
      uint64_t dqda_pages_available;
        uint64_t dqda_rsvd1;        /* reserved for future use */
        uint64_t dqda_rsvd2;        /* reserved for future use */
        uint64_t dqda_rsvd3;        /* reserved for future use */
        uint64_t dqda_rsvd4;        /* reserved for future use */
    } dq_dma_available_t;
```

Execution Environment

The **d_map_query** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Success
Kerrno	Error occurred

d_map_slave Kernel Service

Purpose

Accepts a list of virtual addresses and sizes and sets up the worker DMA controller.

Syntax

```
#include <sys/dma.h>
```

```
int d_map_slave (*handle, flags, minxfer, *vlist, chan_flag)
struct d_handle *handle;
int flags;
int minxfer;
struct dio *vlist;
uint chan_flag;
```

Parameters

Item	Description
handle	Indicates the unique handle returned by the **d_map_init** kernel service.
flags	Specifies one of the following flags:
	DMA_READ Transfers from a device to memory.
	BUS_DMA Transfers from one device to another device.
	DMA_BYPASS Do not check page access.
minxfer	Specifies the minimum transfer size for the device.
vlist	Specifies a list of buffer addresses and lengths.
chan_flag	Specifies the device and bus specific flags for the transfer.

Description

The **d_map_slave** kernel service accepts a list of virtual buffer addresses and sizes and sets up the worker DMA controller for the requested DMA transfer. This includes setting up the system address generation hardware for a specific worker channel to indicate the specified data buffers, and enabling the specific hardware channel. The **d_map_slave** kernel service is not an exported kernel service, but a bus-specific utility routine determined by the **d_map_init** kernel service and provided to the caller through the **d_handle** structure.

This service allows for scatter/gather capability of the worker DMA controller and also allows the device driver to coalesce multiple requests that are contiguous with respect to the device. The list is passed with the **dio** structure. If the **d_map_slave** kernel service is unable to complete the mapping due to resource, an error, **DMA_NORES** is returned, and the **bytes_done** field of the **dio** list is set to the number of bytes that were successfully mapped. This byte count is guaranteed to be a multiple of the *minxfer* parameter size of the device as provided to **d_map_slave**. Also, the *resid_iov* field is set to the index of the remaining *d_iovec* that could not be mapped. Unless the **DMA_BYPASS** flag is set, this service will

verify access permissions to each page. If an access violation is encountered on a page within the list, an error, **DMA_NOACC** is returned and no mapping is done. The *bytes_done* field of the virtual list is set to the number of bytes preceding the faulting *iovec*. Also in this case, the *resid_iov* field is set to the index of the *d_iovec* entry that encountered the access violation.

The virtual addresses provided in the *vlist* parameter can be within multiple address spaces, distinguished by the cross-memory structure pointed to for each element of the **dio** list. Each cross-memory pointer can point to the same cross-memory descriptor for multiple buffers in the same address space, and for global space buffers, the pointers can be set to the address of the exported GLOBAL cross-memory descriptor, *xmem_global*.

The *minxfer* parameter specifies the absolute minimum data transfer supported by the device(the device blocking factor). If the device supports a minimum transfer of 512 bytes (floppy and disks, for example), the *minxfer* parameter would be set to 512. This allows the underlying services to map partial transfers to a correct multiple of the device block size.

Note:

1. The **d_map_slave** kernel service does not support more than one outstanding DMA transfer per channel. Attempts to do multiple worker mappings on a single channel will corrupt the previous mappings.
2. You can use the **D_MAP_SLAVE** macro provided in the **/usr/include/sys/dma.h** file to code calls to the **d_map_clear** kernel service.
3. The possible flag values for the *chan_flag* parameter can be found in **/usr/include/sys/dma.h**. These flags can be logically ORed together to reflect the desired characteristics of the device and channel.
4. If the **CH_AUTOINIT** flag is used then the transfer described by the **vlist** pointer is limited to a single buffer address with a length no greater than 4K bytes.

Return Values

Item	Description
DMA_NORES	Indicates that resources were exhausted during the mapping.
DMA_NOACC	Indicates no access permission to a page in the list.
DMA_BAD_MODE	Indicates that the mode specified by the *chan_flag* parameter is not supported.

Related reference
d_map_init Kernel Service

dmp_add Kernel Service

Purpose

Specifies data to be included in a system dump by adding an entry to the master dump table. Callers should use the . This service is provided for compatibility purposes.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/dump.h>
```

```
int dmp_add
( cdt_func)
struct cdt * ( (*cdt_func) (  ));
```

Description

Kernel extensions use the **dmp_add** service to register data areas to be included in a system dump. The **dmp_add** service adds an entry to the master dump table. A master dump table entry is a pointer to a function provided by the kernel extension that will be called by the kernel dump routine when a system dump occurs. The function must return a pointer to a component dump table structure.

When a dump occurs, the kernel dump routine calls the function specified by the *cdt_func* parameter twice. On the first call, an argument of 1 indicates that the kernel dump routine is starting to dump the data specified by the component dump table. On the second call, an argument of 2 indicates that the kernel dump routine has finished dumping the data specified by the component dump table. Kernel extensions should allocate and pin their component dump tables and call the **dmp_add** service during initialization. The entries in the component dump table can be filled in later. The *cdt_func* routine must not attempt to allocate memory when it is called.

Note: In AIX Version 7.1, this function automatically serializes CDT functions with I/O during dump time. The need for this function is device specific. Only the developer of the device can determine if this routine needs to be used. It is only recommended for devices that can be on the dump I/O path. Serializing I/O during dump time might degrade dump performance. Devices that are not on the dump path must either use the **dmp_ctl** routine or the RAS system dump interface.

The Component Dump Table

The component dump table structure specifies memory areas to be included in the system dump. The structure type (**struct cdt**) is defined in the **/usr/include/sys/dump.h** file. A **cdt** structure consists of a fixed-length header (**cdt_head** structure) and an array of one or more **cdt_entry** structures. The **cdt_head** structure contains a component name field, which should be filled in with the name of the kernel extension, and the length of the component dump table. Each **cdt_entry** structure describes a contiguous data area, giving a pointer to the data area, its length, a segment register, and a name for the data area.

Use of the Formatting Routine

Each kernel extension that includes data in the system dump can install a unique formatting routine in the **/var/adm/ras/dmprtns** directory.The name of the formatting routine must match the component name field of the corresponding component dump table.

The dump image file includes a copy of each component dump table used to dump memory.A sample dump formatter is shipped with **bos.sysmgt.serv_aid** in the **/usr/samples/dumpfmt** directory.

Organization of the Dump Image File

Memory dumped for each kernel extension is laid out as follows in the dump image file. The component dump table is followed by a bitmap for the first data area, then the first data area itself, then a bitmap for the next data area, the next data area itself, and so on.

The bitmap for a specific data area indicates which pages of the data area are present in the dump image and which are not. Pages that were not in memory when the dump occurred were not dumped. The least significant bit of the first byte of the bitmap is set to 1 (one) if the first page is present. The next least significant bit indicates the presence or absence of the second page and so on.

A macro for determining the size of a bitmap is provided in the `/usr/include/sys/dump.h` file.

Parameters

Item	Description
cdt_func	Specifies a function that returns a pointer to a component dump table entry. The function and the component dump table entry both must reside in pinned global memory.

Execution Environment

The **dmp_add** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
-1	Indicates that the function pointer to be added is already present in the master dump table.

Related reference
dmp_ctl Kernel Service
Related information
exec: execl, execle, execlp, execv, execve, execvp, or exect Subroutine
RAS Kernel Services

dmp_compspec and dmp_compext Kernel Services

Purpose

Specifies a component and callback parameters to be included in the dump.

Syntax

```
#include <sys/livedump.h>
```

kerrno_t dmp_compspec (*flags*, *comp*, *anchor*, *extid*, *p1*, *p2*, **...**, **NULL**)
long *flags*;
long *comp*;
void **anchor*;
dmp_extid_t **extid*;
char **p1*;
char **p2*;
...

kerrno_t dmp_compext (*extid*, *p1*, *p2*, **...**, **NULL**)
dmp_extid_t *extid*;
char **p1*;
char **p2*;
...

Parameters

Item	Description
anchor	Points to the associated **ldmp_parms_t** data structure or to an **ldmp_prepare_t** data structure.
comp	Specifies the component, specified as indicated by the flags.

Item	Description
extid	Points to an item of **dmp_extid_t** type, for the **dmp_compspec** kernel service, where an identifier is returned, if you use the **dmp_compext** kernel service to provide additional parameters for the component being dumped. This identifier might then be specified to add additional parameters to the component using the **dmp_compext** kernel service. The *extid* parameter can be NULL.
flags	You can specify the following values:

DCF_FAILING
  Indicates that this is the failing component. You can only specify one failing component.

DCF_FIRST
  Indicates that this component is to be dumped first. Normally components are dumped in the order specified.

  Note:

  - The **DCF_FIRST** value is only valid when the anchor refers to an **ldmp_parms_t** data item. It is not valid when the callback receives the **RASCD_LDMP_PREPARE** command.
  - The last component specified to be dumped first is the one dumped first.

DCF_LEVEL0 - DCF_LEVEL9
  Indicates the detail level, 0 through 9, to dump this component. If none of these flags are set, the component is dumped at its current level.

DCF_MINIMAL
  Indicates the DCF_LEVEL1 level.

DCF_NORMAL
  Indicates the DCF_LEVEL3 level.

DCF_DETAIL
  Indicates the DCF_LEVEL7 level.

DCF_LONG
  Indicates that the parameters are two parameters of long type. Rather than passing in an unlimited number of strings, a component can be passed in two long data items, as in the case with pseudo-components.

One and only one of the following component specification flags must be given. They specify how the component is specified in the dc_component field:

DCF_BYPNAME
  Indicates that the component is specified by path name.

DCF_BYLNAME
  Indicates that the component is specified by logical alias.

DCF_BYTYPE
  Indicates that the component is specified by type.

DCF_BYCB
  Indicates that the component is specified by ras_block_t.

Item	Description
p1, p2 ...	Specifies the component's parameters, the last of which must be NULL. If keyword parameters are being specified, The parameters must be strings, and contain the keyword and its values. If multiple keyword and value pairs appear in a single parameter, they are separated with blanks. For example, the *p1* parameter can be `foo=1234`, and the *p2* parameter can be `bar=5678,16`. Also, the *p1* parameter can be `foo=1234 bar=5678`. If the **DCF_LONG** flag is set, two parameters of long type are passed in. In this case, the *p1* and *p2* parameters contain the values of long type, and no more parameters can be specified.

Description

The **dmp_compspec** and **dmp_compext** kernel services provide components and their callback parameters for a dump. You can only use these kernel services in a live dump.

The **dmp_compspec** kernel service is used before you start a live dump with the **livedump** kernel service. You can also use this kernel service when a component's callback wants to include another component in a live dump, that is, when the callback receives the **RASCD_LDMP_PREPARE** command.

Multiple components can be included in a live dump.

The **dmp_compext** function is used to provide additional parameters for a component.

Return Values

Item	Description
0	Indicates a successful completion.
EINVAL_RAS_DMP_COMPSPEC_FLAGS	Indicates that the flags specification is not valid.
EINVAL_RAS_DMP_COMPSPEC_COMP	Indicates that the component specification is not valid.
EINVAL_RAS_DMP_COMPSPEC_NOTAWARE	Indicates that the specified component must support live dump.
EINVAL_RAS_DMP_COMPSPEC_ANCHOR	Indicates that the anchor specification is not valid.
EFAULT_RAS_DMP_COMPSPEC_ANCHOR	Indicates that the storage the anchor parameter refers to is not valid.
EFAULT_RAS_DMP_COMPSPEC_EXTID	Indicates that the storage the *extid* parameter refers to is not valid.
EFAULT_RAS_DMP_COMPSPEC_PARMS	Indicates that a parameter address is not valid.
EINVAL_RAS_LDMP_ESTIMATE	Indicates that the anchor parameter indicates a dump size estimate request, but the **dmp_compspec** call was not made from the process environment.
EINVAL_RAS_DMP_COMPSPEC_NOADD	Indicates that components cannot be added to this dump, that is, the dump type flags, ldpr_flags, have the LDT_NOADD bit set.
EINVAL_RAS_DMP_COMPSPEC_FAILING	Indicates that the failing component has already been specified.
ENOMEM_RAS_DMP_COMPSPEC	Indicates that no storage is available.
EINVAL_RAS_DMP_COMPEXT_EXTID	Indicates that the *extid* parameter does not refer to a valid component.
EFAULT_RAS_DMP_COMPEXT_EXTID	Indicates that the storage the *extid* parameter refers to is not valid.
EFAULT_RAS_DMP_COMPEXT_PARMS	Indicates that the storage a parameter refers to is not valid.
EBUSY_RAS_DMP_COMPEXT	Indicates that the specification of this component is complete, and no more parameters can be added. This happens if the component the *extid* parameter referred to has already completed its **RASCD_LDMP_PREPARE** processing.
ENOMEM_RAS_DMP_COMPEXT	Indicates that no storage is available.

dmp_ctl Kernel Service

Purpose

Adds and removes entries to the master dump table.

Syntax

```
#include <sys/types.h>
    #include <errno.h>
    #include <sys/dump.h>

    int dmp_ctl(op, parmp)
    int op;
    struct dmpctl_data *parmp;
```

Description

The **dmp_ctl** kernel service is used to manage dump routines. It replaces the **dmp_add** and **dmp_del** kernel services which are still supported for compatibility reasons. The major differences between routines added with the **dmp_add()** command and those added with the **dmp_ctl()** command are:

- The routines are invoked differently from routines added with the **dmp_add** kernel service. Routines added using the **dmp_ctl** kernel service return a void pointer, to a dump table or to a dump size estimate.

- Routines added with the **dmp_ctl** kernel service are expected to ignore functions they don't support. For example, they should not trap if they receive an unrecognized request. This allows future functionality to be added without all users needing to change.

The **dmp_ctl** kernel service is used to request that an amount of memory be set aside in a global buffer. This will then be used by the routine to store data not resident in memory. An example of such data is dump data provided by an adapter. Without a global buffer, the data would need to be placed into a pinned buffer allocated at configuration time. Each component would need to allocate its own pinned buffer.

The system dump facility maintains a global buffer for such data. This buffer is allocated when it is first requested, with the requested size. Another dump routine requesting more data causes the buffer to be reallocated with the larger size. Since this buffer must be maintained in pinned storage for the life of the system, only ask for as much memory as is required. Asking for an excessive amount of storage will compromise system performance by reserving too much pinned storage.

Any dump routine using the global buffer is called whenever dump data is required. Routines are only called once to provide such data. Their dump table addresses are saved and used if the dump is restarted.

Note: The **dmp_ctl** kernel service can also be used by a dump routine to report a routine failure. This may be necessary if the routine detects that it can't dump what needs to be dumped for some reason such as corruption of a data structure.

Note: Beginning with AIX Version 6.1 with the 6100-02 Technology Level, the **dmp_ctl** kernel service supports that DMPFUNC_SERIALIO operation flag.

Dump Tables

A dump routine returns a component dump table that begins with DMP_MAGIC, which is the magic number for the 32- or 64-bit dump table. If the unlimited sized dump table is used, the magic number is DMP_MAGIC_U and the **cdt_u** structure is used. If this is the case, the dump routine is called repeatedly

until it returns a null **cdt_u** pointer. The purpose of the unlimited size dump table is to provide a way to dump an unknown number of data areas without having to preallocate the largest possible array of **cdt_entry** elements as is required for the classic dump table. The definitions for dump tables are in the **sys/dump.h** include file.

Parameters

dmp_ctl operations and the **dmpctl_data** structure are defined in the **dump.h** text file.

Item	Description
op	Specifies the operation to perform.

parmp	Points to a **dmpctl_data** structure containing values for the specified operation. The **dmpctl_data** structure is defined in the **/usr/include/sys/dump.h** file as follows:
	
	 ``
	/* Dump Routine failures data. */
	struct __rtnf {
	        int rv; /* error code. */
	        ulong vaddr; /* address. */
	        vmhandle_t handle; /* handle */
	};
	
	typedef void *((*__CDTFUNCENH)(int op, void *buf));
	struct dmpctl_data {
	        int dmpc_magic; /* magic number */
	        int dmpc_flags; /* dump routine flags. */
	        __CDTFUNCENH dmpc_func;
	        union {
	                u_longlong_t bsize; /* Global buffer size requested. */
	                struct __rtnf rtnf;
	        } dmpc_u;
	};
	#define DMPC_MAGIC1 0xdcdcdc01
	#define DMPC_MAGIC DMPC_MAGIC1
	#define dmpc_bsize dmpc_u.bsize
	#define dmpcf_rv dmpc_u.rtnf.rv
	#define dmpcf_vaddr dmpc_u.rtnf.vaddr
	#define dmpcf_handle dmpc_u.rtnf.handle
	``

The supported operations and their associated data are:

Item	Description
DMPCTL_ADD	Adds the specified dump routine to the master dump table. This requires a pointer to the function and function type flags. Supported type flags are: **DMPFUNC_CALL_ON_RESTART** Calls this function again if the dump is restarted. A dump function is only called once to provide dump data. If the function must be called and the dump is restarted on the secondary dump device, then this flag must be set. The **DMPFUNC_CALL_ON_RESTART** flag must be set if this function uses the global dump buffer. It also must be set if the function uses an unlimited size dump table, a table with DMP_MAGIC_U as the magic number. **DMPFUNC_GLOBAL_BUFFER** This function uses the global dump buffer. The size is specified using the **dmpc_bsize** field. **DMPFUNC_SERIALIO** Enables serialized I/O during dump time. The need for this flag is device specific. Only the developer of the device can determine if this flag needs to be set. It is only recommended for devices that can be on the dump I/O path. Serializing I/O during dump time can degrade dump performance. The default, without this flag, is to allow I/O to occur in parallel with CDT function calls.

Item	Description
DMPCTL_DEL	Deletes the specified dump function from the master dump table.
DMPCTL_RTNFAILURE	Reports an inability to dump required data. The routine must set the dmpc_func, dmpcf_rV, dmpcf_vaddr, and dmpcf_handle fields.

Dump function invocation parameters:

Item	Description
operation code	Specifies the operation the routine is to perform. Operation codes are: **DMPRTN_START** The dump is starting for this dump table. Provide data. **DMPRTN_DONE** The dump is finished. This call is provided so that a dump routine can do any cleanup required after a dump. This is specific to a device for which information was gathered. It does not free memory, since such memory must be allocated before the dump is taken. **DMPRTN_AGAIN** Provide more data for this unlimited dump table. The routine must have first passed back a dump table beginning with DMP_MAGIC_U. When finished, the function must return a NULL. **DMPRTN_ESTIMATE** Provide a size estimate. The function must return a pointer to an item of type dmp_sizeest_t. See the examples later in this article.
buffer pointer	This is a pointer to the global buffer, or NULL if no global buffer space was requested.

Return Values

Item	Description
0	Returned if successful.
EINVAL	Returned if one or more parameter values are invalid.
ENOMEM	Returned if the global buffer request can't be satisfied.
EEXIST	Returned if the dump function has already been added.

Examples

1. To add a dump routine (dmprtn) that can be called once to provide data, type:

```
void *dmprtn(int op, void *buf);
        struct cdt cdt;
        dmp_sizeest_t estimate;

        config()
        {
                struct dmpctl_data parm;
                ...

                parm.dmpc_magic = DMPC_MAGIC1;
                parm.dmpc_func = dmprtn;
                parm.dmpc_flags = 0;
                ret = dmp_ctl(DMPCTL_ADD, &parm);

                ...
        }

        /*
         * Dump routine.
```

```
 *
 * input:
 *    op - dump routine operation.
 *    buf - NULL since no global buffer is used.
 *
 * returns:
 *    A pointer to the component dump table.
 */
void *
dmprtn(int op, void *buf)
{
        void *ret;

        switch(op) {
        case DMPRTN_START: /* Provide dump data. */
                ...
                ret = (void *)&cdt;
                break;
        case DMPRTN_ESTIMATE:
                ret = (void *)&estimate;
                break;
        default:
                        break;
        }

        return(ret);
}
```

2. To add a dump routine (dmprtn) that requests 16 kb of global buffer space, type:

```
...
        #define BSIZ 16*1024
        dmp_sizeest_t estimate;

        config()
        {
                ...
                parm.dmpc_magic = DMPC_MAGIC1;
                parm.dmpc_func = dmprtn;
                parm.dmpc_flags = DMPFUNC_CALL_ON_RESTART|DMPC_GLOBAL_BUFFER;
                parm.dmpc_bsize = BSIZ;
                ret = dmp_ctl(DMPCTL_ADD, &parm);
                ...
        }

        /*
         * Dump routine.
         *
         * input:
         *    op - dump routine operation.
         *    buf - points to the global buffer.
         *
         * output:
         *    Return a pointer to the dump table or to the estimate.
         */
        void *
        dmprtn(int op, void *buf)
        {
                void *ret;

                switch(op) {
                case DMPRTN_START: /* Provide dump data. */
                        ...
                        (Put data in buffer at buf.)
                        ret = (void *)&cdt;
                        break;
                case DMPRTN_ESTIMATE:
                        ret = (void *)&estimate;
                        break;
                default:
                                break;
                }

                return(ret);
        }
```

Related reference
dmp_del Kernel Service

dmp_del Kernel Service

Purpose

Deletes an entry from the master dump table. Callers should use the "dmp_ctl Kernel Service" on page 99. This service is provided for compatibility purposes.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/dump.h>
```

dmp_del (*cdt_func_ptr*)
struct cdt * ((**cdt_func_ptr*) ( ));

Description

Kernel extensions use the **dmp_del** kernel service to unregister data areas previously registered for inclusion in a system dump. A kernel extension that uses the "dmp_add Kernel Service" on page 94 to register such a data area can use the **dmp_del** service to remove this entry from the master dump table.

Parameters

Item	Description
cdt_func_ptr	Specifies a function that returns a pointer to a component dump table. The function and the component dump table must both reside in pinned global memory.

Execution Environment

The **dmp_del** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
-1	Indicates that the function pointer to be deleted is not in the master dump table.

dmp_eaddr, dmp_context, dmp_tid, dmp_pid, dmp_errbuf, dmp_mtrc, dmp_systrace, and dmp_ct Kernel Services

Purpose

Provides functions for common dump tasks.

Syntax

```
#include <sys/dump.h>
```

kerrno_t dmp_eaddr (*flags*, *anchor*, *name*, *addr*, *sz*)
long *flags*;
void **anchor*;
char **name*;
long *addr*;
long *sz*;

kerrno_t dmp_context (*flags*, *anchor*, *name*, *ctx_type*, *p2*)
long *flags*;
void **anchor*;
char **name*;
long *ctx_type*;
long *p2*;

kerrno_t dmp_tid (*flags*, *anchor*, *name*, *tid*, *unused*)
long *flags*;
void **anchor*;
char **name*;
tid_t *tid*;
void **unused*;

kerrno_t dmp_pid (*flags*, *anchor*, *name*, *pid*, *unused*)
long *flags*;
void **anchor*;
char **name*;
pid_t *pid*;
void **unused*;

kerrno_t dmp_errbuf (*flags*, *anchor*, *name*, *erridx*, *unused*)
long *flags*;
void **anchor*;
char **name*;
ulong *erridx*;
long *unused*;

kerrno_t dmp_mtrc (*flags*, *anchor*, *name*, *com_sz*, *rare_sz*)
long *flags*;
void **anchor*;
char **name*;
size_t *com_sz*;
size_t *rare_sz*;

```
kerrno_t dmp_systrace (flags, anchor, name, sz, unused)
long flags;
void *anchor;
char *name;
long sz;
long unused;

kerrno_t dmp_ct (flags, anchor, name, rasb, sz)
long flags;
void *anchor;
char *name;
ras_block_t rasb;
size_t sz;
```

Parameters

Item	Description
anchor	Points to the associated **ldmp_parms_t** data structure or to an **ldmp_prepare_t** data structure.
flags	The *flags* parameter can be one or more of the following values: **DCF_FIRST** Specifies that this component is to be dumped first. Normally components are dumped in the order specified. **Note:** The last component specified to be dumped first is the one dumped first. **DCF_LEVEL0 - DCF_LEVEL9** Dumps the component at the specified detail level, 0 through 9. If none of these flags are set, the component is dumped at CD_LVL_NORMAL, detail level 3.
name	Specifies the name of the pseudo-component's dump table in the dump. The *name* parameter is only valid for the **dmp_eaddr** kernel service. You must specify the *name* parameter to NULL for the **dmp_context**, **dmp_tid**, **dmp_pid**, **dmp_errbuf**, **dmp_mtrc**, **dmp_systrace**, and **dmp_ct** kernel services.
unused	You must specify this parameter to NULL or 0.
The remaining parameters are pseudo-component dependent: **dmp_eaddr***addr*	Specifies the effective address of the memory to be dumped.
sz	Specifies the length of the memory in bytes.

Item	Description
dmp_context*ctx_type*	Specifies the context to dump. It can be one of the following values:

DMP_CTX_CUR
To dump the current context.

DMP_CTX_PREV
To dump the previous context.

DMP_CTX_SPEC
To dump the context specified by the *p2* parameter. The *p2* parameter must contain the address of the **ksmtsave** structure for the context.

DMP_CTX_RWA
To dump the context from the supplied recovery work area. The *p2* parameter must contain the address of the recovery work area, rwa.

DMP_CTX_BID or DMP_CTX_LCPUID
To dump the context for the processor specified by the *p2* parameter. You can specify the processor either by the bind ID or by the logical ID.

DMP_CTX_TID
To dump the context of the thread specified by the *p2* parameter, which must contain the thread ID.

Item	Description
p2	Specifies the address of the context, the logical processor ID, the bind ID, or the thread ID dependent on the value of the *ctx_type* parameter.
dmp_tid*tid*	Specifies the ID of the thread to dump.
dmp_pid*pid*	Specifies the ID of the process to dump.
dmp_errbuf*erridx*	Specifies the kernel workload partition (WPAR) ID of the partition's error logging buffer to dump. The value of 0 stands for the global buffer.
dmp_mtrc*com_sz*	Specifies the amount of common to dump.
rare_sz	Specifies the amount of rare data to dump.
dmp_systrace*sz*	Specifies the amount of system trace data to dump.If the *sz* parameter is set to 0, all the buffered trace data is dumped, up to the amount allowed by the detail level.
dmp_ct*rasb*	Specifies the ras_block_t of the component whose component trace is to be dumped.
sz	Specifies the amount of data to dump. If the *sz* parameter is set to 0, all the components' trace data is dumped, up to the limit for the detail level.

Description

The **dmp_eaddr** kernel service dumps memory by effective address.

The **dmp_context** kernel service dumps the specified thread context.

The **dmp_tid** kernel service dumps the kernel data for a thread.

The **dmp_pid** kernel service dumps the kernel data for a process.

The **dmp_errbuf** kernel service dumps the error logging buffer for the specified partition.

The **dmp_mtrc** kernel service dumps entries from the lightweight memory trace buffers.

The **dmp_systrace** dumps entries from the system trace buffers.

The **dmp_ct** dumps component trace entries.

Execution Environment

The **dmp_eaddr**, **dmp_context**, **dmp_tid**, **dmp_pid**, **dmp_errbuf**, **dmp_mtrc**, **dmp_systrace**, and **dmp_ct** kernel services can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates a successful completion.
EINVAL_DMP_PSEUDO	Indicates that the name parameter is not valid.
EINVAL_DMP_CHECK_ANCHOR	Indicates that no anchor was specified, or the anchor parameter does not point to an area of **ldmp_parms_t** or **ldmp_prepare_t** type.
EFAULT_DMP_CHECK_ANCHOR	Indicates that the storage specified by the *anchor* parameter is not valid.
EINVAL_RAS_DMP_COMPSPEC_FLAGS	Indicates that the flags specification is not valid. This error also occurs if the **DCF_FIRST** flag is specified when the anchor is an **ldmp_prepare_t** data item.
EINVAL_RAS_DMP_COMPSPEC_NOADD	Indicates that components cannot be added to this dump.
ENOMEM_RAS_DMP_COMPSPEC	Indicates that the storage is not sufficient.
EINVAL_RAS_DMP_EADDR	Indicates that the flags parameter is not valid.
EINVAL_RAS_DMP_CONTEXT	Indicates that the parameter of the **dmp_context** kernel service is not valid. This is also returned if the *p2* parameter is not used, but is not NULL.
ENOENT_RAS_DMP_CONTEXT_CTX_NOTFOUND	Indicates that the specified context was not found.
EFAULT_RAS_DMP_CONTEXT	Indicates that the storage the specified context pointer points to is not valid.
EINVAL_RAS_DMP_TID	Indicates that the parameter of the **dmp_tid** kernel service is not valid.
EINVAL_RAS_DMP_PID	Indicates that the parameter of the **dmp_pid** kernel service is not valid.
EINVAL_RAS_DMP_ERRBUF	Indicates that the parameter of the **dmp_errbuf** kernel service is not valid.
ECHRNG_RAS_DMP_ERRBUF	Indicates that the *erridx* parameter is out of range.
EINVAL_RAS_DMP_MTRC	Indicates that the parameter of the **dmp_mtrc** kernel service is not valid.
ENOENT_RAS_DMP_MTRC	Indicates that the lightweight memory trace is not active.
EINVAL_RAS_DMP_SYSTRACE	Indicates that the parameter of the **dmp_systrace** kernel service is not valid.
ENOENT_RAS_DMP_SYSTRACE	Indicates that the system trace is not active.
EINVAL_RAS_DMP_CT	Indicates that the parameter of the **dmp_ct** kernel service is not valid.
ENOMEM_RAS_DMP_CT	Indicates that the storage is not sufficient.
EINVAL_RAS_DMP_CT_GETPATH	Indicates that the specified component is not valid.
EINVAL_RAS_DMP_CT_LOOKUP	Indicates that an error occurred while this component was being validated.
ENOTSUP_RAS_DMP_CT	Indicates that the specified component does not have a component trace.

Related Information

The **livedump** kernel service and **dmp_kernext** kernel service.

Related reference
livedump Kernel Service
dmp_kernext Kernel Service

dmp_kernext Kernel Service

Purpose

Causes the specified kernel extension to be shipped with the live dump for symbol resolution.

Syntax

```
#include <sys/dump.h>
```

```
kerrno_t dmp_kernext (anchor, ptr)void *anchor;
void *ptr;
```

Parameters

Item	Description
anchor	Points to either an **ldmp_parms_t** or **ldmp_prepare_t** structure.
ptr	Specifies an address within the kernel extension. If the value is 0, the dump includes information for all loaded kernel extensions.

Description

The **dmp_kernext** kernel service causes snap to package the specified kernel extension with the current live dump. This also includes loader information for the extension in the dump. You can specify the extension by setting the *ptr* parameter to a text or data address within the extension. The extension's file name is noted in the dump, and snap can be used to cause this file to be bundled with the snap data when the dump is collected for sending to IBM®.

Execution Environment

The **dmp_kernext** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates a successful completion.
EINVAL_RAS_DMP_KERNEXT	Indicates that the *anchor* parameter is not valid.

snap subroutine

d_roundup Kernel Service

Purpose

Rounds the value length up to a given number of cache lines.

Syntax

```
int  d_roundup(length)
```

```
int  length;
```

Parameter

Item	Description
length	Specifies the size in bytes to be rounded.

Description

To maintain cache consistency, buffers must occupy entire cache lines. The **d_roundup** service helps provide that function by rounding the value length up to a given number in integer form.

Execution Environment

The **d_roundup** service can be called from either the process or interrupt environment.

Understanding Direct Memory Access (DMA) Transfers

d_sync_mem Kernel Service

Purpose

Allows a device driver to indicate that previously mapped buffers may need to be refreshed.

Syntax

```
int d_sync_mem(d_handle_t handle, dio_t blist)
```

Description

The **d_sync_mem** service allows a device driver to indicate that previously mapped buffers may need to be refreshed, either because a new DMA is about to start or a previous DMA has now completed. **d_sync_mem** is not an exported kernel service, but a bus-specific utility determined by **d_map_init** based on platform characteristics and provided to the caller through the *d_handle* structure. **d_sync_mem** allows the driver to identify additional coherency points beyond those of the initial mapping (**d_map_list**) and termination of the mapping (**d_unmap_list**). Thus **d_sync_mem** provides a way to long-term map buffers and still handle potential data consistency problems.

The *blist* parameter is a pointer to the **dio** structure that describes the initial mapping, as returned by **d_map_list**. Note that for bounce buffering, the data direction is also implicitly defined by this initial mapping.

- If the **map_list** call describes a transfer from system memory to a device, subsequent **d_sync_mem** calls using the corresponding *blist* will synchronize the memory view. This assumes that the original system memory pages contain the correct data.

- If the **map_list** call describes a transfer from a device to system memory, then subsequent **d_sync_mem** calls will synchronize the memory view. This assumes that the bounce pages the device directly accessed contained the correct data.

Note: You can use the **D_SYNC_MEM** macro provided in the **/usr/include/sys/dma.h** file to code calls to the **d_sync_mem** kernel service.

Parameters

Item	Description
d_handle_t	Indicates the unique dma handle returned by **d_map_init**.
dio_t blist	List of vectors returned by original **d_map_list**.

Return Values

Item	Description
DMA_SUCC	Buffers described by the *blist* have been synchronized.
DMA_FAIL	Buffers could not be synchronized.

DTOM Macro for mbuf Kernel Services

Purpose

Converts an address anywhere within an **mbuf** structure to the head of that **mbuf** structure.

Syntax

```
#include <sys/mbuf.h>
```

DTOM (*bp*);

Parameter

Item	Description
bp	Points to an address within an **mbuf** structure.

Description

The **DTOM** macro converts an address anywhere within an **mbuf** structure to the head of that **mbuf** structure. This macro is valid only for **mbuf** structures without an external buffer (that is, with the **M_EXT** flag not set).

This macro can be viewed as the opposite of the **MTOD** macro, which converts the address of an **mbuf** structure into the address of the actual data contained in the buffer. However, the **DTOM** macro is more general than this view implies. That is, the input parameter can point to any address within the **mbuf** structure, not merely the address of the actual data.

Example

The **DTOM** macro can be used as follows:

```
char             *bp;
struct mbuf      *m;
m = DTOM(bp);
```

MTOD Macro for mbuf Kernel Services
Related information
I/O Kernel Services

d_unmap_list Kernel Service

Purpose

Deallocates resources previously allocated on a **d_map_list** call.

Syntax

```
#include <sys/dma.h>

void d_unmap_list (*handle, *bus_list)
struct d_handle *handle
struct dio *bus_list
```

Note: The following is the interface definition for **d_unmap_list** when the **DMA_ADDRESS_64** and **DMA_ENABLE_64** flags are set on the **d_map_init** call.

```
void d_unmap_list (*handle,
*bus_list)
struct d_handle *handle;
struct dio_64 *bus_list;
```

Parameters

Item	Description
handle	Indicates the unique handle returned by the **d_map_init** kernel service.
bus_list	Specifies a list of bus addresses and lengths.

Description

The **d_unmap_list** kernel service is a bus-specific utility routine determined by the **d_map_init** kernel service that deallocates resources previously allocated on a **d_map_list** call.

The **d_unmap_list** kernel service must be called after I/O completion involving the area mapped by the prior **d_map_list** call. Some device drivers might choose to leave pages mapped for a long-term mapping of certain memory buffers. In this case, the driver must call **d_unmap_list** when it no longer needs the long-term mapping.

Note: You can use the **D_UNMAP_LIST** macro provided in the **/usr/include/sys/dma.h** file to code calls to the **d_unmap_list** kernel service. If not, you must ensure that the **d_unmap_list** function pointer is non-**NULL** before attempting the call. Not all platforms require the unmapping service.

Related reference
d_map_init Kernel Service
d_map_list Kernel Service

d_unmap_slave Kernel Service

Purpose

Deallocates resources previously allocated on a **d_map_slave** call.

Syntax

```
#include <sys/dma.h>
```

```
int d_unmap_slave (*handle)
struct d_handle *handle;
```

Parameters

Item	Description
handle	Indicates the unique handle returned by the **d_map_init** kernel service.

Description

The **d_unmap_slave** kernel service deallocates resources previously allocated on a **d_map_slave** call, disables the physical DMA channel, and returns error and status information following the DMA transfer. The **d_unmap_slave** kernel service is not an exported kernel service, but a bus-specific utility routine that is determined by the **d_map_init** kernel service and provided to the caller through the **d_handle** structure.

Note: You can use the **D_UNMAP_SLAVE** macro provided in the **/usr/include/sys/dma.h** file to code calls to the **d_unmap_slave** kernel service. If not, you must ensure that the **d_unmap_slave** function pointer is non-**NULL** before attempting to call. No all platforms require the unmapping service.

The device driver must call **d_unmap_slave** when the I/O is complete involving a prior mapping by the **d_map_slave** kernel service.

Note: The **d_unmap_slave** kernel should be paired with a previous **d_map_slave** call. Multiple outstanding worker DMA transfers are not supported. This kernel service assumes that there is no DMA in progress on the affected channel and deallocates the current channel mapping.

Return Values

Item	Description
DMA_SUCC	Indicates successful transfer. The DMA controller did not report any errors and that the Terminal Count was reached.
DMA_TC_NOTREACHED	Indicates a successful partial transfer. The DMA controller reported the Terminal Count reached for the intended transfer as set up by the **d_map_slave** call. Block devices consider this an erro; however, for variable length devices this may not be an error.
DMA_FAIL	Indicates that the transfer failed. The DMA controller reported an error. The device driver assumes the transfer was unsuccessful.

d_unmap_page Kernel Service

Purpose

Deallocates resources previously allocated on a **d_unmap_page** call.

Syntax

```
#include <sys/dma.h>

void d_unmap_page (*handle, *busaddr)
struct d_handle *handle
uint *busaddr
```

Note: The following is the interface definition for **d_unmap_page** when the **DMA_ADDRESS_64** and **DMA_ENABLE_64** flags are set on the **d_map_init** call.

```
int d_unmap_page(*handle,
*busaddr)
struct d_handle *handle;
unsigned long long *busaddr;
```

Parameters

Item	Description
handle	Indicates the unique handle returned by the **d_map_init** kernel service.

Item	Description
busaddr	Points to the *busaddr* field.

Description

The **d_unmap_page** kernel service is a bus-specific utility routine determined by the **d_map_init** kernel service that deallocates resources previously allocated on a **d_map_page** call for a DMA master device.

The **d_unmap_page** service must be called after I/O completion involving the area mapped by the prior **d_map_page** call. Some device drivers might choose to leave pages mapped for a long-term mapping of certain memory buffers. In this case, the driver must call **d_unmap_page** when it no longer needs the long-term mapping.

Note: You can use the **D_UNMAP_PAGE** macro provided in the **/usr/include/sys/dma.h** file to code calls to the **d_unmap_page** kernel service. If not, you must ensure that the **d_unmap_page** function pointer is non-**NULL** before attempting the call. Not all platforms require the unmapping service.

dr_reconfig System Call

Purpose

Determines the nature of the DLPAR request.

Syntax

```
#include <sys/dr.h>

int dr_reconfig (flags, dr_info)
int flags;
dr_info_t *dr_info;
```

Description

The **dr_reconfig** system call is used by DLPAR-aware applications to adjust their use of resources in relation to a DLPAR request. Applications are notified about the usage through the **SIGRECONFIG** signal, which is generated three times for each DLPAR event.

The first time is to check with the application whether the DLPAR event should be continued. Using the **DR_EVENT_FAIL** flag, an application can indicate that the operation should be aborted, if it is not DLPAR-safe and its operation is considered vital to the system.

The application is notified the second time before the resource is added or removed, and the third time afterwards. Applications must attempt to control their scheduling priority and policy to guarantee timely delivery of signals. The system does not guarantee that every signal that is sent is delivered before advancing to the next step in the algorithm.

The **dr_reconfig** system call can also be used to notify applications about the changes to the workload partition that they are running. Applications are notified about changes to the CPU, memory capacity, and resources set.

The **dr_reconfig** interface is signal-handler safe and can be used by multi-threaded programs.

The **dr_info** structure is declared within the address space of the application. The kernel fills out data in this structure relative to the current DLPAR request. The user passes this structure identifying the current DLPAR request, as a parameter to the kernel when the **DR_RECONFIG_DONE** flag is used. The **DR_RECONFIG_DONE** flag is used by the application to notify the kernel that necessary action to adjust their use of resources has been taken in response to the **SIGRECONFIG** signal sent to them. It is expected that the signal handler associated with the **SIGRECONFIG** signal calls the interface with the **DR_QUERY** flag to identify the phase of the DLPAR event, takes the appropriate action, and calls the interface with the **DR_RECONFIG_DONE** flag to indicate to the kernel that the signal has been handled.

This type of acknowledgment to the kernel in each of the DLPAR phases enables a DLPAR event to perform efficiently.

With the addition of new fields to the **dr_info** structure, DR-aware applications can support the Micro-Partitioning® feature.

The *bindproc*, *softpset*, and *hardpset* bits are only set, if the request is to remove a cpu. If the *bindproc* is set, the process or one of its threads has a **bindprocessor** attachment, which must be resolved. If the *softpset* bit is set, the process has a Workload Manager (WLM) attachment, which can be changed by calling the appropriate WLM interface or by invoking the appropriate WLM command. If the *hardpset* bit is set, the appropriate **pset** API must be used.

Note: The *bcpu* and *lcpu* fields identify the cpu being removed and do not necessarily indicate that the process has a dependency that must be resolved. The *bindproc*, *softpset*, and *hardpset* bits are provided for that purpose.

The *plock* and *pshm* bits are only set, if the request is to remove memory and the process has **plock** memory or is attached to a pinned shared memory segment. If the *plock* bit is set, the process calls**plock** to unpin itself. If the *pshm* bit is set, the application has pinned shared memory segments, which may need to be detached. The memory remove request can succeed in any case, if there is enough pinnable memory in the system, so an action in this case is not necessarily required. The field *sys_pinnable_frames* provides this information, however, this value and other statistical values are just approximations. They reflect the state of the system at the time of the request. They are not updated during the request. The current size of physical memory can be determined by referencing the *_system_configuration.physmem* field.

To provide support for virtual real memory related DR operations, a new field, *dr_op*, has been added to the **dr_info** structure. The *dr_op* field provides information about the current DR operation. Additionally, all future DR operations use this field and the previously used resource bits will no longer be extended.

dr_wlm_info Structure

```
typedef struct dr_wlm_info {
        unsigned int cpu_add : 1; // cpu wlm resource add for the WPAR
        unsigned int cpu_rem : 1; // cpu wlm resource remove for the WPAR
        unsigned int mem_add : 1; // memory wlm resource add for the WPAR
        unsigned int mem_rem : 1; // memory wlm resource remove for the WPAR
        unsigned int rs_cpu  : 1; // wlm cpu rset change for the WPAR
        unsigned int rs_mem  : 1; // wlm memory rset change for the WPAR
        unsigned int pad1    : 2; // un-used
        unsigned int cpu_cap : 8; // percentage of cpu capacity of the WPAR
        unsigned int mem_cap : 8; // percentage of the memory capacity of the WPAR
        unsigned int pad2    : 8; // un-used
} dr_wlm_info_t;
```

dr_info Structure

```
typedef struct dr_info {
    unsigned int add : 1;      // add request
                 rem : 1;      // remove request
                 cpu : 1;      // target resource is a cpu
                 mem : 1;      // target resource is memory
               check : 1;      // check phase in effect
                 pre : 1;      // pre phase in effect
                post : 1;      // post phase in effect
            posterror : 1;     // post error phase in effect
               force : 1;      // force option is in effect
            bindproc : 1;      // process has bindprocessor dependency
            softpset : 1;      // process has WLM software partition dependency
            hardpset : 1;      // process has processor set API dependency
               plock : 1;      // process has plock'd memory
                pshm : 1;      // process has pinned shared memory
             ent_cap : 1;      // target resource:entitled capacity
             var_wgt : 1;      // target resource:variable weight
       splpar_capable : 1;     // 1/0 partition is/not splpar capable
        splpar_shared : 1;     // 1/0 partition shared/dedicated mode
        splpar_capped : 1;     // 1/0 partition capped/uncapped mode
     splpar_constrained : 1;   // Set to 1 if requested capacity
                                  update is constrained by PHYP to
                                  be within partition capacity bounds.
                            //
```

```
        unsigned int migrate : 1;      // migration operation
        unsigned int hibernate : 1;     // hibernation operation
        unsigned int partition : 1;     // resource is partition
        unsigned int topology_update : 1;    // topology update

        // The following fields are filled out for cpu based requests
        int lcpu;                // logical cpu ID being added or removed
        int bcpu;                // bind cpu ID being added or removed

        // The following fields are filled out for memory based requests
        size64_t  req_memsz_change;      // User request size in bytes
        size64_t  sys_memsz;             // System Memory size at time of request
        rpn64_t   sys_free_frames;       // Number of free frames in the system
        rpn64_t   sys_pinnable_frames;   // Number of pinnable frames in system
        rpn64_t   sys_total_frames;      // Total number of frames in system

        // SPLPAR parameters.
        uint64_t  capacity;              // partition current entitled capacity
                                         //     if ent_cap bit is set, partition's
                                         //     current variable capacity weight
                                         //     if var_wgt bit is set.
                                      //

        int      delta_cap;              // delta capacity added/removed to
                                         //     current value depending on add/rem
                                         //     bit flag value above
                                      //
        dr_wlm_info_t   dr_wlm;      // DR info for the WPAR
        ushort        dr_op;      // type of DR operation

        ushort        dr_pad;      // reserved pad field
        size64_t       mem_capacity; // partition's entitled
 I/O memory or variable capacity.
        ssize64_t   delta_mem_capacity; // amount of I/O being added/removed

        int  reserved[2];

 } dr_info_t;
```

Parameters

Item	Description
flags	The following values are supported:
	DR_QUERY Identifies the current DLPAR request and the actions that the application must take to comply with the current DLPAR request. This information is returned to the caller in the structure identified by the *dr_info* parameter.
	DR_EVENT_FAIL Fail the current DLPAR event. Root authority is required.
	DR_RECONFIG_DONE This flag is used with the **DR_QUERY** flag. The application notifies the kernel that the actions it took to comply with the current DLPAR request are now complete. The **dr_info** structure identifying the DLPAR request that was returned is passed as an input parameter.
dr_info	Contains the address of a **dr_info** structure, which is declared with the address space of the application.

Return Values

Upon success, the **dr_reconfig** system call returns a zero. If unsuccessful, it returns negative one and sets the **errno** variable to the appropriate error value.

Error Codes

Item	Description
EINVAL	Invalid flags.
ENXIO	No DLPAR event in progress.
EPERM	Root authority required for DR_EVENT_FAIL.
EINPROGRESS	Cancellation of DLPAR event may only occur in the check phase.

Related information

Making Programs DLPAR-Aware Using DLPAR APIs

e

The following kernel services begin with the with the letter e.

e_assert_wait Kernel Service

Purpose

Asserts that the calling kernel thread is going to sleep.

Syntax

```
#include <sys/sleep.h>
```

```
void e_assert_wait ( event_word,  interruptible)
tid_t *event_word;
boolean_t interruptible;
```

Parameters

Item	Description
event_word	Specifies the shared event word. The kernel uses the *event_word* parameter as the anchor to the list of threads waiting on this shared event.
interruptible	Specifies if the sleep is interruptible.

Description

The **e_assert_wait** kernel service asserts that the calling kernel thread is about to be placed on the event list anchored by the *event_word* parameter. The *interruptible* parameter indicates wether the sleep can be interrupted.

This kernel service gives the caller the opportunity to release multiple locks and sleep atomically without losing the event should it occur. This call is typically followed by a call to either the **e_clear_wait** or **e_block_thread** kernel service. If only a single lock needs to be released, then the **e_sleep_thread** kernel service should be used instead.

The **e_assert_wait** kernel service has no return values.

Execution Environment

The **e_assert_wait** kernel service can be called from the process environment only.

Related reference
e_clear_wait Kernel Service
e_sleep_thread Kernel Service
Related information
Process and Exception Management Kernel Services

e_block_thread Kernel Service

Purpose

Blocks the calling kernel thread.

Syntax

```
#include <sys/sleep.h>
```

```
int e_block_thread ()
```

Description

The **e_block_thread** kernel service blocks the calling kernel thread. The thread must have issued a request to sleep (by calling the **e_assert_wait** kernel service). If it has been removed from its event list, it remains runnable.

Execution Environment

The **e_block_thread** kernel service can be called from the process environment only.

Return Values

The **e_block_thread** kernel service return a value that indicate how the thread was awakened. The following values are defined:

Item	Description
THREAD_AWAKENED	Denotes a normal wakeup; the event occurred.
THREAD_INTERRUPTED	Denotes an interruption by a signal.
THREAD_TIMED_OUT	Denotes a timeout expiration.
THREAD_OTHER	Delineates the predefined system codes from those that need to be defined at the subsystem level. Subsystem should define their own values greater than or equal to this value.

Related reference
e_assert_wait Kernel Service
Related information
Process and Exception Management Kernel Services

e_clear_wait Kernel Service

Purpose

Clears the wait condition for a kernel thread.

Syntax

```
#include <sys/sleep.h>
```

void e_clear_wait (*tid*, *result***)**
tid_t *tid*;
int *result*;

Parameters

Item	Description
tid	Specifies the kernel thread to be awakened.
result	Specifies the value returned to the awakened kernel thread. The following values can be used:

THREAD_AWAKENED
Usually generated by the **e_wakeup** or **e_wakeup_one** kernel service to indicate a normal wakeup.

THREAD_INTERRUPTED
Indicates an interrupted sleep. This value is usually generated by a signal delivery when the **INTERRUPTIBLE** flag is set.

THREAD_TIMED_OUT
Indicates a timeout expiration.

THREAD_OTHER
Delineates the predefined system codes from those that need to be defined at the subsystem level. Subsystem should define their own values greater than or equal to this value.

Description

The **e_clear_wait** kernel service clears the wait condition for the kernel thread specified by the *tid* parameter, and the thread is made runnable.

This kernel service differs from the **e_wakeup**, **e_wakeup_one**, and **e_wakeup_w_result** kernel services in the fact that it assumes the identity of the thread to be awakened. This kernel service should be used to handle exceptional cases, where a special action needs to be taken. The *result* parameter is used to specify the value returned to the awakened thread by the **e_block_thread** or **e_sleep_thread** kernel service.

The **e_clear_wait** kernel service has no return values.

Execution Environment

The **e_clear_wait** kernel service can be called from either the process environment or the interrupt environment.

e_wakeup, e_wakeup_one, or e_wakeup_w_result Kernel Service
e_block_thread Kernel Service
Related information
Process and Exception Management Kernel Services

e_sleep Kernel Service

Purpose

Forces the calling kernel thread to wait for the occurrence of a shared event.

Syntax

#include <sys/types.h> #include <sys/errno.h> #include <sys/sleep.h> int e_sleep (*event_word*, *flags***) tid_t ****event_word***; int** *flags***;**

Parameters

Item	Description
event_word	Specifies the shared event word. The kernel uses the *event_word* parameter to anchor the list of processes sleeping on this event. The *event_word* parameter must be initialized to **EVENT_NULL** before its first use.
flags	Specifies the flags that control action on occurrence of signals. These flags can be found in the **/usr/include/sys/sleep.h** file. The *flags* parameter is used to control how signals affect waiting for an event. The following flags are available to the **e_sleep** service:

EVENT_SIGRET
  Indicates the termination of the wait for the event by an unmasked signal. The return value is set to **EVENT_SIG**.

EVENT_SIGWAKE
  Indicates the termination of the event by an unmasked signal. This flag results in the transfer of control to the return from the last **setjmpx** service with the return value set to **EINTR**.

EVENT_SHORT
  Prohibits the wait from being terminated by a signal. This flag should only be used for short, guaranteed-to-wakeup sleeps.

Description

The **e_sleep** kernel service is used to wait for the specified shared event to occur. The kernel places the current kernel thread on the list anchored by the *event_word* parameter. This list is used by the **e_wakeup** service to wake up all threads waiting for the event to occur.

The anchor for the event list, the *event_word* parameter, must be initialized to **EVENT_NULL** before its first use. Kernel extensions must not alter this anchor while it is in use.

The **e_wakeup** service does not wake up a thread that is not currently sleeping in the **e_sleep** function. That is, if an **e_wakeup** operation for an event is issued before the process calls the **e_sleep** service for the event, the thread still sleeps, waiting on the next **e_wakeup** service for the event. This implies that routines using this capability must ensure that no timing window exists in which events could be missed due to the **e_wakeup** service being called before the **e_sleep** operation for the event has been called.

Note: The **e_sleep** service can be called with interrupts disabled only if the event or lock word is pinned.

Execution Environment

The **e_sleep** kernel service can be called from the process environment only.

Return Values

Item	Description
EVENT_SUCC	Indicates a successful operation.

Item	Description
EVENT_SIG	Indicates that the **EVENT_SIGRET** flag is set and the wait is terminated by a signal.

Related reference
e_sleepl Kernel Service
e_wakeup, e_wakeup_one, or e_wakeup_w_result Kernel Service
Related information
Process and Exception Management Kernel Services

e_sleepl Kernel Service

Purpose

Forces the calling kernel thread to wait for the occurrence of a shared event.

Syntax

#include <sys/types.h> #include <sys/errno.h> #include <sys/sleep.h> int e_sleepl (*lock_word***,** *event_word***,** *flags***) int ****lock_word***; tid_t ****event_word***; int** *flags***;**

Parameters

Item	Description
lock_word	Specifies the lock word for a conventional process lock.
event_word	Specifies the shared event word. The kernel uses this word to anchor the list of kernel threads sleeping on this event. This event word must be initialized to **EVENT_NULL** before its first use.
flags	Specifies the flags that control action on occurrence of a signal. These flags are found in the **/usr/include/sys/sleep.h** file.

Description

Note: The **e_sleepl** kernel service is provided for porting old applications written for previous versions of the operating system. Use the **e_sleep_thread** kernel service when writing new applications.

The **e_sleepl** kernel service waits for the specified shared event to occur. The kernel places the current kernel thread on the list anchored by the *event_word* parameter. The **e_wakeup** service wakes up all threads on the list.

The **e_wakeup** service does not wake up a thread that is not currently sleeping in the **e_sleepl** function. That is, if an **e_wakeup** operation for an event is issued before the thread calls the **e_sleepl** service for the event, the thread still sleeps, waiting on the next **e_wakeup** operation for the event. This implies that routines using this capability must ensure that no timing window exists in which events could be missed due to the **e_wakeup** service being called before the **e_sleepl** service for the event has been called.

The **e_sleepl** service also unlocks the conventional lock specified by the *lock_word* parameter before putting the thread to sleep. It also reacquires the lock when the thread wakes up.

The anchor for the event list, specified by the *event_word* parameter, must be initialized to **EVENT_NULL** before its first use. Kernel extensions must not alter this anchor while it is in use.

Note: The **e_sleepl** service can be called with interrupts disabled, only if the event or lock word is pinned.

Values for the flags Parameter

The *flags* parameter controls how signals affect waiting for an event. There are three flags available to the **e_sleepl** service:

Item	Description
EVENT_SIGRET	Indicates the termination of the wait for the event by an unmasked signal. The return value is set to EVENT_SIG.
EVENT_SIGWAKE	Indicates the termination of the event by an unmasked signal. This flag also indicates the transfer of control to the return from the last **setjmpx** service with the return value set to **EINTR**.
EVENT_SHORT	Indicates that signals cannot terminate the wait. Use the **EVENT_SHORT** flag for only short, guaranteed-to-wakeup sleeps.

Note: The **EVENT_SIGRET** flag overrides the **EVENT_SIGWAKE** flag.

Execution Environment

The **e_sleepl** kernel service can be called from the process environment only.

Return Values

Item	Description
EVENT_SUCC	Indicates successful completion.
EVENT_SIG	Indicates that the **EVENT_SIGRET** flag is set and the wait is terminated by a signal.

Interrupt Environment

e_sleep_thread Kernel Service

Purpose

Forces the calling kernel thread to wait for the occurrence of a shared event.

Syntax

```
#include <sys/sleep.h>
```

int e_sleep_thread (*event_word*, *lock_word*, *flags*)
tid_t *event_word;
void *lock_word;
int *flags*;

Parameters

Item	Description
event_word	Specifies the shared event word. The kernel uses the *event_word* parameter as the anchor to the list of threads waiting on this shared event.
lock_word	Specifies simple or complex lock to unlock.
flags	Specifies lock and signal handling options.

Description

The **e_sleep_thread** kernel service forces the calling thread to wait until a shared event occurs. The kernel places the calling thread on the event list anchored by the *event_word* parameter. This list is used by the **e_wakeup**, **e_wakeup_one**, and **e_wakeup_w_result** kernel services to wakeup some or all threads waiting for the event to occur.

A lock can be specified; it will be unlocked when the kernel service is entered, just before the thread blocks. This lock can be a simple or a complex lock, as specified by the *flags* parameter. When the kernel service exits, the lock is re-acquired.

Flags

The *flags* parameter specifies options for the kernel service. Several flags can be combined with the bitwise OR operator. They are described below.

The four following flags specify the lock type. If the *lock_word* parameter is not **NULL**, exactly one of these flags must be used.

Flag	Description
LOCK_HANDLER	*lock_word* specifies a simple lock protecting a thread-interrupt or interrupt-interrupt critical section.
LOCK_SIMPLE	*lock_word* specifies a simple lock protecting a thread-thread critical section.
LOCK_READ	*lock_word* specifies a complex lock in shared-read mode.
LOCK_WRITE	*lock_word* specifies a complex lock in exclusive write mode.

The following flag specify the signal handling. By default, while the thread sleeps, signals are held pending until it wakes up.

Item	Description
INTERRUPTIBLE	The signals must be checked while the kernel thread is sleeping. If a signal needs to be delivered, the thread is awakened.

Return Values

The **e_sleep_thread** kernel service return a value that indicate how the kernel thread was awakened. The following values are defined:

Item	Description
THREAD_AWAKENED	Denotes a normal wakeup; the event occurred.
THREAD_INTERRUPTED	Denotes an interruption by a signal. This value can be returned even if the **INTERRUPTIBLE** flag is not set since it may be also generated by the **e_clear_wait** or **e_wakeup_w_result** kernel services.
THREAD_TIMED_OUT	Denotes a timeout expiration. The **e_sleep_thread** has no timeout. However, the **e_clear_wait** or **e_wakeup_w_result** kernel services may generate this return value.
THREAD_OTHER	Delineates the predefined system codes from those that need to be defined at the subsystem level. Subsystem should define their own values greater than or equal to this value.

Execution Environment

The **e_sleep_thread** kernel service can be called from the process environment only.

et_post Kernel Service

Purpose

Notifies a kernel thread of the occurrence of one or more events.

Syntax

#include <sys/types.h> #include <sys/errno.h> #include <sys/sleep.h> void et_post (*events*, *tid***)
unsigned long** *events*; **tid_t** *tid***;**

Parameters

Item	Description
events	Identifies the masks of events to be posted.
tid	Specifies the thread identifier of the kernel thread to be notified.

Description

The **et_post** kernel service is used to notify a kernel thread that one or more events occurred.

The **et_post** service provides the fastest method of interprocess communication, although only the event numbers are passed.

The event numbers must be known by the cooperating components, either through programming convention or the passing of initialization parameters.

The **et_post** service is performed automatically when sending a request to a device queue serviced by a kernel thread or when sending an acknowledgment.

The **EVENT_KERNEL** mask defines the event bits reserved for use by the kernel. For example, a bit with a value of 1 indicates an event bit reserved for the kernel. Kernel extensions should assign their events starting with the most significant bits and working down. If threads using the **et_post** service are also using the device queue management kernel extensions, care must be taken not to use the event bits registered for device queue management.

The **et_wait** service does not sleep but returns immediately if a specified event has already been posted by the **et_post** service.

Execution Environment

The **et_post** kernel service can be called from either the process or interrupt environment.

Return Values

The **et_post** service has no return values.

et_wait Kernel Service

Purpose

Forces the calling kernel thread to wait for the occurrence of an event.

Syntax

#include <sys/types.h> #include <sys/errno.h> #include <sys/sleep.h> unsigned long et_wait (_wait_mask_, _clear_mask_, _flags_) unsigned long _wait_mask_**; unsigned long** _clear_mask_**; int** _flags_**;**

Parameters

Item	Description
_wait_mask_	Specifies the mask of events to await.
_clear_mask_	Specifies the mask of events to clear.
flags	Specifies the flags controling actions on occurrence of a signal.
	The _flags_ parameter is used to control how signals affect waiting for an event. There are two flag values:

EVENT_SIGRET
Causes the wait for the event to be ended by an unmasked signal and the return value set to **EVENT_SIG**.

EVENT_SIGWAKE
Causes the event to be ended by an unmasked signal and control transferred to the return from the last **setjmpx** call, with the return value set to **EXSIG**.

EVENT_SHORT
Prohibits the wait from being terminated by a signal. This flag should only be used for short, guaranteed-to-wakeup sleeps.

Note: The **EVENT_SIGRET** flag overrides the **EVENT_SIGWAKE** flag.

Description

The **et_wait** kernel service forces the calling kernel thread to wait for specified events to occur.

The _wait_mask_ parameter indicates a mask, where each bit set equal to 1 represents an event for which the thread must wait. The _clear_mask_ parameter indicates a mask of events that must clear when the wait is complete. Subsequent calls to the **et_wait** service return immediately unless you clear the bits, which ends the wait.

Note: The **et_wait** service can be called with interrupts disabled only if the event or lock word is pinned.

Strategies for Using et_wait

Calling the **et_wait** kernel service with the **EVENT_SIGRET** flag clears the the pending events field when the signal is received. If **et_wait** is called again by the same kernel thread, the thread waits indefinitely for an event that has already occurred. When this happens, the thread does not run to completion. This problem occurs only if the event and signal are posted at the same time.

To avoid this problem, use one of the following programming methods:

- Use the **EVENT_SHORT** flag to prevent signals from waking the thread up.
- Mask signals prior to the call of **et_wait** by using the limit_sigs kernel service. Then call **et_wait**. Invoke the sigprocmask call to restore the signal mask by using the mask returned previously by limit_sigs.

The **et_wait** service is also used to clear events without waiting for them to occur. This is accomplished by doing one of the following:

- Set the *wait_mask* parameter to **EVENT_NDELAY**.
- Set the bits in the *clear_mask* parameter that correspond with the events to be cleared to 1.

Because the **et_wait** service returns an event mask indicating those events that were actually cleared, these methods can be used to poll the events.

Execution Environment

The **et_wait** kernel service can be called from the process environment only.

Return Values

Upon successful completion, the **et_wait** service returns an event mask indicating the events that terminated the wait. If an **EVENT_NDELAY** value is specified, the returned event mask indicates the pending events that were cleared by this call. Otherwise, it returns the following error code:

Item	Description
EVENT_SIG	Indicates that the **EVENT_SIGRET** flag is set and the wait is terminated by a signal.

Process and Exception Management Kernel Services

e_wakeup, e_wakeup_one, or e_wakeup_w_result Kernel Service

Purpose

Notifies kernel threads waiting on a shared event of the event's occurrence.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/sleep.h>
```

void e_wakeup (*event_word*)
tid_t **event_word*;

void e_wakeup_one (*event_word*)
tid_t **event_word*;

void e_wakeup_w_result (*event_word*, *result*)
tid_t **event_word*;
int *result*;

Parameters

Item	Description
event_word	Specifies the shared event designator. The kernel uses the *event_word* parameter as the anchor to the list of threads waiting on this shared event.

Item	Description
result	Specifies the value returned to the awakened kernel thread. The following values can be used:

    THREAD_AWAKENED
        Indicates a normal wakeup. This is the value automatically generated by the
        e_wakeup or **e_wakeup_one** kernel services.

    THREAD_INTERRUPTED
        Indicates an interrupted sleep. This value is usually generated by a signal delivery
        when the **INTERRUPTIBLE** flag is set.

    THREAD_TIMED_OUT
        Indicates a timeout expiration.

    THREAD_OTHER
        Delineates the predefined system codes from those that need to be defined at the
        subsystem level. Subsystem should define their own values greater than or equal
        to this value.

Description

The **e_wakeup** and **e_wakeup_w_result** kernel services wake up all kernel threads sleeping on the event list anchored by the *event_word* parameter. The **e_wakeup_one** kernel service wakes up only the most favored thread sleeping on the event list anchored by the *event_word* parameter.

When threads are awakened, they return from a call to either the **e_block_thread** or **e_sleep_thread** kernel service. The return value depends on the kernel service called to wake up the threads (the wake-up kernel service):

- **THREAD_AWAKENED** is returned if the **e_wakeup** or **e_wakeup_one** kernel service is called
- The value of the *result* parameter is returned if the **e_wakeup_w_result** kernel service is called.

If a signal is delivered to a thread being awakened by one of the wake-up kernel services, and if the thread specified the **INTERRUPTIBLE** flag, the signal delivery takes precedence. The thread is awakened with a return value of **THREAD_INTERRUPTED**, regardless of the called wake-up kernel service.

The **e_wakeup** and **e_wakeup_w_result** kernel services set the *event_word* parameter to **EVENT_NULL**.

The **e_wakeup**, **e_wakeup_one**, and **e_wakeup_w_result** kernel services have no return values.

Execution Environment

The **e_wakeup**, **e_wakeup_one**, and **e_wakeup_w_result** kernel services can be called from either the process environment or the interrupt environment.

When called by an interrupt handler, the *event_word* parameter must be located in pinned memory.

Process and Exception Management Kernel Services

e_wakeup_w_sig Kernel Service

Purpose

Posts a signal to sleeping kernel threads.

Syntax

```
#include <sys/sleep.h>
```

void e_wakeup_w_sig (*event_word,* *sig***)**
tid_t **event_word;*
int *sig;*

Parameters

Item	Description
event_word	Specifies the shared event word. The kernel uses the *event_word* parameter as the anchor to the list of threads waiting on this shared event.
sig	Specifies the signal number to post.

Description

The **e_wakeup_w_sig** kernel service posts the signal *sig* to each kernel thread sleeping interruptible on the event list anchored by the *event_word* parameter.

The **e_wakeup_w_sig** kernel service has no return values.

Execution Environment

The **e_wakeup_w_sig** kernel service can be called from either the process environment or the interrupt environment.

Process and Exception Management Kernel Services

eeh_broadcast Kernel Service

Purpose

This service is provided for device drivers to coordinate activities during an EEH event.

Syntax

```
void eeh_broadcast(handle, message)
eeh_handle_t    handle;
unsigned long long message;
```

Parameters

Item	Description
handle	EEH handle obtained from **eeh_init** or **eeh_init_multifunc**
message	User- or kernel-defined message

Description

Because single-function drivers do not have a need for coordination, this service is intended for multifunction drivers only. If a single-function driver calls it, it is a NOP. There are two kinds of messages that can be sent among the drivers: kernel-defined messages (such as EEH_DD_SUSPEND and EEH_DD_DEAD) and the user-defined messages. See **sys/eeh.h** for help on how to define user messages. Kernel messages have a higher priority than user messages. Therefore, if user messages and kernel messages are both pending, the kernel messages are sent out before the user messages.

Note: Device drivers should only broadcast their own messages (that is, the user-defined message) and not the kernel messages.

Within the kernel messages, EEH_DD_DEAD has the highest priority. Multiple messages of the same kind may or may not be coalesced depending upon the relative timing. Messages are sent by invoking the callback routines. The callback routines are invoked sequentially but not in any specific order except that the last driver to receive a message will have the EEH_MASTER flag set to indicate that all other drivers have finished processing the message. Only one message is broadcast at a time—that is, all registered callback routines are called sequentially with the same message before moving on to the next message. Finally, they are invoked asynchronously at INTIODONE priority. Because they are broadcast asynchronously, a device driver must not assume on a specific timeout within which the message would arrive.

The macro **EEH_BROADCAST**(*handle*, *message*) is provided for device drivers to call this service.

Execution Environment

This kernel service can be called from the process or interrupt environment.

Return Values

This service has no return value.

eeh_enable_slot Kernel Service
eeh_init_multifunc Kernel Service
eeh_slot_error Kernel Service

eeh_clear Kernel Service

Purpose

This service unregisters a slot for an EEH function and removes resources allocated by the **eeh_init** or **eeh_init_multifunc** kernel service.

Syntax

```
#include <sys/eeh.h>

void eeh_clear(handle)
eeh_handle_t handle;
```

Parameters

Item	Description
handle	EEH handle obtained from the **eeh_init** or **eeh_init_multifunc** kernel services

Description

Single-function Drivers: This service disables EEH function on the slot and frees its **eeh_handle**.

Multifunction Drivers: For a multifunction adapter driver, this service removes the driver from a list of registered drivers under the same parent bus. This service also disables EEH function on the slot if this is the last driver to unregister and the state of the slot is NORMAL.

All device drivers are required to call **eeh_clear** before being removed from the system, so that there are no hot plug conflicts. A subsequent adapter might fail in **eeh_init_multifunc()** on the slot if the **eeh_clear** kernel service has not cleared the prior device drivers on that slot. A driver can unregister at unconfigure/ unload time. The kernel checks the state of the slot when this service is called. If the slot state is neither NORMAL nor DEAD, **eeh_clear** sleeps until the state returns to one of them.

The macro **EEH_CLEAR**(*handle*) is provided for device drivers to call this service. This service is called by a function pointer in the EEH handle.

Execution Environment

This kernel service can only be called from the process environment.

Return Values

This service has no return values.

Related reference
eeh_broadcast Kernel Service

eeh_init Kernel Service

eeh_disable_slot Kernel Service

Purpose

This service disables a slot for the EEH operations.

Syntax

```
#include <sys/eeh.h>

long eeh_disable_slot(handle)
eeh_handle_t handle;
```

Parameters

Item	Description
handle	EEH handle obtained from the**eeh_init** kernel service

Description

This service disables EEH operation on a slot.

⚠ **CAUTION:** CAUTION: Disabling EEH operation on a slot is highly discouraged, because it can cause system crash or worse, data corruption.

This service can only be called by the single-function adapter drivers. If the service fails for a hardware or firmware reason, an error is logged.

Multifunction drivers call this service indirectly via **eeh_clear()**. It fails with EEH_FAIL if called directly by a multifunction driver.

The macro **EEH_DISABLE_SLOT**(*handle*) is provided for device drivers to call this service.

Execution Environment

This kernel service can be called from the process or interrupt environment.

Return Values

Item	Description
EEH_SUCC	Slot successfully disabled
EEH_FAIL	Unable to disable the slot

Related reference
eeh_enable_slot Kernel Service
eeh_read_slot_state Kernel Service
eeh_slot_error Kernel Service

eeh_enable_dma Kernel Service

Purpose

This service enables DMA operations to an adapter after an EEH event.

Syntax

```
#include <sys/eeh.h>

long eeh_enable_dma(handle)
eeh_handle_t handle;
```

Parameters

Item	Description
handle	EEH handle obtained from the**eeh_init** or **eeh_init_multifunc** kernel services

Description

When an EEH event occurs on a slot, all Direct Memory Access (DMA) operations on the slot are inhibited. This service should be called to re-enable DMA after an EEH event. This service can only be called from the dump context (that is, when the dump is in progress).

Single-function Drivers: This service enables the DMA operations on a slot. If this call fails with EEH_FAIL, an error is logged by the kernel.

Multifunction Drivers: On the multifunction adapters, the slot state must be either SUSPEND or DEBUG, and the caller must be an EEH_MASTER. This service is called only from a dump context. While a system dump is in progress, all callbacks and broadcasts are suspended, and a multifunction adapter is treated like a single-function adapter, because the system can no longer support the EEH multifunction kernel services. If the service fails, EEH_FAIL is returned. If the failure is due to hardware or firmware, an error is logged.

There are cases when this kernel service cannot succeed because of the platform state restrictions. In such a case, if a driver calls it, the service would return EEH_FAIL. This causes the slot to be

marked permanently unavailable, which is not correct because the slot can be recovered. To avoid receiving EEH_FAIL from this service, the driver should supply the EEH_ENABLE_NO_SUPPORT_RC flag at **eeh_init_multifunc()** time. If the EEH_ENABLE_NO_SUPPORT_RC flag is supplied, **eeh_enable_dma()** returns EEH_NO_SUPPORT, indicating to the drivers that they cannot collect debug data but must continue with the next step in recovery.

The macro **EEH_ENABLE_DMA**(*handle*) is provided for device drivers to call this service.

Execution Environment

This kernel service can only be called from a process or interrupt environment.

Return Values

This kernel service has no return values.

Related reference
eeh_disable_slot Kernel Service
eeh_enable_pio Kernel Service
eeh_enable_slot Kernel Service

eeh_enable_pio Kernel Service

Purpose

This kernel service enables programmed I/O (PIO or MMIO) to an adapter after an EEH event.

Syntax

```
#include <sys/eeh.h>

long eeh_enable_pio(handle)
eeh_handle_t handle;
```

Parameters

Item	Description
handle	EEH handle obtained from the **eeh_init** or **eeh_init_multifunc** kernel services

Description

When an EEH event occurs on a slot, all load and store operations (such as PIO) are inhibited. This kernel service should be called to re-enable PIO after an EEH event.

Single-function Drivers: This kernel service enables the load and store operations on a slot. If this call fails with EEH_FAIL, an error is logged by the kernel.

Multifunction Drivers: On the multifunction adapters, the state of the slot is checked for either SUSPEND or DEBUG. The caller must be an EEH_MASTER. If the state is SUSPEND, a series of device driver callback routines is executed with a command option of EEH_DD_DEBUG and flag set to EEH_DD_PIO_ENABLED. The callbacks inform device drivers that PIO has been enabled and that further debug procedures can be executed (such as reading command and status register). This service can be called as a result of the EEH_DD_SUSPEND or EEH_DD_DEBUG callback message as many times as needed by the EEH_MASTER. Additional calls to this service trigger a new set of callbacks. If this service fails, EEH_FAIL is returned. If the failure is due to hardware or firmware, an error is logged.

There are cases when this kernel service cannot succeed due to the platform state restrictions. In such a case, if a driver calls it, the kernel service would return EEH_FAIL followed by a

EEH_DD_DEAD message. This causes the slot to be marked permanently unavailable, which is not correct because the slot can be recovered. To avoid receiving EEH_FAIL from this service, the driver should supply the EEH_ENABLE_NO_SUPPORT_RC flag at **eeh_init_multifunc()** time. If the EEH_ENABLE_NO_SUPPORT_RC flag is supplied, **eeh_enable_pio()** returns EEH_NO_SUPPORT, indicating to the drivers that they cannot collect debug data but must continue with the next step in recovery.

The macro **EEH_CLEAR**(*handle*) is provided for device drivers to call this service. This service is called via a function pointer in the EEH handle.

Note: Enabling PIO is not the same as recovering the slot. In fact, this is an optional step in the recovery procedure.

Execution Environment

This kernel service can be called from the process or interrupt environment.

Return Values

Item	Description
EEH_SUCC	PIO successfully enabled.
EEH_FAIL	Invalid call or could not enable PIO.
EEH_NO_SUPPORT	Call is valid according to AIX EEH state, but current platform state precludes normal completion.

eeh_enable_slot Kernel Service

Purpose

This service enables a slot for the EEH operations.

Syntax

```
#include <sys/eeh.h>

long eeh_enable_slot(handle)
eeh_handle_t handle;
```

Parameters

Item	Description
handle	EEH handle obtained from the**eeh_init** kernel service

Description

This service enables EEH operation on a slot so that when certain errors occur on a PCI bus, the slot will freeze (that is, PIO and DMA are disabled, which prevents potential system crash, data corruption, and so on). This service can only be called by the single-function adapter drivers. If the service fails for hardware or firmware reasons, an error is logged.

Multifunction drivers call this service indirectly via **eeh_init_multifunc()**. It fails with EEH_FAIL if called directly by a multifunction driver.

The macro **EEH_ENABLE_SLOT**(*handle*) is provided for device drivers to call this service.

Execution Environment

This kernel service can be called from the process or interrupt environment.

Return Values

Item	Description
EEH_SUCC	Slot successfully enabled
EEH_FAIL	Unable to enable the slot

Related reference

eeh_disable_slot Kernel Service
eeh_enable_dma Kernel Service
eeh_enable_pio Kernel Service

eeh_init Kernel Service

Purpose

This service registers a single-function adapter slot on a PCI/PCI-E bus for EEH function.

Syntax

```
#include <sys/eeh.h>

eeh_handle_t eeh_init(pbid, slot, flag)
long     pbid;
long     slot;
long     flag;
```

Parameters

Item	Description
pbid	AIX parent bus identifier
slot	device slot (device*8+function). This is same as "connwhere" property in CuDv.
flag	flag that enables eeh

Description

The *pbid* argument identifies a bus type and number. The bus type is IO_PCI in the case of PCI and PCI-X bus. If the bus type is IO_PCIE, the device is on PCI-E (PCI Express) bus. The bus number is a unique identifier determined during bus configuration. The **BID_VAL** macro defined in **ioacc.h** is used to generate the *bid*. The *slot* argument is the device/function combination ((device*8) + function) as in the PCI addressing scheme. The *flag* argument of EEH_ENABLE enables the slot. The *flag* argument of EEH_DISABLE does not enable the slot but still allocates an EEH handle. This service should be called only by the single-function adapter drivers.

The macro **EEH_INIT**(*pbid*, *slot*, *flag*) is provided for the device drivers to call this service. The
eeh_handle is defined as follows in <sys/eeh.h>:

```
/*
 * This is the eeh_handle structure for the eeh_* services
 */
typedef struct eeh_handle *        eeh_handle_t;
struct eeh_handle {
        struct  eeh_handle *next;
        long    bid;                    /* bus id passed to eeh_init    */
        long    slot;                   /* slot passed to eeh_init      */
        long    flag;                   /* flag passed to eeh_init      */
        int     config_addr;            /* Configuration Space Address  */
        int     eeh_mode;               /* Indicates safe mode          */
        uint    retry_delay;            /* re-read the slot state after *
                                         * these many seconds.          */
        int     reserved1;
        int     reserved2;
        int     reserved3;
        long long       PHB_Unit_ID;    /* /pci@                   */
        void    (*eeh_clear)(eeh_handle_t);
        long    (*eeh_enable_pio)(eeh_handle_t);
        long    (*eeh_enable_dma)(eeh_handle_t);
        long    (*eeh_reset_slot)(eeh_handle_t, int);
        long    (*eeh_enable_slot)(eeh_handle_t);
        long    (*eeh_disable_slot)(eeh_handle_t);
        long    (*eeh_read_slot_state)(eeh_handle_t, long *, long *);
        long    (*eeh_slot_error)(eeh_handle_t, int, char *, long);
        struct eeh_shared_domain *parent_sd;     /* point back to the parent
                                         * shared domain structure if
                                         * in shared domain, NULL if singlefunc.
                                         */
        void    (*eeh_configure_bridge)(eeh_handle_t);
        void    (*eeh_broadcast)(eeh_handle_t, unsigned long long);
};
```

This is an exported kernel service.

Execution Environment

This service can only be called from the process environment.

Return Values

Item	Description
EEH_FAIL	Unable to allocate EEH handle.
EEH_NO_SUPPORT	EEH not supported on this system, no handle allocated.
struct eeh_handle *	If successful.

Related reference
eeh_broadcast Kernel Service
eeh_clear Kernel Service
eeh_enable_slot Kernel Service

eeh_init_multifunc Kernel Service

Purpose

This kernel service registers a multifunction adapter slot on a PCI/PCI-E bus for EEH function.

Syntax

```
#include <sys/eeh.h>
```

```
eeh_handle_t eeh_init_multifunc(gpbid, pbid, slot, flag, delay_seconds,
                                callback_ptr, dds_ptr)
long gpbid;
long pbid;
long slot;
long flag;
long delay_seconds;
long (*callback_ptr)();
void *dds_ptr;
```

Parameters

Item	Description
gpbid	Bus identifier of grandparent bus.
pbid	Bus identifier of parent bus.
slot	Slot on the parent bus (device*8+function). This is same as "connwhere" property in CuDv for the device.
flag	Flag that enables eeh, checks if the slot is already taken, etc.
delay_seconds	Time delay after a reset (in seconds).
callback_ptr	Device driver callback routine.
dds_ptr	Cookie to a target device driver that is usually a pointer to the adapter structure.

Description

This kernel service is provided for systems that support shared EEH domain, where one or more PCI functions in one or more adapters could belong to the same EEH recovery domain. In the past, this was called "multifunction adapter". The shared EEH domain is a more general concept than just a multifunction adapter. It is also recommended that single function adapters use the shared EEH model. All PCI-E devices, single or multifunction have to use the shared EEH model and hence this kernel service to register for EEH (instead of **eeh_init()**). In a shared EEH domain, multiple instances of device drivers may be operating. The instances are independent of each other and hence oblivious to each other's existence. Therefore, when recovering a slot from an EEH event, there is a need to coordinate the recovery procedure among them. As with **eeh_init()**, this service also returns an **eeh_handle** to the calling device driver.

There are two kinds of adapters: bridged and non-bridged. A bridged adapter has a bridge on the card such as PCI-to-PCI or PCIX-to-PCIX or PCI-E switch. For PCI and PCI-X bridged-adapters, *pbid* is the bus ID of the parent bus, and *gpbid* is the bus ID of the grandparent bus. The parent bus for a bridged adapter is the bus generated by the bridge/switch on the adapter. A *bid* identifies a bus number and type. The bus type is IO_PCI in the case of PCI and PCI-X bus, and IO_PCIE in the case of PCI-E bus. The bus number is a unique identifier determined during bus configuration. The **BID_VAL** macro defined in **ioacc.h** is used to generate the *bid*. For non-bridged adapters, *pbid* and *gpbid* are the same and are the bus IDs of the parent bus. Thus, when *pbid* and *gpbid* have different values for a PCI or PCI-X device, the kernel knows that this is a bridged adapter and needs to the bridge recovered as part of EEH recovery. It is not necessary to know if a PCI-E device is bridged or not for the purposes of EEH. Therefore, *pbid* and *gpbid* must be same and equal to the parent bus bid.

In summary, there are the following cases:

1. PCI/PCI-X non-bridged adapters and all PCI-E adapters: *gpbid* and *pbid* are same and equal to the parent bus *bid*.
2. PCI/PCI-X bridged adapters, *gpbid* is grandparent bus *bid*, and *pbid* is parent bus bid.

The *slot* argument is the device/function combination ((device* 8) + function) as in the PCI addressing scheme. This is the same as the **connwhere** ODM value of the device.

The following flag values are legal:

Item	Description
EEH_ENABLE_FLAG/EEH_DISABLE_FLAG	The slot is always enabled for EEH when this service is called by the first driver on that slot. All subsequent requests to enable the slot via the **EEH_ENABLE** flag are ignored. Therefore, the flag argument of **EEH_ENABLE** is optional, and a flag of **EEH_DISABLE** is ignored.
EEH_CHECK_SLOT	The flag argument of **EEH_CHECK_SLOT** verifies whether a given slot is already registered. A value of either **EEH_SLOT_ACTIVE** or **EEH_SLOT_FREE** is returned. No registration occurs with the **EEH_CHECK_SLOT** flag, and it supersedes all other flags. This flag simply checks the slot and returns without any other action.
EEH_ENABLE_NO_SUPPORT_RC	If the flag is set to **EEH_ENABLE_NO_SUPPORT_RC**, **eeh_enable_pio()** and **eeh_enable_dma()** return **EEH_NO_SUPPORT** under certain conditions. See "eeh_enable_dma Kernel Service" on page 130 and "eeh_enable_pio Kernel Service" on page 131 for more information.

Multiple flags can be logically ORed together.

The slot is always enabled for EEH when this service is called by the first driver on that slot. All subsequent requests to enable the slot via the EEH_ENABLE flag are ignored. Therefore, the *flag* argument of EEH_ENABLE is optional, and a flag of EEH_DISABLE is ignored. The flag argument of EEH_CHECK_SLOT verifies whether a given slot is already registered. A value of either EEH_SLOT_ACTIVE or EEH_SLOT_FREE is returned. No registration will occur with the EEH_CHECK_SLOT flag, and it supersedes all other flags. This flag just checks the slot and returns without any other action. If the flag is set to EEH_ENABLE_NO_SUPPORT_RC, **eeh_enable_pio()** and **eeh_enable_dma()** returns EEH_NO_SUPPORT under certain conditions. See **eeh_enable_pio()** and **eeh_enable_dma()** for more information. It is allowed to logically OR multiple flags together.

The *delay_seconds* argument allows the device driver to set a time delay between completion of PCI reset and configuration of the bridge on the adapter. The delay is enforced even if the adapter is non-bridged. If a value of 0 is specified for *delay_seconds*, a default delay time of 1 second is set. When several drivers register on the same *pbid* (under a shared EEH domain), the highest delay time among all registered drivers is used.

The *callback_ptr* argument is a function pointer to an EEH callback routine. The handler is defined by the device driver and is called by the kernel in order to coordinate recovery among different drivers on the same slot. The driver handles a variety of messages from the kernel in its callback routine. These messages trigger the next step in recovery. The callback routines are called sequentially at INTIODONE interrupt level.

The *dds_ptr* argument is a cookie that is passed to the driver when the callback routine is invoked. Drivers normally specify a pointer to the device driver's adapter structure.

EEH_SAFE mode: A bridged adapter needs to have its bridge reconfigured at the end of PCI reset. However, if the platform firmware does not support reconfiguration of the bridge, the adapter is marked as EEH_SAFE by the kernel. An EEH_SAFE adapter cannot finish error recovery after an EEH event because of the unsatisfied firmware dependency. See **eeh_reset_slot** for information on how the error recovery is handled in EEH_SAFE mode.

The macro **EEH_INIT_MULTIFUNC**(*gpbid*, *pbid*, *slot*, *flag*, *delay_seconds*, *callback_ptr*, *dds_ptr*) is provided for the device drivers in order to call this service. This is an exported kernel service.

Execution Environment

This kernel service can only be called from the process environment.

Return Values

Item	Description
EEH_FAIL	Unable to allocate EEH handle.
EEH_NO_SUPPORT	EEH is not supported on this system, no handle allocated.
EEH_SLOT_ACTIVE	Given slot is already registered.
EEH_SLOT_FREE	Given slot free.
EEH_BUSY	Unable to continue, because the slot is in the middle of error recovery.
struct eeh_handle *	Upon Success.

Related reference
eeh_broadcast Kernel Service
eeh_clear Kernel Service

eeh_read_slot_state Kernel Service

Purpose

This service returns state and capabilities of a slot with respect to EEH operation.

Syntax

```
long eeh_read_slot_state(handle, state, support)
eeh_handle_t handle;
long *state;
long *support;
```

Parameters

Item	Description
handle	EEH handle obtained from **eeh_init** or **eeh_init_multifunc**
state	State of a slot with respect to EEH
support	Indicates if EEH is supported by this slot

Description

This service is used to query the hardware state of a slot and to determine whether a given slot supports EEH. It should be called to confirm an EEH event if the driver suspects that the PIO data is invalid (for example, getting all Fs from reading a register). This service returns the hardware state in *state* and indicates whether the slot supports EEH in *support*. The *state* and *support* parameters are integer values as shown below:

Valid *state* values are as follows:

Item	Description
EEH_NSTOPPED_RST_DEA	Reset deactivated and adapter is not in stopped state.

Item	Description
EEH_NSTOPPED_RST_ACT	Reset activated and adapter is not in stopped state.
EEH_STOPPED_LS_DIS	Adapter in stopped state with reset signal deactivated and Load/Store disabled.
EEH_STOPPED_LS_ENA	Adapter in stopped state with reset signal deactivated and Load/Store enabled.
EEH_UNAVAILABLE	Adapter is either permanently or temporarily unavailable.

Valid *support* values are as follows:

Item	Description
0	EEH not supported.
1	EEH supported.

The driver should call this service and check for EEH_STOPPED_LS_DIS and EEH_STOPPED_LS_ENA as the *state* values if it suspects an EEH event on the adapter. If the *state* is either of those values, the slot is said to be frozen.

Single-function Driver: A single-function adapter driver calls this service to query the state of the slot. If the service fails due to hardware or firmware reasons, an error is logged. If the service fails, *state* and *support* values are undefined, and EEH_FAIL is returned.

Multifunction Driver: For a multifunction adapter driver, this service analyzes the *state* to determine if:

- The state is frozen, or
- it is permanently unavailable (that is, the slot is unusable from hereon), or
- it is temporarily unavailable.

If the slot is in either a frozen or temporarily unavailable state, the EEH_DD_SUSPEND message is broadcast to all registered drivers on this slot. If the slot is permanently unavailable (that is, dead), the EEH_DD_DEAD message is broadcast. Upon receiving this message, the drivers are expected to suspend all further DMA, PIO, interrupt, configuration cycles, and so on until the slot is recovered. If the service fails due to hardware or firmware reasons, an error is logged, EEH_DD_DEAD is broadcast, and EEH_FAIL is returned.

Temporarily versus permanently unavailable state

In addition to *state* and *support*, this service also returns a valid *retry_delay* value in the **eeh_handle** structure if the *state* is EEH_UNAVAILABLE. If *retry_delay* is 0, it is permanently unavailable. If *retry_delay* is non-zero, it is temporarily unavailable. A permanently unavailable state means that the slot is unusable until a hot-plug operation or partition reboot is performed. Therefore, the drivers mark their adapters as unusable when they receive an EEH_UNAVAILABLE message (single-function) or when they receive an EEH_DD_DEAD message (multifunction). A temporarily unavailable state means that the current *state* of a slot is transient and might take a few minutes to settle down. Until that time, the device driver cannot begin recovery because it does not know what the final state will be. The temporarily unavailable state is handled differently by the single-function and multifunction drivers as follows:

Single-function Driver: Because a single-function driver drives its own recovery, it needs to check for *retry_delay* if the *state* is set to EEH_UNAVAILABLE. If *retry_delay* is non-zero, it represents the number of seconds that the driver should wait before calling this kernel service again. It continues to call this service repeatedly as long as the *state* is EEH_UNAVAILABLE and *retry_delay* is non-zero. Eventually, the *state* will end up in one of the following:

- EEH_NSTOPPED_RST_ACT
- EEH_STOPPED_LS_DIS
- EEH_UNAVAILABLE w/ "retry_delay" set to 0 (i.e. permanently unavailable)

At that point, the driver can continue with its normal course of action for a given state.

Multifunction Driver: A multifunction driver does not need to check for the *retry_delay* field when the state is EEH_UNAVAILABLE, because EEH_UNAVAILABLE would only mean permanently unavailable. In the case of temporarily unavailable, a multifunction driver would receive the EEH_DD_SUSPEND or EEH_DD_DEAD message after some time, depending upon the final *state* of the slot. If the final state was EEH_NSTOPPED_RST_ACT or EEH_STOPPED_LS_DIS, then EEH_DD_SUSPEND is broadcast; if it was EEH_UNAVAILABLE, then EEH_DD_DEAD is broadcast. Thus, from the point-of-view of a multifunction driver, there is no difference between frozen and temporarily unavailable.

The macro **EEH_READ_SLOT_STATE**(*handle, state, support*) is provided for device drivers to call this service.

Execution Environment

This kernel service can be called from the process or interrupt environment.

Return Values

Item	Description
EEH_SUCC	Successfully read the slot state and capabilities
EEH_FAIL	Unable to read the slot state and capabilities

eeh_enable_slot Kernel Service
eeh_init Kernel Service
eeh_slot_error Kernel Service

eeh_reset_slot Kernel Service

Purpose

This service activates, deactivates, or toggles the reset line of a PCI slot.

Syntax

```
#include <sys/eeh.h>

long eeh_reset_slot(handle, flag)
eeh_handle_t handle;
long flag;
```

Parameters

Item	Description
handle	EEH handle obtained from the **eeh_init** or **eeh_init_multifunc** kernel services
flag	Flag can be either EEH_ACTIVE or EEH_DEACTIVE.

Description

Single-function Drivers: This service activates and deactivates the reset line between the Terminal Bridge and the adapter. The *flag* argument specifies whether to activate (EEH_ACTIVE) or deactivate (EEH_DEACTIVE) depending upon the required action. To do the reset of a slot, the reset line should be toggled by calling this service twice: once with EEH_ACTIVE followed by a second call with EEH_DEACTIVE. There should be a minimum of 100 milliseconds delay between the activation and

deactivation of the signal. The minimum delay is specified by the PCI System Architecture and should be enforced by the single-function driver.

Multifunction Drivers: On a multifunction adapter, the EEH_MASTER for the slot drives error recovery. Therefore, only the EEH_MASTER can call this service. Unlike the single-function driver, the master calls this service only once with the EEH_ACTIVE flag.

For the multi-function drivers, the service first activates and then deactivates the reset signal on the slot. It enforces a 100–millisecond delay between the activation and deactivation as mandated by the PCI System Architecture. After the reset signal is deactivated, the service attempts to reconfigure the bridge on the adpater, if there is one (only applies to the bridged-adapters), after *dd_trb_timer* seconds specified in **eeh_init_multifunc()**. At the end of a successful reset and optional bridge recovery, an EEH_DD_RESUME message is broadcast to the slot's multifunction drivers notifying them to resume normal operation. If this service fails, the EEH_DD_DEAD message is broadcast. If failure is due to hardware or firmware, an error is logged.

EEH_SAFE mode: If an EEH_SAFE adapter calls this service, the reset signal is activated but is never deactivated, thereby leaving the adapter in a "permanently unavailable" state. Such an adapter becomes available again if either the PCI hot-plug operation is performed on it or if the partition is rebooted. This service returns EEH_FAIL for an EEH_SAFE driver.

The macro **EEH_RESET_SLOT**(*handle*, *flag*) is provided for device drivers to call this service.

Execution Environment

This kernel service can be called from the process or interrupt environment.

Return Values

Item	Description
EEH_SUCC	Slot reset activate/deactivate succeeded
EEH_FAIL	Failed to activate/deactivate the reset line, nonmaster called the service, or EEH_SAFE mode is active
EEH_BUSY	Recovery is already in progress

Related reference
eeh_enable_slot Kernel Service
eeh_read_slot_state Kernel Service
eeh_slot_error Kernel Service

eeh_slot_error Kernel Service

Purpose

This service logs a temporary or permanent error and optionally marks the slot permanently unavailable.

Syntax

```
#include <sys/eeh.h>

long eeh_slot_error(handle, flag, dd_buf, dd_buf_length)
eeh_handle_t    handle;
int             flag;
char            *dd_buf;
long            dd_buf_length;
```

Parameters

Item	Description
handle	EEH handle obtained from **eeh_init** or **eeh_init_multifunc**
flag	EEH_RESET_TEMP or EEH_RESET_PERM
dd_buf	Address of the device driver's error log buffer
dd_buf_length	Length of device driver's error log buffer in bytes

Description

This service performs a number of tasks:

- It collects hardware data to help in understanding the nature and source of an EEH event
- It combines the device-driver-supplied debug data log with the hardware data log and creates an entry in the error log
- It optionally marks the slot permanently unavailable so that subsequent **eeh_read_slot_state()** calls return EEH_UNAVAILABLE with a *retry_delay* value of 0

The behavior of this kernel service is controlled by two *flag* values:

Item	Description
EEH_RESET_TEMP	This flag performs only the first two of the preceding tasks.
EEH_RESET_PERM	This flag performs all three tasks.

Depending on the hardware state of the slot, this service might not be able to collect the hardware data. Thus, the service succeeds but logs no data. If EEH_RESET_PERM was supplied, it still marks the slot permanently unavailable.

The *dd_buf* and *dd_buf_length* parameters are used to combine the device driver error log with the hardware log. The *dd_buf* argument is the address of an error log buffer that contains the device driver's data. The *dd_buf_length* argument is the length of this buffer. If the length exceeds *MAX_DD_LOG_SIZE* bytes, the driver's log data is truncated. If *dd_buf* is NULL, the error log contains only hardware data, if any.

Single-function driver: The kernel service works as in the preceding description. If it fails because of hardware or firmware reasons, EEH_FAIL is returned and an error is logged.

Multifunction driver: For the multifunction drivers, this service works as in the preceding description, except that if EEH_RESET_PERM was supplied, the EEH_DD_DEAD message is broadcast.

The macro **EEH_SLOT_ERROR**(*handle*, *flag*, *dd_buf*, *dd_buf_length*) is provided for device drivers to call this service.

Execution Environment

This kernel service can be called from the process or interrupt environment.

Return Values

Item	Description
EEH_SUCC	Successfully logged error
EEH_FAIL	Failed to log the error and optionally mark the slot permanently unavailable

eeh_read_slot_state Kernel Service

enque Kernel Service

Purpose

Sends a request queue element to a device queue.

Syntax

#include <sys/types.h> #include <sys/errno.h> #include <sys/deviceq.h> int enque (*qe***) struct req_qe ****qe***;**

Parameter

Item	Description
qe	Specifies the address of the request queue element.

Description

The **enque** kernel service is not part of the base kernel, but is provided by the device queue management kernel extension. This queue management kernel extension must be loaded into the kernel before loading any kernel extensions referencing these services.

The **enque** service places the queue element into a specified device queue. It is used for simple process-to-process communication within the kernel. The requester builds a copy of the queue element, indicated by the *qe* parameter, and passes this copy to the **enque** service. The kernel copies this queue element into a queue element in pinned global memory and then enqueues it on the target device queue.

The path identifier in the request queue element indicates the device queue into which the element is placed.

The **enque** service supports the sending of the following types of queue elements:

Queue Element	Description
SEND_CMD	Send command.
START_IO	Start I/O.
GEN_PURPOSE	General purpose.

For simple interprocess communication, general purpose queue elements are used.

The queue element priority value can range from **QE_BEST_PRTY** to **QE_WORST_PRTY**. This value is limited to the value specified when the queue was created.

The operation options in the queue element control how the queue element is processed. There are five standard operation options:

Operation Option	Description
ACK_COMPLETE	Acknowledge completion in all cases.
ACK_ERRORS	Acknowledge completion if the operation results in an error.
SYNC_REQUEST	Synchronous request.
CHAINED	Chained control blocks.
CONTROL_OPT	Kernel control operation.

Note: Only one of **ACK_COMPLETE**, **ACK_ERRORS**, or **SYNC_REQUEST** can be specified. Also, all of these options are ignored if the path specifies that no acknowledgment (**NO_ACK**) should be sent.

With the **SYNC_REQUEST** synchronous request option, control does not return from the **enque** service until the request queue element is acknowledged. This performs in one step what can also be achieved by sending a queue element with the **ACK_COMPLETE** flag on, and then calling either the **et_wait** or **waitq** kernel services.

The kernel calls the server's **check** routine, if one is defined, before a queue element is placed on the device queue. This routine can stop the operation if it detects an error.

The kernel notifies the device queue's server, if necessary, after a queue element is placed on the device queue. This is done by posting the server process (using the **et_post** kernel service) with an event control bit.

Execution Environment

The **enque** kernel service can be called from the process environment only.

Return Values

Item	Description
RC_GOOD	Indicates a successful operation.
RC_ID	Indicates a path identifier that is not valid.

All other error values represent errors returned by the server.

errresume Kernel Service

Purpose

Resumes error logging after an **errlast** command was issued.

Syntax

```
void errresume()
```

Description

When an error is logged with the **errlast** command, no more error logging will happen on the system until an **errresume** call is issued.

Execution Environment

This can be called from either the process or an interrupt level.

Related reference
errsave or errlast Kernel Service
Related information
Error-Logging Facility

errsave or errlast Kernel Service

Purpose

Allows the kernel and kernel extensions to write to the error log.

Syntax

#include <sys/types.h> #include <sys/errno.h> #include <sys/errids.h> void errsave (*buf, cnt***) char
*** *buf*; **unsigned int** *cnt*; **void errlast (***buf, cnt***) char ****buf* **unsigned int** *cnt*;

Parameters

Item	Description
buf	Points to a buffer that contains an error record as described in the **/usr/include/sys/err_rec.h** file.
cnt	Specifies the number of bytes in the error record contained in the buffer pointed to by the *buf* parameter.

Description

The **errsave** kernel service allows the kernel and kernel extensions to write error log entries to the error
device driver. The error record pointed to by the *buf* parameter includes the error ID resource name and
detailed data.

In addition, the **errlast** kernel service disables any future error logging, thus any error logged with **errlast**
will stay on NVRAM. This service is only for use prior to a pending system crash or stop. The **errlast**
service should only be used in extreme circumstances where the system can not continue, such as the
occurance of a machine check.

Execution Environment

The **errsave** kernel service can be called from either the process or interrupt environment.

Return Values

The **errsave** service has no return values.

Related information

RAS Kernel Services

f

The following kernel services begin with the with the letter f.

facility_enable Kernel Service

Purpose

Enables a specified facility to be used in the kernel environment. The specified facility would otherwise be
restricted for use in the kernel environment.

Syntax

```
#include <sys/machine.h>
int facility_enable (facility)
uint64_t facility;
```

Parameter

facility
Specifies the facility that must be enabled.

Description

The `facility_enable` kernel service enables the use of facilities that typically result in a system failure if the facility is used in the kernel environment. Examples of such facilities include the Vector Multimedia Extension (VMX) facility or the Vector Scalar Extension (VSX) facility. Facilities that are supported by the `facility_enable` kernel service are defined in the `/usr/include/sys/machine.h` include file.

The `facility_enable` kernel service saves the state of a requested facility, then disables interrupts until the `facility_disable` kernel service is called.

When the `facility_enable` kernel service is active, the running program must follow the interrupt environment restrictions and the following additional restrictions:

- The `facility_enable` kernel service cannot be used recursively or in a nested manner. That is, each call to the `facility_enable` kernel service must be followed by a call to the `facility_disable` kernel service before the `facility_enable` kernel service is called again.
- The interrupt level cannot be modified when the `facility_enable` kernel service is active.
- Only a single facility can be enabled when the `facility_enable` kernel service is called each time.
- Sleep operations are not allowed while the `facility_enable` kernel service is active and will result in a system failure.
- Block operations are not allowed while the `facility_enable` kernel service is active.
- The `facility_disable` kernel service must be used along with the `facility_enable` kernel service to restore any state change since the call to the `facility_enable` kernel service.

Note: The `facility_enable` kernel service must not be called for instruction sequences that run for a long time. Disabling interrupts for a longer period of time can cause performance issues in the system.

Execution environment

The `facility_enable` kernel service can be called from either the process or interrupt environment.

Return values

0
Facility is enabled successfully and the specified facility is now active.

ENOSYS
Requested facility is not available or is not supported on this system.

EINVAL
The **facility** parameter is invalid.

EBUSY
The `facility_enable` kernel service is already called and is active.

Related information
Interrupt Environment

facility_disable Kernel Service

Purpose

Disables a specified facility that was previously enabled for the kernel environment.

Syntax

```
#include <sys/machine.h>
int facility_disable (facility)
uint64_t facility;
```

Parameter

facility
  Specifies the facility that must be disabled.

Description

The `facility_disable` kernel service disables a facility that was previously enabled by the `facility_enable` kernel service. Examples of such facilities include the Vector Multimedia Extension (VMX) facility or the Vector Scalar Extension (VSX) facility. Facilities that are supported by the `facility_disable` kernel service are defined in the `/usr/include/sys/machine.h` include file.

The `facility_disable` kernel service restores the state of the facility and then enables interrupts.

Execution environment

The `facility_disable` kernel service can be called from either the process or interrupt environment.

Return values

0
  The `facility_disable` kernel service has successfully disabled the facility that was previously enabled by using the `facility_enable` kernel service, and the previous interrupt level is restored.

ENOSYS
  A facility is not disabled because the `facility_enable` kernel service was not called.

fetch_and_add Kernel Services

Purpose

Increments a variable atomically.

Syntax

```
#include <sys/atomic_op.h>
```

```
int fetch_and_add (addr,  value)
atomic_p addr;
int value;
```

```
long fetch_and_addlp (addr,  value)
atomic_l addr;
long value;
```

Parameters

Item	Description
addr	Specifies the address of the variable to be incremented.
value	Specifies the value to be added to the variable.

Description

The **fetch_and_add** kernel services atomically increment a variable.

The **fetch_and_add** kernel service operates on a single word (32 bit) variable while the **fetch_and_addlp** kernel service operates on a double word (64 bit) variable.

These operations are useful when a counter variable is shared between several kernel threads, because it ensures that the fetch, update, and store operations used to increment the counter occur atomically (are not interruptible).

Note:

- The single word variable for the **fetch_and_add** kernel service must be aligned on a word (32 bit) boundary.
- The double word variable for the **fetch_and_addlp** kernel service must be aligned on a double word (64 bit) boundary.

Execution Environment

The **fetch_and_add** kernel services can be called from either the process or interrupt environment.

Return Values

The **fetch_and_add** kernel services return the original value of the variable.

Related reference
fetch_and_and or fetch_and_or Kernel Services
compare_and_swap Kernel Services
Related information
Locking Kernel Services

fetch_and_and or fetch_and_or Kernel Services

Purpose

Clears and sets bits in a variable atomically.

Syntax

```
#include <sys/atomic_op.h>
```

uint fetch_and_and (*addr*, *mask***)**
atomic_p *addr*;**uint** *mask*;

ulong fetch_and_andlp (*addr*, *mask***)**
atomic_l *addr*;
ulong *mask*;

uint fetch_and_or (*addr*, *mask***)**

```
atomic_p addr;
uint mask;

ulong fetch_and_orlp (addr,  mask)
atomic_l addr;
ulong mask;
```

Parameters

Item	Description
addr	Specifies the address of the variable whose bits are to be cleared or set.
mask	Specifies the bit mask which is to be applied to the variable.

Description

The **fetch_and_and** and **fetch_and_or** kernel services respectively clear and set bits in a variable, according to a bit mask, as a single atomic operation. The **fetch_and_and** service clears bits in the variable which correspond to clear bits in the bit mask, and the **fetch_and_or** service sets bits in the variable which correspond to set bits in the bit mask.

The **fetch_and_add** and **fetch_and_or** kernel services operate on a single word (32 bit) variable while the **fetch_and_addlp** and **fetch_and_orlp** kernel services operate on a double word (64 bit) variable.

These operations are useful when a variable containing bit flags is shared between several kernel threads, because they ensure that the fetch, update, and store operations used to clear or set a bit in the variable occur atomically (are not interruptible).

Note:

- For the **fetch_and_and** and **fetch_and_or** kernel services, the single word containing the bit flags must be aligned on a full word (32 bit) boundary.
- For the **fetch_and_addlp** and **fetch_and_orlp** kernel services, the double word containing the bit flags must be aligned on a double word (64 bit) boundary.

Execution Environment

The **fetch_and_and** and **fetch_and_or** kernel services can be called from either the process or interrupt environment.

Return Values

The **fetch_and_and** and **fetch_and_or** kernel services return the original value of the variable.

Related reference
fetch_and_add Kernel Services
compare_and_swap Kernel Services

Locking Kernel Services

fidtovp Kernel Service

Purpose

Maps a file system structure to a file ID.

Maps a file identifier to a mode.

Syntax

#include <sys/types.h> #include <sys/vnode.h> int fidtovp(*fsid***,** ***fid***,** ***vpp***) **fsid_t ****fsid***; struct fileid ****fid***;
struct vnode *****vpp***;**

Parameters

Item	Description
fsid	Points to a file system ID structure. The system uses this structure to determine which virtual file system (VFS) contains the requested file.
fid	Points to a file ID structure. The system uses this pointer to locate the specific file within the VFS.
vpp	Points to a location to store the file's vnode pointer upon successful return of the **fidtovp** kernel service.

Description

The **fidtovp** kernel service returns a pointer to a vnode for the file identified by **fsid** and **fid**, and increments the count on the vnode so the file is not removed. Subroutines that call the **fidtovp** kernel service must call VNOP_RELE to release the vnode pointer.

This kernel service is designed for use by the server side of distributed file systems.

Execution Environment

The **fidtovp** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
ESTALE	Indicates the requested file or file system was removed or recreated since last access with the given file system ID or file ID.

find_input_type Kernel Service

Purpose

Finds the given packet type in the Network Input Interface switch table and distributes the input packet according to the table entry for that type.

Syntax

#include <sys/types.h> #include <sys/errno.h> #include <net/if.h> int find_input_type (*type***,** ***m***,** ***ac***,**
header_pointer) ushort** *type***; struct mbuf *** *m***; struct arpcom *** *ac***; caddr_t** *header_pointer***;**

Parameters

Item	Description
type	Specifies the protocol type.
m	Points to the **mbuf** buffer containing the packet to distribute.

Item	Description
ac	Points to the network common portion (**arpcom**) of the network interface on which the packet was received. This common portion is defined as follows:
	in net/if_arp.h
header_pointer	Points to the buffer containing the input packet header.

Description

The **find_input_type** kernel service finds the given packet type in the Network Input table and distributes the input packet contained in the **mbuf** buffer pointed to by the *m* value. The *ac* parameter is passed to services that do not have a queued interface.

Execution Environment

The **find_input_type** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates that the protocol type was successfully found.
ENOENT	Indicates that the service could not find the type in the Network Input table.

Related reference
add_input_type Kernel Service
del_input_type Kernel Service

Network Kernel Services

fp_access Kernel Service

Purpose

Checks for access permission to an open file.

Syntax

#include <sys/types.h> #include <sys/errno.h> int fp_access (*fp*, *perm***) struct file ****fp***; int** *perm***;**

Parameters

Item	Description
fp	Points to a file structure returned by the **fp_open** or **fp_opendev** kernel service.
perm	Indicates which read, write, and execute permissions are to be checked. The **/usr/include/sys/mode.h** file contains pertinent values (IREAD, IWRITE, IEXEC).

Description

The **fp_access** kernel service is used to see if either the read, write, or exec bit is set anywhere in a file's permissions mode. Set *perm* to one of the following constants from **mode.h**:

IREAD IWRITE IEXEC

Execution Environment

The **fp_access** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates that the calling process has the requested permission.
EACCES	Indicates all other conditions.

Related information

access subroutine

Logical File System Kernel Services

fp_close Kernel Service

Purpose

Closes a file.

Syntax

#include <sys/types.h> #include <sys/errno.h> int fp_close (*fp***) struct file ****fp***;**

Parameter

Item	Description
fp	Points to a file structure returned by the **fp_open**, **fp_getf**, or **fp_opendev** kernel service.

Description

The **fp_close** kernel service is a common service for closing files used by both the file system and routines outside the file system.

Execution Environment

The **fp_close** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
non-zero	The underlying file system implementation might report one of the values from the **/usr/include/errno.h** file, which is returned to the caller as a return value. However, the file is still closed.

Related information

close subroutine

Logical File System Kernel Services

fp_close Kernel Service for Data Link Control (DLC) Devices

Purpose

Allows kernel to close the generic data link control (GDLC) device manager using a file pointer.

Syntax

int fp_close(*fp***)**

Parameters

Item	Description
fp	Specifies the file pointer of the GDLC being closed.

Description

The **fp_close** kernel service disables a GDLC channel. If this is the last channel to close on a port, the GDLC device manager resets to an idle state on that port and the communications device handler is closed. The **fp_close** kernel service may be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful completion.
ENXIO	Indicates an invalid file pointer. This value is defined in the **/usr/include/sys/errno.h** file.

Related reference
fp_close Kernel Service
fp_open Kernel Service for Data Link Control (DLC) Devices
Related information
Generic Data Link Control (GDLC) Environment Overview

fp_fstat Kernel Service

Purpose

Gets the attributes of an open file.

Syntax

#include <sys/types.h> #include <sys/errno.h> int fp_fstat (*fp***,** *statp***,** *len***,** *seg***) struct file*** *fp***; struct stat** **statp***; int** *len***; int** *seg***;**

Parameters

Item	Description
fp	Points to a file structure returned by the **fp_open** kernel service.
statp	Points to a buffer defined to be of **stat** or **fullstat** type structure. The *statsz* parameter indicates the buffer type.
len	Indicates the size of the **stat** or **fullstat** structure to be returned. The **/usr/include/sys/stat.h** file contains information about the **stat** structure.

Item	Description
seg	Specifies the flag indicating where the information represented by the *statbuf* parameter is located:

SYS_ADSPACE
Buffer is in kernel memory.

USER_ADSPACE
Buffer is in user memory.

Description

The **fp_fstat** kernel service is an internal interface to the function provided by the **fstatx** subroutine.

Execution Environment

The **fp_fstat** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.

If an error occurs, one of the values from the **/usr/include/sys/errno.h** file is returned.

Related information
fstatx subroutine
Logical File System Kernel Services

fp_fsync Kernel Service

Purpose

Writes changes for a specified range of a file to permanent storage.

Syntax

```
#include <sys/fp_io.h>

int fp_fsync (fp, how, off, len)
struct file *fp;
int how;
offset_t off;
offset_t len;
```

Description

The **fp_fsync** kernel service is an internal interface to the function provided by the **fsync_range** subroutine.

Parameters

Item	Description
fp	Points to a file structure returned by the **fp_open** kernel service.

Item	Description
how	Specifies the following handling characteristics of the operation:

FDATASYNC

The changed data in the range specified by the `off` and `len` parameters is written to the storage. If the metadata for the file is changed and this changed metadata must read the data, the metadata is also written to the storage. Otherwise, the metadata is not updated.

FFILESYNC

The changed data in the range specified by the `off` and `len` parameters is written to the storage. If any metadata is changed, all of the changed user data is written to the storage. Metadata changes and file attributes including time stamps are also written to the storage.

Item	Description
off	Specifies the starting offset value of the data in the file to be written to the storage.
len	Specifies the length of the file range to be written to the storage. If you specify the value as zero, all cached data is written to the storage.

Execution Environment

The **fp_fsync** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
ERRNO	Returns an error number from the **/usr/include/sys/errno.h** file on failure.

Related information

fsync or fsync_range Subroutine

Logical File System Kernel Services

fp_getdevno Kernel Service

Purpose

Gets the device number or channel number for a device.

Syntax

#include <sys/types.h> #include <sys/errno.h> #include <sys/file.h> int fp_getdevno (*fp, devp, chanp***) struct file ***fp***; dev_t ***devp***; chan_t ***chanp***;**

Parameters

Item	Description
fp	Points to a file structure returned by the **fp_open** or **fp_opendev** service.
devp	Points to a location where the device number is to be returned.
chanp	Points to a location where the channel number is to be returned.

Description

The **fp_getdevno** service finds the device number and channel number for an open device that is associated with the file pointer specified by the *fp* parameter. If the value of either *devp* or *chanp* parameter is null, this service does not attempt to return any value for the argument.

Execution Environment

The **fp_getdevno** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
EINVAL	Indicates that the pointer specified by the *fp* parameter does not point to a file structure for an open device.

Related information
Logical File System Kernel Services

fp_getea Kernel Service

Purpose

Reads the value of an extended attribute value.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
int fp_getea (fp,name, value, size, countp, segflag)
struct file * fp;
const char * name;
void * value;
size_t size;
ssize_t * countp;
int segflag;
```

Parameters

Item	Description
fp	Specifies the file structure returned by the **fp_open** kernel service.
name	Specifies the name of the extended attribute. An extended attribute name is a NULL-terminated string.
value	Specifies the pointer to a buffer in which the attribute is stored. The value of an extended attribute is an opaque byte stream of specified length.
size	Specifies the size of the value buffer. If size is 0, **fp_getea** returns the current size of the named extended attribute, which can be used to estimate whether the size of a buffer is sufficiently large to hold the value associated with the extended attribute.
countp	Specifies the actual size of the content in the value buffer.

Item	Description
segflag	Specifies the flag indicating where the pointer specified by the path parameter is located:

SYS_ADSPACE
> The pointers specified by the *name* and *value* parameters are stored in kernel memory.

USER_ADSPACE
> The pointers specified by the *name* and *value* parameters are stored in application memory.

Description

The **fp_getea** kernel service provides a common service used by:

- The file system for the implementation of the **fgetea** subroutine.
- Kernel routines outside the file system that set extended attribute values.

Execution Environment

The **fp_getea** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
ERRNO	Indicates a failed operation. Returns an error number from the **/usr/include/sys/errno.h** file on failure.

Related information
fgetea subroutine
fp_open subroutine
Logical File System Kernel Services

fp_getf Kernel Service

Purpose

Retrieves a pointer to a file structure.

Syntax

#include <sys/types.h> #include <sys/errno.h> int fp_getf (*fd*, *fpp***) int** *fd*; **struct file *****fpp*;

Parameters

Item	Description
fd	Specifies a file descriptor.
fpp	Points to the location where the file pointer is to be returned.

Description

A process calls the **fp_getf** kernel service when it has a file descriptor for an open file, but needs a file pointer to use other Logical File System services.

The **fp_getf** kernel service uses the file descriptor as an index into the process's open file table. From this table it extracts a pointer to the associated file structure.

As a side effect of the call to the **fp_getf** kernel service, the reference count on the file descriptor is incremented. This count must be decremented when the caller has completed its use of the returned file pointer. The file descriptor reference count is decremented by a call to the **ufdrele** kernel service.

Execution Environment

The **fp_getf** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
EBADF	Indicates that either the file descriptor is invalid or not currently used in the process.

Related reference
ufdhold and ufdrele Kernel Service
Related information
Logical File System Kernel Services

fp_get_path Kernel Service

Purpose

Returns the full path name of the file referenced by the **fp** parameter.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>

int
fp_get_path(struct file      *fp,
            int              flags,
            char             *path,
            size_t           size)
```

Parameters

fp
   Points to a file structure that is returned by the **fp_open** or **fp_opendev** kernel service.

flags
   No flags are defined; this parameter must be 0.

path
   Points to a buffer where the file name is returned.

size
   Specifies the size of the path buffer.

Description

The **fp_get_path** kernel service provides a method to find a path name from a file structure pointer.

Execution environment

The **fp_get_path** kernel service can be called only from the process environment.

Return values

0
  Indicates a successful operation.
EINVAL
  Invalid **fp** or **path** argument, or the **fp** parameter does not refer to a DTYPE_VNODE file structure.

fp_hold Kernel Service

Purpose

Increments the open count for a specified file pointer.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>

void fp_hold ( fp)
struct file *fp;
```

Parameter

Item	Description
fp	Points to a file structure previously obtained by calling the **fp_open**, **fp_getf**, or **fp_opendev** kernel service.

Description

The **fp_hold** kernel service increments the use count in the file structure specified by the *fp* parameter. This results in the associated file remaining opened even when the original open is closed.

If this function is used, and access to the file associated with the pointer specified by the *fp* parameter is no longer required, the **fp_close** kernel service should be called to decrement the use count and close the file as required.

Execution Environment

The **fp_hold** kernel service can be called from the process environment only.

Related information
Logical File System Kernel Services

fp_ioctl Kernel Service

Purpose

Issues a control command to an open device or file.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

int fp_ioctl (*fp, cmd, arg, ext*)
struct file * *fp*;
unsigned long *cmd*;
caddr_t *arg*;
int *ext*;

Parameters

Item	Description
fp	Points to a file structure returned by the **fp_open** or **fp_opendev** kernel service.
cmd	Specifies the specific control command requested.
arg	Indicates the data required for the command.
ext	Specifies an extension argument required by some device drivers. Its content, form, and use are determined by the individual driver.

Description

The **fp_ioctl** kernel service is an internal interface to the function provided by the **ioctl** subroutine.

Execution Environment

The **fp_ioctl** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.

If an error occurs, one of the values from the **/usr/include/sys/errno.h** file is returned. The **ioctl** subroutine contains valid **errno** values.

Related information
ioctl subroutine
Logical File System Kernel Services

fp_ioctl Kernel Service for Data Link Control (DLC) Devices

Purpose

Transfers special commands from the kernel to generic data link control (GDLC) using a file pointer.

Syntax

```
#include <sys/gdlextcb.h>
#include <fcntl.h>
```

```
int fp_ioctl (fp, cmd, arg, ext)
```

Parameters

Item	Description
fp	Specifies the file pointer of the target GDLC.
cmd	Specifies the operation to be performed by GDLC.
arg	Specifies the address of the parameter block. The argument for this parameter must be in the kernel space.
ext	Specifies the extension parameter. This parameter is ignored by GDLC.

Description

Various GDLC functions can be initiated using the **fp_ioctl** kernel service, such as changing configuration parameters, contacting the remote, and testing a link. Most of these operations can be completed before returning to the user synchronously. Some operations take longer, so asynchronous results are returned much later using the **exception** function handler. GDLC calls the kernel user's exception handler to complete these results. Each GDLC supports the **fp_ioctl** kernel service by way of its **dlcioctl** entry point. The **fp_ioctl** kernel service may be called from the process environment only.

Note: The **DLC_GET_EXCEP** ioctl operation is not used since all exception conditions are passed to the kernel user through the exception handler.

Return Values

Item	Description
0	Indicates a successful completion.
ENXIO	Indicates an invalid file pointer.
EINVAL	Indicates an invalid value.
ENOMEM	Indicates insufficient resources to satisfy the **ioctl** subroutine.

These return values are defined in the **/usr/include/sys/errno.h** file.

Related reference
fp_ioctl Kernel Service
Related information
ioctl subroutine
Generic Data Link Control (GDLC) Environment Overview

fp_ioctlx Kernel Service

Purpose

Issues a control command to an open device.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <fcntl.h>

int fp_ioctlx (fp, cmd, arg, ext, flags, retval)
struct file *fp;
unsigned long cmd;
caddr_t arg;
ext_t ext;
unsigned long flags;
long *retval;
```

Description

The **fp_ioctlx** kernel service is an internal interface to the function provided by the **ioctl** subroutine.

The **fp_ioctlx** kernel service issues a control command to an open device. Some drivers need the return value that is returned by the kernel service if there is no error. This value is not available through the **fp_ioctl** kernel service. The **fp_ioctlx** kernel service allows this data to be passed.

Parameters

Item	Description
fp	Points to a file structure returned by the **fp_open** or **fp_opendev** kernel service.
cmd	Specifies the specific control command requested.
arg	Indicates the data required for the command.
ext	Specifies an extension argument required by some device drivers. Its content, form, and use are determined by the individual driver.
flags	Indicates the address space of *arg* parameter. If the *arg* value is in kernel address space, *flags* should be specified as **FKERNEL**. Otherwise, it should be zero (drivers pass data that is in user space).
retval	Points to the location where the return value will be stored on successful return from the call.

Execution Environment

The **fp_ioctlx** kernel service can be called only from the process environment.

Return Values

Upon successful completion, the **fp_ioctlx** kernel service returns 0. If unsuccessful, one of the values from the **/usr/include/sys/errno.h** file is returned. The **ioctl** subroutine contains valid **errno** values. This value will be stored in the *retval* parameter.

Related reference
fp_ioctl Kernel Service

ioctl, ioctlx, ioctl32, or ioctl32x Subroutine

fp_listea Kernel Service

Purpose

Lists the extended attributes associated with a file.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
int fp_listea (fp, list, size, countp, segflag)
struct file * fp;
const char * list;
size_t size;
ssize_t * countp;
int segflag;
```

Parameters

Item	Description
fp	Specifies the file structure returned by the **fp_open** kernel service.
list	Specifies a pointer to a buffer in which the list of attributes will be stored.
size	Specifies the size of the list buffer.
countp	Specifies the actual size of the content in the list buffer.
segflag	Specifies the flags indicating where the pointer specified by the path parameter is located:

    SYS_ADSPACE
        The pointer specified by the list parameter is stored in kernel memory.

    USER_ADSPACE
        The pointer specified by the list parameter is stored in application memory.

Description

The **fp_listea** kernel service provides a common service used by:

- File system for the implementation of the **flistea** subroutine.
- Kernel routines outside the file system that set extend attribute values.

Execution Environment

The **fp_listea** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
ERRNO	Indicates a failed operation. Returns an error number from the **/usr/include/sys/errno.h** file on failure.

Related information
flistea subroutine
fp_open subroutine
Logical File System Kernel Services

fp_lseek, fp_llseek Kernel Service

Purpose

Changes the current offset in an open file.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

int fp_lseek (*fp*, *offset*, *whence*)
struct file *fp;
off_t *offset;
int *whence;

int fp_llseek
(*fp*, *offset*, *whence*)
struct file *fp
offset_t *offset;
int *whence;

Parameters

Item	Description
fp	Points to a file structure returned by the **fp_open** kernel service.
offset	Specifies the number of bytes (positive or negative) to move the file pointer.
whence	Indicates how to use the offset value:

> **SEEK_SET**
>> Sets file pointer equal to the number of bytes specified by the *offset* parameter.
>
> **SEEK_CUR**
>> Adds the number of bytes specified by the *offset* parameter to current file pointer.
>
> **SEEK_END**
>> Adds the number of bytes specified by the *offset* parameter to current end of file.

Description

The **fp_lseek** and **fp_llseek** kernel services are internal interfaces to the function provided by the **lseek** and **llseek** subroutines.

Execution Environment

The **fp_lseek** and **fp_llseek** kernel services can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
ERRNO	Returns an error number from the **/usr/include/sys/errno.h** file on failure.

Related information
lseek subroutine
Logical File System Kernel Services

fp_open Kernel Service

Purpose

Opens special and regular files or directories.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

int fp_open (*path,oflags,mode,ext,segflag,fpp*)
char * *path*;
long *oflags*;
int *mode*;
ext_t *ext*;
int *segflag*;
struct file ** *fpp*;

Parameters

Item	Description
path	Points to the file name of the file to be opened.
oflags	Specifies open mode flags as described in the **open** subroutine.
mode	Specifies the mode (permissions) value to be given to the file if the file is to be created.
ext	Specifies an extension argument required by some device drivers. Individual drivers determine its content, form, and use.
segflag	Specifies the flag indicating where the pointer specified by the *path* parameter is located: **SYS_ADSPACE** The pointer specified by the *path* parameter is stored in kernel memory. **USER_ADSPACE** The pointer specified by the *path* parameter is stored in application memory.
fpp	Points to the location where the file structure pointer is to be returned by the **fp_open** service.

Description

The **fp_open** kernel service provides a common service used by:

- The file system for the implementation of the **open** subroutine
- Kernel routines outside the file system that must open files

Execution Environment

The **fp_open** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.

Also, the *fpp* parameter points to an open file structure that is valid for use with the other Logical File System services. If an error occurs, one of the values from the **/usr/include/sys/errno.h** file is returned. The discussion of the **open** subroutine contains possible **errno** values.

Related information

open subroutine

Logical File System Kernel Services

fp_open Kernel Service for Data Link Control (DLC) Devices

Purpose

Allows kernel to open the generic data link control (GDLC) device manager by its device name.

Syntax

```
#include <sys/gdlextcb.h>
#include <fcntl.h>
```

```
fp_open (path, oflags, cmode, ext, segflag, fpp)
```

Parameters

Item	Description
path	Consists of a character string containing the **/dev** special file name of the GDLC device manager, with the name of the communications device handler appended. The format is shown in the following example: `/dev/dlcether/ent0`
oflags	Specifies a value to set the file status flag. The GDLC device manager ignores all but the following values: **O_RDWR** Open for reading and writing. This must be set for GDLC or the open will not be successful. **O_NDELAY, O_NONBLOCK** Subsequent writes return immediately if no resources are available. The calling process is not put to sleep.
cmode	Specifies the **O_CREAT** mode parameter. This is ignored by GDLC.

Item	Description
ext	Specifies the extended kernel service parameter. This is a pointer to the **dlc_open_ext** extended I/O structure for open subroutines. The argument for this parameter must be in the kernel space.
segflag	Specifies the segment flag indicating where the *path* parameter is located:

FP_SYS
> The *path* parameter is stored in kernel memory.

FP_USR
> The *path* parameter is stored in application memory.

Item	Description
fpp	Specifies the returned file pointer. This parameter is passed by reference and updated by the file I/O subsystem to be the file pointer for this **open** subroutine.

Description

The **fp_open** kernel service allows the kernel user to open a GDLC device manager by specifying the special file names of both the DLC and the communications device handler. Since the GDLC device manager is multiplexed, more than one process can open it (or the same process multiple times) and still have unique channel identifications.

Each open carries the communications device handler's special file name so that the DLC knows which port to transfer data on.

The kernel user must also provide functional entry addresses in order to obtain receive data and exception conditions. Each GDLC supports the **fp_open** kernel service via its **dlcopen** entry point. The **fp_open** kernel service may be called from the process environment only. "Using GDLC Special Kernel Services" in *AIX Version 6.1 Communications Programming Concepts* provides additional information.

Return Values

Upon successful completion, this service returns a value of 0 and a valid file pointer in the *fpp* parameter.

Item	Description
ECHILD	Indicates that the service cannot create a kernel process.
EINVAL	Indicates an invalid value.
ENODEV	Indicates that no such device handler is present.
ENOMEM	Indicates insufficient resources to satisfy the open.
EFAULT	Indicates that the kernel service, such as the **copyin** or **initp** service, has failed.

These return values are defined in the **/usr/include/sys/errno.h** file.

Related reference
fp_open Kernel Service
fp_close Kernel Service for Data Link Control (DLC) Devices
Related information
Generic Data Link Control (GDLC) Environment Overview

fp_opendev Kernel Service

Purpose

Opens a device special file.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

int fp_opendev (*devno*,*flags*,*cname*, *ext*, *fpp*)
dev_t*devno*;
int *flags*;
caddr_t *cname*;
ext_t *ext*;
struct file** *fpp*;

Parameters

Item	Description
devno	Specifies the major and minor device number of device driver to open.
flag	Specifies one of the following values: **DREAD** The device is being opened for reading only. **DWRITE** The device is being opened for writing. **DNDELAY** The device is being opened in nonblocking mode.
cname	Points to a channel specifying a character string or a null value.
ext	Specifies an extension argument required by some device drivers. Its content, form, and use are determined by the individual driver.
fpp	Specifies the returned file pointer. This parameter is passed by reference and is updated by the **fp_opendev** service to be the file pointer for this open instance. This file pointer is used as input to other Logical File System services to specify the open instance.

Description

The kernel or kernel extension calls the **fp_opendev** kernel service to open a device by specifying its device major and minor number. The **fp_opendev** kernel service provides the correct semantics for opening the character or multiplexed class of device drivers.

If the specified device driver is non-multiplexed:

- An in-core i-node is found or created for this device.
- The i-node reference count is increment by 1.
- The device driver's **ddopen** entry point is called with the *devno*, *devflag*, and *ext* parameters. The unused *chan* parameter on the call to the **ddopen** routine is set to 0.

If the device driver is a multiplexed character device driver (that is, its **ddmpx** entry point is defined), an in-core i-node is created for this channel. The device driver's **ddmpx** routine is also called with the *cname*

pointer to the channel identification string if non-null. If the *cname* pointer is null, the **ddmpx** device driver routine is called with the pointer to a null character string.

If the device driver can allocate the channel, the **ddmpx** routine returns a channel ID, represented by the *chan* parameter. If the device driver cannot allocate a channel, the **fpopendev** kernel service returns an **ENXIO** error code. If successful, the i-node reference count is increment by 1. The device driver **ddopen** routine is also called with the *devno*, *flag*, *chan* (provided by **ddmpx** routine), and *ext* parameters.

If the return value from the specified device driver **ddopen** routine is nonzero, it is returned as the return code for the **fp_opendev** kernel service. If the return code from the device driver **ddopen** routine is 0, the **fp_opendev** service returns the file pointer corresponding to this open of the device.

The **fp_opendev** kernel service can only be called in the process environment or device driver top half. Interrupt handlers cannot call it. It is assumed that all arguments to the **fp_opendev** kernel service are in kernel space.

The file pointer (*fpp*) returned by the **fp_opendev** kernel service is only valid for use with a subset of the Logical File System services. These nine services can be called:

- **fp_close**
- **fp_ioctl**
- **fp_poll**
- **fp_select**
- **fp_read**
- **fp_readv**
- **fp_rwuio**
- **fp_write**
- **fp_writev**

Other services return an **EINVAL** return value if called.

Execution Environment

The **fp_opendev** kernel service can be called from the <u>process environment</u> only.

Return Values

Item	Description
0	Indicates a successful operation.

The *fpp field also points to an open file structure that is valid for use with the other Logical File System services. If an error occurs, one of the following values from the **/usr/include/sys/errno.h** file is returned:

Item	Description
EINVAL	Indicates that the major portion of the *devno* parameter exceeds the maximum number allowed, or the *flags* parameter is not valid.
ENODEV	Indicates that the device does not exist.
EINTR	Indicates that the signal was caught while processing the **fp_opendev** request.
ENFILE	Indicates that the system file table is full.
ENXIO	Indicates that the device is multiplexed and unable to allocate the channel.

The **fp_opendev** service also returns any nonzero return code returned from a device driver **ddopen** routine.

fp_poll Kernel Service

Purpose

Checks the I/O status of multiple file pointers, file descriptors, and message queues.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/poll.h>
```

int fp_poll (*listptr, nfdsmsgs, timeout, flags*)
void * *listptr*;
unsigned long *nfdsmsgs*;
long *timeout*;
uint *flags*;

Parameters

Item	Description
listptr	Points to an array of **pollfd** or **pollmsg** structures, or to a single **pollist** structure. Each structure specifies a file pointer, file descriptor, or message queue ID. The events of interest for this file or message queue are also specified.
nfdsmsgs	Specifies the number of files and message queues to check. The low-order 16 bits give the number of elements present in the array of **pollfd** structures. The high-order 16 bits give the number of elements present in the array of **pollmsg** structures. If either half of the *nfdsmsgs* parameter is equal to 0, then the corresponding array is presumed abse1e.
timeout	Specifies how long the service waits for a specified event to occur. If the value of this parameter is -1, the **fp_poll** kernel service does not return until at least one of the specified events has occurred. If the time-out value is 0, the **fp_poll** kernel service does not wait for an event to occur. Instead, the service returns immediately even if none of the specified events have occurred. For any other value of the *timeout* parameter, the **fp_poll** kernel service specifies the maximum length of time (in milliseconds) to wait for at least one of the specified events to occur.
flags	Specifies the type of data in the *listptr* parameter: **POLL_FDMSG** Input is a file descriptor and/or message queue. **0** Input is a file pointer.

Description

Note: The **fp_poll** service applies only to character devices, pipes, message queues, and sockets. Not all character device drivers support the **fp_poll** service.

The **fp_poll** kernel service checks the specified file pointers/descriptors and message queues to see if they are ready for reading or writing, or if they have an exceptional condition pending.

The **pollfd**, **pollmsg**, and **pollist** structures are defined in the **/usr/include/sys/poll.h** file. These are the same structures described for the **poll** subroutine. One difference is that the **fd** field in the **pollfd** structure contains a file pointer when the *flags* parameter on the **fp_poll** kernel service equals 0 (zero). If the *flags* parameter is set to a **POLL_FDMSG** value, the field is taken as a file descriptor in all processed **pollfd** structures. If either the **fd** or **msgid** fields in their respective structures has a negative value, the processing for that structure is skipped.

When performing a poll operation on both files and message queues, the *listptr* parameter points to a **pollist** structure, which can specify both files and message queues. To construct a **pollist** structure, use the **POLLIST** macro as described in the **poll** subroutine.

If the number of **pollfd** elements in the *nfdsmsgs* parameter is 0, then the *listptr* parameter must point to an array of **pollmsg** structures.

If the number of **pollmsg** elements in the *nfdsmsgs* parameter is 0, then the *listptr* parameter must point to an array of **pollfd** structures.

If the number of **pollmsg** and **pollfd** elements are both nonzero in the *nfdsmsgs* parameter, the *listptr* parameter must point to a **pollist** structure as previously defined.

Execution Environment

The **fp_poll** kernel service can be called from the process environment only.

Return Values

Upon successful completion, the **fp_poll** kernel service returns a value that indicates the total number of files and message queues that satisfy the selection criteria. The return value is similar to the *nfdsmsgs* parameter in the following ways:

- The low-order 16 bits give the number of files.
- The high-order 16 bits give the number of message queue identifiers that have nonzero *revents* values.

Use the **NFDS** and **NMSGS** macros to separate these two values from the return value. A return code of 0 (zero) indicates that:

- The call has timed out.
- None of the specified files or message queues indicates the presence of an event.

In other words, all *revents* fields are 0 (zero).

When the return code from the **fp_poll** kernel service is negative, it is set to the following value:

Item	Description
EINTR	Indicates that a signal was caught during the **fp_poll** kernel service.

fp_read Kernel Service

Purpose

Performs a read on an open file with arguments passed.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
int fp_read (fp, buf, nbytes, ext, segflag, countp)
struct file * fp;
char * buf;
ssize_t   nbytes;
ext_t     ext;
int   segflag;
ssize_t * countp;
```

Parameters

Item	Description
fp	Points to a file structure returned by the **fp_open** or **fp_opendev** kernel service.
buf	Points to the buffer where data read from the file is to be stored.
nbytes	Specifies the number of bytes to be read from the file into the buffer.
ext	Specifies an extension argument required by some device drivers. Its content, form, and use are determined by the individual driver.
segflag	Indicates in which part of memory the buffer specified by the *buf* parameter is located: **SYS_ADSPACE** The buffer specified by the *buf* parameter is in kernel memory. **USER_ADSPACE** The buffer specified by the *buf* parameter is in application memory.
countp	Points to the location where the count of bytes actually read from the file is to be returned.

Description

The **fp_read** kernel service is an internal interface to the function provided by the **read** subroutine.

Execution Environment

The **fp_read** kernel service can be called from the process environment only.

Return Values

Ite m	Description
0	Indicates successful completion.

If an error occurs, one of the values from the **/usr/include/sys/errno.h** file is returned.

Logical File System Kernel Services

fp_readv Kernel Service

Purpose

Performs a read operation on an open file with arguments passed in **iovec** elements.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

int fp_readv
(*fp, iov, iovcnt, ext,*
seg, countp)
struct file * *fp*;
struct iovec * *iov*;
ssize_t *iovcnt*;
ext_t *ext*;
int *seg*;
ssize_t *countp*;

Parameters

Item	Description
fp	Points to a file structure returned by the **fp_open** kernel service.
iov	Points to an array of **iovec** elements. Each **iovec** element describes a buffer where data to be read from the file is to be stored.
iovcnt	Specifies the number of **iovec** elements in the array pointed to by the *iov* parameter.
ext	Specifies an extension argument required by some device drivers. Its content, form, and use are determined by the individual driver.
seg	Indicates in which part of memory the array specified by the *iov* parameter is located: **SYS_ADSPACE** 　　The array specified by the *iov* parameter is in kernel memory. **USER_ADSPACE** 　　The array specified by the *iov* parameter is in application memory.
countp	Points to the location where the count of bytes actually read from the file is to be returned.

Description

The **fp_readv** kernel service is an internal interface to the function provided by the **readv** subroutine.

Execution Environment

The **fp_readv** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.

If an error occurs, one of the values from the **/usr/include/sys/errno.h** file is returned.

Logical File System Kernel Services

fp_removeea Kernel Service

Purpose

Removes an extended attribute.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
int fp_removeea (fp, name, segflag)
struct file * fp;
const char * name;
int segflag;
```

Parameters

Item	Description
fp	Specifies a file structure returned by the **fp_open** kernel service.
name	Specifies the name of the extended attribute. An extended attribute name is a NULL-terminated string.
segflag	Specifies the flag indicating where the pointer specified by the path parameter is located:

> **SYS_ADSPACE**
> The pointer specified by the *name* parameter is stored in kernel memory.
>
> **USER_ADSPACE**
> The pointer specified by the *name* parameter is stored in application memory.

Description

The **fp_removeea** kernel service provides a common service used by:

- The file system for the implementation of the **fremoveea** subroutine
- Kernel routines outside the file system that set extended attribute values

Execution Environment

The **fp_removeea** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
ERRNO	Indicates a failed operation. Returns an error number from the **/usr/include/sys/errno.h** file on failure.

Related information

fremoveea subroutine

fp_open subroutine

Logical File System Kernel Services

fp_rwuio Kernel Service

Purpose

Performs read and write on an open file with arguments passed in a **uio** structure.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

int fp_rwuio
(*fp*, *rw*, *uiop*, *ext*)
struct file **fp*;
enum uio_rw *rw*;
struct uio **uiop*;
ext_t *ext*;

Parameters

Item	Description
fp	Points to a file structure returned by the **fp_open** or **fp_opendev** kernel service.
rw	Indicates whether this is a read operation or a write operation. It has a value of **UIO_READ** or **UIO_WRITE**.
uiop	Points to a **uio** structure, which contains information such as where to move data and how much to move.
ext	Specifies an extension argument required by some device drivers. Its content, form, and use are determined by the individual driver.

Description

The **fp_rwuio** kernel service is not the preferred interface for read and write operations. The **fp_rwuio** kernel service should only be used if the calling routine has been passed a **uio** structure. If the calling routine has not been passed a **uio** structure, it should not attempt to construct one and call the **fp_rwuio** kernel service with it. Rather, it should pass the requisite **uio** components to the **fp_read** or **fp_write** kernel services.

Execution Environment

The **fp_rwuio** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.

If an error occurs, one of the values from the **/usr/include/sys/errno.h** file is returned.

fp_select Kernel Service

Purpose

Provides for cascaded, or redirected, support of the select or poll request.

Syntax

#include <sys/types.h> #include <sys/errno.h> int fp_select (*fp*, *events*, *rtneventp*, *notify*) **struct file ***fp*; **ushort** *events*; **ushort ***rtneventp*; **void (*** *notify*)()**;**

Parameters

Item	Description
fp	Points to the open instance of the device driver, socket, or pipe for which the low-level select operation is intended.
events	Identifies the events that are to be checked. There are three standard event flags defined for the **poll** and **select** functions and one informational flag. The **/usr/include/sys/poll.h** file details the event bit definition. The four basic indicators are:

> **POLLIN**
> Input is present for the specified object.
>
> **POLLOUT**
> The specified file object is capable of accepting output.
>
> **POLLPRI**
> An exception condition has occurred on the specified object.
>
> **POLLSYNC**
> This is a synchronous request only. If none of the requested events are true, the selected routine should not remember this request as pending. That is, the routine does not need to call the **selnotify** service because of this request.

Item	Description
rtneventp	Indicates the returned events pointer. This parameter, passed by reference, is used to indicate which selected events are true at the current time. The returned event bits include the requested events plus an additional error event indicator:

POLLERR
> An error condition was indicated by the object's select routine. If this flag is set, the nonzero return code from the specified object's select routine is returned as the return code from the **fp_select** kernel service.

Item	Description
notify	Points to a routine to be called when the specified object invokes the **selnotify** kernel service for an outstanding asynchronous select or poll event request. If no routine is to be called, this parameter must be NULL.

Description

The **fp_select** kernel service is a low-level service used by kernel extensions to perform a select operation for an open device, socket, or named pipe. The **fp_select** kernel service can be used for both synchronous and asynchronous select requests. Synchronous requests report on the current state of a device, and asynchronous requests allow the caller to be notified of future events on a device.

Invocation from a Device Driver's ddselect Routine

A device driver's **ddselect** routine can call the **fp_select** kernel service to pass select/poll requests to other device drivers. The **ddselect** routine for one device invokes the **fp_select** kernel service, which calls the **ddselect** routine for a second device, and so on. This is required when event information for the original device depends upon events occurring on other devices. A cascaded chain of select requests can be initiated that involves more than two devices, or a single device can issue **fp_select** calls to several other devices.

Each **ddselect** routine should preserve, in its call to the **fp_select** kernel service, the same **POLLSYNC** indicator that it received when previously called by the **fp_select** kernel service.

Invocation from Outside a Device Driver's ddselect Routine

If the **fp_select** kernel service is invoked outside of the device driver's **ddselect** routine, the **fp_select** kernel service sets the **POLLSYNC** flag, always making the request synchronous. In this case, no notification of future events for the specified device occurs, nor is a **notify** routine called, if specified. The **fp_select** kernel service can be used in this manner (unrelated to a poll or select request in progress) to check an object's current status.

Asynchronous Processing and the Use of the notify Routine

For asynchronous requests, the **fp_select** kernel service allows its callers to register a **notify** routine to be called by the kernel when specified events become true. When the relevant device driver detects that one or more pending events have become true, it invokes the **selnotify** kernel service. The **selnotify** kernel service then calls the **notify** routine, if one has been registered. Thus, the **notify** routine is called at interrupt time and must be programmed to run in an interrupt environment.

Use of a **notify** routine affects both the calling sequence at interrupt time and how the requested information is actually reported. Generalized asynchronous processing entails the following sequence of events:

1. A select request is initiated on a device and passed on (by multiple **fp_select** kernel service invocations) to further devices. Eventually, a device driver's **ddselect** routine that is not dependent on other devices for information is reached. This **ddselect** routine finds that none of the requested events are true, but remembers the asynchronous request, and returns to the caller. In this way, the

entire chain of calls is backed out, until the origin of the select request is reached. The kernel then puts the originating process to sleep.

2. Later, one or more events become true for the device remembering the asynchronous request. The device driver routine (possibly an interrupt handler) calls the **selnotify** kernel service.

3. If the events are still being waited on, the **selnotify** kernel service responds in one of two ways. If no **notify** routine was registered when the select request was made for the device, then all processes waiting for events on this device are awakened. If a **notify** routine exists for the device, then this routine is called. The **notify** routine determines whether the original requested event should be reported as true, and if so, calls the **selnotify** kernel service on its own.

The following example details a cascaded scenario involving several devices. Suppose that a request has been made for Device A, and Device A depends on Device B, which depends on Device C. When specified events become true at Device C, the **selnotify** kernel service called from Device C's device driver performs differently depending on whether a **notify** routine was registered at the time of the request.

Cascaded Processing without the Use of notify Routines

If no **notify** routine was registered from Device B, then the **selnotify** kernel service determines that the specified events are to be considered true for the device driver at the head of the cascading chain. (The head of the chain, in this case Device A, is the first device driver to issue the **fp_select** kernel service from its select routine.) The **selnotify** kernel service awakens all processes waiting for events that have occurred on Device A.

It is important to note that when no **notify** routine is used, any device driver in the calling chain that reports an event with the **selnotify** kernel service causes that event to appear true for the first device in the chain. As a result, any processes waiting for events that have occurred on that first device are awakened.

Cascaded Processing with notify Routines

If, on the other hand, **notify** routines have been registered throughout the chain, then each interrupting device (by calling the **selnotify** kernel service) invokes the **notify** routine for the device above it in the calling chain. Thus in the preceding example, the **selnotify** kernel service for Device C calls the **notify** routine registered when Device B's **ddselect** routine invoked the **fp_select** kernel service. Device B's **notify** routine must then decide whether to again call the **selnotify** kernel service to alert Device A's **notify** routine. If so, then Device A's **notify** routine is called, and makes its own determination whether to call another **selnotify** routine. If it does, the **selnotify** kernel service wakes up all the processes waiting on occurred events for Device A.

A variation on this scenario involves a cascaded chain in which only some device drivers have registered **notify** routines. In this case, the **selnotify** kernel service at each level calls the **notify** routine for the level above, until a level is encountered for which no **notify** routine was registered. At this point, all events of interest are determined to be true for the device driver at the head of the cascading chain. If any **notify** routines were registered in levels above the current level, they are never called.

Returning from the fp_select Kernel Service

The **fp_select** kernel service does not wait for any selected events to become true, but returns immediately after the call to the object's **ddselect** routine has completed.

If the object's select routine is successfully called, the return code for the **fp_select** kernel service is set to the return code provided by the object's **ddselect** routine.

Execution Environment

The **fp_select** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
EAGAIN	Indicates that the allocation of internal data structures failed. The *rtneventp* parameter is not updated.
EINVAL	Indicates that the *fp* parameter is not a valid file pointer. The *rtneventp* parameter has the **POLLNVAL** flag set.

The **fp_select** kernel service can also be set to the nonzero return code from the specified object's **ddselect** routine. The *rtneventp* parameter has the **POLLERR** flag set.

select subroutine

fp_select Kernel Service notify Routine

Purpose

Registers the **notify** routine.

Syntax

#include <sys/types.h> #include <sys/errno.h> void notify (*id*, *sub_id*, *rtnevents*, *pid***) int** *id*; **int** *sub_id* ; **ushort** *rtnevents* ; **pid_t** *pid*;

Parameters

Item	Description
id	Indicates the selected function ID specified by the routine that made the call to the **selnotify** kernel service to indicate the occurrence of an outstanding event. For device drivers, this parameter is equivalent to the *devno* (device major and minor number) parameter.
sub_id	Indicates the unique ID specified by the routine that made the call to the **selnotify** kernel service to indicate the occurrence of an outstanding event. For device drivers, this parameter is equivalent to the *chan* parameter: channel for multiplexed drivers; 0 for nonmultiplexed drivers.
rtnevents	Specifies the *rtnevents* parameter supplied by the routine that made the call to the **selnotify** service indicating which events are designated as true.
pid	Specifies the process ID of a process waiting for the event corresponding to this call of the **notify** routine.

When a **notify** routine is provided for a cascaded function, the **selnotify** kernel service calls the specified **notify** routine instead of posting the process that was waiting on the event. It is up to this **notify** routine to determine if another **selnotify** call should be made to notify the waiting process of an event.

The **notify** routine is not called if the request is synchronous (that is, if the **POLLSYNC** flag is set in the *events* parameter) or if the original poll or select request is no longer outstanding.

Note: When more than one process has requested notification of an event and the **fp_select** kernel service is used with a **notify** routine specified, the notification of the event causes the **notify** routine to be called once for each process that is currently waiting on one or more of the occurring events.

Description

The **fp_select** kernel service **notify** routine is registered by the caller of the **fp_select** kernel service to be called by the kernel when specified events become true. The option to register this **notify** routine is available in a cascaded environment. The **notify** routine can be called at interrupt time.

Execution Environment

The **fp_select** kernel service **notify** routine can be called from either the process or interrupt environment.

fp_setea Kernel Service

Purpose

Sets an extended attribute value.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
int fp_setea (fp, name, value, size, flags, segflag)
struct file *fp;
const char * name;
void * value;
size_t size;
intflags
int segflag;
```

Parameters

Item	Description
fp	Specifies a file structure returned by the **fp_open** kernel service.
name	Specifies the name of the extended attribute. An extended attribute name is a NULL terminated string.
value	Specifies a pointer to the value of an attribute. The value of an extended attribute is an opaque byte stream of specified length.
size	Specifies the length of the value.
flags	None of the flags are defined at this time.

Item	Description
segflag	Specifies the flag indicating where the pointer specified by the *path* parameter is located: **SYS_ADSPACE** The pointers specified by the *name* and *value* parameters are stored in kernel memory. **USER_ADSPACE** The pointers specified by the *name* and *value* parameters are stored in application memory.

Description

The **fp_setea** kernel service provides a common service used by the following routines:

- The file system for the implementation of the **fsetea** subroutine
- Kernel routines outside the file system that set extended attribute values

Execution Environment

The **fp_setea** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
ERRNO	Indicates a failed operation. Returns an error number from the **/usr/include/sys/errno.h** file on failure.

#include <sys/errno.h>
int fp_statea ( fp, name, buffer, segflag)
struct file * fp;
const char * name;
struct stat64x * buffer;
int segflag;
```

Parameters

Item	Description
fp	Specifies a file structure returned by the **fp_open** kernel service.
name	Specifies the name of the extended attribute. An extended attribute name is a NULL terminated string.
buffer	Specifies a pointer to the **stat** structure in which information is returned.
segflag	Specifies the flag indicating the location of the pointer stored by the *path* parameter is located:

> **SYS_ADSPACE**
> The pointers specified by the *name* and *value* parameters are stored in kernel memory.
>
> **USER_ADSPACE**
> The pointers specified by the *name* and *value* parameters are stored in application memory.

Description

The **fp_statea** kernel service provides a common service used by the following routines:

- The file system for the implementation of the **fstatea** subroutine
- Kernel routines outside the file system that set extended attribute values.

Execution Environment

The **fp_statea** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
ERRNO	Indicates a failed operation. Returns an error number from the **/usr/include/sys/errno.h** file on failure.

write subroutine
Logical File System Kernel Services

fp_write Kernel Service for Data Link Control (DLC) Devices

Purpose

Allows kernel data to be sent using a file pointer.

Syntax

#include <sys/gdlextcb.h> #include <sys/fp_io.h> int fp_write (*fp***,** *buf***,** *nbytes***,** *ext***,** *segflag***,** *countp***)**

Parameters

Item	Description
fp	Specifies file pointer returned from the **fp_open** kernel service.
buf	Points to a kernel **mbuf** structure.
nbytes	Contains the byte length of the write data. It is not necessary to set this field to the actual length of write data, however, since the **mbuf** contains a length field. Instead, this field can be set to any non-negative value (generally set to 0).
ext	Specifies the extended kernel service parameter. This is a pointer to the **dlc_io_ext** extended I/O structure for writes. The argument for this parameter must be in the kernel space.
segflag	Specifies the segment flag indicating where the *path* parameter is located. The only valid value is: **FP_SYS** The *path* parameter is stored in kernel memory.
countp	Points to the location where a count of bytes actually written is to be returned (must be in kernel space). GDLC does not provide this information for a kernel user since **mbufs** are used, but the file system requires a valid address and writes a copy of the *nbytes* parameter to that location.

Description

Four types of data can be sent to generic data link control (GDLC). Network data can be sent to a service access point (SAP), and normal, exchange identification (XID) or datagram data can be sent to a link station (LS).

Kernel users pass a communications memory buffer (**mbuf**) directly to GDLC on the **fp_write** kernel service. In this case, a **uiomove** kernel service is not required, and maximum performance can be achieved by merely passing the buffer pointer to GDLC. Each write buffer is required to have the proper buffer header information and enough space for the data link headers to be inserted. A write data offset is passed back to the kernel user at start LS completion for this purpose.

All data must fit into a single packet for each write call. That is, GDLC does not separate the user's write data area into multiple transmit packets. A maximum write data size is passed back to the user at **DLC_ENABLE_SAP** completion and at **DLC_START_LS** completion for this purpose.

Normally, a write subroutine can be satisfied immediately by GDLC by completing the data link headers and sending the transmit packet down to the device handler. In some cases, however, transmit packets can be blocked by the particular protocol's flow control or a resource outage. GDLC reacts to this differently, based on the system blocked/nonblocked file status flags (set by the file system and based on the **O_NDELAY** and **O_NONBLOCKED** values passed on the **fp_open** kernel service). Nonblocked **write** subroutines that cannot get enough resources to queue the communications memory buffer (**mbuf**) return an error indication. Blocked write subroutines put the calling process to sleep until the resources free up or an error occurs. Each GDLC supports the **fp_write** kernel service via its **dlcwrite** entry point. The **fp_write** kernel service may be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
EAGAIN	Indicates that transmit is temporarily blocked, and the calling process cannot be put to sleep.

Item	Description
EINTR	Indicates that a signal interrupted the kernel service before it could complete successfully.
EINVAL	Indicates an invalid argument, such as too much data for a single packet.
ENXIO	Indicates an invalid file pointer.

These return values are defined in the **/usr/include/sys/errno.h** file.

Generic Data Link Control (GDLC) Environment Overview

fp_writev Kernel Service

Purpose

Performs a write operation on an open file with arguments passed in **iovec** elements.

Syntax

#include <sys/types.h> #include <sys/errno.h> int fp_writev (*fp*, *iov*, *iovcnt*, *ext*, *seg*, *countp***) struct file * ***fp***; struct iovec * ***iov***; ssize_t ***iovcnt***; ext_t ***ext***; int ***seg***; ssize_t * ***countp***;**

Parameters

Item	Description
fp	Points to a file structure returned by the **fp_open** kernel service.
iov	Points to an array of **iovec** elements. Each **iovec** element describes a buffer containing data to be written to the file.
iovcnt	Specifies the number of **iovec** elements in an array pointed to by the *iov* parameter.
ext	Specifies an extension argument required by some device drivers. Its content, form, and use are determined by the individual driver.
segflag	Indicates which part of memory the information designated by the *iov* parameter is located in:
	SYS_ADSPACE The information designated by the *iov* parameter is in kernel memory.
	USER_ADSPACE The information designated by the *iov* parameter is in application memory.
countp	Points to the location where the count of bytes actually written to the file is to be returned.

Description

The **fp_writev** kernel service is an internal interface to the function provided by the **writev** subroutine.

Execution Environment

The **fp_writev** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.

If an error occurs, one of the values from the **/usr/include/sys/errno.h** file is returned.

Related information

writev subroutine

Logical File System Kernel Services

fskv_reg Kernel Service

Purpose

Registers callout handlers for validation of file system operations.

Syntax

```
#include <sys/xfops.h>

int fskv_reg(fskv_t *fs_kv, ulong options);

typedef struct fskv {
        int version_number;
        int (*kv_open)(struct xfid *xfp,
                               long flags,
                               cred_ext_t *crxp);
        int (*kv_setattr)(struct xfid *xfp,
                               long op,
                               long arg1,
                               long arg2,
                               long arg3,
                               cred_ext_t *crxp);
} fskv_t;
```

Parameters

fs_kv
Specifies an array of callout functions that are called to validate file system operations in the kernel.

options
Specifies a bit mask of registration options. The **options** parameter is not defined currently. The caller must set the **options** parameter to 0.

Description

The `fskv_reg` kernel service registers an array of functions that are called before the execution of file system-specific operations.

After a callout handler is registered, each of the affected operations is preceded by a call to the corresponding validation routine.

Only one callout array can be registered. After a callout array is registered with the `fskv_reg` kernel service, the subsequent invocation of the `fskv_reg` kernel service does not succeed until the `fskv_unreg` kernel service is called. The caller of the `fskv_reg` kernel service must have root authority.

Execution environment

The `fskv_reg` kernel service can be called only from the process environment.

Return values

On successful completion, the `fskv_reg` kernel service returns a value of 0.

The following error codes can be returned on failure:

EEXIST
  The callout array is already registered.

EPERM
  The caller does not have permission to invoke this function.

EINVAL
  A parameter is invalid.

Callout handlers

Callouts can be specified for the open, `chmod`, `chown`, and `utimes` system calls. The `chmod`, `chown`, and `utimes` system calls are handled in a single operation in the kernel with the `setattr` call.

If the validation callout routine returns a nonzero value, the file system operation is stopped and the system call returns the EPERM value.

The validation routines are called only for local physical file systems (JFS2 and JFS) and network file system (NFS)-mounted file systems. The callout functions accept the following arguments. The `xfid` argument uniquely identifies the file within the current running system.

```
typedef struct xfid {
        fsid_t x_fsid;
        fid_t x_fid;
} xfid_t;
```

kv_open() callout function

The `kv_open` callout function contains the information that is available to the open routines of the file system to track and validate open calls.

Syntax

```
#include <sys/file.h>
#include <sys/cred.h>

int     (*kv_open)(struct xfid *xfp,
        long flags,
        void *nrp,
        cred_ext_t *crxp);
```

Parameters

xfp
  Pointer to an `xfid` structure that identifies the file system and object.

nrp
  Name resolution information. If the `xfidToName` kernel service is called, this parameter must be passed to it. This pointer is not valid after it is returned from the callout function.

flags
  Open flags that are passed by the application.

crxp

Pointer to the credentials for the calling process.

Return values

Zero

Indicates that the validation completed successfully.

Nonzero

Indicates that the validation failed.

kv_setattr() callout function

The `kv_setattr` callout function contains the information that is available to the system call that initiated this function. The `setattr` function is called by the `chown`, `chmod`, and `utimes` system calls and the variants of those system calls (for example, `fchown`, `fchmod`, and `futimens` system calls).

Syntax

```
#include <sys/vattr.h>
#include <sys/cred.h>

int (*kv_setattr)(struct xfid *xfp,
        long op,
        long arg1,
        long arg2,
        long arg3,
        void *nrp,
        cred_ext_t *crxp);
```

Parameters

xfp

Pointer to an `xfid` structure that identifies the file system and object.

op

Specifies one of the following operations:

V_OWN

Sets file ownership.

V_MODE

Sets file mode.

V_UTIME

Sets the file time specified by the user.

V_STIME

Sets the file time requested by the system.

arg*n*

Specifies the following values for each of the listed operations.

Table 1. kv_setattr() callout function: argn parameter values

Operations	arg1	arg2	arg3

V_OWN	flag:
	
	`T_OWNER_AS_IS`
	`T_GROUP_AS_IS`
	
	(For information about the file ownership changes, see chownx subroutine.)
		`uid_t newuid`	`gid_t newgid`

V_MODE	`mode_t newmode`	Unused	Unused

Table 1. kv_setattr() callout function: argn parameter values (continued)			
Operations	**arg1**	**arg2**	**arg3**
V_UTIME	flag: `V_SETTIME` Ignore arguments and set time to the current time.	`timestruct_t *atime` Set the access time.	`timestruct_t *mtime` Set the modification time.
V_STIME	NULL or `timestruct_t *atime` Set the access time.	NULL or `timestruct_t *mtime` Set the modification time.	NULL or `timestruct_t *ctime` Set the change time.

nrp
   Indicates the name resolution information. If the `xfidToName` kernel service is called, this parameter must be passed to it. This parameter is a pointer to temporary information that is not valid after it is returned from the validation routine.

crxp
   Pointer to credentials for the calling process.

Return values

Zero
   Indicates that the validation completed successfully.

Nonzero
   Indicates that the validation failed.

Related reference
nameToXfid() Kernel Service
xfidToName() Kernel Service

fskv_unreg Kernel Service

Purpose

Unregisters callout handlers for validation of file system operations.

Syntax

```
    #include <sys/xfops.h>

  int fskv_unreg(ulong options);
```

Parameters

options
   Specifies a bit mask of registration options. The **options** parameter is not defined currently. The caller must set the **options** parameter to 0.

Description

The `fskv_unreg` kernel service removes the registration of the functions to be called before the execution of file system operations. After this service completes, the callout handlers are not executed.

The caller of the `fskv_unreg` kernel service must have root authority.

Execution environment

The `fskv_unreg` kernel service can be called only from the process environment.

Return values

On successful completion, the `fskv_unreg` kernel service returns a value of 0.

The following error codes are returned on failure:

EPERM
The caller does not have permission to invoke this function.

EINVAL
A parameter is invalid.

fubyte Kernel Service

Purpose

Retrieves a byte of data from user memory.

Syntax

#include <sys/types.h> #include <sys/errno.h> int fubyte (*uaddr***) uchar ****uaddr***;**

Parameter

Item	Description
uaddr	Specifies the address of the user data.

Description

The **fubyte** kernel service fetches, or retrieves, a byte of data from the specified address in user memory. It is provided so that system calls and device heads can safely access user data. The **fubyte** service ensures that the user has the appropriate authority to:

- Access the data.
- Protect the operating system from paging I/O errors on user data.

The **fubyte** service should be called only while executing in kernel mode in the user process.

Execution Environment

The **fubyte** kernel service can be called from the process environment only.

Return Values

When successful, the **fubyte** service returns the specified byte.

Item	Description
-1	Indicates a *uaddr* parameter that is not valid.

The access is not valid under the following circumstances:

- The user does not have sufficient authority to access the data.

- The address is not valid.
- An I/O error occurs while referencing the user data.

Related reference
fuword Kernel Service
subyte Kernel Service
Related information
Accessing User-Mode Data while in Kernel Mode

fuword Kernel Service

Purpose

Retrieves a word of data from user memory.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

int fuword (*uaddr*)
int **uaddr;*

Parameter

Item	Description
uaddr	Specifies the address of user data.

Description

The **fuword** kernel service retrieves a word of data from the specified address in user memory. It is provided so that system calls and device heads can safely access user data. The **fuword** service ensures that the user had the appropriate authority to:

- Access the data.
- Protect the operating system from paging I/O errors on user data.

The **fuword** service should be called only while executing in kernel mode in the user process.

Execution Environment

The **fuword** kernel service can be called from the process environment only.

Return Values

When successful, the **fuword** service returns the specified word of data.

Item	Description
-1	Indicates a *uaddr* parameter that is not valid.

The access is not valid under the following circumstances:

- The user does not have sufficient authority to access the data.

- The address is not valid.
- An I/O error occurred while referencing the user data.

For the **fuword** service, a retrieved value of -1 and a return code of -1 are indistinguishable.

Accessing User-Mode Data while in Kernel Mode

g

The following kernel services begin with the with the letter g.

getblk Kernel Service

Purpose

Assigns a buffer to the specified block.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
```

```
struct buf *getblk
( dev,  blkno)
dev_t  dev;
daddr_t  blkno;
```

Parameters

Item	Description
dev	Specifies the device that contains the block to be allocated.
blkno	Specifies the block to be allocated.

Description

The `getblk` kernel service first checks whether the specified buffer is in the buffer cache. If the buffer resides there, but is in use, the **e_sleep** service is called to wait until the buffer is no longer in use. Upon waking, the `getblk` service tries again to access the buffer. If the buffer is in the cache and not in use, it is removed from the free list and marked as busy. Its buffer header is then returned. If the buffer is not in the buffer cache, another buffer is taken from the free list and returned.

Execution Environment

The `getblk` kernel service can be called from the process environment only.

Return Values

The `getblk` service returns a pointer to the buffer header. A nonzero value for B_ERROR in the `b_flags` field of the buffer header (`buf`structure) indicates an error. If this occurs, the caller should release the block's buffer using the `brelse` kernel service.

On a platform that supports storage keys, the buffer header is allocated from the storage that is protected by the KKEY_BLOCK_DEV kernel key.

Block I/O Buffer Cache Kernel Services: Overview

I/O Kernel Services

getc Kernel Service

Purpose

Retrieves a character from a character list.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <cblock.h>
```

int getc (*header***)**
struct clist **header***;**

Parameter

Item	Description
header	Specifies the address of the **clist** structure that describes the character list.

Description

> **Attention:** The caller of the **getc** service must ensure that the character list is pinned. This includes the **clist** header and all the **cblock** character buffers. Otherwise, the system may crash.

The **getc** kernel service returns the character at the front of the character list. After returning the last character in the buffer, the **getc** service frees that buffer.

Execution Environment

The **getc** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
-1	Indicates that the character list is empty.

Related information

I/O Kernel Services

getcb Kernel Service

Purpose

Removes the first buffer from a character list and returns the address of the removed buffer.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <cblock.h>
```

struct cblock *getcb
(*header***)**
struct clist **header***;**

Parameter

Item	Description
header	Specifies the address of the **clist** structure that describes the character list.

Description

> **Attention:** The caller of the **getcb** service must ensure that the character list is pinned. This includes the **clist** header and all the **cblock** character buffers. Character buffers acquired from the **getcf** service are pinned. Otherwise, the system may crash.

The **getcb** kernel service returns the address of the character buffer at the start of the character list and removes that buffer from the character list. The user must free the buffer with the **putcf** service when finished with it.

Execution Environment

The **getcb** kernel service can be called from either the process or interrupt environment.

Return Values

A null address indicates the character list is empty.

The **getcb** service returns the address of the character buffer at the start of the character list when the character list is not empty.

Related reference
getcf Kernel Service
Related information
I/O Kernel Services

getcbp Kernel Service

Purpose

Retrieves multiple characters from a character buffer and places them at a designated address.

Syntax

```
#include <cblock.h>
```

int getcbp (*header***,** *dest***,** *n***)**
struct clist **header***;**
char **dest***;**
int *n***;**

Parameters

Item	Description
header	Specifies the address of the **clist** structure that describes the character list.
dest	Specifies the address where the characters obtained from the character list are to be placed.
n	Specifies the number of characters to be read from the character list.

Description

> **Attention:** The caller of the **getcbp** services must ensure that the character list is pinned. This includes the **clist** header and all the **cblock** character buffers. Character buffers acquired from the **getcf** service are pinned. Otherwise, the system may crash.

The **getcbp** kernel service retrieves as many as possible of the *n* characters requested from the character buffer at the start of the character list. The **getcbp** service then places them at the address pointed to by the *dest* parameter.

Execution Environment

The **getcbp** kernel service can be called from either the process or interrupt environment.

Return Values

The **getcbp** service returns the number of characters retrieved from the character buffer.

Related reference
getcf Kernel Service
Related information
I/O Kernel Services

getcf Kernel Service

Purpose

Retrieves a free character buffer.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <cblock.h>
```

```
struct cblock *getcf ( )
```

Description

The **getcf** kernel service retrieves a character buffer from the list of available ones and returns that buffer's address. The returned character buffer is pinned. If you use the **getcf** service to get a character buffer, be sure to free the space when you have finished using it. The buffers received from the **getcf** service should be freed by using the **putcf** kernel service.

Before starting the **getcf** service, the caller should request enough **clist** resources by using the **pincf** kernel service. The proper use of the **getcf** service ensures that there are sufficient pinned buffers available to the caller.

If the **getcf** service indicates that there is no available character buffer, the **waitcfree** service can be called to wait until a character buffer becomes available.

The **getcf** service has no parameters.

Execution Environment

The **getcf** kernel service can be called from either the process or interrupt environment.

Return Values

Upon successful completion, the **getcf** service returns the address of the allocated character buffer.

A null pointer indicates no buffers are available.

Related reference
pincf Kernel Service
putcf Kernel Service
Related information
I/O Kernel Services

getcx Kernel Service

Purpose

Returns the character at the end of a designated list.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <cblock.h>
```

int getcx (*header***)**
struct clist **header***;**

Parameter

Item	Description
header	Specifies the address of the **clist** structure that describes the character list.

Description

> **Attention:** The caller of the **getcx** service must ensure that the character list is pinned. This includes the **clist** header and all the **cblock** character buffers. Character buffers acquired from the **getcf** service are pinned.

The **getcx** kernel service is identical to the **getc** service, except that the **getcx** service returns the character at the end of the list instead of the character at the front of the list. The character at the end of the list is the last character in the first buffer, not in the last buffer.

Execution Environment

The **getcx** kernel service can be called from either the process or interrupt environment.

Return Values

The **getcx** service returns the character at the end of the list instead of the character at the front of the list.

geteblk Kernel Service

Purpose

Allocates a free buffer.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
```

```
struct buf *geteblk ( )
```

Description

⚠ **Attention:** The use of the **geteblk** service by character device drivers is strongly discouraged. As an alternative, character device drivers can use the **xmalloc** service to allocate the memory space directly, or the character I/O kernel services such as the **getcb** or **getcf** services.

The **geteblk** kernel service allocates a buffer and buffer header and returns the address of the buffer header. If no free buffers are available, then the **geteblk** service waits for one to become available. Block device drivers can retrieve buffers using the **geteblk** service.

In the header, the b_forw, b_back, b_flags, b_bcount, b_dev, and b_un fields are used by the system and cannot be modified by the driver. The av_forw and av_back fields are available to the user of the **geteblk** service for keeping a chain of buffers by the user of the **geteblk** service. (This user could be the kernel file system or a device driver.) The b_blkno and b_resid fields can be used for any purpose.

The **brelse** service is used to free this type of buffer.

The **geteblk** service has no parameters.

Execution Environment

The **geteblk** kernel service can be called from the process environment only.

Return Values

The **geteblk** service returns a pointer to the buffer header. There are no error codes because the **geteblk** service waits until a buffer header becomes available.

On a platform that supports storage keys, the buffer header is allocated from the storage protected by the **KKEY_BLOCK_DEV** kernel key.

geterror Kernel Service

Purpose

Determines the completion status of the buffer.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
```

int geterror (*bp*)
**struct buf ***bp*;

Parameter

Item	Description
bp	Specifies the address of the buffer structure whose status is to be checked.
	On a platform that supports storage keys, the passed in *bp* parameter must be in the **KKEY_PUBLIC** or **KKEY_BLOCK_DEV** protection domain.

Description

The **geterror** kernel service checks the specified buffer to see if the **b_error** flag is set. If that flag is not set, the **geterror** service returns 0. Otherwise, it returns the nonzero **B_ERROR** value or the **EIO** value (if **b_error** is 0).

Execution Environment

The **geterror** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates that no I/O error occurred on the buffer.
b_error value	Indicates that an I/O error occurred on the buffer.
EIO	Indicates that an unknown I/O error occurred on the buffer.

Related information
Block I/O Buffer Cache Kernel Services: Overview
I/O Kernel Services

getexcept Kernel Service

Purpose

Allows kernel exception handlers to retrieve additional exception information.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/except.h>
```

```
void getexcept
( exceptp)
struct except *exceptp;
```

Parameter

Item	Description
exceptp	Specifies the address of an **except** structure, as defined in the **/usr/include/sys/except.h** file. The **getexcept** service copies detailed exception data from the current machine-state save area into this caller-supplied structure.

Description

The **getexcept** kernel service provides exception handlers the capability to retrieve additional information concerning the exception from the machine-state save area.

The **getexcept** service should only be used by exception handlers when called to handle an exception. The contents of the structure pointed at by the *exceptp* parameter is platform-specific, but is described in the **/usr/include/sys/except.h** file for each type of exception that provides additional data. This data is typically included in any error logging data for the exception. It can be also used to attempt to handle or recover from the exception.

Execution Environment

The **getexcept** kernel service can be called from either the process or interrupt environment. It should be called only when handling an exception.

Return Values

The **getexcept** service has no return values.

Related information
Kernel Extension and Device Driver Management Kernel Services and

getfslimit Kernel Service

Purpose

Returns the maximum file size limit of the current process.

Syntax

#include <sys/types.h> offset_t getfslimit (void)

Description

The **getfslimit** kernel service returns the file size limit of the current process as a 64 bit integer. This can be used by file systems to implement the checks needed to enforce limits. The **getfslimit** kernel service is called from the process environment.

Return Values

The **getfslimit** kernel service returns the the file size limit, there are no error values.

Related information
ulimit subroutine
getrlimit subroutine

get_pag or get_pag64 Kernel Service

Purpose

Retrieves a Process Authentication Group (PAG) value for the current process.

Syntax

```
#include <sys/cred.h>

int get_pag ( type, pag )
int type;
int *pag;

int get_pag64 ( type, pag )
int type;
uint64_t *pag;
```

Parameters

Item	Description
type	PAG type to retrieve
pag	Pointer to buffer where operating system returns the PAG

Description

The `get_pag` and `get_pag64` kernel services copy the requested PAG from the current process into *pag*. The value of *type* must be a defined PAG ID. The PAG ID for the Distributed Computing Environment (DCE) is 0.

Execution Environment

The `get_pag` and `get_pag64` kernel services can be called from the process environment only.

Return Values

A value of `0` is returned upon successful completion. If unsuccessful, `errno` is set to a value that explains the error.

Error Codes

The `get_pag` kernel service fails if one or both of the following conditions are true:

Item	Description
EINVAL	Invalid PAG specification
EOVERFLOW	PAG value is 64-bit (should be using `get_pag64`)

The `get_pag64` kernel service fails if the following condition is true:

Item	Description
EINVAL	Invalid PAG specification

Related information
Security Kernel Services

getpid Kernel Service

Purpose

Gets the process ID of the current process.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
pid_t getpid ()
```

Description

The **getpid** kernel service returns the process ID of the calling process.

The **getpid** service can also be used to check the environment that the routine is being executed in. If the caller is executing in the interrupt environment, the **getpid** service returns a process ID of -1. If a routine is executing in a process environment, the **getpid** service obtains the current process ID.

Execution Environment

The **getpid** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
-1	Indicates that the **getpid** service was called from an interrupt environment.

The **getpid** service returns the process ID of the current process if called from a process environment.

Related information

Process and Exception Management Kernel Services
Understanding Execution Environments

getppidx Kernel Service

Purpose

Gets the parent process ID of the specified process.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
pid_t getppidx (ProcessID)
pid_t ProcessID;
```

Parameter

Item	Description
ProcessID	Specifies the process ID. If this parameter is 0, then the parent process ID of the calling process is returned.

Description

The `getppidx()` kernel service accepts a process ID as an input. If the input process ID is 0, the `getppidx()` subroutine returns the process ID of the calling process' parent process. If the input process ID is nonzero and a valid value, the parent ID of the input process ID is returned. If the input process ID is invalid, the `getppidx()` kernel service returns -1.

Execution Environment

The `getppidx()` kernel service can be called from the process environment only.

Return Values

Item	Description
-1	Indicates that the **ProcessID** parameter is invalid.

Related reference
getpid Kernel Service

getuerror Kernel Service

Purpose

Allows kernel extensions to read the **ut_error** field for the current thread.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
int getuerror ()
```

Description

The **getuerror** kernel service allows a kernel extension in a process environment to retrieve the current value of the current thread's **ut_error** field. Kernel extensions can use the **getuerror** service when using system calls or other kernel services that return error information in the **ut_error** field.

For system calls, the system call handler copies the value of the **ut_error** field in the per thread **uthread** structure to the **errno** global variable before returning to the caller. However, when kernel services use available system calls, the system call handler is bypassed. The **getuerror** service must then be used to obtain error information.

Execution Environment

The **getuerror** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.

When an error occurs, the **getuerror** kernel service returns the current value of the **ut_error** field in the per thread **uthread** structure. Possible return values for this field are defined in the **/usr/include/sys/errno.h** file.

Related reference
setuerror Kernel Service

getufdflags and setufdflags Kernel Services

Purpose

Queries and sets file-descriptor flags.

Syntax

#include <sys/user.h> int getufdflags(*fd, flagsp***) int** *fd***; int ****flagsp***; #include <sys/user.h> int setufdflags(***fd***,** *flags***) int** *fd***; int** *flags***;**

Parameters

Item	Description
fd	Identifies the file descriptor.
flags	Sets attribute flags for the specified file descriptor. Refer to the **sys/user.h** file for the list of valid flags.
flagsp	Points to an integer field where the flags associated with the file descriptor are stored on successful return.

Description

The **setufdflags** and **getufdflags** kernel services set and query the file descriptor flags. The file descriptor flags are listed in **fontl.h**.

Execution Environment

These kernel services can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
EBADF	Indicates that the *fd* parameter is not a file descriptor for an open file.

get_umask Kernel Service

Purpose

Queries the file mode creation mask.

Syntax

```
int get_umask(void)
```

Description

The **get_umask** service gets the value of the file mode creation mask currently set for the process.

Note: There is no corresponding kernel service to set the umask because kernel routines that need to set the umask can call the **umask** subroutine.

Execution Environment

The **get_umask** kernel service can be called from the process environment only.

Return Values

The **get_umask** kernel service always completes successfully. Its return value is the current value of the **umask**.

gfsadd Kernel Service

Purpose

Adds a file system type to the **gfs** table.

Syntax

#include <sys/types.h> #include <sys/errno.h> int gfsadd (*gfsno*, *gfsp***) int** *gfsno*; **struct gfs ****gfsp*;

Parameters

Item	Description
gfsno	Specifies the file system number. This small integer value is either defined in the **/usr/include/sys/vmount.h** file or a user-defined number of the same order.
gfsp	Points to the file system description structure.

Description

The **gfsadd** kernel service is used during configuration of a file system. The configuration routine for a file system invokes the **gfsadd** kernel service with a **gfs** structure. This structure describes the file system type.

The **gfs** structure type is defined in the **/usr/include/sys/gfs.h** file. The **gfs** structure must have the following fields filled in:

Field	Description
gfs_type	Specifies the integer type value. The predefined types are listed in the **/usr/include/sys/vmount.h** file.
gfs_name	Specifies the character string name of the file system. The maximum length of this field is 16 bytes. Shorter names must be null-padded.

Field	Description
gfs_flags	Specifies the flags that define the capabilities of the file system. The following flag values are defined:

GFS_AHAFS_INFO
GFS supports AHAFS FS monitoring.

GFS_AIX_FLOCK
Uses **common_reclock()** to manage advisory locks.

GFS_DIROP
Call parent **vnop** instead of **obj**.

GFS_FASTPATH
GFS supports AIO fast path.

GFS_FUMNT
File system supports forced unmount.

GFS_INIT
GFS has been initialized

GFS_MEMCNTL
New **memcntl** vnode operation

GFS_MLS
GFS supports MLS.

GFS_NAMED_OPEN
File system supports named open.

GFS_NO_ACCT
Do not do file system account on this file system.

GFS_NOEXPORT
GFS cannot be exported by NFS.

GFS_NOUMASK
File system does not apply umask when creating new objects.

GFS_OFLAGS64
GFS supports 64 bit open flags.

GFS_REMNT
File system supports remount of a mounted file system.

Field	Description

GFS_REMOTE
  File system is remote (ie. NFS).

GFS_STATFSVP
  File system supports **vfs_statfsvp** VFS interface. (new vfs operation: **vfs_statfsvp**)

GFS_SYS5DIR
  File system that uses the System V-type directory structure.

GFS_SYNCVFS
  The **syncvfs** vnode operation.

GFS_VERSION4
  File system supports AIX Version 4 V-node interface.

GFS_VERSION42
  File system supports AIX 4.2 V-node interface. (new vnode operation: vnop_seek)

GFS_VERSION421
  File system supports AIX 4.2.1 V-node interface.(new vnode operations: **vnop_sync_range**, **vnop_create_attr**, **vnop_finfo**, **vnop_map_lloff**, **vnop_readdir_eofp**, **vnop_rdwr_attr**)

GFS_VERSION43
  File system supports AIX 4.3 V-node interface. (new file flag for vnop_sync_range:FMSYNC)

GFS_VERSION53
  File system supports AIX 5.3 V-node interface (new vnode operations: vnop_getxacl, vnop_setxacl) and AIX 5.3 VFS interface. (new vfs operation: vfs_aclxcntl)

GFS_VREGSEL
  GFS wants to select vnode operation called for **VREG** files.

gfs_ops	Specifies the array of pointers to **vfs** operation implementations.
gn_ops	Specifies the array of pointers to v-node operation implementations.

The file system description structure can also specify:

Item	Description
gfs_init	Points to an initialization routine to be called by the **gfsadd** kernel service. This field must be null if no initialization routine is to be called.
gfs_data	Points to file system private data.

Execution Environment

The **gfsadd** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
EBUSY	Indicates that the file system type has already been installed.
EINVAL	Indicates that the *gfsno* value is larger than the system-defined maximum. The system-defined maximum is indicated in the **/usr/include/sys/vmount.h** file.

Related reference
vfs_init Entry Point

gfsdel Kernel Service

Purpose

Removes a file system type from the **gfs** table.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

int gfsdel (*gfsno***)**
int *gfsno***;**

Parameter

Item	Description
gfsno	Specifies the file system number. This value identifies the type of the file system to be deleted.

Description

The **gfsdel** kernel service is called to delete a file system type. It is not valid to mount any file system of the given type after that type has been deleted.

Execution Environment

The **gfsdel** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
ENOENT	Indicates that the indicated file system type was not installed.
EINVAL	Indicates that the *gfsno* value is larger than the system-defined maximum. The system-defined maximum is indicated in the **/usr/include/sys/vmount.h** file.
EBUSY	Indicates that there are active **vfs** structures for the file system type being deleted.

Virtual File System Kernel Services

gn_closecnt Subroutine

Purpose

Maintains the using count on a **gnode** structure.

Syntax

```
#include <sys/vnode.h>
#include <sys/fcntl.h>
```

void gn_closecnt (*gnode*, *flags*)
struct gnode * *gnode*;
long *flags*;

Parameters

Item	Description
gnode	Points to a **gnode** structure.
flags	Specifies the open mode (**FREAD**, **FWRITE**, **FEXEC**, **FRSHARE**) from the open file flags.

Description

The **gn_closecnt** subroutine uses the passed in *flags* value to determine the appropriate using counts to decrease in the *gnode* structure. For example, if the **FREAD** flag is set, the **gn_closecnt** subroutine decreases the gn_rdcnt field. The following table shows the mapping of the *flags* value to the counts field in the *gnode* structure:

Item	Description
FREAD	gn_rdcnt
FWRITE	gn_wrcnt
FEXEC	gn_excnt
FRSHARE	gn_rshcnt

Return Values

The **gn_closecnt** subroutine returns no return values.

Error Codes

The **gn_closecnt** subroutine returns no error codes.

Related information

Understanding Data Structures and Header Files for Virtual File Systems

gn_common_memcntl Subroutine

Purpose

Changes or queries the physical attachment of a file.

Syntax

```
#include <sys/vnode.h>
#include <sys/fcntl.h>
```

int gn_common_memcntl (*gnode*, *cmd*, *arg*)
struct gnode * *gnode*;

```
int cmd;
void * arg;
```

Parameters

Item	Description
gnode	Points to a **gnode** structure.
cmd	Specifies the operation to be performed. The *cmd* parameter can be one of the following values:
	• **F_ATTACH**
	• **F_DETACH**
	• **F_ATTINFO**
arg	Points to a structure containing information for the specified *cmd* parameter.
	F_ATTACH attach_desc_t
	F_DETACH detach_desc_t
	F_ATTINFO attinfo_desc_t

Description

The **gn_common_memcntl** subroutine is to be called by file system **vnop_memcntl** implementations. It performs the normal function of such operations. If the *cmd* parameter is set to **F_ATTACH**, the **gn_common_memcntl** subroutine attaches the segment specified by the *gn_seg* field in the **gnode** structure. If the *cmd* parameter is set to **F_DETACH**, the **gn_common_memcntl** subroutine detaches the segment. If the *cmd* parameter is set to **F_ATTINFO**, the **gn_common_memcntl** subroutine returns information about the current state of attachment.

Return Values

Item	Description
0	Success.
non-zero	Failure.

Error Codes

Item	Description
EINVAL	The *cmd* parameter is not valid.
ENOMEM	Resources are not available to attach the memory segment.

gn_mapcnt Subroutine

Purpose

Maintains the mapping count in a **gnode** structure.

Syntax

```
#include <sys/vnode.h>
#include <sys/shm.h>
```

```
void gn_mapcnt (gnode, flags)
struct gnode * gnode;
long flags;
```

Parameters

Item	Description
gnode	Points to a **gnode** structure.
flags	Specifies the following mapping flag:

> **SHM_RDONLY**
>   Only read access is required.

Description

The **gn_mapcnt** subroutine uses the passed in *flags* value to determine the appropriate mapping count to increase in the *gnode* structure. If the **SHM_RDONLY** flag is set, the **gn_mapcnt** subroutine increases the gn_mrdcnt field. Otherwise, the **gn_mapcnt** subroutine increases the gn_mwrcnt field.

Return Values

The **gn_mapcnt** subroutine returns no return values.

Error Codes

The **gn_mapcnt** subroutine returns no error codes.

Related information

mmap subroutine

shmat subroutine

gn_opencnt Subroutine

Purpose

Maintains the using count on a **gnode** structure.

Syntax

```
#include <sys/vnode.h>
#include <sys/fcntl.h>
```

```
void gn_opencnt (gnode, flags)
struct gnode * gnode;
long flags;
```

Parameters

Item	Description
gnode	Points to a **gnode** structure.
flags	Specifies the open mode (**FREAD**, **FWRITE**, **FEXEC**, **FRSHARE**) from the open file flags.

Description

The **gn_opencnt** subroutine uses the passed in *flags* value to determine the appropriate using counts to increase in the *gnode* structure. The following table shows the mapping of the *flags* value to the counts field in the *gnode* structure:

Item	Description
FREAD	gn_rdcnt
FWRITE	gn_wrcnt
FEXEC	gn_excnt
FRSHARE	gn_rshcnt

Return Values

The **gn_opencnt** subroutine returns no return values.

Error Codes

The **gn_opencnt** subroutine returns no error codes.

Related information

gn_unmapcnt Subroutine

Purpose

Maintains the mapping count in a **gnode** structure.

Syntax

```
#include <sys/vnode.h>
#include <sys/shm.h>
```

void gn_unmapcnt (*gnode*, *flags*)
struct gnode * *gnode*;
long *flags*;

Parameters

Item	Description
gnode	Points to a **gnode** structure.
flags	Specifies the following mapping flag:

    SHM_RDONLY
        Only read access is required.

Description

The **gn_unmapcnt** subroutine uses the passed in *flags* value to determine the appropriate mapping count to decrease in the *gnode* structure. If the **SHM_RDONLY** flag is set, the **gn_unmapcnt** subroutine decreases the gn_mrdcnt field. Otherwise, the **gn_unmapcnt** subroutine decreases the gn_mwrcnt field.

Return Values

The **gn_unmapcnt** subroutine returns no return values.

Error Codes

The **gn_unmapcnt** subroutine returns no error codes.

Related information

groupmember, groupmember_cr Subroutines

Purpose

Determines if the named group is a member of a credential group set.

Syntax

```
#include <sys/types.h>
#include <sys/cred.h>
```

int groupmember (*gid*)
gid_t *gid*;

int groupmember_cr (*gid*, *cred*)
gid_t *gid*;
cred_t * *cred*;

Parameters

Item	Description
gid	Specifies an identifier for a group.
cred	Points to a **ucred** structure.

Description

The **groupmember** subroutines determine if a group is included in the group set of a credential structure. The **groupmember** subroutine queries the credential associated with the current thread. The **groupmember_cr** subroutine checks for the group within the specified **ucred** structure.

Return Values

The **groupmember** subroutines return TRUE if the **ucred** structure contains the specified *gid* parameter or if the specified *gid* parameter is the current effective group ID for the thread. Otherwise, these routines return FALSE.

Error Codes

The **groupmember** subroutines return no error codes.

Security Kernel Services

h

The following kernel services begin with the with the letter h.

heap_create Kernel Service

Purpose

Initializes a new heap to be used with kernel memory management services. The **heap_create** kernel service replaces the **init_heap** kernel service. It returns a heap handle that can be used with the **xmalloc** and the **xmfree** kernel services.

Syntax

```
#include <sys/types.h>
#include <sys/malloc.h>
#include <sys/skeys.h>
#include <sys/kerrno.h>
```

kerrno_t heap_create (heapattr_t * *heapattr*, **heapaddr_t *** *heapptr*);

Parameters

Item	Description
heapattr	Points to an initialized heap attribute structure. See the **sys/malloc.h** file. This structure is initialized by the caller of **heap_create**.
heapptr	Points to an external heap descriptor. The caller must initialize this parameter to the **HPA_INVALID_HEAP** value.

The *heapattr* structure contains the following fields:

Item	Description
eye_catch8b_t hpa_eyec	Must be initialized to the **EYEC_HEAPATTR** value.
short hpa_version	Must be initialized to the **HPA_VERSION** value.
long hpa_flags	The following flags describe heap properties: **HPA_PAGED** The heap returns pageable memory. **HPA_PINNED** The heap returns pinned memory. **HPA_SHARED** The returned descriptor is backed by a common sub-heap. **HPA_PRIVATE** The returned descriptor is backed by isolated storage.
void * hpa_heapaddr	Must be set to NULL (reserved).
size_t hpa_heapsize	Heap size in bytes. It is only used for private heaps.
size_t hpa_limit	Usage barrier independent from size. Limits the amount available from a private heap that is less than or equal to the actual size of the private heap.
long hpa_debug_level	Heap debug level. The **HPA_DEFAULT_DEBUG** value gives the heap the system debug level.
uint hpa_kkey	Kernel key requested for the storage allocated.

Description

The **heap_create** service is a replacement for the **init_heap** service. It can be used to create private heaps, and to create shared sub-heaps. After this service creates a private heap or a handle to a shared sub-heap, the returned **heapaddr_t** value can be used with the **xmalloc** service or the **xmfree** service to allocate or free memory from that heap.

The most common usage for the **heap_create** service is to get a handle to a shared sub-heap. This is done by setting the **HPA_SHARED** flag in the input attribute structure. See the **sys_malloc.h** file.

Private heaps can be created by specifying the **HPA_PRIVATE** flag. This allows the **heap_create** service to initialize and manage an area of virtual memory as a private heap. The **hpa_heapaddr** field must be set to zero. The **heap_create** service provides the storage but this field is reserved for future use. The **hpa_size** field indicates the size of the private heap in bytes.

Private heaps can make use of the **hpa_limit** field. Use the **hpa_size** field to reserve a maximum effective address space. Then use the **hpa_limit** field to alter and control the amount of effective address space that is in use. The value of the **hpa_limit** field must be less than or equal to the value of the **hpa_size** field.

The **hpa_debug** and **hpa_kkey** fields are required for shared and private heaps. The **hpa_debug** level allows a component run-time debug level to be applied to allocations using the returned heap handle. The **hpa_kkey** field associates a kernel key with a sub-heap that can limit the kernel accessibility.

On a successful completion, the *heapattr* field contains the address of a heap structure. This can be used as a parameter to the **xmalloc** and the **xmfree** kernel services. The memory returned by these services and the internal heap structures are protected by the **hpa_kkey** field. When calling the **xmalloc** and the **xmfree** heap services, the caller must hold the key that was used when creating the heap.

Execution Environment

The **heap_create** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful completion. A descriptor is returned in the *heapptr* parameter.

Item	Description
EINVAL_HEAP_CREATE	Indicates one or more of the following inputs that were not valid:

- heapattr is NULL.
- *heapptr != HPA_INVALID_HEAP.
- heapattr->hpa_eyec != EYEC_HEAPATTR.
- heapattr->hpa_version != HPA_VERSION.
- Flags: Both the **HPA_SHARED** and the **HPA_PRIVATE** flags are specified.
- Flags: Neither the **HPA_SHARED** nor the **HPA_PRIVATE** flag is specified.
- Flags: Both the **HPA_PINNED** and the **HPA_PAGED** flags are specified.
- Flags: Neither the **HPA_PINNED** nor the **HPA_PAGED** flag is specified.
- Keys: kernel key specified is not valid.
- Other: Size is specified with a shared heap.
- Other: Limit is specified with a shared heap.
- Other: Address specified is not NULL.
- Other: Limit > size for private heap.
- Other: Private heap size is too small (less than 8M).

Item	Description
ENOMEM_HEAP_CREATE	Indicates insufficient memory available to complete the request.

Related reference
heap_modify Kernel Service
heap_destroy Kernel Service

heap_destroy Kernel Service

Purpose

Removes a heap.

Syntax

```
#include <sys/types.h>
#include <sys/malloc.h>
#include <sys/kerrno.h>
```

kerrno_t heap_destroy (heapattr_t *heap*, **long** *flags***);**

Parameters

Item	Description
heap	The heap to destroy.
flags	Must be zero.

Description

This service removes a heap and its internal resources from the system. There must be no outstanding allocations when a heap is destroyed.

Execution Environment

The **heap_destroy** kernel service can be called from the process environment only.

Return Values

Item	Description
EINVAL_HEAP_DESTROY	The *heap* parameter is not recognizable.
EBUSY_HEAP_DESTROY	The heap is still in use.

Related reference
heap_create Kernel Service
heap_modify Kernel Service

heap_modify Kernel Service

Purpose

Modifies the attributes of a heap.

Syntax

```
#include <sys/types.h>
#include <sys/malloc.h>
#include <sys/kerrno.h>
```

kerrno_t heap_modify (heapattr_t *heap*, **long** *command*, **long** *argument*);

Parameters

Item	Description
heap	The heap handle returned from the **heap_create** kernel service.
command	Specifies the operation to perform. The following values are supported:
	HPA_SET_LIMIT Modifies the limit value of a private heap.
	HPA_SET_DEBUG Modifies the debug level. Debug levels from 0 to 9 are supported.
argument	Command specific data (new limit or debug level).

Description

The **heap_modify** kernel service is used to alter the heap characteristics at run time.

Execution Environment

The **heap_modify** kernel service can be called from the process environment only with interrupts enabled.

Return Values

Item	Description
0	Success.
EINVAL_HEAP_MODIFY	The command or the execution environment is not valid.
ERANGE_HEAP_MODIFY	Heap property is outside the supported range.

Related reference
heap_create Kernel Service
heap_destroy Kernel Service

hkeyset_add, hkeyset_replace, hkeyset_restore, or hkeyset_get Kernel Service

Purpose

Manipulates the protection domain (page access as controlled by storage keys) in use for code execution in the kernel environment.

Syntax

```
#include <sys/skeys.h>
```

hkeyset_t hkeyset_add (hkeyset_t *keyset* **);**
hkeyset_t hkeyset_replace (hkeyset_t *keyset* **);**
void hkeyset_restore (hkeyset_t *keyset* **);**
hkeyset_t hkeyset_get (*void* **);**

Parameters

Item	Description
keyset	The hardware keyset to be activated.

Description

If storage protection keys are enabled, every memory page has a hardware storage protection key associated with it. A keyset is a representation of the access rights to a set of storage protection keys. To access a memory page, a hardware keyset containing the storage key associated with the memory page must be active.

The **hkeyset_add** kernel service updates the protection domain by adding the hardware keyset specified by the *keyset* parameter to the currently addressable hardware keyset. The previous hardware keyset is returned.

The **hkeyset_replace** kernel service updates the protection domain by loading the hardware keyset specified by the *keyset* parameter as the currently addressable storage set. The previous hardware keyset is returned.

The **hkeyset_restore** kernel service restores a caller's hardware keyset when returning from a module entry point. It does not return any value.

The **hkeyset_get** kernel service reads the current hardware keyset without altering it.

Execution Environment

The **hkeyset_add**, **hkeyset_replace**, **hkeyset_restore**, or **hkeyset_get** kernel service can be called from either the process environment or the interrupt environment.

Return Values

The **hkeyset_add**, **hkeyset_replace**, and **hkeyset_get** kernel services return the *keyset* value that was active before the call. The **hkeyset_restore** kernel service does not return any value.

hkeyset_restore_userkeys Kernel Service

Purpose

Restores the previous user-memory access.

Syntax

```
#include <sys/skeys.h>
```

```
kerrno_t hkeyset_restore_userkeys (oldset)
hkeyset_t oldset;
```

Parameters

Item	Description
oldset	Specifies the previous hardware keyset returned by the **hkeyset_update_userkeys** kernel service.

Description

The **hkeyset_restore_userkeys** kernel service is a specialized protection gate that restores only the user-mode portion of the current hardware keyset. This is normally done by the kernel after this kernel service accesses user memory.

Execution Environment

The **hkeyset_restore_userkeys** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful completion.
EINVAL_HKEYSET_RESTORE_USERKEYS	Indicates that the execution environment is not valid.

hkeyset_update_userkeys Kernel Service

Purpose

Establishes accessibility to user memory.

Syntax

```
#include <sys/skeys.h>
```

kerrno_t hkeyset_update_userkeys (*oldset***)**
hkeyset_t **oldset***;**

Parameters

Item	Description
oldset	Contains the returned previous hardware keyset. The valid parameter must be an 8-byte aligned address.

Description

The **hkeyset_update_userkeys** kernel service is a specialized protection gate that alters only the user-mode portion of the current hardware keyset. The user-mode storage keys for the currently running thread is placed into the current hardware keyset. This is normally done by the kernel when this kernel service accesses user memory.

The previous hardware keyset is returned in the memory specified by the *oldset* parameter. You can use the **hkeyset_restore_userkeys** kernel service to remove the user accessibility when it is no longer needed.

Important: Kernel services such as **xmemin**, **xmemout**, **uiomove**, **copyin**, and **coypout** are the suggested ways to access user memory from the kernel. If possible, avoid using kernel code to directly access user memory.

Execution Environment

The **hkeyset_update_userkeys** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful completion.
EINVAL_HKEYSET_UPDATE_USERKEYS	Indicates that the parameter or execution environment is not valid.

Related reference
hkeyset_restore_userkeys Kernel Service
xmemin Kernel Service
uiomove Kernel Service

i

The following kernel services begin with the with the letter i.

i_clear Kernel Service

Purpose

Removes an interrupt handler.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/intr.h>
```

void i_clear (*handler***)**
**struct intr ***handler;*

Parameter

Item	Description
handler	Specifies the address of the interrupt handler structure passed to the **i_init** service.

Description

The **i_clear** service removes the interrupt handler specified by the *handler* parameter from the set of interrupt handlers that the kernel knows about. "Coding an Interrupt Handler" in *Kernel Extensions and Device Support Programming Concepts* contains a brief description of interrupt handlers.

The **i_mask** service is called by the **i_clear** service to disable the interrupt handler's bus interrupt level when this is the last interrupt handler for the bus interrupt level. The **i_clear** service removes the interrupt handler structure from the list of interrupt handlers. The kernel maintains this list for that bus interrupt level.

Execution Environment

The **i_clear** kernel service can be called from the process environment only.

Return Values

The **i_clear** service has no return values.

Related reference
i_init Kernel Service
Related information
I/O Kernel Services
Understanding Interrupts

i_disable Kernel Service

Purpose

Disables interrupt priorities.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/intr.h>
```

int i_disable (*new***)**
**int ***new;*

Parameter

Item	Description
new	Specifies the new interrupt priority.

Description

> **Attention:** The **i_disable** service has two side effects that result from the replaceable and pageable nature of the kernel. First, it prevents process dispatching. Second, it ensures, within limits, that the caller's stack is in memory. Page faults that occur while the interrupt priority is not equal to **INTBASE** crash the system.

Note: The **i_disable** service is very similar to the standard UNIX **spl** service.

The **i_disable** service sets the interrupt priority to a more favored interrupt priority. The interrupt priority is used to control which interrupts are allowed.

A value of **INTMAX** is the most favored priority and disables all interrupts. A value of **INTBASE** is the least favored and disables only interrupts not in use. The **/usr/include/sys/intr.h** file defines valid interrupt priorities.

The interrupt priority is changed only to serialize code executing in more than one environment (that is, process and interrupt environments).

For example, a device driver typically links requests in a list while executing under the calling process. The device driver's interrupt handler typically uses this list to initiate the next request. Therefore, the device driver must serialize updating this list with device interrupts. The **i_disable** and **i_enable** services provide this ability. The **I_init** kernel service contains a brief description of interrupt handlers.

Note: When serializing such code in a multiprocessor-safe kernel extension, locking must be used as well as interrupt control. For this reason, new code should call the **disable_lock** kernel service instead of **i_disable**. The **disable_lock** service performs locking only on multiprocessor systems, and helps ensure that code is portable between uniprocessor and multiprocessor systems.

The **i_disable** service must always be used with the **i_enable** service. A routine must always return with the interrupt priority restored to the value that it had upon entry.

The **i_mask** service can be used when a routine must disable its device across a return.

Because of these side effects, the caller of the **i_disable** service should ensure that:

- The reference parameters are pinned.
- The code executed during the disable operation is pinned.
- The amount of stack used during the disable operation is less than 1KB.
- The called programs use less than 1KB of stack.

In general, the caller of the **i_disable** service should also call only services that can be called by interrupt handlers. However, processes that call the **i_disable** service can call the **e_sleep**, **e_wait**, **e_sleepl**, **lockl**, and **unlockl** services as long as the event word or lockword is pinned.

The kernel's first-level interrupt handler sets the interrupt priority for an interrupt handler before calling the interrupt handler. The interrupt priority for a process is set to **INTBASE** when the process is created and is part of each process's state. The dispatcher sets the interrupt priority to the value associated with the process to be executed.

Execution Environment

The **i_disable** kernel service can be called from either the process or interrupt environment.

Return Value

The **i_disable** service returns the current interrupt priority that is subsequently used with the **i_enable** service.

Related reference
disable_lock Kernel Service
i_enable Kernel Service
Related information
Understanding Interrupts

i_enable Kernel Service

Purpose

Enables interrupt priorities.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/intr.h>
```

void i_enable (*old***)**
int *old***;**

Parameter

Item	Description
old	Specifies the interrupt priority returned by the **i_disable** service.

Description

The **i_enable** service restores the interrupt priority to a less-favored value. This value should be the value that was in effect before the corresponding call to the **i_disable** service.

Note: When serializing a thread with an interrupt handler in a multiprocessor-safe kernel extension, locking must be used as well as interrupt control. For this reason, new code should call the **unlock_enable** kernel service instead of **i_enable**. The **unlock_enable** service performs locking only on multiprocessor systems, and helps ensure that code is portable between uniprocessor and multiprocessor systems.

Execution Environment

The **i_enable** kernel service can be called from either the process or interrupt environment.

Return Values

The **i_enable** service has no return values.

Related reference
i_disable Kernel Service
unlock_enable Kernel Service
Related information
Understanding Interrupts

i_eoi Kernel Service

Purpose

Issues an End of Interrupt (EOI) for a given handler.

Syntax

```
int i_eoi(struct intr   *handler)
```

Description

The **i_eoi** kernel service allows a device driver to issue an End of Interrupt (EOI) for its device explicitly. For level-triggered interrupts, after the second level interrupt handler (SLIH) has completed, the kernel issues an EOI on behalf of the device driver. For ISA (8259) edge-triggered interrupts, the kernel issues the EOI on behalf of the device driver before calling the SLIH. However, in the case of some edge-triggered interrupts (for example, PCI and PCI-E style edge-triggered interrupt), it is desirable that the device driver checks for pending work before the EOI is issued, and the driver is required to check for any additional work after the EOI is issued. The **i_eoi** kernel service facilitates such operations and issues an EOI for an edge-triggered interrupt source. The **i_eoi** kernel service fails if called for a level-triggered interrupt source.

Parameters

Item	Description
handler	Pointer to the interrupt handler

Execution Environment

The **i_eoi** kernel service can be called from process or interrupt environment.

Return Values

INTR_SUCC if successful

INTR_FAIL if unsuccessful (the **INTR_EDGE** flag was not set on **i_init**()).

Virtual device drivers' interrupt services are similar to the PCI interrupt services. Interrupts are registered with a **bus_type** of **BUS_BID**. The primary difference is that the edge flag should be set for vdevices. For example:

```
Parent  CuDv  "bus_id"        VDEVICE bus BID
Device  CuAt  "bus_intr_lvl"   Adapter interrupt level

intr.flags    |= INTR_EDGE
intr.bus_type   = BUS_BID
intr.bid    = Parent_CuDv.bus_id
intr.level    = Device_CuAt.bus_intr_lvl
```

PCI-E interrupts are Message Signalled Interrupts, and hence, they are edge-triggered. Therefore, **INTR_EDGE** flag should be specified.

ifa_ifwithaddr Kernel Service

Purpose

Locates an interface based on a complete address.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/socket.h>
#include  <net/if.h>
#include  <net/af.h>
```

struct ifaddr * ifa_ifwithaddr (*addr***)**
struct sockaddr ***addr*;**

Parameter

Item	Description
addr	Specifies a complete address.

Description

The **ifa_ifwithaddr** kernel service is passed a complete address and locates the corresponding interface. If successful, the **ifa_ifwithaddr** service returns the **ifaddr** structure associated with that address.

Execution Environment

The **ifa_ifwithaddr** kernel service can be called from either the process or interrupt environment.

Return Values

If successful, the **ifa_ifwithaddr** service returns the corresponding **ifaddr** structure associated with the address it is passed. If no interface is found, the **ifa_ifwithaddr** service returns a null pointer.

Example

To locate an interface based on a complete address, invoke the **ifa_ifwithaddr** kernel service as follows:

```
ifa_ifwithaddr((struct sockaddr *)&ipaddr);
```

ifa_ifwithdstaddr Kernel Service

Purpose

Locates the point-to-point interface with a given destination address.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/socket.h>
#include <net/if.h>
```

struct ifaddr * ifa_ifwithdstaddr (*addr***)**
struct sockaddr ***addr*;**

Parameter

Item	Description
addr	Specifies a destination address.

Description

The **ifa_ifwithdstaddr** kernel service searches the list of point-to-point addresses per interface and locates the connection with the destination address specified by the *addr* parameter.

Execution Environment

The **ifa_withdstaddr** kernel service can be called from either the process or interrupt environment.

Return Values

If successful, the **ifa_ifwithdstaddr** service returns the corresponding **ifaddr** structure associated with the point-to-point interface. If no interface is found, the **ifa_ifwithdstaddr** service returns a null pointer.

Example

To locate the point-to-point interface with a given destination address, invoke the **ifa_ifwithdstaddr** kernel service as follows:

```
ifa_ifwithdstaddr((struct sockaddr *)&ipaddr);
```

ifa_ifwithnet Kernel Service

Purpose

Locates an interface on a specific network.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/socket.h>
#include <net/if.h>
```

struct ifaddr * ifa_ifwithnet (*addr*)
register struct sockaddr **addr*;

Parameter

Item	Description
addr	Specifies the address.

Description

The **ifa_ifwithnet** kernel service locates an interface that matches the network specified by the address it is passed. If more than one interface matches, the **ifa_ifwithnet** service returns the first interface found.

Execution Environment

The **ifa_ifwithnet** kernel service can be called from either the process or interrupt environment.

Return Values

If successful, the **ifa_ifwithnet** service returns the **ifaddr** structure of the correct interface. If no interface is found, the **ifa_ifwithnet** service returns a null pointer.

Example

To locate an interface on a specific network, invoke the **ifa_ifwithnet** kernel service as follows:

```
ifa_ifwithnet((struct sockaddr *)&ipaddr);
```

if_attach Kernel Service

Purpose

Adds a network interface to the network interface list.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/if.h>
```

if_attach (*ifp*)
struct ifnet **ifp*;

Parameter

Item	Description
ifp	Points to the interface network (**ifnet**) structure that defines the network interface.

Description

The **if_attach** kernel service registers a Network Interface Driver (NID) in the network interface list.

Execution Environment

The **if_attach** kernel service can be called from either the process or interrupt environment.

Return Values

The **if_attach** kernel service has no return values.

Related reference
if_detach Kernel Service
Related information
Network Kernel Services

if_detach Kernel Service

Purpose

Deletes a network interface from the network interface list.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/if.h>
```

if_detach (*ifp*)
struct ifnet **ifp*;

Parameter

Item	Description
ifp	Points to the interface network (**ifnet**) structure that describes the network interface to delete.

Description

The **if_detach** kernel service deletes a Network Interface Driver (NID) entry from the network interface list.

Execution Environment

The **if_detach** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates that the network interface was successfully deleted.
ENOENT	Indicates that the **if_detach** kernel service could not find the NID in the network interface list.

Related reference
if_attach Kernel Service
Related information
Network Kernel Services

if_down Kernel Service

Purpose

Marks an interface as down.

Syntax

#include <sys/types.h> #include <sys/errno.h> #include <net/if.h> void if_down (*ifp***) register struct ifnet ****ifp***;**

Parameter

Item	Description
ifp	Specifies the **ifnet** structure associated with the interface array.

Description

The **if_down** kernel service:

- Marks an interface as down by setting the `flags` field of the **ifnet** structure appropriately.
- Notifies the protocols of the transaction.
- Flushes the output queue.

The *ifp* parameter specifies the **ifnet** structure associated with the interface as the structure to be marked as down.

Execution Environment

The **if_down** kernel service can be called from either the process or interrupt environment.

Return Values

The **if_down** service has no return values.

Example

To mark an interface as down, invoke the **if_down** kernel service as follows:

```
if_down(ifp);
```

Related information
Network Kernel Services

if_nostat Kernel Service

Purpose

Zeroes statistical elements of the interface array in preparation for an attach operation.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/if.h>
```

void if_nostat (*ifp***)**
struct ifnet **ifp***;**

Parameter

Item	Description
ifp	Specifies the **ifnet** structure associated with the interface array.

Description

The **if_nostat** kernel service zeroes the statistic elements of the **ifnet** structure for the interface. The *ifp* parameter specifies the **ifnet** structure associated with the interface that is being attached. The **if_nostat** service is called from the interface attach routine.

Execution Environment

The **if_nostat** kernel service can be called from either the process or interrupt environment.

Return Values

The **if_nostat** service has no return values.

Example

To zero statistical elements of the interface array in preparation for an attach operation, invoke the **if_nostat** kernel service as follows:

```
if_nostat(ifp);
```

Related information
Network Kernel Services

ifunit Kernel Service

Purpose

Returns a pointer to the **ifnet** structure of the requested interface.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/if.h>
```

```
struct ifnet *
ifunit ( name)
char *name;
```

Parameter

Item	Description
name	Specifies the name of an interface (for example, en0).

Description

The **ifunit** kernel service searches the list of configured interfaces for an interface specified by the *name* parameter. If a match is found, the **ifunit** service returns the address of the **ifnet** structure for that interface.

Execution Environment

The **ifunit** kernel service can be called from either the process or interrupt environment.

Return Values

The **ifunit** kernel service returns the address of the **ifnet** structure associated with the named interface. If the interface is not found, the service returns a null value.

Example

To return a pointer to the **ifnet** structure of the requested interface, invoke the **ifunit** kernel service as follows:

```
ifp = ifunit("en0");
```

Related information

Network Kernel Services

i_init Kernel Service

Purpose

Defines an interrupt handler.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/intr.h>
```

int i_init
(*handler***)**
struct intr **handler*;

Parameter

Item	Description
handler	Designates the address of the pinned interrupt handler structure.

Description

> **Attention:** The interrupt handler structure must not be altered between the call to the **i_init** service to define the interrupt handler and the call to the **i_clear** service to remove the interrupt handler. The structure must also stay pinned. If this structure is altered at those times, a kernel panic may result.

The **i_init** service allows device drivers to define an interrupt handler to the kernel. The interrupt handler **intr** structure pointed to by the *handler* parameter describes the interrupt handler. The caller of the **i_init** service must initialize all the fields in the **intr** structure. The **/usr/include/sys/intr.h** file defines these fields and their valid values.

The **i_init** service enables interrupts by linking the interrupt handler structure to the end of the list of interrupt handlers defined for that bus level. If this is the first interrupt handler for the specified bus interrupt level, the **i_init** service enables the bus interrupt level by calling the **i_unmask** service.

The interrupt handler can be called before the **i_init** service returns if the following two conditions are met:

- The caller of the **i_init** service is executing at a lower interrupt priority than the one defined for the interrupt.
- An interrupt for the device or another device on the same bus interrupt level is already pending.

On multiprocessor systems, all interrupt handlers defined with the **i_init** kernel service run by default on the first processor started when the system was booted. This ensures compatibility with uniprocessor interrupt handlers. If the interrupt handler being defined has been designed to be multiprocessor-safe, or is an EPOW (Early Power-Off Warning) or off-level interrupt handler, set the **INTR_MPSAFE** flag in the `flags` field of the **intr** structure passed to the **i_init** kernel service. The interrupt handler will then run on any available processor.

Coding an Interrupt Handler

The kernel calls the interrupt handler when an enabled interrupt occurs on that bus interrupt level. The interrupt handler is responsible for determining if the interrupt is from its own device and processing the interrupt. The interface to the interrupt handler is as follows:

int *interrupt_handler* **(**ticket*handler***) struct intr ****handler***;**

The *handler* parameter points to the same interrupt handler structure specified in the call to the **i_init** kernel service. The device driver can pass additional parameters to its interrupt handler by declaring the interrupt handler structure to be part of a larger structure that contains these parameters.

The interrupt handler can return one of two return values. A value of **INTR_SUCC** indicates that the interrupt handler processed the interrupt and reset the interrupting device. A value of **INTR_FAIL** indicates that the interrupt was not from this interrupt handler's device.

Registering Early Power-Off Warning (EPOW) Routines

The **i_init** kernel service can also be used to register an EPOW (Early Power-Off Warning) notification routine.

The return value from the EPOW interrupt handler should be **INTR_SUCC**, which indicates that the interrupt was successfully handled. All registered EPOW interrupt handlers are called when an EPOW interrupt is indicated.

Execution Environment

The **i_init** kernel service can be called from the process environment only.

Return Values

Item	Description
INTR_SUCC	Indicates a successful completion.
INTR_FAIL	Indicates an unsuccessful completion. The **i_init** service did not define the interrupt handler.
	An unsuccessful completion occurs when there is a conflict between a shared and a nonshared bus interrupt level. An unsuccessful completion also occurs when more than one interrupt priority is assigned to a bus interrupt level.

Related information
Understanding Interrupts
I/O Kernel Services

i_mask Kernel Service

Purpose

Disables a bus interrupt level.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/intr.h>
```

void i_mask (*handler***)**
struct intr **handler***;**

Parameter

Item	Description
handler	Specifies the address of the interrupt handler structure that was passed to the **i_init** service.

Description

The **i_mask** service disables the bus interrupt level specified by the *handler* parameter.

The **i_disable** and **i_enable** services are used to serialize the execution of various device driver routines with their device interrupts.

The **i_init** and **i_clear** services use the **i_mask** and **i_unmask** services internally to configure bus interrupt levels.

Device drivers can use the **i_disable**, **i_enable**, **i_mask**, and **i_unmask** services when they must perform off-level processing with their device interrupts disabled. Device drivers also use these services to allow process execution when their device interrupts are disabled.

Execution Environment

The **i_mask** kernel service can be called from either the process or interrupt environment.

Return Values

The **i_mask** service has no return values.

I/O Kernel Services

in_localaddr Kernel Service

Purpose

Determine whether an IPv4 address is on the local network

Syntax

#include <arpa/inet.h>

int in_localaddr (*struct in_addr in***)**

Parameters

in
　Specifies the IPv4 address

Description

Indicates that the IPv4 address in is for a local host (one to which we have a connection). If subnetsarelocal is true, this includes other subnets of the local net. Otherwise, it includes only the directly-connected (sub)nets.

Execution Environment

The **in_localaddr** kernel service can be called from the process environment only.

Return Values

1
　Indicates that the internet address is for a local host (one to which we have a connection). If `subnetsarelocal` is true, this includes other subnets of the local net. Otherwise, it includes only the directly-connected (sub)nets.

init_heap Kernel Service

Purpose

Initializes a new heap to be used with kernel memory management services.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/xmalloc.h>
#include <sys/malloc.h>
```

heapaddr_t init_heap (*area*, *size*, *heapp***)**
caddr_t *area*;
int *size*;
heapaddr_t *heapp;

Parameters

Item	Description
area	Specifies the virtual memory address used to define the starting memory area for the heap. This address must be page-aligned.
size	Specifies the size of the heap in bytes. This value must be an integral number of system pages.
heapp	Points to the external heap descriptor. This must have a null value. The base kernel uses this field is used to specify special heap characteristics that are unavailable to kernel extensions.

Description

The **init_heap** kernel service is most commonly used by a kernel process to initialize and manage an area of virtual memory as a private heap. Once this service creates a private heap, the returned **heapaddr_t** value can be used with the **xmalloc** or **xmfree** service to allocate or deallocate memory from the private heap. Heaps can be created within other heaps, a kernel process private region, or even on a stack.

Few kernel extensions ever require the **init_heap** service because the exported global **kernel_heap** and **pinned_heap** are normally used for memory allocation within the kernel. However, kernel processes can use the **init_heap** service to create private nonglobal heaps within their process private region for controlling kernel access to the heap and possibly for performance considerations.

Execution Environment

The **init_heap** kernel service can be called from the process environment only.

Using Kernel Processes

initp Kernel Service

Purpose

Changes the state of a kernel process from idle to ready.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

int initp
(*pid, func, init_parms,*
parms_length, name)
pid_t *pid*;
void (*func*) (**int**
flag, **void*** *init_parms,* **int** *parms_length*);
void * *init_parms*;
int *parms_length*;
char * *name*;

Parameters

Item	Description
pid	Specifies the process identifier of the process to be initialized.
func	Specifies the process's initialization routine.
init_parm	Specifies the pointer to the initialization parameters.
parms_length	Specifies the length of the initialization parameters.
name	Specifies the process name.

Description

The **initp** kernel service completes the transition of a kernel process from idle to ready. The idle state for a process is represented by **p_status == SIDL**. Before calling the **initp** service, the **creatp** service is called to create the process. The **creatp** service allocates and initializes a process table entry.

The **initp** service creates and initializes the process-private segment. The process is marked as a kernel process by a bit set in the **p_flag** field in the process table entry. This bit, the SKPROC bit, signifies that the process is a kernel process.

The process calling the **initp** service to initialize a newly created process must be the same process that called the **creatp** service to create the new process.

"Using Kernel Processes" in *Kernel Extensions and Device Support Programming Concepts* further explains how the **initp** kernel service completes the initialization process begun by the **creatp** service.

The *pid* parameter identifies the process to be initialized. It must be valid and identify a process in the SIDL (idle) state.

The *name* parameter points to a character string that names the process. The leading characters of this string are copied to the user structure. The number of characters copied is implementation-dependent, but at least four are always copied.

The *func* parameter indicates the main entry point of the process. The new process is made ready to run this function. If the *init_parms* parameter is not null, it points to data passed to this routine. The parameter structure must be agreed upon between the initializing and initialized process. The **initp** service copies the data specified by the *init_parm* parameter (with the exact number of bytes specified by the *parms_length* parameter) of data to the new process's stack.

Execution Environment

The **initp** kernel service can be called from the process environment only.

Example

To initialize the kernel process running the function *main_kproc*, enter:

```
{
.
.
.
pid = creatp();
initp(pid, main_kproc, &node_num, sizeof(int), "tkproc");
.
.
}
void
main_kproc(int flag, void* init_parms, int parms_length)
{
        .
        .
        .
        int i;
        i = *( (int *)init_parms );
        .
        .
        .
}
```

Return Values

Item	Description
0	Indicates a successful operation.
ENODEV	The process could not be scheduled because it has a processor attachment that does not contain any available processors. This can be caused by Dynamic Processor Deallocation.
ENOMEM	Indicates that there was insufficient memory to initialize the process.
EINVAL	Indicates an *pid* parameter that was not valid.

creatp Kernel Service

initp Kernel Service func Subroutine

Purpose

Directs the process initialization routine.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

void *func* (*flag*, *init_parms*, *parms_length*)
int *flag*;
void * *init_parms*;
int *parms_length*;

Parameters

Item	Description
func	Specifies the process's initialization routine.
flag	Has a 0 value if this subroutine is executed as a result of initializing a process with the **initp** service.
init_parms	Specifies the pointer to the initialization parameters.
parms_length	Specifies the length of the initialization parameters.

Process and Exception Management Kernel Services

io_map Kernel Service

Purpose

Attach to an I/O mapping

Syntax

```
#include <sys/adspace.h>

void *  io_map (io_handle)
io_handle_t io_handle;
```

Description

The **io_map** kernel service sets up addressibility to the I/O address space defined by the **io_handle_t** structure. It returns an effective address representing the start of the mapped region.

The **io_map** kernel service is a replacement call for the **iomem_att** kernel service, which is deprecated on AIX 6.1. However, the **io_map** kernel service might replace multiple **iomem_att** calls depending on the device, the driver, and whether multiple regions were mapped into a single virtual segment. Like the **iomem_att** kernel service, this service does not return any kind of failure. If something goes wrong, the system crashes.

There is a major difference between **io_map** and **iomem_att**. **iomem_att** took an **io_map** structure containing a bus address and returned a fully qualified effective address with any byte offset from the bus address preserved and computed into the returned effective address. The **io_map** kernel service always returns a segment-aligned effective address representing the beginning of the I/O segment corresponding to **io_handle_t**. Manipulation of page and byte offsets within the segment are responsibilities of the device driver.

The **io_map** kernel service is subject to nesting rules regarding the number of attaches allowed. A total system number of active temporary attaches is 4. However, it is recommended that no more than one active attach be owned by a driver calling the interrupt or DMA kernel services. It is also recommended that no active attaches be owned by a driver when calling other kernel services.

Parameters

Item	Description
io_handle	Received on a prior successful call to io_map_init. Describes the I/O space to attach to.

Execution Environment

The **io_map** kernel service can be called from the process or interrupt environment.

Return Values

The **io_map** kernel service returns a segment-aligned effective address to access the I/O address spaces.

Related reference
io_map_init Kernel Service
io_unmap Kernel Service
Related information
Programmed I/O (PIO) Kernel Services

io_map_clear Kernel Service

Purpose

Removes an I/O mapping segment.

Syntax

```
#include <sys/adspace.h>

void io_map_clear (io_handle)
io_handle_t io_handle;
```

Description

This service destroys all mappings defined by the *io_handle_t* parameter.

There should be no active mappings (outstanding **io_map** calls) to this handle when **io_map_clear** is called. The segment previously created by an **io_map_init** call or multiple **io_map_init** calls, is deleted.

Parameters

Item	Description
io_handle	Received on a prior successful call to io_map_init. Describes the I/O space to be removed.

Execution Environment

The **io_map_clear** kernel service can be called from the process environment only.

Related reference
io_map Kernel Service
io_unmap Kernel Service
Related information
Programmed I/O (PIO) Kernel Services

io_map_init Kernel Service

Purpose

Creates and initializes an I/O mapping segment.

Syntax

```
#include <sys/adspace.h>
#include <sys/vm_types.h>

io_handle_t io_map_init (io_map_ptr, page_offset, io_handle)
struct io_map *io_map_ptr;
vpn_t page_offset;
io_handle_t io_handle;

struct io_map {
        int key;                        /* structure version number */
        int flags;                      /* flags for mapping */
        int32long64_t size;             /* size of address space needed */
        int bid;                        /* bus ID */
        long long busaddr;              /* bus address */
};
```

Description

The **io_map_init** kernel service will create a segment to establish a cache-inhibited virtual-to-real translation for the bus address region defined by the contents of the **io_map** struct. The *flags* parameter of the **io_map** structure can be used to customize the mapping such as making the region read-only, using the **IOM_RDONLY** flag.

The **io_map_init** kernel service returns a handle of an opaque type *io_handle_t* to be used on future **io_map** or **io_unmap** calls. All services that use the *io_handle* returned by **io_map_init** must use the handle from the most recent call. Using an old handle is a programming error.

The *vpn_t* type parameter represents the virtual page number offset to allow the caller to specify where, in the virtual segment, to map this region. The offset must not conflict with a previous mapping in the segment. The caller should map the most frequently accessed and performance critical I/O region at

vpn_t offset 0 into the segment. This is due to the fact that the subsequent **io_map** calls using this *io_handle* will return an effective address representing the start of the segment (that is, page offset 0). The device driver is responsible for managing various offsets into the segment. A single bus memory address page can be mapped multiple times at different *vpn_t* offsets within the segment.

The *io_handle_t* parameter is useful when the caller wants to append a new mapping to an existing segment. For the initial creation of a new I/O segment, this parameter must be NULL. For appended mappings to the same segment, this parameter is the *io_handle_t* returned from the last successful **io_map_init** call. If the mapping fails for any reason (offset conflicts with prior mapping, or no more room in the segment), NULL is returned. In this case, the previous *io_handle_t* is still valid. If successful, the *io_handle_t* returned should be used on all future calls. In this way, a device driver can manage multiple I/O address spaces of a single adapter within a single virtual address segment, requiring the driver to do only a single attach, io_map, to gain addressibility to all of the mappings.

Parameters

Item	Description
io_map_ptr	Pointer to **io_map** structure describing the address region to map.
page_offset	Page offset at which to map the specified region into the virtual address segment.
io_handle	For the first call, this parameter should be NULL. When adding to an existing mapping, this parameter is the *io_handle* received on a prior successful call to **io_map_init**.

Execution Environment

The **io_map_init** kernel service can be called from the process environment only.

Return Values

Item	Description
io_handle_t	An opaque handle to the mapped I/O segment in the virtual memory that must be used in subsequent calls to this service.
NULL	Failed to create or append mapping.

Related reference
io_map_clear Kernel Service
io_unmap Kernel Service

Programmed I/O (PIO) Kernel Services

io_unmap Kernel Service

Purpose

Detach from an I/O mapping

Syntax

```
#include <sys/adspace.h>
```

```
void io_unmap (eaddr)
void *eaddr;
```

Description

The **io_unmap** kernel service removes addressibility to the I/O address space defined by the *eaddr* parameter. There must be a valid active mapping from a previous **io_map** call for this effective address. The *eaddr* parameter can be any valid effective address within the segment, and it does not have to be exactly the same as the address returned by **io_map**.

The **io_unmap** kernel service is a replacement call for the **iomem_det** kernel service, which is deprecated on AIX 6.1. However, the **io_unmap** kernel service might replace multiple **iomem_det** calls depending on the device, the driver, and whether multiple regions were mapped into a single virtual segment using the **io_map_init** kernel service.

Parameters

Item	Description
eaddr	Received on a prior successful call to io_map. Effective address for the I/O space to detach from.

Execution Environment

The **io_unmap** kernel service can be called from the process or interrupt environment.

Related reference
io_map_clear Kernel Service

Programmed I/O (PIO) Kernel Services

iodone Kernel Service

Purpose

Performs block I/O completion processing.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
```

void iodone (*bp*)
struct buf **bp*;

Parameter

Item	Description
bp	Specifies the address of the **buf** structure for the buffer whose I/O has completed.
	On a platform that supports storage keys, the passed in *bp* parameter must be in the **KKEY_PUBLIC** or **KKEY_BLOCK_DEV** protection domain.

Description

A device driver calls the **iodone** kernel service when a block I/O request is complete. The device driver must not reference or alter the buffer header or buffer after calling the **iodone** service.

The **iodone** service takes one of two actions, depending on the current interrupt level. Either it invokes the caller's individual **iodone** routine directly, or it schedules I/O completion processing for the buffer to be performed off-level, at the **INTIODONE** interrupt level. The interrupt handler for this level then calls the iodone routine for the individual device driver. In either case, the individual iodone routine is defined by the b_iodone buffer header field in the buffer header. This iodone routine is set up by the caller of the device's strategy routine.

For example, the file I/O system calls set up a routine that performs buffered I/O completion processing. The **uphysio** service sets up a routine that performs raw I/O completion processing. Similarly, the pager sets up a routine that performs page-fault completion processing.

Setting up an iodone Routine

Under certain circumstances, a device driver can set up an **iodone** routine. For example, the logical volume device driver can follow this procedure:

1. Take a request for a logical volume.
2. Allocate a buffer header.
3. Convert the logical volume request into a physical volume request.
4. Update the allocated buffer header with the information about the physical volume request. This includes setting the b_iodone buffer header field to the address of the individual iodone routine.
5. Call the physical volume device driver strategy routine.

   Here, the caller of the logical volume strategy routine has set up an iodone routine that is started when the logical volume request is complete. The logical volume strategy routine in turn sets up an iodone routine that is invoked when the physical volume request is complete.

The key point of this example is that only the caller of a strategy routine can set up an iodone routine and even then, this can only be done while setting up the request in the buffer header.

The interface for the **iodone** routine is identical to the interface to the **iodone** service.

Execution Environment

The **iodone** kernel service can be called from either the process or interrupt environment.

Return Values

The **iodone** service has no return values.

I/O Kernel Services

iostadd Kernel Service

Purpose

Registers an I/O statistics structure that is used for updating I/O statistics reported by the **iostat** subroutine.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/iostat.h>
#include <sys/devinfo.h>
```

int iostadd (*devtype,* *devstatp***)**
int *devtype;*
union {
      struct ttystat *ttystp;
      struct dkstat *dkstp;
      } *devstatp;*

Description

The **iostadd** kernel service is used to register the I/O statistics structure that is required to maintain statistics on a device. The **iostadd** service is typically called by a tty, disk, or CD-ROM device driver to provide the statistical information that is used by the **iostat** subroutine. The **iostat** subroutine displays statistic information for tty and disk devices on the system. The **iostadd** service must be used once for each configured device.

The **iostadd** kernel service and the **dkstat** structure support Multi-Path I/O (MPIO). For an MPIO device, the anchor is the disk's **dkstat** structure. This anchor must be the first **dkstat** structure that is registered by using the **iostadd** kernel service. Any path **dkstat** structures that are registered later must reference the address of the anchor **dkstat** (disk) structure in the dkstat.dk_mpio_anchor field.

For tty devices, the *devtype* parameter has a value of **DD_tty**. In this case, the **iostadd** service uses the *devstatp* parameter to return a pointer to a **ttystat** structure.

For disk or CD-ROM devices with a *devtype* value of **DD_DISK** or **DD_CD-ROM**, the caller must provide a pinned and initialized **dkstat** structure as an input parameter. This structure is pointed to by the *devstatp* parameter on entry to the **iostadd** kernel service.

If the device driver support for a device is terminated, the **dkstat** or **ttystat** structure that is registered with the **iostadd** kernel service must be deregistered by calling the **iostdel** kernel service.

I/O Statistics Structures

The **iostadd** kernel service uses two structures that are found in the **usr/include/sys/iostat.h** file: the **ttystat** structure and the **dkstat** structure.

The **ttystat** structure contains the following fields:

Field	Description
rawinch	Count of raw characters that are received by the tty device
caninch	Count of canonical characters that are generated from canonical processing
outch	Count of the characters output to a tty device

The second structure that is used by the **iostadd** kernel service is the **dkstat** structure, which contains information about disk devices. This structure contains the following fields:

Field	Description
diskname	32-character string name for the disk's logical device
dknextp	Pointer to the next **dkstat** structure in the chain
dk_status	Disk entry-status flags
dk_time	Time the disk is active
dk_bsize	Number of bytes in a block

Field	Description
dk_xfers	Number of transfers to or from the disk
dk_rblks	Number of blocks that are read from the disk
dk_wblks	Number of blocks that are written to the disk
dk_seeks	Number of seek operations for disks
dk_version	Version of the **dkstat** structure
dk_q_depth	Queue depth
dk_mpio_anchor	Pointer to the path data anchors (disk)
dk_mpio_next_path	Pointer to the next path **dkstat** structure in the chain
dk_mpio_path_id	Path ID

tty Device Driver Support

The `rawinch` field in the **ttystat** structure must be incremented by the number of characters that are received by the tty device. The `caninch` field in the **ttystat** structure must be incremented by the number of input characters that are generated from canonical processing. The `outch` field is increased by the number of characters output to tty devices. These fields must be incremented by the device driver, but never be cleared.

Disk Device Driver Support

A disk device driver must perform these four tasks:

- Allocate and pin a **dkstat** structure during device initialization.
- Update the `dkstat.diskname` field with the device's logical name.
- Update the `dkstat.dk_bsize` field with the number of bytes in a block on the device.
- Set all other fields in the structure to 0.

If a disk device driver supports MPIO, it must perform the following tasks:

- Allocate and pin a **dkstat** structure during device initialization.
- Update the `dkstat.diskname` field with the device's logical name.
- Update the `dkstat.dk_bsize` field with the number of bytes in a block on the device.
- Set the value of `dkstat.dk_version` to **dk_qd_mpio_magic**.
- Set the value of `dkstat.dk_mpio_anchor` to 0 if the **dkstat** added structure is the disk.
- Set the value of `dkstat.dk_mpio_anchor` to the address of the path's anchor (disk) **dkstat** structure, and set `dkstat.dk_mpio_path_id` to the path's ID if the **dkstat** added structure is a path.
- Set all other fields to 0.

If the device supports discrete seek commands, the `dkstat.dk_xrate` field in the structure must be set to the transfer rate capability of the device (KB/sec). The device's **dkstat** structure must then be registered by using the **iostadd** kernel service.

During drive operation update, the `dkstat.dk_status` field must show the busy or non-busy state of the device. It can be done by setting and resetting the **IOST_DK_BUSY** flag. The `dkstat.dk_xfers` field must be incremented for each transfer initiated to or from the device. The `dkstat.dk_rblks` and `dkstat.dk_wblks` fields must be incremented by the number of blocks that are read or written.

If the device supports discrete seek commands, the `dkstat.dk_seek` field must be incremented by the number of seek commands that are sent to the device. If the device does not support discrete seek commands, both the `dkstat.dk_seek` and `dkstat.dk_xrate` fields must be left with a value of 0.

The base kernel updates the `dkstat.dk_nextp` and `dkstat.dk_time` fields. They mut not be modified by the device driver after initialization. For MPIO devices, the base kernel also updates the `dkstat.dk_mpio_next_path` field.

Note: The same **dkstat** structure must not be registered more than once.

In addition to basic tasks, a disk driver must perform the following tasks before it calls the **iostadd** kernel service if the driver supports the **-D** option of the **iostat** command:

- Set the value of `dkstat.dk_version` to **dk_qd_service2_magic**.
- Set the `dkstat.ident.adapter` field to the adapter name if the driver does not support MPIO.

During I/O operations, the driver must perform the following tasks:

- Increase the `dkstat.__dk_rxfers` field for each read transfer.
- Update the `dkstat.dk_q_depth` field with the number of I/O requests which are in progress.
- Increase the `dkstat.dk_q_full` field when the number of I/O requests which are in progress reaches the maximum queue depth.
- Increase the `dkstat.dk_rserv` field by the service time which is the delta-time base value between when the **devstrat** kernel service sends a read request to the adapter driver and when the **iodone** kernel service returns the request from the adapter driver.
- Increase the `dkstat.dk_rtimeout` field when the driver tries a failed read request again.
- Increase the `dkstat.dk_rfailed` field when the driver returns a failed read request as an error.
- Update the `dkstat.dk_min_rserv` field with the minimum service time for a read request.
- Update the `dkstat.dk_max_rserv` field with the maximum service time for a read request.
- Increase the `dkstat.dk_wserv` field by the service time which is the delta-time base value between when the **devstrat** kernel service sends a write request to the adapter driver and when the **iodone** kernel service returns the request from the adapter driver.
- Increase the `dkstat.dk_wtimeout` field when the driver tries a failed write request again.
- Increase the `dkstat.dk_wfailed` field when the driver returns a failed write request as an error.
- Update the `dkstat.dk_min_wserv` field with the minimum service time for a write request.
- Update the `dkstat.dk_max_wserv` field with the maximum service time for a write request.
- Increase and decrease the `dkstat.dk_wq_depth` field when the driver enqueues and dequeues an I/O request.
- Increase the `dkstat.dk_wq_time` field by the wait time which is the delta-time base value between when the driver enqueues an I/O request and when the **devstrat** kernel service sends the request to the adapter driver.
- Update the `dkstat.dk_wq_min_time` field with the minimum wait time.
- Update the `dkstat.dk_wq_max_time` field with the maximum wait time.

Parameters

Item	Description
devtype	Specifies the type of device for which I/O statistics are kept. The various device types are defined in the **/usr/include/sys/devinfo.h** file. Currently, I/O statistics are only kept for disks, CD-ROMs, and tty devices. Possible values for this parameter are:

        DD_DISK
            For disks

        DD_CD-ROM
            For CD-ROMs

        DD_TTY
            For tty devices

Item	Description
devstatp	Points to an I/O statistics structure for the device type that is specified by the *devtype* parameter. For a *devtype* parameter of **DD_tty**, the address of a pinned **ttystat** structure is returned. For a *devtype* parameter of **DD_DISK** or **DD_CD-ROM**, the parameter is an input parameter that points to a **dkstat** structure previously allocated by the caller.
	On a platform that supports storage keys, the passed in *devstatp* parameter must be in the **KKEY_PUBLIC** or **KKEY_BLOCK_DEV** protection domain.

Execution Environment

The **iostadd** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates that no error is detected.
EINVAL	Indicates that the *devtype* parameter specified a device type that is not valid. For MPIO devices, indicates that an anchor for a path **dkstat** structure was not found.

iostat subroutine
Kernel Extension and Device Driver Management Kernel Services

iostdel Kernel Service

Purpose

Removes the registration of an I/O statistics structure that is used for maintaining I/O statistics on a particular device.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/iostat.h>
```

```
void iostdel ( devstatp)
union {
        struct ttystat *ttystp;
        struct dkstat  *dkstp;
    } devstatp;
```

Description

The **iostdel** kernel service removes the registration of an I/O statistics structure for a terminating device. The device's **ttystat** or **dkstat** structure must be previously registered by using the **iostadd** kernel service. Following a return from the **iostdel** service, the **iostat** command no longer displays statistics for the device that is terminated.

The **iostdel** kernel service supports Multi-Path I/O (MPIO). For an MPIO device, the anchor is the disk's **dkstat** structure. An anchor (disk) might have several paths that are associated with it. Each of these paths can have a **dkstat** structure that is registered by using the **iostadd** kernel service. The semantics

for unregistering a **dkstat** structure for an MPIO device are more restrictive than for a non-MPIO device. All paths must unregister before the anchor (disk) is unregistered. If the anchor (disk) **dkstat** structure is unregistered before all of the paths that are associated with it are unregistered, the **iostdel** kernel service removes the registration of the anchor (disk) **dkstat** structure and all remaining registered paths.

Parameters

Item	Description
devstatp	Points to an I/O statistics structure previously registered by using the **iostadd** kernel service.
	On a platform that supports storage keys, the passed in *devstatp* parameter must be in the **KKEY_PUBLIC** or **KKEY_BLOCK_DEV** protection domain.

Execution Environment

The **iostdel** kernel service can be called from the process environment only.

Return Values

The **iostdel** service has no return values.

Related reference
iostadd Kernel Service

iostat command
Kernel Extension and Device Driver Management Kernel Services

iowait Kernel Service

Purpose

Waits for block I/O completion.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>
```

int iowait (*bp***)**
struct buf * *bp***;**

Parameter

Item	Description
bp	Specifies the address of the **buf** structure for the buffer with in-process I/O.
	On a platform that supports storage keys, the passed in *bp* parameter must be in the **KKEY_PUBLIC** or **KKEY_BLOCK_DEV** protection domain.

Description

The **iowait** kernel service causes a process to wait until the I/O is complete for the buffer specified by the *bp* parameter. Only the caller of the strategy routine can call the **iowait** service. The **B_ASYNC** bit in the buffer's b_flags field should not be set.

The **iodone** kernel service must be called when the block I/O transfer is complete. The **buf** structure pointed to by the *bp* parameter must specify an iodone routine. This routine is called by the iodone interrupt handler in response to the call to the **iodone** kernel service. This iodone routine must call the **e_wakeup** service with the bp->b_events field as the event. This action awakens all processes waiting on I/O completion for the **buf** structure using the **iowait** service.

Execution Environment

The **iowait** kernel service can be called from the process environment only.

Return Values

The **iowait** service uses the **geterror** service to determine which of the following values to return:

Item	Description
0	Indicates that I/O was successful on this buffer.
EIO	Indicates that an I/O error has occurred.
b_error value	Indicates that an I/O error has occurred on the buffer.

ip_fltr_in_hook, ip_fltr_out_hook, ipsec_decap_hook, inbound_fw, outbound_fw Kernel Service

Purpose

Contains hooks for IP filtering.

Syntax

```
#define FIREWALL_OK         0  /* Accept IP packet                      */
#define FIREWALL_NOTOK      1  /* Drop IP packet                        */
#define FIREWALL_OK_NOTSEC  2  /* Accept non-encapsulated IP packet
                                  (ipsec_decap_hook only)      */
#include <sys/mbuf.h>
#include <net/if.h>

int (*ip_fltr_in_hook)(struct mbuf **pkt, void **arg)

int (*ipsec_decap_hook)(struct mbuf **pkt, void **arg)

int (*ip_fltr_out_hook)(struct ifnet *ifp, struct mbuf **pkt,
int flags)
```

```
#include <sys/types.h>

#include <sys/mbuf.h>

#include <netinet/ip_var.h>

void (*inbound_fw)(struct ifnet *ifp, struct mbuf *m,
inbound_fw_args_t *args)
```

```
void ipintr_noqueue_post_fw(struct ifnet *ifp, struct mbuf *m,
inbound_fw_args_t *args)

inbound_fw_args_t *inbound_fw_save_args(inbound_fw_args_t *args)

int (*outbound_fw)(struct ifnet *ifp, struct mbuf *
m0, outbound_fw_args_t *args)

int ip_output_post_fw( struct ifnet *ifp, struct mbuf *m0,
outbound_fw_args_t *args)

outbound_fw_args_t *outbound_fw_save_args(outbound_fw_args_t *args)
```

Parameters

Item	Description
pkt	Points to the mbuf chain containing the IP packet to be received (**ip_fltr_in_hook**, **ipsec_decap_hook**) or transmitted **(ip_fltr_out_hook**). The *pkt* parameter may be examined and/or changed in any of the three hook functions.
arg	Is the address of a pointer to *void* that is locally defined in the function where **ip_fltr_in_hook** and **ipsec_decap_hook** are called. The *arg* parameter is initially set to NULL, but the address of this pointer is passed to the two hook functions, **ip_fltr_in_hook** and **ipsec_decap_hook**. The *arg* parameter may be set by either of these functions, thereby allowing a void pointer to be shared between them.
ifp	Is the outgoing interface on which the IP packet will be transmitted for the **ip_fltr_out_hook** function.
flags	Indicates the ip_output flags passed by a transport layer protocol. Valid flags are currently defined in the **/usr/include/netinet/ip_var.h** files. See the Flags section below.

Description

These routines provide kernel-level hooks for IP packet filtering enabling IP packets to be selectively accepted, rejected, or modified during reception, transmission, and decapsulation. These hooks are initially NULL, but are exported by the netinet kernel extension and will be invoked if assigned non-NULL values.

The **ip_fltr_in_hook** routine is used to filter incoming IP packets, the **ip_fltr_out_hook** routine filters outgoing IP packets, and the **ipsec_decap_hook** routine filters incoming encapsulated IP packets.

The **ip_fltr_in_hook** function is invoked for every IP packet received by the host, whether addressed directly to this host or not. It is called after verifying the integrity and consistency of the IP packet. The function is free to examine or change the IP packet (*pkt*) or the pointer shared with **ipsec_decap_hook** (*arg*). The return value of the **ip_fltr_in_hook** indicates whether *pkt* should be accepted or dropped. The return values are described in Expected Return Values below. If *pkt* is accepted (a return value of **FIREWALL_OK**) and it is addressed directly to the host, the **ipsec_decap_hook** function is invoked next. If *pkt* is accepted, but is not directly addressed to the host, it is forwarded if IP forwarding is enabled. If **ip_fltr_in_hook** indicates *pkt* should be dropped (a return value of **FIREWALL_NOTOK**), it is neither delivered nor forwarded.

The **ipsec_decap_hook** function is called after reassembly of any IP fragments (the **ip_fltr_in_hook** function will have examined each of the IP fragments) and is invoked only for IP packets that are directly addressed to the host. The **ipsec_decap_hook** function is free to examine or change the IP packet (*pkt*) or the pointer shared with **ipsec_decap_hook** (*arg*). The hook function should perform decapsulation if necessary, back into *pkt* and return the proper status so that the IP packet can be processed appropriately. See the Expected Return Values section below. For acceptable encapsulated IP packets (a return value of **FIREWALL_OK**), the decapsulated packet is processed again by jumping to the beginning of the IP input processing loop. Consequently, the decapsulated IP packet will be examined first by **ip_fltr_in_hook** and, if addressed to the host, by **ipsec_decap_hook**. For acceptable non-encapsulated IP packets (a return value of **FIREWALL_OK_NOTSEC**), IP packet delivery simply

continues and *pkt* is processed by the transport layer. A return value of **FIREWALL_NOTOK** indicates that *pkt* should be dropped.

The **ip_fltr_out_hook** function is called for every IP packet to be transmitted, provided the outgoing IP packet's destination IP address is NOT an IP multicast address. If it is, it is sent immediately, bypassing the **ip_fltr_out_hook** function. This hook function is invoked after inserting the IP options from the upper protocol layers, constructing the complete IP header, and locating a route to the destination IP address. The **ip_fltr_out_hook** function may modify the outgoing IP packet (*pkt*), but the interface and route have already been assigned and may not be changed. The return value from the **ip_fltr_out_hook** function indicates whether *pkt* should be transmitted or dropped. See the Expected Return Values section below. If *pkt* is not dropped (**FIREWALL_OK**), it's source address is verified to be local and, if *pkt* is to be broadcast, the ability to broadcast is confirmed. Thereafter, *pkt* is enqueued on the interfaces (*ifp*) output queue. If *pk*t is dropped (**FIREWALL_NOTOK**), it is not transmitted and **EACCES** is returned to the process.

The **inbound_fw** and **outbound_fw** firewall hooks allow kernel extensions to get control of packets at the place where IP receives them. If **inbound_fw** is set, **ipintr_noqueue**, the IP input routine, calls **inbound_fw** and then exits. If not, **ipintr_noqueue** calls **ipintr_noqueue_post_fw** and then exits. If the **inbound_fw** hook routine wishes to pass the packet into IP, it can call **ipintr_noqueue_post_fw**. **inbound_fw** may copy its *args* parameter by calling **inbound_fw_save_args**, and may free its copy of its *args* parameter by calling **inbound_fw_free_args**.

Similarly, **ip_output** calls **outbound_fw** if it is set, and calls **ip_output_post_fw** if not. The **outbound_fw** hook can call **ip_output_post_fw** if it wants to send a packet. **outbound_fw** may copy its *args* parameter by calling **outbound_fw_save_args**, and later free its copy of its *args* parameter by calling **outbound_fw_free_args**.

Flags

Item	Description
IP_FORWARDING	Indicates that most of the IP headers exist.
IP_RAWOUTPUT	Indicates that the raw IP header exists.
IP_MULTICAST_OPTS	Indicates that multicast options are present.
IP_ROUTETOIF	Contains bypass routing tables.
IP_ALLOWBROADCAST	Provides capability to send broadcast packets.
IP_BROADCASTOPTS	Contains broadcast options inside.
IP_PMTUOPTS	Provides PMTU discovery options.
IP_GROUP_ROUTING	Contains group routing gidlist.

Expected Return Values

Item	Description
FIREWALL_OK	Indicates that *pkt* is acceptable for any of the filtering functions. It will be delivered, forwarded, or transmitted as appropriate.
FIREWALL_NOTOK	Indicates that *pkt* should be dropped. It will not be received (**ip_fltr_in_hook**, **ipsec_decap_hook**) or transmitted (**ip_fltr_out_hook**).
FIREWALL_OK_NOTSEC	Indicates a return value only valid for the **ipsec_decap_hook** function. This indicates that *pkt* is acceptable according to the filtering rules, but is not encapsulated; *pkt* will be processed by the transport layer rather than processed as a decapsulated IP packet.

Network Kernel Services

i_sched Kernel Service

Purpose

Schedules off-level processing.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/intr.h>
```

void i_sched (*handler*)
struct intr *handler;

Parameter

Item	Description
handler	Specifies the address of the pinned interrupt handler structure.

Description

The **i_sched** service allows device drivers to schedule some of their work to be processed at a less-favored interrupt priority. This capability allows interrupt handlers to run as quickly as possible, avoiding interrupt-processing delays and overrun conditions. See the **i_init** kernel service for a brief description of interrupt handlers.

Processing can be scheduled off-level in the following situations:

- The interrupt handler routine for a device driver must perform time-consuming processing.
- This work does not need to be performed immediately.

> **Attention:** The caller cannot alter any fields in the **intr** structure from the time the **i_sched** service is called until the kernel calls the off-level routine. The structure must also stay pinned. Otherwise, the system may crash.

The interrupt handler structure pointed to by the *handler* parameter describes an off-level interrupt handler. The caller of the **i_sched** service must set up all fields in the **intr** structure. The **INIT_OFFL***n* macros in the **/usr/include/sys/intr.h** file can be used to initialize the *handler* parameter. The *n* value represents the priority class that the off-level handler should run at. Currently, classes from 0 to 3 are defined.

Use of the **i_sched** service has two additional restrictions:

First, the **i_sched** service will not re-register an **intr** structure that is already registered for off-level handling. Since **i_sched** has no return value, the service will simply return normally without registering the specified structure if it was already registered but not yet executed. The kernel removes the **intr** structure from the registration list immediately prior to calling the off-level handler specified in the structure. It is therefore possible for the off-level handler to use the structure again to register another off-level request.

Care must be taken when scheduling off-level requests from a second-level interrupt handler (SLIH). If the off-level request is already registered but has not yet executed, a second registration will be ignored. If the off-level handler is currently executing, or has already run, a new request will be registered. Users of this service should be aware of these timing considerations and program accordingly.

Second, the kernel uses the `flags` field in the specified **intr** structure to determine if this structure is already registered. This field should be initialized once before the first call to the **i_sched** service and should remain unmodified for future calls to the **i_sched** service.

Note: Off-level interrupt handler path length should not exceed 5,000 instructions. If it does exceed this number, real-time support is adversely affected.

Execution Environment

The **i_sched** kernel service can be called from either the process or interrupt environment.

Return Values

The **i_sched** service has no return values.

IS64U Kernel Service

Purpose

Determines if the current user-address space is 64-bit or not.

Syntax

#include <sys/types.h> #include <sys/user.h> int IS64U

Description

The **IS64U** kernel service returns 1 if the current user-address space is 64-bit. It returns 0 otherwise.

Execution Environment

The **IS64U** kernel service can be called from a process or interrupt handler environment. In either case, it will operate only on the current user-address space.

Return Values

Item	Description
0	The current user-address space is 32-bits.
1	The current user-address space is 64-bits.

k

The following kernel services begin with the with the letter k.

k_cpuextintr_ctl Kernel Service

Purpose

Performs CPU external interrupt control related operations.

Syntax

```
#include <sys/intr.h>
```

kerrno_t k_cpuextintr_ctl (*command* , *cpuset* , *flags***)**
extintctl_t *command***;**
rsethandle_t *cpuset***;**
unit *flags***;**

Description

This kernel services provides means of enabling, disabling, and querying the external interrupt state on the CPUs described by the CPU resource set. Enabling or disabling an CPU external interrupt could affect the external interrupt delivery to the CPU. Normally, on multiple CPU system, external interrupts can be delivered to any running CPU, and the distribution among the CPUs is determined by a predefined method. Any external interrupt can only be delivered to a CPU if its interrupt priority is more favored than the current external interrupt priority of the CPU. When external interrupts are disabled via this interface, any external interrupt priority less favored than **INTMAX** will be blocked until interrupts are enabled again. This kernel service is applicable only on selective hardware types.

Note: Since this kernel service change the way that interrupts are delivered, system performance may be affected. This service guarantees at least one online CPU will have external interrupts enabled for all device interrupts. Any DLPAR CPU removal can fail if the operation breaks this guarantee. On an I/O bound system, one CPU may not be enough to handle all of the external interrupts received by the partition. Performance may suffer when there are not enough CPUs enabled to handle external interrupts.

Parameters

Item	Description
command	Specifies the operation to the CPU specified by the CPU resource set. One of the following values defined in **<sys/intr.h>** can be used:
	The following commands are supported:
	• EXTINTDISABLE: Disable external interrupts on the CPUs specified by the CPU resource set.
	• EXTINTENABLE: Enable external interrupts on the CPUs specified by the CPU resource set
	• QUERYEXTINTDISABLE: Return a CPU resource set containing the CPUs that have external interrupts disabled.
	• QUERYEXTINTENABLE: Return a CPU resource set containing the CPUs that have externals interrupt enabled.
cpuset	Reference to a CPU resource set. Upon successful return from this kernel service, the CPUs that have the external interrupt control operation done will be set in the CPU resource set.
	The CPUs specified by this *cpuset* parameter are logic CPU ids.
flags	Always set to 0 or **EINVAL_INTR_DIS_BAD_FLAGS** will be returned.

Security

The caller must have root authority with **CAP_NUMA_ATTACH** capability or **PV_KER_CONF** privilege in the RBAC environment.

Execution Environment

The **k_cpuextintr_ctl** kernel service can be called from process environment only.

Return Values

Upon successful completion, the **k_cpuextintr_ctl** kernel service returns a 0. If unsuccessful, one of the following **kerrno** value is returned.

Item	Description
kerrno	Description

Item	Description
EINVAL_EXTINTR_BAD_COMMAND	The command value is not valid.
EINVAL_EXTINTR_BAD_FLAGS	The flags value is unknown.
EINVAL_EXTINTR_BAD_CPUSET	The *cpuset* references NULL.
EINVAL_EXTINTR _NO_RSET	The *cpuset* is empty.
ENOTSUP_EXTINTR_CALLER	The kernel service is called from the interrupt environment.
ENOSYS_EXTINTR_PLATFORM	This function is not implemented on the platform.
EPERM_EXTINTR_OPER	The caller does not have enough privilege to perform the requested operation.

Note: A return value of success does not necessarily indicate that external interrupts have been enabled or disabled on all of the specified CPUs. For example, if a CPU is not online, then the enable or disable operation will not be performed on that CPU. The caller should check the returned *cpuset* to see which CPUs have this operation successfully done. The **k_cpuextintr_ctl kernel** service will not block DR CPU add/remove operation during the whole period of system call.

kcap_is_set and kcap_is_set_cr Kernel Service

Purpose

Determines if the given capability is present in an effective capability set.

Syntax

```
kcap_is_set (capability)
cap_value_t capability;

kcap_is_set_cr (capability, cred)
cap_value_t capability;
struct ucred *cred;
```

Parameters

Item	Description
capability	Specifies the capability to be examined. Must be one of the capabilities named in the **sys/capabilities.h** header file.
cred	Pointer to the credentials to be examined.

Description

The **kcap_is_set** subroutine determines if the given capability is present in the current process' effective capability set. The **kcap_is_set_cr** subroutine determines if the given capability is present in the effective capability set of the credentials structure referenced by the *cred* parameter. The *cred* parameter must be a valid referenced credentials structure.

Return Values

The **kcap_is_set** and **kcap_is_set_cr** subroutines return 1 if the capability is present. Otherwise, they return 0.

kcid_curproc Kernel Service

Purpose

Returns the current workload partition ID associated with the calling process.

Syntax

```
#include <sys/wparid.h>
```

cid_t kcid_curproc ( )

Description

The **kcid_curproc** kernel service returns the workload partition ID associated with the calling process. You can use this service to determine whether the requesting process is operating within a workload partition (WPAR).

Execution Environment

The **kcid_curproc** kernel service can be called from the process environment only.

Return Values

If the **kcid_curproc** kernel service is successful, it returns the workload partition ID associated with the calling process. If the calling process is not operating within a WPAR, the ID returned is equivalent to the WPAR_GLOBAL definition found in the **wparid.h** header file.

kwpar_r2vmap_pid Kernel Service
kwpar_v2rmap_pid Kernel Service

kcred_genpagvalue Kernel Service

Purpose

Generates a system-wide unique PAG value for a given PAG type.

Syntax

```
int  kcred_genpagvalue(crp, pag_type, pag_value, pag_flags);
cred_t          *crp;
int          pag_type;
uint64_t  *  pag_value;
int           pag_flags;
```

Description

The **kcred_genpagvalue** kernel service generates a new PAG value for a given PAG type. It is essential that for this function to succeed the PAG type must have been previously registered with the operating system using the **kcred_setpagname** kernel service. The scope of the **kcred_genpagvalue** kernel service is limited to maintaining information about the last generated PAG number and accordingly generating a new number. This service optionally stores the PAG value in the **cred** structure. It does not monitor the PAG values stored in the **cred** structure by other means.

The caller must convert a PAG name to a PAG type using the **kcred_getpagid** kernel service prior to invoking the **kcred_genpagvalue** kernel service.

The *pag_flags* parameter with the **PAG_SET_VALUE** value set causes the generated value to be atomically stored in the process's credentials.

The PAG value returned is of size 64 bits. The number of significant bits is determined by the requested PAG type. 32-bit PAGs have 32 significant bits. 64-bit PAGs have 62 significant bits.

Parameters

Item	Description
pag_type	The *pag_type* parameter is the ID value associated with a PAG name.
pag_value	This pointer points to a buffer where the OS will return the newly generated PAG value.
pag_flags	This parameter must be 0 or the value **PAG_SET_VALUE**.

Return Values

A value of 0 is returned upon successful completion. A negative value is returned if unsuccessful.

Error Codes

Item	Description
EINVAL	The PAG value cannot be generated because the named PAG type does not exist as part of the table.
EPERM	The named PAG type is a 32-bit PAG and the caller does not have the SET_PROC_DAC privilege.

genpagvalue Subroutine

kcred_getcap Kernel Service

Purpose

Copies a capability vector from a credentials structure.

Syntax

```
#include <sys/capabilities.h>

#include <sys/cred.h>

int kcred_getcap ( crp, cap )
struct ucred * cr;
struct __cap_t * cap;
```

Parameters

Item	Description
crp	Pointer to a credentials structure
cap	Capabilities set

Description

The **kcred_getcap** kernel service copies the capability set from the credentials structure referenced by *crp* into *cap*. *crp* must be a valid, referenced credentials structure.

Execution Environment

The **kcred_getcap** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Success.
-1	An error has occurred.

Related information
Security Kernel Services

kcred_getgroups Kernel Service

Purpose

Copies the concurrent group set from a credentials structure.

Syntax

#include <sys/cred.h>

```
int kcred_getgroups ( crp, ngroups, groups )
struct ucred * cr;
int ngroups;
gid_t * groups;
```

Parameters

Item	Description
crp	Pointer to a credentials structure
ngroups	Size of the array of group ID values
groups	Array of group ID values

Description

The **kcred_getgroups** kernel service returns up to *ngroups* concurrent group set members from the credentials structure pointed to by *crp*. *crp* must be a valid referenced credentials structure.

Execution Environment

The **kcred_getgroups** kernel service can be called from the process environment only.

Return Values

Item	Description
>= 0	The number of concurrent groups copied to groups.
-1	An error has occurred.

Related information
Security Kernel Services

kcred_getpag or kcred_getpag64 Kernel Service

Purpose

Copies a process authentication group (PAG) ID from a credentials structure.

Syntax

```
#include <sys/cred.h>

int kcred_getpag ( crp, which, pag )
struct ucred * cr;
int which;
int * pag;

int kcred_getpag64 ( crp, which, pag )
struct ucred * cr;
int which;
uint64 * pag;
```

Parameters

Item	Description
crp	Pointer to a credentials structure
which	PAG ID to get
pag	Process authentication group

Description

The **kcred_getpag** or **kcred_getpag64** kernel service copies the requested PAG from the credentials structure referenced by *crp* into *pag*. The value of *which* must be a defined PAG ID. The PAG ID for the *Distributed Computing Environment* (DCE) is 0. *crp* must be a valid, referenced credentials structure.

Execution Environment

The **kcred_getpag** or **kcred_getpag64** kernel service can be called from the process environment only.

Return Values

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned, and the **errno** global variable is set to indicate the error.

Error Codes

The **kcred_getpag** kernel service fails if the following condition is true:

Item	Description
-EOVERFLOW	PAG value is 64-bit (should be using `kcred_getpag64`)

Related information
Security Kernel Services

kcred_getpagid Kernel Service

Purpose

Returns the PAG identifier for a PAG name.

Syntax

```
int kcred_getpagid (name)
char *name;
```

Description

Given a PAG type name, the **kcred_getpagid** subroutine returns the PAG identifier for that PAG name.

Parameters

Item	Description
name	A pointer to the name of the PAG type whose integer PAG identifer is to be returned.

Return Values

A return value greater than or equal to 0 is the PAG identifier. A value less than 0 indicates an error.

Error Codes

Item	Description
ENOENT	The *name* parameter doesn't refer to an existing PAG entry.

Related reference
__pag_getid System Call
__pag_getvalue System Call
kcred_getpagname Kernel Service

kcred_getpaginfo Kernel Service

Purpose

Returns a Process Authentication Group (PAG) flags for a given PAG type.

Syntax

```
#include <sys/cred.h>

int kcred_getpaginfo ( type, infop, infosz )
int type;
struct paginfo *  infop
int infosz;
```

Parameters

Item	Description
type	PAG for which the flags are returned
infop	Pointer to PAG info structure
infosz	Size of `paginfo` structure

Description

The `kcred_getpaginfo` kernel service retrieves the flags for the specific PAG type and stores them in a PAG info structure. The value of *type* must be a defined PAG ID. The PAG ID for the Distributed Computing Environment (DCE) is 0. The *infop* parameter must be a valid, referenced PAG info structure of the size specified by *infosz*.

Execution Environment

The `kcred_getpaginfo` kernel service can be called from the process environment only.

Return Values

A value of 0 is returned upon successful completion. Upon failure, a -1 is returned and `errno` is set to a value that explains the error.

Related information

Security Kernel Services

kcred_getpagname Kernel Service

Purpose

Retrieves the name of a PAG.

Syntax

```
int kcred_getpagname (type, buf, size)
int type;
char *buf;
int size;
```

Description

The **kcred_getpagname** kernel service retrieves the name of a PAG type given its integer value.

Parameters

Item	Description
type	The integer valued identifier representing the PAG type.
buf	A **char *** to where the PAG name is copied.
size	An **int** that specifies the size of *buf* in bytes. The size of the buffer must be PAG_NAME_LENGTH_MAX+1.

Return Values

If successful, a 0 is returned. If unsuccessful, an error code value less than 0 is returned. The PAG name associated with *type* is copied into the caller-supplied buffer *buf*.

Error Codes

Item	Description
EINVAL	The value of *id* is less than 0 or greater than the maximum PAG identifier.
ENOENT	There is no PAG associated with *id*.

Item	Description
ENOSPC	The *size* parameter is insufficient to hold the PAG name.

kcred_getppriv Kernel Service

Purpose

Copies a privilege vector from a credentials structure.

Syntax

```
#include <sys/priv.h>
#include <sys/cred.h>
```

int kcred_getppriv (*crp*, *which*, *privset***)**
struct ucred **crp***;**
int *which***;**
privg_t *privset***;**

Parameters

Item	Description
crp	Points to a credentials structure.
which	Specifies the privilege set to get.
privset	Specifies the privilege set.

Description

The **kcred_getppriv** kernel service returns a single privilege set from the credentials structure referenced by the *crp* parameter. The *which* parameter is one of the values of **PRIV_EFFECTIVE**, **PRIV_MAXIMUM**, **PRIV_INHERITED**, **PRIV_LIMITING**, and **PRIV_USED**. The corresponding privilege set is copied to the *privset* parameter. The *crp* parameter must be a valid, referenced credentials structure.

Execution Environment

The **kcred_getppriv** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Success.
-1	An error has occurred.

Related information

Syntax

```
#include <sys/priv.h>

#include <sys/cred.h>

int kcred_getpriv ( crp, which, priv )
struct ucred * cr;
int which;
priv_t * priv;
```

Parameters

Item	Description
crp	Pointer to a credentials structure
which	Privilege set to get
priv	Privilege set

Description

The **kcred_getpriv** kernel service returns a single privilege set from the credentials structure referenced by *crp*. The *which* parameter is one of **PRIV_BEQUEATH**, **PRIV_EFFECTIVE**, **PRIV_INHERITED**, or **PRIV_MAXIMUM**. The corresponding privilege set will be copied to *priv*. *rp* must be a valid, referenced credentials structure.

Execution Environment

The **kcred_getpriv** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Success. to priv.
-1	An error has occurred.

```
void kcred_setcap ( crp, cap )
struct ucred * cr;
struct __cap_t * cap;
```

Parameters

Item	Description
crp	Pointer to a credentials structure
cap	Capabilities set

Description

The **kcred_setcap** kernel service initializes the capability set in the credentials structure referenced by *crp* with *cap*. *rp* must be a valid, referenced credentials structure and must not be the current credentials of any process.

Execution Environment

The **kcred_setcap** kernel service can be called from the process environment only.

Return Values

The **kcred_setcap** kernel service has no return values.

Related information
Security Kernel Services

kcred_setgroups Kernel Service

Purpose

Copies a concurrent group set into a credentials structure.

Syntax

```
#include <sys/cred.h>

int kcred_setgroups ( crp, ngroups, groups )
struct ucred * cr;
int ngroups;
gid_t * groups;
```

Parameters

Item	Description
crp	Pointer to a credentials structure
ngroups	Size of the array of group ID values
groups	Array of group ID values

Description

The **kcred_setgroups** kernel service copies *ngroups* concurrent group set members into the credentials structure pointed to by *crp*. *crp* must be a valid, referenced credentials structure and must not be the current credentials of any process.

Execution Environment

The **kcred_setgroups** kernel service can be called from the process environment only.

Return Values

Item	Description
0	The concurrent group set has been copied successfully.
-1	An error has occurred.

Related information

Security Kernel Services

kcred_setpag or kcred_setpag64 Kernel Service

Purpose

Copies a process authentication group ID into a credentials structure.

Syntax

```
#include <sys/cred.h>

int kcred_setpag ( crp, which, pag )
struct ucred * cr;
int which;
int pag;

int kcred_setpag64 ( crp, which, pag )
struct ucred * cr;
int which;
uint64 * pag;
```

Parameters

Item	Description
crp	Pointer to a credentials structure
which	PAG ID to set
pag	Process authentication group

Description

The **kcred_setpag** or **kcred_setpag64** kernel service initializes the specified PAG in the credentials structure referenced by *crp* with *pag*. The value of *which* must be a defined PAG ID. The PAG ID for the *Distributed Computing Environment* (DCE) is 0. *Crp* must be a valid, referenced credentials structure. *crp* may be a reference to the current credentials of a process.

Execution Environment

The **kcred_setpag** or **kcred_setpag64** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Success.

Item	Description
-1	An error has occurred.

Related information

Security Kernel Services

kcred_setpagname Kernel Service

Purpose

Copies a process authentication group ID into a credentials structure.

Syntax

```
int kcred_setpagname (name, flags, func)
char *name;
int flags;
```

Description

The **kcred_setpagname** kernel service registers the name of a PAG and returns the PAG type identifier. If the PAG name has already been registered, the previously returned PAG type identifier is returned if the *flags* and *func* parameters match their earlier values.

Parameters

Item	Description
name	The *name* parameter is a 1 to 4 character, NULL-terminated name for the PAG type. Typical values might include "*afs*", "*dfs*", "*pki*" and "*krb5*."
flags	The *flags* parameter indicates if each PAG value is unique (PAG_UNIQUEVALUE) or multivalued (PAG_MULTIVALUED). A multivalued PAG type allows multiple calls to the **kcred_setpag** kernel service to be made to store multiple values for a single PAG type.
func	The *func* parameter is a pointer to an allocating and deallocating function. The *flag* parameter to that function is either PAGVALUE_ALLOC or PAGVALUE_FREE. The *value* parameter is the actual PAG value. The *func* parameter will be invoked by the **crfree** kernel service with a flag value of PAGVALUE_FREE on the last free value of a credential. Whenever a credentials structure is initialized with new PAG values, *func* will be invoked by that function with a value of PAGVALUE_ALLOC. This parameter may be ignored and an error returned if the value of *func* is non-NULL.

Return Values

A value of 0 or greater is returned upon successful completion. This value is the PAG type identifier which is used with other kernel services, such as the **kcred_getpag** and **kcred_setpag** subroutines . A negative value is returned if unsuccessful.

Error Codes

Item	Description
ENOSPC	The PAG table is full.
EEXISTS	The named PAG type already exists in the table and the *flags* and *func* parameters do not match their earlier values.

Item	Description
EINVAL	The *flags* parameter is an invalid value.

```

int kcred_setppriv (_crp_, _which_, _privset_**)**
struct ucred *_crp_**;**
int _which_**;**
privg_t _privset_**;**

Parameters

Item	Description
crp	Points to a credentials structure.
which	Specifies the privilege set to set.
privset	Specifies the privilege set.

Description

The **kcred_setppriv** kernel service sets one or more single privilege sets in the credentials structure referenced by the *crp* parameter. The *which* parameter is the bitwise OR of one or more values of **PRIV_EFFECTIVE**, **PRIV_MAXIMUM**, **PRIV_INHERITED**, **PRIV_LIMITING**, and **PRIV_USED**. The *privset* parameter initializes the corresponding privilege sets. The *crp* parameter must be a valid, referenced credentials structure and cannot be the current credentials of any process.

Execution Environment

kern_soaccept Kernel Service

Purpose

Accepts the first queued connection by assigning it to the new socket.

Syntax

```
#include <sys/kern_socket.h>
int kern_soaccept( ksocket_t  so,
```

```
ksocket_t  *aso,
struct mbuf **name,
int nonblock )
```

Parameters

Item	Description
so	The socket that is used in the **kern_solisten()** Kernel Service.
aso	The new socket for the accepted connection. The caller must pass in the address of the **ksocket_t**.
name	A **struct sockadr** address is returned in a **mbuf** buffer whose address is stored in the ***name** parameter. The caller should pass in the address of the struct **mbuf *** structure. The caller sets the **mbuf** buffer free after the function returns successfully.
nonblock	A flag to specify if this call should be nonblocking. The value of 1 is for nonblocking and 0 is for blocking.

Description

The **kern_soaccept** kernel service accepts the first queued connection by assigning it to the new socket.

Execution Environment

The **kern_soaccept** kernel service can be called from the process environment.

Examples

```
struct mbuf *name = NULL;
ksocket_t   so;
ksocket_t   aso;
struct sockaddr_in laddr;
int          rc;
rc = kern_socreate(AF_INET, &so, SOCK_STREAM, IPPROTO_TCP);
if (rc != 0 )
{
     return(-1);
}
bzero(&laddr, sizeof(struct sockaddr_in));
laddr.sin_family = AF_INET;
laddr.sin_port = 12345;
laddr.sin_len = sizeof(struct sockaddr_in);
laddr.sin_addr.s_addr = inet_addr("9.3.108.208");
rc = kern_sobind(so, (struct sockaddr *)&laddr);
if (rc != 0 )
{
     return(-1);
}
rc = kern_solisten(so, 5);
if (rc != 0 )
{
     return(-1);
}
rc = kern_soaccept(so, &aso, &name, 0);
if (rc != 0 )
{
     return(-1);
}
m_freem(name); /* Caller needs to free the mbuf after kern_soaccept */
```

Return Values

Item	Description
0	Upon Success

Item	Description
>0	Error

The non-zero return value is the error number that is defined in the **/usr/include/sys/errno.h** file.

faddr.sin_family = AF_INET;
faddr.sin_port = 23456;
faddr.sin_len = sizeof(struct sockaddr_in);
faddr.sin_addr.s_addr = inet_addr("9.3.108.210");
rc = kern_soconnect(so, (struct sockaddr *) &faddr);
if (rc != 0 )
{
        return(-1);
}
```

Return Values

Item	Description
0	Upon Success
>0	Error

The nonzero return value is the error number that is defined in the **/usr/include/sys/errno.h** file.

kern_socreate Kernel Service

Purpose

Used to create a socket of the specified address family and type. If the protocol is left unspecified (zero), then the system selects the protocol based on the address family and type.

Syntax

```
#include <sys/kern_socket.h>
int kern_socreate (int addressfamily, ksocket_t  *so, int type, int protocol)
```

Parameters

Item	Description
addressfamily	The address family for the newly created socket. The file **<sys/socket.h>** contains the definitions for the family. Currently AIX supports: **AF_INET** Denotes the IPv4 Internet addresses. **AF_INET6** Denotes the IPv6 Internet addresses.
so	The socket assigned by the **create()** call. The caller must pass the address of **ksocket_t**.
type	The requested socket type. The file **<sys/socket.h>** contains the definition for the socket type. Currently AIX supports **SOCK_STREAM**.
protocol	The file **<netinet/in.h>** contains the definition for the protocol. Currently AIX supports **IPPROTO_TCP**

Description

The **kern_socreate** kernel service creates a socket based on the address family, type and protocol.

Execution Environment

The **kern_socreate** kernel service can be called from the process environment.

Examples

```
ksocket_t      so;
ksocket _t     so2;
kern_socreate(AF_INET, &so, SOCK_STREAM, IPPROTO_TCP);
kern_socreate(AF_INET6, &so2, SOCK_STREAM, 0);
```

Return Values

Item	Description
0	Upon Success

Item	Description
>0	Error

The nonzero return value is the error number that is defined in the **/usr/include/sys/errno.h** file.

Related reference

kern_soclose Kernel Service
kern_soconnect Kernel Service
kern_soshutdown Kernel Service

kern_sogetopt Kernel Service

Purpose

Obtains the option associated with the socket, either at the socket level or at the protocol level.

Syntax

```
#include <sys/kern_socket.h>
int  kern_sogetopt( ksocket_t  so, int level, int optname, struct mbuf **mp )
```

Parameters

Item	Description
so	The socket that will be used to retrieve the option.
level	The socket level (e.g. **SOL_SOCKET**) or protocol level (**IPPROTO_TCP**)
optname	The option name to retrieve. Socket options can be found in **<sys/socket.h>** and TCP options can be found in **<netinet/tcp.h>** mp
mp	The **mbuf** that will be returned with the option value. The **mp->m_len** will be the size of the value. The caller must pass the address of the **struct mbuf ***. The caller must set the **mbuf** free after the function returns successfully.

Description

The **kern_sogetopt** kernel service obtains the option associated with the socket, either at the socket level, or at the protocol level.

Execution Environment

The **kern_sogetopt** kernel service can be called from the process environment.

Examples

```
ksocket_t   so;
int         rc;
struct mbuf *sopt = NULL;
int  tcp_nodelay = -1;
rc = kern_socreate(AF_INET, &so, SOCK_STREAM, IPPROTO_TCP);
if (rc != 0 )
{
        return(-1);
}
rc = sogetopt(so, IPPROTO_TCP, TCP_NODELAY, &sopt);
if (rc != 0 )
{
        return(-1);
}
```

```
tcp_nodelay = *mtod(sopt, int *) ? 1 : 0;
m_free(sopt); /* Caller needs to free the mbuf after kern_sogetopt */
```

Return Values

Item	Description
0	Upon Success
>0	Error

The nonzero return value is the error number that is defined in the **/usr/include/sys/errno.h** file.

Related reference

kern_socreate Kernel Service

kern_solisten Kernel Service

Purpose

Prepares to accept incoming connections on the socket.

Syntax

```
#include <sys/kern_socket.h>
int kern_solisten( ksocket_t  so,  int backlog )
```

Parameters

Item	Description
so	The socket that was created by **kern_socreate()** and used in **kern_sobind()**
backlog	Limit the number of connection requests that can be queued on this socket. The maximum value that can be passed to this parameter equals the minimum number of user backlog number and the network option **somaxconn** value.

Description

The **kern_solisten** kernel service prepares to accept incoming connection on the socket.

Execution Environment

The **kern_solisten** kernel service can be called from the process environment.

Examples

```
struct mbuf *name = NULL;
ksocket_t   so;
struct sockaddr_in laddr;
int           rc;
rc = kern_socreate(AF_INET, &so, SOCK_STREAM, IPPROTO_TCP);
if (rc != 0 )
{
         return(-1);
}
bzero(&laddr, sizeof(struct sockaddr_in));
laddr.sin_family = AF_INET;
laddr.sin_port = 12345;
laddr.sin_len = sizeof(struct sockaddr_in);
laddr.sin_addr.s_addr = inet_addr("9.3.108.208");
rc = kern_sobind(so, (struct sockaddr *)&laddr);
if (rc != 0 )
```

```
{
        return(-1);
}
rc = kern_solisten(so, 5);
if (rc != 0 )
{
        return(-1);
}
```

Return Values

Item	Description
0	Upon Success
>0	Error

The nonzero return value is the error number that is defined in the **/usr/include/sys/errno.h** file.

Related reference
kern_socreate Kernel Service
kern_soaccept Kernel Service

kern_soreceive Kernel Service

Purpose

The routine processes one record per call and returns the number of bytes requested.

Syntax

```
#include <sys/kern_socket.h>
int  kern_soreceive( ksocket_t   so,
struct mbuf **paddr,
long len,
struct mbuf **mp,
struct mbuf **controlp,
int *flagp )
```

Parameters

Item	Description
so	The socket to receive the data.
paddr	The foreign socket address information is returned in this pointer. Caller should pass in address of **struct mbuf *** . Caller needs to free this **mbuf** after the function returns successfully. Caller can pass in NULL if caller doesn't need foreign address information.
len	The length of the data to be received.
mp	The **mbuf** pointer so that data can be returned in an **mbuf** chain. The caller must pass in the address of **struct mbuf ***. The caller must free this **mbuf** after the function returns.
controlp	Pointer to an **mbuf** containing the control information. Caller should pass in address of **struct mbuf *** . Caller needs to free this **mbuf** after the function returns successfully. Caller can pass in NULL if there is no control information.

Item	Description
flagp	If *flagp* is not NULL, caller can pass in actual flag. The flags are defined in the **<sys/socket.h>** file. The **kern_soreceive** routine will use flags set in *flagp*. The caller can set the *flagsp* to **MSG_WAITALL** or **MSG_NONBLOCK**. On return, it will set *flagp* to **MSG_TRUNC**, **MSG_OOB** wherever applicable.

Description

The **kern_soreceive** kernel service processes one record per call and returns the number of bytes that are requested. If there is data in the socket receive buffer, the **kern_soreceive** kernel service returns up to < len> bytes as a **mbuf** chain. The actual number of bytes returned is computed by adding the **m_len** fields of each **mbuf** in the chain. If there is no data, but the connection is still established, the **kern_soreceive** kernel service either returns EAGAIN with *mp set to NULL (if MSG_NONBLOCK is set) or returns wait for data to arrive (if MSG_NONBLOCK is not set). If the connection is closed before the call or while waiting for data, the *mp is set to NULL and 0 is returned. Waiting may be interrupted, in which case **kern_soreceive** returns EAGAIN, EINTR, or ERESTART and *mp is undefined. The application might return EINTR, but calls the **kern_soreceive** kernel service again.

Execution Environment

The **kern_soreceive** kernel service can be called from the process environment.

Examples

```
ksocket_t   so;
struct mbuf *data = NULL;
struct sockaddr_in faddr;
long        len = 512;
int         flags = 0;
int             rc;
rc = kern_socreate(AF_INET, &so, SOCK_STREAM, IPPROTO_TCP);
if (rc != 0 )
{
            return(-1);
}
bzero(&faddr, sizeof(struct sockaddr_in));
faddr.sin_family = AF_INET;
faddr.sin_port = 23456;
faddr.sin_len = sizeof(struct sockaddr_in);
faddr.sin_addr.s_addr = inet_addr("9.3.108.210");
rc = kern_soconnect(so, (struct sockaddr *) &faddr);
if (rc != 0 )
{
        return(-1);
}
do
{
            rc = kern_soreceive(so, NULL, len, &data, NULL, &flags);
}  while (rc == EAGAIN || rc == EINTR || rc == ERESTART);
if ((rc == 0) && data)
{
        /* process the data */
        ...
   m_freem(data); /* Caller needs to free the mbuf after kern_soreceive. */
}
else
{
     return(-1);
}
```

Return Values

Item	Description
0	Upon Success
>0	Error

The nonzero return value is the error number that is defined in the **/usr/include/sys/errno.h** file.

Related reference
kern_socreate Kernel Service
kern_sosend Kernel Service

kern_soreserve Kernel Service

Purpose

The routine enforces the limit for the send and receive buffer space for a socket. It does not actually allocate memory only sets the buffer size.

Syntax

```
#include <sys/kern_socket.h>
int kern_soreserve( ksocket_t  so, uint64_t sndcc, uint64_t rcvcc )
```

Parameters

Item	Description
so	The socket that will be used in reserving the space.
sndcc	Send buffer size in bytes.
rcvcc	Receive buffer size in bytes.

Description

The **kern_soreserve** kernel service enforces the limit for the send and receive buffer space for a socket. It does not actually allocate memory. It sets the buffer size.

Execution Environment

The **kern_soreserve** kernel service can be called from the process environment.

Examples

```
ksocket_t   so;
uint64_t    sb_snd_hiwat = 2048;
uint64_t    sb_rcv_hiwat = 2048;
int             rc;
rc = kern_socreate(AF_INET, &so, SOCK_STREAM, IPPROTO_TCP);
if (rc != 0 )
{
        return(-1);
}
rc = kern_soreserve(so, sb_snd_hiwat, sb_rcv_hiwat);
if (rc != 0 )
{
    return(-1);
}
```

Return Values

Item	Description
0	Upon Success
>0	Error

The nonzero return value is the error number that is defined in the **/usr/include/sys/errno.h** file.

Related reference

kern_socreate Kernel Service

kern_sosend Kernel Service

Purpose

Pass data and control information to the protocol associated send routines.

Syntax

```
#include <sys/kern_socket.h>
int  kern_sosend( ksocket_t  so, struct sockaddr *faddr,
struct mbuf *top,
struct mbuf *control,
int flags )
```

Parameters

Item	Description
so	The socket to send data.
faddr	The destination address, only necessary if the socket is not connected.
top	The **mbuf** chain of data to be sent. Remember that the first **mbuf** must have the packet header filled out. Set the **top->m_pkthdr.len** to the total length of the data in the **mbuf** chain and the **m_flags** to **M_PKTHDR**. The caller must allocate **mbuf** memory before calling the routine.
control	Pointer to an **mbuf** containing the control information to be sent. The caller must allocate **mbuf** memory before calling the function if the caller wants to pass in control information.
flags	Flags options for this write call. Caller can set flags to **MSG_NONBLOCK**.

Description

The **kern_sosend** kernel service passes data and control information to the protocol associated send routines.

Execution Environment

The **kern_sosend** kernel service can be called from process environment.

Examples

```
ksocket_t  so;
int flags = 0;
struct sockaddr_in faddr;
struct mbuf *send_mbuf;
struct sockaddr_in  faddr;
char        msg[100];
int         i, rc;
rc = kern_socreate(AF_INET, &so, SOCK_STREAM, IPPROTO_TCP);
if (rc != 0 )
{
        return(-1);
}
bzero(&faddr, sizeof(struct sockaddr_in));
faddr.sin_family = AF_INET;
faddr.sin_port = 23456;
```

```
faddr.sin_len = sizeof(struct sockaddr_in);
faddr.sin_addr.s_addr = inet_addr("9.3.108.210");
rc = kern_soconnect(so, (struct sockaddr *) &faddr);
if (rc != 0 )
{
    return(-1);
}
send_mbuf = MGETBUF(sizeof(msg), M_DONOTWAIT); /* Caller needs to allocate mbuf memory
*/
if (send_mbuf == NULL)
{
    return (-1);
}
for (i=0; i < 100, i++)
{
        msg[i] = 0x2A;
}
bcopy(msg, mtod(send_mbuf, caddr_t), sizeof(msg));
send_mbuf->m_len = send_mbuf->m_pkthdr.len = sizeof(msg);
rc = kern_sosend(so, NULL, send_mbuf, 0, MSG_NONBLOCK));
if (rc != 0 )
{
    return(-1);
}
```

Return Values

Item	Description
0	Upon Success
>0	Error

The nonzero return value is the error number that is defined in the **/usr/include/sys/errno.h** file.

kern_sosetopt Kernel Service

Purpose

Sets the option associated with the socket, either at the socket level or at the protocol level.

Syntax

```
#include <sys/kern_socket.h>
int  sosetopt( ksocket_t  so,
int level, int optname,
struct mbuf *mp )
```

Parameters

Item	Description
so	The socket that will be used to set the option.
level	The socket level (e.g. **SOL_SOCKET**) or protocol level (**IPPROTO_TCP**)
optname	The option name to set. Socket options can be found in **<sys/socket.h>** and the TCP options can be found in **<netinet/tcp.h>**.
mp	The **mbuf** that contains the option value and will be used to modify the field specified by the option name. The **mp->m_len** should be the size of the value. The caller must allocate **mbuf** memory before calling the function.

Description

The **kern_sosettopt** kernel service sets the option associated with the socket, either at the socket level, or at the protocol level.

Execution Environment

The **kern_sosetopt** kernel service can be called from the process environment.

Examples

```
ksocket_t    so;
struct mbuf *mp = NULL;
struct linger *linger;
int rc;
rc = kern_socreate(AF_INET, &so, SOCK_STREAM, IPPROTO_TCP);
if (rc != 0 )
{
      return(-1);
}
mp = m_get(M_DONTWAIT, MT_SOOPTS); /* Caller of kern_sosetopt needs to allocated mbuf  memory
*/
if (mp == NULL)
{
      return (-1);
}
mp->m_len = sizeof(struct linger);
linger = mtod(mp, struct linger *);
linger->l_linger = 5;
linger->l_onoff = 1;
rc = kern_sosetopt(so, SOL_SOCKET, SO_LINGER, mp);
if (rc != 0 )
{
      return(-1);
}
```

Return Values

Item	Description
0	Upon Success
>0	Error

The nonzero return value is the error number that is defined in the **/usr/include/sys/errno.h** file.

kern_socreate Kernel Service

kern_soshutdown Kernel Service

Purpose

Closes the read-half, write-half or both read and write of a connection.

Syntax

```
#include <sys/kern_socket.h>
int  kern_soshutdown( ksocket_t  so, int how )
```

Parameters

Item	Description
so	The socket to which the shutdown will be issued.
how	0 read, 1 write, 2 read and write

Description

The **kern_soshutdown** kernel service closes the read-half, write-half or both read and write of a connection.

Execution Environment

The **kern_soshutdown** kernel service can be called from the process environment.

Examples

```
ksocket_t    so;

/* Create the socket so */

kern_socreate(AF_INET, &so, SOCK_STREAM, IPPROTO_TCP);

/* Shutting down both the read/write */

kern_soshutdown(so, 2);
```

Return Values

Item	Description
0	Upon Success
>0	Error

Related reference
kern_socreate Kernel Service

kgethostname Kernel Service

Purpose

Retrieves the name of the current host.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
int
kgethostname ( name,  namelen)
char *name;
int *namelen;
```

Parameters

Item	Description
name	Specifies the address of the buffer in which to place the host name.
namelen	Specifies the address of a variable in which the length of the host name will be stored. This parameter should be set to the size of the buffer before the **kgethostname** kernel service is called.

Description

The **kgethostname** kernel service returns the standard name of the current host as set by the **sethostname** subroutine. The returned host name is null-terminated unless insufficient space is provided.

Execution Environment

The **kgethostname** kernel service can be called from either the process or interrupt environment.

Return Value

Item	Description
0	Indicates successful completion.

Related information

sethostname subroutine

Network Kernel Services

kgetpname Kernel Service

Purpose

Provides the calling process's base program name.

Syntax

```
#include <sys/encap.h>
int kgetpname (char * Buffer, size_t *BufferSize);
```

Description

The kgetpname kernel service copies the program name of the calling process into the buffer specified by *Buffer*. Including the null terminator, the service copies no more than the lesser of **BufferSize*, MAXCOMLEN, or the actual size of the program name in bytes into the buffer. If *Buffer* is NULL, or **BufferSize* is 0, no copy is performed. If the full program name is copied into the buffer, the total number of bytes copied is written to **BufferSize*. If kgetpname cannot copy the full program name into the buffer, the size in bytes of the full program name is written to **BufferSize*, and ENAMETOOLONG is returned.

Execution Environment

The kgetpname kernel service can only be called from the process environment.

Return Values

Item	Description
0	The full program name was successfully written to the buffer.
ENAMETOOLONG	Only part of the full program name was written to the buffer, and `kgetpname` stored the (positive) length in bytes (including the null character) of the full program name into *BufferSize*.
EINVAL	*Buffer* is Null, *BufferSize* is NULL, or *BufferSize* is 0.
ENOTSUP	The `kgetpname` kernel service was called from inside an interrupt context.

kgetrlimit64 Kernel Service

Purpose

Controls maximum system resource consumption.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/time.h>
#include <sys/resource.h>
```

void kgetrlimit64 (*Resource1*, *RLP*)
int *Resource1*;
struct rlimit64 *RLP;

Parameters

Item	Description
Resource1	The *Resource1* parameter can be one of the following values:

> **RLIMIT_AS**
> The maximum size, in bytes, of the total available memory of a process. This limit is enforced by the kernel only if the *XPG_SUS_ENV=ON* environment variable is set in the user's environment before the process is executed. If the *XPG_SUS_ENV* environment variable is not set in the user's environment, the limit is not enforced.
>
> **RLIMIT_CORE**
> The largest size, in bytes, of a core file that can be created. This limit is enforced by the kernel. If the value of the **RLIMIT_FSIZE** limit is less than the value of the **RLIMIT_CORE** limit, the system uses the **RLIMIT_FSIZE** limit value as the soft limit.
>
> **RLIMIT_CPU**
> The maximum amount of central processing unit (CPU) time, in seconds, to be used by each process. If a process exceeds its soft CPU limit, the kernel sends a **SIGXCPU** signal to the process. After the hard limit is reached, the process is killed with **SIGXCPU**, even if it handles, blocks, or ignores that signal.
>
> **RLIMIT_DATA**
> The maximum size, in bytes, of the data region for a process. This limit defines how far a program can extend its break value with the **sbrk** subroutine. This limit is enforced by the kernel.
>
> **RLIMIT_FSIZE**
> The largest size, in bytes, of any single file that can be created. When a process attempts to write, truncate, or clear beyond its soft **RLIMIT_FSIZE** limit, the operation fails with the *errno* variable set to **EFBIG**. If the environment variable *XPG_SUS_ENV=ON* is set in the user's environment before the process is issued, then the **SIGXFSZ** signal is also generated.
>
> **RLIMIT_NOFILE**
> This is a number one greater than the maximum value that the system can assign to a newly-created descriptor.
>
> **RLIMIT_STACK**
> The maximum size, in bytes, of the stack region for a process. This limit defines how far a program stack region can be extended. The system automatically performs stack extension. This limit is enforced by the kernel. When the stack limit is reached, the process receives a **SIGSEGV** signal. If this signal is not caught by a handler using the signal stack, the signal ends the process.
>
> **RLIMIT_RSS**
> The maximum size, in bytes, to which the resident set size of a process can grow. This limit is not enforced by the kernel. A process might exceed its soft limit size without being ended.

Item	Description
RLP	Points to the **rlimit64** structure where the requested limits are returned by the **kgetrlimit64** kernel service.

Description

The **kgetrlimit64** kernel service returns the values of limits on system resources used by the current process and its children processes.

Note: The initial values returned by the **kgetrlimit64** kernel service are the ulimit values in effect when the process was started. For maxdata programs the initial soft limit for data is set to the lower of data ulimit value or a value corresponding to the number of data segments reserved for data segments.

The **rlimit64** structure specifies the hard and soft limits for a resource, as defined in the **sys/resource.h** file. The RLIM64_INFINITY value defines an infinite value for a limit.

Execution Environment

The **kgetrlimit64** kernel service can be called from either the process or interrupt environment.

Return Values

The **kgetrlimit64** kernel service has no return values.

Related information
getrlimit64 subroutine

kgetsystemcfg Kernel Service

Purpose

Displays the system configuration information.

Syntax

```
#include <systemcfg.h>
uint64_t kgetsystemcfg ( int name)
```

Description

Displays the system configuration information.

Parameters

Item	Description
name	Specifies the system variable setting to be returned. Valid values for the *name* parameter are defined in the **systemcfg.h** file.

Return Values

If the value specified by the *name* parameter is system-defined, the **kgetsystemcfg** kernel service returns the data that is associated with the structure member represented by the *input* parameter. Otherwise, the **kgetsystemcfg** kernel service will return **UINT64_MAX**, and the **errno** will be set.

Error Codes

The **kgetsystemcfg** subroutine will fail if:

Item	Description
EINVAL	The value of the *name* parameter is invalid.

Related information
getsystemcfg subroutine

kgettickd Kernel Service

Purpose

Retrieves the current status of the systemwide time-of-day timer-adjustment values.

Syntax

```
#include <sys/types.h>
```

```
int kgettickd (timed, tickd, time_adjusted)
int *timed;
int *tickd;
int *time_adjusted;
```

Parameters

Item	Description
timed	Specifies the current amount of time adjustment in microseconds remaining to be applied to the systemwide timer.
tickd	Specifies the time-adjustment rate in microseconds.
time_adjusted	Indicates if the systemwide timer has been adjusted. A value of True indicates that the timer has been adjusted by a call to the **adjtime** or **settimer** subroutine. A value of False indicates that it has not. The use of the **ksettimer** kernel service has no effect on this flag. This flag can be changed by the **ksettickd** kernel service.

Description

The **kgettickd** kernel service provides kernel extensions with the capability to determine if the **adjtime** or **settimer** subroutine has adjusted or changed the systemwide timer.

The **kgettickd** kernel service is typically used only by kernel extensions providing time synchronization functions. This includes coordinated network time (which is the periodic synchronization of all system clocks to a common time by a time server or set of time servers on a network), where use of the **adjtime** subroutine is insufficient.

Execution Environment

The **kgettickd** kernel service can be called from either the process or interrupt environment.

Return Values

The **kgettickd** service always returns a value of 0.

Using Fine Granularity Timer Services and Structures

kkey_assign_private Kernel Service

Purpose

Requests a private kernel-key assignment.

Syntax

```
#include <sys/types.h>
#include <sys/skeys.h>
#include <sys/kerrno.h>
```

kerrno_t kkey_assign_private (*id, instance, flags, kkey*)
char **id;*
long *instance;*
unsigned long *flags;*
kkey_t **kkey;*

Parameters

Item	Description
id	Specifies a null-terminated string. The **kkey_assign_private** kernel service uses the string value to assign a private key. This normally contains a load module name associated with the calling kernel subsystem, but you can specify any unique string.
instance	Specifies a unique number for each private key requested by a subsystem. This must be an integer value starting from 0 and increases with each kernel-key requested.
flags	You must specify this parameter to zero.
kkey	Contains the returned assigned kernel key. The valid pointer must be a 4-byte aligned address (**kkey_t**'s natural alignment).

Description

The **kkey_assign_private** kernel service assigns a private kernel key to the caller. Private kernel keys are used to limit data accessibility by external kernel code. The **kkey_assign_private** kernel service distributes requests for private kernel keys among a predetermined range (from KKEY_PRIVATE1 to KKEY_PRIVATE32). The intention is to perform a uniform distribution on behalf of requests by multiple kernel subsystems. The assignment is made based on the *id* and *instance* parameters and might return the same private key to multiple callers. It might also return the same private key when the instance number is different.

The **kkey_assign_private** kernel service does not perform a resource allocation. It only provides a recommended kernel key to use for data protection.

Execution Environment

The **kkey_assign_private** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful completion.
EINVAL_KKEY_ASSIGN_PRIVATE	Indicates that the parameter or execution environment is not valid.

kkeyset_add_key Kernel Service

Purpose

Adds a kernel key to a kernel keyset.

Syntax

```
#include <sys/kerrno.h>
#include <sys/skeys.h>
```

kerrno_t kkeyset_add_key (*set*, *key*, *flags*)
kkeyset_t *set*;
kkey_t *key*;
unsigned long *flags*;

Parameters

Item	Description
set	Specifies the kernel keyset to which the **kkeyset_add_key** kernel service will add a key.
key	Specifies the kernel key to add.
flags	You can specify the *flags* parameter to one of the following values:

> **KA_READ**
> Specifies that the read access for the key is to be added.
>
> **KA_WRITE**
> Specifies that the write access for the key is to be added.
>
> **KA_RW**
> Specifies that both the read access and the write access are to be added. This is equivalent to the value of **KA_READ** | **KA_WRITE**.

Description

The **kkeyset_add_key** kernel service adds a single kernel key specified by the *key* parameter to the kernel keyset specified by the *set* parameter. You must specify the *flags* parameter to control the read or write authority.

Execution Environment

The **kkeyset_add_key** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful completion.
EINVAL_KKEYSET_ADD_KEY	Indicates that the parameter or execution environment is not valid.

kkeyset_add_set Kernel Service

Purpose

Adds members of one kernel keyset to an existing kernel keyset.

Syntax

```
#include <sys/kerrno.h>
#include <sys/skeys.h>
```

```
kerrno_t kkeyset_add_set (set, addset)
kkeyset_t set;
kkeyset_t addset;
```

Parameters

Item	Description
set	Specifies an existing kernel keyset. This set contains the resulting union on completion.
addset	Specifies the kernel keyset to add.

Description

The **kkeyset_add_set** kernel service adds a kernel keyset specified by the *addset* parameter to the kernel keyset specified by the *set* parameter.

Execution Environment

The **kkeyset_add_set** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful completion.
EINVAL_KKEYSET_ADD_SET	Indicates that the parameter or execution environment is not valid.

kkeyset_create Kernel Service

Purpose

Creates and initializes a kernel keyset.

Syntax

```
#include <sys/kerrno.h>
#include <sys/skeys.h>
```

```
kerrno_t kkeyset_create (set)
kkeyset_t *set;
```

Parameters

Item	Description
set	Contains the returned newly-created keyset.

Description

The **kkeyset_create** kernel service creates a new (empty) kernel keyset. You can add or remove the access to an individual or groups of kernel keys using the **kkeyset_add_key**, **kkeyset_remove_key**, **kkeyset_add_set**, and **kkeyset_remove_set** kernel services.

Important: The **kkeyset_create** kernel service allocates hidden kernel resources. You must release these resources using the **kkeyset_delete** kernel service when the kernel keyset is no longer in use. When

creating a new set, the caller of the **kkeyset_create** kernel service must initialize the storage that will contain the returned kernel keyset (**set*) to the value of KKEYSET_INVALID.

Execution Environment

The **kkeyset_create** kernel service can be called from the <u>process</u> environment only.

Return Values

Item	Description
0	Indicates a successful completion.
ENOMEM_KKEYSET_CREATE	Indicates that the available memory is not sufficient to satisfy the request.
EINVAL_KKEYSET_CREATE	Indicates that the parameter or execution environment is not valid.

Related reference
kkeyset_add_key Kernel Service
kkeyset_remove_key Kernel Service
kkeyset_delete Kernel Service

kkeyset_delete Kernel Service

Purpose

Deletes a kernel keyset.

Syntax

```
#include <sys/kerrno.h>
#include <sys/skeys.h>
```

```
kerrno_t kkeyset_delete (set)
kkeyset_t set;
```

Parameters

Item	Description
set	Specifies the keyset to be destroyed.

Description

The **kkeyset_delete** kernel service destroys a kernel keyset. The kernel service releases the hidden resources associated with this keyset.

Execution Environment

The **kkeyset_delete** kernel service can be called from the <u>process</u> environment only.

Return Values

Item	Description
0	Indicates a successful completion.

Item	Description
EINVAL_KKEYSET_DELETE	Indicates that the parameter or execution environment is not valid.

kkeyset_remove_key Kernel Service

Purpose

Removes a kernel key from a kernel keyset.

Syntax

```
#include <sys/kerrno.h>
#include <sys/skeys.h>
```

kerrno_t kkeyset_remove_key (_set_**,** _key_**,** _flags_**)**
kkeyset_t _set_**;**
kkey_t _key_**;**
unsigned long _flags_**;**

Parameters

Item	Description
set	Specifies the kernel keyset from which the **kkeyset_remove_key** kernel service will remove a key.
key	Specifies the kernel key to remove.

flags	You can specify the _flags_ parameter to one of the following values:
	
	KA_READ
	    Specifies that the read access for the key is to be removed.
	
	KA_WRITE
	    Specifies that the write access for the key is to be removed.
	
	KA_RW
	    Specifies that both the read access and the write access are to be removed. This is equivalent to the value of **KA_READ** | **KA_WRITE**.

Description

The **kkeyset_remove_key** kernel service removes a single kernel key specified by the _key_ parameter from the kernel keyset specified by the _set_ parameter. You must specify the _flags_ parameter to control the read or write authority.

Execution Environment

The **kkeyset_remove_key** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful completion.
EINVAL_KKEYSET_REMOVE_KEY	Indicates that the parameter or execution environment is not valid.

kkeyset_remove_set Kernel Service

Purpose

Removes members of one kernel keyset from an existing kernel keyset.

Syntax

```
#include <sys/kerrno.h>
#include <sys/skeys.h>
```

```
kerrno_t kkeyset_remove_set (set, removeset)
kkeyset_t set;
kkeyset_t removeset;
```

Parameters

Item	Description
set	Specifies the kernel keyset from which the **kkeyset_remove_set** kernel service will remove a keyset.
removeset	Specifies the kernel keyset to remove.

Description

The **kkeyset_remove_set** kernel service removes a kernel keyset specified by the *removeset* parameter from the kernel keyset specified by the *set* parameter.

Execution Environment

The **kkeyset_remove_set** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful completion.
EINVAL_KKEYSET_REMOVE_SET	Indicates that the parameter or execution environment is not valid.

kkeyset_to_hkeyset Kernel Service

Purpose

Computes the hardware keyset associated with a kernel keyset.

Syntax

```
#include <sys/kerrno.h>
#include <sys/skeys.h>
```

```
kerrno_t kkeyset_to_hkeyset (kkeyset, hkeyset)
kkeyset_t kkeyset;
hkeyset_t *hkeyset;
```

Parameters

Item	Description
kkeyset	Specifies the input kernel keyset to be mapped.
hkeyset	Specifies the hardware keyset that is mapped to. The valid pointer must be an 8-byte aligned address.

Description

The **kkeyset_to_hkeyset** kernel service maps a kernel keyset to its associated hardware keyset.

Execution Environment

The **kkeyset_to_hkeyset** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful completion.
EINVAL_KKEYSET_TO_HKEYSET	Indicates that the parameter or execution environment is not valid.

klpar_get_info Kernel Service

Purpose

Retrieves the calling partition's characteristics.

Syntax

```
#include  <sys/dr.h>

int klpar_get_info (command, lparinfo, bufsize)
int command;
void *lparinfo;
size_t bufsize;
```

Parameters

Item	Description
command	Specifies whether the user wants **format1**, **format2**, or **processor module** details.
lparinfo	Pointer to the user-allocated buffer that is passed in.
bufsize	Size of the buffer that is passed in.

Description

The **klpar_get_info** kernel service retrieves LPAR and Micro-Partitioning attributes of both low-frequency use and high-frequency use and also retrieves processor module information. Because the low-frequency attributes, as defined in the **lpar_info_format1_t** structure, are static in nature, a reboot is required to effect any change. The high-frequncy attributes, as defined in the **lpar_info_format2_t** structure, can be changed dynamically while the partition is running. The signature of this kernel service, its parameter types, and the order of the member fields in both the **lpar_info_format1_t** and

lpar_info_format2_t structures are specific to the AIX platform. If you requests **processor module** information, the kernel service provides this information as an array of **proc_module_info_t** structures. To obtain this information, the caller must provide a buffer of the exact length to accommodate one **proc_module_info_t** structure for each module type. You can obtain the module count using the **NUM_PROC_MODULE_TYPES** command. The module count is in the form of a **uint64_t** type. Processor module information is reported for the entire system. This information is available on POWER6® and later systems.

To see the complete structures of **lpar_info_format1_t**, **lpar_info_format2_t**, and **proc_module_info_t**, refer to the **dr.h** header file.

Return Values

Upon success, the **klpar_get_info** kernel service returns a value of 0. Upon failure, the **klpar_get_info** kernel service returns an error code.

Error Codes

Item	Description
EINVAL	Invalid input parameter.
ENOSYS	The hardware or the firmware level does not support this operation.
ENOTSUP	The platform does not support this operation.

Related information
lpar_get_info subroutine

kmod_entrypt Kernel Service

Purpose

Returns a function pointer to a kernel module's entry point.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/ldr.h>
```

void (*(kmod_entrypt (*kmid*, *flags***)))( )**
mid_t *kmid*;
uint *flags*;

Parameters

Item	Description
kmid	Specifies the kernel module ID of the object file for which the entry point is requested. This parameter is the kernel module ID returned by the **kmod_load** kernel service.
flags	Flag specifying entry point options. The following flag is defined:

> **0**
>> Returns a function pointer to the specified module's entry point as specified in the module header.

Description

The **kmod_entrypt** kernel service obtains a function pointer to a specified module's entry point. This function pointer is typically used to invoke a routine in the module for initializing or terminating its functions. Initialization and termination occurs after loading and before unloading. The module for which the entry point is requested is specified by the kernel module ID represented by the *kmid* parameter.

Execution Environment

The **kmod_entrypt** kernel service can be called from the process environment only.

Return Values

A nonnull function pointer indicates a successful completion. This function pointer contains the module's entry point. A null function pointer indicates an error.

Related reference
kmod_load Kernel Service
Related information
Kernel Extension and Device Driver Management Kernel Services

kmod_load Kernel Service

Purpose

Loads an object file into the kernel or queries for an object file already loaded.

Syntax

```
#include <sys/ldr.h>
#include <sys/types.h>
#include <sys/errno.h>

int kmod_load (pathp,
flags,libpathp, kmidp)
caddr_t   pathp;
uint   flags;
caddr_t
 libpathp;
mid_t * kmidp;
```

Parameters

Item	Description
pathp	Points to a character string containing the path-name of the object file to load or query.

Item	Description
flags	Specifies a set of loader flags describing which loader options to invoke. The following flags are defined:

LD_USRPATH

The character strings pointed to by the *pathp* and *libpathp* parameters are in user address space. If the **LD_USRPATH** flag is not set, the character strings are assumed to be in kernel, or system, space.

LD_KERNELEX

Puts this object file's exported symbols into the **/usr/lib/boot/unix** name space. Additional object files loaded due to symbol resolution for the specified file do not have their exported symbols placed in kernel name space.

LD_SINGLELOAD

When this flag is set, the object file specified by the *pathp* parameter is loaded into the kernel only if an object file with the same path-name has not already been loaded. If an object file with the same path-name has already been loaded, its module ID is returned (using the *kmidp* parameter) and its load count incremented. If the object file is not yet loaded, this service performs the load as if the flag were not set.

This option is useful in supporting global kernel routines where only one copy of the routine and its data can be present. Typically, routines that export symbols to be added to kernel name space are of this type.

Note: A path-name comparison is done to determine whether the same object file has already been loaded. This service will erroneously load a new copy of the object file into the kernel if the path-name to the object file is expressed differently than it was on a previous load request.

If neither this flag nor the **LD_QUERY** flag is set, this service loads a new copy of the object file into the kernel. This occurs even if other copies of the object file have previously been loaded.

LD_QUERY

This flag specifies that a query operation will determine if the object file specified by the *pathp* parameter is loaded. If not loaded, a kernel module ID of 0 is returned using the *kmidp* parameter. Otherwise, the kernel module ID assigned to the object file is returned.

If multiple instances of this file have been loaded into the kernel, the kernel module ID of the most recently loaded object file is returned.

The *libpathp* parameter is not used for this option.

Note: A path-name comparison is done to determine whether the same object file has been loaded. This service will erroneously return a `not loaded` condition if the path-name to the object file is expressed differently than it was on a previous load request.

If this flag is set, no object file is loaded and the **LD_SINGLELOAD** and **LD_KERNELEX** flags are ignored, if set.

Item	Description
libpathp	Points to a character string containing the search path to use for finding object files required to complete symbol resolution for this load. If the parameter is null, the search path is set from the specification in the object file header for the object file specified by the *pathp* parameter.
kmidp	Points to an area where the kernel module ID associated with this load of the specified module is to be returned. The data in this area is not valid if the **kmod_load** service returns a nonzero return code.

Description

The **kmod_load** kernel service loads into the kernel a kernel extension object file specified by the *pathp* parameter. This service returns a kernel module ID for that instance of the module.

You can specify flags to request a single load, which ensures that only one copy of the object file is loaded into the kernel. An additional option is simply to query for a given object file (specified by path-name). This allows the user to determine if a module is already loaded and then access its assigned kernel module ID.

The **kmod_load** service also provides load-time symbol resolution of the loaded module's imported symbols. The **kmod_load** service loads additional kernel object modules if required for symbol resolution.

Loader Symbol Binding Support

Symbols imported from the kernel name space are resolved with symbols that exist in the kernel name space at the time of the load. (Symbols are imported from the kernel name space by specifying the **#!/unix** character string as the first field in an import list at link-edit time.)

Kernel modules can also import symbols from other kernel object modules. These other kernel object modules are loaded along with the specified object module if they are needed to resolve the imported symbols.

Any symbols exported by the specified kernel object module are added to the kernel name space if the *flags* parameter has the **LD_KERNELEX** flag set. This makes the symbols available to other subsequently loaded kernel object modules. Kernel object modules loaded on behalf of the specified kernel object module (to resolve imported symbols) do not have their exported symbols added to the kernel name space.

Kernel export symbols specified (at link-edit time) with the **SYSCALL** keyword in the primary module's export list are added to the system call table. These kernel export symbols are available to application programs as system calls.

Finding Shared Object Modules for Resolving Symbol References

The search path search string is taken from the module header of the object module specified by the *pathp* parameter if the *libpathp* parameter is null. The module header of the object module specified by the *pathp* parameter is used.

If the module header contains an unqualified base file name for the symbol (no / [slash] characters in the name), a search string is used to find the location of the shared object module required to resolve the import. This search string can be taken from one of two places. If the *libpathp* parameter on the call to the **kmod_load** service is not null, then it points to a character string specifying the search path to be used. However, if the *libpathp* parameter is null, then the search path is to be taken from the module header for the object module specified by the *pathp* parameter.

The search path specification found in object modules loaded to resolve imported symbols is not used. The kernel loader service does not support deferred symbol resolution. The load of the kernel module is terminated with an error if any imported symbols cannot be resolved.

Execution Environment

The **kmod_load** kernel service can be called from the process environment only.

Return Values

If the object file is loaded without error, the module ID is returned in the location pointed to by the *kmidp* parameter and the return code is set to 0.

Error Codes

If an error results, the module is not loaded, and no kernel module ID is returned. The return code is set to one of the following return values:

Return Value	Description
EACCES	Indicates that an object module to be loaded is not an ordinary file or that the mode of the object module file denies read-only access.
EACCES	Search permission is denied on a component of the path prefix.
EFAULT	Indicates that the calling process does not have sufficient authority to access the data area described by the *pathp* or *libpathp* parameters when the **LD_USRPATH** flag is set. This error code is also returned if an I/O error occurs when accessing data in this area.
ENOEXEC	Indicates that the program file has the appropriate access permission, but has an XCOFF indicator that is not valid in its header. The **kmod_load** kernel service supports loading of XCOFF (Extended Common Object File Format) object files only. This error code is also returned if the loader is unable to resolve an imported symbol.
EINVAL	Indicates that the program file has a valid XCOFF indicator in its header, but the header is either damaged or incorrect for the machine on which the file is to be loaded.
ENOMEM	Indicates that the load requires more kernel memory than allowed by the system-imposed maximum.
ETXTBSY	Indicates that the object file is currently open for writing by some process.
ENOTDIR	Indicates that a component of the path prefix is not a directory.
ENOENT	Indicates that no such file or directory exists or the path-name is null.
ESTALE	Indicates that the caller's root or current directory is located in a virtual file system that has been unmounted.
ELOOP	Indicates that too many symbolic links were encountered in translating the *path* or *libpathp* parameter.
ENAMETOOLONG	Indicates that a component of a path-name exceeded 255 characters, or an entire path-name exceeded 1023 characters.
EIO	Indicates that an I/O error occurred during the operation.

Related reference
kmod_unload Kernel Service
Related information
kmod_util subroutine
Kernel Extension and Device Driver Management Kernel Services

kmod_unload Kernel Service

Purpose

Unloads a kernel object file.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/ldr.h>
```

int kmod_unload (*kmid*
, *flags***)**
mid_t *kmid***;**
uint *flags***;**

Parameters

Item	Description
kmid	Specifies the kernel module ID of the object file to be unloaded. This kernel module ID is returned when using the **kmod_load** kernel service.
flags	Flags specifying unload options. The following flag is defined:

0

Unloads the object module specified by its *kmid* parameter and any object modules that were loaded as a result of loading the specified object file if this file is not still in use.

Description

The **kmod_unload** kernel service unloads a previously loaded kernel extension object file. The object to be unloaded is specified by the *kmid* parameter. Upon successful completion, the following objects are unloaded or marked *unload pending*:

- The specified object file
- Any imported kernel object modules that were loaded as a result of the loading of the specified module

Users of these exports or system calls are modules bound to this module's exported symbols. If there are no users of any of the module's kernel exports or system calls, the module is immediately unloaded. If there are users of this module, the module is not unloaded but marked *unload pending*.

Marking a module *unload pending* removes the module's exported symbols from the kernel name space. Any system calls exported by this module are also removed. This prohibits new users of these symbols. The module is unloaded only when all current users have been unloaded.

If the unload is successfully completed or marked *pending*, a value of 0 is returned. When an error occurs, the specified module and any imported modules are not unloaded. A nonzero return value indicates the error.

Execution Environment

The **kmod_unload** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
EINVAL	Indicates that the *kmid* parameter, which specifies the kernel module, is not valid or does not correspond to a currently loaded module.
EBUSY	The *kmid* parameter specifies a kernel extension that is still intercepting system calls.

Related reference
kmod_load Kernel Service
Related information
kmod_util subroutine
Kernel Extension and Device Driver Management Kernel Services

kmod_util Kernel Service

Purpose

Registers routines to be called before and after specified system calls are invoked.

Syntax

```
#include <sys/sysconfig.h>
```

```
int kmod_util ( flags, buffer, blen)
int flags;
void * buffer;
long blen;
```

Parameters

Item	Description
flags	Specifies the operation. Valid values are **KU_INTERCEPT**, **KU_INTERCEPT_STOP**, and **KU_INTERCEPT_CANCEL**.
buffer	Points to a buffer containing a system call interception header and an array of system call interception structures.
blen	Specifies the length of the buffer.

Description

The **kmod_util** kernel service allows system calls to be intercepted. Routines called **pre-sc** functions are specified to be called before the intercepted system call. Routines called **post-sc** functions are specified to be called after the intercepted system call. In addition, a **pre-sc** function is allowed to abort the system call, providing its own return value and preventing subsequent **pre-sc** functions and the system call itself from being called. Similarly, each **post-sc** function may examine and alter the return value. If a system call does not return (e.g., **thread_terminate**), **post-sc** functions are not called.

For each intercepted system call, either a **pre-sc** function, a **post-sc** function, or both, must be specified. If a **pre-sc** function and **post-sc** function are registered for the same system call in the same **kmod_util** invocation, they are considered paired. All **pre-sc** and **post-sc** functions specified in a **kmod_util** call must be defined in the same kernel extension as the caller of the **kmod_util** kernel service. Other kernel extensions, however, can intercept the same system calls. The most recently registered **pre-sc** function is called first, and its paired **post-sc** function is called last.

The interception of a system call is implemented so that all calls to the system call are intercepted, even for existing processes.

It may be necessary to prevent the interception of certain system calls to avoid destabilizing the system. A future version or release of the **kmod_util** kernel service may prevent the interception of additional system calls, and such a change will not be considered a violation of binary compatibility.

The prototype of a **pre-sc** function is

```
int pre_sc(uintptr_t *rc, void *parms, uintptr_t cookie, void *buffer);
```

where *parms* is a pointer to the parameters of the system call, *cookie* is an opaque value specified by the caller of **kmod_util**, *buffer* is a scratch 128-byte buffer for use by the **pre-sc** function and its paired **post-sc** function.

If the **pre-sc** function returns non-zero, the system call is aborted. The *rc* parameter is the address where an alternate return value can be specified. Subsequent **pre_sc** functions are not called, nor is the system call. For **pre-sc** functions already called, their paired **post-sc** functions are called.

The prototype of a post-sc function is

```
void post_sc(uintptr_t *rc, void *parms, uintptr_t cookie,
          void *buffer);
```

The parameters of the **post-sc** function are the same as those of the **pre-sc** function. In particular, the *buffer* parameter is the same buffer that was passed to the paired **pre-sc** function. The return value can be modified by a **post-sc** function.

For calls to the **kmod_util** kernel service, the buffer contains a header and an array of elements about system calls to be intercepted. The layout of these structures is defined in **<sys/sysconfig.h>**.

An array element is ignored if the **KU_IGNORE** flag is set in the **kue_iflag** field. Otherwise, each array element in the input buffer is validated, and if any errors are found, the entire call fails without any partial execution.

Intercepting System Calls
> Calls to **kmod_util()** with the **KU_INTERCEPT** flag initiate system call interception.

Stopping System Call Interception

> Calls to **kmod_util()** with the **KU_INTERCEPT_STOP** flag suspend the interception of the specified system calls. If a **pre-sc** function has already been called for a specified system call, its paired **post-sc** function will still be called, but future calls to the system call will not invoke either the **pre-sc** or **post-sc** function. It is not valid to stop interception of a system call that was not originally intercepted by the calling kernel extension.

> If the interception of a system call has been suspended, it may be resumed by calling the **kmod_util()** function with the **KU_INTERCEPT** flag, as long as the same values are specified, such as the **pre-sc** and **post-sc** functions.

Cancelling System Call Interception

> System call interception can be cancelled by specifying the KU_INTERCEPT_CANCEL flag. When interception is cancelled, the **post-sc** function is not called even if its paired **pre-sc** function was called. It is not valid to cancel interception of a system call that was not originally intercepted by the calling kernel extension, but interception can be cancelled without first stopping interception.

> Once interception of a system call has been cancelled, it can be intercepted anew by calling the **kmod_util()** function with the **KU_INTERCEPT** flag. Different **pre-sc** and **pre-sc** functions can be specified in this case.

Return Values

If the specified operations can be enacted for all specified system calls, 0 is returned. Otherwise, a non-zero value is returned and no change in the state of system call interception occurs. If an error occurs because of a validation error in a particular array element, the **kue_oflags** field usually identifies the error in more detail.

Error Codes

If an error results, one of the following error values is returned:

Return Value	Description
EINVAL	The flags parameter is not **KU_INTERCEPT, KU_INTERCEPT_STOP**, nor **KU_INTERCEPT_CANCEL**.
	The fields in the header are invalid or the *blen* parameter is not consistent with the number of array elements.
	The buffer was invalid. For **KU_INTERCEPT**, at least one of the **pre-sc** and **post-sc** must be supplied for each system call to be intercepted. All **pre-sc** and **post-sc** functions must be in the same kernel extension as the caller of **kmod_util()**.

Return Value	Description
EBUSY	A request was made to intercept a system call that was already being intercepted.
ENOENT	A request was made to stop or cancel interception of a system call that was not being intercepted.
ENOMEM	Memory could not be allocated to satisfy the request.
ENOTSUPP	One of the specified system calls is not allowed to be intercepted.

Kernel Extension and Device Driver Management Kernel Services

kmsgctl Kernel Service

Purpose

Provides message-queue control operations.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/ipc.h>
#include <sys/msg.h>
```

int kmsgctl (*msqid*, *cmd*, *buf*)
int *msqid*, *cmd*;
struct msqid_ds **buf*;

Parameters

Item	Description
msqid	Specifies the message queue ID, which indicates the message queue for which the control operation is being requested for.
cmd	Specifies which control operation is being requested. There are three valid commands.
buf	Points to the **msqid_ds** structure provided by the caller of the **kmsgctl** service. Data is obtained either from this structure or from status returned in this structure, depending on the *cmd* parameter. The **msqid_ds** structure is defined in the **/usr/include/sys/msg.h** file.

Description

The **kmsgctl** kernel service provides a variety of message-queue control operations as specified by the *cmd* parameter. The **kmsgctl** kernel service provides the same functions for user-mode processes in kernel mode as the **msgctl** subroutine performs for kernel processes or user-mode processes in user mode. The **kmsgctl** service can be called by a user-mode process in kernel mode or by a kernel process. A kernel process can also call the **msgctl** subroutine to provide the same function.

The following three commands can be specified with the *cmd* parameter:

Item	Description
IPC_STAT	Sets only documented fields. See the **msgctl** subroutine.
IPC_SET	Sets the value of the following fields of the data structure associated with the *msqid* parameter to the corresponding values found in the structure pointed to by the *buf* parameter:

- `msg_perm.uid`
- `msg_perm.gid`
- `msg_perm.mode` (only the low-order 9 bits)
- `msg_qbytes`

To perform the **IPC_SET** operation, the current process must have an effective user ID equal to the value of the `msg_perm.uid` or `msg_perm.cuid` field in the data structure associated with the *msqid* parameter. To raise the value of the `msg_qbytes` field, the calling process must have the appropriate system privilege.

Item	Description
IPC_RMID	Removes from the system the message-queue identifier specified by the *msqid* parameter. This operation also destroys both the message queue and the data structure associated with it. To perform this operation, the current process must have an effective user ID equal to the value of the `msg_perm.uid` or `msg_perm.cuid` field in the data structure associated with the *msqid* parameter.

Execution Environment

The **kmsgctl** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
EINVAL	Indicates either

- The identifier specified by the *msqid* parameter is not a valid message queue identifier.
- The command specified by the *cmd* parameter is not a valid command.

Item	Description
EACCES	The command specified by the *cmd* parameter is equal to **IPC_STAT** and read permission is denied to the calling process.
EPERM	The command specified by the *cmd* parameter is equal to **IPC_RMID**, **IPC_SET**, and the effective user ID of the calling process is not equal to that of the value of the `msg_perm.uid` field in the data structure associated with the *msqid* parameter.
EPERM	Indicates the following conditions:

- The command specified by the *cmd* parameter is equal to **IPC_SET**.
- An attempt is being made to increase to the value of the `msg_qbytes` field, but the calling process does not have the appropriate system privilege.

Related information

msgctl subroutine
Message Queue Kernel Services
Understanding System Call Execution

kmsgget Kernel Service

Purpose

Obtains a message queue identifier.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/stat.h>
#include <sys/ipc.h>
#include <sys/msg.h>
```

int kmsgget (*key,* *msgflg,* *msqid***)**
key_t *key;*
int *msgflg;*
int **msqid;*

Parameters

Item	Description
key	Specifies either a value of **IPC_PRIVATE** or an IPC key constructed by the **ftok** subroutine (or a similar algorithm).
msgflg	Specifies that the *msgflg* parameter is constructed by logically ORing one or more of these values:

IPC_CREAT
Creates the data structure if it does not already exist.

IPC_EXCL
Causes the **kmsgget** kernel service to fail if **IPC_CREAT** is also set and the data structure already exists.

S_IRUSR
Permits the process that owns the data structure to read it.

S_IWUSR
Permits the process that owns the data structure to modify it.

S_IRGRP
Permits the process group associated with the data structure to read it.

S_IWGRP
Permits the process group associated with the data structure to modify it.

S_IROTH
Permits others to read the data structure.

S_IWOTH
Permits others to modify the data structure.

The values that begin with **S_I**... are defined in the **/usr/include/sys/stat.h** file. They are a subset of the access permissions that apply to files.

Item	Description
msqid	A reference parameter where a valid message-queue ID is returned if the **kmsgget** kernel service is successful.

Description

The **kmsgget** kernel service returns the message-queue identifier specified by the *msqid* parameter associated with the specified *key* parameter value. The **kmsgget** kernel service provides the same functions for user-mode processes in <u>kernel mode</u> as the **msgget** subroutine performs for kernel processes or user-mode processes in <u>user mode</u>. The **kmsgget** service can be called by a user-mode

process in kernel mode or by a kernel process. A kernel process can also call the **msgget** subroutine to provide the same function.

Execution Environment

The **kmsgget** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion. The *msqid* parameter is set to a valid message-queue identifier.

If the **kmsgget** kernel service fails, the *msqid* parameter is not valid and the return code is one of these four values:

Item	Description
EACCES	Indicates that a message queue ID exists for the *key* parameter but operation permission as specified by the *msgflg* parameter cannot be granted.
ENOENT	Indicates that a message queue ID does not exist for the *key* parameter and the **IPC_CREAT** command is not set.
ENOSPC	Indicates that a message queue ID is to be created but the system-imposed limit on the maximum number of allowed message queue IDs systemwide will be exceeded.
EEXIST	Indicates that a message queue ID exists for the value specified by the *key* parameter, and both the **IPC_CREAT** and **IPC_EXCL** commands are set.

Related information

msgget subroutine
Message Queue Kernel Services
Understanding System Call Execution

kmsgrcv Kernel Service

Purpose

Reads a message from a message queue.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/ipc.h>
#include <sys/msg.h>
```

int kmsgrcv
(*msqid, msgp, msgsz,*
msgtyp, msgflg, flags, bytes)
int *msqid*;
struct msgxbuf * *msgp*;
    or **struct msgbuf ****msgp*;
int *msgsz*;
mtyp_t *msgtyp*;
int *msgflg*;

```
int     flags;
ssize_t * bytes;
```

Parameters

Item	Description
msqid	Specifies the message queue from which to read.
msgp	Points to either an **msgxbuf** or an **msgbuf** structure where the message text is placed. The type of structure pointed to is determined by the values of the *flags* parameter. These structures are defined in the **/usr/include/sys/msg.h** file.
msgsz	Specifies the maximum number of bytes of text to be received from the message queue. The received message is truncated to the size specified by the *msgsz* parameter if the message is longer than this size and **MSG_NOERROR** is set in the *msgflg* parameter. The truncated part of the message is lost and no indication of the truncation is given to the calling process.
msgtyp	Specifies the type of message requested as follows: - If the *msgtyp* parameter is equal to 0, the first message on the queue is received. - If the *msgtyp* parameter is greater than 0, the first message of the type specified by the *msgtyp* parameter is received. - If the *msgtyp* parameter is less than 0, the first message of the lowest type that is less than or equal to the absolute value of the *msgtyp* parameter is received.
msgflg	Specifies a value of 0, or is constructed by logically ORing one of several values: **MSG_NOERROR** Truncates the message if it is longer than the number of bytes specified by the *msgsz* parameter. **IPC_NOWAIT** Specifies the action to take if a message of the desired type is not on the queue: - If **IPC_NOWAIT** is set, then the **kmsgrcv** service returns an **ENOMSG** value. - If **IPC_NOWAIT** is not set, then the calling process suspends execution until one of the following occurs: - A message of the desired type is placed on the queue. - The message queue ID specified by the *msqid* parameter is removed from the system. When this occurs, the **kmsgrcv** service returns an **EIDRM** value. - The calling process receives a signal that is to be caught. In this case, a message is not received and the **kmsgrcv** service returns an **EINTR** value.
flags	Specifies a value of 0 if a normal message receive is to be performed. If an extended message receive is to be performed, this flag should be set to an **XMSG** value. With this flag set, the **kmsgrcv** service functions as the **msgxrcv** subroutine would. Otherwise, the **kmsgrcv** service functions as the **msgrcv** subroutine would.
bytes	Specifies a reference parameter. This parameter contains the number of message-text bytes read from the message queue upon return from the **kmsgrcv** service. If the message is longer than the number of bytes specified by the *msgsz* parameter bytes but **MSG_NOERROR** is not set, then the **kmsgrcv** kernel service fails and returns an **E2BIG** return value.

Description

The **kmsgrcv** kernel service reads a message from the queue specified by the *msqid* parameter and stores the message into the structure pointed to by the *msgp* parameter. The **kmsgrcv** kernel service

provides the same functions for user-mode processes in kernel mode as the **msgrcv** and **msgxrcv** subroutines perform for kernel processes or user-mode processes in user mode.

The **kmsgrcv** service can be called by a user-mode process in kernel mode or by a kernel process. A kernel process can also call the **msgrcv** and **msgxrcv** subroutines to provide the same functions.

Execution Environment

The **kmsgrcv** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
EINVAL	Indicates that the ID specified by the *msqid* parameter is not a valid message queue ID.
EACCES	Indicates that operation permission is denied to the calling process.
EINVAL	Indicates that the value of the *msgsz* parameter is less than 0.
E2BIG	Indicates that the message text is greater than the maximum length specified by the *msgsz* parameter and **MSG_NOERROR** is not set.
ENOMSG	Indicates that the queue does not contain a message of the desired type and **IPC_NOWAIT** is set.
EINTR	Indicates that the **kmsgrcv** service received a signal.
EIDRM	Indicates that the message queue ID specified by the *msqid* parameter has been removed from the system.

Related information

msgrcv subroutine

msgxrcv subroutine

Message Queue Kernel Services

kmsgsnd Kernel Service

Purpose

Sends a message using a previously defined message queue.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/ipc.h>
#include <sys/msg.h>
```

int kmsgsnd (*msqid, msgp, msgsz, msgflg*)
int *msqid*;
struct msgbuf * *msgp*;
int *msgsz, msgflg*;

Parameters

Item	Description
msqid	Specifies the message queue ID that indicates which message queue the message is to be sent on.
msgp	Points to an **msgbuf** structure containing the message. The **msgbuf** structure is defined in the **/usr/include/sys/msg.h** file.
msgsz	Specifies the size of the message to be sent in bytes. The *msgsz* parameter can range from 0 to a system-imposed maximum.
msgflg	Specifies the action to be taken if the message cannot be sent for one of several reasons.

Description

The **kmsgsnd** kernel service sends a message to the queue specified by the *msqid* parameter. The **kmsgsnd** kernel service provides the same functions for user-mode processes in kernel mode as the **msgsnd** subroutine performs for kernel processes or user-mode processes in user mode. The **kmsgsnd** service can be called by a user-mode process in kernel mode or by a kernel process. A kernel process can also call the **msgsnd** subroutine to provide the same function.

There are two reasons why the **kmsgsnd** kernel service cannot send the message:

- The number of bytes already on the queue is equal to the **msg_qbytes** member.
- The total number of messages on all queues systemwide is equal to a system-imposed limit.

There are several actions to take when the **kmsgsnd** kernel service cannot send the message:

- If the *msgflg* parameter is set to **IPC_NOWAIT**, then the message is not sent, and the **kmsgsnd** service fails and returns an **EAGAIN** value.
- If the *msgflg* parameter is 0, then the calling process suspends execution until one of the following occurs:
  - The condition responsible for the suspension no longer exists, in which case the message is sent.
  - The message queue ID specified by the *msqid* parameter is removed from the system. When this occurs, the **kmsgsnd** service fails and an **EIDRM** value is returned.
  - The calling process receives a signal that is to be caught. In this case, the message is not sent and the calling process resumes execution as described in the **sigaction** kernel service.

Execution Environment

The **kmsgsnd** kernel service can be called from the process environment only.

The calling process must have write permission to perform the **kmsgsnd** operation.

Return Values

Item	Description
0	Indicates a successful operation.
EINVAL	Indicates that the *msqid* parameter is not a valid message queue ID.
EACCES	Indicates that operation permission is denied to the calling process.
EAGAIN	Indicates that the message cannot be sent for one of the reasons stated previously, and the *msgflg* parameter is set to **IPC_NOWAIT**.
EINVAL	Indicates that the *msgsz* parameter is less than 0 or greater than the system-imposed limit.
EINTR	Indicates that the **kmsgsnd** service received a signal.

Item	Description
EIDRM	Indicates that the message queue ID specified by the *msqid* parameter has been removed from the system.
ENOME M	Indicates that the system does not have enough memory to send the message.

Related information

msgsnd subroutine

Message Queue Kernel Services

Understanding System Call Execution

kra_attachrset Subroutine

Purpose

Attaches a work component to a resource set.

Syntax

```
#include <sys/rset.h>
int kra_attachrset (rstype, rsid, rset, flags)
rstype_t rstype;
rsid_t rsid;
rsethandle_t rset;
unsigned int flags;
```

Description

The **kra_attachrset** subroutine attaches a work component specified by the *rstype* and *rsid* parameters to a resource set specified by the *rset* parameter.

The work component is an existing process identified by the process ID or an existing kernel thread identified by the kernel thread ID (tid). A process ID or thread ID value of RS_MYSELF indicates the attachment applies to the current process or the current kernel thread, respectively.

The following conditions must be met to successfully attach a process to a resource set:

- The resource set must contain processors that are available in the system.
- The calling process must either have root authority or have CAP_NUMA_ATTACH capability.
- The calling process must either have root authority or the same effective userid as the target process.
- The target process must not contain any threads that have bindprocessor bindings to a processor.
- The resource set must be contained in (be a subset of) the target process' partition resource set.
- The resource set must be a superset of all the thread's *rset* in the target process.

The following conditions must be met to successfully attach a kernel thread to a resource set:

- The resource set must contain processors that are available in the system.
- The calling process must either have root authority or have CAP_NUMA_ATTACH capability.
- The calling process must either have root authority or the same effective userid as the target process.
- The target thread must not have bindprocessor bindings to a processor.
- The resource set must be contained in (be a subset of) the target thread's process effective and partition resource set.

If any of these conditions are not met, the attachment will fail.

Once a process is attached to a resource set, the threads in the process will only run on processors contained in the resource set. Once a kernel thread is attached to a resource set, that thread will only run on processors contained in the resource set.

The *flags* parameter can be set to indicate the policy for using the resources contained in the resource set specified in the *rset* parameter. The only supported scheduling policy is R_ATTACH_STRSET, which is useful only when the processors of the system are running in simultaneous multithreading mode. Processors like the POWER5 support simultaneous multithreading, where each physical processor has two execution engines, called *hardware threads*. Each hardware thread is essentially equivalent to a single CPU, and each is identified as a separate CPU in a resource set. The R_ATTACH_STRSET flag indicates that the process is to be scheduled with a single-threaded policy; namely, that it should be scheduled on only one hardware thread per physical processor. If this flag is specified, then all of the available processors indicated in the resource set must be of exclusive use. A new resource set, called an *ST resource set,* is constructed from the specified resource set and attached to the process according to the following rules:

- All offline processors are ignored.
- If all the hardware threads (CPUs) of a physical processor (when running in simultaneous multithreading mode, there will be more than one active hardware thread per physical processor) are not included in the specified resource set, the other CPUs of the processor are ignored when constructing the ST resource set.
- Only one CPU (hardware thread) resource per physical processor is included in the ST resource set.

Parameters

Item	Description
rstype	Specifies the type of work component to be attached to the resource set specified by the *rset* parameter. The *rstype* parameter must be the following value, defined in **rset.h**: • R_PROCESS: existing process • R_THREAD: existing kernel thread
rsid	Identifies the work component to be attached to the resource set specified by the *rset* parameter. The *rsid* parameter must be the following: • Process ID (for *rstype* of R_PROCESS): set the *rsid_t at_pid* field to the desired process' process ID. • Kernel thread ID (for *rstype* of R_THREAD): set the *rsid_t at_tid* field to the desired kernel thread's thread ID.
rset	Specifies which work component (specified by the *rstype* and *rsid* parameters) to attach to the resource set.
flags	Specifies the scheduling policy for the work component being attached. The only supported value is R_ATTACH_STRSET value, which is only applicable if the *rstype* parameter is set to R_PROCESS. The R_ATTACH_STRSET value indicates that the process is to be scheduled with a single-threaded policy (only on one hardware thread per physical processor).

Return Values

Upon successful completion, the **kra_attachrset** subroutine returns a 0. If unsuccessful, one or more of the following are true:

Item	Description
EINVAL	One of the following is true:

- The *flags* parameter contains an invalid value.
- The *rstype* parameter contains an invalid type qualifier.
- The R_ATTACH_STRSET *flags* parameter is specified and one or more processors in the *rset* parameter are not assigned for exclusive use.

ENODEV	The resource set specified by the *rset* parameter does not contain any available processors, or the R_ATTACH_STRSET *flags* parameter is specified and the constructed ST resource set does not have any available processors.
ESRCH	The process or kernel thread identified by the *rstype* and *rsid* parameters does not exist.
EPERM	One of the following is true:

- If the *rstype* is R_PROCESS, either the resource set specified by the *rset* parameter is not included in the partition resource set of the process identified by the *rstype* and *rsid* parameters, or any of the thread's R_THREAD *rset* in this process is not a subset of the resource set specified by the *rset* parameter.
- If the *rstype* is R_THREAD, the resource set specified by the *rset* parameter is not included in the target thread's process effective or partition (real) resource set.
- The calling process has neither root authority nor CAP_NUMA_ATTACH attachment privilege.
- The calling process has neither root authority nor the same effective user ID as the process identified by the *rstype* and *rsid* parameters.
- The process or thread identified by the *rstype* and *rsid* parameters has one or more threads with a bindprocessor processor binding.

Exclusive use processor resource sets

kra_creatp Kernel Service

Purpose

Creates a new kernel process and attaches the new kernel process to a resource set.

Syntax

```
#include <sys/rset.h>
int kra_creatp (pid, rstype, rsid, flags)
pid_t *pid;
rstype_t rstype;
rsid_t rsid;
unsigned int flags;
```

Description

The **kra_creatp** kernel service creates a new kernel process and attaches the new kernel process to a resource set specified by the *rstype* and *rsid* parameters.

The **kra_creatp** kernel service can be used similar to the **creatp** kernel service for creating a new kernel process.

To successfully attach a kernel process to a resource set, the following conditions must be met:

- The resource set must contain processors that are available in the system.
- The calling process must either have the root authority or have **CAP_NUMA_ATTACH** capability.
- The calling thread must not have a bindprocessor binding to a processor.
- The resource set must be contained in the partition resource set of the calling process.

Note: When the **kra_creatp** kernel service is used, the new kernel process inherits resource set attachments of the parent kernel process, unless a value is specified for the **R_NOINHERIT** flag.

Parameters

Item	Description
pid	Pointer to a **pid_t** field to receive the process ID of the new kernel process.
rstype	Specifies the resource set type to which the new kernel process will be attached. As defined in the `rset.h` file, this parameter must be set to the following value: R_RSET: resource set.
rsid	Identifies the resource set to which the new kernel process will be attached. This *rsid* parameter accepts the following value: Resource set ID (for the *rstype* parameter value of R_RSET): set the *rsid_t at_rset* field to the resource set that you want.
flags	Specifies how to create the new kernel process. The *flags* parameter accepts the following value: R_NOINHERIT (or specify as 0): The new kernel process does not inherit the resource set attachments of the parent kernel process.

Return Values

Upon successful completion, the **kra_creatp** kernel service returns a value of zero (0). If unsuccessful, the **kra_creatp** kernel service returns one of the following errors:

Item	Description
EINVAL	Indicates one of the following conditions: - The *rstype* parameter contains an invalid type identifier. - The *flags* parameter contains an invalid flag value.
ENODEV	The specified resource set does not contain any available processors.
EFAULT	Invalid address.
EPERM	Indicates one of the following conditions: - The calling process has neither the root authority nor the **CAP_NUMA_ATTACH** attachment privilege. - The calling process contains one or more threads with a bindprocessor binding to the processor. - The specified resource set is not included in the partition resource set of the calling process.
ENOMEM	There is not enough memory available to create a new kernel process.

Related reference
creatp Kernel Service
initp Kernel Service

kra_detachrset Subroutine

Purpose

Detaches a work component from a resource set.

Syntax

```
#include <sys/rset.h>
int kra_detachrset (rstype, rsid, flags)
rstype_t rstype;
rsid_t rsid;
unsigned int flags;
```

Description

The **kra_detachrset** subroutine detaches a work component specified by *rstype* and *rsid* from a resource set.

The work component is an existing process identified by the process ID or an existing kernel thread identified by the kernel thread ID (tid). A process ID or thread ID value of RS_MYSELF indicates the detach command applies to the current process or the current kernel thread, respectively.

The following conditions must be met to detach a process or kernel thread from a resource set:

- The calling process must either have root authority or have CAP_NUMA_ATTACH capability.
- The calling process must either have root authority or the same effective userid as the target process.

If these conditions are not met, the operation will fail.

Once a process is detached from a resource set, the threads in the process can run on all available processors contained in the process' partition resource set. Once a kernel thread is detached from a resource set, that thread can run on all available processors contained in its process effective or partition resource set.

Parameters

Item	Description
rstype	Specifies the type of work component to be detached from to the resource set specified by *rset*. This parameter must be the following value, defined in **rset.h**: • R_PROCESS: existing process • R_THREAD: existing kernel thread
rsid	Identifies the work component to be attached to the resource set specified by *rset*. This parameter must be the following: • Process ID (for *rstype* of R_PROCESS): set the *rsid_t at_pid* field to the desired process' process ID. • Kernel thread ID (for *rstype* of R_THREAD): set the *rsid_t at_tid* field to the desired kernel thread's thread ID.
flags	For *rstype* of R_PROCESS, the R_DETACH_ALLTHRDS indicates that R_THREAD *rsets* are detached from all threads in a specified process. The process' effective *rset* is not detached in this case. Reserved for future use. Specify as 0.

Return Values

Upon successful completion, the **kra_detachrset** subroutine returns a 0. If unsuccessful, one or more of the following are true:

Item	Description
EINVAL	One of the following is true:

- The *flags* parameter contains an invalid value.
- The *rstype* contains an invalid type qualifier.

Item	Description
ESRCH	The process or kernel thread identified by the *rstype* and *rsid* parameters does not exist.
EPERM	One of the following is true:

- The calling process has neither root authority nor CAP_NUMA_ATTACH attachment privilege.
- The calling process has neither root authority nor the same effective user ID as the process identified by the *rstype* and *rsid* parameters.

kra_getrset Subroutine

Purpose

Gets the resource set to which a work component is attached.

Syntax

```
#include <sys/rset.h>
int kra_getrset (rstype, rsid, flags, rset, rset_type)
rstype_t rstype;
rsid_t rsid;
unsigned int flags;
rsethandle_t rset;
unsigned int *rset_type;
```

Description

The **kra_getrset** subroutine returns the resource set to which a specified work component is attached.

The work component is an existing process identified by the process ID or an existing kernel thread identified by the kernel thread ID (tid). A process ID or thread ID value of RS_MYSELF indicates the resource set attached to the current process or the current kernel thread, respectively, is requested.

Upon successful completion, one of the following types of resource set is returned into the *rset_type* parameter:

- A value of RS_EFFECTIVE_RSET indicates the process was explicitly attached to the resource set. This may have been done with the **kra_attachrset** subroutine.
- A value of RS_PARTITION_RSET indicates the process was not explicitly attached to a resource set. However, the process had an explicitly set partition resource set. This may be set with the **krs_setpartition** subroutine or through the use of WLM work classes with resource sets.
- A value of RS_DEFAULT_RSET indicates the process was not explicitly attached to a resource set nor did it have an explicitly set partition resource set. The system default resource set is returned.
- A value of RS_THREAD_RSET indicates the kernel thread was explicitly attached to the resource set. This might have been done with the `ra_attachrset` subroutine.

Parameters

Item	Description
rstype	Specifies the type of the work component whose resource set attachment is requested. This parameter must be the following value, defined in **rset.h**: • R_PROCESS: existing process • R_THREAD: existing kernel thread
rsid	Identifies the work component whose resource set attachment is requested. This parameter must be the following: • Process ID (for *rstype* of R_PROCESS): set the *rsid_t at_pid* field to the desired process' process ID. • Kernel thread ID (for *rstype* of R_THREAD): set the *rsid_t at_tid* field to the desired kernel thread's thread ID.
flags	Reserved for future use. Specify as 0.
rset	Specifies the resource set to receive the work component's resource set.
rset_type	Points to an unsigned integer field to receive the resource set type.

Return Values

Upon successful completion, the **kra_getrset** subroutine returns a 0. If unsuccessful, one or more of the following are true:

Item	Description
EINVAL	One of the following is true: • The *flags* parameter contains an invalid value. • The *rstype* parameter contains an invalid type qualifier.
EFAULT	Invalid address.
ESRCH	The process or kernel thread identified by the *rstype* and *rsid* parameters does not exist.

kra_thread_create Kernel Service

Purpose

Creates a new kernel thread in the calling process and attaches the new kernel thread to a resource set.

Syntax

```
#include <sys/rset.h>
tid_t kra_thread_create (rstype, rsid, flags)
rstype_t rstype;
rsid_t rsid;
unsigned int flags;
```

Description

The **kra_thread_create** kernel service creates a new kernel-only thread in the calling kernel process and attaches the new kernel thread to a resource set as specified in the *rstype* and *rsid* parameters. After the kernel thread is created, the ID of the new kernel thread is returned. The returned ID of the new kernel thread is unique throughout the system.

The **kra_thread_create** kernel service can be used similar to the **thread_create** kernel service for creating a new kernel thread in the calling process.

The new kernel thread does not start immediately after it is created and the state of the new kernel thread is set to **TSIDL**. The new kernel thread starts after a call to the **kthread_start** kernel service. If the new kernel thread process exits before the new kernel thread starts, resources of the new kernel thread are released immediately. The signal-mask of the new kernel thread is inherited from the calling thread and the set of pending signals of the kernel thread is cleared. If the new kernel thread is in the **TSIDL** state, all the signals that are sent to the new kernel thread are marked as **Pending**.

To successfully attach a kernel thread to a resource set, the following conditions must be met:

- The resource set must contain processors that are available in the system.
- The calling process must either have the root authority or have the **CAP_NUMA_ATTACH** capability.
- The calling process must either have the root authority or have the same effective user ID as that of the target process.
- The calling thread must not have a bindprocessor bindings to a processor.
- The resource set must be contained in partition resource set of the calling process.

Parameters

Item	Description
rstype	Specifies the resource set type to which the new kernel thread of the calling process will be attached. The valid values are: • **R_RSET**: resource set. • **R_SRADID**: Scheduler Resource Allocation Domain Identifier (SRAD ID).
rsid	Specifies the resource set that is associated with the *rstype* parameter. The valid values are: • **Resource set (when *rstype* = R_RSET)**: Set the *rsid_t at_rset* field to the resource set that you want. • **SRADID (when *rstype* = R_SRADID):** Set the *rsid_t at_sradid* field to the SRAD ID that you want.
flags	Reserved for future use. You can specify the value as 0.

Return Values

Upon successful completion, the **kra_thread_create** kernel service returns a value of zero (0). If unsuccessful, the kra_thread_create kernel service returns one of the following errors:

Item	Description
EINVAL	Indicates one of the following conditions: • The *rstype* parameter contains an invalid type identifier. • The *flags* parameter contains an invalid value.
ENODEV	The specified resource set does not contain a processor that is available in the system.
EFAULT	Invalid address.

Item	Description
EPERM	Indicates one of the following conditions:

- The calling process has neither the root authority nor the **CAP_NUMA_ATTACH** attachment privilege.
- The calling process contains one or more threads with a bindprocessor binding to the processor.
- The specified resource set is not included in the partition resource set of the calling process.

Item	Description
ENOMEM	Available memory is not sufficient to create the kernel thread.
EAGAIN	The total number of kernel threads executing system-wide or the maximum number of kernel threads per process would be exceeded.
ENOTSUP	The **kra_thread_create** kernel service is called directly from a kernel extension.

krs_alloc Subroutine

Purpose

Allocates a resource set and returns its handle.

Syntax

```
#include <sys/rset.h>
int krs_alloc (rset, flags)
rsethandle_t *rset;
unsigned int flags;
```

Description

The **krs_alloc** subroutine allocates a resource set and initializes it according to the information specified by the *flags* parameter. The value of the *flags* parameter determines how the new resource set is initialized.

Parameters

Item	Description
rset	Points to an **rsethandle_t** where the resource set handle is stored on successful completion.
flags	Specifies how the new resource set is initialized. It takes one of the following values, defined in **rset.h**:

- **RS_EMPTY** (or 0 value): The resource set is initialized to contain no resources.
- **RS_SYSTEM**: The resource set is initialized to contain available system resources.
- **RS_ALL**: The resource set is initialized to contain all resources.
- **RS_PARTITION**: The resource set is initialized to contain the resources in the caller's process partition resource set.

Return Values

Upon successful completion, the **krs_alloc** subroutine returns a 0. If unsuccessful, one or more of the following is returned:

Item	Description
EINVAL	The *flags* parameter contains an invalid value.
ENOMEM	There is not enough space to create the data structures related to the resource set.

krs_free Subroutine

krs_getinfo Subroutine

krs_init Subroutine

krs_free Subroutine

Purpose

Frees a resource set.

Syntax

```
#include <sys/rset.h>
void krs_free(rset)
rsethandle_t rset;
```

Description

The **krs_free** subroutine frees a resource set identified by the *rset* parameter. The resource set must have been allocated by the **krs_alloc** subroutine.

Parameters

Item	Description
rset	Specifies the resource set whose memory will be freed.

krs_alloc Subroutine

krs_getassociativity Subroutine

Purpose

Gets the hardware associativity values for a resource.

Syntax

```
#include <sys/rset.h>
int krs_getassociativity (type, id, assoc_array, array_size)
unsigned int type;
unsigned int id;
unsigned int *assoc_array;
unsigned int array_size;
```

Description

The **krs_getassociativity** subroutine returns the array of hardware associativity values for a specified resource.

This is a special purpose subroutine intended for specialized root applications needing the hardware associativity value information. The **krs_getinfo**, **krs_getrad**, and **krs_numrads** subroutines are provided for typical applications to discover system hardware topology.

The calling process must have root authority to get hardware associativity values.

Parameters

Item	Description
type	Specifies the resource type whose associativity values are requested. The only value supported to retrieve values for a processor is R_PROCS.
id	Specifies the logical resource id whose associativity values are requested.
assoc_array	Specifies the address of an array of unsigned integers to receive the associativity values.
array_size	Specifies the number of unsigned integers in *assoc_array*.

Return Values

Upon successful completion, the **krs_getassociativity** subroutine returns a 0. The *assoc_array* parameter array contains the resource's associativity values. The first entry in the array indicates the number of associativity values returned. If the hardware system does not provide system topology data, a value of 0 is returned in the first array entry. If unsuccessful, one or more of the following are returned:

Item	Description
EINVAL	One of the following occurred:

- The *array_size* parameter was specified as 0.
- An invalid *type* parameter was specified.

Item	Description
ENODEV	The resource specified by the *id* parameter does not exist.
EFAULT	Invalid address.
EPERM	The calling process does not have root authority.

krs_getinfo Subroutine
krs_getrad Subroutine
krs_numrads Subroutine

krs_get_homesrad Subroutine

Purpose

Gets the currently running thread's home SRADID (Scheduler Resource Allocation Domain Identifier).

Library

Standard C library (**libc.a**)

Syntax

```
#include <sys/rset.h>
sradid_t krs_get_homesrad(void)
```

Description

The krs_get_homesrad is a kernel service and if the ENHANCED_AFFINITY services are enabled, the **krs_get_homesrad** subroutine returns the home SRADID of the currently running thread. If the ENHANCED_AFFINITY services are not enabled, the **krs_get_homesrad** subroutine returns SRADID_ANY. SRADID is the index of a RAD (Resource Allocation Domain) at the R_SRADSDL system detail level.

Return Values

If the ENHANCED_AFFINITY services are enabled, the home SRADID of the currently running thread is returned. Otherwise, SRADID_ANY is returned.

krs_getinfo Subroutine

Purpose

Gets information about a resource set.

Syntax

```
#include <sys/rset.h>
int krs_getinfo(rset, info_type, flags, result)
rsethandle_t rset;
rsinfo_t info_type;
unsigned int flags;
int *result;
```

Description

The **krs_getinfo** subroutine retrieves information about the resource set identified by the *rset* parameter. Depending on the value of the *info_type* parameter, the **krs_getinfo** subroutine returns information about the number of available processors, the number of available memory pools, or the amount of available memory contained in the resource *rset*.

The subroutine can also return global system information such as the maximum system detail level, the symmetric multiprocessor (SMP) and multiple chip module (MCM) system detail levels, and the maximum number of processor or memory pool resources in a resource set.

Parameters

Item	Description
rset	Specifies a resource set handle of a resource set the information should be retrieved from. This parameter is not meaningful if the *info_type* parameter is R_MAXSDL, R_MAXPROCS, R_MAXMEMPS, R_SMPSDL, or R_MCMSDL.

Item	Description
info_type	Specifies the type of information being requested. One of the following values (defined in **rset.h**) can be used:

- **R_NUMPROCS**: The number of available processors in the resource set is returned.
- **R_NUMMEMPS**: The number of available memory pools in the resource set is returned.
- **R_MEMSIZE**: The amount of available memory (in MB) contained in the resource set is returned.
- **R_MAXSDL**: The maximum system detail level of the system is returned.
- **R_MAXPROCS**: The maximum number of processors that may be contained in a resource set is returned.
- **R_MAXMEMPS**: The maximum number of memory pools that may be contained in a resource set is returned.
- **R_SMPSDL**: The system detail level that corresponds to the traditional notion of an SMP is returned. A system detail level of 0 is returned if the hardware system does not provide system topology data.
- **R_MCMSDL**: The system detail level that corresponds to resources packaged in an MCM is returned. A system detail level of 0 is returned if the hardware system does not have MCMs or does not provide system topology data.

flags	Reserved for future use. Must be specified as 0.
result	Points to an integer where the result is stored on successful completion.

Return Values

Upon successful completion, the **krs_getinfo** subroutine returns a 0, and the *result* field contains the requested information. If unsuccessful, one or more of the following are returned:

Item	Description
EINVAL	One of the following is true:

- The *info_type* parameter specifies an invalid resource type value.
- The *flags* parameter was not specified as 0.

EFAULT	Invalid address.

krs_getpartition Subroutine

Purpose

Gets the partition resource set to which a process is attached.

Syntax

```
#include <sys/rset.h>
int krs_getpartition (pid, flags, rset, rset_type)
pid_t pid;
unsigned int flags;
rsethandle_t rset;
unsigned int *rset_type;
```

Description

The **krs_getpartition** subroutine returns the partition resource set attached to the specified process. A process ID value of RS_MYSELF indicates the partition resource set attached to the current process is requested.

Upon successful completion, the type of resource set is returned into the *rset_type* parameter.

A value of RS_PARTITION_RSET indicates the process has a partition resource set that is set explicitly. This may be set with the **krs_setpartition** subroutine or through the use of WLM work classes with resource sets.

A value of RS_DEFAULT_RSET indicates the process did not have an explicitly set partition resource set. The system default resource set is returned.

Parameters

Item	Description
pid	Specifies the process ID whose partition *rset* is requested.
flags	Reserved for future use. Specify as 0.
rset	Specifies the resource set to receive the process' partition resource set.
rset_type	Points to an unsigned integer field to receive the resource set type.

Return Values

Upon successful completion, the **krs_getpartition** subroutine returns a 0. If unsuccessful, one or more of the following are true:

Item	Description
EFAULT	Invalid address.
ESRCH	The process identified by the *pid* parameter does not exist.

krs_getrad Subroutine

Purpose

Returns a system resource allocation domain (RAD) contained in an input resource set.

Syntax

```
#include <sys/rset.h>
int krs_getrad (rad, sdl, index, flags)
rsethandle_t rad;
unsigned int sdl;
unsigned int index;
unsigned int flags;
```

Description

The **krs_getrad** subroutine returns a system RAD at a specified system detail level and index.

The system RAD is specified by system detail level *sdl* and index number *index*.

The *rad* parameter must be allocated (using the **krs_alloc** subroutine) prior to calling the **krs_getrad** subroutine.

Parameters

Item	Description
rad	Specifies a resource set handle to receive the desired system RAD.
sdl	Specifies the system detail level of the desired system RAD.
index	Specifies the index of the system RAD that should be returned from among those at the specified *sdl*. This parameter must belong to the **[0, krs_numrads(***rset, sdl, flags***)- 1]** interval.
flags	Reserved for future use. Specify as 0.

Return Values

Upon successful completion, the **krs_getrad** subroutine returns a 0. If unsuccessful, one or more of the following are true:

Item	Description
EINVAL	One of the following is true: • The *flags* parameter contains an invalid value. • The *sdl* parameter is greater than the maximum system detail level. • The RAD specified by the *index* parameter does not exist at the system detail level specified by the *sdl* parameter.
EFAULT	Invalid address.

krs_getinfo Subroutine
krs_alloc Subroutine

krs_init Subroutine

Purpose

Initializes a previously allocated resource set.

Syntax

```
#include <sys/rset.h>
int krs_init (rset, flags)
rsethandle_t rset;
unsigned int flags;
```

Description

The **krs_init** subroutine initializes a previously allocated resource set. The resource set is initialized according to information specified by the *flags* parameter.

Parameters

Item	Description
rset	Specifies the handle of the resource set to initialize.

Item	Description
flags	Specifies how the resource set is initialized. It takes one of the following values, defined in **rset.h**:

- **RS_EMPTY**: The resource set is initialized to contain no resources.
- **RS_SYSTEM**: The resource set is initialized to contain available system resources.
- **RS_ALL**: The resource set is initialized to contain all resources.
- **RS_PARTITION**: The resource set is initialized to contain the resources in the caller's process partition resource set.

Return Values

Upon successful completion, the krs_init subroutine returns a 0. If unsuccessful, the following is returned:

Item	Description
EINVAL	The *flags* parameter contains an invalid value.

Related reference
krs_alloc Subroutine

krs_numrads Subroutine

Purpose

Returns the number of system resource allocation domains (RADs) that have available resources.

Syntax

```
#include <sys/rset.h>
int krs_numrads(rset, sdl, flags)
rsethandle_t rset;
unsigned int sdl;
unsigned int flags;
```

Description

The **krs_numrads** subroutine returns the number of system RADs at system detail level *sdl*, that have available resources contained in the resource set identified by the *rset* parameter.

The number of atomic RADs contained in the *rset* parameter is returned if the *sdl* parameter is equal to the maximum system detail level.

Parameters

Item	Description
rset	Specifies the resource set handle for the resource set being queried.
sdl	Specifies the system detail level in which the caller is interested.
flags	Reserved for future use. Specify as 0.

Return Values

Upon successful completion, the number of RADs is returned. If unsuccessful, a -1 is returned and one or more of the following are true:

- The *flags* parameter contains an invalid value.
- The *sdl* parameter is greater than the maximum system detail level.

Related reference
krs_getrad Subroutine
krs_getinfo Subroutine

krs_op Subroutine

Purpose

Performs a set of operations on one or two resource sets.

Syntax

```
#include <sys/rset.h>
int krs_op (command, rset1, rset2, flags, id)
unsigned int command;
rsethandle_t rset1, rset2;
unsigned int flags;
unsigned int id;
```

Description

The **krs_op** subroutine performs the operation specified by the *command* parameter on resource set *rset1*, or both resource sets *rset1* and *rset2*.

Parameters

Item	Description
command	Specifies the operation to apply to the resource sets identified by *rset1* and *rset2*. One of the following values, defined in **rset.h**, can be used:

- **RS_UNION**: The resources contained in either *rset1* or *rset2* are stored in *rset2*.
- **RS_INTERSECTION**: The resources that are contained in both *rset1* and *rset2* are stored in *rset2*.
- **RS_EXCLUSION**: The resources in *rset1* that are also in *rset2* are removed from *rset2*. On completion, *rset2* contains all the resources that were contained in *rset2* but were not contained in *rset1*.
- **RS_COPY**: All resources in *rset1* whose type is *flags* are stored in *rset2*. If *rset1* contains no resources of this type, *rset2* will be empty. The previous content of *rset2* is lost, while the content of *rset1* is unchanged.
- **RS_ISEMPTY**: Test if resource set *rset1* is empty.
- **RS_ISEQUAL**: Test if resource sets *rset1* and *rset2* are equal.
- **RS_ISCONTAINED**: Test if all resources in resource set *rset1* are also contained in resource set *rset2*.
- **RS_TESTRESOURCE**: Test if the resource whose type is *flags* and index is *id* is contained in resource set *rset1*.
- **RS_ADDRESOURCE**: Add the resource whose type is *flags* and index is *id* to resource set *rset1*.
- **RS_DELRESOURCE**: Delete the resource whose type is *flags* and index is *id* from resource set *rset1*.
- RS_STSET: Constructs an ST resource set by including only one hardware thread per physical processor included in *rset1* and stores it in *rset2*. Only available processors are considered when constructing the ST resource set.

Item	Description
rset1	Specifies the resource set handle for the first of the resource sets involved in the *command* operation.
rset2	Specifies the resource set handle for the second of the resource sets involved in the *command* operation. This resource set is also used, on return, to store the result of the operation, and its previous content is lost. The *rset2* parameter is ignored on the RS_ISEMPTY, RS_TESTRESOURCE, RS_ADDRESOURCE, and RS_DELRESOURCE commands.
flags	When combined with the RS_COPY command, the *flags* parameter specifies the type of the resources that will be copied from *rset1* to *rset2*. This parameter is constructed by logically ORing one or more of the following values, defined in **rset.h**:

- **R_PROCS:** processors
- **R_MEMPS:** memory pools
- **R_ALL_RESOURCES:** processors and memory pools

If none of the above are specified for *flags*, R_ALL_RESOURCES is assumed.

id	On the RS_TESTRESOURCE, RS_ADDRESOURCE, and RS_DELRESOURCE commands, the *id* parameter specifies the index of the resource to be tested, added, or deleted. This parameter is ignored on the other commands.

Return Values

Item	Description
0	Successful completion. The tested condition is not met for the RS_ISEMPTY, RS_ISEQUAL, RS_ISCONTAINED, and RS_TESTRESOURCE commands.
1	Successful completion. The tested condition is met for the RS_ISEMPTY, RS_ISEQUAL, RS_ISCONTAINED, and RS_TESTRESOURCE commands.
-1	Unsuccessful completion. One or more of the following are true:

- *rset1* identifies an invalid resource set.
- *rset2* identifies an invalid resource set.
- *command* identifies an invalid operation.
- *flags* identifies an invalid resource type.
- *id* specifies a resource index that is too large.
- Invalid address.

krs_setpartition Subroutine

Purpose

Sets the partition resource set of a process.

Syntax

```
#include <sys/rset.h>
int krs_setpartition(pid, rset, flags)
pid_t pid;
rsethandle_t rset;
unsigned int flags;
```

Description

The **krs_setpartition** subroutine sets a process' partition resource set. The subroutine can also be used to remove a process' partition resource set.

The partition resource set limits the threads in a process to running only on the processors contained in the partition resource set.

The work component is an existing process identified by process ID. A process ID value of RS_MYSELF indicates the attachment applies to the current process.

The following conditions must be met to set a process' partition resource set:

- The calling process must have root authority.
- The resource set must contain processors that are available in the system.
- The new partition resource set must be equal to, or a superset of the target process' effective resource set.
- The target process must not contain any threads that have bindprocessor bindings to a processor.

The *flags* parameter can be set to indicate the policy for using the resources contained in the resource set specified in the *rset* parameter. The only supported scheduling policy is R_ATTACH_STRSET, which is useful only when the processors of the system are running in simultaneous multithreading mode. Processors like the POWER5 support simultaneous multithreading, where each physical processor has two execution engines, called *hardware threads*. Each hardware thread is essentially equivalent to a single CPU, and each is identified as a separate CPU in a resource set. The R_ATTACH_STRSET flag indicates that the process is to be scheduled with a single-threaded policy; namely, that it should be scheduled on only one hardware thread per physical processor. If this flag is specified, then all of the available processors indicated in the resource set must be of exclusive use. A new resource set, called an *ST resource set*, is constructed from the specified resource set and attached to the process according to the following rules:

- All offline processors are ignored.
- If all the hardware threads (CPUs) of a physical processor (when running in simultaneous multithreading mode, there will be more than one active hardware thread per physical processor) are not included in the specified resource set, the other CPUs of the processor are ignored when constructing the ST resource set.
- Only one CPU (hardware thread) resource per physical processor is included in the ST resource set.

Parameters

Item	Description
pid	Specifies the process ID of the process whose partition resource set is to be set. A value of RS_MYSELF indicates the current process' partition resource set should be set.
rset	Specifies the partition resource set to be set. A value of RS_DEFAULT indicates the process' partition resource set should be removed.
flags	Specifies the policy to use for the process. A value of R_ATTACH_STRSET indicates that the process is to be scheduled with a single-threaded policy (only on one hardware thread per physical processor).

Return Values

Upon successful completion, the **krs_setpartition** subroutine returns a 0. If unsuccessful, one or more of the following are true:

Item	Description
EINVAL	The R_ATTACH_STRSET *flags* parameter is specified and one or more processors in the *rset* parameter are not assigned for exclusive use.

Item	Description
ENODEV	The resource set specified by the *rset* parameter does not contain any available processors, or the R_ATTACH_STRSET *flags* parameter is specified and the constructed ST resource set does not have any available processors.
ESRCH	The process identified by the *pid* parameter does not exist.
EFAULT	Invalid address.
ENOMEM	Memory not available.
EPERM	One of the following is true:

- The calling process does not have root authority.
- The process identified by the *pid* parameter has one or more threads with a bindprocessor processor binding.
- The process identified by the *pid* parameter has an effective resource set and the new partition resource set identified by the *rset* parameter does not contain all of the effective resource set's resources.

Exclusive use processor resource sets

ksettickd Kernel Service

Purpose

Sets the current status of the systemwide timer-adjustment values.

Syntax

```
#include <sys/types.h>

int ksettickd (timed, tickd, time_adjusted)
int *timed;
int *tickd;
int *time_adjusted;
```

Parameters

Item	Description
timed	Specifies the number of microseconds by which the systemwide timer is to be adjusted unless set to a null pointer.
tickd	Specifies the adjustment rate of the systemwide timer unless set to a null pointer. This rate determines the number of microseconds that the systemwide timer is adjusted with each timer tick. Adjustment continues until the time has been corrected by the amount specified by the *timed* parameter.
time_adjusted	Sets the kernel-maintained time adjusted flag to True or False. If the *time_adjusted* parameter is a null pointer, calling the **ksettickd** kernel service always sets the kernel's *time_adjusted* parameter to False.

Description

The **ksettickd** kernel service provides kernel extensions with the capability to update the *time_adjusted* parameter, and set or change the systemwide time-of-day timer adjustment amount and rate. The timer-adjustment values indicated by the *timed* and *tickd* parameters are the same values used by the **adjtime** subroutine. A call to the **settimer** or **adjtime** subroutine for the systemwide time-of-day timer sets the *time_adjusted* parameter to True, as read by the **kgettickd** kernel service.

This kernel service is typically used only by kernel extensions providing time synchronization functions such as coordinated network time where the **adjtime** subroutine is insufficient.

Note: The **ksettickd** service provides no serialization with respect to the **adjtime** and **settimer** subroutines, the **ksettimer** kernel service, or the timer interrupt handler, all of which also use and update these values. The caller of this kernel service must provide the necessary serialization to ensure appropriate operation.

Execution Environment

The **ksettickd** kernel service can be called from either the process or interrupt environment.

Return Value

The **ksettickd** kernel service always returns a value of 0.

Using Fine Granularity Timer Services and Structures

ksettimer Kernel Service

Purpose

Sets the systemwide time-of-day timer.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/time.h>
```

```
int ksettimer (nct)
struct timestruc_t *nct;
```

Parameter

Item	Description
nct	Points to a **timestruc_t** structure, which contains the new current time to be set. The nanoseconds member of this structure is valid only if greater than or equal to 0, and less than the number of nanoseconds in a second.

Description

The **ksettimer** kernel service provides a kernel extension with the capability to set the systemwide time-of-day timer. Kernel extensions typically use this kernel service to support network coordinated

time, which is the periodic synchronization of all system clocks to a common time by a time server or set of time servers on a network. The newly set "current" time must represent the amount of time since 00:00:00 GMT, January 1, 1970.

Execution Environment

The **ksettimer** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.
EINVAL	Indicates that the new current time specified by the *nct* parameter is outside the range of the systemwide timer.
EIO	Indicates that an error occurred while this kernel service was accessing the timer device.

Related information

Using Fine Granularity Timer Services and Structures

Timer and Time-of-Day Kernel Services

kthread_kill Kernel Service

Purpose

Posts a signal to a specified kernel-only thread.

Syntax

```
#include <sys/thread.h>
```

void kthread_kill (*tid*, *sig***)**
tid_t *tid*;
int *sig*;

Parameters

Item	Description
tid	Specifies the target kernel-only thread. If its value is -1, the signal is posted to the calling thread.
sig	Specifies the signal number to post.

Description

The **kthread_kill** kernel service posts the signal *sig* to the kernel thread specified by the *tid* parameter. When the service is called from the process environment, the target thread must be in the same process as the calling thread. When the service is called from the interrupt environment, the signal is posted to the target thread, without a permission check.

Execution Environment

The **kthread_kill** kernel service can be called from either the process environment or the interrupt environment.

Return Values

The **kthread_kill** kernel service has no return values.

Related reference
sig_chk Kernel Service
Related information
Process and Exception Management Kernel Services

kthread_start Kernel Service

Purpose

Starts a previously created kernel-only thread.

Syntax

```
#include <sys/thread.h>
```

int kthread_start (*tid*, *i_func*, *i_data_addr*, *i_data_len*,

i_stackaddr,
*i_sigmask***)**
tid_t *tid*;
int (*i_func***) (void *);**
void **i_data_addr***;**
size_t *i_data_len*;
void **i_stackaddr***;**
sigset_t **i_sigmask***;**

Parameters

Item	Description
tid	Specifies the kernel-only thread to start.
i_func	Points to the entry-point routine of the kernel-only thread.
i_data_addr	Points to data that will be passed to the entry-point routine.
i_data_len	Specifies the length of the data chunk.
i_stackaddr	Specifies the stack's base address for the kernel-only thread.
i_sigmask	Specifies the set of signal to block from delivery when the new kernel-only thread begins execution.

Description

The **kthread_start** kernel service starts the kernel-only thread specified by the *tid* parameter. The thread must have been previously created with the **thread_create** kernel service, and its state must be **TSIDL**.

This kernel service initializes and schedules the thread for the processor. Its state is changed to **TSRUN**. The thread is initialized so that it begins executing at the entry point specified by the *i_func* parameter, and that the signals specified by the *i_sigmask* parameter are blocked from delivery.

The thread's entry point gets one parameter, a pointer to a chunk of data that is copied to the base of the thread's stack. The *i_data_addr* and *i_data_len* parameters specify the location and quantity of data to copy. The format of the data must be agreed upon by the initializing and initialized thread.

The thread's stack's base address is specified by the *i_stackaddr* parameter. If a value of zero is specified, the kernel will allocate the memory for the stack (96K). This memory will be reclaimed by the system when the thread terminates. If a non-zero value is specified, then the caller should allocate the backing memory for the stack. Since stacks grow from high addresses to lower addresses, the *i_stackaddr* parameter specifies the highest address for the thread's stack.

The thread will be automatically terminated when it returns from the entry point routine. If it is the last thread in the process, then the process will be exited.

Execution Environment

The **kthread_start** kernel service can be called from the process environment only.

Return Values

The **kthread_start** kernel service returns one of the following values:

Item	Description
0	Indicates a successful start.
ESRCH	Indicates that the *tid* parameter is not valid.

Process and Exception Management Kernel Services

kvmgetinfo Kernel Service

Purpose

Retrieves Virtual Memory Manager (VMM) information.

Syntax

```
#include <sys/vminfo.h>
```

int kvmgetinfo (void *_out_, int _command_, int _arg_**)**

Description

The **kvmgetinfo** kernel service returns the current value of certain VMM parameters.

Parameters

Item	Description
out	Specifies the address where VMM information should be returned.

Item	Description
command	Specifies which information should be returned. The valid values for the *command* parameter are decribed below:

VMINFO

The content of **vminfo** structure (described in **sys/vminfo.h**) will be returned. The *out* parameter should point to a **vminfo** structure and the *arg* parameter should be the size of this structure. The smaller of the *arg* or *sizeof* (**struct vminfo**) parameters will be copied.

VMINFO_ABRIDGED

The content of the **vminfo** structure (described in the **sys/vminfo.h** file) is returned. For this command, only the non-time consuming statistics are updated, so this command must be used in performance-critical applications rather than the **VMINFO** command. The *out* parameter must point to a **vminfo** structure and the *arg* parameter must be the size of this structure. The smaller of the *arg* or *sizeof* (**struct vminfo**) parameters are copied.

VM_PAGE_INFO

The size, in bytes, of the page backing the address specified in the *addr* field of the **vm_page_info** structure (described in the **sys/vminfo.h** file) is returned. The *out* parameter should point to a **vm_page_info** structure with the *addr* field set to the desired address of which to query the page size. This address, *addr*, is interpreted as an address in the address space of the current running process. The *arg* parameter should be the size of the **vm_page_info** structure.

IPC_LIMITS

The content of the **ipc_limits** struct (described in the **sys/vminfo.h** file) is returned. The *out* parameter should point to an **ipc_limits** structure and *arg* should be the size of this structure. The smaller of the *arg* or *sizeof* (struct **ipc_limits**) parameters will be copied. The **ipc_limits** struct contains the inter-process communication (IPC) limits for the system.

VMINFO_GETPSIZES

Reports a system's supported page sizes. When *arg* is 0, the *out* parameter is ignored, and the number of supported page sizes is returned. When *arg* is greater than 0, *arg* indicates the number of page sizes to report, and *out* must be a pointer to an array with *arg* number of psize_t types. The array of psize_t types is updated with the system's supported page sizes in sorted order starting with the smallest supported page size. The number of array entries updated with page sizes is returned.

VMINFO_PSIZE

Reports detailed VMM statistics for a specified page size. The *out* parameter must point to a **vminfo_psize** structure with the *psize* field set to a page size, in bytes, for which to return statistics. The *arg* parameter should be the size of the **vminfo_psize** structure.

Item	Description
arg	An additional parameter that will depend upon the *command* parameter.

Execution Environment

The **kvmgetinfo** kernel service can be called from the process environment only.

Return Values

The following return values apply to all commands other than **VMINFO_GETPSIZES**:

Item	Description
0	Indicates successful completion.
ENOSYS	Indicates the *command* parameter is not valid (or not yet implemented).
EINVAL	When VM_PAGE_INFO is the command, the *adr* field of the **vm_page_info** structure is an invalid address.

When **VMINFO_GETPSIZES** is specified as the command, -1 is returned if the **kvmgetinfo()** kernel service is unsuccessful. Otherwise, the **kvmgetinfo()** kernel service returns a number of page sizes when the **VMINFO_GETPSIZES** command is specified.

Memory Kernel Services

Understanding Virtual Memory Manager Interfaces

kwpar_checkpoint_status Kernel Service

Purpose

Provides a method for kernel services to inform the system that an event occurred within a workload partition (WPAR) that denies or subsequently reallows a checkpoint of the WPAR.

Syntax

```
#include <sys/wparid.h>
```

int kwpar_checkpoint_status (*kcid*, *cmd*, *varp***)**
cid_t *kcid***;**
int *cmd***;**
void * *varp***;**

Parameters

Item	Description
cmd	An integer command that informs the API what action to take on behalf of the caller.
kcid	The WPAR ID where the command operation is to take place.
varp	A void pointer to different elements that depends on the *cmd* parameter. • If the *cmd* parameter is set to the **WPAR_CHECKPOINT_TRY** value, the *varp* parameter is a pointer to an integer variable that contains the number of seconds that the caller is willing to wait before a blocking event is removed. • If the *cmd* parameter is set to the **WPAR_CHECKPOINT_DENY** value, the *varp* parameter is a pointer to a null terminated character string that contains a user readable reason for posting the event.

Cmd Types

The *cmd* parameter is supplied on input to the **kwpar_checkpoint_status** API and describes the type of action or event notification the caller is expecting. The following *cmd* types are supported:

Item	Description
WPAR_CHECKPOINT_DENY	The caller is experiencing an event within the WPAR identified by the *kcid* parameter that would deny a checkpoint operation. The caller must supply a pointer to a user readable character string in the *varp* parameter.

Item	Description
WPAR_CHECKPOINT_ALLOW	The caller is clearing a previous checkpoint denial operation. Deny and allow operations are cumulative and thus each denial operation must be matched with an allow operation before a checkpoint is finally reallowed.
WPAR_CHECKPOINT_TRY	Used by the AIX checkpoint system itself. The caller supplies the *varp* pointer to an integer that contains a "willing to wait" timeout in seconds before a checkpoint denial operation is cleared.
WPAR_CHECKPOINT_CLEAR	Used by the AIX checkpoint system itself. The caller completed a checkpoint after a successful **WPAR_TRY_CHKPNT** operation.
WPAR_RESTART_CLEAR	Used by the AIX checkpoint system itself. The caller completed a restart. The WPAR restart state is initially set when the WPAR is re-created on the arrival system.

Description

The **kwpar_checkpoint_status** kernel service provides a mechanism for kernel services to inform or query the system about a checkpoint denial event. Kernel extensions that experience a temporary event which prevents a WPAR from being the target of a checkpoint operation, must use this API to deny and then to subsequently reallow a checkpoint when the event clears. An example denial event might occur if a device open is in an unserialized interim state that cannot handle a checkpoint operation.

Execution Environment

The **kwpar_checkpoint_status** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Success.
non-zero	Failure.

Error Codes

The **kwpar_checkpoint_status** service fails if one or more of the following errors occur:

Item	Description
EINVAL	The caller supplied an invalid *cmd* or other parameter.
ENOENT	No WPAR with the *kcid* ID is active in the system.
EBUSY	Either of the following situations can lead to the **EBUSY** error. • WPAR is in a checkpoint or restart state. The caller is unsuccessful in a **WPAR_CHECKPOINT_DENY** operation. • WPAR is in a state that cannot participate in a checkpoint. The caller is unsuccessful in a **WPAR_CHECKPOINT_TRY** operation.
ETIMEDOUT	The caller is waiting for a timeout period during a **WPAR_CHECKPOINT_TRY** operation but the timer expired.

kwpar_err Kernel Service

Purpose

Logs an error message for a given Workload Partition.

Syntax

```
int kwpar_err(kcid,cat_file_name,msg_set_no,msg_no,default_fmt_msg)
cid_t kcid;
char* cat_file_name;
unsigned int msg_set_no;
unsigned int msg_no;
char* default_fmt_msg;
```

Description

The **kwpar_err** interface provides a mechanism to log error messages for a given WPAR from a kernel routine. Each WPAR can hold up to 1 KB of error messages. If there is enough space to log the new message, the command logs the message; otherwise, it fails. The **kwpar_err** routine is pinned and as such can be called from the interrupt handlers as well.

Parameter

Item	Description
kcid	Specified the **cid** of the WPAR.
cat_file_name	Specifies the catalog file name to be used for translation.
msg_set_no	Specifies the message set number of the error message in the catalog file.
msg_no	Specifies the message number of the error message.
default_fmt_msg	Specifies the default message string. Follows the same syntax as the **printf** subroutine *Format* parameter. Floating point is not supported.
...	Specifies the arguments to the message if any.

Return values

Item	Description
0	Success
-1	Failure

Error codes

Item	Description
ENOMEM	Not enough memory
EINVAL	Invalid parameter

Example

```
To log an error message into WPAR with cid 4, enter

kwpar_err(4, "wparerrs.cat",1,10,"%s : command failed", "mycommand");
…
```

wpar_log_err subroutine

wpar_print_err subroutine

kwpar_getname Kernel Service

Purpose

Returns the workload partition name associated with the requested ID.

Syntax

```
#include<sys/wparid.h>
#include<sys/xmem.h>

int kwpar_getname(kcid, buffer, length, adspace)
cid_t kcid;
char * buffer;
size_t length;
int adspace;
```

Description

Get the name associated with the workload partition ID (*kcid*) and write it to the output buffer. The maximum number of bytes to write is limited by the *length* parameter. The *length* parameter cannot exceed MAXCORRALNAMELEN. The service writes to either user space or kernel space, depending on the value specified for the *adspace* parameter.

Parameters

Item	Description
kcid	Specifies the workload partition ID.
buffer	Points to the buffer where the workload partition name is stored.
length	Specifies the maximum number of bytes to return.
adspace	Indicates in which part of memory the buffer parameter is located:

SYS_ADSPACE
Indicates that the *buffer* parameter is in the kernel memory.

USER_ADSPACE
Indicates that the *buffer* parameter is in the application memory.

Execution Environment

Process environment only.

Return Values

Item	Description
0	The command completed successfully.
EINVAL	Invalid WPAR ID or specified length is greater than MAXCORRALNAMELEN.
EFAULT	Error during copyout to user space.

kwpar_getrootpath Kernel Service

Purpose

Returns the root path of the workload partition associated with the requested ID.

Syntax

```
#include<sys/wparid.h>

int kwpar_getrootpath(kcid, length,  buffer)
cid_t kcid;
size_t * length;
char * buffer;
```

Description

Get the root path of the workload partition associated with the *kcid* parameter and copy it to the output buffer. On entry, the value specified for the *length* parameter indicates the size of the output buffer. On return, the value specified for the *length* parameter, contains the size of the root path. If the value for the *length* parameter on entry is smaller than the actual path length, then **ENOSPC** is returned. Then, the *length* parameter is set to the actual length of the root path.

Parameters

Item	Description
kcid	Specifies the workload partition ID.
length	Specifies the maximum number of bytes to return.
buffer	Points to the buffer where the workload partition root path will be stored.

Execution Environment

Process environment only.

Return Values

Item	Description
0	The command completed successfully.
EINVAL	Error indicating that *buffer* is NULL, *length* is NULL, or **length* is 0.
ENOENT	Invalid WPAR ID specified for the *kcid* parameter.
ENOSPC	Insufficient space in *buffer* to copy path.

kwpar_isappwpar Kernel Service

Purpose

Returns whether a workload partition is an application workload partition.

Syntax

```
#include <sys/wparid.h>

int kwpar_isappwpar(kcid)
cid_t kcid;
```

Description

Checks whether the workload partition associated with the *kcid* is an application workload partition.

Parameters

Item	Description
kcid	Specifies the workload partition ID.

Execution Environment

Process environment only.

Return Values

Item	Description
1	Workload partition is an application workload partition.
0	Workload partition is not an application workload partition.
-1	Indicates that the command did not complete successfully.

kwpar_r2vmap_devno Kernel Service

Purpose

Maps a real device number to the corresponding virtual device number for a given workload partition (WPAR).

Syntax

```
#include <sys/wparid.h>
```

int kwpar_r2vmap_devno (*wparid*, *vdevno*, *rdevno***)**
cid_t *wparid***;**
dev_t *rdevno***;**
dev_t * *vdevno***;**

Parameters

Item	Description
wparid	WPAR identifier. This parameter is required.
rdevno	Real device number. This parameter is required.
vdevno	Points to the data area that will contain the virtual device number. This parameter is passed by reference. This parameter is optional.

Description

The **kwpar_r2vmap_devno** kernel service provides the ability to translate a real device number, maintained in the kernel device switch table, to the corresponding virtual device number maintained in the user space. The caller must specify an existing WPAR identifier with the *wparid* parameter and a valid real device number with the *rdevno* parameter. The **kwpar_r2vmap_devno** kernel service writes the corresponding virtual device number to the data area pointed to by the *vdevno* parameter (if specified). If

the *vdevno* parameter is not specified, the return code indicates whether a mapping exists for the given WPAR identifier and real device number.

A mapping for the specified virtual device number must exist for the **kwpar_v2rmap_devno** kernel service to succeed.

Execution Environment

The **kwpar_r2vmap_devno** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Success.
non-zero	Failure.

Error Codes

The **kwpar_r2vmap_devno** service fails if one or more of the following errors occur:

Item	Description
EINVAL	Either the *wparid* or *rdevno* argument is invalid.
ENXIO	Unable to locate the WPAR device map associated with the given WPAR ID.
ESRCH	Unable to locate a mapping for the given real device number *rdevno*.

kwpar_unregdevno Kernel Service

kwpar_r2vmap_pid Kernel Service

Purpose

Maps a real process ID to the equivalent virtual process ID assigned within a workload partition.

Syntax

```
#include <sys/wparid.h>
```

pid_t kwpar_r2vmap_pid (*kcidp, rpid***)**
cid_t * *kcidp***;**
pid_t *rpid***;**

Parameters

Item	Description
kcidp	A pointer to a memory location where the workload partition (WPAR) ID associated with the *rpid* parameter is returned.
rpid	The real process ID on which to translate a real process ID to a virtual process ID.

Description

The **kwpar_r2vmap_pid** kernel service provides a mapping from a real process ID to a virtual process ID assigned within the workload partition. In most instances, the real and virtual process IDs are the same except in cases where the Workload Partition Mobility is in effect or for certain system services such as the **init** command which always have different real and virtual process IDs.

Usually kernel services dealing with process IDs only accept real process IDs. However, in some instances it might be necessary for kernel extensions, which communicate with other WPAR services or with processes within the WPAR, to know and communicate with virtual process IDs.

Execution Environment

The **kwpar_r2vmap_pid** kernel service can be called from the process environment only.

Return Values

If the **kwpar_r2vmap_pid** kernel service succeeds, it returns the virtual *pid_t* value associated with the *rpid* value provided on input. If the kernel service fails or if there is no virtual process ID associated with the *rpid* value, the *rpid* value is returned.

Related reference
kwpar_v2rmap_pid Kernel Service

kwpar_r2vmap_tid Kernel Service

Purpose

Maps a real thread ID to the equivalent virtual thread ID assigned within a workload partition.

Syntax

```
#include <sys/wparid.h>
```

tid_t kwpar_r2vmap_tid (*kcidp*, *rtid***)**
cid_t * *kcidp***;**
tid_t *rtid***;**

Parameters

Item	Description
kcidp	A pointer to a memory location where the WPAR ID associated with the *rtid* parameter is returned.
rtid	The real thread ID on which to translate a real process ID to a virtual process ID.

Description

The **kwpar_r2vmap_tid** kernel service provides a mapping from a real thread ID to a virtual thread ID assigned within the workload partition. In most instances, the real and virtual thread IDs are the same except in cases where the Workload Partition Mobility is in effect.

Normally kernel services dealing with thread IDs accept only real thread IDs. However, in some instances it might be necessary for kernel extensions, which communicate with other WPAR services or with processes within the WPAR, to know and communicate with virtual thread IDs.

Execution Environment

The **kwpar_r2vmap_tid** kernel service can be called from the process environment only.

Return Values

If the **kwpar_r2vmap_tid** kernel service succeeds, it returns the virtual *tid_t* value associated with the *rtid* value provided on input. If the kernel service fails or if there is no virtual process ID associated with the *rtid* value, the *rtid* value is returned.

Related reference
kwpar_v2rmap_tid Kernel Service

kwpar_regdevno Kernel Service

Purpose

Registers a virtual device number for a given workload partition (WPAR) by mapping it to a real device number in the device switch table.

Syntax

```
#include <sys/wparid.h>
```

int kwpar_regdevno (*wparid, vdevno, rdevno***)**
cid_t *wparid***;**
dev_t *vdevno***;**
dev_t * *rdevno***;**

Parameters

Item	Description
wparid	WPAR ID. This parameter is required.
vdevno	Virtual device number. This parameter is required.
rdevno	Points to the data area that will contains the real device number. This parameter is passed by reference. This parameter is required.

Description

The **kwpar_regdevno** kernel service provides the ability to register a virtual device number for a given WPAR by mapping it to a real device number in the device switch table. The **kwpar_regdevno** kernel service performs the following steps:

1. Locates a free slot in the kernel device switch table and reserves it for the WPAR specified by the *wparid* parameter.
2. Creates a mapping between the virtual device number, which is specified by the *vdevno* parameter, to the real device number reserved in the previous step.
3. The newly reserved real device number is passed back to the caller through the *rdevno* parameter.

Execution Environment

The **kwpar_regdevno** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Success.
non-zero	Failure.

Error Codes

The **kwpar_regdevno** kernel service fails if one or more of the following errors occur:

Item	Description
EINVAL	Either the *wparid* or *vdevno* argument is not valid.
ENXIO	Unable to locate the WPAR device map associated with the given WPAR ID.
ENOTEMPTY	The virtual device number *vdevno* is already mapped.

kwpar_v2rmap_devno Kernel Service
kwpar_unregdevno Kernel Service

kwpar_reghook Kernel Service

Purpose

Registers a function callback with workload partition (WPAR) kernel services. Callback functions are subsequently performed when specific WPAR conditions occur.

Syntax

```
#include <sys/wparid.h>
```

regkey_t kwpar_reghook (*hooktype*, *hookp***)**
int *hooktype***;**
void * *hookp***;**

Parameters

Item	Description
hooktype	Identifies the form of the *hookp* pointer.
hookp	A pointer to a memory location that might contain function pointers or other structure elements that are interpreted depending on the supplied *hooktype* value.

Hook Types

The *hooktype* parameter is supplied on input to the **kwpar_reghook** return and describes the form of the second parameter. The supported hook types are as follows:

Item	Description
WPAR_NOTIFY_HOOK	Identifies the form of the *hookp* parameter as being of type **wpar_config_hook_t**.

The **wpar_config_hook_t** structure contains the following fields:

Item	Description
uint current_hiwater	On output from the **kwpar_reghook** service, this field contains the current upper number of WPARs that became active on this boot instance of the AIX operating system. WPAR IDs are allocated in numeric order. Kernel subsystems that want to size internal components according to the number of active WPARs must register a **WPAR_NOTIFY_HOOK** hook type and examine the **current_hiwater** value for existing WPARs during registration. Future WPAR activation after hook registration calls the specified **configp** function within the **wpar_config_hook_t** element. See the **WPARSTART** flags later in this section for a further description of the WPAR activation.
wpar_config_func_t configp	On input, this field contains a pointer to a callback routine that is started by the WPAR kernel services during the activation and the deactivation of workload partitions within the AIX kernel.

The syntax for the **wpar_config_func_t** is as follows:

```
#include <sys/wpar.h>
```

typedef int * wpar_config_func_t (*flags, cid, corralp, unused***)**
int *flags***;**
cid_t *cid***;**
struct corral * *corralp***;**
void * *unused***;**

The parameters are as follows:

Item	Description
flags	Information regarding the type of condition that is occurring within the workload partition.
cid	The ID for the workload partition experiencing the condition.
corralp	A pointer to a kernel copy of the **corral** structure that might be supplied from the user space at the start of the condition processing.
unused	Currently unused and must be set to NULL. It might be expanded to contain more information in later revisions of this API.

The *flags* parameter can have the following potential values:

Item	Description
WPARSTART	Signifies that the WPAR is undergoing activation. The callout to registered routines occurs before any other kernel subsystem processing occurs. Kernel components registering and desiring to see the WPAR activation are informed that a new WPAR with the *cid* parameter set is going to enter the AIX kernel system.
WPARSTOP	Signifies that the WPAR underwent deactivation. The callout to registered routines occurs after all other kernel subsystem processing occurs. Kernel components registering and desiring to see the WPAR deactivation are informed that an existing WPAR with the *cid* parameter set left the AIX kernel system.

Description

The **kwpar_reghook** kernel service provides a mechanism for other kernel services to register callbacks and retrieve information when certain workload partition conditions occur.

Execution Environment

The **kwpar_reghook** kernel service can be called from the process environment only.

Return Values

If the **kwpar_reghook** kernel service is successful, it returns a registration key that can subsequently be used with the **kwpar_unreghook** kernel service. If the kernel service fails, it returns a numeric value equivalent to the BADREGKEY definition found in the **wparid.h** file.

Error Codes

The **kwpar_reghook** kernel service fails if no space remains to record additional registration hook.

Related reference
kwpar_unreghook Kernel Service

kwpar_unregdevno Kernel Service

Purpose

Unregisters the mapping associated with a real device number for a given workload partition (WPAR).

Syntax

```
#include <sys/wparid.h>
```

int kwpar_unregdevno (*wparid, rdevno***)**
cid_t *wparid***;**
dev_t *rdevno***;**

Parameters

Item	Description
wparid	WPAR identifier. This parameter is required.
rdevno	Real device number. This parameter is required.

Description

The **kwpar_unregdevno** kernel service provides the ability to unregister the mapping associated with a real device number for a given WPAR. The **kwpar_unregdevno** kernel service will perform the following steps:

1. Deletes the virtual-to-real mapping associated with the real device number specified by the *rdevno* parameter for the WPAR specified by the *wparid* parameter.
2. Releases the reserve associated with the real device number specified by the *rdevno* parameter.

Execution Environment

The **kwpar_unregdevno** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Success.
non-zero	Failure.

Error Codes

The **kwpar_unregdevno** kernel service fails if one or more of the following errors occur:

Item	Description
EINVAL	Either the *wparid* or *rdevno* argument is not valid.

Item	Description
ENXIO	Unable to locate the WPAR device map associated with the given WPAR ID.
ESRCH	Unable to locate the mapping for the given real device number *rdevno*.

Related reference

kwpar_r2vmap_devno Kernel Service
kwpar_v2rmap_devno Kernel Service
kwpar_regdevno Kernel Service

kwpar_unreghook Kernel Service

Purpose

Removes a previously registered workload partition (WPAR) callback hook.

Syntax

```
#include <sys/wparid.h>
```

int kwpar_unreghook (*key***)**
regkey_t *key***;**

Parameters

Item	Description
key	The registration key of the hook that the caller wants to un-register. This key is equivalent to the key returned from a hook registration with the **kwpar_reghook** kernel service.

Description

The **kwpar_unreghook** kernel service informs workload partitions that the caller no longer wants to receive callouts for WPAR conditions.

Execution Environment

The **kwpar_unreghook** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Success.
non-zero	Failure.

Error Codes

The **kwpar_unreghook** service fails if one or more of the following errors occur:

Item	Description
EINVAL	Not a valid registration key.
EPERM	Not allowed to un-register this key.

kwpar_v2rmap_devno Kernel Service

Purpose

Maps a virtual device number to the corresponding real device number in the device switch table for a given workload partition (WPAR).

Syntax

```
#include <sys/wparid.h>
```

int **kwpar_v2rmap_devno (** *wparid*, *vdevno*, *rdevno***)**
cid_t *wparid*;
dev_t *vdevno*;
dev_t * *rdevno*;

Parameters

Item	Description
wparid	WPAR identifier. This parameter is required.
vdevno	Virtual device number. This parameter is required.
rdevno	Points to the data area that will contain the real device number. This parameter is passed by reference. This parameter is optional.

Description

The **kwpar_v2rmap_devno** kernel service provides the ability to translate a virtual device number maintained in user space to the corresponding real device number maintained in the kernel device switch table. The caller must specify an existing WPAR identifier with the *wparid* parameter and a valid virtual device number with the *vdevno* parameter. The **kwpar_v2rmap_devno** kernel service will write the corresponding real device number to the data area pointed to by the *rdevno* parameter if it is specified. If the *rdevno* parameter is not specified, the return code will indicate whether a mapping exists for the given WPAR identifier and virtual device number.

A mapping for the specified virtual device number must exist for the **kwpar_v2rmap_devno** kernel service to succeed.

Execution Environment

The **kwpar_v2rmap_devno** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Success.
non-zero	Failure.

Error Codes

The **kwpar_v2rmap_devno** service fails if one or more of the following errors occur:

Item	Description
EINVAL	Either the *wparid* or *vdevno* argument is not valid.
ENXIO	Unable to locate the WPAR device map associated with the given WPAR id.
ENODEV	Unable to locate the mapping for the given virtual device number.

kwpar_unregdevno Kernel Service

kwpar_v2rmap_pid Kernel Service

Purpose

Maps a virtual process ID associated with a process within a workload partition to the equivalent real process ID.

Syntax

```
#include <sys/wparid.h>
```

pid_t kwpar_v2rmap_pid (*kcid, vpid***)**
cid_t *kcid***;**
pid_t *vpid***;**

Parameters

Item	Description
kcid	The workload partition (WPAR) ID associated with the *vpid* parameter. Equivalent virtual process IDs can be in use across different processes in different WPARs. Thus the caller must provide the WPAR ID for which a virtual to real mapping is to occur.
vpid	The virtual process ID on which to perform a virtual to real mapping.

Description

The **kwpar_v2rmap_pid** kernel service provides a mapping from a virtual process ID associated with a process in a workload partition to the equivalent real process ID. In most instances, both the real and virtual process IDs are the same, except in cases where the Workload Partition Mobility is in effect.

Normally, kernel services dealing with process IDs accept only real thread IDs. In some instances where a kernel extension is communicating with other WPAR services or with processes within the WPAR, a mapping from virtual to real process IDs might be needed.

Execution Environment

The **kwpar_v2rmap_pid** kernel service can be called from the process environment only.

Return Values

If the **kwpar_v2rmap_pid** kernel service succeeds, it returns the real *pid_t* value associated with the *vpid* value provided on input. If the kernel service fails, or if there is no real thread ID associated with the *vpid* value, then the *vpid* value is returned.

Related reference

kwpar_r2vmap_pid Kernel Service

Purpose

Maps a virtual thread ID associated with a thread within a workload partition to the equivalent real thread ID.

Syntax

```
#include <sys/wparid.h>
```

tid_t kwpar_v2rmap_tid (*kcid, vtid***)**
cid_t *kcid***;**
tid_t *vtid***;**

Parameters

Item	Description
kcid	The workload partition (WPAR) ID associated with the *vtid* parameter. Equivalent virtual thread IDs can be in use across different threads in different WPARs. Thus the caller must provide the WPAR ID for which a virtual to real mapping is to occur.
vtid	The virtual thread ID on which to perform a virtual to real mapping.

Description

The **kwpar_v2rmap_tid** kernel service provides a mapping from a virtual thread ID associated with a thread in a workload partition to the equivalent real thread ID. In most instances, both the real and virtual thread IDs are the same, except in cases where the Workload Partition Mobility is in effect. Normally, kernel services dealing with thread IDs accept only real thread IDs. In some instances where a kernel extension is communicating with other WPAR services or with processes within the WPAR, a mapping from virtual to real thread IDs might be needed.

Execution Environment

The **kwpar_v2rmap_tid** kernel service can be called from the process environment only.

Return Values

If the **kwpar_v2rmap_tid** kernel service succeeds, it returns the real *tid_t* value associated with the *vtid* value provided on input. If the kernel service fails, or if there is no real thread ID associated with the *vtid* value then the *vtid* value is returned.

Related reference

kwpar_r2vmap_tid Kernel Service

l

The following kernel services begin with the with the letter l.

ldata_alloc Kernel Service

Purpose

Allocates a pinned storage element from an **ldata** pool.

Syntax

```
#include <sys/ldata.h>

void * ldata_alloc (ldatap)

ldata_t ldatap;
```

Description

The **ldata_alloc** kernel service allocates a pinned storage element from a **ldata** pool and returns the address of the element. The **ldata_alloc** kernel service makes a pinned storage element from the **ldata** pool available for use by the caller. The sub-pool from which the element is allocated corresponds to the SRAD on which the call was made. If there are no free pinned elements, a new element cannot be allocated and a NULL value is returned.

After it is allocated, the pinned storage element can be freed to the **ldata** pool through the **ldata_free** kernel service.

Parameters

Item	Description
ldatap	Specifies the handle of the **ldata** pool.

Execution Environment

The **ldata_alloc** kernel service can be called from the process or interrupt environment.

Return Values

Returns a pointer to a pinned storage element allocated from an **ldata** pool or NULL if no element could be allocated.

Implementation Specifics

The **ldata_alloc** kernel service is part of the Base Operating System (BOS) Runtime.

Related reference
ldata_create Kernel Service
ldata_grow Kernel Service
ldata_free Kernel Service

ldata_create Kernel Service

Purpose

Creates a SRAD-aware pinned storage element pool (**ldata** pool) and returns its handle.

Syntax

```
#include <sys/ldata.h>

int ldata_create (size, initcount, maxcount, kkey, ldatap)

size_t size;
long initcount;
long maxcount;
kkey_t kkey;
ldata_t * ldatap;
```

Description

The **ldata_create** kernel service creates a SRAD-aware pool (**ldata** pool) of pinned storage elements, each of the specified size, and returns a handle to the newly-allocated pool. An **ldata** pool consists of a number of sub-pools (one per SRAD). Each sub-pool is physically backed with memory local to its corresponding SRAD. The size of each sub-pool is equal to the value of the *maxcount* parameter multiplied by the value of the *size* parameter. The parameter (*initcount*) specifies the number of pinned storage elements in each sub-pool that should be pre-allocated.

The **ldata** pool can be created with a kernel storage protection key by specifying one through the *kkey* parameter. For compatibility with previous releases, a *kkey* parameter of zero requests no protection. When a protection key is specified, the caller must hold this key when calling any ldata service, including the **ldata_create** kernel service.

After an **ldata** pool is created, its handle can be used to allocate pinned storage elements from the pool through the **ldata_alloc** kernel service and free these elements to the pool through the **ldata_free** kernel services. Elements are allocated and freed to the sub-pool corresponding to the SRAD on which **ldata_alloc** and **ldata_free** are called. If a sub-pool is exhausted of its pinned storage elements, it can be grown by calling the **ldata_grow** kernel service up to *maxcount*.

An **ldata** pool created through the **ldata_create** service can be destroyed by the **ldata_destroy** kernel service.

Parameters

Item	Description
size	Specifies the size, in bytes, of each pinned storage element of the **ldata** pool.
initcount	Specifies the initial count of pinned storage elements, to be contained within the **ldata** pool. Must be a positive integer.
maxcount	Specifies the maximum count of pinned storage elements that can be contained with the **ldata** pool. The value of *maxcount* must be positive and greater than or equal to the value of *initcount*.
kkey	Specifies the kernel storage protection key to be applied to the newly created **ldata** pool. The value must be a valid kernel key number, or zero to indicate that storage protection is not requested.
ldatap	Specifies an address to be set on successful completion with the handle for the newly created **ldata** pool.

Execution Environment

The **ldata_create** kernel service can be called only from the process environment.

Return Values

Item	Description
0	Completed successfully. The handle for **ldata** storage is returned in *ldatap*.
EINVAL	Invalid input parameters given. Invalid *initcount, maxcount* or *kkey*. The *ldatap* parameter is undefined.
ENOMEM	Error encountered. Insufficient memory to satisfy request. The *ldatap* parameter is undefined.

Implementation Specifics

The **ldata_create** kernel service is part of the Base Operating System (BOS) Runtime.

Related reference
ldata_destroy Kernel Service
ldata_grow Kernel Service
ldata_alloc Kernel Service

ldata_destroy Kernel Service

Purpose

Destroys an **ldata** pool created by the **ldata_create** kernel service.

Syntax

```
#include <sys/ldata.h>

void ldata_destroy (ldatap)

ldata_t ldatap;
```

Description

The **ldata_destroy** kernel service destroys an **ldata** pool previously created by an **ldata_create** call. This routine assumes that all elements allocated from the pool have been freed back to the pool and there are no longer any active elements in the pool.

The **ldata_destroy** call unpins and frees all of the storage associated with the handle.

Parameters

Item	Description
ldatap	Specifies the handle of the **ldata** pool to be destroyed.

Execution Environment

The **ldata_destroy** kernel service can be called from the process environment only.

Return Values

None.

Implementation Specifics

The **ldata_destroy** kernel service is part of the Base Operating System (BOS) Runtime.

Related reference
ldata_create Kernel Service
ldata_alloc Kernel Service
ldata_free Kernel Service

ldata_free Kernel Service

Purpose

Frees a storage element that is pinned to an **ldata** pool.

Syntax

```
#include <sys/ldata.h>

void ldata_free (ldatap, elementp)

ldata_t ldatap;
void * elementp;
```

Description

The **ldata_free** kernel service frees a pinned storage element that was previously allocated to an **ldata** pool. The pinned storage element is identified through the *elementp* parameter. The element identified by *elementp* is freed to the sub-pool corresponding to the SRAD that allocated the element.

Parameters

Item	Description
ldatap	Specifies the handle of the **ldata** pool.
elementp	Specifies the address of the pinned storage element to be freed.

Execution Environment

The **ldata_free** kernel service can be called from the process or interrupt environment.

Return Values

None.

Implementation Specifics

The **ldata_free** kernel service is part of Base Operating System (BOS) Runtime.

ldata_grow Kernel Service

Purpose

Expands the count of available pinned storage elements contained within an **ldata** pool.

Syntax

```
#include <sys/ldata.h>

int ldata_grow (ldatap, count)

ldata_t ldatap;
long count;
```

Description

The **ldata_grow** kernel service increases the number of pinned storage elements contained within a per-SRAD sub-pool associated with the **ldata** handle *ldatap*, by *count*. If the **ldata_alloc** call fails because there are no more free pinned storage elements in a sub-pool, use the **ldata_grow** kernel service. The **ldata_grow** kernel service pins additional count elements from the sub-pool and makes them available for the **ldata_alloc** call. All of the sub-pools associated with the handle are grown. If count elements are not available or there is not enough pinned memory available, the **ldata_grow** kernel service fails.

Parameters

Item	Description
ldatap	Specifies the handle of the **ldata** pool.
count	Specifies the additional number of storage elements to be pinned in the sub-pool. The *count* value should be greater than 0 and should not increase the sub-pool size beyond the value of *maxcount* specified with the **ldata_create** call.

Execution Environment

The **ldata_grow** kernel service can be called only from the process environment.

Return Values

Item	Description
0	Success.
-1	Error encountered. Illegal parameters or insufficient resources.

Implementation Specifics

The **ldata_grow** kernel service is part of the Base Operating System (BOS) Runtime.

ldmp_bufest, ldmp_timeleft, ldmp_xmalloc, ldmp_xmfree, and ldmp_errstr Kernel Services

Purpose

Obtains information about the current live dump.

Syntax

```
#include <sys/livedump.h>

kerrno_t ldmp_bufest (id, cb, len)
dumpid_t id;
```

```
ras_block_t cb;
size_t *len;

kerrno_t ldmp_timeleft (id, timeleft)
dumpid_t id;
long *timeleft;

kerrno_t ldmp_xmalloc (id, size, align, p)
dumpid_t id;
size_t size;
uint align;
void **p;

kerrno_t ldmp_xmfree (id, p)
dumpid_t id;
void *p;

kerrno_t ldmp_errstr (id, cb, str)
dumpid_t id;
ras_block_t cb;
char *str;
```

Parameters

Item	Description
align	Specifies the log base 2 of the desired alignment. The maximum allowed alignment is 12, 4096 byte alignment.
cb	Specifies the ras_block_t for the component.
id	Specifies the ID of the dump.
len	Specifies the estimate of data in bytes that can still be buffered by the specified component in this pass.
p	Specifies the memory block to be allocated or freed.
size	Specifies the memory size to be allocated.
str	Specifies the error message.
timeleft	Specifies the time, in nanoseconds, remaining for this pass. This value only has meaning for a serialized dump. It can be negative.

Description

The **ldmp_bufest** kernel service estimates the number of bytes of dump buffer storage available to this component.

The **ldmp_timeleft** kernel service estimates the time, in nanoseconds, remaining in this pass.

The **ldmp_xmalloc** kernel service allocates storage from the live dump heap.

The **ldmp_xmfree** kernel service frees live dump heap storage.

The **ldmp_errstr** kernel service records an error to be part of the live dump status reporting. The string is contained in the live dump and reported in the error log entry if there is sufficient space.

Important: An error log entry has a maximum length of 2048 bytes. The error string is limited to 128 bytes, including the trailing NULL, and is truncated if too long. The component's path name is also logged.

Tip: The **ldmp_errstr** kernel service can be called multiple times to report multiple errors.

Components are encouraged to limit the size of error strings due to limited space in the error log entry.

Return Values

Item	Description
0	Indicates a successful completion.
EINVAL_RAS_xxx_BADARGS	Indicates that the arguments for the service are not valid.
EFAULT_RAS_xxx_BADARGS	Indicates that an address argument is not a valid address.
ENOMEM_RAS_LDMP_XMALLOC	Indicates that there is insufficient space in the live dump heap to satisfy this request.

ldmp_freeparms Kernel Service

Purpose

Frees any data allocated by the live dump associated with an unused **ldmp_parms_t** data item.

Syntax

```
#include <sys/livedump.h>
```

```
kerrno_t ldmp_freeparms (parms)
ldmp_parms_t *parms;
```

Parameters

Item	Description
parms	Points to an item of **ldmp_parms_t** type.

Description

The **ldmp_freeparms** kernel service is used in the event that you have partially set up the **ldmp_parms_t** data item, but do not want to take a dump. You can use the **ldmp_freeparms** kernel service to clean up any data allocated by the live dump subsystem. However, you can always call the **ldmp_freeparms** kernel service after the **livedump** kernel service, and the **ldmp_freeparms** kernel service returns normally if there is nothing to free.

Execution Environment

The **ldmp_freeparms** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates a successful completion.
EINVAL_RAS_LDMP_FREEPARMS	Indicates that the area is not a valid **ldmp_parms_t** data area.
EFAULT_RAS_LDMP_FREEPARMS	Indicates that a memory fault results.

ldmp_setupparms Kernel Service

Purpose

Sets up the **ldmp_parms_t** parameter for the **livedump** kernel service.

Syntax

```
#include <sys/livedump.h>
```

kerrno_t ldmp_setupparms (*parms***)**
ldmp_parms_t ***parms;*

Parameters

Item	Description
parms	Points to an item of **ldmp_parms_t** type.

Description

The **ldmp_setupparms** kernel service simplifies the process of setting up a live dump by setting up the **ldmp_parms_t** parameter. It does not allocate any storage.

The **ldmp_setupparms** kernel service performs the following setup for the **ldmp_parms_t** parameter:

Item	Description
Field	Value
ldp_eyec	eyecatcher for ldmp_parms
ldp_vers	current version
ldp_flags	0
ldp_prio	LDPP_CRITICAL
ldp_recov	NULL
ldp_func	NULL
ldp_namepref	NULL
ldp_errcode	0
ldp_symptom	NULL
ldp_title	NULL
ldp_rsvd1	NULL

Execution Environment

The **ldmp_setupparms** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates a successful completion.
EFAULT_RAS_LDMP_SETUPPARMS	Indicates that the address is not valid.

limit_sigs or sigsetmask Kernel Service

Purpose

Changes the signal mask for the calling kernel thread.

Syntax

```
#include <sys/encap.h>
```

void limit_sigs (
 siglist,
 *old_mask***)**
sigset_t **siglist***;**
sigset_t **old_mask***;**

void sigsetmask (*old_mask*)
sigset_t **old_mask***;**

Parameters

Item	Description
siglist	Specifies the signal set to deliver.
old_mask	Points to the old signal set.

Description

The **limit_sigs** kernel service changes the signal mask for the calling kernel thread such that only the signals specified by the *siglist* parameter will be delivered, unless they are currently being blocked or ignored.

The old signal mask is returned via the *old_mask* parameter. If the *siglist* parameter is **NULL**, the signal mask is not changed; it can be used for getting the current signal mask.

The **sigsetmask** kernel service should be used to restore the set of blocked signals for the calling thread. The typical usage of these services is the following:

```
sigset_t allowed = limited set of signals
sigset_t old;

/* limits the set of delivered signals */
limit_sigs (&allowed, &old);

    /* do something with a limited set of delivered signals */

/* restore the original set */
sigsetmask (&old);
```

Execution Environment

The **limit_sigs** and **sigsetmask** kernel services can be called from the process environment only.

Return Values

The **limit_sigs** and **sigsetmask** kernel services have no return values.

Related reference
kthread_kill Kernel Service
Related information
Process and Exception Management Kernel Services

livedump Kernel Service

Purpose

Starts a live dump.

Syntax

```
 #include <sys/livedump.h>
```

kerrno_t livedump (*parms***)**
ldmp_parms_t **parms***;**

Parameters

Item	Description
parms	Points to an item of **ldmp_parms_t** type.

Description

The **livedump** kernel service initiates a live dump. It can be called from either the kernel or a kernel extension. Storage associated with the dump is not entirely freed until the dump has been written to disk, or the **livedump** kernel service returns an error indicating the dump was not taken.

Execution Environment

The **livedump** kernel service can be called from either the process or interrupt environment. Only a serialized, synchronous dump can be started from the interrupt level, and the dump is limited to one pass.

Return Values

Item	Description
0	Indicates a successful completion.
EINVAL_RAS_LIVEDUMP_PARM	Indicates that one or more parameters are not valid.
EFAULT_RAS_LIVEDUMP_PARM	Indicates that a memory fault occurs.
EINVAL_RAS_LIVEDUMP_COMP	Indicates one or more components are not valid.
EINVAL_RAS_LIVEDUMP_NOCOMPS	Indicates that no valid components were given.

Related reference
dmp_compspec and dmp_compext Kernel Services

lock_alloc Kernel Service

Purpose

Allocates system memory for a simple or complex lock.

Syntax

```
#include <sys/lock_def.h>
#include <sys/lock_alloc.h>
```

void lock_alloc (** *lock_addr*,   *flags*,   *class*,   *occurrence*)**
void **lock_addr***;**
int *flags***;**
short *class***;**
short *occurrence***;**

Parameters

Item	Description
lock_addr	Specifies a valid simple or complex lock address.
flags	Specifies whether the memory allocated is to be pinned or pageable. Set this parameter as follows:

> **LOCK_ALLOC_PIN**
> Allocate pinned memory; use if it is not permissible to take a page fault while calling a locking kernel service for this lock.
>
> **LOCK_ALLOC_PAGED**
> Allocate pageable memory; use if it is permissible to take a page fault while calling a locking kernel service for this lock.

Item	Description
class	Specifies the family which the lock belongs to.
occurrence	Identifies the instance of the lock within the family. If only one instance of the lock is defined, this parameter should be set to -1.

Description

The **lock_alloc** kernel service allocates system memory for a simple or complex lock. The **lock_alloc** kernel service must be called for each simple or complex before the lock is initialized and used. The memory allocated is for internal lock instrumentation use, and is not returned to the caller; no memory is allocated if instrumentation is not used.

Execution Environment

The **lock_alloc** kernel service can be called from the process environment only.

Return Values

The **lock_alloc** kernel service has no return values.

Understanding Locking

lock_clear_recursive Kernel Service

Purpose

Prevents a complex lock from being acquired recursively.

Syntax

```
#include <sys/lock_def.h>
```

void lock_clear_recursive (*lock_addr*)
complex_lock_t *lock_addr*;

Parameter

Item	Description
lock_addr	Specifies the address of the lock word that will be protected from being acquired recursively.

Description

The **lock_clear_recursive** kernel service prevents the specified complex lock from being acquired recursively. The complex lock must have been made recursive by using the **lock_set_recursive** kernel service. The calling thread must hold the specified complex lock in write-exclusive mode.

Note: The **lock_set_recursive** and **lock_clear_recursive** kernel services must be used in pairs and must be called only when recursion is likely to occur. The **lock_set_recursive** kernel service must be called after making a call to the **lock_write** kernel service and the **lock_clear_recursive** kernel service must be called before making the call to the **lock_done** kernel service in routines where recursion might occur down the call stack.

Execution Environment

The **lock_clear_recursive** kernel service can be called from the process environment only.

Return Values

The **lock_clear_recursive** kernel service has no return values.

Related reference
lock_init Kernel Service
lock_done Kernel Service
Related information
Locking Kernel Services

lock_done Kernel Service

Purpose

Unlocks a complex lock.

Syntax

```
#include <sys/lock_def.h>
```

```
void lock_done ( lock_addr)
complex_lock_t lock_addr;
```

Parameter

Item	Description
lock_addr	Specifies the address of the lock word to unlock.

Description

The **lock_done** kernel services unlocks a complex lock. The calling kernel thread must hold the lock either in shared-read mode or exclusive-write mode. If one or more kernel threads are waiting to acquire the lock in exclusive-write mode, one of these kernel threads (the one with the highest priority) is made runnable and may compete for the lock. Otherwise, any kernel threads which are waiting to acquire the lock in shared-read mode are made runnable. If there was at least one kernel thread waiting for the lock, the priority of the calling kernel thread is recomputed.

If the lock is held recursively, it is not actually released until the **lock_done** kernel service has been called once for each time that the lock was locked.

Execution Environment

The **lock_done** kernel service can be called from the process environment only.

Return Values

The **lock_done** kernel service has no return values.

Locking Kernel Services

lock_free Kernel Service

Purpose

Frees the memory of a simple or complex lock.

Syntax

```
#include <sys/lock_def.h>
#include <sys/lock_alloc.h>
```

```
void lock_free ( lock_addr)
void *lock_addr;
```

Parameter

Item	Description
lock_addr	Specifies the address of the lock word whose memory is to be freed.

Description

The **lock_free** kernel service frees the memory of a simple or complex lock. The memory freed is the internal operating system memory which was allocated with the **lock_alloc** kernel service.

Note: It is only necessary to call the **lock_free** kernel service when the memory that the corresponding lock was protecting is released. For example, if you allocate memory for an i-node which is to be protected by a lock, you must allocate and initialize the lock before using it. The memory may be used with several i-nodes, each taken from, and returned to, the free i-node pool; the **lock_init** kernel service must be called each time this is done.The **lock_free** kernel service must be called when the memory allocated for the inode is finally freed.

Execution Environment

The **lock_free** kernel service can be called from the process environment only.

Return Values

The **lock_free** kernel service has no return values.

Related reference
lock_alloc Kernel Service

Understanding Locking
Locking Kernel Services

lock_init Kernel Service

Purpose

Initializes a complex lock.

Syntax

```
#include <sys/lock_def.h>
```

void lock_init (*lock_addr,* *can_sleep***)**
complex_lock_t *lock_addr;*
boolean_t *can_sleep;*

Parameters

Item	Description
lock_addr	Specifies the address of the lock word.
can_sleep	This parameter is ignored.

Description

The **lock_init** kernel service initializes the specified complex lock. This kernel service must be called for each complex lock before the lock is used. The complex lock must previously have been allocated with the **lock_alloc** kernel service. The *can_sleep* parameter is included for compatibility with OSF/1 1.1, but is ignored. Using a value of **TRUE** for this parameter will maintain OSF/1 1.1 semantics.

Execution Environment

The **lock_init** kernel service can be called from the process environment only.

Return Values

The **lock_init** kernel service has no return values.

Related reference
lock_alloc Kernel Service
lock_free Kernel Service
Related information
Understanding Locking
Locking Kernel Services

lock_islocked Kernel Service

Purpose

Tests whether a complex lock is locked.

Syntax

```
#include <sys/lock_def.h>
```

int lock_islocked (*lock_addr* **)**
complex_lock_t *lock_addr*;

Parameter

Item	Description
lock_addr	Specifies the address of the lock word to test.

Description

The **lock_islocked** kernel service determines whether the specified complex lock is free, or is locked in either shared-read or exclusive-write mode.

Execution Environment

The **lock_islocked** kernel service can be called from the process environment only.

Return Values

Item	Description
TRUE	Indicates that the lock was locked.
FALSE	Indicates that the lock was free.

Related reference
lock_init Kernel Service
Related information
Understanding Locking
Locking Kernel Services

lockl Kernel Service

Purpose

Locks a conventional process lock.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/lockl.h>
```

int lockl (*lock_word,* *flags***)**
lock_t *lock_word;
int *flags*;

Parameters

Item	Description
lock _word	Specifies the address of the lock word.
flags	Specifies the flags that control waiting for a lock. The *flags* parameter is used to control how signals affect waiting for a lock. The four flags are:

    LOCK_NDELAY
        Controls whether the caller waits for the lock. Setting the flag causes the request
        to be terminated. The lock is assigned to the caller. Not setting the flag causes
        the caller to wait until the lock is not owned by another process before the lock is
        assigned to the caller.

    LOCK_SHORT
        Prevents signals from terminating the wait for the lock. **LOCK_SHORT** is the default
        flag for the **lockl** Kernel Service. This flag causes non-preemptive sleep.

    LOCK_SIGRET
        Causes the wait for the lock to be terminated by an unmasked signal.

    LOCK_SIGWAKE
        Causes the wait for the lock to be terminated by an unmasked signal and control
        transferred to the return from the last operation by the **setjmpx** kernel service.

    Note: The **LOCK_SIGRET** flag overrides the **LOCK_SIGWAKE** flag.

Description

Note: The **lockl** kernel service is provided for compatibility only and should not be used in new code, which should instead use simple locks or complex locks.

The **lockl** kernel service locks a conventional lock

The lock word can be located in shared memory. It must be in the process's address space when the **lockl** or **unlockl** services are called. The kernel accesses the lock word only while executing under the caller's process.

The *lock_word* parameter is typically part of the data structure that describes the resource managed by the lock. This parameter must be initialized to the **LOCK_AVAIL** value before the first call to the **lockl** service. Only the **lockl** and **unlockl** services can alter this parameter while the lock is in use.

The **lockl** service is nestable. The caller should use the **LOCK_SUCC** value for determining when to call the **unlockl** service to unlock the conventional lock.

The **lockl** service temporarily assigns the owner the process priority of the most favored waiter for the lock.

A process must release all locks before terminating or leaving kernel mode. Signals are not delivered to kernel processes while those processes own any lock. "Understanding System Call Execution" in *Kernel Extensions and Device Support Programming Concepts* discusses how system calls can use the **lockl** service when accessing global data.

Execution Environment

The **lockl** kernel service can be called from the process environment only.

Return Values

Item	Description
LOCK_SUCC	Indicates that the process does not already own the lock or the lock is not owned by another process when the *flags* parameter is set to **LOCK_NDELAY**.
LOCK_NEST	Indicates that the process already owns the lock or the lock is not owned by another process when the *flags* parameter is set to **LOCK_NDELAY**.
LOCK_FAIL	Indicates that the lock is owned by another process when the *flags* parameter is set to **LOCK_NDELAY**.
LOCK_SIG	Indicates that the wait is terminated by a signal when the *flags* parameter is set to **LOCK_SIGRET**.

Locking Kernel Services

lock_mine Kernel Service

Purpose

Checks whether a simple or complex lock is owned by the caller.

Syntax

```
#include <sys/lock_def.h>
```

boolean_t lock_mine (*lock_addr*)
void *lock_addr;

Parameter

Item	Description
lock_addr	Specifies the address of the lock word to check.

Description

The **lock_mine** kernel service checks whether the specified simple or complex lock is owned by the calling kernel thread. Because a complex lock held in shared-read mode has no owner, the service returns FALSE in this case. This kernel service is provided to assist with debugging.

Execution Environment

The **lock_mine** kernel service can be called from the process environment only.

Return Values

Item	Description
TRUE	Indicates that the calling kernel thread owns the lock.
FALSE	Indicates that the calling kernel thread does not own the lock, or that a complex lock is held in shared-read mode.

Related reference
lock_init Kernel Service
lock_read or lock_try_read Kernel Service
lock_write or lock_try_write Kernel Service

Locking Kernel Services

lock_read or lock_try_read Kernel Service

Purpose

Locks a complex lock in shared-read mode.

Syntax

```
#include <sys/lock_def.h>
```

void lock_read (*lock_addr***)**
complex_lock_t *lock_addr***;**

boolean_t lock_try_read (*lock_addr***)**
complex_lock_t *lock_addr***;**

Parameter

Item	Description
lock_addr	Specifies the address of the lock word to lock.

Description

The **lock_read** kernel service locks the specified complex lock in shared-read mode; it blocks if the lock is locked in exclusive-write mode. The lock must previously have been initialized with the **lock_init** kernel service. The **lock_read** kernel service has no return values.

The **lock_try_read** kernel service tries to lock the specified complex lock in shared-read mode; it returns immediately if the lock is locked in exclusive-write mode, otherwise it locks the lock in shared-read mode. The lock must previously have been initialized with the **lock_init** kernel service.

Execution Environment

The **lock_read** and **lock_try_read** kernel services can be called from the process environment only.

Return Values

The **lock_try_read** kernel service has the following return values:

Item	Description
TRUE	Indicates that the lock was successfully acquired in shared-read mode.
FALSE	Indicates that the lock was not acquired.

Related reference
lock_init Kernel Service

Understanding Locking
Locking Kernel Services

lock_read_to_write or lock_try_read_to_write Kernel Service

Purpose

Upgrades a complex lock from shared-read mode to exclusive-write mode.

Syntax

```
#include <sys/lock_def.h>
```

boolean_t lock_read_to_write (*lock_addr*)
complex_lock_t *lock_addr*;

boolean_t lock_try_read_to_write (*lock_addr*)
complex_lock_t *lock_addr*;

Parameter

Item	Description
lock_addr	Specifies the address of the lock word to be converted from read-shared to write-exclusive mode.

Description

The **lock_read_to_write** and **lock_try_read_to_write** kernel services try to upgrade the specified complex lock from shared-read mode to exclusive-write mode. The lock is successfully upgraded if no other thread has already requested write-exclusive access for this lock. If the lock cannot be upgraded, it is no longer held on return from the **lock_read_to_write** kernel service; it is still held in shared-read mode on return from the **lock_try_read_to_write** kernel service.

The calling kernel thread must hold the lock in shared-read mode.

Execution Environment

The **lock_read_to_write** and **lock_try_read_to_write** kernel services can be called from the process environment only.

Return Values

The following only apply to **lock_read_to_write**:

Item	Description
TRUE	Indicates that the lock was not upgraded and is no longer held.
FALSE	Indicates that the lock was successfully upgraded to exclusive-write mode.

The following only apply to **lock_try_read_to_write**:

Item	Description
TRUE	Indicates that the lock was successfully upgraded to exclusive-write mode.
FALSE	Indicates that the lock was not upgraded and is held in read mode.

Locking Kernel Services

lock_set_recursive Kernel Service

Purpose

Prepares a complex lock for recursive use.

Syntax

```
#include <sys/lock_def.h>
```

void lock_set_recursive (*lock_addr***)**
complex_lock_t *lock_addr***;**

Parameter

Item	Description
lock_addr	Specifies the address of the lock word to be prepared for recursive use.

Description

The **lock_set_recursive** kernel service prepares the specified complex lock for recursive use. A complex lock cannot be nested until the **lock_set_recursive** kernel service is called for it. The calling kernel thread must hold the specified complex lock in write-exclusive mode.

When a complex lock is used recursively, the **lock_done** kernel service must be called once for each time that the thread is locked in order to unlock the lock.

Only the kernel thread which calls the **lock_set_recursive** kernel service for a lock may acquire that lock recursively.

Note: The **lock_set_recursive** and **lock_clear_recursive** kernel services must be used in pairs and must be called only when recursion is likely to occur. The **lock_set_recursive** kernel service must be called after making a call to the **lock_write** kernel service and the **lock_clear_recursive** kernel service must be

called before making the call to the **lock_done** kernel service in routines where recursion might occur down the call stack.

Execution Environment

The **lock_set_recursive** kernel service can be called from process environment only.

Return Values

The **lock_set_recursive** kernel service has no return values.

lock_write or lock_try_write Kernel Service

Purpose

Locks a complex lock in exclusive-write mode.

Syntax

```
#include <sys/lock_def.h>
```

void lock_write (** *lock_addr* **)
complex_lock_t *lock_addr*;

boolean_t lock_try_write (** *lock_addr* **)
complex_lock_t *lock_addr*;

Parameter

Item	Description
lock_addr	Specifies the address of the lock word to lock.

Description

The **lock_write** kernel service locks the specified complex lock in exclusive-write mode; it blocks if the lock is busy. The lock must have been previously initialized with the **lock_init** kernel service. The **lock_write** kernel service has no return values.

The **lock_try_write** kernel service tries to lock the specified complex lock in exclusive-write mode; it returns immediately without blocking if the lock is busy. The lock must have been previously initialized with the **lock_init** kernel service.

Execution Environment

The **lock_write** and **lock_try_write** kernel services can be called from the process environment only.

Return Values

The **lock_try_write** kernel service has the following parameters:

Item	Description
TRUE	Indicates that the lock was successfully acquired.
FALSE	Indicates that the lock was not acquired.

Related reference

Understanding Locking
Locking Kernel Services

lock_write_to_read Kernel Service

Purpose

Downgrades a complex lock from exclusive-write mode to shared-read mode.

Syntax

```
#include <sys/lock_def.h>
```

void lock_write_to_read (*lock_addr*)
complex_lock_t *lock_addr*;

Parameter

Item	Description
lock_addr	Specifies the address of the lock word to be downgraded from exclusive-write to shared-read mode.

Description

The **lock_write_to_read** kernel service downgrades the specified complex lock from exclusive-write mode to shared-read mode. The calling kernel thread must hold the lock in exclusive-write mode.

Once the lock has been downgraded to shared-read mode, other kernel threads will also be able to acquire it in shared-read mode.

Execution Environment

The **lock_write_to_read** kernel service can be called from the process environment only.

Return Values

The **lock_write_to_read** kernel service has no return values.

Related reference
lock_islocked Kernel Service
lock_read_to_write or lock_try_read_to_write Kernel Service

Understanding Locking

loifp Kernel Service

Purpose

Returns the address of the software loopback interface structure.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
struct ifnet *loifp ()
```

Description

The **loifp** kernel service returns the address of the **ifnet** structure associated with the software loopback interface. The interface address can be used to examine the interface flags. This address can also be used to determine whether the **looutput** kernel service can be called to send a packet through the loopback interface.

Execution Environment

The **loifp** kernel service can be called from either the process or interrupt environment.

Return Values

The **loifp** service returns the address of the **ifnet** structure describing the software loopback interface.

Related reference
looutput Kernel Service
Related information
Network Kernel Services

longjmpx Kernel Service

Purpose

Allows exception handling by causing execution to resume at the most recently saved context.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
int longjmpx ( ret_val)
int ret_val;
```

Parameters

Item	Description
ret_val	Specifies the return value to be supplied on the return from the **setjmpx** kernel service for the resumed context. This value normally indicates the type of exception that has occurred.

Description

The **longjmpx** kernel service causes the normal execution flow to be modified so that execution resumes at the most recently saved context. The kernel mode lock is reacquired if it is necessary. The interrupt priority level is reset to that of the saved context.

The **longjmpx** service internally calls the **clrjmpx** service to remove the jump buffer specified by the *jump_buffer* parameter from the list of contexts to be resumed. The **longjmpx** service always returns a nonzero value when returning to the restored context. Therefore, if the value of the *ret_val* parameter is 0, the **longjmpx** service returns an **EINTR** value to the restored context.

If there is no saved context to resume, the system crashes.

Execution Environment

The **longjmpx** kernel service can be called from either the process or interrupt environment.

Return Values

A successful call to the **longjmpx** service does not return to the caller. Instead, it causes execution to resume at the return from a previous **setjmpx** call with the return value of the *ret_val* parameter.

Understanding Exception Handling

Process and Exception Management Kernel Services

lookupvp, lookupname, lookupname_cur Kernel Services

Purpose

Retrieves the v-node that corresponds to the named path.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/uio.h>
```

int lookupvp (*namep*, *flags*, *compvpp*, *crp*)
char **namep*;
int *flags*;
struct vnode **compvpp;
struct ucred *crp;

int lookupname (*namep*, *seg*, *flags*, *dirvpp*, *compvpp*, *crp*)
char **namep*;
int *seg*;
int *flags*;
struct vnode **dirvpp;
struct vnode **compvpp;
struct cred *crp;

int lookupname_cur (*namep*, *seg*, *flags*, *dirvpp*, *compvpp*, *curdvp*, *crp*)
char **namep*;
int *seg*;
int *flags*;

```
struct vnode **dirvpp;
struct vnode **compvpp;
struct vnode **curdvp;
struct cred *crp;
```

Parameters

Item	Description
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.
namep	Points to a character string path name.
flags	Specifies lookup directives, including these six flags: **L_LOC** The path-name resolution must not cross a mount point into another file system implementation. **L_NOFOLLOW** If the final component of the path name resolves to a symbolic link, the link is not to be traversed. **L_NOXMOUNT** If the final component of the path name resolves to a mounted-over object, the mounted-over object, rather than the root of the next virtual file system, is to be returned. **L_CRT** The object is to be created. **L_DEL** The object is to be deleted. **L_EROFS** An error is to be returned if the object resides in a read-only file system.
seg	Specifies whether the *namep* buffer is in user space (UIO_USERSPACE) or kernel space (UIO_SYSSPACE).
compvpp	Points to the location where the vnode pointer for the named object is to be returned to the calling routine.
dirvpp	Points to the location where the vnode pointer for the directory containing the named object is to be returned.
curdvp	Points to the vnode for a current directory to be used instead of u_cdir.

Description

The **lookupvp** kernel service provides translation of the path name provided by the *namep* parameter into a virtual file system node. The **lookupvp** service provides a flexible interface to path-name resolution by regarding the *flags* parameter values as directives to the lookup process. The lookup process is a cooperative effort between the logical file system and underlying virtual file systems (VFS). Several v-node and VFS operations are employed to:

- Look up individual name components
- Read symbolic links
- Cross mount points

The **lookupvp** kernel service determines the process's current and root directories by consulting the u_cdir and u_rdir fields in the **u** structure. Information about the virtual file system and file system installation for transient v-nodes is obtained from each name component's **vfs** or **gfs** structure. The **lookupvp** kernel service assumes that the named path is in kernel address space.

The **lookupname** kernel service provides the same service as the **lookupvp** kernel service, but allows the caller to specify whether the path name is in kernel or user space. It also provides the ability to retrieve the vnode for the directory containing the named object. The **lookupname_cur** kernel service further extends the interface by allowing the lookup to proceed relative to the given *curdvp* directory.

The vnodes returned by the **lookup** services are held. The calling routine is responsible for releasing the hold by calling the **vnop_rele** entry point when it completes its operation.

Execution Environment

The **lookup** kernel services can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
errno	Indicates an error. This number is defined in the **/usr/include/sys/errno.h** file.

Related information

Virtual File System Overview
Virtual File System (VFS) Kernel Services

looutput Kernel Service

Purpose

Sends data through a software loopback interface.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
int looutput ( ifp,   m0,   dst)
struct   ifnet *ifp;
struct   mbuf *m0;
struct   sockaddr *dst;
```

Parameters

Item	Description
ifp	Specifies the address of an **ifnet** structure describing the software loopback interface.
m0	Specifies an **mbuf** chain containing output data.
dst	Specifies the address of a **sockaddr** structure that specifies the destination for the data.

Description

The **looutput** kernel service sends data through a software loopback interface. The data in the *m0* parameter is passed to the input handler of the protocol specified by the *dst* parameter.

Execution Environment

The **looutput** kernel service can be called from either the <u>process</u> or <u>interrupt</u> environment.

Return Values

Item	Description
0	Indicates that the data was successfully sent.
ENOBUFS	Indicates that resource allocation failed.
EAFNOSUPPORT	Indicates that the address family specified by the *dst* parameter is not supported.

Related reference
<u>loifp Kernel Service</u>
Related information
<u>Network Kernel Services</u>

ltpin Kernel Service

Purpose

Pins the address range in the system (kernel) space and frees the page space for the associated pages.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/pin.h>
```

```
int ltpin (addr, length)
caddr_t   addr;
int       length;
```

Parameters

Item	Description
addr	Specifies the address of the first byte to pin.
length	Specifies the number of bytes to pin.

Description

The **ltpin** (long term pin) kernel service pins the real memory pages touched by the address range specified by the *addr* and *length* parameters in the system (kernel) address space. It pins the real-memory pages to ensure that page faults do not occur for memory references in this address range. The **ltpin** kernel service increments the long-term pin count for each real-memory page. While either the long-term or short-term pin count is nonzero, the page cannot be paged out of real memory.

The **ltpin** kernel service pins either the entire address range or none of it. Only a limited number of pages are pinned in the system. If there are not enough unpinned pages in the system, the **ltpin** kernel service returns an error code. The **ltpin** kernel service is not a published interface.

Note: The operating system pins only whole pages at a time. Therfore, if the requested range is not aligned on a page boundary, then memory outside this range is also pinned.

The **ltpin** kernel service can only be called for addresses within the system (kernel) address space.

Return Values

Item	Description
0	Indicates successful completion.
EINVAL	Indicates that the *length* parameter has a negative value. Otherwise, the area of memory beginning at the address of the first byte to pin (the **addr** parameter) and extending for the number of bytes specified by the *length* parameter is not defined.
EIO	Indicates that a permanent I/O error occurred while referencing data.
ENOMEM	Indicates that the **pin** kernel service was unable to pin due to insufficient real memory or exceeding the system-wide pin count.
ENOSPC	Indicates insufficient file system or paging space.

Related reference

ltunpin Kernel Service

ltunpin Kernel Service

Purpose

Unpins the address range in system (kernel) address space and reallocates paging space for the specified region.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/pin.h>
```

```
int    ltunpin (addr, length)
caddr_t  addr;
int      length;
```

Parameters

Item	Description
addr	Specifies the address of the first byte to unpin.
length	Specifies the number of bytes to unpin.

Description

The **ltunpin** kernel service decreases the long-term pin count of each page in the address range. When the long-term pin count becomes 0, the backing storage (paging space) for the memory region is allocated and assigned to the pages. When both the long-term and short-term pin counts are 0, the page is no longer pinned and the **ltunpin** kernel service will assert. If allocating backing pages would put the system below the low paging space threshold, the call waits until paging space becomes available.

The **ltunpin** kernel service can only be called with addresses in the system (kernel) address space from the process environment.

Return Values

Item	Description
0	Indicates successful completion.
EINVAL	Indicates that the *length* parameter is a negative value.

Item	Description
EIO	Indicates that a permanent I/O error occurred while referencing data.

Related reference

ltpin Kernel Service

m

The following kernel services begin with the with the letter m.

m_adj Kernel Service

Purpose

Adjusts the size of an **mbuf** chain.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
```

```
void m_adj ( m,  diff)
struct mbuf *m;
int diff;
```

Parameters

Item	Description
m	Specifies the **mbuf** chain to be adjusted.
diff	Specifies the number of bytes to be removed.

Description

The **m_adj** kernel service adjusts the size of an **mbuf** chain by the number of bytes specified by the *diff* parameter. If the number specified by the *diff* parameter is nonnegative, the bytes are removed from the front of the chain. If this number is negative, the alteration is done from back to front.

Execution Environment

The **m_adj** kernel service can be called from either the process or interrupt environment.

Return Values

The **m_adj** service has no return values.

Related information

I/O Kernel Services

mbreq Structure for mbuf Kernel Services

Purpose

Contains **mbuf** structure registration information for the **m_reg** and **m_dereg** kernel services.

Syntax

```
#include <sys/mbuf.h>
```

```
struct mbreq {
                int low_mbuf;
                int low_clust;
                int initial_mbuf;
                int initial_clust;
}
```

Parameters

Item	Description
low_mbuf	Specifies the **mbuf** structure low-water mark.
low_clust	Specifies the page-sized **mbuf** structure low-water mark.
initial_mbuf	Specifies the initial allocation of **mbuf** structures.
initial_clust	Specifies the initial allocation of page-sized **mbuf** structures.

Description

The **mbreq** structure specifies the **mbuf** structure usage expectations for a user of **mbuf** kernel services.

Related reference
m_dereg Kernel Service
m_reg Kernel Service

I/O Kernel Services

mbstat Structure for mbuf Kernel Services

Purpose

Contains **mbuf** usage statistics.

Syntax

```
#include <sys/mbuf.h>
```

```
struct mbstat {
ulong m_mbufs;
ulong m_clusters;
ulong m_spare;
ulong m_clfree;
ulong m_drops;
ulong m_wait;
ulong m_drain;
short m_mtypes[256];
}
```

Parameters

Item	Description
m_mbufs	Specifies the number of **mbuf** structures allocated.
m_clusters	Specifies the number of clusters allocated.
m_spare	Specifies the spare field.

Item	Description
m_clfree	Specifies the number of free clusters.
m_drops	Specifies the times failed to find space.
m_wait	Specifies the times waited for space.
m_drain	Specifies the times drained protocols for space.
m_mtypes	Specifies the type-specific **mbuf** structure allocations.

Description

The **mbstat** structure provides usage information for the **mbuf** services. Statistics can be viewed through the **netstat -m** command.

Related information

netstat subroutine

I/O Kernel Services

m_cat Kernel Service

Purpose

Appends one **mbuf** chain to the end of another.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
```

```
void m_cat ( m, n)
struct mbuf *m;
struct mbuf *n;
```

Parameters

Item	Description
m	Specifies the **mbuf** chain to be appended to.
n	Specifies the **mbuf** chain to append.

Description

The **m_cat** kernel service appends an **mbuf** chain specified by the *n* parameter to the end of **mbuf** chain specified by the *m* parameter. Where possible, compaction is performed.

Execution Environment

The **m_cat** kernel service can be called from either the process or interrupt environment.

Return Values

The **m_cat** service has no return values.

m_clattach Kernel Service

Purpose

Allocates an **mbuf** structure and attaches an external cluster.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
```

struct mbuf *
m_clattach(*ext_buf*, *ext_free*, *ext_size*, *ext_arg*, *wait***)**
caddr_t *ext_buf*;
int (***ext_free*)();
int *ext_size*;
int *ext_arg*;
int *wait*;

Parameters

Item	Description
ext_buf	Specifies the address of the external data area.
ext_free	Specifies the address of a function to be called when this **mbuf** structure is freed.
ext_size	Specifies the length of the external data area.
ext_arg	Specifies an argument to pass to the above function.
wait	Specifies either the **M_WAIT** or **M_DONTWAIT** value.

Description

The **m_clattach** kernel service allocates an **mbuf** structure and attaches the cluster specified by the *ext_buf* parameter. This data is owned by the caller. The m_data field of the returned **mbuf** structure points to the caller's data. Interrupt handlers can call this service only with the *wait* parameter set to **M_DONTWAIT**.

Note: The **m_clattach** kernel service replaces the **m_clgetx** kernel service, which is no longer supported.

The calling function is required to fill out the mbuf structure sufficiently to support normal usage. This includes support for the DMA functions during network transmission. To support DMA functions, the **ext_hasxm** flag field needs to be set to true and the **ext_xmemd** structure needs to be filled out. For buffers allocated from the kernel pinned heap, the **ext_xmemd.aspace_id** field should be set to XMEM_GLOBAL.

Execution Environment

The **m_clattach** kernel service can be called from either the process or interrupt environment.

Return Values

The **m_clattach** kernel service returns the address of an allocated **mbuf** structure. If the *wait* parameter is set to **M_DONTWAIT** and there are no free **mbuf** structures, the **m_clattach** service returns null.

m_clget Macro for mbuf Kernel Services

Purpose

Allocates a page-sized **mbuf** structure cluster.

Syntax

```
#include <sys/mbuf.h>
```

int m_clget (_m_)
struct mbuf *_m_;

Parameter

Item	Description
_m_	Specifies the **mbuf** structure with which the cluster is to be associated.

Description

The **m_clget** macro allocates a page-sized **mbuf** cluster and attaches it to the given **mbuf** structure. If successful, the length of the **mbuf** structure is set to **CLBYTES**.

Execution Environment

The **m_clget** macro can be called from either the process or interrupt environment.

Return Values

Item	Description
1	Indicates successful completion.
0	Indicates an error.

Related reference
m_clgetm Kernel Service
Related information
I/O Kernel Services

m_clgetm Kernel Service

Purpose

Allocates and attaches an external buffer.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
#include <net/net_globals.h>
```

```
int
m_clgetm( m,  how,  size)
struct mbuf *m;
int  how;
int  size;
```

Parameters

Item	Description
m	Specifies the **mbuf** structure that the cluster will be associated with.
how	Specifies either the **M_DONTWAIT** or **M_WAIT** value.
size	Specifies the size of external cluster to attach. Any value less than MAXALLOCSAVE is valid. For larger values, M_WAIT must be specified.

Description

The **m_clgetm** service allocates an **mbuf** cluster of the specified number of bytes and attaches it to the **mbuf** structure indicated by the *m* parameter. If successful, the **m_clgetm** service sets the **M_EXT** flag.

Execution Environment

The **m_clgetm** kernel service can be called from either the process or interrupt environment.

An interrupt handler can specify the *wait* parameter as **M_DONTWAIT** only.

Return Values

Item	Description
1	Indicates a successful operation.

If there are no free **mbuf** structures, the **m_clgetm** kernel service returns a null value.

Related reference
m_freem Kernel Service
m_get Kernel Service
m_clget Macro for mbuf Kernel Services
Related information
I/O Kernel Services

m_collapse Kernel Service

Purpose

Guarantees that an **mbuf** chain contains no more than a given number of **mbuf** structures.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
```

struct mbuf *m_collapse (*m*, *size*)
struct mbuf *m;
int *size*;

Parameters

Item	Description
m	Specifies the **mbuf** chain to be collapsed.
size	Denotes the maximum number of **mbuf** structures allowed in the chain.

Description

The **m_collapse** kernel service reduces the number of **mbuf** structures in an **mbuf** chain to the number of **mbuf** structures specified by the *size* parameter. The **m_collapse** service accomplishes this by copying data into page-sized **mbuf** structures until the chain is of the desired length. (If required, more than one page-sized **mbuf** structure is used.)

Execution Environment

The **m_collapse** kernel service can be called from either the process or interrupt environment.

Return Values

If the chain cannot be collapsed into the number of **mbuf** structures specified by the *size* parameter, a value of null is returned and the original chain is deallocated. Upon successful completion, the head of the altered **mbuf** chain is returned.

Related information

I/O Kernel Services

m_copy Macro for mbuf Kernel Services

Purpose

Creates a copy of all or part of a list of **mbuf** structures.

Syntax

```
#include <sys/mbuf.h>
```

struct mbuf *m_copy (*m*, *off*, *len*)
struct mbuf *m;
int *off*;
int *len*;

Parameters

Item	Description
m	Specifies the **mbuf** structure, or the head of a list of **mbuf** structures, to be copied.
off	Specifies an offset into data from which copying starts.
len	Denotes the total number of bytes to copy.

Description

The **m_copy** macro makes a copy of the structure specified by the *m* parameter. The copy begins at the specified bytes (represented by the *off* parameter) and continues for the number of bytes specified by the *len* parameter. If the *len* parameter is set to **M_COPYALL**, the entire **mbuf** chain is copied.

Execution Environment

The **m_copy** macro can be called from either the process or interrupt environment.

Return Values

Upon successful completion, the address of the copied list (the **mbuf** structure that heads the list) is returned. If the copy fails, a value of null is returned.

I/O Kernel Services

m_copydata Kernel Service

Purpose

Copies data from an **mbuf** chain to a specified buffer.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
```

```
void m_copydata (m, off, len, cp)
struct mbuf  * m;
int     off;
int     len;
caddr_t    cp;
```

Parameters

Item	Description
m	Indicates the **mbuf** structure, or the head of a list of **mbuf** structures, to be copied.
off	Specifies an offset into data from which copying starts.

Ite m	Description
len	Denotes the total number of bytes to copy.
cp	Points to a data buffer into which to copy the **mbuf** data.

Description

The **m_copydata** kernel service makes a copy of the structure specified by the *m* parameter. The copy begins at the specified bytes (represented by the *off* parameter) and continues for the number of bytes specified by the *len* parameter. The data is copied into the buffer specified by the *cp* parameter.

Execution Environment

The **m_copydata** kernel service can be called from either the process or interrupt environment.

Return Values

The **mcopydata** service has no return values.

Related reference
m_copy Macro for mbuf Kernel Services
Related information
I/O Kernel Services

m_copym Kernel Service

Purpose

Creates a copy of all or part of a list of **mbuf** structures.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
```

struct mbuf *
m_copym(*m,*   *off,*   *len,*   *wait***)**
struct mbuf   *m;*
int   *off;*
int   *len;*
int   *wait;*

Parameters

Item	Description
m	Specifies the **mbuf** structure to be copied.
off	Specifies an offset into data from which copying will start.
len	Specifies the total number of bytes to copy.
wait	Specifies either the **M_DONTWAIT** or **M_WAIT** value.

Description

The **m_copym** kernel service makes a copy of the **mbuf** structure specified by the *m* parameter starting at the specified offset from the beginning and continuing for the number of bytes specified by the *len* parameter. If the *len* parameter is set to **M_COPYALL**, the entire **mbuf** chain is copied.

If the **mbuf** structure specified by the *m* parameter has an external buffer attached (that is, the **M_EXT** flag is set), the copy is done by reference to the external cluster. In this case, the data must not be altered or both copies will be changed. Interrupt handlers can specify the *wait* parameter as **M_DONTWAIT** only.

Execution Environment

The **m_copym** kernel service can be called from either the process or interrupt environment.

Return Values

The address of the copy is returned upon successful completion. If the copy fails, null is returned. If the *wait* parameter is set to **M_DONTWAIT** and there are no free **mbuf** structures, the **m_copym** kernel service returns a null value.

Related reference

m_dereg Kernel Service

Purpose

Deregisters expected **mbuf** structure usage.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
```

void m_dereg (*mbp***)**
struct mbreq *mbp***;**

Parameter

Item	Description
mbp	Defines the address of an **mbreq** structure that specifies expected **mbuf** usage.

Description

The **m_dereg** kernel service deregisters requirements previously registered with the **m_reg** kernel service. The **m_dereg** service is mandatory if the **m_reg** service is called.

Execution Environment

The **m_dereg** kernel service can be called from the process environment only.

Return Values

The **m_dereg** service has no return values.

m_free Kernel Service

Purpose

Frees an **mbuf** structure and any associated external storage area.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
```

struct mbuf *m_free(*m*)
struct mbuf *m;

Parameter

Item	Description
m	Specifies the **mbuf** structure to be freed.

Description

The **m_free** kernel service returns an **mbuf** structure to the buffer pool. If the **mbuf** structure specified by the *m* parameter has an attached cluster (that is, a paged-size **mbuf** structure), the **m_free** kernel service also frees the associated external storage.

Execution Environment

The **m_free** kernel service can be called from either the process or interrupt environment.

Return Values

If the **mbuf** structure specified by the *m* parameter is the head of an **mbuf** chain, the **m_free** service returns the next **mbuf** structure in the chain. A null value is returned if the structure specified by the *m* parameter is not part of an **mbuf** chain.

Related reference
m_get Kernel Service

I/O Kernel Services

m_freem Kernel Service

Purpose

Frees an entire **mbuf** chain.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
```

```
void m_freem ( m)
struct mbuf *m;
```

Parameter

Item	Description
m	Indicates the head of the **mbuf** chain to be freed.

Description

The **m_freem** kernel service starts the **m_free** kernel service for each **mbuf** structure in the chain headed by the head specified by the *m* parameter.

Execution Environment

The **m_freem** kernel service can be called from either the process or interrupt environment.

Return Values

The **m_freem** service has no return values.

m_get Kernel Service

Purpose

Allocates a memory buffer (mbuf) from the **mbuf** pool.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
```

```
struct mbuf *m_get ( wait,  type)
int  wait;
int  type;
```

Parameters

Item	Description
wait	Indicates the action to be taken if there are no free **mbuf** structures. Possible values are:

> **M_DONTWAIT**
>> Called from either an interrupt or process environment.
>
> **M_WAIT**
>> Called from a process environment.

Item	Description
type	Specifies a valid **mbuf** type, as listed in the **/usr/include/sys/mbuf.h** file.

Description

The **m_get** kernel service allocates an **mbuf** structure of the specified type. If the buffer pool is empty and the *wait* parameter is set to **M_WAIT**, the **m_get** kernel service does not return until an **mbuf** structure is available.

Execution Environment

The **m_get** kernel service can be called from either the process or interrupt environment.

An interrupt handler can specify the *wait* parameter as **M_DONTWAIT** only.

Return Values

Upon successful completion, the **m_get** service returns the address of an allocated **mbuf** structure. If the *wait* parameter is set to **M_DONTWAIT** and there are no free **mbuf** structures, the **m_get** kernel service returns a null value.

I/O Kernel Services

m_getclr Kernel Service

Purpose

Allocates and zeroes a memory buffer from the **mbuf** pool.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
```

struct mbuf *m_getclr (*wait*, *type*)
int *wait*;
int *type*;

Parameters

Item	Description
wait	This flag indicates the action to be taken if there are no free **mbuf** structures. Possible values are:

    M_DONTWAIT
        Called from either an interrupt or process environment.

    M_WAIT
        Called from a process environment only.

Item	Description
type	Specifies a valid **mbuf** type, as listed in the **/usr/include/sys/mbuf.h** file.

Description

The **m_getclr** kernel service allocates an **mbuf** structure of the specified type. If the buffer pool is empty and the *wait* parameter is set to **M_WAIT** value, the **m_getclr** service does not return until an **mbuf** structure is available.

The **m_getclr** kernel service differs from the **m_get** kernel service in that the **m_getclr** service zeroes the data portion of the allocated **mbuf** structure.

Execution Environment

The **m_getclr** kernel service can be called from either the process or interrupt environment. Interrupt handlers can call the **m_getclr** service only with the *wait* parameter set to the **M_DONTWAIT** value.

Return Values

The **m_getclr** kernel service returns the address of an allocated **mbuf** structure. If the *wait* parameter is set to the **M_DONTWAIT** value and there are no free **mbuf** structures, the **m_getclr** kernel service returns a null value.

m_getclust Macro for mbuf Kernel Services

Purpose

Allocates an **mbuf** structure from the **mbuf** buffer pool and attaches a page-sized cluster.

Syntax

```
#include <sys/mbuf.h>
```

```
struct mbuf *m_getclust ( wait,  type)
int  wait;
int  type;
```

Parameters

Item	Description
wait	Indicates the action to be taken if there are no available **mbuf** structures. Possible values are:

> **M_DONTWAIT**
> Called from either an interrupt or process environment.
>
> **M_WAIT**
> Called from a process environment only.

Item	Description
type	Specifies a valid **mbuf** type from the **/usr/include/sys/mbuf.h** file.

Description

The **m_getclust** macro allocates an **mbuf** structure of the specified type. If the allocation succeeds, the **m_getclust** macro then attempts to attach a page-sized cluster to the structure.

If the buffer pool is empty and the *wait* parameter is set to **M_WAIT**, the **m_getclust** macro does not return until an **mbuf** structure is available.

Execution Environment

The **m_getclust** macro can be called from either the process or interrupt environment.

Return Values

The address of an allocated **mbuf** structure is returned on success. If the *wait* parameter is set to **M_DONTWAIT** and there are no free **mbuf** structures, the **m_getclust** macro returns a null value.

Related reference
m_getclustm Kernel Service
Related information
I/O Kernel Services

m_getclustm Kernel Service

Purpose

Allocates an **mbuf** structure and attaches a cluster of the specified size, both from the **mbuf** buffer pool.

Syntax

```
#include <sys/mbuf.h>
#include <net/net_globals.h>
```

struct mbuf *
m_getclustm(*wait,   type,   size***)**
int *wait***;**
int *type***;**
int *size***;**

Parameters

Item	Description
wait	Specifies either the **M_DONTWAIT** or **M_WAIT** value.
type	Specifies a valid **mbuf** type from the **/usr/include/sys/mbuf.h** file.

Item	Description
size	Specifies the size of the external cluster to attach. Any value less than MAXALLOCSAVE is valid. For larger values, M_WAIT must be specified.

Description

The **m_getclustm** service allocates an **mbuf** structure of the specified type. If successful, the **m_getclustm** service then attempts to attach a cluster of the indicated size (specified by the *size* parameter) to the **mbuf** structure. If the buffer pool is empty and the *wait* parameter is set to **M_WAIT**, the **m_get** service does not return until an **mbuf** structure is available. Interrupt handlers should call this service only with the *wait* parameter set to **M_DONTWAIT**.

Execution Environment

The **m_getclustm** kernel service can be called from either the process or interrupt environment.

An interrupt handler can specify the *wait* parameter as **M_DONTWAIT** only.

Return Values

The **m_getclustm** kernel service returns the address of an allocated **mbuf** structure on success. If the *wait* parameter is set to **M_DONTWAIT** and there are no free **mbuf** structures, the **m_getclustm** kernel service returns null.

m_gethdr Kernel Service

Purpose

Allocates a header memory buffer from the **mbuf** pool.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
```

struct mbuf *
m_gethdr (*wait*, *type*)
int *wait*;
int *type*;

Parameters

Item	Description
wait	Specifies either the **M_DONTWAIT** or **M_WAIT** value.
type	Specifies the valid **mbuf** type from the **/usr/include/sys/mbuf.h** file.

Description

The **m_gethdr** kernel service allocates an **mbuf** structure of the specified type. If the buffer pool is empty and the *wait* parameter is set to **M_WAIT**, the **m_gethdr** kernel service will not return until an **mbuf** structure is available. Interrupt handlers should call this kernel service only with the *wait* parameter set to **M_DONTWAIT**. The **M_PKTHDR** flag is set for the returned **mbuf** structure.

Execution Environment

The **m_gethdr** kernel service can be called from either the process or interrupt environment.

An interrupt handler can specify the *wait* parameter as **M_DONTWAIT** only.

Return Values

The address of an allocated **mbuf** structure is returned on success. If the *wait* parameter is set to **M_DONTWAIT** and there are no free **mbuf** structure, the **m_gethdr** kernel service returns null.

Related Information

The **m_free** kernel service, **m_freem** kernel service.

M_HASCL Macro for mbuf Kernel Services

Purpose

Determines if an **mbuf** structure has an attached cluster.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
```

struct mbuf * *m*;
M_HASCL (*m*);

Parameter

Item	Description
m	Indicates the address of the **mbuf** structure in question.

Description

The **M_HASCL** macro determines if an **mbuf** structure has an attached cluster.

Execution Environment

The **M_HASCL** macro can be called from either the process or interrupt environment.

Example

The **M_HASCL** macro can be used as in the following example:

```
struct mbuf  *m;
if (M_HASCL(m))
    printf("mbuf has attached cluster");
```

Related information
I/O Kernel Services

m_pullup Kernel Service

Purpose

Adjusts an **mbuf** chain so that a given number of bytes is in contiguous memory in the data area of the head **mbuf** structure.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
```

struct mbuf *m_pullup (*m*, *size*)
struct mbuf *m;
int *size*;

Parameters

Item	Description
m	Specifies the **mbuf** chain to be adjusted.
size	Specifies the number of bytes to be contiguous.

Description

The **m_pullup** kernel service guarantees that the **mbuf** structure at the head of a chain has in contiguous memory within its data area at least the number of data bytes specified by the *size* parameter.

Execution Environment

The **m_pullup** kernel service can be called from either the process or interrupt environment.

Return Values

Upon successful completion, the head structure in the altered **mbuf** chain is returned.

A value of null is returned and the original chain is deallocated under the following circumstances:

- The size of the chain is less than indicated by the *size* parameter.
- The number indicated by the *size* parameter is greater than the data portion of the head-size **mbuf** structure.

m_reg Kernel Service

Purpose

Registers expected **mbuf** usage.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
```

void m_reg (*mbp*)
struct mbreq *mbp*;

Parameter

Item	Description
mbp	Defines the address of an **mbreq** structure that specifies expected **mbuf** usage.

Description

The **m_reg** kernel service lets users of **mbuf** services specify initial requirements. The **m_reg** kernel service also allows the buffer pool low-water and deallocation marks to be adjusted based on expected usage. Its use is recommended for better control of the buffer pool.

When the number of free **mbuf** structures falls below the low-water mark, the total **mbuf** pool is expanded. When the number of free **mbuf** structures rises above the deallocation mark, the total **mbuf** pool is contracted and resources are returned to the system.

Execution Environment

The **m_reg** kernel service can be called from the process environment only.

Return Values

The **m_reg** service has no return values.

md_restart_block_read Kernel Service

Purpose

A copy of the **RESTART_BLOCK** structure in the **NVRAM** header will be placed in the caller's buffer.

Syntax

```
#include <sys/mdio.h>
```

```
int md_restart_block_read (md)
                struct mdio *md;
```

Parameters

Item	Description
md	Specifies the address of the **mdio** structure. The **mdio** structure contains the following fields:

    md_data
        Pointer to the data buffer.

    md_size
        Number of bytes in the data buffer.

    md_addr
        Contains the value PMMode on return in the least significant byte.

Description

The RestartBlock which is in the **NVRAM** header will be copied to the user supplied buffer. This block is a communication vehicle for the software and the firmware.

Return Values

Returns 0 for successful completion.

Item	Description
ENOMEM	Indicates that there was not enough room in the user supplied buffer to contain the RestartBlock.
EINVAL	Indicates this is not a PowerPC® reference platform.

Prerequisite Information

Kernel Extensions and Device Driver Management Kernel Services in Kernel Extensions and Device Support Programming Concepts.

Machine Device Driver

md_restart_block_upd Kernel Service

Purpose

The caller supplied RestartBlock will be copied to the **NVRAM** header.

Syntax

```
#include <sys/mdio.h>
```

```
int md_restart_block_upd (md, pmmode)
                struct mdio *md;
                unsigned char pmmode;
```

Description

The 8-bit value in *pmmode* will be stored into the **NVRAM** header at the PMMode offset.The RestartBlock which is in the caller's buffer will be copied to the **NVRAM** after the RestartBlock checksum is calculated and a new Crc1 value is computed.

Parameters

Item	Description
md	Specifies the address of the **mdio** structure. The **mdio** structure contains the following fields: **md_data** Pointer to the RestartBlock structure..
pmmode	Value to be stored into PMMode in the **NVRAM** header.

Return Values

Returns 0 for successful completion.

Item	Description
EINVAL	Indicates this is not a PowerPC reference platform.

Prerequisite Information

Kernel Extensions and Device Driver Management Kernel Services in Kernel Extensions and Device Support Programming Concepts.

MTOCL Macro for mbuf Kernel Services

Purpose

Converts a pointer to an **mbuf** structure to a pointer to the head of an attached cluster.

Syntax

```
#include <sys/mbuf.h>
```

```
struct mbuf * m;
MTOCL (m);
```

Parameter

Item	Description
m	Indicates the address of the **mbuf** structure in question.

Description

The **MTOCL** macro converts a pointer to an **mbuf** structure to a pointer to the head of an attached cluster.

The **MTOCL** macro can be used as in the following example:

```
caddr_t attcls;
struct mbuf       *m;
attcls = (caddr_t) MTOCL(m);
```

Execution Environment

The **MTOCL** macro can be called from either the <u>process</u> or <u>interrupt</u> environment.

Related reference
<u>M_HASCL Macro for mbuf Kernel Services</u>
Related information
<u>I/O Kernel Services</u>

MTOD Macro for mbuf Kernel Services

Purpose

Converts a pointer to an **mbuf** structure to a pointer to the data stored in that **mbuf** structure.

Syntax

```
#include <sys/mbuf.h>
```

MTOD (_m_, _type_);

Parameters

Item	Description
_m_	Identifies the address of an **mbuf** structure.
type	Indicates the type to which the resulting pointer should be cast.

Description

The **MTOD** macro converts a pointer to an **mbuf** structure into a pointer to the data stored in the **mbuf** structure. This macro can be used as in the following example:

```
char    *bufp;
        bufp = MTOD(m, char *);
```

Execution Environment

The **MTOD** macro can be called from either the <u>process</u> or <u>interrupt</u> environment.

Related reference
<u>DTOM Macro for mbuf Kernel Services</u>
Related information
<u>I/O Kernel Services</u>

M_XMEMD Macro for mbuf Kernel Services

Purpose

Returns the address of an **mbuf** cross-memory descriptor.

Syntax

```
#include    <sys/mbuf.h>
#include    <sys/xmem.h>
```

struct mbuf * *m***;**

```
M_XMEMD (m);
```

Parameter

Item	Description
m	Specifies the address of the **mbuf** structure in question.

Description

The **M_XMEMD** macro returns the address of an **mbuf** cross-memory descriptor.

Execution Environment

The **M_XMEMD** macro can be called from either the process or interrupt environment.

Example

The **M_XMEMD** macro can be used as in the following example:

```
struct mbuf    *m;
struct xmem    *xmemd;
```

```
xmemd = M_XMEMD(m);
```

Related information
I/O Kernel Services

mycpu Kernel Service

Purpose

Gets the bind ID of the processor we are running on.

Syntax

```
#include <sys/processor.h>
```

cpu_t myc ()

Description

The **mycpu** kernel service returns the bind ID of the processor we are currently running on.

Execution Environment

The **mycpu** kernel services can be called from either the process or interrupt environment. This routine must be called disabled. Otherwise, the calling thread might be preempted and resume execution on a different processor resulting in a stale value being returned.

Return Values

The **mycpu** kernel service returns the bind ID of the current processor.

Related reference

bindprocessor Kernel Service

n

The following kernel services begin with the with the letter n.

nameToXfid() Kernel Service

Purpose

Obtains the `xfid` value and attributes for a specific file name.

Syntax

```
#include <sys/xfops.h>
#include <sys/vattr.h>

int     nameToXfid(char *pathname,
                        struct xfid *xfp,
                        struct vattr *vap,
                        long flags);
```

Description

A kernel extension might need to convert a path name to an `xfid_t` structure. The `nameToXfid()` kernel service returns the `xfid` value for a specific path name.

Parameters

pathname
   Full path name of the file for which an `xfid` value is needed.

xfp
   Pointer to an `xfid_t` structure to hold the `xfid` value that is set by this routine.

vap
   Pointer to a `vattr` structure to be entered by this routine. No attributes are set if the pointer is null.

flags
   Operation modifiers. This parameter must be set to zero.

Return values

0
   Indicates success. The `xfid` value and the optional `vattr` structure are returned.

ENOENT
   Name not found.

EPERM
   No permission for lookup.

EINVAL
   Invalid parameter is specified.

net_attach Kernel Service

Purpose

Opens a communications I/O device handler.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <aixif/net_if.h>
#include <sys/comio.h>
```

```
int net_attach (kopen_ext, device_req, netid, netfpp)
struct   kopen_ext * kopen_ext;
struct   device_req * device_req;
struct   netid_list * netid;
struct file  ** netfpp;
```

Parameters

Item	Description
kopen_ext	Specifies the device handler kernel open extension.
device_req	Indicates the address of the device description structure.
netid	Indicates the address of the network ID list.
netfpp	Specifies the address of the variable that will hold the returned file pointer.

Description

The **net_attach** kernel service opens the device handler specified by the *device_req* parameter and then starts all the network IDs listed in the address specified by the *netid* parameter. The **net_attach** service then sleeps and waits for the asynchronous `start completion` notifications from the **net_start_done** kernel service.

Execution Environment

The **net_attach** kernel service can be called from the process environment only.

Return Values

Upon success, a value of 0 is returned and a file pointer is stored in the address specified by the *netfpp* parameter. Upon failure, the **net_attach** service returns either the error codes received from the **fp_opendev** or **fp_ioctl** kernel service, or the value **ETIMEDOUT**. The latter value is returned when an open operation times out.

Related reference

Network Kernel Services

net_detach Kernel Service

Purpose

Closes a communications I/O device handler.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <aixif/net_if.h>
```

int net_detach (*netfp***)**
struct file *****netfp*;**

Parameter

Item	Description
netfp	Points to an open file structure obtained from the **net_attach** kernel service.

Description

The **net_detach** kernel service closes the device handler associated with the file pointer specified by the *netfp* parameter.

Execution Environment

The **net_detach** kernel service can be called from the process environment only.

Return Values

The **net_detach** service returns the value it obtains from the **fp_close** service.

Related reference
fp_close Kernel Service
net_attach Kernel Service

net_error Kernel Service

Purpose

Handles errors for communication network interface drivers.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/if.h>
#include <sys/comio.h>
```

net_error (*ifp*, *error_code*, *netfp***)**
struct ifnet *****ifp*;**
int *error_code*;**
struct file *****netfp*;**

Parameters

Item	Description
error_code	Specifies the error code listed in the **/usr/include/sys/comio.h** file.
ifp	Specifies the address of the **ifnet** structure for the device with an error.

Item	Description
netfp	Specifies the file pointer for the device with an error.

Description

The **net_error** kernel service provides generic error handling for communications network interface (**if**) drivers. Network interface (**if**) kernel extensions call this service to trace errors and, in some instances, perform error recovery.

Errors traced include those:

- Received from the communications adapter drivers.
- Occurring during input and output packet processing.

Execution Environment

The **net_error** kernel service can be called from either the <u>process</u> or <u>interrupt</u> environment.

Return Values

The **net_error** service has no return values.

Related reference
<u>net_attach Kernel Service</u>
<u>net_detach Kernel Service</u>

<u>Network Kernel Services</u>

net_sleep Kernel Service

Purpose

Sleeps on the specified wait channel.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/pri.h>
```

net_sleep (*chan*, *flags*)
int *chan*;
int *flags*;

Parameters

Item	Description
chan	Specifies the wait channel to sleep upon.
flags	Sleep flags described in the **sleep** kernel service.

Description

The **net_sleep** kernel service puts the caller to sleep waiting on the specified wait channel. If the caller holds the network lock, the **net_sleep** kernel service releases the lock before sleeping and reacquires the lock when the caller is awakened.

Execution Environment

The **net_sleep** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates that the sleeping process was not awakened by a signal.
1	Indicates that the sleeper was awakened by a signal.

Related reference
net_wakeup Kernel Service
sleep Kernel Service

Network Kernel Services

net_start Kernel Service

Purpose

Starts network IDs on a communications I/O device handler.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <aixif/net_if.h>
#include <sys/comio.h>
```

struct file *net_start (*netfp*, *netid*)
struct file ***netfp;**
struct netid_list ***netid;**

Parameters

Item	Description
netfp	Specifies the file pointer of the device handler.
netid	Specifies the address of the network ID list.

Description

The **net_start** kernel service starts all the network IDs listed in the list specified by the *netid* parameter. This service then waits for the asynchronous notification of completion of starts.

Execution Environment

The **net_start** kernel service can be called from the process environment only.

Return Values

The **net_start** service uses the return value returned from a call to the **fp_ioctl** service requesting the **CIO_START** operation.

Item	Description
ETIMEDOUT	Indicates that the start for at least one network ID timed out waiting for start-done notifications from the device handler.

Related reference
fp_ioctl Kernel Service
net_attach Kernel Service
net_start_done Kernel Service

Network Kernel Services

net_start_done Kernel Service

Purpose

Starts the done notification handler for communications I/O device handlers.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <aixif/net_if.h>
#include <sys/comio.h>
```

```
void net_start_done ( netid,  sbp)
struct   netid_list *netid;
struct   status_block *sbp;
```

Parameters

Item	Description
netid	Specifies the address of the network ID list for the device being started.
sbp	Specifies the status block pointer returned from the device handler.

Description

The **net_start_done** kernel service is used to mark the completion of a network ID start operation. When all the network IDs listed in the *netid* parameter have been started, the **net_attach** kernel service returns to the caller. The **net_start_done** service should be called when a **CIO_START_DONE** status block is received from the device handler. If the status block indicates an error, the start process is immediately aborted.

Execution Environment

The **net_start_done** kernel service can be called from either the process or interrupt environment.

Return Values

The **net_start_done** service has no return values.

net_wakeup Kernel Service

Purpose

Wakes up all sleepers waiting on the specified wait channel.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

net_wakeup (*chan*)
int *chan*;

Parameter

Item	Description
chan	Specifies the wait channel.

Description

The **net_wakeup** service wakes up all network processes sleeping on the specified wait channel.

Execution Environment

The **net_wakeup** kernel service can be called from either the process or interrupt environment.

Return Values

The **net_wakeup** service has no return values.

net_xmit Kernel Service

Purpose

Transmits data using a communications device handler .

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <aixif/net_if.h>
```

int net_xmit (*ifp, m, netfp, lngth, m_ext*)
struct ifnet * *ifp*;
struct mbuf * *m*;

```
struct  file *  netfp;
int     lngth;
struct mbuf *  m_ext;
```

Parameters

Item	Description
ifp	Indicates an address of the **ifnet** structure for this interface.
m	Specifies the address of an **mbuf** structure containing the data to transmit.
netfp	Indicates the open file pointer obtained from the **net_attach** kernel service.
lngth	Indicates the total length of the buffer being transmitted.
m_ext	Indicates the address of an **mbuf** structure containing a write extension.

Description

The **net_xmit** kernel service builds a **uio** structure and then invokes the **fp_rwuio** service to transmit a packet. The **net_xmit_trace** kernel service is an alternative for network interfaces that choose not to use the **net_xmit** kernel service.

Execution Environment

The **net_xmit** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates that the packet was transmitted successfully.
ENOBUFS	Indicates that buffer resources were not available.

The **net_xmit** kernel service returns a value from the **fp_rwuio** service when an error occurs during a call to that service.

Related reference

net_xmit_trace Kernel Service

Purpose

Traces transmit packets.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
int net_xmit_trace (  ifp,   mbuf )
struct ifnet *ifp;
struct mbuf *mbuf;
```

Parameters

Item	Description
ifp	Designates the address of the **ifnet** structure for this interface.
mbuf	Designates the address of the **mbuf** structure to be traced.

Description

The **net_xmit_trace** kernel service traces the data pointed to by the *mbuf* parameter. This kernel service was added for those network interfaces that choose not to use the **net_xmit** kernel service to transmit packets. An application program (the **iptrace** command) reads the trace data and writes it to a file for the **ipreport** command to interpret.

Execution Environment

The **net_xmit_trace** kernel service can be called from either the process or interrupt environment.

Return Values

The **net_xmit_trace** kernel service has no return values.

NLuprintf Kernel Service

Purpose

Submits a request to print an internationalized message to a process' controlling terminal.

Syntax

```
#include <sys/uprintf.h>
```

```
int NLuprintf (Uprintf)
struct uprintf *Uprintf;
```

Parameters

Item	Description
Uprintf	Points to a **uprintf** request structure.

Description

The **NLuprintf** kernel service submits a internationalized kernel message request with the **uprintf** request structure specified by the *Uprintf* parameter as input. Once the request has been successfully submitted, the **uprintfd** daemon retrieves, converts, formats, and writes the message described by the **uprintf** request structure to a process' controlling terminal.

The caller must initialize the **uprintf** request structure before calling the **NLuprintf** kernel service. Fields in the **uprintf** request structure use several constants. The following constants are defined in the **/usr/include/sys/uprintf.h** file:

- **UP_MAXSTR**
- **UP_MAXARGS**
- **UP_MAXCAT**
- **UP_MAXMSG**

The **uprintf** request structure consists of the following fields:

Field	Description
`Uprintf->upf_defmsg`	Points to a default message format. The default message format is a character string that contains either or both of two types of objects:

- Plain characters, which are copied to the message output stream
- Conversion specifications, each of which causes zero or more items to be fetched from the *Uprintf->arg* value parameter array

Each conversion specification consists of a % (percent sign) followed by a character that indicates the type of conversion to be applied:

%
> Performs no conversion. Prints a % character.

d, i
> Accepts an integer value and converts it to signed decimal notation.

u
> Accepts an integer value and converts it to unsigned decimal notation.

o
> Accepts an integer value and converts it to unsigned octal notation.

x
> Accepts an integer value and converts it to unsigned hexadecimal notation.

c
> Accepts and prints a **char** value.

s
> Accepts a value as a string (character pointer). Characters from the string are printed until a \0 (null character) is encountered.

Field-width or precision conversion specifications are not supported.

The maximum length of the default message-format string pointed to by the `Uprintf->upf_defmsg` field is the number of characters specified by the **UP_MAXSTR** constant. The `Uprintf->upf_defmsg` field must be a nonnull character.

The default message format is used in constructing the kernel message if the message format described by the `Uprintf->upf_NLsetno` and `Uprint->upf_NLmsgno` fields cannot be retrieved from the message catalog specified by `Uprintf->upf_NLcatname`. The conversion specifications contained within the default message format should match those contained in the message format specified by the `upf_NLsetno` and `upf_NLmsgno` fields.

Field	Description
`Uprintf->upf_arg[UP_MAXARGS]`	Specifies from zero to the number of value parameters specified by the **UP_MAXARGS** constant. A *Value* parameter may be a integer value, a character value, or a string value (character pointer). Strings are limited in length to the number of characters specified by the **UP_MAXSTR** constant. String value parameters must be nonnull characters. The number, type, and order of items in the *Value* parameter array should match the conversion specifications within the message format string.
`Uprintf->upf_NLcatname`	Points to the message catalog file name. If the catalog file name referred to by the `Uprintf->upf_NLcatname` field begins with a / (slash), it is assumed to be an absolute path name. If the catalog file name is not an absolute path name, the process environment determines the directory paths to search. The maximum length of the catalog file name is limited to the number of characters specified by the **UP_MAXCAT** constant. The value of the `Uprintf->upf_NLcatname` field must be a nonnull character.
`Uprintf->upf_NLsetno`	Specifies the set ID.
`Uprintf->upf_NLmsgno`	Specifies the message ID. The `Uprintf->upf_NLsetno` and `Uprintf->upf_NLmsgno` fields specify a particular message format string to be retrieved from the message catalog specified by the `Uprintf->upf_NLcatname` field. The maximum length of the constructed kernel message is limited to the number of characters specified by the **UP_MAXMSG** constant. Messages larger then the number of characters specified by the **UP_MAXMSG** constant are discarded.

Execution Environment

The **NLuprintf** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
ENOMEM	Indicates that memory is not available to buffer the request.
ENODEV	Indicates that a controlling terminal does not exist for the process.
ESRCH	Indicates the **uprintfd** daemon is not active. No requests may be submitted.
EINVAL	Indicates that the message catalog file-name pointer is null or the catalog file name is greater than the number of characters specified by the **UP_MAXCAT** constant.
EINVAL	Indicates that a string-value parameter pointer is null or the string-value parameter is greater than the number of characters specified by the **UP_MAXCAT** constant.

Item	Description
EINVAL	Indicates one of the following:

- Default message format pointer is null.
- Number of characters in the default message format is greater than the number specified by the **UP_MAXSTR** constant.
- Number of conversion specifications contained within the default message format is greater than the number specified by the **UP_MAXARGS** constant.

uprintfd subroutine

Process and Exception Management Kernel Services

ns_add_demux Network Kernel Service

Purpose

Adds a demuxer for the specified type of network interface.

Syntax

```
#include <sys/ndd.h>
#include <sys/cdli.h>
```

```
int ns_add_demux (ndd_type, demux)
        u_long    ndd_type;
        struct ns_demuxer * demux;
```

Parameters

Item	Description
ndd_type	Specifies the interface type of the demuxer to be added.
demux	Specifies the pointer to an **ns_demux** structure that defines the demuxer.

Description

The **ns_add_demux** network service adds the specified demuxer to the list of available network demuxers. Only one demuxer per network interface type can exist. An interface type describes a certain class of network devices that have the same characteristics (such as ethernet or token ring). The values of the *ndd_type* parameter listed in the **/usr/include/sys/ndd.h** file are the numbers defined by Simple Network Management Protocol (SNMP). If the desired type is not in the **ndd.h** file, the SNMP value should be used if it is defined. Otherwise, any undefined type above **NDD_MAX_TYPE** may be used.

Note: The **ns_demuxer** structure must be allocated and pinned by the network demuxer.

Examples

The following example illustrates the **ns_add_demux** network service:

```
struct ns_demuxer demuxer;
bzero (&demuxer, sizeof (demuxer));
demuxer.nd_add_filter = eth_add_filter;
demuxer.nd_del_filter = eth_del_filter;
demuxer.nd_add_status = eth_add_status;
demuxer.nd_del_status = eth_del_status;
demuxer.nd_receive = eth_receive;
```

```
demuxer.nd_status = eth_status;
demuxer.nd_response = eth_response;
demuxer.nd_use_nsdnx = 1;
ns_add_demux(NDD_ISO88023, &demuxer);
```

Return Values

Item	Description
0	Indicates the operation was successful.
EEXIST	Indicates a demuxer already exists for the given type.

ns_add_filter Network Service

Purpose

Registers a receive filter to enable the reception of packets.

Syntax

```
#include <sys/cdli.h>
#include <sys/ndd.h>
```

int ns_add_filter (*nddp*, *filter*, *len*, *ns_user*)
        struct ndd * *nddp*;
        caddr_t *filter*;
        int *len*;
        struct ns_user * *ns_user*;

Parameters

Item	Description
nddp	Specifies the **ndd** structure to which this add request applies.
filter	Specifies the pointer to the receive filter.
len	Specifies the length in bytes of the receive filter to which the *filter* parameter points.
ns_user	Specifies the pointer to a **ns_user** structure that defines the user.

Description

The **ns_add_filter** network service registers a receive filter for the reception of packets and enables a network demuxer to route packets to the appropriate users. The **add** request is passed on to the **nd_add_filter** function of the demuxer for the specified NDD. The caller of the **ns_add_filter** network service is responsible for relinquishing filters before calling the **ns_free** network service.

Examples

The following example illustrates the **ns_add_filter** network service:

```
struct ns_8022 dl;
struct ns_user ns_user;

dl.filtertype = NS_LLC_DSAP_SNAP;
dl.dsap = 0xaa;
dl.orgcode[0] = 0x0;
dl.orgcode[1] = 0x0;
dl.orgcode[2] = 0x0;
dl.ethertype = 0x0800;
```

```
ns_user.isr = NULL;
ns_user.isr_data = NULL;
ns_user.protoq = &ipintrq;
ns_user.netisr = NETISR_IP;
ns_user.ifp = ifp;
ns_user.pkt_format = NS_PROTO_SNAP;

ns_add_filter(nddp, &dl, sizeof(dl), &ns_user);
```

There are two ways a user (that is, the entity that is interested in receiving incoming packets) can be invoked when a packet arrives. In the first method, a protocol queue can be defined in which incoming packets are queued upon receipt, and the specified *netisr* is scheduled to let the user know that there are new packets in the queue. For example, the preceding code assumes a network interrupt service request (netisr) with the name **NETISR_IP** has been defined. When a packet arrives for the specified user, the packet is queued on the specified protocol queue (in this case, **ipintrq**) and the **NETISR_IP** request is scheduled to be executed. Because of its complexity, this mode is not currently being used by any network user.

The preferred way of receiving incoming packets is by registering an interrupt service request (isr) function that handles incoming packets; **ns_user.isr** points to the function that will get invoked whenever a packet that matches the specified filter arrives. This function should expect the following four arguments:

```
void isr (ndd_t *nddp, mbuf *m, caddr_t macp, caddr_t extp)
```

where

Item	Description
nddp	Pointer to the **ndd** structure representing the adapter where the packet was received.
m	Pointer to the **mbuf** structure representing the packet that was received.
macp	Pointer to the start of the MAC header of the packet that was received.
extp	Pointer to the (optional) structure specified in **ns_user.isr_data**, or NULL if none was specified.

In the following code, the function **bpf_cdli_tap** will be called when a new packet arrives; a pointer to the **bp** structure will be passed as the fourth parameter when **bpf_cdli_tap** is called.

```
dl.filtertype = NS_TAP;

ns_user.isr = bpf_cdli_tap;
ns_user.isr_data = (caddr_t) bp;
ns_user.protoq = (struct ifqueue *) NULL;
ns_user.netisr = 0;
ns_user.ifp = (struct ifnet *) NULL;
ns_user.pkt_format = NS_INCLUDE_MAC;
```

Note: Both modes of receiving packets are mutually exclusive. In other words, if the **ns_user.protoq** member is non-null, the protocol queue method is used; otherwise, the direct isr function method is used, and the **ns_user.isr** function pointer must be a valid function pointer.

In both cases, **ns_user.ifp** can optionally point to the **ifnet** structure of the interface where the packets will be received. If it is non-null, the state of the interface will be verified when a packet is received. If the interface is not up, the packet will be dropped and it will not be delivered to the user. If the interface is up, the statistics for the number of received packets will be incremented, and the ifp will be saved in the packet's **mbuf** structure's **m_pkthdr.rcvif** field.

The **ns_user.pkt_format** member determines how much of the MAC header the user is interested in receiving. Its possible values are:

Item	Description
NS_PROTO	Do not include the LLC header (but include the SNAP header, if there is one).

Item	Description
NS_PROTO_SNAP	Do not include the LLC SNAP header (that is, remove the entire MAC header and deliver only the data).
NS_INCLUDE_LLC	Include the LLC header.
NS_INCLUDE_MAC	Include the entire MAC header.
NS_HANDLE_HEADERS	Instead of passing the specified **ns_user.isr_data** structure by itself, build an **isr_data_ext** structure containing header information, as well as a pointer to the specified **ns_user.isr_data**. These are the fields that will be set in the **isr_data_ext** structure:

isr_data_ext.isr_data
> Pointer to the structure passed as **ns_user.isr_data**.

isr_data_ext.dstp
> Pointer to the destination MAC address.

isr_data_ext.dstlen
> Length of the destination MAC address.

isr_data_ext.srcp
> Pointer to the source MAC address.

isr_data_ext.seclen
> Length of the source MAC address.

isr_data_ext.segp
> Pointer to the routing segment.

isr_data_ext.seglen
> Length of the routing segment.

isr_data_ext.llcp
> Pointer to the LLC.

isr_data_ext.llclen
> Length of the LLC.

It is possible to combine **NS_HANDLE_HEADERS** with one of the other flags by means of a logical OR operator (for example, `ns_user.pkt_format = NS_INCLUDE_MAC | NS_HANDLE_HEADERS`). The other flags, however, are mutually exclusive.

Return Values

Item	Description
0	Indicates the operation was successful.

The network demuxer may supply other return values.

ns_add_status Network Service

Purpose

Adds a status filter for the routing of asynchronous status.

Syntax

```
#include <sys/cdli.h>
#include <sys/ndd.h>
```

```
int ns_add_status (nddp, statfilter, len, ns_statuser)
        struct ndd * nddp;
        caddr_t   statfilter;
        int   len;
        struct ns_statuser * ns_statuser;
```

Parameters

Item	Description
nddp	Specifies a pointer to the **ndd** structure to which this add request applies.
statfilter	Specifies a pointer to the status filter.
len	Specifies the length, in bytes, of the value of the *statfilter* parameter.
ns_statuser	Specifies a pointer to an **ns_statuser** structure that defines this user.

Description

The **ns_add_status** network service registers a status filter. The add request is passed on to the **nd_add_status** function of the demuxer for the specified network device driver (NDD). This network service enables the user to receive asynchronous status information from the specified device.

Note: The user's status processing function is specified by the `isr` field of the **ns_statuser** structure. The network demuxer calls the user's status processing function directly when asynchronous status information becomes available. Consequently; the status processing function cannot be a scheduled routine. The caller of the **ns_add_status** network service is responsible for relinquishing status filters before calling the **ns_free** network service.

Examples

The following example illustrates the **ns_add_status** network service:

```
struct ns_statuser   user;
struct ns_com_status   filter;

filter.filtertype = NS_STATUS_MASK;
filter.mask = NDD_HARD_FAIL;
filter.sid = 0;
user.isr = status_fn;
user.isr_data = whatever_makes_sense;

error = ns_add_status(nddp, &filter, sizeof(filter), &user);
```

Return Values

Item	Description
0	Indicates the operation was successful.

The network demuxer may supply other return values.

ns_alloc Network Service

Purpose

Allocates use of a network device driver (NDD).

Syntax

```
#include <sys/ndd.h>
```

int ns_alloc (*nddname,* *nddpp***)**
        char * *nddname***;**
        struct ndd ** *nddpp***;**

Parameters

Item	Description
nddname	Specifies the device name to be allocated.
nddpp	Indicates the address of the pointer to a **ndd** structure.

Description

The **ns_alloc** network service searches the Network Service (NS) device chain to find the device driver with the specified *nddname* parameter. If the service finds a match, it increments the reference count for the specified device driver. If the reference count is incremented to 1, the **ndd_open** subroutine specified in the **ndd** structure is called to open the device driver.

Examples

The following example illustrates the **ns_alloc** network service:

```
struct ndd   *nddp;
error = ns_alloc("en0", &nddp);
```

Return Values

If a match is found and the **ndd_open** subroutine to the device is successful, a pointer to the **ndd** structure for the specified device is stored in the *nddpp* parameter. If no match is found or the open of the device is unsuccessful, a non-zero value is returned.

Item	Description
0	Indicates the operation was successful.
ENODEV	Indicates an invalid network device.
ENOENT	Indicates no network demuxer is available for this device.

The **ndd_open** routine may specify other return values.

ns_attach Network Service

Purpose

Attaches a network device to the network subsystem.

Syntax

```
#include <sys/ndd.h>
```

```
int ns_attach (nddp)
        struct ndd * nddp;
```

Parameters

Item	Description
nddp	Specifies a pointer to an **ndd** structure describing the device to be attached.

Description

The **ns_attach** network service places the device into the available network service (NS) device chain. The network device driver (NDD) should be prepared to be opened after the **ns_attach** network service is called.

Note: The **ndd** structure is allocated and initialized by the device. It should be pinned.

Examples

The following example illustrates the **ns_attach** network service:

```
struct ndd ndd;
ndd.ndd_name = "en0";
ndd.ndd_addrlen = 6;
ndd.ndd_hdrlen = 14;
ndd.ndd_mtu = ETHERMTU;
ndd.ndd_mintu = 60;
ndd.ndd_type = NDD_ETHER;
ndd.ndd_flags =
    NDD_BROADCAST | NDD_SIMPLEX;
ndd.ndd_open = entopen;
ndd.ndd_output = entwrite;
ndd.ndd_ctl = entctl;
ndd.ndd_close = entclose;
.
.
.
ns_attach(&ndd);
```

Return Values

Item	Description
0	Indicates the operation was successful.
EEXIST	Indicates the device is already in the available NS device chain.

ns_del_demux Network Service

Purpose

Deletes a demuxer for the specified type of network interface.

Syntax

```
#include <sys/ndd.h>
```

```
int ns_del_demux (ndd_type)
        u_long   ndd_type;
```

Parameters

Item	Description
ndd_type	Specifies the network interface type of the demuxer that is to be deleted.

Description

If the demuxer is not currently in use, the **ns_del_demux** network service deletes the specified demuxer from the list of available network demuxers. A demuxer is in use if a network device driver (NDD) is open for the demuxer.

Examples

The following example illustrates the **ns_del_demux** network service:

```
ns_del_demux(NDD_ISO88023);
```

Return Values

Item	Description
0	Indicates the operation was successful.
ENOENT	Indicates the demuxer of the specified type does not exist.

ns_del_filter Network Service

Purpose

Deletes a receive filter.

Syntax

```
#include <sys/cdli.h>
#include <sys/ndd.h>
```

int ns_del_filter (*nddp*, *filter*, *len*)
      struct ndd * *nddp*;
      caddr_t *filter*;
      int *len*;

Parameters

Item	Description
nddp	Specifies the **ndd** structure that this delete request is for.
filter	Specifies the pointer to the receive filter.
len	Specifies the length in bytes of the receive filter.

Description

The **ns_del_filter** network service deletes the receive filter from the corresponding network demuxer. This disables packet reception for packets that match the filter. The delete request is passed on to the **nd_del_filter** function of the demuxer for the specified network device driver (NDD).

Examples

The following example illustrates the **ns_del_filter** network service:

```
struct ns_8022 dl;

dl.filtertype = NS_LLC_DSAP_SNAP;
dl.dsap = 0xaa;
dl.orgcode[0] = 0x0;
dl.orgcode[1] = 0x0;
dl.orgcode[2] = 0x0;
dl.ethertype = 0x0800;
ns_del_filter(nddp, &dl, sizeof(dl));
```

Return Values

Item	Description
0	Indicates the operation was successful.

The network demuxer may supply other return values.

Related reference

ns_add_filter Network Service
ns_alloc Network Service

ns_del_status Network Service

Purpose

Deletes a previously added status filter.

Syntax

```
#include <sys/cdli.h>
#include <sys/ndd.h>
```

int ns_del_status (*nddp, statfilter, len***)**
    struct ndd * *nddp***;**
    caddr_t *statfilter***;**
    int *len***;**

Parameters

Item	Description
nddp	Specifies the pointer to the **ndd** structure to which this delete request applies.
statfilter	Specifies the pointer to the status filter.
len	Specifies the length, in bytes, of the value of the *statfilter* parameter.

Description

The **ns_del_status** network service deletes a previously added status filter from the corresponding network demuxer. The delete request is passed on to the **nd_del_status** function of the demuxer for the specified network device driver (NDD). This network service disables asynchronous status notification from the specified device.

Examples

The following example illustrates the **ns_del_status** network service:

```
error = ns_add_status(nddp, &filter,
sizeof(filter));
```

Return Values

Item	Description
0	Indicates the operation was successful.

The network demuxer may supply other return values.

ns_detach Network Service

Purpose

Removes a network device from the network subsystem.

Syntax

```
#include <sys/ndd.h>
```

int ns_detach (*nddp*)
       struct ndd * *nddp***;**

Parameters

Item	Description
nddp	Specifies a pointer to an **ndd** structure describing the device to be detached.

Description

The **ns_detach** service removes the **ndd** structure from the chain of available NS devices.

Examples

The following example illustrates the **ns_detach** network service:

```
ns_detach(nddp);
```

Return Values

Item	Description
0	Indicates the operation was successful.
ENOENT	Indicates the specified *ndd* structure was not found.
EBUSY	Indicates the network device driver (NDD) is currently in use.

ns_free Network Service

Purpose

Relinquishes access to a network device.

Syntax

```
#include <sys/ndd.h>
```

void ns_free (*nddp*)
      struct ndd * *nddp*;

Parameters

Item	Description
nddp	Specifies the **ndd** structure of the network device that is to be freed from use.

Description

The **ns_free** network service relinquishes access to a network device. The **ns_free** network service also decrements the reference count for the specified **ndd** structure. If the reference count becomes 0, the **ns_free** network service calls the **ndd_close** subroutine specified in the **ndd** structure.

Examples

The following example illustrates the **ns_free** network service:

```
struct ndd *nddp
ns_free(nddp);
```

Item	Description
net/cdli.c	

p

The following kernel services begin with the with the letter p.

__pag_getid System Call

Purpose

Invokes the **kcred_getpagid** kernel service and returns the PAG identifier for that PAG name.

Syntax

```
int __pag_getid (name)
char *name;
```

Description

Given a PAG type name, the **__pag_getid** invokes the **kcred_getpagid** kernel service and returns the PAG identifier for that PAG name.

Parameters

Item	Description
name	A **char *** value which references a NULL-terminated string of not more than PAG_NAME_LENGTH_MAX characters.

Return Values

If successful, a value greater than or equal to 0 is returned and represents the PAG type. This value may be used in subsequent calls to other PAG system calls that require a *type* parameter on input. If unsuccessful, -1 is returned and the **errno** global variable is set to a value reflecting the cause of the error.

Error Codes

Item	Description
ENOENT	The *name* parameter doesn't refer to an existing PAG type.
ENAMETOOLONG	The *name* parameter refers to a string that is longer than PAG_NAME_LENGTH_MAX.

Related reference

__pag_getname System Call
__pag_setname System Call
kcred_getpagid Kernel Service

__pag_getname System Call

Purpose

Retrieves the name of a PAG type.

Syntax

```
int __pag_getname (type, buf, size)
int type;
char *buf;
int size;
```

Description

The **__pag_getname** system call retrieves the name of a PAG type given its integer value by invoking the **kcred_getpagname** kernel service with the given parameters.

Parameters

Item	Description
type	A numerical PAG identifier.
buf	A **char *** value that points to an array at least PAG_NAME_LENGTH_MAX+1 bytes in length.
size	An **int** value that gives the size of *buf* in bytes.

Return Values

If successful, 0 is returned and the *buf* parameter contains the PAG name associated with the *type* parameter. If unsuccessful, -1 is returned and the **errno** global variable is set to a value reflecting the cause of the error.

Error Codes

Item	Description
EINVAL	The value of the *type* parameter is less than 0 or greater than the maximum PAG identifier.
ENOENT	There is no PAG associated with the *type* parameter.
ENOSPC	The value of the *size* parameter is insuffient to hold the PAG name and its terminating NULL character.

Related reference
__pag_getvalue System Call
__pag_setname System Call
kcred_getpagname Kernel Service

__pag_getvalue System Call

Purpose

Invokes the **kcred_getpag** kernel service and returns the PAG value.

Syntax

```
int __pag_getvalue (type)
int type;
```

Description

Given a PAG type, the **__pag_getvalue** system call invokes the **kcred_getpag** kernel service and returns the PAG value for the value of the *type* parameter.

Parameters

Item	Description
type	An **int** value indicating the desired PAG.

Return Values

If successful, the value of the PAG (or 0 when there is no value for that PAG type) is returned. If unsuccessful, -1 is returned and the **errno** global variable is set to a value reflecting the cause of the error.

Error Codes

Item	Description
EINVAL	The *type* parameter is less than 0 or greater than the maximum PAG type value.
ENOENT	The *type* parameter doesn't reference and existing PAG type.

Note: It is not an error for a defined PAG to not have a value in the current process' credentials.

Related reference
__pag_getid System Call
__pag_setvalue System Call
kcred_getpagname Kernel Service

__pag_setname System Call

Purpose

Invokes the **kcred_setpagname** kernel service and returns the PAG type identifier.

Syntax

```
int __pag_setname (name, flags)
char *name;
int flags;
```

Description

The **__pag_setname** system call invokes the **kcred_setpagname** kernel service to register the name of a PAG and returns the PAG type identifier. The value of the *func* parameter to **kcred_setpagname** will be NULL. The other parameters to this system call are the same as with the underlying kernel service. This system call requires the SYS_CONFIG privilege.

Parameters

Item	Description
name	A **char *** value giving the symbolic name of the requested PAG.
flags	Either PAG_UNIQUEVALUE or PAG_MULTIVALUED 1 .

Return Values

A return value greater than or equal to 0 is the PAG type associated with the *name* parameter. This value may be used with other PAG-related system calls which require a numerical PAG identifier. If unsuccessful, -1 is returned and the **errno** global variable is set to indicate the cause of the error.

Error Codes

Item	Description
ENOSPC	The PAG name table is full.
EEXIST	The named PAG type already exists in the table, and the *flags* and *func* parameters do not match their previous values.
EPERM	The calling process does not have the SYS_CONFIG privilege.

Related reference
__pag_getname System Call
__pag_setvalue System Call
kcred_setpagname Kernel Service

__pag_setvalue System Call

Purpose

Invokes the **kcred_setpag** kernel service and sets the value of PAG type to *pag*.

Syntax

```
int __pag_setvalue (type, pag)
int type;
int pag;
```

Description

Given a PAG type and value, the **__pag_setvalue** system call invokes the **kcred_setpag** kernel service and sets the value of PAG type to *pag*. This system call requires the SET_PROC_DAC privilege.

Parameters

Item	Description
type	An **int** value indicating the desired PAG.
pag	An **int** value containing the new PAG value.

Return Values

If successful, 0 is returned. If unsuccessful, -1 is returned and the **errno** global variable is set to a value reflecting the cause of the error.

Error Codes

Item	Description
ENOENT	The *type* parameter doesn't reference an existing PAG type.
EINVAL	The value of *pag* is -1.
EPERM	The calling process lacks the appropriate privilege.

Related reference

panic Kernel Service

Purpose

Crashes the system.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
panic ( s)
char *s;
```

Parameter

Item	Description
s	Points to a character string to be written to the error log.

Description

The **panic** kernel service is called when a catastrophic error occurs and the system can no longer continue to operate. The **panic** service performs these two actions:

- Writes the character string pointed to by the *s* parameter to the error log.
- Performs a system dump.

The system halts after the dump. You should wait for the dump to complete, reboot the system, and then save and analyze the dump.

Execution Environment

The **panic** kernel service can be called from either the process or interrupt environment.

Return Values

The **panic** kernel service has no return values.

pci_cfgrw Kernel Service

Purpose

Reads and writes PCI bus slot configuration registers.

Syntax

```
#include <sys/mdio.h>
```

```
int pci_cfgrw(bid, md, write_flag)
int bid;
struct mdio *md;
int write_flag;
```

Description

The **pci_cfgrw** kernel service provides serialized access to the configuration registers for a PCI bus. To ensure data integrity in a multi-processor environment, a lock is required before accessing the configuration registers. Depending on the value of the *write_flag* parameter, a read or write to the configuration register is performed at offset *md_addr* for the device identified by *md_sla*.

The **pci_cfgrw** kernel service provides for kernel extensions the same services as the **MIOPCFGET** and **MIOPCFPUT** ioctls provides for applications. The **pci_cfgrw** kernel service can be called from either the process or the interrupt environment.

Parameters

Item	Description
bid	Specifies the bus identifier.

Item	Description
md	Specifies the address of the *mdio* structure. The *mdio* structure contains the following fields:

md_addr
Starting offset of the configuration register to access (**0** to **0xFF** for PCI/PCI-X, and 0 to 0xFFF for PCI-E).

md_data
Pointer to the data buffer.

md_size
Number of items of size specified by the *md_incr* parameter. The maximum size is 256 bytes for PCI/PCI-X, and 4096 for PCI-E.

md_incr
Access types, **MV_BYTE**, **MV_WORD**, or **MV_SHORT**.

md_sla
Device Number and Function Number.

(Device Number * 8) + Function.

Item	Description
write_flag	Set to **1** for write and **0** for read.

Return Values

Returns 0 for successful completion.

Item	Description
ENOMEM	Indicates no memory could be allocated.
EINVAL	Indicated that the bus, device/function, or size is not valid.
EPERM	Indicates that the platform does not allow the requested operation

pfctlinput Kernel Service

Purpose

Invokes the **ctlinput** function for each configured protocol.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/domain.h>
```

void pfctlinput (*cmd*, *sa***)**
int *cmd*;
struct sockaddr **sa;**

Parameters

Item	Description
cmd	Specifies the command to pass on to protocols.
sa	Indicates the address of a **sockaddr** structure that is passed to the protocols.

Description

The **pfctlinput** kernel service searches through the protocol switch table of each configured domain and invokes the protocol **ctlinput** function if defined. Both the *cmd* and *sa* parameters are passed as parameters to the protocol function.

Execution Environment

The **pfctlinput** kernel service can be called from either the process or interrupt environment.

Return Values

The **pfctlinput** service has no return values.

Understanding Socket Header Files

pffindproto Kernel Service

Purpose

Returns the address of a protocol switch table entry.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/domain.h>
```

struct protosw *pffindproto (*family, protocol, type***)**
int *family*;
int *protocol*;
int *type*;

Parameters

Item	Description
family	Specifies the address family for which to search.
protocol	Indicates the protocol within the address family.
type	Specifies the type of socket (for example, **SOCK_RAW**).

Description

The **pffindproto** kernel service first searches the domain switch table for the address family specified by the *family* parameter. If found, the **pffindproto** service then searches the protocol switch table for that domain and checks for matches with the *type* and *protocol* parameters.

If a match is found, the **pffindproto** service returns the address of the protocol switch table entry. If the *type* parameter is set to **SOCK_RAW**, the **pffindproto** service returns the first entry it finds with protocol equal to 0 and type equal to **SOCK_RAW**.

Execution Environment

The **pffindproto** kernel service can be called from either the process or interrupt environment.

Return Values

The **pffindproto** service returns a null value if a protocol switch table entry was not found for the given search criteria. Upon success, the **pffindproto** service returns the address of a protocol switch table entry.

pgsignal Kernel Service

Purpose

Sends a signal to all of the processes in a process group.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

void pgsignal (*pid*, *sig***)**
pid_t *pid*;
int *sig*;

Parameters

Item	Description
pid	Specifies the process ID of a process in the group of processes to receive the signal.
sig	Specifies the signal to send.

Description

The **pgsignal** kernel service sends a signal to each member in the process group to which the process identified by the *pid* parameter belongs. The *pid* parameter must be the process identifier of the member of the process group to be sent the signal. The *sig* parameter specifies which signal to send.

Device drivers can get the value for the *pid* parameter by using the **getpid** kernel service. This value is the process identifier for the currently executing process.

The **sigaction** subroutine contains a list of the valid signals.

Execution Environment

The **pgsignal** kernel service can be called from either the process or interrupt environment.

Return Values

The **pgsignal** service has no return values.

pidsig Kernel Service

Purpose

Sends a signal to a process.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

void pidsig (*pid,* *sig***)**
pid_t *pid;*
int *sig;*

Parameters

Item	Description
pid	Specifies the process ID of the receiving process.
sig	Specifies the signal to send.

Description

The **pidsig** kernel service sends a signal to a process. The *pid* parameter must be the process identifier of the process to be sent the signal. The *sig* parameter specifies the signal to send. See the **sigaction** subroutine for a list of the valid signals.

Device drivers can get the value for the *pid* parameter by using the **getpid** kernel service. This value is the process identifier for the currently executing process.

The **pidsig** kernel service can be called from an interrupt handler execution environment if the process ID is known.

Execution Environment

The **pidsig** kernel service can be called from either the process or interrupt environment.

Return Values

The **pidsig** service has no return values.

pin Kernel Service

Purpose

Pins the address range in the system (kernel) space.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/pin.h>
```

int pin (*addr,* *length***)**
caddr_t *addr;*
int *length;*

Parameters

Item	Description
addr	Specifies the address of the first byte to pin.
length	Specifies the number of bytes to pin.

Description

The **pin** service pins the real memory pages touched by the address range specified by the *addr* and *length* parameters in the system (kernel) address space. It pins the real-memory pages to ensure that page faults do not occur for memory references in this address range. The **pin** service increments the pin count for each real-memory page. While the pin count is nonzero, the page cannot be paged out of real memory.

The **pin** routine pins either the entire address range or none of it. Only a limited number of pages can be pinned in the system. If there are not enough unpinned pages in the system, the **pin** service returns an error code.

Note: If the requested range is not aligned on a page boundary, then memory outside this range is also pinned. This is because the operating system pins only whole pages at a time.

The **pin** service can only be called for addresses within the system (kernel) address space. The **xmempin** service should be used for addresses within kernel or user space.

Execution Environment

The **pin** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
EINVAL	Indicates that the value of the *length* parameter is negative or 0. Otherwise, the area of memory beginning at the address of the first byte to pin (the *addr* parameter) and extending for the number of bytes specified by the *length* parameter is not defined.
EIO	Indicates that a permanent I/O error occurred while referencing data.
ENOMEM	Indicates that the **pin** service was unable to pin due to insufficient real memory or exceeding the systemwide pin count.
ENOSPC	Indicates insufficient file system or paging space.

Related reference
xmempin Kernel Service
xmemunpin Kernel Service

Memory Kernel Services

pin_context_stack or unpin_context_stack Kernel Service

Purpose

Pins and unpins hidden kernel stack region.

Syntax

```
#include <sys/pin.h>
```

kerrno_t pin_context_stack (*flags*)
long *flags*;

kerrno_t unpin_context_stack (*flags*)
long *flags*;

Parameters

Item	Description
flags	Various flags to the kernel service. Must be set to 0.

Description

Kernel code that pins its system call stack should call this service before the first kernel stack pin and call the **unpin_context_stack()** service after the last unpin. These services do not pin or unpin the C execution stack, but instead pin or unpin a hidden stack resource used for the kernel-key support.

Execution Environment

These services must be called in the process environment.

Return Values

Item	Description
0	Indicates a successful completion.
ENOMEM_PIN_CONTEXT_STACK	Indicates that the memory is not sufficient to satisfy the request.
ENOSPC_PIN_CONTEXT_STACK	Indicates that the page space is not sufficient.
EINVAL_PIN_CONTEXT_STACK	Indicates that the execution environment is not valid.
EINVAL_UNPIN_CONTEXT_STACK	Indicates that the execution environment is not valid. (For example, the service is not in the process environment or the kernel keys are not enabled or the value of the *flag* parameter is not valid.)

pincf Kernel Service

Purpose

Manages the list of free character buffers.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <cblock.h>
```

int pincf (*delta***)**
int *delta***;**

Parameter

Item	Description
delta	Specifies the amount by which to change the number of free-pinned character buffers.

Description

The **pincf** service is used to control the size of the list of free-pinned character buffers. A positive value for the *delta* parameter increases the size of this list, while a negative value decreases the size.

All device drivers that use character blocks need to use the **pincf** service. These drivers must indicate with a positive delta value the maximum number of character blocks they expect to be using concurrently. Device drivers typically call this service with a positive value when the **ddopen** routine is called. They should call the **pincf** service with a negative value of the same amount when they no longer need the pinned character blocks. This occurs typically when the **ddclose** routine is called.

Execution Environment

The **pincf** kernel service can be called in the process environment only.

Return Values

The **pincf** service returns a value representing the amount by which the service changed the number of free-pinned character buffers.

I/O Kernel Services

pincode Kernel Service

Purpose

Pins the code and data associated with a loaded object module.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/pin.h>
```

int pincode (*func***)**
int (**func***) ();**

Parameter

Item	Description
func	Specifies an address used to determine the object module to be pinned. The address is typically that of a function exported by this object module.

Description

The **pincode** service uses the **pin** service to pin the specified object module. The loader entry for the object module is used to determine the size of both the code and data.

Execution Environment

The **pincode** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
EINVAL	Indicates that the *func* parameter is not a valid pointer to the function.
ENOMEM	Indicates that the **pincode** service was unable to pin the module due to insufficient real memory.

When an error occurs, the **pincode** service returns without pinning any pages.

Memory Kernel Services

Process State-Change Notification Routine

Purpose

Allows kernel extensions to be notified of major process and thread state transitions.

Syntax

```
void prochadd_handler ( term,  type,  id)
struct proch *term;
int type;
long id;

void proch_reg_handler ( term,  type,  id)
struct prochr *term;
int type;
long id;
```

Parameters

Item	Description
term	Points to the **proch** structure used in the **prochadd** call or to the **prochr** structure used in the **proch_reg** call.

Item	Description
type	Defines the state change event being reported: process initialization, process termination, process exec, thread initialization, or thread termination. These values are defined in the **/usr/include/sys/proc.h** file. The values that may be passed as *type* also depend on how the callout is requested.

Possible **prochadd_handler** *type* values:

PROCH_INITIALIZE
> Process is initializing.

PROCH_TERMINATE
> Process is terminating.

PROCH_EXEC
> Process is about to exec a new program.

THREAD_INITIALIZE
> A new thread is created.

THREAD_TERMINATE
> A thread is terminated.

Possible **proch_reg_handler** *type* values:

PROCHR_INITIALIZE
> Process is initializing.

PROCHR_TERMINATE
> Process is terminating.

PROCHR_EXEC
> Process is about to exec a new program.

PROCHR_THREAD_INIT
> A new thread is created.

PROCHR_THREAD_TERM
> A thread is terminated.

Item	Description
id	Defines either the process ID or the thread ID.

Description

The notification callout is set up by using either the **prochadd** or the **proch_reg** kernel service. If you request the notification using the **prochadd** kernel service, the callout follows the syntax shown first as **prochadd_handler**. If you request the notification using the **proch_reg** kernel service, the callout follows the syntax shown second as **proch_reg_handler**.

For process initialization, the **process state-change notification** routine is called in the execution environment of a parent process for the initialization of a newly created child process. For kernel processes, the notification routine is called when the **initp** kernel service is called to complete initialization.

For process termination, the notification routines are called before the kernel handles default termination procedures. The routines must be written so as not to allocate any resources under the terminating process. The notification routine is called under the process image of the terminating process.

proch_reg Kernel Service

Purpose

Registers a callout handler.

Syntax

```
#include <sys/proc.h>
```

```
int proch_reg(struct prochr *)
```

Note: The prochr structure contains the following elements that must be set prior to calling **proch_reg**:

```
void (* proch_handler)(struct prochr *, int, long)
unsigned int   int prochr_mask
```

Parameters

Item	Description
int prochr_mask	Specifies the set of kernel events for which a callout is requested. Unlike the old_style interface, the callout is invoked only for the specified events. This mask is formed by ORing together any of these defined values: **PROCHR_INITIALIZE** Process created. **PROCHR_TERMINATE** Process terminated **PROCHR_EXEC** Process has issued the exec system call **PROCHR_THREADINIT** Thread created **PROCHR_THREADTERM** Thread terminated
proch_handler	Specifies the callout function to be called when specified kernel events occur.

Description

If the same **struct prochr *** is registered more than once, only the most recently specified information is retained in the kernel.

The **struct prochr *** is not copied to a new location in memory. As a result, if the structure is changed, results are unpredictable. This structure does not need to be pinned.

The primary consideration for the new-style interface is to improve scalability. A lock is only acquired when callouts are made. A summary mask of all currently registered callout event types is maintained. This summary mask is updated every time **proch_reg** or **proch_unreg** is called, even when registering an identical **struct prochr ***. Further, the lock is a complex lock, so once callouts have been registered, there is no lock contention in invoking them because the lock is held read-only.

When a callout to a registered handler function is made, the parameters passed are:

- a pointer to the registered prochr structure
- a callout request value to indicate the reason for the callout
- a thread or process ID

Return Values

On successful completion, the **proch_reg** kernel service returns a value of 0. The only error (non-zero) return is from trying to register with a NULL pointer.

Execution Environment

The **proch_reg** kernel service can be called from the process environment only.

proch_unreg Kernel Service

Purpose

Unregisters a callout handler that was previously registered using the **proch_reg** kernel service.

Syntax

```
#include <sys/proc.h>
```

```
int proch_unreg(struct prochr *old_prochr);
```

Parameter

Item	Description
old_prochr	Specifies the address of the **proch** structure to be unregistered.

Description

Unregisters an existing callout handler that was previously registered using the **proch_reg()** kernel service.

Return Values

On successful completion, the **proch_unreg** kernel service returns a value of 0. An error (non-zero) return occurs when trying to unregister a handler that is not presently registered.

Execution Environment

The **proch_unreg** kernel service can be called from the process environment only.

prochadd Kernel Service

Purpose

Adds a system-wide process state-change notification routine.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/proc.h>
```

void prochadd (*term***)**
struct proch **term***;**

Parameters

Item	Description
term	Points to a **proch** structure containing a notification routine to be added from the chain of systemwide notification routines.

Description

The **prochadd** kernel service allows kernel extensions to register for notification of major process state transitions. The **prochadd** service allows the caller to be notified when a process:

- Has just been created.
- Is about to be terminated.
- Is executing a new program.

The complete list of callouts is:

Callout	Description
PROCH_INITIALIZE	Process (pid) created (**initp**, **kforkx**)
PROCH_TERMINATE	Process (pid) terminated (**kexitx**)
PROCH_EXEC	Process (pid) executing (**execvex**)
THREAD_INITIALIZE	Thread (tid) created (**kforkx**, **thread_create**)
THREAD_TERMINATE	Thread (tid) created (**kexitx**, **thread_terminate**)

The **prochadd** service is typically used to allow recovery or reassignment of resources when processes undergo major state changes.

The caller should allocate a **proch** structure and update the `proch.handler` field with the entry point of a caller-supplied notification routine before calling the **prochadd** kernel service. This notification routine is called once for each process in the system undergoing a major state change.

The **proch** structure has the following form:

```
struct proch
{
        struct proch *next
        void                 *handler ();
}
```

Execution Environment

The **prochadd** kernel service can be called from the process environment only.

prochdel Kernel Service

Purpose

Deletes a process state change notification routine.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/proc.h>
```

void prochdel (*term*)
struct proch *term;**

Parameter

Item	Description
term	Points to a **proch** structure containing a notification routine to be removed from the chain of system-wide notification routines. This structure was previously registered by using the **prochadd** kernel service.

Description

The **prochdel** kernel service removes a process change notification routine from the chain of system-wide notification routines. The registered notification routine defined by the handler field in the **proch** structure is no longer to be called by the kernel when major process state changes occur.

If the **proch** structure pointed to by the *term* parameter is not found in the chain of structures, the **prochdel** service performs no operation.

Execution Environment

The **prochdel** kernel service can be called from the process environment only.

Kernel Extension and Driver Management Kernel Services

probe or kprobe Kernel Service

Purpose

Logs errors with symptom strings.

Library (for probe)

Run-time Services Library.

Syntax

#include <sys/probe.h>
or
#include <sys/sysprobe.h>
int probe (*probe_p*)
probe_t *probe_p*

```
int kprobe (probe_p)
probe_t *probe_p
```

Description

The probe subroutine logs an entry to the error log. The entry consists of an error log entry as defined in the **errlog** subroutine and the **err_rec.h** header file, and a symptom string.

The **probe** subroutine is called from an application, while **kprobe** is called from the Kernel and Kernel extensions. Both **probe** and **kprobe** have the same interfaces, except for return codes.

IBM software should use the **sys/sysprobe.h** header file while non-IBM programs should include the **sys/probe.h file**. This is because IBM symptom strings must conform to different rules than non-IBM

strings. It also tells any electronic support application whether or not to route the symptom string to IBM's Retain database.

Parameters

Item	Description
probe_p	is a pointer to the data structure which contains the pointer and length of the error record, and the data for the probe. The error record is described under the **errlog** subroutine and defined in **err_rec.h**.
	The first word of the structure is a magic number to identify this version of the structure. The magic number should be set to PROBE_MAGIC.
	Note: PROBE_MAGIC is different between **probe.h** and **sysprobe.h** to distinguish an IBM symptom string from a non-IBM string.
	The probe data consists of flags which control probe handling, the number of symptom string keywords, followed by an array consisting of one element for each keyword.

Flags

Item	Description
SSNOSEND	indicates this symptom string shouldn't be forwarded to automatic problem opening facilities. An example where **SSNOSEND** should be used is in symptom data used for debugging purposes.
nsskwd	This gives the number of keywords specified (i.e.), the number of elements in the sskwds array.

Item	Description
sskwds	This is an array of keyword/value pairs. The keywords and their values are in the following table. The **I/S** value indicates whether the *keyword* and *value* are informational or are part of the logged symptom string. The number in parenthesis indicates, where applicable, the maximum string length.

```
keyword           I/S    value    type    Description

SSKWD_LONGNAME    I      char *  (30)    Product's long name
SSKWD_OWNER       I      char *  (16)    Product's owner
SSKWD_PIDS        S      char *  (11)    product id.
(required for IBM symptom strings)
SSKWD_LVLS        S      char *  (5)     product level

(required for IBM symptom strings)
SSKWD_APPLID      I      char *  (8)     application id.
SSKWD_PCSS        S      char *  (8)     probe id

(required for all symptom strings)
SSKWD_DESC        I      char *  (80)    problem description
SSKWD_SEV         I      int             severity from
                                                                    1
(highest) to 4 (lowest).
                                                                    3 is
the default.
SSKWD_AB          S      char *  (5)     abend code
SSKWD_ADRS        S      void *          address. If used at all,
                                                                    this
should be a relative address.
SSKWD_DEVS        S      char *  (6)     Device type
SSKWD_FLDS        S      char *  (9)     arbitrary character string.
                                                                    This
is usually a field name and
                                         the SSKWD_VALUE

keyword specifies the value.
SSKWD_MS          S      char *  (11)    Message number
SSKWD_OPCS        S      char *  (8)     OP code
SSKWD_OVS         S      char *  (9)     overwritten storage
SSKWD_PRCS        S                      unsigned long return code
SSKWD_REGS        S      char *  (4)     Register name (e.g.)
                                                                    GR15
or LR unsigned long Value
SSKWD_VALU        S
SSKWD_RIDS        S      char *  (8)     resource or module id.
SSKWD_SIG         S .    int             Signal number
SSKWD_SN          S      char *  (7)     Serial Number
SSKWD_SRN         S      char *  (9)     Service Req. Number If specified,
                                                                    and
no error is logged,
                                         a hardware error is assumed.
SSKWD_WS          S      char *  (10)    Coded wait
```

Note: The **SSKWD_PCSS** value is always required. This is the probe id. Additionally, for IBM symptom strings, the **SSKWD_PIDS** and **SSKWD_LVLS** keywords are also required

If either the **erecp** or **erecl** fields in the **probe_rec** structure is 0 then no error logging record is being passed, and one of the default templates for symptom strings is used. The default template indicating a software error is used unless the **SSKWD_SRN** keyword is specified. If it is, the error is assumed to be a hardware error. If you don't want to log your own error with a symptom string, and you want to have a hardware error, and don't want to use the **SSKWD_SRN** value, then you can supply an error log record using the error identifier of **ERRID_HARDWARE_SYMPTOM**, see the **/usr/include/sys/errids.h** file.

Return Values for probe Subroutine

Item	Description
0	Successful
-1	Error. The errno variable is set to

Item	Description
EINVAL	Indicates an invalid parameter
EFAULT	Indicates an invalid address

Return Values for kprobe Kernal Service

Item	Description
0	Successful
EINVAL	Indicates an invalid parameter

Execution Environment

probe is executed from the application environment.

kprobe is executed from the Kernel and Kernel extensions. Currently, **kprobe** must not be called with interrupts disabled.

Files

Item	Description
/usr/include/sys/probe.h	Contains parameter definition.

Error Logging Overview
errlog subroutine

purblk Kernel Service

Purpose

Purges the specified block from the buffer cache.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>

void purblk ( dev,  blkno)
dev_t dev;
daddr_t blkno;
```

Parameters

Item	Description
dev	Specifies the device containing the block to be purged.
blkno	Specifies the block to be purged.

Description

The **purblk** kernel service purges (that is, makes unreclaimable by marking the block with a value of **STALE**) the specified block from the buffer cache.

Execution Environment

The **purblk** kernel service can be called from the process environment only.

Return Values

The **purblk** service has no return values.

Block I/O Buffer Cache Kernel Services: Overview

putc Kernel Service

Purpose

Places a character at the end of a character list.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <cblock.h>
```

```
int putc ( c,   header)
char c;
struct clist *header;
```

Parameters

Item	Description
c	Specifies the character to place on the character list.
header	Specifies the address of the **clist** structure that describes the character list.

Description

> **Attention:** The caller of the **putc** service must ensure that the character list is pinned. This includes the **clist** header and all the **cblock** character buffers. Character blocks acquired from the **getcf** service are also pinned. Otherwise, the system may crash.

The **putc** kernel service puts the character specified by the *c* parameter at the end of the character list pointed to by the *header* parameter.

If the **putc** service indicates that there are no more buffers available, the **waitcfree** service can be used to wait until a character block is available.

Execution Environment

The **putc** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates successful completion.
-1	Indicates that the character list is full and no more buffers are available.

I/O Kernel Services

putcb Kernel Service

Purpose

Places a character buffer at the end of a character list.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <cblock.h>
```

void putcb (*p*, *header*)
struct cblock *p;
struct clist *header;

Parameters

Item	Description
p	Specifies the address of the character buffer to place on the character list.
header	Specifies the address of the **clist** structure that describes the character list.

Description

> **Attention:** The caller of the **putcb** service must ensure that the character list is pinned. This includes the **clist** header and all the **cblock** character buffers. Character blocks acquired from the **getcf** service are pinned. Otherwise, the system may crash.

The **putcb** kernel service places the character buffer pointed to by the *p* parameter on the end of the character list specified by the *header* parameter. Before calling the **putcb** service, you must load this new buffer with characters and set the `c_first` and `c_last` fields in the **cblock** structure. The *p* parameter is the address returned by either the **getcf** or the **getcb** service.

Execution Environment

The **putcb** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates successful completion.
-1	Indicates that the character list is full and no more buffers are available.

Related reference
getcb Kernel Service
putcf Kernel Service

I/O Kernel Services

putcbp Kernel Service

Purpose

Places several characters at the end of a character list.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <cblock.h>
```

```
int putcbp ( header,  source,  n)
struct clist *header;
char *source;
int n;
```

Parameters

Item	Description
header	Specifies the address of the **clist** structure that describes the character list.
source	Specifies the address from which characters are read to be placed on the character list.
n	Specifies the number of characters to be placed on the character list.

Description

> **Attention:** The caller of the **putcbp** service must ensure that the character list is pinned. This includes the **clist** header and all of the **cblock** character buffers. Character blocks acquired from the **getcf** service are pinned. Otherwise, the system may crash.

The **putcbp** kernel service operates on the characters specified by the *n* parameter starting at the address pointed to by the *source* parameter. This service places these characters at the end of the character list pointed to by the *header* parameter. The **putcbp** service then returns the number of characters added to the character list. If the character list is full and no more buffers are available, the **putcbp** service returns a 0. Otherwise, it returns the number of characters written.

Execution Environment

The **putcbp** kernel service can be called from either the process or interrupt environment.

Return Values

The **putcbp** service returns the number of characters written or a value of 0 if the character list is full, and no more buffers are available.

putcf Kernel Service
waitcfree Kernel Service

putcf Kernel Service

Purpose

Frees a specified buffer.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <cblock.h>
```

void putcf (*p*)
struct cblock *p;

Parameter

Item	Description
p	Identifies which character buffer to free.

Description

The **putcf** kernel service unpins the indicated character buffer.

The **putcf** service returns the specified buffer to the list of free character buffers.

Execution Environment

The **putcf** kernel service can be called from either the process or interrupt environment.

Return Values

The **putcf** service has no return values.

Related information

I/O Kernel Services

putcfl Kernel Service

Purpose

Frees the specified list of buffers.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <cblock.h>
```

void putcfl (*header***)**
struct clist **header***;**

Parameter

Item	Description
header	Identifies which list of character buffers to free.

Description

The **putcfl** kernel service returns the specified list of buffers to the list of free character buffers. The **putcfl** service unpins the indicated character buffer.

Note: The caller of the **putcfl** service must ensure that the header and **clist** structure are pinned.

Execution Environment

The **putcfl** kernel service can be called from either the process or interrupt environment.

Return Values

The **putcfl** service has no return values.

Related information
I/O Kernel Services

putcx Kernel Service

Purpose

Places a character on a character list.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/cblock.h>
```

int putcx (*c*, *header***)**
char *c***;**
struct clist **header***;**

Parameters

Item	Description
c	Specifies the character to place at the front of the character list.
header	Specifies the address of the **clist** structure that describes the character list.

Description

The **putcx** kernel service puts the character specified by the *c* parameter at the front of the character list pointed to by the *header* parameter. The **putcx** service is identical to the **putc** service, except that it puts the character at the front of the list instead of at the end.

If the **putcx** service indicates that there are no more buffers available, the **waitcfree** service can be used to wait until a character buffer is available.

Note: The caller of the **putcx** service must ensure that the character list is pinned. This includes the **clist** header and all the **cblock** character buffers. Character blocks acquired from the **getcf** service are pinned.

Execution Environment

The **putcx** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates successful completion.
-1	Indicates that the character list is full and no more buffers are available.

q

The following kernel services begin with the with the letter q.

query_proc_info Kernel Service

Purpose

Returns specific information about the current process or thread.

Syntax

```
#include <sys/encap.h>
```

```
int query_proc_info (type)
int type;
```

Parameters

Item	Description
type	Specifies the type of process or thread information requested. The *type* parameter can be one of the following values:

    QPI_XPG_SUS_ENV
        Queries whether the calling process has SPEC 1170 environment active.

    QTI_FUNNELLED
        Queries whether the current thread is funneled.

Description

The **query_proc_info** kernel service returns information about the current process or thread.

When called with the value QPI_XPG_SUS_ENV as the *type* parameter, it returns TRUE (1) when the process has SPEC 1170 active, that is, the process was issued with the environment variable XPG_SUS_ENV defined. Otherwise, the routine returns FALSE (0). When called with the value QTI_FUNNELLED as the *type* parameter, the **query_proc_info** kernel service returns TRUE (1) if the current thread has been funneled. Otherwise, the routine returns FALSE (0).

Execution Environment

The **query_proc_info** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
1	True.
0	False.

r

The following kernel services begin with the with the letter r.

RAS_BLOCK_NULL Exported Data Structure

Purpose

Allows for the silent failure of **ras_register** calls due to memory allocation errors.

Syntax

```
#include <sys/ras.h>
```

extern const ras_block_t RAS_BLOCK_NULL

Description

The **RAS_BLOCK_NULL** data structure allows components to go through their normal code paths when they receive an ENOMEM error from the **ras_register** kernel service. The presence of this data structure does not need to be explicitly checked by callers of RAS functions. All RAS domain functions (such as Component Tracing) are disabled with this control block.

Related reference
ras_register and ras_unregister Exported Kernel Services
ras_customize Exported Kernel Service
Related information
CT_HOOKx subroutine

ras_control Exported Kernel Service

Purpose

Controls component RAS characteristics.

Syntax

```
#include <sys/ras.h>
```

```
kerrno_t ras_control (
ras_block_t ras_blk,
ras_cmd_t command,
void * arg,
long argsize);
```

Description

The **ras_control** kernel service passes a command to the callback for the component referenced by the *ras_blk* parameter. If the *ras_blk* parameter is not known, use the **ras_path_control** call.

Note: During the **ras_control** process, callbacks to the registrant of the component might be initiated for changes that the RAS infrastructure makes to the component. The registrant should be aware of this for locking purposes (for instance, the registrant should not hold any locks that the callback needs).

If the *ras_blk* input parameter has a value of RAS_BLOCK_NULL, the **ras_control** kernel service returns without errors and takes no action.

Parameters

Item	Description
ras_blk	The target control block pointer.
command	Command passed to the callback. Commands are specific to a given RAS domain, such as Component Trace.
arg	Optional argument for the command.
argsize	Size of the argument, if a buffer or structure.

Execution Environment

The calling environment of the **ras_control** kernel service varies by individual command. The calling environment of a particular command is documented with the command itself.

Return Values

The **ras_control** kernel service returns 0 for success and a non-zero error code for failure.

Related reference

ras_callback subroutine

ras_customize Exported Kernel Service

Purpose

Loads persistent customized properties for a RAS control block.

Syntax

```
#include <sys/ras.h>
```

kerrno_t ras_customize (ras_block_t *ras_blk***);**

Description

The **ras_customize** kernel service checks for, and applies persistent customized properties for a given *ras_blk* parameter. After applying any persistent properties, the **ras_customize** kernel service puts the *ras_blk* parameter in a usable state. Registration is not complete without a call to the **ras_customize** kernel service.

Note: During the **ras_customize** process, callbacks to the registrant might be initiated for changes that the RAS infrastructure makes to the component. The registrant should be aware of this for locking and initialization purposes (for example, the registrant should not be holding any locks that the callback needs, and the private data for the callback should be initialized before **ras_customize** is called).

If the *ras_blk* input parameter has a value of RAS_BLOCK_NULL, the **ras_customize** kernel service returns without errors and takes no action.

Parameters

Item	Description
ras_blk	The control block to act on. Must be previously allocated by the **ras_register** kernel service.

Execution Environment

The **ras_customize** kernel service must be called from the process environment.

Return Values

Item	Description
0	Successful.
non-zero	Unsuccessful.

Related reference
ras_control Exported Kernel Service
Related information

ras_callback subroutine

ras_path_control Exported Kernel Services

Purpose

Controls component RAS characteristics.

Syntax

```
#include <sys/ras.h>
```

kerrno_t ras_path_control (
char * *path***,**

```
ras_cmd_t command,
void * arg,
long argsize);
```

Description

The **ras_path_control** kernel service passes a command to the RAS component specified by the *path* parameter.

Note: During the **ras_path_control** process, callbacks to the registrant of the component might be initiated for changes that the RAS infrastructure makes to the component. The registrant should be aware of this for locking purposes (for instance, the registrant should not be holding any locks the callback needs).

Parameters

Item	Description
path	The pathname of the component to receive the *command* parameter.
command	Command passed to the callback. Commands are specific to a given RAS domain, such as Component Trace.
arg	Optional argument for the command.
argsize	Size of the argument, if a buffer or structure.

Execution Environment

The calling environment of the **ras_path_control** kernel service varies by individual command. The calling environment of a particular command is documented with the command itself.

Return Values

Item	Description
0	Successful.
non-zero	Unsuccessful.

Component Trace Facility

ras_register and ras_unregister Exported Kernel Services

Purpose

Registers and unregisters a RAS component.

Syntax

```
#include <sys/ras.h>
```

```
kerrno_t ras_register (
ras_block_t * rasbp,
char * name,
```

```
ras_block_t parent,
ras_type_t typesubtype,
char * desc,
long flags,
ras_callback_t ras_callback,
void * private_data);

kerrno_t ras_unregister (ras_block_t ras_blk);
```

Description

The **ras_register** kernel service and the **ras_unregister** kernel service register and unregister RAS handlers which are invoked by the kernel when the system needs to communicate various RAS commands to each component.

The **ras_register** kernel service registers a component with the given name under the *parent* provided. If the parent is NULL, the **ras_register** kernel service registers name as a base component, but the *typesubtype* parameter must be provided. The *name* parameter specifies the name for the subcomponent or base component (it is not a full component path). The *flags* field is used to specify what aspects of RAS the component understands. The *ras_callback* is the mechanism by which the RAS subsystem communicates various commands to the component, depending on what aspects of RAS the component understands. The *desc* parameter provides a short description for the component as a service aid.

The **ras_register** kernel service allocates a ras_block_t member and returns the control block for the component through the *rasbp* argument. This control block can be used in **ras_control** calls and further **ras_register** calls (to allocate children, for instance).

If the registration fails due to the system being out of memory, the value of the *rasbp* argument is set to RAS_BLOCK_NULL. All RAS functions for this component are disabled. RAS kernel services accept RAS_BLOCK_NULL control blocks but take no action. If the control block is set to RAS_BLOCK_NULLRAS, domain related functions (such as the **CT_HOOKx** and **CT_GEN** macros) run correctly but take no action. This action allows the ENOMEM type failures from the **ras_register** kernel service to be safely ignored. The value of the *rasbp* argument for all other types of errors is undefined.

The **ras_unregister** kernel service unregisters a component previously registered with the **ras_register** kernel service. The *ras_blk* parameter should have no further children.

Parameters

Item	Description
rasbp	The newly allocated ras_block_t member.
name	The name of the component, not its full pathname. Individual node names are limited to the number of characters specified by the value of the **RAS_NAME_MAX** parameter (including the terminating NULL character). The full component path (the concatenated names of a child component and all of its ancestors) is limited to the number of characters specified by the value of the **RAS_PATH_MAX** parameter (including the terminating NULL character). The **ras_register** kernel service reconstructs the full component path and rejects registrations for components whose full path exceeds the value of the **RAS_PATH_MAX** parameter. Node names are restricted to the character set "A-Z","a-z","0-9" and "_".
parent	An optional pointer to the parent component or NULL if none.

Item	Description
typesubtype	If parent is NULL, mandatory parameter is used to categorize the component. The top 16-bits of the lower word of this field are the type, and the bottom 16-bits are the subtype. The *typesubtype* is a ras_type_t member, which is an enum. See the **sys/ras_base.h** file for a description of the types available. If parent is non-NULL, this parameter is required to be the value of the **RAS_TYPE_CHILD** parameter.
desc	A short description string for the component. The *desc* string is limited to the number of characters specified by the value of the **RAS_DESC_MAX** parameter (including the terminating null). The *desc* string has no character set restriction. Any static elements of the string should be in U.S. English, but dynamic elements have no restriction.
flags	Indicates what type of RAS systems this component is aware of. Valid choices are the following: • **RASF_TRACE_AWARE**: Component is Component Trace aware. • **RASF_ERROR_AWARE**: Component is Error Checking aware. These flags are defined in the **sys/ras.h** file.
ras_callback	A function pointer provided by the registrant and called by the framework each time an external event modifies a property of the component. See the **ras_callback** interface specification.
private_data	An optional pointer to a component private memory area passed to the **ras_callback** function upon callback.
ras_blk	The control block to remove.

Execution Environment

Both the **ras_register** kernel service and the **ras_unregister** kernel service must be called from the process environment.

Return Values

The following are the return values of the **ras_register** kernel service.

Item	Description
0	Successful.
non-zero	Unsuccessful.

The following are the return values of the **ras_unregister** kernel service.

Item	Description
0	Successful.
non-zero	Unsuccessful.

ras_callback subroutine

ras_ret_query_parms Kernel Service

Purpose

Returns callback parameters in the **ras_query_parms** structure.

Syntax

```
#include <sys/ras.h>
```

```
kerrno_t ras_ret_query_parms (retp, fmtstr, numstrings, descr)
ras_query_parms_t *retp;
char *fmtstr;
int numstrings;
char *descr[];
```

Parameters

Item	Description
retp	Points to the **ras_query_parms_t** data item to be filled in.

fmtstr	This is a format specifier. It has the following form:
	
	`spec-list`
	
	or
	
	`kywd=spec-list kywd=spec-list ...`
	
	Where the *spec-list* variable is of the form: *spec,spec,...* . The *spec* variable must be %x, %xx, %d, %dd, %s, or %ss. If the characters x, d, or s are doubled, for example, %xx, this indicates that multiple values are allowed.
	
	The following are some valid *fmtstr* values:
	
	%x
	　One hexidecimal value.
	
	%x,%d
	　One hexadecimal and one decimal value.
	
	%xx
	　Multiple hexadecimal values.
	
	k1=%x,%d k2=%dd
	　Keyword k1 takes one hexadecimal value and one decimal value. Keyword k2 takes multiple decimal values.

numstrings	Specifies the number of strings in the *descr* string array. The value must be at least 1.
descr	Specifies the component and parameters. There must be at least one string. The first string describes the component's function. If the component takes positional parameters, the following string(s) describe those. If keyword parameters are supplied, each keyword must have a corresponding *descr* string in the array describing that keyword. The **ras_ret_query_parms** kernel service does not return an error if the number of the *descr* strings does not match the format string. Instead, either the last keywords do not have help text, or the excess help strings are simply displayed.

Description

The **ras_ret_query_parms** kernel service can be used by a callback to aid in filling in the **ras_query_parms_t** structure when it receives the RASC_QUERY_PARMS call. This function formats the help text and places it into the **ras_query_parms_t** structure. If there is insufficient space for the help text in the provided **ras_query_parms_t** item, it returns **ENOMEM_RASC_CONTROL_QUERYPARMS**. The callback then just returns this error code.

The help text provided must follow the following conventions:

```
component - first line of description
component:parameters - parameter(s) description
```

or

```
component - first line of description
component:kywd1=parms - kywd1:parms description
component:kywd2=parms - kywd2:parms description
```

Execution Environment

The **ras_ret_query_parms** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful completion.
EINVAL_RAS_CONTROL_QUERYPARMS	Indicates that one or more parameters was not valid.
EFAULT_RAS_CONTROL_QUERYPARMS	Indicates that one or more parameter addresses was not valid.
ENOMEM_RAS_CONTROL_QUERYPARMS	Indicates that the rqp_text size was not large enough.

raschk_eaddr_hkeyset Kernel Service

Purpose

Checks if an effective address can be referenced with a hardware keyset.

Syntax

```
#include <sys/raschk.h>
#include <sys/skeys.h>
#include <sys/kerrno.h>
```

```
kerrno_t rashchk_eaddr_hkeyset (eaddr, hset, flags)
void * eaddr;
hkeyset_t hset;
unsigned long flags;
```

Parameters

Item	Description
eaddr	Effective address to validate. Only one byte is checked.
hset	Hardware keyset to validate against.

Item	Description
flags	The following flags are defined:

> **RCHK_EHK_NOFAULT**
> No page faults are permitted while performing this check.
>
> **RCHK_EHK_NOPAGEIN**
> No page in is performed during this check.
>
> **RCHK_EHK_READ**
> Validates for read access.
>
> **RCHK_EHK_WRITE**
> Validates for write access.

Description

The **raschk_eaddr_hkeyset** kernel service performs an advisory runtime check to determine if an effective address can be referenced with a hardware keyset.

Read and write access checks are independently specified in the *flags* field. A check for read and write access requires both flags to be set.

Execution Environment

The **raschk_eaddr_hkeyset** kernel service can be called from the process or interrupt environment.

Return Values

Item	Description
0	Successful.
EFAULT_RASCHK_EADDR_HKEYSET	Operation failed because a page in or page fault was not allowed.
EFAULT_RASCHK_EADDR_HKEYSET_PROT	The address failed the protection check.
EINVAL_RASCHK_EADDR_HKEYSET	The address to validate was determined to be invalid, or neither READ nor WRITE checking was requested.

raschk_eaddr_kkey Kernel Service

Purpose

Checks if an effective address can be referenced with a kernel-key.

Syntax

```
#include <sys/raschk.h>
#include <sys/kerrno.h>
```

kerrno_t raschk_eaddr_kkey (*eaddr, kkey, flags*)
void * *eaddr*;
kkey_t *kkey*;
unsigned long *flags*;

Parameters

Item	Description
eaddr	Effective address to validate. Only one byte is checked.

Item	Description
kkey	Kernel-key to check.
flags	The following flags are defined:

RCHK_EK_NOFAULT
No page faults of any kind are permitted while performing this check.

RCHK_EK_NOPAGEIN
No page in will be performed during this check.

Description

The **raschk_eaddr_kkey** kernel service performs an advisory runtime check to determine if an effective address can be referenced with a kernel-key. Note that read/write attributes are not maintained at a page granularity. This service only checks if the kernel-key assigned to an effective address matches the *kkey* value.

Execution Environment

The **raschk_eaddr_kkey** kernel service can be called from the process or interrupt environment.

Return Values

Item	Description
0	Successful.
EFAULT_RASCHK_EADDR_KKEY	Operation cannot be performed because a page in or page fault was not allowed.
EINVAL_RASCHK_EADDR_KKEY	The address to validate was determined to be invalid.
EINVAL_RASCHK_EADDR_KKEY_PROT	The address failed the protection check.

raschk_stktrace Kernel Service

Purpose

Generates a runtime compact stack trace for only call chain addresses.

Syntax

```
#include <sys/raschk.h>
```

kerrno_t rashchk_stktrace (*trcbufsz*, *flags*, *trcbuf*)
size_t *trcbufsz*;
long *flags*;
void * *trcbuf*;

Parameters

Item	Description
trcbufsz	Size of the stack trace buffer the caller allocated.

Item	Description
flags	The following flags are defined:

RAS_STK_DO_CURMST
> If this flag bit value is set, this service will not look at the previous MST to get the stack trace. The stack trace is obtained only for the current context.

RAS_STK_DO_PREVMST
> If this flag bit value is set, this service will skip the current MST and start getting the stack trace from the previous MST.

RAS_STK_DO_ONEMST
> This flag bit value can be combined with the above bit values to get stack trace for that MST.

RAS_STK_GET_SYMBOLS
> If this flag bit value is set, then all the call chain addresses are translated into a stream of bytes containing symbols with offset (null terminated) and placed in the caller's buffer.

RAS_STK_DO_CURRWA
> If this flag bit value is set, this service will use the RWA (recovery work area) associated with the current MST to begin the trace back.

Note:

The **RAS_STK_DO_PREVMST**, **RAS_STK_DO_CURMST**, and **RAS_STK_DO_CURRWA** flags are mutually exclusive. Specifying the **RAS_STK_DO_ONEMST** flag without specifying the **RAS_STK_DO_PREVMST** flag is equivalent to specifying the **RAS_STK_DO_CURMST** flag.

If the **RAS_STK_GET_SYMBOLS** flag is not set, the end of the stack trace is indicated by an entry containing 0. A value of -2 in *trcbuf* indicates the start of a new **mst** trace if any. Also, the stack trace will stop once we reach the system call boundary as we are interested only in kernel stack trace and we can only validate kernel stack addresses.

If the **RAS_STK_GET_SYMBOLS** flag is set, the output buffer will contain a null-terminated string with the symbolic representation of the stack trace. A call to **raschk_addr2sym()** is performed for each entry in the stack trace and the resulting strings are concatenated in the output buffer, and separated by '\n' characters. Special values in the stack trace will be translated to appropriate strings.

Item	Description
trcbuf	Pointer to the buffer that the caller allocated to get stack trace.

Note: Ensure that *trcbuf* is pinned when called disabled.

Description

This kernel service can be used to generate a runtime compact stack trace. The algorithm is performed for:

- All MSTs starting from the current MST (default, and none of **RAS_STK_DO_CURMST**, **RAS_STK_DO_PREVMST**, **RAS_STK_DO_CURRWA**, nor **RAS_STK_DO_ONEMST** flag bits specified.)
- Only for the current MST (**RAS_STK_DO_CURMST** bit flag is set)
- All the MSTs starting from previous MST (**RAS_STK_DO_PREVMST** bit flag is set)
- Only for the previous MST (**RAS_STK_DO_PREVMST** and **RAS_STK_DO_ONEMST** bits are set)
- For the current MST recovery work area (RWA) context and previous MSTs. (**RAS_STK_DO_CURRWA** flag bit is set.)

- Only for the current MST recovery work area (RWA) context. (**RAS_STK_DO_CURRWA** and **RAS_STK_DO_ONEMST** flag bits are set.)
- Getting all the symbols plus offset corresponding to the call addresses obtained in *trcbuf* and replacing *trcbuf* with symbol information in a string format. (**RAS_STK_GET_SYMBOLS** bit flag is set)

Execution Environment

The **raschk_stktrace** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Successful
kerrno	Unsuccessful

raw_input Kernel Service

Purpose

Builds a **raw_header** structure for a packet and sends both to the raw protocol handler.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
void raw_input (m0, proto, src, dst)
struct  mbuf * m0;
struct  sockproto * proto;
struct  sockaddr * src;
struct  sockaddr * dst;
```

Parameters

Item	Description
m0	Specifies the address of an **mbuf** structure containing input data.
proto	Specifies the protocol definition of data.
src	Identifies the **sockaddr** structure indicating where data is from.
dst	Identifies the **sockaddr** structure indicating the destination of the data.

Description

The **raw_input** kernel service accepts an input packet, builds a **raw_header** structure (as defined in the **/usr/include/net/raw_cb.h** file), and passes both on to the raw protocol input handler.

Execution Environment

The **raw_input** kernel service can be called from either the process or interrupt environment.

Return Values

The **raw_input** service has no return values.

raw_usrreq Kernel Service

Purpose

Implements user requests for raw protocols.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

void raw_usrreq (*so, req, m, nam, control*)
struct socket * *so*;
int *req*;
struct mbuf * *m*;
struct mbuf * *nam*;
struct mbuf * *control*;

Parameters

Item	Description
so	Identifies the address of a raw socket.
req	Specifies the request command.
m	Specifies the address of an **mbuf** structure containing data.
nam	Specifies the address of an **mbuf** structure containing the **sockaddr** structure.
control	This parameter should be set to a null value.

Description

The **raw_usrreq** kernel service implements user requests for the raw protocol.

The **raw_usrreq** service supports the following commands:

Command	Description
PRU_ABORT	Aborts (fast DISCONNECT, DETACH).
PRU_ACCEPT	Accepts connection from peer.
PRU_ATTACH	Attaches protocol to up.
PRU_BIND	Binds socket to address.
PRU_CONNECT	Establishes connection to peer.
PRU_CONNECT2	Connects two sockets.
PRU_CONTROL	Controls operations on protocol.
PRU_DETACH	Detaches protocol from up.
PRU_DISCONNECT	Disconnects from peer.
PRU_LISTEN	Listens for connection.
PRU_PEERADDR	Fetches peer's address.
PRU_RCVD	Have taken data; more room now.

Command	Description
PRU_RCVOOB	Retrieves out of band data.
PRU_SEND	Sends this data.
PRU_SENDOOB	Sends out of band data.
PRU_SENSE	Returns status into m.
PRU_SOCKADDR	Fetches socket's address.
PRU_SHUTDOWN	Will not send any more data.

Any unrecognized command causes the **panic** kernel service to be called.

Execution Environment

The **raw_userreq** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
EOPNOTSUPP	Indicates an unsupported command.
EINVAL	Indicates a parameter error.
EACCES	Indicates insufficient authority to support the **PRU_ATTACH** command.
ENOTCONN	Indicates an attempt to detach when not attached.
EISCONN	Indicates that the caller tried to connect while already connected.

Network Kernel Services

reconfig_register, reconfig_register_ext, reconfig_unregister, or reconfig_complete, reconfig_register_list Kernel Service

Purpose

Register and unregister reconfiguration handlers.

Syntax

```
#include <sys/dr.h>

int reconfig_register (handler, actions,
 h_arg, h_token, name)
int (*handler)(void *event, void *h_arg, int req,
void *resource_info);
int actions;
void *h_arg;
ulong *h_token;
char *name;

int reconfig_register_ext (handler, actions, h_arg, h_token, name)
int (*handler)(void *event, void *h_arg, unsigned long long req,
void *resource_info);
unsigned long long actions;
void *h_arg;
ulong *h_token;
char *name;
```

```
int reconfig_unregister (h_token)
ulong h_token;

void reconfig_complete (event, rc)
void *event;
int rc;

int reconfig_register_list (handler, event_list,  list_size, h_arg, h_token, name)
int (*handler)(void *event, void *h_arg, dr_kevent_t event_in_prog,
void *resource_info);
dr_kevent_t event_list[];
size_t list_size;
void *h_arg;
ulong *h_token;
char *name;
```

Description

The **reconfig_register, reconfig_register_ext**, **reconfig_register_list** and **reconfig_unregister** kernel services register and unregister reconfiguration handlers, which are invoked by the kernel both before and after DLPAR operations depending on the set of events specified by the kernel extension when registering.

Starting with AIX 6.1 with 6100-02, all future kernel extensions use the **reconfig_register_list** kernel service when registering for DLPAR operations. The **reconfig_register_list** kernel service supports previous and new DLPAR operations. The **reconfig_register** or **reconfig_register_ext** kernel services will no longer support all future DLPAR operations.

The **reconfig_complete** kernel service is used to indicate that the request has completed. If a kernel extension expects that the operation is likely to take a long time (several seconds), the handler must return **DR_WAIT** to the caller, but proceed with the request asynchronously. In this case, the handler must indicate that it has completed the request by invoking the **reconfig_complete** kernel service.

Parameters

Item	Description
actions	Allows the kernel extension to specify which of the following events require notification:

- **DR_PMIG_CHECK**
- **DR_PMIG_PRE**
- **DR_PMIG_POST**
- **DR_PMIG_POST_ERROR**
- **DR_CAP_ADD_CHECK**
- **DR_CAP_ADD_PRE**
- **DR_CAP_ADD_POST**
- **DR_CAP_ADD_POST_ERROR**
- **DR_CAP_REMOVE_CHECK**
- **DR_CAP_REMOVE_PRE**
- **DR_CAP_REMOVE_POST**
- **DR_CAP_REMOVE_POST_ERROR**
- **DR_CPU_ADD_CHECK**
- **DR_CPU_ADD_PRE**
- **DR_CPU_ADD_POST**
- **DR_CPU_ADD_POST_ERROR**
- **DR_CPU_REMOVE_CHECK**
- **DR_CPU_REMOVE_PRE**
- **DR_CPU_REMOVE_POST**
- **DR_CPU_REMOVE_POST_ERROR**
- **DR_MEM_ADD_CHECK**
- **DR_MEM_ADD_OP_POST**
- **DR_MEM_ADD_PRE**
- **DR_MEM_ADD_POST**
- **DR_MEM_ADD_POST_ERROR**
- **DR_MEM_REMOVE_CHECK**
- **DR_MEM_REMOVE_OP_POST**
- **DR_MEM_REMOVE_OP_PRE**
- **DR_MEM_REMOVE_PRE**
- **DR_MEM_REMOVE_POST**
- **DR_MEM_REMOVE_POST_ERROR**

Item	Description
event	Passed to the handler and intended to be used only when calling the **reconfig_complete** kernel service.
event_list	Specifies which events require notification. For the supported values, see the **dr.h** file.
handler	Specifies the kernel extension function to be invoked.

Item	Description
h_arg	Specified by the kernel extension, remembered by the kernel along with the function descriptor for the handler, and passed to the handler when it is invoked. It is not used directly by the kernel, but is intended to support kernel extensions that manage multiple adapter instances. This parameter points to an adapter control block.
h_token	An output parameter that is used when unregistering the handler.
list_size	Specifies the memory size of the **event_list** array.
name	Provided for information purposes and may be included within an error log entry, if the driver returns an error. It is provided by the kernel extension and must be limited to 15 ASCII characters.
rc	Can be set to **DR_FAIL** or **DR_SUCCESS**.
resource_info	Identifies the resource specific information for the current DLPAR request. If the request is cpu based, the *resource_info* data is provided through a **dri_cpu** structure. Otherwise a **dri_mem** structure is used. On a Micro-Partitioning partition, if the request is CPU-capacity based, the *resource_info* data is provided through a **dri_cpu_capacity** structure, which has the following format. The kernel extensions are not notified of changes in variable capacity weight in an uncapped Micro-Partitioning environment.

```
*/
struct dri_cpu_capacity {
    uint64_t    ent_capacity;    /* partition current entitled capacity*/
    int         delta_ent_cap;   /* delta capacity added/removed*/
    int         status;          /* capacity update constrained or not */
};

/*
 * dri_cpu_capacity.status flags.
 */
#define    CAP_UPDATE_SUCCESS      0x0
#define    CAP_UPDATE_CONSTRAINED    0x1
```

Note: The capacity update is constrained by the Hypervisor.

If the request is memory capacity based, the *resource_info* data is provided through a **dri_mem_capacity** structure, which has the following format:

```
struct dri_mem_capacity {
        size64_t    mem_capacity;    /* partition current entitled
capacity*/
        ssize64_t    delta_mem_capacity;
        uint         flags;
        int          status;          /* capacity update constrained or not */
        uchar        reserved[7];
    };

    /*
     * dri_mem_capacity.status flags.
     */
    #define    CAP_UPDATE_SUCCESS      0x0
    #define    CAP_UPDATE_CONSTRAINED    0x1
```

Item	Description
req	Indicates the following DLPAR operation to be performed by the handler:

- **DR_PMIG_CHECK**
- **DR_PMIG_PRE**
- **DR_PMIG_POST**
- **DR_PMIG_POST_ERROR**
- **DR_CAP_ADD_CHECK**
- **DR_CAP_ADD_PRE**
- **DR_CAP_ADD_POST**
- **DR_CAP_ADD_POST_ERROR**
- **DR_CAP_REMOVE_CHECK**
- **DR_CAP_REMOVE_PRE**
- **DR_CAP_REMOVE_POST**
- **DR_CAP_REMOVE_POST_ERROR**
- **DR_CPU_ADD_CHECK**
- **DR_CPU_ADD_PRE**
- **DR_CPU_ADD_POST**
- **DR_CPU_ADD_POST_EEROR**
- **DR_CPU_REMOVE_CHECK**
- **DR_CPU_REMOVE_PRE**
- **DR_CPU_REMOVE_POST**
- **DR_CPU_REMOVE_POST_ERROR**
- **DR_MEM_ADD_CHECK**
- **DR_MEM_ADD_OP_POST**
- **DR_MEM_ADD_PRE**
- **DR_MEM_ADD_POST**
- **DR_MEM_ADD_POST_ERROR**
- **DR_MEM_REMOVE_CHECK**
- **DR_MEM_REMOVE_OP_POST**
- **DR_MEM_REMOVE_OP_PRE**
- **DR_MEM_REMOVE_PRE**
- **DR_MEM_REMOVE_POST**
- **DR_MEM_REMOVE_POST_ERROR**

List of dr_kevent_t events

The following events are used with the **reconfig_register_list()** call for the **event_list** array:

- **DR_KEVENT_CPU_ADD_CHECK**
- **DR_KEVENT_CPU_ADD_PRE**
- **DR_KEVENT_CPU_ADD_POST**
- **DR_KEVENT_CPU_ADD_POST_ERROR**
- **DR_KEVENT_CPU_RM_CHECK**
- **DR_KEVENT_CPU_RM_PRE**

- **DR_KEVENT_CPU_RM_POST**
- **DR_KEVENT_CPU_RM_POST_ERROR**
- **DR_KEVENT_MEM_ADD_CHECK**
- **DR_KEVENT_MEM_ADD_PRE**
- **DR_KEVENT_MEM_ADD_POST**
- **DR_KEVENT_MEM_ADD_POST_ERROR**
- **DR_KEVENT_MEM_RM_CHECK**
- **DR_KEVENT_MEM_RM_PRE**
- **DR_KEVENT_MEM_RM_POST**
- **DR_KEVENT_MEM_RM_POST_ERROR**
- **DR_KEVENT_MEM_ADD_RES**
- **DR_KEVENT_MEM_RM_RES**
- **DR_KEVENT_CPU_CAP_ADD_CHECK**
- **DR_KEVENT_CPU_CAP_ADD_PRE**
- **DR_KEVENT_CPU_CAP_ADD_POST**
- **DR_KEVENT_CPU_CAP_ADD_POST_ERROR**
- **DR_KEVENT_CPU_CAP_RM_CHECK**
- **DR_KEVENT_CPU_CAP_RM_PRE**
- **DR_KEVENT_CPU_CAP_RM_POST**
- **DR_KEVENT_CPU_CAP_RM_POST_ERROR**
- **DR_KEVENT_MEM_RM_OP_PRE**
- **DR_KEVENT_MEM_RM_OP_POST**
- **DR_KEVENT_MEM_ADD_OP_POST**
- **DR_KEVENT_PMIG_CHECK**
- **DR_KEVENT_PMIG_PRE**
- **DR_KEVENT_PMIG_POST**
- **DR_KEVENT_PMIG_POST_ERROR**
- **DR_KEVENT_PMIG_POST_INTERNAL**
- **DR_KEVENT_WMIG_CHECK**
- **DR_KEVENT_WMIG_PRE**
- **DR_KEVENT_WMIG_POST**
- **DR_KEVENT_WMIG_POST_ERROR**
- **DR_KEVENT_WMIG_CHECKPOINT_CHECK**
- **DR_KEVENT_WMIG_CHECKPOINT_PRE**
- **DR_KEVENT_WMIG_CHECKPOINT_DOIT**
- **DR_KEVENT_WMIG_CHECKPOINT_ERROR**
- **DR_KEVENT_WMIG_CHECKPOINT_POST**
- **DR_KEVENT_WMIG_CHECKPOINT_POST_ERROR**
- **DR_KEVENT_WMIG_RESTART_CHECK**
- **DR_KEVENT_WMIG_RESTART_PRE**
- **DR_KEVENT_WMIG_RESTART_DOIT**
- **DR_KEVENT_WMIG_RESTART_ERROR**
- **DR_KEVENT_WMIG_RESTART_POST**

- **DR_KEVENT_WMIG_RESTART_POST_ERROR**
- **DR_KEVENT_MEM_CAP_ADD_CHECK**
- **DR_KEVENT_MEM_CAP_ADD_PRE**
- **DR_KEVENT_MEM_CAP_ADD_POST**
- **DR_KEVENT_MEM_CAP_ADD_POST_ERROR**
- **DR_KEVENT_MEM_CAP_RM_CHECK**
- **DR_KEVENT_MEM_CAP_RM_PRE**
- **DR_KEVENT_MEM_CAP_RM_POST**
- **DR_KEVENT_MEM_CAP_RM_POST_ERROR**
- **DR_KEVENT_MEM_CAP_WGT_ADD_CHECK**
- **DR_KEVENT_MEM_CAP_WGT_ADD_PRE**
- **DR_KEVENT_MEM_CAP_WGT_ADD_POST**
- **DR_KEVENT_MEM_CAP_WGT_ADD_POST_ERROR**
- **DR_KEVENT_MEM_CAP_WGT_RM_CHECK**
- **DR_KEVENT_MEM_CAP_WGT_RM_PRE**
- **DR_KEVENT_MEM_CAP_WGT_RM_POST**
- **DR_KEVENT_MEM_CAP_WGT_RM_POST_ERROR**
- **DR_KEVENT_TOPOLOGY_PRE**
- **DR_KEVENT_TOPOLOGY_POST**
- **DR_KEVENT_AME_FACTOR_CHECK**
- **DR_KEVENT_AME_FACTOR_PRE**
- **DR_KEVENT_AME_FACTOR_POST**
- **DR_KEVENT_AME_FACTOR_POST_ERROR**

Return Values

Upon successful completion, the **reconfig_register, reconfig_register_ext** and **reconfig_unregister** kernel services return zero. If unsuccessful, the appropriate **errno** value is returned.

Execution Environment

The **reconfig_register, reconfig_register_ext**, **reconfig_unregister**, and **handler** interfaces are invoked in the process environment only.

The **reconfig_complete** kernel service may be invoked in the process or interrupt environment.

Related information
Making Kernel Extensions DLPAR-Aware

refmon Kernel Service

Purpose

Performs various access checks such as privileges, authorizations, discretionary access control checks and so on.

Syntax

```
#include <refmon.h>
```

```
int refmon (crp, action, flags, nargs, args[])
cred_t *crp;
rfm_action_t action;
uint_t flags;
int nargs;
void *args[];
```

Parameters

Item	Description
crp	Specifies the caller's (subject) credentials; If NULL, then current process credentials are referenced.
action	Specifies the type of access check that needs to be carried out.
flags	Enables auditing of this event. You can only set this parameter to the value of REFMON_AUDIT.
nargs	Specifies the number of arguments in the *args* parameter.
args	Specifies an array of void pointers used as input to the **refmon** kernel service based on the *action* parameter.

Description

The **refmon** kernel service provides an interface to perform various access checks. You can call the **refmon** kernel service to determine access to system resources. Most of the actions that are passed to the **refmon** kernel service check for specific privileges. Many of the system calls and kernel services call the **refmon** kernel service to check whether you are authorized or privileged to use such functions. The *action* parameter determines which type of checks needs to be performed. The **sys/refmon.h** header file contains a complete list of these actions and their corresponding description.

Execution Environment

The **refmon** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Success.
EINVAL	The *action* parameter is not valid or a value that is not allowed is passed in for an action.
EPERM	The caller does not have permission to perform the intended action.

Security Kernel Services

register_HA_handler Kernel Service

Purpose

Registers a High Availability Event Handler with the Kernel.

Syntax

```
#include <sys/high_avail.h>
```

```
int register_HA_handler (ha_handler)
ha_handler_ext_t * ha_handler;
```

Parameter

Item	Description
ha_handler	Specifies a pointer to a structure of the type **ha_handler_ext_t** as defined in /**usr/include/sys/high_avail.h**.

Description

The **register_HA_handler** kernel registers the **High Availability Event Handler (HAEH)** function to those kernel extensions that need to be made aware of high availability events such as processor deallocation. This function is called by the kernel, at base level, when a high availability event is initiated, due to some hardware fault.

The **ha_handler_ext_t** structure has 3 fields:

Field	Description
_fun	Contains a pointer to the high availability event handler function.
_data	Contains a user defined value which will be passed as an argument by the kernel when calling the function.
_name	Component name

When a high availability event is initiated, the kernel calls *_fun()* at base level (that is, process environment) with 2 parameters:

- The first is the data the user passed in the *_data* field at registration time.

- The second is a pointer to a **haeh_event_t** structure defined in **/usr/include/sys/high_avail.h**.

The fields of interest in this structure are:

Field	Description
_magic	Identifies the event type. The only possible value is **HA_CPU_FAIL**.
dealloc_cpu	The logical number of the CPU being deallocated.

The high availability even handler, in addition to user specific functions, must unbind its threads bound to *dealloc_cpu* and stop the timer request blocks (TRB) started by those bound threads when applicable.

The high availability event handler must return one of the following values:

Value	Description
HA_ACCEPTED	The user processing of the event has succeeded.
HA_REFUSED	The user processing of the event was not successful.

Any return value different from **HA_ACCEPTED** causes the kernel to abort the processing of the event. In the case of a processor failure, the processor deallocation is aborted. In this case, a CPU_DEALLOC_ABORTED error log entry is created, and the value passed in the *_name* field appears in the detailed data area of the error log entry.

An extension may register the same HAEH *N* times (*N* > 1). Although it is considered as an incorrect behaviour, no error is reported. The given HAEH is invoked *N* times for each HA event. This handler has to be unregistered as many times as it was registered.

Since the kernel calls the HAEH in turn, it is possible for a HAEH to be called multiple times for the same event. The kernel extensions should be ready to deal with this possibility. For example, two kernel extensions **K1** and **K2** have registered HA Handlers. A CPU deallocation is initiated. The HAEH for **K1** gets invoked, does its job and returns HA_ACCEPTED. **K2** gets invoked next and for some reason returns HA_REFUSED. The deallocation is aborted, and an error log entry reports **K2** as the reason for failure. Later, the system administer unloads **K2** and restarts the deallocation by manually running **ha_star**. The result is that the HAEH for **K1** gets invoked again with the same parameters.

Execution Environment

The **register_HA_handler** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.

A non zero value indicates an error.

RAS Kernel Services

rmalloc Kernel Service

Purpose

Allocates an area of memory from the **real_heap** heap.

Syntax

```
#include <sys/types.h>
```

```
caddr_t rmalloc (size, align)
int size
int align
```

Parameters

Item	Description
size	Specifies the number of bytes to allocate.
align	Specifies alignment characteristics.

Description

The **rmalloc** kernel service allocates an area of memory from the contiguous real memory heap. This area is the number of bytes in length specified by the *size* parameter and is aligned on the byte boundary specified by the *align* parameter. The *align* parameter is actually the log base 2 of the desired address boundary. For example, an *align* value of 4 requests that the allocated area be aligned on a 16-byte boundary.

The contiguous real memory heap, **real_heap**, is a heap of contiguous real memory pages located in the low 16MB of real memory. This heap is virtually mapped into the kernel extension's address space. By nature, this heap is implicitly pinned, so no explicit pinning of allocated regions is necessary.

The **real_heap** heap is useful for devices that require DMA transfers greater than 4K but do not provide a scatter/gather capability. Such a device must be given contiguous bus addresses by its device driver. The device driver should pass the **DMA_CONTIGUOUS** flag on its **d_map_init** call in order to obtain contiguous mappings. On certain platforms it is possible that a **d_map_init** call using the **DMA_CONTIGUOUS** flag could fail. In this case, the device driver can make use of the **real_heap** heap (using **rmalloc**) to obtain contiguous bus addresses for its device driver. Because the **real_heap** heap is a limited resource, device drivers should always attempt to use the **DMA_CONTIGUOUS** flag first.

On unsupported platforms, the **rmalloc** service returns NULL if the requested memory cannot be allocated.

The **rmfree** kernel service should be called to free allocation from a previous **rmalloc** call. The **rmalloc** kernel service can be called from the process environment only.

Return Values

Upon successful completion, the **rmalloc** kernel service returns the address of the allocated area. A **NULL** pointer is returned if the requested memory cannot be allocated.

rmfree Kernel Service

Purpose

Frees memory allocated by the **rmalloc** kernel service.

Syntax

```
#include <sys/types.h>
```

int rmfree (** *pointer,* *size*)**
caddr_t *pointer*
int *size*

Parameters

Item	Description
pointer	Specifies the address of the area in memory to free.
size	Specifies the size of the area in memory to free.

Description

The **rmfree** kernel service frees the area of memory pointed to by the *pointer* parameter in the contiguous real memory heap. This area of memory must be allocated with the **rmalloc** kernel service, and the *pointer* must be the pointer returned from the corresponding **rmalloc** kernel service call. Also, the *size* must be the same size that was used on the corresponding **rmalloc** call.

Any memory allocated in a prior **rmalloc** call must be explicitly freed with an **rmfree** call. This service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.

Ite m	Description
-1	Indicates one of the following:

- The area was not allocated by the **rmalloc** kernel service.
- The heap was not initialized for memory allocation.

rmmap_create Kernel Service

Purpose

Defines an Effective Address [EA] to Real Address [RA] translation region.

Syntax

```
#include <sys/ioacc.h>
#include <sys/adspace.h>
```

int rmmap_create (_eaddrp_, _iomp_, _flags_)
void **_eaddrp_**;**
struct io_map *_iomp_**;**
int _flags_**;**

Parameters

Item	Description
eaddr	Required process effective address of the mapping region.
iomp	The bus memory to which the effective address described by the _eaddr_ parameter must correspond. For real memory, the bus id must be set to **REALMEM_BID** and the bus address must be set to the real memory address. The size field must be at least **PAGESIZE**, no larger than **SEGSIZE**, and a multiple of **PAGESIZE**. The key must be set to **IO_MEM_MAP**. The flags field is not used.

Item	Description
flags	The flags select page and segment attributes of the translation. Not all page attribute flags are compatible. The valid combinations of page attribute flags follow.

RMMAP_PAGE_W
> PowerPC "Write Through" page attribute. Write-through mode is not supported, and if this flag is set, **EINVAL** is reported.

RMMAP_PAGE_I
> PowerPC "Cache Inhibited" page attribute. This flag is valid for I/O mappings, but is not allowed for real memory mappings.

RMMAP_PAGE_M
> PowerPC "Memory Coherency Required" page attribute. This flag is optional for I/O mappings; however, it is required for memory mappings. The default operating mode for real memory pages has this bit set.

RMMAP_PAGE_G
> PowerPC "Guarded" page attribute. This flag is optional for I/O mappings, and must be 0 for real memory mappings. Although optional for I/O, it is recommended that this flag must be set for I/O mappings. When set, the processor does not make unnecessary (speculative) references to the page. It includes out of order read or write operations and branch fetching. When clear, normal PowerPC speculative execution rules apply.

RMMAP_RDONLY
> When set, the page protection bits used in the **HTAB** does not allow write operations regardless of the setting of the key bit in the associated segment register. Exactly one of **RMMAP_RDONLY** and **RMMAP_RDWR** must be specified.

RMMAP_RDWR
> When set, the page protection bits used in the **HTAB** allows read and write operations regardless of the setting of the key bit in the associated segment register. Exactly one of: **RMMAP_RDONLY**, and **RMMAP_RDWR** must be specified.

RMMAP_PRELOAD
> When set, the protection attributes of this region are entered immediately into the hardware page table. It is very slow initially, but prevents each referenced page in the region from faulting in separately. It is only advisory. This flag is not maintained as an attribute of the map region, it is used only during the current call.

RMMAP_INHERIT
> When set, this protection attribute specifies that the translation region created by this **rmmap_create** invocation must be inherited on a **fork** operation, to the child process. This inheritance is achieved with copy-semantics. The child has its own private mapping to the same I/O or real memory address range as the parent.

Description

The translation regions that are created with **rmmap_create** kernel service are maintained in I/O mapping segments. Any single such segment might translate up to 256 Megabytes of real memory or memory mapped I/O in a single region. The only granularity for which the **rmmap_remove** service might be started is a single mapping that is created by a single call to the **rmmap_create**.

There are constraints on the size of the mapping and the *flags* parameter, described later, which causes the call to fail regardless of whether adequate effective address space exists.

If **rmmap_create** kernel service is called with the effective address of zero, the function attempts to find free space in the process address space. If successful, an I/O mapping segment is created and the effective address (which is passed by reference) is changed to the effective address which is mapped to the first page of the *iomp* memory.

If **rmmap_create** kernel service is called with a non-zero effective address, it is taken as the required effective address which must translate to the passed *iomp* memory. This function verifies that the

requested range is free. If not, it fails and returns **EINVAL**. If the mapping at the effective address is not contained in a single segment, the function fails and returns **ENOSPC**. Otherwise, the region is allocated and the effective address is not modified. The effective address is mapped to the first page of the *iomp* memory. References outside of the mapped regions but within the same segment are invalid.

The effective address (if provided) and the bus address must be a multiple of **PAGESIZE** or **EINVAL** is returned.

I/O mapping segments are not inherited by child processes after a **fork** subroutine.

I/O mapping segments are not inherited by child processes after a **fork** subroutine, except when **RMMAP_INHERIT** is specified. These segments are deleted by **exec**, **exit**, or **rmmap_remove** of the last range in a segment.

Only certain combinations of flags are permitted, depending on the type of memory that is mapped. For real memory mappings, **RMMAP_PAGE_M** is required while **RMMAP_PAGE_W**, **RMMAP_PAGE_I**, and **RMMAP_PAGE_G** are not allowed. For I/O mappings, it is valid to specify only **RMMAP_PAGE_M**, with no other page attribute flags. It is also valid to specify **RMMAP_PAGE_I** and optionally, either or both of **RMMAP_PAGE_M**, and **RMMAP_PAGE_G**. **RMMAP_PAGE_W** is never allowed.

The real address range that is described by the *iomp* parameter must be unique within this I/O mapping segment.

Execution Environment

The **rmmap_create** kernel service can be called only from the process environment.

Return Values

On successful completion, **rmmap_create** kernel service returns zero and modifies the effective address to the value at which the newly created mapping region was attached to the process address space. Otherwise, it returns one of following errors:

Item	Description
EINVAL	Some type of parameter error occurred. These parameters include, but are not limited to, size errors and mutually exclusive flag selections.
ENOMEM	The operating system cannot allocate the necessary data structures to represent the mapping.
ENOSPC	Effective address space exhausted in the region indicated by *eaddr*.
EPERM	This hardware platform does not implement this service.

Implementation Specifics

This service only functions on PowerPC microprocessors.

Understanding Virtual Memory Manager Interfaces

rmmap_getwimg Kernel Service

Purpose

Returns wimg information about a particular effective address range within an effective address to real address translation region.

Syntax

```
#include <sys/adspace.h>
```

```
int rmmap_getwimg(eaddr, npages, results)
unsigned long long eaddr;
unsigned int   npages;
char* results;
```

Parameters

Item	Description
eaddr	The process effective address of the start of the desired mapping region. This address should point somewhere inside the first page of the range. This address is interpreted as a 64-bit quantity if the current user address space is 64-bits, and is interpreted as a 32-bit (not remapped) quantity if the current user address space is 32-bits.
npages	The number of pages whose wimg information is returned, starting from the page indicated by **eaddr**.
results	This is an array of bytes, where the wimg information is returned. The address of this is passed in by the caller, and **rmmap_getwimg** stores the wimg information for each page in the range in each successive byte in this array. The size of this array is indicated by *npages* as specified by the caller. The caller is responsible for ensuring that the storage allocated for this array is large enough to hold *npage* bytes.

Description

The wimg information corresponding to the input effective address range is returned.

This routine only works for regions previously mapped with an I/O mapping segment as created by **rmmap_create**.

npages should not be such that the range crosses a segment boundary. If it does, EINVAL is returned.

The wimg information is returned in the **results** array. Each element of the **results** array is a character. Each character may be added with the following fields to examine wimg information: **RMMAP_PAGE_W**, **RMMAP_PAGE_I**, **RMMAP_PAGE_M** or **RMMAP_PAGE_G**. The array is valid if the return value is 0.

Execution Environment

The **rmmap_getwimg** kernel service is called from the process environment only.

Return Values

Item	Description
0	Successful completion. Indicates that the *results* array is valid and should be examined.
EINVAL	An error occurred. Most likely the region was not mapped via **rmmap_create** previously. .
EINVAL	Input range crosses a certain boundary.
EINVAL	The hardware platform does not implement this service.

Implementation Specifics

This service only functions on PowerPC microprocessors.

rmmap_remove Kernel Service

Purpose

Destroys an effective address to real address translation region.

Syntax

```
#include <sys/adspace.h>
int rmmap_remove (eaddrp);
void **eaddrp;
```

Parameters

Item	Description
eaddrp	Pointer to the process effective address of the desired mapping region.

Description

Destroys an effective address to real address translation region. If **rmmap_remove** kernel service is called with the effective address within the region of a previously created I/O mapping segment, the region is destroyed. This service must be called from the process level.

Execution Environment

The **rmmap_remove** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
EINVAL	The provided *eaddr* does not correspond to a valid I/O mapping segment.
EINVAL	This hardware platform does not implement this service.

Implementation Specifics

This service only functions on PowerPC microprocessors.

rtalloc Kernel Service

Purpose

Allocates a route.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/route.h>
```

void rtalloc (*ro*)
register struct route ***ro*;

Parameter

Item	Description
ro	Specifies the route.

Description

The **rtalloc** kernel service allocates a route, which consists of a destination address and a reference to a routing entry.

Execution Environment

The **rtalloc** kernel service can be called from either the process or interrupt environment.

Return Values

The **rtalloc** service has no return values.

Example

To allocate a route, invoke the **rtalloc** kernel service as follows:

```
rtalloc(ro);
```

Related information
Network Kernel Services

rtalloc_gr Kernel Service

Purpose

Allocates a route.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/route.h>
```

void rtalloc_gr (*ro*, *gidlist*)
register struct route ***ro*;
struct gidstruct ***gidlist*;

Parameter

Item	Description
ro	Specifies the route.
gidlist	Points to the group list.

Description

The **rtalloc_gr** kernel service allocates a route, which consists of a destination address and a reference to a routing entry.

A route can be allocated only if its group id restrictions specify that it can be used by a user with the *gidlist* that is passed in.

Execution Environment

The **rtalloc_gr** kernel service can be called from either the process or interrupt environment.

Return Values

The **rtalloc_gr** service has no return values.

Example

To allocate a route, invoke the **rtalloc_gr** kernel service as follows:

```
rtalloc_gr (ro, gidlist);
```

Related reference
rtalloc Kernel Service

Network Kernel Services

rtfree Kernel Service

Purpose

Frees the routing table entry.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/route.h>
```

int rtfree (*rt*)
register struct rtentry *rt;**

Parameter

Item	Description
rt	Specifies the routing table entry.

Description

The **rtfree** kernel service frees the entry it is passed from the routing table. If the route does not exist, the **panic** service is called. Otherwise, the **rtfree** service frees the **mbuf** structure that contains the route and decrements the routing reference counters.

Execution Environment

The **rtfree** kernel service can be called from either the process or interrupt environment.

Return Values

The **rtfree** kernel service has no return values.

Example

To free a routing table entry, invoke the **rtfree** kernel service as follows:

```
rtfree(rt);
```

Related reference
panic Kernel Service
Related information
Network Kernel Services

rtinit Kernel Service

Purpose

Sets up a routing table entry typically for a network interface.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/socket.h>
#include <net/route.h>
```

int rtinit (*ifa, cmd, flags*)
struct ifaddr * *ifa*;
int *cmd,* *flags*;

Parameters

Item	Description
ifa	Specifies the address of an **ifaddr** structure containing destination address, interface address, and netmask.
cmd	Specifies a request to add or delete route entry.
flags	Identifies routing flags, as defined in the **/usr/include/net/route.h** file.

Description

The **rtinit** kernel service creates a routing table entry for an interface. It builds an **rtentry** structure using the values in the *ifa* and *flags* parameters.

The **rtinit** service then calls the **rtrequest** kernel service and passes the *cmd* parameter and the **rtentry** structure to process the request. The *cmd* parameter contains either the value **RTM_ADD** (a request to

add the route entry) or the value **RTM_DELETE** (delete the route entry). Valid routing flags to set are defined in the **/usr/include/route.h** file.

Execution Environment

The **rtinit** kernel service can be called from either the process or interrupt environment.

Return Values

The **rtinit** kernel service returns values from the **rtrequest** kernel service.

Example

To set up a routing table entry, invoke the **rtinit** kernel service as follows:

```
rtinit(ifa, RMT_ADD, flags ( RTF_DYNAMIC);
```

Related reference
rtrequest Kernel Service
Related information
Network Kernel Services

rtredirect Kernel Service

Purpose

Forces a routing table entry with the specified destination to go through a given gateway.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
#include <net/route.h>
```

rtredirect (*dst*, *gateway*, *netmask*, *flags*, *src*, *rtp*)
struct sockaddr **dst, *gateway, *netmask, *src;*
int *flags;*
struct rtentry ***rtp;*

Parameters

Item	Description
dst	Specifies the destination address.
gateway	Specifies the gateway address.
netmask	Specifies the network mask for the route.
flags	Indicates routing flags as defined in the **/usr/include/net/route.h** file.
src	Identifies the source of the redirect request.
rtp	Indicates the address of a pointer to a **rtentry** structure. Used to return a constructed route.

Description

The **rtredirect** kernel service forces a routing table entry for a specified destination to go through the given gateway. Typically, the **rtredirect** service is called as a result of a routing redirect message from

the network layer. The *dst*, *gateway*, and *flags* parameters are passed to the **rtrequest** kernel service to process the request.

Execution Environment

The **rtredirect** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates a successful operation.

If a bad redirect request is received, the routing statistics counter for bad redirects is incremented.

Example

To force a routing table entry with the specified destination to go through the given gateway, invoke the **rtredirect** kernel service:

```
rtredirect(dst, gateway, netmask, flags, src, rtp);
```

Related reference
rtinit Kernel Service

Network Kernel Services

rtrequest Kernel Service

Purpose

Carries out a request to change the routing table.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
#include <net/if.h>
#include <net/af.h>
#include <net/route.h>
```

int rtrequest (*req*,
***dst*,**
***gateway*,**
***netmask*,**
***flags*, *ret_nrt*)**
int *req*;
struct sockaddr *dst, ******gateway*, ******netmask*;
int *flags*;
struct rtentry **ret_nrt;

Parameters

Item	Description
req	Specifies a request to add or delete a route.

Item	Description
dst	Specifies the destination part of the route.
gateway	Specifies the gateway part of the route.
netmask	Specifies the network mask to apply to the route.
flags	Identifies routing flags, as defined in the **/usr/include/net/route.h** file.
ret_nrt	Specifies to return the resultant route.

Description

The **rtrequest** kernel service carries out a request to change the routing table. Interfaces call the **rtrequest** service at boot time to make their local routes known for routing table ioctl operations. Interfaces also call the **rtrequest** service as the result of routing redirects. The request is either to add (if the *req* parameter has a value of **RMT_ADD**) or delete (the *req* parameter is a value of **RMT_DELETE**) the route.

Execution Environment

The **rtrequest** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates a successful operation.
ESRCH	Indicates that the route was not there to delete.
EEXIST	Indicates that the entry the **rtrequest** service tried to add already exists.
ENETUNREACH	Indicates that the **rtrequest** service cannot find the interface for the route.
ENOBUFS	Indicates that the **rtrequest** service cannot get an **mbuf** structure to add an entry.

Example

To carry out a request to change the routing table, invoke the **rtrequest** kernel service as follows:

```
rtrequest(RTM_ADD, dst, gateway, netmask, flags, &rtp);
```

Related reference
rtinit Kernel Service

rtrequest_gr Kernel Service

Purpose

Carries out a request to change the routing table.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/mbuf.h>
#include <net/if.h>
```

```
#include <net/af.h>
#include <net/route.h>
```

int rtrequest_gr (*req,* *dst,* *gateway,* *netmask,* *flags,* *ret_nrt,* *rt_parm***)**
int *req;*
struct sockaddr **dst,* *****
gateway
, ******netmask;*
int *flags;*
struct rtentry **
ret_nrt;
struct rtreq_parm *
rt_parm;

Parameters

Item	Description
req	Specifies a request to add or delete a route.
dst	Specifies the destination part of the route.
gateway	Specifies the gateway part of the route.
netmask	Specifies the network mask to apply to the route.
flags	Identifies routing flags, as defined in the **/usr/include/net/route.h** file.
ret_nrt	Specifies to return the resultant route.
rt_parm	Points to the **rtreq_parm** structure. The **/usr/include/net/radix.h** file contains the **rtreq_parm** structure. Through this structure, the route attributes like group list, policy, weight, WPAR ID, interface can be specified.

Description

The **rtrequest_gr** kernel service carries out a request to change the routing table. Interfaces call the **rtrequest_gr** service at boot time to make their local routes known for routing table ioctl operations. Interfaces also call the **rtrequest_gr** service as the result of routing redirects. The request is either to add (if the *req* parameter has a value of **RMT_ADD**) or delete (the *req* parameter is a value of **RMT_DELETE**) the route.

Execution Environment

The **rtrequest_gr** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates a successful operation.
ESRCH	Indicates that the route was not there to delete.
EEXIST	Indicates that the entry the **rtrequest_gr** service tried to add already exists.
ENETUNREACH	Indicates that the **rtrequest_gr** service cannot find the interface for the route.
ENOBUFS	Indicates that the **rtrequest_gr** service cannot get an **mbuf** structure to add an entry.

Example

To carry out a request to change the routing table, invoke the **rtrequest_gr** kernel service as follows:

```
rtrequest_gr(RTM_ADD, dst, gateway, netmask, flags, &rtp, &rtreq);
```

rusage_incr Kernel Service

Purpose

Increments a field of the **rusage** structure.

Syntax

```
#include <sys/encap.h>
```

void rusage_incr (*field*, *amount*)
int *field*;
int *amount*;

Parameters

Item	Description
field	Specifies the field to increment. It must have one of the following values:

> **RUSAGE_INBLOCK**
> Denotes the `ru_inblock` field. This field specifies the number of times the file system performed input.
>
> **RUSAGE_OUTBLOCK**
> Denotes the `ru_outblock` field. This field specifies the number of times the file system performed output.
>
> **RUSAGE_MSGRCV**
> Denotes the `ru_msgrcv` field. This field specifies the number of IPC messages received.
>
> **RUSAGE_MSGSENT**
> Denotes the `ru_msgsnd` field. This field specifies the number of IPC messages sent.

Item	Description
amount	Specifies the amount to increment to the field.

Description

The **rusage_incr** kernel service increments the field specified by the *field* parameter of the calling process' **rusage** structure by the amount *amount*.

Execution Environment

The **rusage_incr** kernel service can be called from the process environment only.

Return Values

The **rusage_incr** kernel service has no return values.

s

The following kernel services begin with the with the letter s.

schednetisr Kernel Service

Purpose

Schedules or invokes a network software interrupt service routine.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <net/netisr.h>
```

int schednetisr (*anisr*)
int *anisr*;

Parameter

Item	Description
anisr	Specifies the software interrupt number to issue. Refer to `netisr.h` for the range of values of *anisr* that are already in use. Also, other kernel extensions that are not AIX and that use network ISRs currently running on the system can make use of additional values not mentioned in `netisr.h`.

Description

The **schednetisr** kernel service schedules or calls a network interrupt service routine. The **add_netisr** kernel service establishes interrupt service routines. If the service was added with a service level of **NET_OFF_LEVEL**, the **schednetisr** kernel service directly calls the interrupt service routine. If the service level was **NET_KPROC**, a network kernel dispatcher is notified to call the interrupt service routine.

Execution Environment

The **schednetisr** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
EFAULT	Indicates that a network interrupt service routine does not exist for the specified interrupt number.
EINVAL	Indicates that the *anisr* parameter is out of range.

Related reference

add_netisr Kernel Service

del_netisr Kernel Service

Network Kernel Services

selnotify Kernel Service

Purpose

Wakes up processes waiting in a **poll** or **select** subroutine or in the **fp_poll** kernel service.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

void selnotify (*id*, *subid*, *rtnevents*)
int *id*;
int *subid*;
ushort *rtnevents*;

Parameters

Item	Description
id	Indicates a primary resource identification value. This value along with the subidentifier (specified by the *subid* parameter) is used by the kernel to notify the appropriate processes of the occurrence of the indicated events. If the resource on which the event has occurred is a device driver, this parameter must be the device major/minor number (that is, a **dev_t** structure that has been cast to an **int**). The kernel has reserved values for the *id* parameter that do not conflict with possible device major or minor numbers for sockets, message queues, and named pipes.
subid	Helps identify the resource on which the event has occurred for the kernel. For a multiplexed device driver, this is the number of the channel on which the requested events occurred. If the device driver is nonmultiplexed, the *subid* parameter must be set to 0.
rtnevents	Consists of a set of bits indicating the requested events that have occurred on the specified device or channel. These flags have the same definition as the event flags that were provided by the *events* parameter on the unsatisfied call to the object's select routine.

Description

The **selnotify** kernel service should be used by device drivers that support select or poll operations. It is also used by the kernel to support select or poll requests to sockets, named pipes, and message queues.

The **selnotify** kernel service wakes up processes waiting on a **select** or **poll** subroutine. The processes to be awakened are those specifying the given device and one or more of the events that have occurred on the specified device. The **select** and **poll** subroutines allow a process to request information about one or more events on a particular device. If none of the requested events have yet happened, the process is put to sleep and re-awakened later when the events actually happen.

The **selnotify** service should be called whenever a previous call to the device driver's **ddselect** entry point returns and both of the following conditions apply:

- The status of all requested events is false.
- Asynchronous notification of the events is requested.

The **selnotify** service can be called for other than these conditions but performs no operation.

Sequence of Events for Asynchronous Notification

The device driver must store information about the events requested while in the driver's **ddselect** routine under the following conditions:

- None of the requested events are true (at the time of the call).
- The **POLLSYNC** flag is not set in the *events* parameter.

The **POLLSYNC** flag, when not set, indicates that asynchronous notification is desired. In this case, the **selnotify** service should be called when one or more of the requested events later becomes true for that device and channel.

When the device driver finds that it can satisfy a **select** request, (perhaps due to new input data) and an unsatisfied request for that event is still pending, the **selnotify** service is called with the following items:

- Device major and minor number specified by the *id* parameter
- Channel number specified by the *subid* parameter
- Occurred events specified by the *rtnevents* parameter

These parameters describe the device instance and requested events that have occurred on that device. The notifying device driver then resets its requested-events flags for the events that have occurred for that device and channel. The reset flags thus indicate that those events are no longer requested.

If the *rtnevents* parameter indicated by the call to the **selnotify** service is no longer being waited on, no processes are awakened.

Execution Environment

The **selnotify** kernel service can be called from either the process or interrupt environment.

Return Values

The **selnotify** service has no return values.

Implementation Specifics

The **selnotify** kernel service is part of Base Operating System (BOS) Runtime.

poll subroutine
select subroutine
Kernel Extension and Device Driver Management Kernel Services

selreg Kernel Service

Purpose

Registers an asynchronous poll or select request with the kernel.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/poll.h>
```

int selreg (*corl*, *dev_id*, *unique_id*, *reqevents*, *notify*)
int *corl*;
int *dev_id*;
int *unique_id*;
ushort *reqevents*;
void (**notify*) ( );

Parameters

Item	Description
corl	The correlator for the poll or select request. The *corl* parameter is used by the **poll** and **select** subroutines to correlate the returned events in a specific select control block with a process' file descriptor or message queue.
dev_id	Primary resource identification value. Along with the *unique_id* parameter, the *dev_id* parameter is used to record in the select control block the resource on which the requested poll or select events are expected to occur.
unique_id	Unique resource identification value. Along with the *dev_id* parameter, the *unique_id* parameter denotes the resource on which the requested events are expected to occur. For a multiplexed device driver, this parameter specifies the number of the channel on which the requested events are expected to occur. For a nonmultiplexed device driver, this parameter must be set to 0.
reqevents	Requested events parameter. The *reqevents* parameter consists of a set of bit flags denoting the events for which notification is being requested. These flags have the same definitions as the event flags provided by the *events* parameter on the unsatisfied call to the object's **select** subroutine (see the **sys/poll.h** file for the definitions). **Note:** The **POLLSYNC** bit flag should not be set in this parameter.
notify	Notification routine entry point. This parameter points to a notification routine used for nested poll and select calls.

Description

The **selreg** kernel service is used by **select** file operations in the top half of the kernel to register an unsatisfied asynchronous poll or select event request with the kernel. This registration enables later calls to the **selnotify** kernel service from resources in the bottom half of the kernel to correctly identify processes awaiting events on those resources.

The event requests may originate from calls to the **poll** or **select** subroutine, from processes, or from calls to the **fp_poll** or **fp_select** kernel service. A **select** file operation calls the **selreg** kernel service under the following circumstances:

- The poll or select request is asynchronous (the **POLLSYNC** flag is not set for the requested event's bit flags).
- The poll or select request determines (by calling the underlying resource's **ddselect** entry point) that the requested events have not yet occurred.

A registered event request takes the form of a select control block. The select control block is a structure containing the following:

- Requested event bit flags
- Returned event bit flags
- Primary resource identifier
- Unique resource identifier
- Pointer to a **proc** table entry
- File descriptor correlator
- Pointer to a notification routine that is non-null only for nested calls to the **poll** and **select** subroutines

The **selreg** kernel service allocates and initializes a select control block each time it is called.

When an event occurs on a resource that supports the **select** file operation, the resource calls the **selnotify** kernel service. The **selnotify** kernel service locates all select control blocks whose primary and unique identifiers match those of the resource, and whose requested event flags match the occurred events on the resource. Then, for each of the matching control blocks, the **selnotify** kernel service takes

one of two courses of action, depending upon whether the control block's notification routine pointer is non-null (nested) or null (non-nested):

- In nested calls to the **select** or **poll** subroutines, the notification routine is called with the primary and unique resource identifiers, the returned event bit flags, and the process identifiers.
- In non-nested calls to the **select** or **poll** subroutine (the usual case), the SSEL bit of the process identified in the block is cleared, the returned event bit flags in the block are updated, and the process is awakened. A process awakened in this manner completes the **poll** or **select** call in which it was sleeping. The **poll** or **select** subroutine then collects the returned event bit flags in its processes' select control blocks for return to the user mode process, deallocates the control blocks, and returns tallys of the numbers of requested events that occurred to the user process.

Execution Environment

The **selreg** kernel service can be called from the process environment only.

Returns Values

Item	Description
0	Indicates successful completion.
EAGAIN	Indicates the **selreg** kernel service was unable to allocate a select control block.

Related information

select subroutine

Kernel Extension and Device Driver Management Kernel Services

set_pag or set_pag64 Kernel Service

Purpose

Sets a Process Authentication Group (PAG) value for the current process.

Syntax

```
#include <sys/cred.h>

int set_pag ( type, pag )
int type;
int pag;

int set_pag64 ( type, pag )
int type;
uint64_t *pag;
```

Parameters

Item	Description
type	PAG type to change
pag	PAG value

Description

The `set_pag` or `set_pag64` kernel service copies the requested PAG for the current process. The caller must synchronize the `set_pag` and `set_pag64` kernel services with `validate_pag` because `set_pag` and `set_pag64` do not lock process creation across the system. The value of *type* must be a defined PAG ID. The PAG ID for the Distributed Computing Environment (DCE) is 0.

Execution Environment

The `set_pag` and `set_pag64` kernel services can be called from the process environment only.

Return Values

A value of `0` is returned upon successful completion. Upon failure, a `-1` is returned and `errno` is set to a value that explains the error.

Error Codes

The `set_pag` and `set_pag64` kernel services fails if one or both of the following conditions are true:

Item	Description
EINVAL	Invalid PAG specification

Related information
Security Kernel Services

setioctlrv Subroutine

Purpose

Sets a value to be returned by an **ioctl** routine.

Syntax

```
void setioctlrv (ioctlrv)
int ioctlrv;
```

Parameters

Item	Description
ioctlrv	Specifies an integer value to be returned by a successful completion of the **ioctl** subroutine.

Description

The **setioctlrv** subroutine sets the value of the u_ioctlrv field in the **uthread** structure of the running thread. The value in the u_ioctlrv field is returned by the**ioctl** or **fp_ioctl** subroutine on a successful completion. If the **ioctl** subroutine fails, an errno value is returned instead.

Return Values

The **setioctlrv** subroutine returns no return values.

Error Codes

The **setioctlrv** subroutine returns no error codes.

setjmpx Kernel Service

Purpose

Allows saving the current execution state or context.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

int setjmpx (*jump_buffer*)
label_t **jump_buffer;*

Parameter

Item	Description
jump_buffer	Specifies the address of the caller-supplied jump buffer that was specified on the call to the **setjmpx** service.

Description

The **setjmpx** kernel service saves the current execution state, or context, so that a subsequent **longjmpx** call can cause an immediate return from the **setjmpx** service. The **setjmpx** service saves the context with the necessary state information including:

- The current interrupt priority.
- Whether the process currently owns the kernel mode lock.

Other state variables include the nonvolatile general purpose registers, the current program's table of contents and stack pointers, and the return address.

Calls to the **setjmpx** service can be nested. Each call to the **setjmpx** service causes the context at this point to be pushed to the top of the stack of saved contexts.

Execution Environment

The **setjmpx** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
Nonzero value	Indicates that a **longjmpx** call caused the **setjmpx** service to return.
0	Indicates any other circumstances.

Related reference
clrjmpx Kernel Service

Handling Signals While in a System Call
Exception Processing

setpinit Kernel Service

Purpose

Sets the parent of the current kernel process to the initialization process.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/device.h>
```

```
int setpinit()
```

Description

The **setpinit** kernel service can be called by a kernel process to set its parent process to the **init** process. This is done to redirect the death of child signal for the termination of the kernel process. As a result, the init process is allowed to perform its default zombie process cleanup.

The **setpinit** service is used by a kernel process that can terminate, but does not want the user-mode process under which it was created to receive a death of child process notification.

Execution Environment

The **setpinit** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
EINVAL	Indicates that the current process is not a kernel process.

Related information
Using Kernel Processes
Process and Exception Management Kernel Services

setuerror Kernel Service

Purpose

Allows kernel extensions to set the **ut_error** field for the current thread.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
int setuerror ( errno)
int errno;
```

Parameter

Item	Description
errno	Contains a value found in the **/usr/include/sys/errno.h** file that is to be copied to the current thread **ut_error** field.

Description

The **setuerror** kernel service allows a kernel extension in a process environment to set the **ut_error** field in current thread's **uthread** structure. Kernel extensions providing system calls available to user-mode

applications typically use this service. For system calls, the value of the **ut_error** field in the per thread **uthread** structure is copied to the **errno** global variable by the system call handler before returning to the caller.

Execution Environment

The **setuerror** kernel service can be called from the process environment only.

Return Codes

The **setuerror** kernel service returns the *errno* parameter.

shutdown_notify_reg Kernel Service

Purpose

Allows kernel extensions to register a shutdown notification.

Syntax

```
#include <sys/reboot.h>

int shutdown_notify_reg(sn)
shutdown_notify_t *sn;

typedef struct _shutdown_notify {
    struct _shutdown_notify *next;        /* Next in the link-list */
    int             version;      /* Version of structure */
    int             oper;          /* Bit map of the operation being performed */
    int             status;        /* The current status of this notify */
    uchar           cb_retry;     /* Internal use */
    uchar           scope;         /* Partition or system wide */
    uchar           reason;         /* User initiated or EPOW */
    uchar           padding;        /* padding */
    long            (*func)();    /* Function kernel calls to notify ext. */
    void            *uaddr;
/* Address to help extension identify the object this structure refers to */
} shutdown_notify_t;

/* Valid values
for shutdown_notify_t->oper */
#define SHUTDOWN_NOTIFY_PREPARE    0x1    /* Shutdown has started */
#define SHUTDOWN_NOTIFY_REBOOT    0x2    /*
Final notify that shutdown will be a reboot */
#define SHUTDOWN_NOTIFY_HALT     0x4
/* Final notify that shutdown will be a halt */
#define SHUTDOWN_NOTIFY_QUERY     0x8
/* Check to see if finished shutdown */

/* Valid values for
shutdown_notify_t->status and
for SHUTDOWN_NOTIFY_QUERY return code */
#define SHUTDOWN_STATUS_PREPARE        0x1    /* Preparing for shutdown */
#define SHUTDOWN_STATUS_COMMENCE      0x2    /* Commencing shutdown */
#define SHUTDOWN_STATUS_FINISH        0x4    /* Finished shutdown */

#define SHUTDOWN_NOTIFY_VERSION        1   /* Increment by 1
                            * every time add more
                            * variables to
                            * shutdown_notify_t
                            */
/* Valid values for shutdown_notify_t->scope */
#define         SHUTDOWN_SCOPE_PARTITION    1
#define         SHUTDOWN_SCOPE_SYSTEM       2
```

```
/* Valid values for shutdown_notify_t->reason */
#define       SHUTDOWN_REASON_USER       1
#define       SHUTDOWN_REASON_EPOW       2

/* Valid handler return codes
during the SHUTDOWN_NOTIFY_PREPARE phase */
#define       SHUTDOWN_RC_SUCCESS          0
#define       SHUTDOWN_RC_DELAY            1

#define    SHUTDOWN_NOTIFY_VERSION        2
```

Description

The shutdown notify subsystem has been extended to provide additional information during a shutdown operation. During the **SHUTDOWN_NOTIFY_PREPARE** phase, the kernel provides information on the scope and reason for the shutdown action. Additionally, when a handler is called, before its completion, it can now delay the shutdown operation in order to finalize any outstanding jobs. The kernel again then calls out to the handler after some small amount of time. This process continues until all handlers return **SHUTDOWN_RC_SUCCESS**. This functionality is only present for **shutdown_notify_t** version 2 and preceding handlers. For version 1 handlers, the new fields are not present and the return code from the handler is ignored.

Parameters

Item	Description
cb_retry	Internal use.
func	Pointer to the function called to notify registered extension.
next	Pointer to next **shutdown_notify_t** structure in list.
oper	Bit map of operation(s) being performed.
padding	Padding.
reason	User initiated or EPOW event.
scope	Shutdown at the partition or system level.
sn	Pointer to a structure that the calling extension fills out when it registers.
status	Current status of notify.
uaddr	Place for extension to store an address to help it identify the object to which this structure refers.
version	Version of structure. Set to 1.
SHUTDOWN_NOTIFY_HALT	A halt is occurring.
SHUTDOWN_NOTIFY_PREPARE	Shutdown has started.
SHUTDOWN_NOTIFY_QUERY	Check to see if finished shutdown.
SHUTDOWN_NOTIFY_REBOOT	A reboot is occurring.
SHUTDOWN_NOTIFY_VERSION	Version number of structure.
SHUTDOWN_RC_DELAY	Return from registered handler to indicate its processing is not complete and wants to delay the shutdown operation.
SHUTDOWN_RC_SUCCESS	Return from registered handler to indicate all processing is complete and the shutdown operation can proceed.
SHUTDOWN_REASON_EPOW	EPOW event.
SHUTDOWN_REASON_USER	User initiated shutdown.
SHUTDOWN_SCOPE_PARTITION	Shutdown at the partition level.
SHUTDOWN_SCOPE_SYSTEM	Shutdown at the system level.
SHUTDOWN_STATUS_COMMENCE	Wrap up shutdown.
SHUTDOWN_STATUS_FINISH	Shutdown has completed.

Item	Description
SHUTDOWN_STATUS_PREPARE	Preparing for shutdown.

Execution Environment

Process environment only.

Return Values

Item	Description
0	Success.
EPERM	Attempted to register after prepare notification has started.
EINVAL	Invalid argument passed.

shutdown_notify_unreg Kernel Service

Purpose

Unregisters an extension from getting notified in the event of a shutdown.

Syntax

```
#include <sys/reboot.h>

int shutdown_notify_unreg(sn)
shutdown_notify_t *sn;
```

Description

The **shutdown_notify_unreg** kernel service unregisters an extension from getting notified in the event of a shutdown. The extension passes in the **shutdown_notify_t** instance it wants to unregister. This function will fail if it is called after the **SHUTDOWN_NOTIFY_HALT** and **SHUTDOWN_NOTIFY_REBOOT** notification process has started.

Parameters

Item	Description
sn	Pointer to a structure that the calling extension wants to unregister.

Execution Environment

Process environment only.

Return Values

Item	Description
0	Success
EPERM	Attempted to unregister after final notification has started.
EINVAL	Invalid argument passed.

sig_chk Kernel Service

Purpose

Provides a kernel process the ability to poll for receipt of signals.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/signal.h>
```

```
int sig_chk ()
```

Description

> **Attention:** A system crash will occur if the **sig_chk** service is not called by a kernel process.

The **sig_chk** kernel service can be called by a kernel thread in kernel mode to determine if any unmasked signals have been received. Signals do not preempt threads because serialization of critical data areas would be lost. Instead, threads must poll for signals, either periodically or after a long sleep has been interrupted by a signal.

The **sig_chk** service checks for any pending signal that has a specified *signal catch* or *default* action. If one is found, the service returns the signal number as its return value. It also removes the signal from the pending signal mask. If no signal is found, this service returns a value of 0. The **sig_chk** service does not return signals that are blocked or ignored. It is the responsibility of the kernel process to handle the signal appropriately.

For kernel-only threads, the **sig_chk** kernel service clears the returned signal from the list of pending signals. For other kernel threads, the signal is not cleared, but left pending. It will be delivered to the kernel thread as soon as it returns to the user mode.

Understanding Kernel Threads in *Kernel Extensions and Device Support Programming Concepts* provides more information about kernel-only thread signal handling.

Execution Environment

The **sig_chk** kernel service can be called from the process environment only.

Return Values

Upon completion, the **sig_chk** service returns a value of 0 if no pending unmasked signal is found. Otherwise, it returns a nonzero signal value indicating the number of the highest priority signal that is pending. Signal values are defined in the **/usr/include/sys/signal.h** file.

Related information

Introduction to Kernel Processes
Process and Exception Management Kernel Services

simple_lock or simple_lock_try Kernel Service

Purpose

Locks a simple lock.

Syntax

```
#include <sys/lock_def.h>
```

void simple_lock (** *lock_addr*)**
simple_lock_t *lock_addr***;**

boolean_t simple_lock_try (** *lock_addr*)**
simple_lock_t *lock_addr***;**

Parameter

Item	Description
lock_addr	Specifies the address of the lock word to lock.

Description

The **simple_lock** kernel service locks the specified lock; it blocks if the lock is busy. The lock must have been previously initialized with the **simple_lock_init** kernel service. The **simple_lock** kernel service has no return values.

The **simple_lock_try** kernel service tries to lock the specified lock; it returns immediately without blocking if the lock is busy. If the lock is free, the **simple_lock_try** kernel service locks it. The lock must have been previously initialized with the **simple_lock_init** kernel service.

Note: When using simple locks to protect thread-interrupt critical sections, it is recommended that you use the **disable_lock** kernel service instead of calling the **simple_lock** kernel service directly.

Execution Environment

The **simple_lock** and **simple_lock_try** kernel services can be called from the process environment only.

Return Values

The **simple_lock_try** kernel service has the following return values:

Item	Description
TRUE	Indicates that the simple lock has been successfully acquired.
FALSE	Indicates that the simple lock is busy, and has not been acquired.

Related reference
disable_lock Kernel Service
simple_unlock Kernel Service

Understanding Locking
Locking Kernel Services

simple_lock_init Kernel Service

Purpose

Initializes a simple lock.

Syntax

```
#include <sys/lock_def.h>
```

void simple_lock_init (*lock_addr***)**
simple_lock_t *lock_addr***;**

Parameter

Item	Description
lock_addr	Specifies the address of the lock word.

Description

The **simple_lock_init** kernel service initializes a simple lock. This kernel service must be called before the simple lock is used. The simple lock must previously have been allocated with the **lock_alloc** kernel service.

Execution Environment

The **simple_lock_init** kernel service can be called from the process environment only.

The **simple_lock_init** kernel service may be called either the process or interrupt environments.

Return Values

The **simple_lock_init** kernel service has no return values.

Related reference
lock_alloc Kernel Service
Related information
Understanding Locking
Locking Kernel Services

simple_unlock Kernel Service

Purpose

Unlocks a simple lock.

Syntax

```
#include <sys/lock_def.h>
```

void simple_unlock (*lock_addr***)**
simple_lock_t *lock_addr***;**

Parameter

Item	Description
lock_addr	Specifies the address of the lock word to unlock.

Description

The **simple_unlock** kernel service unlocks the specified simple lock. The lock must be held by the thread which calls the **simple_unlock** kernel service. Once the simple lock is unlocked, the highest priority thread (if any) which is waiting for it is made runnable, and may compete for the lock again. If at least one kernel thread was waiting for the lock, the priority of the calling kernel thread is recomputed.

Note: When using simple locks to protect thread-interrupt critical sections, it is recommended that you use the **unlock_enable** kernel service instead of calling the **simple_unlock** kernel service directly.

Execution Environment

The **simple_unlock** kernel service can be called from the process environment only.

Return Values

The **simple_unlock** kernel service has no return values.

Related reference

simple_lock_init Kernel Service
simple_lock or simple_lock_try Kernel Service

Understanding Locking

sleep Kernel Service

Purpose

Forces the calling kernel thread to wait on a specified channel.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/pri.h>
#include <sys/proc.h>
```

int sleep (*chan,* *priflags***)**
void *∗chan;*
int *priflags;*

Parameters

Item	Description
chan	Specifies the channel number. For the **sleep** service, this parameter identifies the channel to wait for (sleep on).
priflags	Specifies two conditions:
	• The priority at which the kernel thread is to run when it is reactivated.
	• Flags indicating how a signal is to be handled by the **sleep** kernel service.

The valid flags and priority values are defined in the **/usr/include/sys/pri.h** file.

Description

The **sleep** kernel service is provided for compatibility only and should not be invoked by new code. The **e_sleep_thread** or **et_wait** kernel service should be used when writing new code.

The **sleep** service puts the calling kernel thread to sleep, causing it to wait for a wakeup to be issued for the channel specified by the *chan* parameter. When the process is woken up again, it runs with the priority specified in the *priflags* parameter. The new priority is effective until the process returns to user mode.

All processes that are waiting on the channel are restarted at once, causing a race condition to occur between the activated threads. Thus, after returning from the **sleep** service, each thread should check whether it needs to sleep again.

The channel specified by the *chan* parameter is simply an address that by convention identifies some event to wait for. When the kernel or kernel extension detects such an event, the **wakeup** service is called with the corresponding value in the *chan* parameter to start up all the threads waiting on that channel. The channel identifier must be unique systemwide. The address of an external kernel variable (which can be defined in a device driver) is generally used for this value.

If the **SWAKEONSIG** flag is not set in the *priflags* parameter, signals do not terminate the sleep. If the **SWAKEONSIG** flag is set and the **PCATCH** flag is not set, the kernel calls the **longjmpx** kernel service to resume the context saved by the last **setjmpx** call if a signal interrupts the sleep. Therefore, any system call (such as those calling device driver **ddopen**, **ddread**, and **ddwrite** routines) or kernel process that does an interruptible sleep without the **PCATCH** flag set must have set up a context using the **setjmpx** kernel service. This allows the sleep to resume in case a signal is sent to the sleeping process.

> **Attention:** The caller of the **sleep** service must own the kernel-mode lock specified by the *kernel_lock* parameter. The **sleep** service does not provide a compatible level of serialization if the kernel lock is not owned by the caller of the **sleep** service.

Execution Environment

The **sleep** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
1	Indicates that a signal has interrupted a sleep with both the **PCATCH** and **SWAKEONSIG** flags set in the *priflags* parameter.

Related information

Locking Strategy in Kernel Mode

Process and Exception Management Kernel Services

sleepx Kernel Service

Purpose

Wait for an event.

Syntax

#include <sys/sleep.h>

int sleepx (*tchan_t chan int pri flags_t flags***)**

Parameters

chan
Specifies the channel number. For the **sleep** service, this parameter identifies the channel to wait for (sleep on).

pri
Specifies the wakeup priority

flags
Signal control flags

Description

Wait for an event to occur. This procedure can only be called by a thread. Callers of this service must be prepared for a premature return and check that the reason for waiting has gone away.

The **pri** parameter will be the priority of the thread when it becomes runnable again (if that priority is more favorable). The process will keep that priority until it is dispatched. The range of the wakeup priority is `0 <= pri <= PRI_LOW`. If the **pri** parameter is outside of that range, it is forced to the lower or upper boundary.

Execution Environment

The **sleepx** kernel service can be called from the process environment only.

Return Values

0
Indicates that the event occurred.

1
Indicates that the event signalled out.

subyte Kernel Service

Purpose

Stores a byte of data in user memory.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

int subyte (*uaddr*, *c***)**
uchar **uaddr***;**
uchar *c***;**

Parameters

Item	Description
uaddr	Specifies the address of user data.
c	Specifies the character to store.

Description

The **subyte** kernel service stores a byte of data at the specified address in user memory. It is provided so that system calls and device heads can safely access user data. The **subyte** service ensures that the user has the appropriate authority to:

- Access the data.
- Protect the operating system from paging I/O errors on user data.

The **subyte** service should only be called while executing in kernel mode in the user process.

Execution Environment

The **subyte** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
-1	Indicates a *uaddr* parameter that is not valid for one of the following reasons:

- The user does not have sufficient authority to access the data.
- The address is not valid.
- An I/O error occurs when the user data is referenced.

Related reference
fubyte Kernel Service

Accessing User-Mode Data While in Kernel Mode
Memory Kernel Services

suser Kernel Service

Purpose

Determines the privilege state of a process.

Syntax

```
#include <sys/types.h>
#include  <sys/errno.h>
```

```
int suser ( ep)
char *ep;
```

Parameter

Item	Description
ep	Points to a character variable where the **EPERM** value is stored on failure.

Description

The **suser** kernel service checks whether a process has any effective privilege (that is, whether the process's uid field equals 0).

Execution Environment

The **suser** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates failure. The character pointed to by the *ep* parameter is set to the value of **EPERM**. This indicates that the calling process does not have any effective privilege.
Nonzero value	Indicates success (the process has the specified privilege).

Related information

Security Kernel Services

suword Kernel Service

Purpose

Stores a word of data in user memory.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

int suword (*uaddr*, *w*)
int *uaddr;
int *w*;

Parameters

Item	Description
uaddr	Specifies the address of user data.
w	Specifies the word to store.

Description

The **suword** kernel service stores a word of data at the specified address in user memory. It is provided so that system calls and device heads can safely access user data. The **suword** service ensures that the user had the appropriate authority to:

- Access the data.
- Protect the operating system from paging I/O errors on user data.

The **suword** service should only be called while executing in kernel mode in the user process.

Execution Environment

The **suword** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
-1	Indicates a *uaddr* parameter that is not valid for one of these reasons:

- The user does not have sufficient authority to access the data.
- The address is not valid.
- An I/O error occurs when the user data is referenced.

Memory Kernel Services
Accessing User-Mode Data While in Kernel Mode

t

The following kernel services begin with the with the letter t.

TE_verify_reg Kernel Service

Purpose

Registers a callout handler for Trusted Execution (TE) file verification during the exec() functions, kernel extension loads, and library load operations.

Syntax

```
#include <sys/file.h>
typedef int (*TE_verify)(char *, int, struct file *);

int TE_verify_reg(TE_verify verify_fn, uint_64 options)
```

Parameters

verify_fn
Specifies the callout function to be called for the verification checks with the exec() functions for the Trusted Execution of the AIX kernel level, loading of kernel extensions, and library loading events instead of the default AIX Trusted Execution method.

For more information about the function definition of this callout handler, see the `alt_verify_fn` section.

options
Specifies a bit mask of registration options. The **options** parameter is not defined currently. The caller must set the **options** parameter to 0.

Description

The `TE_verify_reg` kernel service registers a callout handler for the AIX Trusted Execution framework.

After a callout handler is registered, the handler is invoked for the exec() functions, loading kernel extensions, and library load-time checks for Trusted Execution in the AIX kernel. The default AIX Trusted Execution logic is not invoked and any AIX-configured policies for Trusted Execution not applied. The

registered alternative handler becomes the active Trusted Execution engine for AIX to provide security policy as implemented in the handler and its associated management components.

After a callout handler is registered with the `TE_verify_reg` kernel service, subsequent invocation of the `TE_verify_reg` service returns with an error code of EEXIST.

You must have root authority to call the `TE_verify_reg` kernel service.

Return values

On successful completion, the `TE_verify_reg` service kernel service returns a value of 0.

The following error codes are returned on failure:

EEXIST
    The callout handler is already registered.

EPERM
    The caller does not have permission to invoke this function.

EINVAL
    The callout handler or the **options** parameters are invalid.

Execution environment

The `TE_verify_reg` kernel service can be called from the process environment only.

The registered alternative Trusted Execution handler must conform to the behaviors that are described in the following section.

alt_verify_fn callout function

Purpose

Verifies the integrity of a file.

Syntax

```
#include <sys/file.h>

#define VERIFY_EXECUTABLES 2
#define VERIFY_SHLIBS 3
#define VERIFY_SCRIPTS 4
#define VERIFY_KERNEXTS 5

int alt_TE_verify (char *path_name, int type, struct file *path_fp)
```

Description

The `alt_TE_verify` callout function is started from the loader and the program execution path to verify the integrity of a file that is specified under the *path_name* parameter. The *path_fp* parameter is a file pointer to the file object that is associated with the *path_name* parameter.

The *type* parameter can be one of the following values:

VERIFY_EXECUTABLES
    This value is specified when the `alt_TE_verify` function is started from the kernel exec() function to verify executable programs.

VERIFY_SCRIPTS
    This value is specified when the `alt_TE_verify` function is started from the exec() function and the *path_name* value is a shell file.

VERIFY_KERNEXTS
    This value is specified when the `alt_TE_verify` function is started for loading a kernel extension.

VERIFY_SHLIBS
    This value is specified when the `alt_TE_verify` function is started for loading a shared library.

Input parameters

path_name
Specifies the path to the file that must be verified.

type
Indicates the type of verification that must be performed.

path_fp
Indicates the file pointer to the *path_name* file.

Return values

0
Indicates that the verification completed successfully.

Nonzero
Indicates that the verification failed.

The nonzero return value blocks loading of the file. An error number is set by the AIX kernel functions that start the `alt_verify_fn` callout function.

TE_verify_unreg Kernel Service

Purpose

Unregisters a previously registered callout handler for trusted execution.

Syntax

```
#include <sys/file.h>
typedef int (*TE_verify)(char *, int, struct file *);

int TE_verify_unreg(TE_verify verify_fn, uint_64 options)
```

Parameters

verify_fn
Specifies the callout function that must be used when you register the handler by using the `TE_verify_reg()` kernel service.

options
Specifies a bit mask of registration options. The **options** parameter is not defined currently. The caller must set the **options** parameter to 0.

Description

The `TE_verify_unreg` kernel service unregisters a callout handler for the AIX Trusted Execution (TE) framework. The *verify_fn* parameter must match with the currently registered TE callout handler. Otherwise, the `TE_verify_unreg` kernel service returns an error code of EPERM.

After a callout handler is unregistered, the default AIX trusted execution logic is applied based on the configured AIX trusted execution policies.

The caller of the `TE_verify_unreg` kernel service must have root authority.

Return values

On successful completion, the `TE_verify_unreg` kernel service returns a value of 0.

The following error codes are returned on failure:

EPERM

The caller does not have permission to start this function. Or, the registered callout handler is not same as the *verify_fn* parameter.

EINVAL

No callout handler is registered or the *options* parameters are invalid.

Execution environment

The `TE_verify_unreg` kernel service can be called only from the process environment.

talloc Kernel Service

Purpose

Allocates a timer request block before starting a timer request.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/timer.h>
```

```
struct trb *talloc()
```

Description

The **talloc** kernel service allocates a timer request block. The user must call it before starting a timer request with the **tstart** kernel service. If successful, the **talloc** service returns a pointer to a pinned timer request block.

Execution Environment

The **talloc** kernel service can be called from the process environment only.

Return Values

The **talloc** service returns a pointer to a timer request block upon successful allocation of a **trb** structure. Upon failure, a null value is returned.

Related reference

tfree Kernel Service

Using Fine Granularity Timer Services and Structures

tfree Kernel Service

Purpose

Deallocates a timer request block.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/timer.h>
```

```
void tfree ( t)
struct trb *t;
```

Parameter

Item	Description
t	Points to the timer request structure to be freed.

Description

The **tfree** kernel service deallocates a timer request block that was previously allocated with a call to the **talloc** kernel service. The caller of the **tfree** service must first cancel any pending timer request associated with the timer request block being freed before attempting to free the request block. Canceling the timer request block can be done using the **tstop** kernel service.

Execution Environment

The **tfree** kernel service can be called from either the process or interrupt environment.

Note: Do not use the **tfree** kernel service to free the timer request block that is passed to the timer completion handler.

Return Values

The **tfree** service has no return values.

Related reference
talloc Kernel Service

thread_create Kernel Service

Purpose

Creates a new kernel thread in the calling process.

Syntax

```
#include <sys/thread.h>
```

```
tid_t thread_create ()
```

Description

The **thread_create** kernel service creates a new kernel-only thread in the calling kernel process. The thread's ID is returned; it is unique system wide.

The new thread does not begin running immediately; its state is set to **TSIDL**. The execution will start after a call to the **kthread_start** kernel service. If the process is exited prior to the thread being made runnable, the thread's resources are released immediately. The thread's signal mask is inherited from the calling thread; the set of pending signals is cleared. Signals sent to the thread are marked pending while the thread is in the **TSIDL** state.

If the calling thread is bound to a specific processor, the new thread will also be bound to the processor.

Execution Environment

The **thread_create** kernel service can be called from the process environment only. This service cannot be called directly from a kernel extension.

Return Values

Upon successful completion, the new thread's ID is returned. Otherwise, -1 is returned, and the error code can be checked by calling the **getuerror** kernel service.

Error Codes

Item	Description
EAGAIN	The total number of kernel threads executing system wide or the maximum number of kernel threads per process would be exceeded.
ENOMEM	There is not sufficient memory to create the kernel thread.
ENOTSUP	The **thread_create** service was called directly from a kernel extension.

Process and Exception Management Kernel Services

thread_self Kernel Service

Purpose

Returns the caller's kernel thread ID.

Syntax

```
#include <sys/thread.h>
```

```
tid_t thread_self ()
```

Description

The **thread_self** kernel service returns the thread process ID of the calling process.

The **thread_self** service can also be used to check the environment that the routine is being executed in. If the caller is executing in the interrupt environment, the **thread_self** service returns a process ID of -1. If a routine is executing in a process environment, the **thread_self** service obtains the thread process ID.

Execution Environment

The **thread_self** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
-1	Indicates that the **thread_self** service was called from an interrupt environment.

The **thread_self** service returns the thread process ID of the current process if called from a process environment.

Related information
Process and Exception Management Kernel Services
Understanding Execution Environments

thread_setsched Kernel Service

Purpose

Sets kernel thread scheduling parameters.

Syntax

```
#include <sys/thread.h>
#include <sys/sched.h>
```

int thread_setsched (*tid*, *priority*, *policy***)**
tid_t *tid*;
int *priority*;
int *policy*;

Parameters

Item	Description
tid	Specifies the kernel thread.
priority	Specifies the priority. It must be in the range from 0 to **PRI_LOW**; 0 is the most favored priority.
policy	Specifies the scheduling policy. It must have one of the following values:

> **SCHED_FIFO**
> Denotes fixed priority first-in first-out scheduling.
>
> **SCHED_FIFO2**
> Allows a thread that sleeps for a relatively short amount of time to be requeued to the head, rather than the tail, of its priority run queue.
>
> **SCHED_FIFO3**
> Causes threads to be enqueued to the head of their run queues.
>
> **SCHED_RR**
> Denotes fixed priority round-robin scheduling.
>
> **SCHED_OTHER**
> Denotes the default scheduling policy.

Description

The **thread_setsched** subroutine sets the scheduling parameters for a kernel thread. This includes both the priority and the scheduling policy, which are specified in the *priority* and *policy* parameters. The calling and the target thread must be in the same process.

When setting the scheduling policy to **SCHED_OTHER**, the system chooses the priority; the *priority* parameter is ignored. The only way to influence the priority of a thread using the default scheduling policy is to change the process nice value.

The calling thread must belong to a process with root authority to change the scheduling policy of a thread to either **SCHED_FIFO**, **SCHED_FIFO2**, **SCHED_FIFO3**, or **SCHED_RR**.

Execution Environment

The **thread_setsched** kernel service can be called from the process environment only.

Return Values

Upon successful completion, 0 is returned. Otherwise, -1 is returned, and the error code can be checked by calling the **getuerror** kernel service.

Error Codes

Item	Description
EINVAL	The *priority* or *policy* parameters are not valid.
EPERM	The calling kernel thread does not have sufficient privilege to perform the operation.
ESRCH	The kernel thread *tid* does not exist.

Process and Exception Management Kernel Services

thread_set_smt_priority or thread_read_smt_priority System Call

Purpose

Sets or reads the current simultaneous multithreading (SMT) thread priority for a user-thread.

Syntax

```
#include <sys/errno.h>
#include <sys/thread.h>
#include <sys/processor.h>
```

int thread_set_smt_priority (*Priority*)
smt_thread_priority_t Priority;

```
#include <sys/errno.h>
#include <sys/thread.h>
#include <sys/processor.h>
```

smt_thread_priority_t thread_read_smt_priority ( )

Description

The SMT thread priority that is associated with a logical CPU, SMT hardware thread, controls the relative priority of the logical CPU in relation to the other logical CPUs on the same processor core. The relative priority between the SMT hardware threads on a processor core determines how decode cycles are granted to each SMT hardware thread. The SMT thread priority can be used to cause a particular application thread to be favored over other application threads that are running on the other SMT hardware threads in the same processor core. It is done by increasing the SMT thread priority of the logical CPU the application is running on, or by lowering the SMT thread priority of the application threads that are running on the other logical CPUs associated with the same processor core.

The **thread_set_smt_priority** and **thread_read_smt_priority** system calls provide a way to register and read back the current SMT thread priority on a per process-thread basis.

Note:

These interfaces are not supported on some processor architectures.

If the process-thread is dispatched to a logical CPU that is running in non-SMT mode, the SMT thread priority level has no effect.

Callers of the **thread_set_smt_priority** system call with normal user-level privileges can set their SMT thread priority level to one of the following levels:

- LOW
- MEDIUM LOW
- NORMAL

Callers that have RBAC PV_PROC_VARS privilege can set their priority level to one of the following levels:

- VERY LOW
- LOW
- MEDIUM LOW
- NORMAL
- MEDIUM HIGH
- HIGH

The default thread priority level is NORMAL.

Note: The only supported means for altering the SMT thread priority level is by using the **thread_set_smt_priority** system call. If an alternative means of setting the SMT priority is used, the kernel does not know the process-thread's current SMT priority level, and overwrites the required SMT priority level without restoring it.

The **thread_read_smt_priority** system call returns the current SMT priority level that is registered by the process thread. If the process thread did not register a required SMT priority level, then the default priority level of NORMAL is returned.

Parameters

Item	Description
Priority	Used to specify one of the following parameters:
	- `T_VERYLOW_SMT_PRI`
	- `T_LOW_SMT_PRI`
	- `T_MEDIUMLOW_SMT_PRI`
	- `T_NORMAL_SMT_PRI`
	- `T_MEDIUMHIGH_SMT_PRI`
	- `T_HIGH_SMT_PRI`

Execution Environment

The **thread_read_smt_priority** and **thread_set_smt_priority** system calls can be called from the process environment only.

Return Values

On successful completion, the **thread_set_smt_priority** system call returns 0. Otherwise, **-1** is returned and the **errno** global variable is set to indicate the error.

On successful completion, the **thread_read_smt_priority** system call returns the current required SMT priority. Otherwise, **-1** is returned and the **errno** global variable is set to indicate the error.

Error Codes

Item	Description
EPERM	The process attempted to set the SMT thread priority level to a value other than T_LOW_SMT_PRI, T_MEDIUMLOW_SMT_PRI, or T_NORMAL_SMT_PRI and does not have the necessary privileges.
EINVAL	The required priority value that is specified is invalid.
ENOSYS	SMT thread priority level manipulation is not supported on this system.

thread_terminate Kernel Service

Purpose

Terminates the calling kernel thread.

Syntax

```
#include <sys/thread.h>
```

```
void thread_terminate ()
```

Description

The **thread_terminate** kernel service terminates the calling kernel thread and cleans up its structure and its kernel stack. If it is the last thread in the process, the process will exit.

The **thread_terminate** kernel service is automatically called when a thread returns from its entry point routine (defined in the call to the **kthread_start** kernel service).

Execution Environment

The **thread_terminate** kernel service can be called from the process environment only.

Return Values

The **thread_terminate** kernel service never returns.

Related reference
kthread_start Kernel Service
Related information
Process and Exception Management Kernel Services

timeout Kernel Service

Attention: This service must not be used because it is not multi-processor safe. The base kernel timer and watchdog services must be used instead.

Purpose

Schedules a function to be called after a specified interval.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
void timeout ( func,  arg,  ticks)
void (*func)();
caddr_t *arg;
int ticks;
```

Parameters

Item	Description
func	Indicates the function to be called.
arg	Indicates the parameter to supply to the function specified by the *func* parameter.
ticks	Specifies the number of timer ticks that must occur before the function specified by the *func* parameter is called. Many timer ticks can occur per second. The HZ label that is found in the **/usr/include/sys/m_param.h** file can be used to determine the number of ticks per second.

Description

The **timeout** service is not part of the kernel. However, it is a compatibility service that is provided in the **libsys.a** library. To use the **timeout** service, a kernel extension must be bound with the **libsys.a** library. The **timeout** service, like the associated kernel services **untimeout** and **timeoutcf**, can be bound and used only in the pinned part of a kernel extension or the bottom half of a device driver because these services use interrupt disable for serialization.

The **timeout** service schedules the function pointed to by the *func* parameter to be called with the *arg* parameter after the number of timer ticks that are specified by the *ticks* parameter. Use the **timeoutcf** routine to allocate enough callout elements for the maximum number of simultaneous active time outs that you expect.

Note: The **timeoutcf** routine must be called before the **timeout** service is called.

Calling the **timeout** service without allocating enough callout table entries can result in a kernel panic because of a lack of pinned callout table elements. The value of a timer tick depends on the hardware's capability. You can use the **restimer** subroutine to determine the minimum granularity.

Multiple pending **timeout** requests with the same *func* and *arg* parameters are not allowed.

The func Parameter

The function that is specified by the *func* parameter must be declared as follows:

```
void func (arg)
void *arg;
```

Execution Environment

The **timeout** routine can be called from either the process or interrupt environment.

The function that is specified by the *func* parameter is called in the interrupt environment. Therefore, it must follow the conventions for interrupt handlers.

Return Values

The **timeout** service has no return values.

Related reference
untimeout Kernel Service
timeoutcf Subroutine for Kernel Services
Related information
restimer subroutine

timeoutcf Subroutine for Kernel Services

Attention: This service must not be used because it is not multi-processor safe. The base kernel timer and watchdog services must be used instead.

Purpose

Allocates or deallocates callout table entries for use with the **timeout** kernel service.

Library

libsys.a (Kernel extension runtime routines)

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

int timeoutcf (*cocnt***)**
int *cocnt***;**

Parameter

Item	Description
cocnt	Specifies the callout count. This value indicates the number of callout elements by which to increase or decrease the current allocation. If this number is positive, the number of callout entries for use with the **timeout** service is increased. If this number is negative, the number of elements is decreased by the amount specified.

Description

The **timeoutcf** subroutine is not part of the kernel. It is a compatibility service that is provided in the **libsys.a** library. To use the **timeoutcf** subroutine, a kernel extension must be bound with the **libsys.a** library. The **timeoutcf** subroutine, like the associated kernel **libsys** services **untimeout** and **timeout**, can be bound and used only in the pinned part of a kernel extension or the bottom half of a device driver because these services use interrupt disable for serialization.

The **timeoutcf** subroutine registers an increase or decrease in the number of callout table entries available for the **timeout** subroutine to use. Before a subroutine can use the **timeout** kernel service, the **timeoutcf** subroutine must increase the number of callout table entries available to the **timeout** kernel service. It increases this number by the maximum number of outstanding time outs that the routine can have pending at one time.

The **timeoutcf** subroutine must be used to decrease the number of callout table entries by the amount it was increased under the following conditions:

- The routine that uses the **timeout** subroutine finished using it.
- The calling routine has no more outstanding timeout requests that are pending.

Typically the **timeoutcf** subroutine is called in a device driver's **open** and **close** routine. It is called to allocate and deallocate sufficient elements for the maximum expected use of the **timeout** kernel service for that instance of the open device.

Attention: A kernel panic results either of these two circumstances:

- A request to decrease the callout table allocation is made that is greater than the number of unused callout table entries.

- The **timeoutcf** subroutine is called in an interrupt environment.

Execution Environment

The **timeoutcf** subroutine can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful allocation or deallocation of the requested callout table entries.
-1	Indicates an unsuccessful operation.

trc_ishookon Exported Kernel Service

Purpose

Checks if a given trace hook word is being traced by system trace.

Syntax

```
#include <sys/trcmacros.h>
```

int trc_ishookon (int *chan*, **long** *hkwd***);**

Description

The **trc_ishookon** kernel service informs the user if tracing is on and the specified hook word is being traced.

Parameters

Item	Description
chan	The channel to query with the range from 0 to 7.
hkwd	The hook word to be traced by system trace.

Return Values

Item	Description
1	The hook word is being traced.
0	Hook word is not being traced or system trace is off.

Related information
trace subroutine

trcgenk Kernel Service

Purpose

Records a trace event for a generic trace channel.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/trchkid.h>
```

void trcgenk (*chan*, *hk_word*, *data_word*, *len*, *buf*)
unsigned int *chan*, *hk_word*, *data_word*, *len*;
**char ** *buf*;

Parameters

Item	Description
chan	Specifies the channel number for the trace session. This number is obtained from the **trcstart** subroutine.
hk_word	An integer containing a hook ID and a hook type:

> **hk_id**
> Before AIX 6.1 the hook identifier is a 12-bit value. On AIX 6.1 and above, the hook identifier is a 16-bit value. A 16-bit value of the form hhh0 is equivalent to a 12-bit value of the form hhh.
>
> **hk_type**
> A 4-bit hook type. The **trcgenk** service automatically records this information. This value is only valid before AIX 6.1.

Item	Description
data_word	Specifies a word of user-defined data.
len	Specifies the length in bytes of the buffer specified by the *buf* parameter.
buf	Points to a buffer of trace data. The maximum amount of trace data is 4096 bytes.

Description

The **trcgenk** kernel service records a trace event if a trace session is active for the specified trace channel. If a trace session is not active, the **trcgenk** kernel service simply returns. The **trcgenk** kernel service is located in pinned kernel memory.

The **trcgenk** kernel service is used to record a trace entry consisting of an *hk_word* entry, a *data_word* entry, a variable number of bytes of trace data, and, in AIX 5L Version 5.3 with the 5300-05 Technology Level and above, a time stamp.

Execution Environment

The **trcgenk** kernel service can be called from either the process or interrupt environment.

Return Values

The **trcgenk** kernel service has no return values.

Related reference

#include <sys/errno.h>
#include <sys/trchkid.h>
```

void trcgenkt (*chan, hk_word, data_word, len, buf*)
unsigned int *chan, hk_word, data_word, len*;
**char * *buf*;

Parameters

Item	Description
chan	Specifies the channel number for the trace session. This number is obtained from the **trcstart** subroutine.
hk_word	An integer containing a hook ID and a hook type:
	hk_id Before AIX 6.1 the hook identifier is a 12-bit value. On AIX 6.1 and above, the hook identifier is a 16-bit value. A 16-bit value of the form hhh0 is equivalent to a 12-bit value of the form hhh.
	hk_type A 4-bit hook type. The **trcgenkt** service automatically records this information. This value is only valid before AIX 6.1.
data_word	Specifies a word of user-defined data.
len	Specifies the length, in bytes, of the buffer identified by the *buf* parameter.
buf	Points to a buffer of trace data. The maximum amount of trace data is 4096 bytes.

Description

The **trcgenkt** kernel service records a trace event if a trace session is active for the specified trace channel. If a trace session is not active, the **trcgenkt** service simply returns. The **trcgenkt** kernel service is located in pinned kernel memory.

The **trcgenkt** service records a trace entry consisting of an *hk_word* entry, a *data_word* entry, a variable number of bytes of trace data, and a time stamp.

Execution Environment

The **trcgenkt** kernel service can be called from either the process or interrupt environment.

Return Values

The **trcgenkt** service has no return values.

trcgenkt Kernel Service for Data Link Control (DLC) Devices

Purpose

Records a trace event, including a time stamp, for a DLC trace channel.

Syntax

```
#include <sys/trchkid.h>
```

void trcgenkt (*chan*, *hk_word*, *data_word*, *len*, *buf*)
unsigned int *chan*, *hk_word*, *data_word*, *len*;
char * *buf*;

Parameters

Item	Description
chan	Specifies the channel number for the trace session. This number is obtained from the **trcstart** subroutine.
hk_word	Contains the trace hook identifier defined in the **/usr/include/sys/trchkid.h** file. The types of link trace entries registered using the hook ID include:

> **HKWD_SYSX_DLC_START**
>   Start link station completions
>
> **HKWD_SYSX_DLC_TIMER**
>   Time-out completions
>
> **HKWD_SYSX_DLC_XMIT**
>   Transmit completions
>
> **HKWD_SYSX_DLC_RECV**
>   Receive completions
>
> **HKWD_SYSX_DLC_HALT**
>   Halt link station completions

Item	Description
data_word	Specifies trace data format field. This field varies depending on the hook ID. Each of these definitions are in the **/usr/include/sys/gdlextcb.h** file:

- The first half-word always contains the data link protocol field including one of these definitions:

  DLC_DL_SDLC
  SDLC

  DLC_DL_HDLC
  HDLC

  DLC_DL_BSC
  BISYNC

  DLC_DL_ASC
  ASYNC

  DLC_DL_PCNET
  PC Network

  DLC_DL_ETHER
  Standard Ethernet

  DLC_DL_802_3
  IEEE 802.3

  DLC_DL_TOKEN
  Token-Ring

- On start or halt link station completion, the second half-word contains the physical link protocol in use:

  DLC_PL_EIA232
  EIA-232D Telecommunications

  DLC_PL_EIA366
  EIA-366 Auto Dial

  DLC_PL_X21
  CCITT X.21 Data Network

  DLC_PL_PCNET
  PC Network Broadband

  DLC_PL_ETHER
  Standard Baseband Ethernet

  DLC_PL_SMART
  Smart Modem Auto Dial

  DLC_PL_802_3
  IEEE 802.3 Baseband Ethernet

  DLC_PL_TBUS
  IEEE 802.4 Token Bus

  DLC_PL_TRING
  IEEE 802.5 Token-Ring

  DLC_PL_EIA422
  EIA-422 Telecommunications

  DLC_PL_V35
  CCITT V.35 Telecommunications

  DLC_PL_V25BIS
  CCITT V.25 bis Autodial for Telecommunications

Item	Description

- On timeout completion, the second half-word contains the type of timeout occurrence:

  DLC_TO_SLOW_POLL
  Slow station poll

  DLC_TO_IDLE_POLL
  Idle station poll

  DLC_TO_ABORT
  Link station aborted

  DLC_TO_INACT
  Link station receive inactivity

  DLC_TO_FAILSAFE
  Command failsafe

  DLC_TO_REPOLL_T1
  Command repoll

  DLC_TO_ACK_T2
  I-frame acknowledgment

- On transmit completion, the second half-word is set to the data link control bytes being sent. Some transmit packets only have a single control byte; in that case, the second control byte is not displayed.

- On receive completion, the second half-word is set to the data link control bytes that were received. Some receive packets only have a single control byte; in that case, the second control byte is not displayed.

len   Specifies the length in bytes of the entry specific data specified by the *buf* parameter.

buf   Specifies the pointer to the entry specific data that consists of:

Start Link Station Completions
Link station diagnostic tag and the remote station's name and address.

Time-out Completions
No specific data is recorded.

Transmit Completions
Either the first 80 bytes or all the transmitted data, depending on the short/long trace option.

Receive Completions
Either the first 80 bytes or all the received data, depending on the short/long trace option.

Halt Link Station Completions
Link station diagnostic tag, the remote station's name and address, and the result code.

Description

The **trcgenkt** kernel service records a trace event if a trace session is active for the specified trace channel. If a trace session is not active, the **trcgenkt** kernel service simply returns. The **trcgenkt** kernel service is located in pinned kernel memory.

The **trcgenkt** kernel service is used to record a trace entry consisting of an *hk_word* entry, a *data_word* entry, a variable number of bytes of trace data, and a time stamp.

Execution Environment

The **trcgenkt** kernel service can be called from either the process or interrupt environment.

Return Values

The **trcgenkt** kernel service has no return values.

Generic Data Link Control (GDLC) Environment Overview
RAS Kernel Services

tstart Kernel Service

Purpose

Submits a timer request.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/timer.h>
```

void tstart (_t_)
struct trb *_t_;

Parameter

Item	Description
_t_	Points to a timer request structure.

Description

The **tstart** kernel service submits a timer request with the timer request block specified by the _t_
parameter as input. The caller of the **tstart** kernel service must first call the **talloc** kernel service to
allocate the timer request structure. The caller must then initialize the structure's fields before calling the
tstart kernel service.

Once the request has been submitted, the kernel calls the `t->func` timer function when the amount of
time specified by the `t->timeout.it` value has elapsed. The `t->func` timer function is called on an
interrupt level. Therefore, code for this routine must follow conventions for interrupt handlers.

The **tstart** kernel service examines the `t->flags` field to determine if the timer request being submitted
represents an absolute request or an incremental one. An absolute request is a request for a time out at
the time represented in the **it_value** structure. An incremental request is a request for a time out at the
time represented by now, plus the time in the **it_value** structure.

The caller should place time information for both absolute and incremental timers in the **itimerstruc_t t.it**
value substructure. The **T_ABSOLUTE** absolute request flag is defined in the **/usr/include/sys/timer.h**
file and should be ORed into the `t->flag` field if an absolute timer request is desired.

When the **T_MOVE_OK** flag is set, the associated timer is moved to another processor when the owning
processor is folded.

When **T_LATE_OK** flag is set, the associated timer is put to sleep when the owning processor is put
to sleep (folded) mode. The timer expiration handler is called when the owning processor is awakened
(unfolded) if the scheduled expiration time has past. The time spent sleeping is therefore counted with

respect to the expiration time. When this flag is set, there is no guarantee as to when the timer might expire.

Note: The **T_MOVE_OK** and **T_LATE_OK** flags are not required. They are intended to improve the effectiveness of processor folding by reducing the load on folded processors.

Modifications to the system time are added to incremental timer requests, but not to absolute ones. Consider the user who has submitted an absolute timer request for noon on 12/25/88. If a privileged user then modifies the system time by adding four hours to it, then the timer request submitted by the user still occurs at noon on 12/25/88.

By contrast, suppose it is presently 12 noon and a user submits an incremental timer request for 6 hours from now (to occur at 6 p.m.). If, before the timer expires, the privileged user modifies the system time by adding four hours to it, the user's timer request will then expire at 2200 (10 p.m.).

Execution Environment

The **tstart** kernel service can be called from either the process or interrupt environment.

Return Values

The **tstart** service has no return values.

tstop Kernel Service

Purpose

Cancels a pending timer request.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/timer.h>
```

```
int tstop ( t)
struct trb *t;
```

Parameter

Item	Description
t	Specifies the pending timer request to cancel.

Description

The **tstop** kernel service cancels a pending timer request. The **tstop** kernel service must be called before a timer request block can be freed with the **tfree** kernel service.

In a multiprocessor environment, the timer function associated with a timer request block may be active on another processor when the **tstop** kernel service is called. In this case, the timer request cannot be canceled. A multiprocessor-safe driver must therefore check the return code and take appropriate action if the cancel request failed.

In a uniprocessor environment, the call always succeeds. This is untrue in a multiprocessor environment, where the call will fail if the timer is being handled by another processor. Therefore, the function now has a return value, which is set to 0 if successful, or -1 otherwise. Funnelled device drivers do not need to check the return value since they run in a logical uniprocessor environment. Multiprocessor-safe and multiprocessor-efficient device drivers need to check the return value in a loop. In addition, if a driver uses locking, it must release and reacquire its lock within this loop. A delay should be used between the release and reacquiring the lock as shown below:

```
while (tstop(&trp)) {
        release_any_lock;
        delay_some_time;
        reacquire_the_lock;
} /* null while loop if locks not used */
```

Execution Environment

The **tstop** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates that the request was successfully canceled.
-1	Indicates that the request could not be canceled.

tinode_t * t;
```

Description

The **tuning_register_handler** kernel service is used to add a file at the location specified by the *path* parameter. When this file is read from or written to, one of the two callbacks passed as parameters to the function is invoked.

Accesses to the file are viewed in terms of streams. A single stream is created by a sequence of one open, one or more reads, and one close on the file. While the file is open by one process, attempts to open the same file by other processes will be blocked unless **O_NONBLOCK** is passed in the flags to the **open** subroutine.

The *readfunc* callback behaves like a producer function. The function is called when the user attempts to read from the file. The *mode* parameter is equal to **TH_MORE** unless the user closes the file prematurely. On entry, the *size* parameter is an integer containing the size of the buffer. The *context* parameter is the context pointer passed to the registration function. Upon return, *size* should contain either the actual amount of data returned, or a zero if an end-of-file condition should be returned to the user. The return value of the function can also be used to signal end-of-file, as described below.

Note: It is expected that the *readfunc* callback has already done any necessary end-of-file cleanup when it returns the end-of-file signal.

If the amount of data returned is nonzero, the *buf* parameter may be modified to point to a new buffer. If this is done, the callback is responsible for freeing the new buffer.

If the buffer provided by the caller is too small, the caller may instead set *buf* to NULL. In this case, the *size* parameter should be modified to indicate the size of the buffer needed. The caller will then re-invoke the callback with a buffer of at least the requested size.

If the user closes the file before the callback indicates end-of-file, the callback will be invoked one last time with *mode* equal to **TH_ABORT**. In this case, the *size* parameter is equal to 0 on entry, and any data returned is discarded. The callback must reset its state because no further callbacks will be made for this stream.

The *writefunc* callback behaves as a consumer function and is used when the user attempts to write to the file. The *mode* parameter is set to **TH_EOF** if no further data can be expected on this stream (for example, the user called the **close** subroutine on the file). Otherwise, *mode* is set to **TH_MORE**. The *size* parameter contains the size of the data passed in the buffer. The *buf* parameter is the pointer to the buffer.

Note: There will be zero or more calls with the *mode* parameter set to **TH_MORE** and one call with the *mode* parameter set to **TH_EOF** for every stream.

The *buf* parameter may change between invocations. Upon return from the callback, the *size* parameter must be modified to reflect the amount of data consumed from the buffer, and the buffer must not be freed even if all data is consumed. The function is expected to consume data in a linear (first in, first out) fashion. Unconsumed data is present at the beginning of the buffer at the next invocation of the callback. The *size* parameter will include the size of the unconsumed data.

Both callbacks' return values are expected to be zero. If unsuccessful, a positive value will be placed into the **errno** global variable (with the accompanying indication of an error return from the kernel service). If the return value of a callback is less than 0, end-of-file will be signaled to the user, and the return value will be treated as its unary negation (For example, -1 will be treated like 0). In this case, no further callbacks will be made for this stream.

The **tuning_register_bint32**, **tuning_register_buint32**, **tuning_register_bint64**, and **tuning_register_buint64** kernel services are used to add a file at the location specified by the *path* parameter that, when read from, will return the ASCII value of the integer variable pointed to by the *variable* parameter. When written to, this file will set the integer variable to the value whose ASCII value was written, unless that value does not satisfy the relation low <= value < high. In this case, the integer variable is not modified, and an error is returned to the user through an error return of the kernel service during which the invalid attempt is detected (probably either **write** or **close**).

The **tuning_register_b*x** functions operate similarly to their non-**x** variants, but they use a pair of callbacks to retrieve (*rfunc*) and set (*wfunc*) the variable. The callback is passed the value (if setting) and the context parameter. This permits more complex operations on read/write, such as serialization and memory allocation and deallocation.

The **tuning_get_context** kernel service returns the *context* of the registration function used to create the **tinode_t** structure referred to by the *argument* parameter.

The **tuning_register** kernel service is the basic interface by which a file can be added to the **/proc/sys** directory hierarchy. This function is not exported to kernel extensions, and its direct use in the kernel is strongly discouraged. The *path* parameter contains the path relative to the **/proc/sys** root at which the file should appear. Intermediate path components are automatically created. The *mode* parameter contains the UNIX permissions and the type of the file to be created (as per the **st_mode** field of the **stat** struct). If the file type is not specified, it is assumed to be **S_IFREG**. In most cases this parameter will be 0644 or 0600. The *vnops* parameter is used to dispatch all operations on the file.

The **tuning_deregister** kernel service is used to remove a file from the **/proc/sys** directory hierarchy. It is exported to kernel extensions. It should only be used when a specific file's implementation is no longer available. The *t* parameter is a **tinode_t** structure as returned by **tuning_register**. If the file is currently open, any further access to it after this call returns **ESTALE**.

Parameters

Item	Description
mode	Is set to either **TH_EOF** if no further data is expected from the user for this change, or **TH_MORE** if further data is expected.
size	Contains the size of the data passed in the buffer.
buf	Points to the buffer.
context	Points to the context passed to the registration function.
path	Specifies the location of the file to be added.
readfunc	Behaves as a producer function.
rfunc	Retrieves the variable.
wfunc	Sets the variable.
writefunc	Behaves as a consumer function.
variable	Specifies the variable.
high	Specifies the maximum value that the *variable* parameter can contain.
low	Specifies the minimum value that the *variable* parameter can contain.
t	A **tinode_t** structure as returned by **tuning_register**.

Return Values

Upon successful completion, the **tuning_register** kernel service returns the newly created **tinode_t** structure. If unsuccessful, a NULL value is returned.

Examples

A user of this interface might include the following line in their initialization routine:

```
tuning_var = tuning_register_buint64
("fs/jfs2/max_readahead", 0644 &j2_max_read_ahead, 0, 1024);
```

In this example *tuning_var* is a global variable of type **tinode_t ***. This causes the **fs** and **fs/jfs2** directories to be created, and a file (pipe) to be created as **fs/jfs2/max_readahead**. The file returns the value of **j2_max_readahead** in ASCII when read. The variable is read at the time of the first read. A write would set the value of the variable, but only at the time of either the first newline being written or a **close** function being performed. In order to write the variable after reading it, one must close the file and reopen it for write. This file is not seekable.

u

The following kernel services begin with the with the letter u.

ue_proc_check Kernel Service

Purpose

Determines if a process is critical to the system.

Syntax

```
int ue_proc_check (pid)
pid_t pid;
```

Description

The **ue_proc_check** kernel service determines if a particular process is critical to the system. A critical process is either a kernel process or a process registered as critical by the **ue_proc_register** system call. A process that is critical will cause the system to terminate if that process has an unrecoverable hardware error associated with the process. Unrecoverable hardware errors associated with a process are determined by the kernel machine check handler on systems that support UE-Gard error processing.

The **ue_proc_check** kernel service should be called only while executing in kernel mode in the user process.

Parameters

Item	Description
pid	Specifies the process' ID to be checked as critical.

Execution Environment

The **ue_proc_check** kernel service can be called from the interrupt environment only.

Return Values

Item	Description
0	Indicates that the *pid* is not critical.
EINVAL	Indicates that the *pid* is critical.
-1	Indicates that the *pid* parameter is not valid or the process no longer exists.

ue_proc_register Subroutine

Purpose

Registers a process as critical to the system.

Syntax

```
int ue_proc_register (pid, argument)
pid_t pid;
int argument;
```

Description

The **ue_proc_register** system call registers a particular process as critical to the system. A process that is critical will cause the system to terminate if that process has an unrecoverable hardware error associated with the process. Unrecoverable hardware errors associated with a process are determined by the kernel machine check handler on systems that support UE-Gard error processing.

An execed process from a critical process must register itself to be critical. A fork from a process inherits the critical registration unless the argument is set to **NONCRITFORK**.

If the value of the *pid* parameter is equal to (**pid_t**) 0, the subroutine is registering the calling process.

The **ue_proc_register** system call should be called only while executing with root authority in the user process.

Parameters

Item	Description
pid	Specifies the process' ID to be registered critical.
argument	Defined in the **sys/proc.h** header file. Can be the following value:

    NONCRITFORK
        The *pid* forks are not critical.

Execution Environment

The **ue_proc_register** system call can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
EINVAL	Indicates that the *pid* parameter is not valid or the process no longer exists.
EACCES	Indicates that the caller does not have sufficient authority to alter the *pid* registration.

ue_proc_unregister Subroutine

Purpose

Unregisters a process from being critical to the system.

Syntax

```
int ue_proc_register (pid)
pid_t pid;
```

Description

The **ue_proc_unregister** system call unregisters a particular process as being no longer critical to the system. A process that has been previously registered critical will cause the system to terminate if that process has an unrecoverable hardware error associated with the process. Unrecoverable hardware errors associated with a process are determined by the kernel machine check handler on systems that support UE-Gard error processing.

If the value of the *pid* parameter is equal to (**pid_t**) 0, the subroutine is unregistering the calling process.

The **ue_proc_unregister** service should be called only while executing with root authority in the user process.

Parameters

Item	Description
pid	Specifies the process' ID to be unregistered.

Execution Environment

The **ue_proc_unregister** system call can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
EINVAL	Indicates that the *pid* parameter is not valid or the process no longer exists.
EACCES	Indicates that the caller does not have sufficient authority to alter the *pid* registration.

uexadd Kernel Service

Purpose

Adds a systemwide exception handler for catching user-mode process exceptions.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/except.h>
```

void uexadd (*exp***)**
struct uexcepth **exp;*

Parameter

Item	Description
exp	Points to an exception handler structure. This structure must be pinned and is used for registering user-mode process exception handlers. The **uexcepth** structure is defined in the **/usr/include/sys/except.h** file.

Description

The **uexadd** kernel service is typically used to install a systemwide exception handler to catch exceptions occurring during execution of a process in user mode. The **uexadd** kernel service adds the exception handler structure specified by the *exp* parameter, to the chain of exception handlers to be called if an exception occurs while a process is executing in user mode. The last exception handler registered is the first exception handler called for a user-mode exception.

The **uexcepth** structure has:

- A chain element used by the kernel to chain the registered user exception handlers.
- A function pointer defining the entry point of the exception handler being added.

Additional exception handler-dependent information can be added to the end of the structure, but must be pinned.

> **Attention:** The **uexcepth** structure must be pinned when the **uexadd** kernel service is called. It must remain pinned and unmodified until after the call to the **uexdel** kernel service to delete the specified exception handler. Otherwise, the system may crash.

Execution Environment

The **uexadd** kernel service can be called from the process environment only.

Return Values

The **uexadd** kernel service has no return values.

Related reference

uexdel Kernel Service

User-Mode Exception Handler for the uexadd Kernel Service

Related information

User-Mode Exception Handling

Kernel Extension and Device Driver Management Services

User-Mode Exception Handler for the uexadd Kernel Service

Purpose

Handles exceptions that occur while a kernel thread is executing in user mode.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/except.h>
```

int func (*exp, type, tid, mst*)
struct excepth * *exp*;
int *type*;
tid_t *tid*;
struct kmstsave * *mst*;

Parameters

Item	Description
exp	Points to the **excepth** structure used to register this exception handler.
mst	Points to the current **kmstsave** area for the process. This pointer can be used to access the **kmstsave** area to obtain additional information about the exception.

Item	Description
tid	Specifies the thread ID of the kernel thread that was executing at the time of the exception.
type	Denotes the type of exception that has occurred. This type value is platform specific. Specific values are defined in the **/usr/include/sys/except.h** file.

Description

The user-mode exception handler (*exp->***func**) is called for synchronous exceptions that are detected while a kernel thread is executing in user mode. The kernel exception handler saves exception information in the **kmstsave** area of the structure. For user-mode exceptions, it calls the first exception handler found on the user exception handler list. The exception handler executes in an interrupt environment at the priority level of either **INTPAGER** or **INTIODONE**.

If the registered exception handler returns a return code indicating that the exception was handled, the kernel exits from the exception handler without calling additional exception handlers from the list. If the exception handler returns a return code indicating that the exception was not handled, the kernel invokes the next exception handler on the list. The last exception handler in the list is the default handler. This is typically signalling the thread.

The kernel exception handler must not page fault. It should also register an exception handler using the **setjmpx** kernel service if any exception-handling activity can result in an exception. This is important particularly if the exception handler is handling the I/O. If the exception handler did not handle the exception, the return code should be set to the **EXCEPT_NOT_HANDLED** value for user-mode exception handling.

Execution Environment

The user-mode exception handler for the **uexadd** kernel service is called in the interrupt environment at the **INTPAGER** or **INTIODONE** priority level.

Return Values

Item	Description
EXCEPT_HANDLED	Indicates that the exception was successfully handled.
EXCEPT_NOT_HANDLED	Indicates that the exception was not handled.

Kernel Extension and Device Driver Management Kernel Services

uexblock Kernel Service

Purpose

Makes the currently active kernel thread nonrunnable when called from a user-mode exception handler.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/except.h>
```

void uexblock (*tid*)
tid_t *tid;

Parameter

Item	Description
tid	Specifies the thread ID of the currently active kernel thread to be put into a wait state.

Description

The **uexblock** kernel service puts the currently active kernel thread specified by the *tid* parameter into a wait state until the **uexclear** kernel service is used to make the thread runnable again. If the **uexblock** kernel service is called from the process environment, the *tid* parameter must specify the current active thread; otherwise the system will crash with a kernel panic.

The **uexblock** kernel service can be used to lazily control user-mode threads access to a shared serially usable resource. Multiple threads can use a serially used resource, but only one process at a time. When a thread attempts to but cannot access the resource, a user-mode exception can be set up to occur. This gives control to an exception handler registered by the **uexadd** kernel service. This exception handler can then block the thread using the **uexblock** kernel service until the resource is made available. At this time, the **uexclear** kernel service can be used to make the blocked thread runnable.

Execution Environment

The **uexblock** kernel service can be called from either the process or interrupt environment.

Return Values

The **uexblock** service has no return values.

Related reference
uexclear Kernel Service
Related information
User-Mode Exception Handling
Kernel Extension and Device Driver Management Services

uexclear Kernel Service

Purpose

Makes a kernel thread blocked by the **uexblock** service runnable again.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/except.h>
```

void uexclear (*tid*)
tid_t *tid;

Parameter

Item	Description
tid	Specifies the thread ID of the previously blocked kernel thread to be put into a run state.

Description

The **uexclear** kernel service puts a kernel thread specified by the *tid* parameter back into a runnable state after it was made nonrunnable by the **uexblock** kernel service. A thread that has been sent a **SIGSTOP** stop signal is made runnable again when it receives the **SIGCONT** continuation signal.

The **uexclear** kernel service can be used to lazily control user-mode thread access to a shared serially usable resource. A serially used resource is usable by more than one thread, but only by one at a time. When a thread attempts to access the resource but does not have access, a user-mode exception can be setup to occur.

This setup gives control to an exception handler registered by the **uexadd** kernel service. Using the **uexblock** kernel service, this exception handler can then block the thread until the resource is later made available. At that time, the **uexclear** service can be used to make the blocked thread runnable.

Execution Environment

The **uexclear** kernel service can be called from either the process or interrupt environment.

Return Values

The **uexclear** service has no return values.

Related reference
uexblock Kernel Service
Related information
User-Mode Exception Handling
Kernel Extension and Device Driver Management Services

uexdel Kernel Service

Purpose

Deletes a previously added systemwide user-mode exception handler.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/except.h>
```

void uexdel (*exp***)**
struct uexcepth **exp;*

Parameter

Item	Description
exp	Points to the exception handler structure used to add the exception handler with the **uexadd** kernel service.

Description

The **uexdel** kernel service removes a user-mode exception handler from the systemwide list of exception handlers maintained by the kernel's exception handler.

The **uexdel** kernel service removes the exception handler structure specified by the *exp* parameter from the chain of exception handlers to be called if an exception occurs while a process is executing in user

mode. Once the **uexdel** kernel service has completed, the specified exception handler is no longer called. In addition, the **uexcepth** structure can be modified, freed, or unpinned.

Execution Environment

The **uexdel** kernel service can be called from the process environment only.

Return Values

The **uexdel** kernel service has no return values.

Related reference
uexadd Kernel Service
Related information
User-Mode Exception Handling
Kernel Extension and Device Driver Management Services

ufdcreate Kernel Service

Purpose

Allocates and initializes a file descriptor.

Syntax

```
#include <fcntl.h>
#include <sys/types.h>
#include <sys/file.h>
```

```
int ufdcreate (flags, ops, datap, type, fdp, cnp)
```

int *flags*;
struct fileops * *ops*;
void * *datap*;
short *type*;
int * *fdp*;
 struct ucred *crp;

Parameters

Item	Description
flags	Specifies the flags to save in a **file** structure. The **file** structure is defined in the **sys/file.h** file. If a **read** or **write** subroutine is called with the file descriptor returned by this routine, the **FREAD** and **FWRITE** flags must be set appropriately. Valid flags are defined in the **fcntl.h** file.
ops	Points to the list of subsystem-supplied routines to call for the file system operations: read/ write, ioctl, select, fstat, and close. The **fileops** structure is defined in the **sys/file.h** file. See "File Operations" for more information.
datap	Points to type-dependent structures. The system saves this pointer in the **file** structure. As a result, the pointer is available to the file operations when they are called.
type	Specifies the unique type value for the **file** structure. Valid types are listed in the **sys/file.h** file.
fdp	Points to an integer field where the file descriptor is stored on successful return.
crp	Points to a credentials structure. This pointer is saved in the file struct for use in subsequent operations. It must be a valid **ucred** struct. The **crref()** kernel service can be used to obtain a **ucred** struct.

Description

The **ufdcreate** kernel service provides a file interface to kernel extensions. Kernel extensions use this service to create a file descriptor and file structure pair. Also, this service allows kernel extensions to provide their own file descriptor-based system calls, enabling read/write, ioctl, select, fstat, and close operations on objects outside the file system. The **ufdcreate** kernel services does not require the extension to understand or conform to the synchronization requirements of the logical file system (LFS).

The **ufdcreate** kernel service provides a file descriptor to the caller and creates the underlying file structure. The caller must include pointers to subsystem-supplied routines for the read/write, ioctl, select, fstat, and close operations. If any of the operations are not needed by the calling subsystem, then the caller must provide a pointer to an appropriate **errno** value. Typically, the **EOPNOTSUPP** value is used for this purpose. See "File Operations" for information about the requirements for the subsystem-supplied routines.

Removing a File Descriptor

There is no corresponding operation to remove a file descriptor (and the attendant structures) created by the **ufdcreate** kernel service. To remove a file descriptor, use a call to the **close** subroutine. The **close** subroutine can be called from a routine or from within the kernel or kernel extension. If the close is not called, the file is closed when the process exits.

Once a call is made to the **ufdcreate** kernel service, the file descriptor is considered open before the call to the service returns. When a **close** or **exit** subroutine is called, the close file operation specified on the call to the **ufdcreate** interface is called.

File Operations

The **ufdcreate** kernel service allows kernel extensions to provide their own file descriptor-based system calls, enabling read/write, ioctl, select, fstat, and close operations on objects outside the file system. The **fileops** structure defined in the **sys/file.h** file provides interfaces for these routines.

read/write Requirements

The read/write operation manages input and output to the object specified by the *fp* parameter. The actions taken by this operation are dependent on the object type. The syntax for the operation is as follows:

```
#include <sys/types.h>
#include <sys/uio.h>
```

```
int (*fo_rw) (fp, rw, uiop, ext)
```

```
struct file *fp;
enum uio_rw rw;
struct uio *uiop;
int ext;
```

The parameters have the following values:

Value	Description
fp	Points to the **file** structure. This structure corresponds to the file descriptor used on the **read** or **write** subroutine.
rw	Contains a **UIO_READ** value for a read operation or **UIO_WRITE** value for a write operation.
uiop	Points to a **uio** structure. This structure describes the location and size information for the input and output requested. The **uio** structure is defined in the **uio.h** file.

Valu e	Description
ext	Specifies subsystem-dependent information. If the **readx** or **writex** subroutine is used, the value passed by the operation is passed through to this subroutine. Otherwise, the value is 0.

If successful, the **fo_rw** operation returns a value of 0. A nonzero return value should be programmed to indicate an error. See the **sys/errno.h** file for a list of possible values.

Note: On successful return, the `uiop->uio_resid` field must be updated to include the number of bytes of data actually transferred.

ioctl Requirements

The ioctl operation provides object-dependent special command processing. The **ioctl** subroutine performs a variety of control operations on the object associated with the specified open **file** structure. This subroutine is typically used with character or block special files and returns an error for ordinary files.

The control operation provided by the ioctl operation is specific to the object being addressed, as are the data type and contents of the *arg* parameter.

The syntax for the ioctl operation is as follows:

```
#include <sys/types.h>
#include <sys/ioctl.h>
```

```
int (*fo_ioctl) (fp, cmd, arg, ext, kflag)
```

```
struct file *fp;
int cmd, ext, kflag;
caddr_t arg;
```

The parameters have the following values:

Value	Description
fp	Points to the **file** structure. This structure corresponds to the file descriptor used by the **ioctl** subroutine.
cmd	Defines the specific request to be acted upon by this routine.
arg	Contains data that is dependent on the *cmd* parameter.
ext	Specifies subsystem-specific information. If the **ioctlx** subroutine is used, the value passed by the application is passed through to this subroutine. Otherwise, the value is 0.
kflag	Determines where the call is made from. The *kflag* parameter has the value **FKERNEL** (from the **fcntl.h** file) if this routine is called through the **fp_ioctl** interface. Otherwise, its value is 0.

If successful, the **fo_ioctl** operation returns a value of 0. For errors, the **fo_ioctl** operation should return a nonzero return value to indicate an error. Refer to the **sys/errno.h** file for the list of possible values.

select Requirements

The select operation performs a select operation on the object specified by the *fp* parameter. The syntax for this operation is as follows:

```
#include <sys/types.h>
```

```
int (*fo_select) (fp, corl, reqevents, rtneventsp, notify)
```

```
struct file *fp;
int corl;
ushort reqevents, *rtneventsp;
void (notify) ();
```

The parameters have the following values:

Value	Description
fp	Points to the **file** structure. This structure corresponds to the file descriptor used by the **select** subroutine.
corl	Specifies the ID used for correlation in the **selnotify** kernel service.
reqevents	Identifies the events to check. The poll and select functions define three standard event flags and one informational flag. The **sys/poll.h** file details the event bit definition. See the **fp_select** kernel service for information about the possible flags.
rtneventsp	Indicates the returned events pointer. This parameter, passed by reference, indicates the events that are true at the current time. The returned event bits include the request events and an error event indicator.
notify	Points to a routine to call when the specified object invokes the **selnotify** kernel service for an outstanding asynchronous select or poll event request. If no routine is to be called, this parameter must be null.

If successful, the **fo_select** operation returns a value of 0. This operation should return a nonzero return value to indicate an error. Refer to the **sys/errno.h** file for the list of possible values.

fstat Requirements

The fstat operation fills in an **attribute** structure. Depending on the object type specified by the *fp* parameter, many fields in the structure may not be applicable. The value passed back from this operation is dependent upon both the object type and what any routine that understands the type is expecting. The syntax for this operation is as follows:

```
#include <sys/types.h>
```

```
int (*fo_fstat) (fp, sbp)
```

```
struct file *fp;
struct stat *sbp;
```

The parameters have the following values:

Value	Description
fp	Points to the **file** structure. This structure corresponds to the file descriptor used by the **stat** subroutine.
sbp	Points to the **stat** structure to be filled in by this operation. The address supplied is in kernel space.

If successful, the **fo_fstat** operation returns a value of 0. A nonzero return value should be programmed to indicate an error. Refer to the **sys/errno.h** file for the list of possible values.

close Requirements

The close operation invalidates routine access to objects specified by the *fp* parameter and releases any data associated with that access. This operation is called from the **close** subroutine code when the **file** structure use count is decremented to 0. For example, if there are multiple accesses to an object (created by the **dup**, **fork**, or other subsystem-specific operation), the **close** subroutine calls the close operation when it determines that there is no remaining access through the **file** structure being closed.

A file descriptor is considered open once a file descriptor and **file** structure have been set up by the LFS. The close file operation is called whenever a close or exit is specified. As a result, the close operation must be able to close an object that is not fully open, depending on what the caller did before the **file** structure was initialized.

The syntax for the close operation is as follows:

```
#include <sys/file.h>
```

```
int (*fo_close) (fp)
struct file *fp;
```

The parameter is:

Item	Description
fp	Points to the **file** structure. This structure corresponds to the file descriptor used by the **close** subroutine.

If successful, the **fo_close** operation returns a value of 0. This operation should return a nonzero return value to indicate an error. Refer to the **sys/errno.h** file for the list of possible values.

Execution Environment

The **ufdcreate** kernel service can be called from the process environment only.

Return Values

If the **ufdcreate** kernel service succeeds, it returns a value of 0. If the kernel service fails, it returns a nonzero value and sets the **errno** global variable.

Error Codes

The **ufdcreate** kernel service fails if one or more of the following errors occur:

Error	Description
EINVAL	The *ops* parameter is null, or the **fileops** structure does not have entries for for every operation.
EMFILE	All file descriptors for the process have already been allocated.
ENFILE	The system file table is full.

close subroutine
exit, atexit, or _exit
Logical File System Kernel Services

ufdgetf Kernel Service

Purpose

Returns a pointer to a file structure associated with a file descriptor.

Syntax

```
#include <sys/file.h>
```

```
int ufdgetf( fd, fpp)
int fd;
struct file **fpp;
```

Parameters

Item	Description
fd	Identifies the file descriptor. The descriptor must be for an open file.
fpp	Points to a location to store the file pointer.

Description

The **ufdgetf** kernel service returns a pointer to a file structure associated with a file descriptor. The calling routine must have a use count on the file descriptor. To obtain a use count on the file descriptor, the caller must first call the **ufdhold** kernel service.

Execution Environment

The **ufdget** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
EBADF	Indicates that the *fd* parameter is not a file descriptor for an open file.

Related reference
ufdhold and ufdrele Kernel Service

ufdhold and ufdrele Kernel Service

Purpose

Increment or decrement a file descriptor reference count.

Syntax

int ufdhold(*fd*)
int *fd*;

```
int ufdrele(fd)
int fd;
```

Parameter

Item	Description
fd	Identifies the file descriptor.

Description

> **Attention:** It is extremely important that the calls to **ufdhold** and **ufdrele** kernel service are balanced. If a file descriptor is held more times than it is released, the **close** subroutine on the descriptor never completes. The process hangs and cannot be killed. If the descriptor is released more times than it is held, the system panics.

The **ufdhold** and **ufdrele** kernel services increment and decrement a file-descriptor reference count. Together, these kernel services maintain the file descriptor reference count. The **ufdhold** kernel service increments the count. The **ufdrele** kernel service decrements the count.

These subroutines are supported for kernel extensions that provide their own file-descriptor-based system calls. This support is required for synchronization with the **close** subroutine.

When a thread is executing a file-descriptor-based system call, it is necessary that the logical file system (LFS) be aware of it. The LFS uses the count in the file descriptor to monitor the number of system calls currently using any particular file descriptor. To keep the count accurately, any thread using the file descriptor must increment the count before performing any operation and decrement the count when all activity using the file descriptor is completed for that system call.

Execution Environment

These kernel services can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
EBADF	Indicates that the *fd* parameter is not a file descriptor for an open file.

Related reference
ufdgetf Kernel Service
Related information
close subroutine

uiomove Kernel Service

Purpose

Moves a block of data between kernel space and a space defined by a **uio** structure.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/uio.h>
```

int uiomove (** *cp*, *n*, *rw*, *uiop*)**
caddr_t *cp*;
int *n*;
uio_rw *rw*;
struct uio *uiop;

Parameters

Item	Description
cp	Specifies the address in kernel memory to or from which data is moved.
n	Specifies the number of bytes to move.

Item	Description
rw	Indicates the direction of the move:

UIO_READ
   Copies data from kernel space to space described by the **uio** structure.

UIO_WRITE
   Copies data from space described by the **uio** structure to kernel space.

uiop	Points to a **uio** structure describing the buffer used in the data transfer.

Description

The **uiomove** kernel service moves the specified number of bytes of data between kernel space and a space described by a **uio** structure. Device driver top halves, especially character device drivers, frequently use the **uiomove** service to transfer data into or out of a user area. The `uio_resid` and `uio_iovcnt` fields in the **uio** structure describing the data area must be greater than 0 or an error is returned.

The **uiomove** service moves the number of bytes of data specified by either the *n* or *uio_resid* parameter, whichever is less. If either the *n* or *uio_resid* parameter is 0, no data is moved. The `uio_segflg` field in the **uio** structure is used to indicate if the move is accessing a user- or kernel-data area, or if the caller requires cross-memory operations and has provided the required cross-memory descriptors. If a cross-memory operation is indicated, there must be a cross-memory descriptor in the **uio_xmem** array for each `iovec` element.

If the move is successful, the following fields in the **uio** structure are updated:

Field	Description
`uio_iov`	Specifies the address of current `iovec` element to use.
`uio_xmem`	Specifies the address of the current xmem element to use.
`uio_iovcnt`	Specifies the number of remaining `iovec` elements.
`uio_iovdcnt`	Specifies the number of already processed `iovec` elements.
`uio_offset`	Specifies the character offset on the device performing the I/O.
`uio_resid`	Specifies the total number of characters remaining in the data area described by the **uio** structure.
`iov_base`	Specifies the address of the data area described by the current `iovec` element.
`iov_len`	Specifies the length of remaining data area in the buffer described by the current `iovec` element.

Execution Environment

The **uiomove** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
ENOMEM	Indicates that there was no room in the buffer.
EIO	Indicates a permanent I/O error file space.
ENOSPC	Indicates insufficient disk space.
EFAULT	Indicates a user location that is not valid.

Memory Kernel Services

unlock_enable Kernel Service

Purpose

Unlocks a simple lock if necessary, and restores the interrupt priority.

Syntax

```
#include <sys/lock_def.h>
```

void unlock_enable (*int_pri*, *lock_addr***)**
int *int_pri*;
simple_lock_t *lock_addr*;

Parameters

Item	Description
int_pri	Specifies the interrupt priority to restore. This must be set to the value returned by the corresponding call to the **disable_lock** kernel service.
lock_addr	Specifies the address of the lock word to unlock.

Description

The **unlock_enable** kernel service unlocks a simple lock if necessary, and restores the interrupt priority, in order to provide optimized thread-interrupt critical section protection for the system on which it is executing. On a multiprocessor system, calling the **unlock_enable** kernel service is equivalent to calling the **simple_unlock** and **i_enable** kernel services. On a uniprocessor system, the call to the **simple_unlock** service is not necessary, and is omitted. However, you should still pass the valid lock address which was used with the corresponding call to the **disable_lock** kernel service. Never pass a **NULL** lock address.

Execution Environment

The **unlock_enable** kernel service can be called from either the process or interrupt environment.

Return Values

The **unlock_enable** kernel service has no return values.

unlockl Kernel Service

Purpose

Unlocks a conventional process lock.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

void unlockl (*lock_word***)**
lock_t **lock_word***;**

Parameter

Item	Description
lock_word	Specifies the address of the lock word.

Description

Note: The **unlockl** kernel service is provided for compatibility only and should not be used in new code, which should instead use simple locks or complex locks.

The **unlockl** kernel service unlocks a conventional lock. Only the owner of a lock can unlock it. Once a lock is unlocked, the highest priority thread (if any) which is waiting for the lock is made runnable and may compete again for the lock. If there was at least one process waiting for the lock, the priority of the caller is recomputed. Preempting a System Call discusses how system calls can use locking kernel services when accessing global data.

The **lockl** and **unlockl** services do not maintain a nesting level count. A single call to the **unlockl** service unlocks the lock for the caller. The return code from the **lockl** service should be used to determine when to unlock the lock.

Note: The **unlockl** kernel service can be called with interrupts disabled, only if the event or lock word is pinned.

Execution Environment

The **unlockl** kernel service can be called from the process environment only.

Return Values

The **unlockl** service has no return values.

Example

A call to the **unlockl** service can be coded as follows:

```
int lock_ret;          /* return code from lockl() */
extern int lock_word;  /* lock word that is external
                          and was initialized to
                          LOCK_AVAIL */
...
/* get lock prior to using resource */
lock_ret = lockl(lock_word, LOCK_SHORT)
/* use resource for which lock was obtained */
...
/* release lock if this was not a nested use */
if ( lock_ret != LOCK_NEST )
   unlockl(lock_word);
```

Understanding Locking

unpin Kernel Service

Purpose

Unpins the address range in system (kernel) address space.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/pin.h>
```

int unpin (*addr*, *length*)
caddr *addr*;
int *length*;

Parameters

Item	Description
addr	Specifies the address of the first byte to unpin in the system (kernel) address space.
length	Specifies the number of bytes to unpin.

Description

The **unpin** kernel service decreases the pin count of each page in the address range. When the pin count is 0, the page is not pinned and can be paged out of real memory. Upon finding an unpinned page, the **unpin** service returns the **EINVAL** error code and leaves any remaining pinned pages still pinned.

The **unpin** service can only be called with addresses in the system (kernel) address space. The **xmemunpin** service should be used where the address space might be in either user or kernel space.

Execution Environment

The **unpin** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	Indicates successful completion.
EINVAL	Indicates that the value of the *length* parameter is negative or 0. Otherwise, the area of memory beginning at the byte specified by the *base* parameter and extending for the number of bytes specified by the *len* parameter is not defined. If neither cause is responsible, an unpinned page was specified.

Understanding Execution Environments

unpincode Kernel Service

Purpose

Unpins the code and data associated with a loaded object module.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/pin.h>
```

int unpincode (*func***)**
int (*func***) ( );**

Parameter

Item	Description
func	Specifies an address used to determine the object module to be unpinned. The address is typically that of a function that is exported by this object module.

Description

The **unpincode** kernel service uses the **ltunpin** kernel service to decrement the pin count for the pages associated with the following items:

- Code associated with the object module
- Data area of the object module that contains the function specified by the *func* parameter

The loader entry for the module is used to determine the size of both the code and the data area.

Execution Environment

The **unpincode** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
EINVAL	Indicates that the *func* parameter is not a valid pointer to the function.
EFAULT	Indicates that the calling process does not have access to the area of memory that is associated with the module.

Memory Kernel Services

unregister_HA_handler Kernel Service

Purpose

Removes from the kernel the registration of a High Availability Event Handler.

Syntax

```
#include <sys/high_avail.h>

int register_HA_handler (ha_handler)
ha_handler_ext_t  * ha_handler;
```

Parameter

Item	Description
ha_handler	Specifies a pointer to a structure of the type **ha_handler_ext_t** defined in /**usr/include/sys/high_avail.h**. This structure must be identical to the one passed to **register_HA_handler** at the time of registration.

Description

The **unregister_HA_handler** kernel service cancels an unconfigured kernel extensions that have registered a high availability event handler, done by the **register_HA_handler** kernel service, so that the kernel extension can be unloaded.

Failure to do so may cause a system crash when a high availability event such as a processor deallocation is initiated due to some hardware fault.

Execution Environment

The **unregister_HA_handler** kernel service can be called from the process environment only.

An extension may register the same HAEH *N* times (*N* > 1). Although this is considered an incorrect behaviour, no error is reported. The given HAEH will be invoked *N* times for each HA event. This handler has to be unregistered as many times as it was registered.

Return Values

Item	Description
0	Indicates a successful operation.

A non-zero value indicates an error.

Related reference
register_HA_handler Kernel Service

RAS Kernel Services

untimeout Kernel Service

Attention: This service must not be used because it is not multi-processor safe. The base kernel timer and watchdog services must be used instead. See talloc and w_init for more information.

Purpose

Cancels a pending timer request.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
void untimeout ( func,  arg)
void (*func)();
caddr_t *arg;
```

Parameters

Item	Description
func	Specifies the function that is associated with the timer to be canceled.
arg	Specifies the function argument that is associated with the timer to be canceled.

Description

The **untimeout** kernel service is not part of the kernel. However, it is a compatibility service that is provided in the **libsys.a** library. To use the **untimeout** service, a kernel extension must be bound with the **libsys.a** library. The **untimeout** service, like the associated kernel libsys services **timeoutcf** and **timeout**, can be bound and used only in the pinned part of a kernel extension or the bottom half of a device driver because these services use interrupt disable for serialization.

The **untimeout** kernel service cancels a specific request that is made with the **timeout** service. The *func* and *arg* parameters must match the parameters that are used in the **timeout** kernel service request that is to be canceled.

Upon return, the specified timer request is canceled, if found. If no timer request matches the *func* and *arg* parameters, no operation is performed.

Execution Environment

The **untimeout** kernel service can be called from either the process or interrupt environment.

Return Values

The **untimeout** kernel service has no return values.

Related reference
timeout Kernel Service
Related information
Timer and Time-of-Day Kernel Services

uphysio or uphysio_fast Kernel Service

Purpose

Performs character I/O for a block device using a **uio** structure.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
#include <sys/buf.h>
#include <sys/uio.h>
```

int uphysio (*uiop, rw, buf_cnt, devno, strat, mincnt, minparms***)**
struct uio * *uiop*;
int *rw*;
uint *buf_cnt*;
dev_t *devno*;
int (* *strat*)( );
int (* mincnt)( );
void * *minparm*s;

int uphysio_fast*(uiop, rw, buf_cnt, devno, strat, max_xfer, options,*
blk_align)
struct uio *uiop;
int *rw*;
uint *buf_cnt*;
dev_t *devno*;
int (* *strat*)( );
uint64_t *max_xfer*;
uint32_t *options*;
uint32_t *blk_align*;

Parameters

The following table includes the parameters for **uphysio** and **uphysio_fast**:

Item	Description
uiop	Points to the **uio** structure describing the buffer of data to transfer using character-to-block I/O.
rw	Indicates either a read or write operation. A value of **B_READ** for this flag indicates a read operation. A value of **B_WRITE** for this flag indicates a write operation.
buf_cnt	Specifies the maximum number of **buf** structures to use when calling the strategy routine specified by the *strat* parameter. This parameter is used to indicate the maximum amount of concurrency the device can support and minimize the I/O redrive time. The value of the *buf_cnt* parameter can range from 1 to 64.
devno	Specifies the major and minor device numbers. With the **uphysio** service, this parameter specifies the device number to be placed in the **buf** structure before calling the strategy routine specified by the *strat* parameter.
strat	Represents the function pointer to the **ddstrategy** routine for the device.
mincnt	Represents the function pointer to a routine used to reduce the data transfer size specified in the **buf** structure, as required by the device before the strategy routine is started. The routine can also be used to update extended parameter information in the **buf** structure before the information is passed to the strategy routine.
minparms	Points to parameters to be used by the *mincnt* parameter.
max_xfer	Specifies the maximum transfer size for the device in bytes.

Item	Description
options	Specifies the value to store in **b_options** field of buffer headers.
blk_align	Optional parameter to enforce a minimum block alignment on all transfers sent to the specified I/O strategy routine. This value is specified in bytes. When a non-zero value is specified, each I/O vector will be checked to ensure it is a multiple of this value. The transfer request will fail if not on an alignment boundary. When a block alignment is specified, it is assumed that the maximum transfer size, specified by the *max_xfer* parameter, is block aligned.

Description

The **uphysio** or **uphysio_fast** kernel service performs character I/O for a block device. The **uphysio** or **uphysio_fast** service attempts to send to the specified strategy routine the number of **buf** headers specified by the *buf_cnt* parameter. These **buf** structures are constructed with data from the **uio** structure specified by the *uiop* parameter.

The **uphysio** or **uphysio_fast** service initially transfers data area descriptions from each `iovec` element found in the **uio** structure into individual **buf** headers. These headers are later sent to the strategy routine. The **uphysio** or **uphysio_fast** kernel service tries to process as many data areas as the number of **buf** headers permits. It then invokes the strategy routine with the list of **buf** headers.

The **uphysio_fast** service uses the specified maximum transfer size to tailor the length of data transfers and avoids the context switch overhead encountered with the **mincnt** routine that is required by the **uphysio** service. In environments where the maximum transfer size is already known by the caller and the buffer header fields do not need to be updated, this service should be used to reduce I/O pathlength.

Preparing Individual buf Headers

The routine specified by the *mincnt* parameter is called before the **buf** header, built from an `iovec` element, is added to the list of **buf** headers to be sent to the strategy routine. The *mincnt* parameter is passed a pointer to the **buf** header along with the *minparms* pointer. This arrangement allows the *mincnt* parameter to tailor the length of the data transfer described by the **buf** header as required by the device performing the I/O. The *mincnt* parameter can also optionally modify certain device-dependent fields in the **buf** header.

When the *mincnt* parameter returns with no error, an attempt is made to pin the data buffer described by the **buf** header. If the pin operation fails due to insufficient memory, the data area described by the **buf** header is reduced by half. The **buf** header is again passed to the *mincnt* parameter for modification before trying to pin the reduced data area.

This process of downsizing the transfer specified by the **buf** header is repeated until one of the three following conditions occurs:

- The pin operation succeeds.
- The *mincnt* parameter indicates an error.
- The data area size is reduced to 0.

When insufficient memory indicates a failed pin operation, the number of **buf** headers used for the remainder of the operation is reduced to 1. This is because trying to pin multiple data areas simultaneously under these conditions is not desirable.

If the user has not already obtained cross-memory descriptors, further processing is required. (The `uio_segflg` field in the **uio** structure indicates whether the user has already initialized the cross-memory descriptors. The **usr/include/sys/uio.h** file contains information on possible values for this flag.)

When the data area described by the **buf** header has been successfully pinned, the **uphysio** or **uphysio_fast** service verifies user access authority for the data area. It also obtains a cross-memory descriptor to allow the device driver interrupt handler limited access to the data area.

Calling the Strategy Routine

After the **uphysio** or **uphysio_fast** kernel service obtains a cross-memory descriptor to allow the device driver interrupt handler limited access to the data area, the **buf** header is then put on a list of **buf** headers to be sent to the strategy routine specified by the *strat* parameter.

The strategy routine specified by the *strat* parameter is called with the list of **buf** headers when:

- The list reaches the number of **buf** structures specified by the *buf_cnt* parameter.
- The data area described by the **uio** structure has been completely described by **buf** headers.

The **buf** headers in the list are chained together using the av_back and av_forw fields before they are sent to the strategy routine.

Waiting for buf Header Completion

When all available **buf** headers have been sent to the strategy routine, the **uphysio** or **uphysio_fast** service waits for one or more of the **buf** headers to be marked complete. The **IODONE** handler is used to wake up the **uphysio** or **uphysio_fast** service when it is waiting for completed **buf** headers from the strategy routine.

When the **uphysio** or **uphysio_fast** service is notified of a completed **buf** header, the associated data buffer is unpinned and the cross-memory descriptor is freed. (However, the cross-memory descriptor is freed only if the user had not already obtained it.) An error is detected on the data transfer under the following conditions:

- The completed **buf** header has a nonzero b_resid field.
- The b_flags field has the **B_ERROR** flag set.

When an error is detected by the **uphysio** or **uphysio_fast** service, no new **buf** headers are sent to the strategy routine.

The **uphysio** or **uphysio_fast** service waits for any **buf** headers already sent to the strategy routine to be completed and then returns an error code to the caller. If no errors are detected, the **buf** header and any other completed **buf** headers are again used to send more data transfer requests to the strategy routine as they become available. This process continues until all data described in the **uio** structure has been transferred or until an error has been detected.

The **uphysio** or **uphysio_fast** service returns to the caller when:

- All **buf** headers have been marked complete by the strategy routine.
- All data specified by the **uio** structure has been transferred.

The **uphysio** or **uphysio_fast** service also returns an error code to the caller if an error is detected.

Error Detection by the uphysio or uphysio_fast Kernel Service

When it detects an error, the **uphysio** or **uphysio_fast** kernel service reports the error that was detected closest to the start of the data area described by the **uio** structure. No additional **buf** headers are sent to the strategy routine. The **uphysio** or **uphysio_fast** kernel service waits for all **buf** headers sent to the strategy routine to be marked complete.

However, additional **buf** headers may have been sent to the strategy routine between these two events:

- After the strategy routine detects the error.
- Before the **uphysio** or **uphysio_fast** service is notified of the error condition in the completed **buf** header.

When errors occur, various fields in the returned **uio** structure may or may not reflect the error. The `uio_iov` and `uio_iovcnt` fields are not updated and contain their original values.

The `uio_resid` and `uio_offset` fields in the returned **uio** structure indicate the number of bytes transferred by the strategy routine according to the sum of all (the `b_bcount` field minus the `b_resid` fields) fields in the **buf** headers processed by the strategy routine. These headers include the **buf** header indicating the error nearest the start of the data area described by the original **uio** structure. Any data counts in **buf** headers completed after the detection of the error are not reflected in the returned **uio** structure.

Execution Environment

The **uphysio** or **uphysio_fast** kernel service can be called from the [process environment](#) only.

Return Values

Item	Description
0	Indicates successful completion.
ENOMEM	Indicates that no memory is available for the required **buf** headers.
EAGAIN	Indicates that the operation fails due to a temporary insufficient resource condition.
EFAULT	Indicates that the `uio_segflg` field indicated user space and that the user does not have authority to access the buffer.
EIO or the b_error field in a buf header	Indicates an I/O error in a **buf** header processed by the strategy routine.
Return code from the mincnt parameter	Indicates that the return code from the *mincnt* parameter if the routine returned with a nonzero return code.

[uphysio Kernel Service mincnt Routine](#)
[buf Structure](#)
[uio Structure](#)

uphysio Kernel Service mincnt Routine

Purpose

Tailors a **buf** data transfer request to device-dependent requirements.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/buf.h>

int mincnt ( bp, minparms)
```

```
struct buf *bp;
void *minparms;
```

Parameters

Item	Description
bp	Points to the **buf** structure to be tailored.
minparms	Points to parameters.

Description

Only the following fields in the **buf** header sent to the routine specified by the **uphysio** kernel service *mincnt* parameter can be modified by that routine:

- b_bcount
- b_work
- b_options

The *mincnt* parameter cannot modify any other fields without the risk of error. If the *mincnt* parameter determines that the **buf** header cannot be supported by the target device, the routine should return a nonzero return code. This stops the **buf** header and any additional **buf** headers from being sent to the **ddstrategy** routine.

The **uphysio** kernel service waits for all **buf** headers already sent to the strategy routine to complete and then returns with the return code from the *mincnt* parameter.

uprintf Kernel Service

Purpose

Submits a request to print a message to the controlling terminal of a process.

Syntax

```
#include <sys/uprintf.h>
```

```
int uprintf ( Format [,
Value, ...])
char *Format;
```

Parameters

Item	Description

Format   Specifies a character string containing either or both of two types of objects:

- Plain characters, which are copied to the message output stream.

- Conversion specifications, each of which causes 0 or more items to be retrieved from the *Value* parameter list. Each conversion specification consists of a % (percent sign) followed by a character that indicates the type of conversion to be applied:

    %
    Performs no conversion. Prints %.

    d, i
    Accepts an integer *Value* and converts it to signed decimal notation.

    u
    Accepts an integer *Value* and converts it to unsigned decimal notation.

    o
    Accepts an integer *Value* and converts it to unsigned octal notation.

    x
    Accepts an integer *Value* and converts it to unsigned hexadecimal notation.

    s
    Accepts a *Value* as a string (character pointer), and characters from the string are printed until a \ 0 (null character) is encountered. *Value* must be non-null and the maximum length of the string is limited to **UP_MAXSTR** characters.

    Field width or precision conversion specifications are not supported.

    The following constants are defined in the **/usr/include/sys/uprintf.h** file:

    – **UP_MAXSTR**
    – **UP_MAXARGS**
    – **UP_MAXCAT**
    – **UP_MAXMSG**

    The *Format* string may contain from 0 to the number of conversion specifications specified by the **UP_MAXARGS** constant. The maximum length of the *Format* string is the number of characters specified by the **UP_MAXSTR** constant. *Format* must be non-null.

    The maximum length of the constructed kernel message is limited to the number of characters specified by the **UP_MAXMSG** constant. Messages larger then the number of characters specified by the **UP_MAXMSG** constant are discarded.

Value   Specifies, as an array, the value to be converted. The number, type, and order of items in the *Value* parameter list should match the conversion specifications within the *Format* string.

Description

The **uprintf** kernel service submits a kernel message request. Once the request has been successfully submitted, the **uprintfd** daemon constructs the message based on the *Format* and *Value* parameters of the request. The **uprintfd** daemon then writes the message to the process' controlling terminal.

Execution Environment

The **uprintf** kernel service can be called from the <u>process</u> environment only.

Return Values

Item	Description
0	Indicates a successful operation.
ENOMEM	Indicates that memory is not available to buffer the request.
ENODEV	Indicates that a controlling terminal does not exist for the process.
ESRCH	Indicates that the **uprintfd** daemon is not active. No requests may be submitted.
EINVAL	Indicates that a string *Value* string pointer is null or the string *Value* parameter is greater than the number of characters specified by the **UP_MAXSTR** constant.
EINVAL	Indicates one of the following:

- *Format* string pointer is null.
- Number of characters in the *Format* string is greater than the number specified by the **UP_MAXSTR** constant.
- Number of conversion specifications contained within the *Format* string is greater than the number specified by the **UP_MAXARGS** constant.

NLuprintf Kernel Service

Related information

uprintfd command

Process and Exception Management Kernel Services

ureadc Kernel Service

Purpose

Writes a character to a buffer described by a **uio** structure.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/uio.h>
```

```
int ureadc ( c,  uiop)
int c;
struct uio *uiop;
```

Parameters

Item	Description
c	Specifies a character to be written to the buffer.
uiop	Points to a **uio** structure describing the buffer in which to place a character.

Description

The **ureadc** kernel service writes a character to a buffer described by a **uio** structure. Device driver top half routines, especially character device drivers, frequently use the **ureadc** kernel service to transfer data into a user area.

The uio_resid and uio_iovcnt fields in the **uio** structure describing the data area must be greater than 0. If these fields are not greater than 0, an error is returned. The uio_segflg field in the **uio** structure is used to indicate whether the data is being written to a user- or kernel-data area. It is also used to indicate if the caller requires cross-memory operations and has provided the required cross-memory descriptors. The values for the flag are defined in the **/usr/include/sys/uio.h** file.

If the data is successfully written, the following fields in the **uio** structure are updated:

Field	Description
uio_iov	Specifies the address of current `iovec` element to use.
uio_xmem	Specifies the address of current xmem element to use (used for cross-memory copy).
uio_iovcnt	Specifies the number of remaining `iovec` elements.
uio_iovdcnt	Specifies the number of `iovec` elements already processed.
uio_offset	Specifies the character offset on the device from which data is read.
uio_resid	Specifies the total number of characters remaining in the data area described by the `uio` structure.
iov_base	Specifies the address of the next available character in the data area described by the current `iovec` element.
iov_len	Specifies the length of remaining data area in the buffer described by the current `iovec` element.

Execution Environment

The **ureadc** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
ENOMEM	Indicates that there is no room in the buffer.
EFAULT	Indicates that the user location is not valid for one of these reasons:

- The `uio_segflg` field indicates user space and the base address (`iov_base` field) points to a location outside of the user address space.
- The user does not have sufficient authority to access the location.
- An I/O error occurs while accessing the location.

Memory Kernel Services

uwritec Kernel Service

Purpose

Retrieves a character from a buffer described by a **uio** structure.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/uio.h>
```

int uwritec (*uiop***)**
struct uio **uiop***;**

Parameter

Item	Description
uiop	Points to a **uio** structure describing the buffer from which to read a character.

Description

The **uwritec** kernel service reads a character from a buffer described by a **uio** structure. Device driver top half routines, especially character device drivers, frequently use the **uwritec** kernel service to transfer data out of a user area. The `uio_resid` and `uio_iovcnt` fields in the **uio** structure must be greater than 0 or an error is returned.

The `uio_segflg` field in the **uio** structure indicates whether the data is being read out of a user- or kernel-data area. This field also indicates whether the caller requires cross-memory operations and has provided the required cross-memory descriptors. The values for this flag are defined in the **/usr/include/sys/uio.h** file.

If the data is successfully read, the following fields in the **uio** structure are updated:

Field	Description
uio_iov	Specifies the address of the current `iovec` element to use.
uio_xmem	Specifies the address of the current xmem element to use (used for cross-memory copy).
uio_iovcnt	Specifies the number of remaining `iovec` elements.
uio_iovdcnt	Specifies the number of `iovec` elements already processed.
uio_offset	Specifies the character offset on the device to which data is written.
uio_resid	Specifies the total number of characters remaining in the data area described by the **uio** structure.
iov_base	Specifies the address of the next available character in the data area described by the current `iovec` element.
iov_len	Specifies the length of the remaining data in the buffer described by the current `iovec` element.

Execution Environment

The **uwritec** kernel service can be called from the process environment only.

Return Values

Upon successful completion, the **uwritec** service returns the character it was sent to retrieve.

Item	Description
-1	Indicates that the buffer is empty or the user location is not valid for one of these three reasons:

- The `uio_segflg` field indicates user space and the base address (`iov_base` field) points to a location outside of the user address space.
- The user does not have sufficient authority to access the location.
- An I/O error occurred while the location was being accessed.

Related reference
uiomove Kernel Service
uphysio or uphysio_fast Kernel Service

v

The following kernel services begin with the letter v.

validate_pag or validate_pag64 Kernel Service

Purpose

Validates the Process Authentication Group (PAG) value.

Syntax

```
#include <sys/cred.h>

int validate_pag ( type, pg, npags )
int type;
struct paglist pg[];
int npags;

int validate_pag64 ( type, pg, npags )
int type;
struct paglist64 pg[];
int npags;
```

Parameters

Item	Description
type	PAG type to validate
pg	PAG list (must be in pinned memory)
npags	Number of PAGs to validate

Description

The `validate_pag` or `validate_pag64` kernel service validates the PAGs specified in *pg*. These services support the garbage collection of data structures by kernel extensions associated with PAGs. These structures are associated with a `set_pag` interface process. PAG values are inherited from parent to child across the `fork` system call, so one kernel extension structure can map to many processes. This routine is required to synchronize the execution of forks so that the process table can be scanned to identify a particular PAG. The `validate_pag` and `validate_pag64` kernel services cannot be used simultaneously with the `set_pag` interface. The application is required to provide this synchronization.

The value of *type* must be a defined PAG ID. The PAG ID for the Distributed Computing Environment (DCE) is 0. The *pg* parameter must be a valid, referenced PAG list in pinned memory.

Execution Environment

The `validate_pag` and `validate_pag64` kernel services can be called from the process environment only.

Return Values

A value of 0 is returned upon successful completion. Upon failure, a -1 is returned and `errno` is set to a value that explains the error.

Error Codes

The `validate_pag` and `validate_pag64` kernel services fail if the following condition is true:

Item	Description
EINVAL	Invalid PAG specification

Related Information

Security Kernel Services in *Kernel Extensions and Device Support Programming Concepts*.

vec_clear Kernel Service

Purpose

Removes a virtual interrupt handler.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

void vec_clear (*levsublev*)
int *levsublev*;

Parameter

Item	Description
levsublev	Represents the value returned by **vec_init** kernel service when the virtual interrupt handler was defined.

Description

The **vec_clear** kernel service is not part of the base kernel but is provided by the device queue management kernel extension. This queue management kernel extension must be loaded into the kernel before loading any kernel extensions referencing these services.

The **vec_clear** kernel service removes the association between a virtual interrupt handler and the virtual interrupt level and sublevel that was assigned by the **vec_init** kernel service. The virtual interrupt handler at the sublevel specified by the *levsublev* parameter no longer registers upon return from this routine.

Execution Environment

The **vec_clear** kernel service can be called from the process environment only.

Return Values

The **vec_clear** kernel service has no return values. If no virtual interrupt handler is registered at the specified sublevel, no operation is performed.

vec_init Kernel Service

Purpose

Defines a virtual interrupt handler.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
int vec_init ( level,   routine,   arg)
int level;
void (*routine) ();
int arg;
```

Parameters

Item	Description
level	Specifies the virtual interrupt level. This level value is not used by the **vec_init** kernel service and implies no relative priority. However, it is returned with the sublevel assigned for the registered virtual interrupt handler.
routine	Identifies the routine to call when a virtual interrupt occurs on a given interrupt sublevel.
arg	Specifies a value that is passed to the virtual interrupt handler.

Description

The **vec_init** kernel service is not part of the base kernel but provided by the device queue management kernel extension. This queue management kernel extension must be loaded into the kernel before loading any kernel extensions referencing these services.

The **vec_init** kernel service associates a virtual interrupt handler with a level and sublevel. This service searches the available sublevels to find the first unused one. The *routine* and *arg* parameters are used to initialize the open sublevel. The **vec_init** kernel service then returns the level and assigned sublevel.

There is a maximum number of available sublevels. If this number is exceeded, the **vec_init** service halts the system. This service should be called to initialize a virtual interrupt before any device queues using the virtual interrupt are created.

The *level* parameter is not used by the **vec_init** service. It is provided for compatibility reasons only. However, its value is passed back intact with the sublevel.

Execution Environment

The **vec_init** kernel service can be called from the process environment only.

Return Values

The **vec_init** kernel service returns a value that identifies the virtual interrupt level and assigned sublevel. The low-order 8 bits of this value specify the sublevel, and the high-order 8 bits specify the level. The **attchq** kernel service uses the same format. This level value is the same value as that supplied by the *level* parameter.

vfsrele Kernel Service

Purpose

Releases all resources associated with a virtual file system.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

```
int vfsrele ( vfsp)
struct vfs *vfsp;
```

Parameter

Item	Description
vfsp	Points to a virtual file system structure.

Description

The **vfsrele** kernel service releases all resources associated with a virtual file system.

When a file system is unmounted, the **VFS_UNMOUNTED** flag is set in the **vfs** structure, indicating that it is no longer valid to do path name-related operations within the file system. When this flag is set and a **vnop_rele** v-node operation releases the last active v-node within the file system, the **vnop_rele** v-node implementation must call the **vfsrele** kernel service to complete the deallocation of the **vfs** structure.

Execution Environment

The **vfsrele** kernel service can be called from the process environment only.

Return Values

The **vfsrele** kernel service always returns a value of 0.

Related information
Virtual File System Overview
Virtual File System (VFS) Kernel Services

vm_att Kernel Service

Purpose

Maps a specified virtual memory object to a region in the current address space.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

```
caddr_t vm_att ( vmhandle,   offset)
vmhandle_t   vmhandle;
caddr_t offset;
```

Parameters

Item	Description
vmhandle	Specifies the handle for the virtual memory object to be mapped.
offset	Specifies the offset in the virtual memory object and region.

Description

The **vm_att** kernel service performs the following tasks:

• Selects an unallocated region in the current address space and allocates it.

- Maps the virtual memory object specified by the *vmhandle* parameter with the access permission specified in the handle.
- Constructs the address in the current address space corresponding to the offset in the virtual memory object and region.

The **vm_att** kernel service assumes an address space model of fixed-size virtual memory objects and address space regions.

> **Attention:** If there are no more free regions, this call cannot complete and calls the **panic** kernel service.

Execution Environment

The **vm_att** kernel service can be called from either the process or interrupt environment.

Return Values

The **vm_att** kernel service returns the address that corresponds to the *offset* parameter in the address space.

Understanding Virtual Memory Manager Interfaces

vm_cflush Kernel Service

Purpose

Flushes the processor's cache for a specified address range.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

```
void vm_cflush ( eaddr,  nbytes)
caddr_t eaddr;
int nbytes;
```

Parameters

Item	Description
eaddr	Specifies the starting address of the specified range.
nbytes	Specifies the number of bytes in the address range. If this parameter is negative or 0, no lines are invalidated.

Description

The **vm_cflush** kernel service writes to memory all modified cache lines that intersect the address range (*eaddr*, *eaddr* + *nbytes* -1). The *eaddr* parameter can have any alignment in a page.

The **vm_cflush** kernel service can only be called with addresses in the system (kernel) address space.

Execution Environment

The **vm_cflush** kernel service can be called from both the interrupt and the process environment.

Return Values

The **vm_cflush** kernel service has no return values.

Related information

Memory Kernel Services

Understanding Virtual Memory Manager Interfaces

vm_det Kernel Service

Purpose

Unmaps and deallocates the region in the current address space that contains a given address.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

void vm_det (*eaddr***)**
caddr_t *eaddr;*

Parameter

Item	Description
eaddr	Specifies the effective address in the current address space. The region containing this address is to be unmapped and deallocated.

Description

The **vm_det** kernel service unmaps the region containing the *eaddr* parameter and deallocates the region, adding it to the free list for the current address space.

The **vm_det** kernel service assumes an address space model of fixed-size virtual memory objects and address space regions.

> **Attention:** If the region is not mapped, or a system region is referenced, the system will halt.

Execution Environment

The **vm_det** kernel service can be called from either the process or interrupt environment.

Memory Kernel Services

Understanding Virtual Memory Manager Interfaces

vm_flushp Kernel Service

Purpose

Flushes the specified range of pages.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

int vm_flushp (*sid*, *pfirst*, *npages***)**
vmid_t *sid***;**
vpn_t *pfirst***;**
vpn_t *npages***;**

Parameters

Item	Description
sid	Identifies the base segment.
pfirst	The first page number within the range.
npages	The number of pages to flush starting from the *pfirst* value. All pages must be in the same segment.

Description

The **vm_flushp** kernel service routine initiates page-out for the specified page range in the virtual memory object. I/O is initiated for the modified pages only. If page-out is initiated, or the pages are currently undergoing page I/O, then they are flagged to have their page frames released upon completion. If the pages are not modified, their page frames are immediately released.

The caller can wait for the completion of I/O initiated by this and prior calls by calling the **vms_iowait** kernel service.

Note: The **vm_flushp** subroutine is not supported for use on large pages.

Execution Environment

The **vm_flushp** kernel service can be called from the process environment only.

This is intended for files, and might not be called for working storage segments.

Return Values

Item	Description
0	Indicates the completion of the flush operation.
EINVAL	Indicates one of the following errors:

- *pfirst* = 0 and *npages* = 0.
- *pfirst* < 0.
- *npages* < 0.
- Page interval not in one segment.
- Invalid *sid* parameter.
- Invalid segment type.

Related reference
vm_writep Kernel Service
vm_invalidatep Kernel Service

vm_galloc Kernel Service

Purpose

Allocates a region of global memory in the 64-bit kernel.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>

int vm_galloc (int  type, vmsize_t  size, ulong * eaddr)
```

Description

The **vm_galloc** kernel service allocates memory from the kernel global memory pool on the 64-bit kernel. The allocation size is rounded up to the nearest 4K boundary. The default page protection key for global memory segments is 00 unless overridden with the **V_UREAD** flag.

The type field may have the following values, which may be combined:

Item	Description
V_WORKING	Required. Creates a working storage segment.
V_SYSTEM	The new allocation is a global system area that does not belong to any application. Storage reference errors to this area will result in system crashes.
V_UREAD	Overrides the default page protection of 00 and creates the new region with a default page protection of 01.
V_NOEXEC	Pages in the region will have no-execute protection by default. Only supported on POWER4 and later hardware.

The **vm_galloc** kernel service is intended for subsystems that have large data structures for which **xmalloc** is not the best choice for management. The kernel **xmalloc** heap itself does reside in global memory.

Parameters

Item	Description
type	Flags that may be specified to control the allocation.
size	Specifies the size, in bytes, of the desired allocation.
eaddr	Pointer to where **vm_galloc** will return the start address of the allocated storage.

Execution Environment

The **vm_galloc** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Successful completion. A new region was allocated, and its start address is returned at the address specified by the **eaddr** parameter.
EINVAL	Invalid size or type specified.
ENOSPC	Not enough space in the **galloc** heap to perform the allocation.
ENOMEM	Insufficient resources available to satisfy the request.

Related reference
vm_gfree Kernel Service
Related information
Memory Kernel Services
Understanding Virtual Memory Manager Interfaces

vm_gfree Kernel Service

Purpose

Frees a region of global memory in the kernel previously allocated with the **vm_galloc** kernel service.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>

int vm_gfree (ulong  eaddr, vmsize_t  size)
```

Description

The **vm_gfree** kernel service frees up a global memory region previously allocated with the **vm_galloc** kernel service. The start address and size must exactly match what was previously allocated by the **vm_galloc** kernel service. It is not valid to free part of a previously allocated region in the **vm_galloc** area.

Any I/O to or from the region being freed up must be quiesced before calling the **vm_gfree** kernel service.

Parameters

Item	Description
eaddr	Start address of the region to free.
size	Size in bytes of the region to free.

Execution Environment

The **vm_gfree** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Successful completion. The region was freed.
EINVAL	Invalid size or start address specified. This could mean that the region is out of range of the **vm_galloc** heap, was not previously allocated with **vm_galloc**, or does not exactly match a previous allocation from **vm_galloc**.

Related reference
vm_galloc Kernel Service
Related information
Memory Kernel Services
Understanding Virtual Memory Manager Interfaces

vm_guatt Kernel Service

Purpose

Attaches an area of global kernel memory to the current process's address space.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>

int vm_guatt (kaddr, size, key, flags, uaddr)
void * kaddr;
vmsize_t size;
vmkey_t key;
long flags;
void ** uaddr;
```

Parameters

Item	Description
kaddr	Kernel address to be attached (returned from **vm_galloc** when the global memory was allocated).
size	Length of the region to be inserted into the process address space, in bytes.
key	Protection key that the process will use when accessing the attached region.
flags	Type of **vm_guatt** operation; must be set to **VU_ANYWHERE**.
uaddr	Pointer to user space address where the region was attached by vm_guatt. The location pointed to by *uaddr* (*uaddr*) must be null when the **vm_guatt** call is made.

Description

vm_guatt is a kernel service used to attach a region of global kernel memory that was allocated with **vm_galloc** to a process's address space. If the call is successful, the address in the process address space where the memory was attached is returned in the location pointed to by *uaddr*.

key can be set to **VM_PRIV** or **VM_UNPRIV**. If it is set to **VM_PRIV**, the process will be able to read and write the attached region. If it is set to **VM_UNPRIV**, the process will not be able to write the region and will only be able to read it if the **vm_galloc** of the region was done with the **V_UREAD** flag on.

vm_guatt attachments are not inherited across a process fork.

Execution Environment

The **vm_guatt** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
EINVAL	Indicates one of the following errors:

- *flags* or *key* is not set to a valid value, *size* is 0, or the value pointed to by *uaddr* is non-NULL.
- Region indicated by *kaddr* and *size* does not lie within a region previously allocated by **vm_galloc**.

Implementation Specifics

The **vm_guatt** kernel service is part of Base Operating System (BOS) Runtime.

Related reference
vm_galloc Kernel Service
vm_gudet Kernel Service
Related information
Memory Kernel Services

vm_gudet Kernel Service

Purpose

Removes a region attached with **vm_guatt** from the current process's address space.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>

int vm_gudet (kaddr, uaddr, size, flags)
void * kaddr;
void * uaddr;
vmsize_t size;
long flags;
```

Parameters

Item	Description
kaddr	Kernel address attached by **vm_guatt**.
uaddr	Location in the process address space where the kernel region was attached.
size	Length of the attached region, in bytes.
flags	Type of **vm_gudet** operation, must be **VU_ANYWHERE**.

Description

vm_gudet is a kernel service that detaches a region of global kernel memory that was attached by **vm_guatt**. This memory must still be allocated, detaching a region after it has been deallocated with **vm_gfree** is an error. If the detach is successful, the global kernel memory region at *kaddr* will no longer be addressable at *uaddr* by the calling process.

Execution Environment

The **vm_gudet** kernel service can be called from the process environment only.

Return Values

Item	Description
0	User address detached successfully.
EINVAL	Indicates one of the following errors:

- Invalid flags.
- Region indicated by *kaddr* and *size* does not lie within a region allocated by **vm_galloc**.

Implementation Specifics

The **vm_gudet** kernel service is part of Base Operating System (BOS) Runtime.

Related reference

Memory Kernel Services

vm_handle Kernel Service

Purpose

Constructs a virtual memory handle for mapping a virtual memory object with a specified access level.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

vmhandle_t vm_handle (*vmid,* *key***)**
vmid_t *vmid;*
int *key;*

Parameters

Item	Description
vmid	Specifies a virtual memory object identifier, as returned by the **vms_create** kernel service.
key	Specifies an access key. This parameter has a 1 value for limited access and a 0 value for unlimited access, respectively.

Description

The **vm_handle** kernel service constructs a virtual memory handle for use by the **vm_att** kernel service. The handle identifies the virtual memory object specified by the *vmid* parameter and contains the access key specified by the *key* parameter.

A virtual memory handle is used with the **vm_att** kernel service to map a virtual memory object into the current address space.

The **vm_handle** kernel service assumes an address space model of fixed-size virtual memory objects and address space regions.

Execution Environment

The **vm_handle** kernel service can be called from the process environment only.

Return Values

The **vm_handle** kernel service returns a virtual memory handle type.

Related reference
vm_att Kernel Service
vms_create Kernel Service

Understanding Virtual Memory Manager Interfaces

vm_invalidatep Kernel Service

Purpose

Releases page frames in the specified range for a non-journaled persistent segment or client segment.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

int vm_invalidatep (*sid*, *pfirst*, *npages***)**
vmid_t *sid***;**
vpn_t *pfirst***;**
ulong *npages***;**

Parameters

Item	Description
sid	Identifies the base segment.
pfirst	The first page number within the range.
npages	The number of pages to invalidate starting from the *pfirst* value. All pages must be in the same segment.

Description

The **vm_invalidatep** kernel service routine discards any page frames associated with the virtual memory object in the specified page range.

If a page within the specified range is found in page-in or page-out state, then the thread is synchronously put to sleep until the page I/O completes. When the I/O is complete, any memory-resident page frame is then freed.

Note: The **vm_invalidatep** subroutine is not supported for use on large pages.

Execution Environment

The **vm_invalidatep** kernel service can be called from the process environment only.

This is intended for files, and might not be called for working storage segments.

Return Values

Item	Description
0	Indicates the completion of the invalidating operations.
EINVAL	Indicates one of the following errors:

- *pfirst* < 0.
- *npages* < 0.
- Page interval not in one segment.
- Invalid *sid* parameter.
- Invalid segment type.

vm_ioaccessp Kernel Service

Purpose

Initiates asynchronous page-in or page-out for the range of pages specified.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

int **vm_ioaccessp** (*bsid*, *pfirst*, *npages*, *modifier*)
vmid_t *bsid*;
vpn_t *pfirst*;
vpn_t *npages*;
uint *modifier*;

Parameters

Item	Description
bsid	Identifies the base segment.
pfirst	The first page number within the range.

Item	Description
npages	The number of pages to access starting from the *pfirst* value. All pages must be in the same segment.
modifie *r*	Flags passed in by the user. These flags are detailed below.

Description

The **vm_ioaccessp** kernel service routine enables a client file system with a thread-level strategy routine to access the pages specified. This call is strictly advisory and might return without having done anything. If you want to actually move the data, call the **vm_uiomove** kernel service. If you want to pre-page the target, then call the **vm_readp** kernel service.

The flags passed in through the *modifier* parameter determine what type of action taken by the **vm_ioaccessp** kernel service. For details of each flag's purpose, see the table below.

The flags carry certain restrictions. You cannot request both a make and a flush operation. Also, if the **VM_IOACCESSP_WAITONLY** flag is declared then you must specify at least one type of wait operation. Finally, you cannot request a make or a flush operation if the **VM_IOACCESSP_WAITONLY** flag is declared.

Flags

Value	Name	Purpose
0x0001	**VM_IOACCESSP_MAKE**	Creates new pages in the page-in state in the specified range. Can only make up to 1MB of pages.
0x0002	**VM_IOACCESSP_FLUSH**	Flushes pages in the specified range.
0x0004	**VM_IOACCESSP_PGINWAIT**	If a page in the specified range is in page-in state, then block until page-in is complete.
0x0008	**VM_IOACCESSP_PGOUTWAIT**	If a page in the specified range is in page-out state, then block until page-out is complete.
0x0010	**VM_IOACCESSP_WAITONLY**	Returns once the specified wait is complete. The **VM_IOACCESSP_PGINWAIT** flag and the **VM_IOACCESSP_PGOUTWAIT** flag must also be specified.

Execution Environment

The **vm_ioaccessp** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates the completion of the I/O access operations.

Item	Description
EINVAL	Indicates one of the following errors:

- *pfirst* = 0 and *npages* = 0.
- *pfirst* < 0.
- *npages* < 0.
- Page interval not in one segment.
- Invalid *sid* parameter.
- Page make requests > 1 MB.
- Not a client file system.
- Unsupported flag used.
- Both the **VM_IOACCESSP_MAKE** and the **VM_IOACCESSP_FLUSH** flags are set.
- The **VM_IOACCESSP_WAITONLY** flag is set and the **VM_IOACCESSP_PGINWAIT** flag or the **VM_IOACCESSP_PGOUTWAIT** flag is not set.
- The **VM_IOACCESSP_WAITONLY** flag and the **VM_IOACCESSP_MAKE** flag or the **VM_IOACCESSP_FLUSH** flag are set.

Memory Kernel Services

Understanding Virtual Memory Manager Interfaces

vm_makep Kernel Service

Purpose

Makes a page in client storage.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

int vm_makep (*vmid,* *pno***)**
vmid_t *vmid*;
int *pno*;

Parameters

Item	Description
vmid	Specifies the ID of the virtual memory object.
pno	Specifies the page number in the virtual memory object.

Description

The **vm_makep** kernel service makes the page specified by the *pno* parameter addressable in the virtual memory object without requiring a page-in operation. The **vm_makep** kernel service is restricted to client storage.

The page is not initialized to any particular value. It is assumed that the page is completely overwritten. If the page is already in memory, a value of 0, indicating a successful operation, is returned.

Execution Environment

The **vm_makep** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
EINVAL	Indicates a virtual memory object type or page number that is not valid.
EFBIG	Indicates that the page number exceeds the file-size limit.

Understanding Virtual Memory Manager Interfaces

vm_mem_policy System Call

Purpose

Allows callers to get or set their applications' default memory placement policies.

Library

Standard C Library (**libc.a**)

Syntax

#include <sys/rset.h>

#include <sys/vminfo.h>

int vm_mem_policy(int cmd, int *early_lru, int *policies, int num_policies)

Description

The **vm_mem_policy** system call allows callers to get or set their applications' default memory placement policies for different types of memory.

Following are the different types of placement policies:

Item	Description
P_FIRST_TOUCH	Places the memory at the **MCM** where the application first referenced it. This is also achieved by setting the **MEMORY_AFFINITY** environment variable to **MCM** and benefit the applications with an identified home **MCM** to run on.
P_BALANCED	Uses the stripe memory in the application across all the system's **MCM**s. This benefits applications that do not identify a home **MCM** to run on, or on global memory objects that is accessed by many applications.
P_DEFAULT	Accepts the system's default policy for memory placement, which can be either the first touch or balanced policy, depending on the circumstances and the type of memory.

The **vm_mem_policy** system call allows the caller to get or set the **early_lru** flag, which triggers the system to look for stealable pages immediately after a **P_FIRST_TOUCH** driven scan for local memory (the memory on the same **MCM** the application is running on) does not find any available pages.

The parameters *policies*, and *num_policies* allow a caller to fine control over the default memory placement policies of different types of memory. The policy settings take effect on any new memory page the application creates after having called this function. The existing memory pages of the application retains their existing memory placement.

Parameters

Item	Description
cmd	A command that is either **VM_SET_POLICY** or **VM_GET_POLICY**. The **VM_GET_POLICY** command copies the current policy setting into the buffers supplied by the caller, and does not change any of the process policies. The **VM_SET_POLICY** command reads input from the supplied buffers and changes the process policies accordingly.
early_lru	A pointer to an integer that indicates the state of the *early_lru* setting for first touch policy. Enabling *early_lru* causes memory to be paged out in order to fulfill a first-touch request for memory placement.

The possible values for *early_lru* are:

0
  turn off *early_lru*.

1
  turn on *early_lru*.

-1
  do not modify *early_lru* setting for **VM_SET_POLICY**.

Item	Description
policies	A pointer to an array of policies for distinct types of memory. Each array element contains one of the policy types. The array element contains -1 to leave the policy unchanged for the corresponding memory type. The array must be declared with a length of **VM_NUM_POLICIES**. The list that follows enumerates the memory types whose policies can be changed in the form of constants. Enter the constant that is an array index into the policies array for the corresponding memory type.

VM_POLICY_TEXT
  policy for executable program text

VM_POLICY_STACK
  policy for program stack

VM_POLICY_DATA
  policy for program heap and private **mmap** data

VM_POLICY_SHM_NAMED
  policy for shared memory obtained via **shm_open()** or **shmget()** with a key

VM_POLICY_SHM_ANON
  policy for anonymous mmap memory, or shared memory obtained via **shmget()** with **IPC_PRIVATE** key

VM_POLICY_MAPPED_FILE
  policy for files mapped into the address space via **shmat()** or **mmap()**

VM_POLICY_UNMAPPED_FILE
  policy for open files that are not mapped

Item	Description
num_policies	Number of elements in the policies array. This value must be set to **VM_NUM_POLICIES**.

vm_mount Kernel Service

Purpose

Adds a file system to the paging device table.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include  <sys/vmuser.h>
```

int vm_mount (*type*, *ptr*, *nbufstr*)
int *type*;
int (**ptr*)();
int *nbufstr*;

Parameters

Item	Description
type	Specifies the type of device. The *type* parameter must have a value of **D_REMOTE**.
ptr	Points to the file system's strategy routine.
nbufstr	Specifies the number of **buf** structures to use.

Description

The **vm_mount** kernel service allocates an entry in the paging device table for the file system. This service also allocates the number of **buf** structures specified by the *nbufstr* parameter for the calls to the strategy routine.

Execution Environment

The **vm_mount** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
ENOMEM	Indicates that there is no memory for the **buf** structures.
EINVAL	Indicates that the file system strategy pointer is already in the paging device table.

Related reference
vm_umount Kernel Service

Memory Kernel Services
Understanding Virtual Memory Manager Interfaces

vm_mounte Kernel Service

Purpose

Adds a file system with a thread-level strategy routine to the paging device table.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

int vm_mounte (*in_dtype*, *in_devid*, *in_thrinfop***)**
int *in_dtype*;

dev_t *in_devid*;
struct thrpginfo * *in_thrinfop*;

Parameters

Item	Description
in_dtype	Specifies the type of device. Supported device types are **D_REMOTE**, **D_LOGDEV**, **D_SERVER**, **D_LOCALCLIENT**. Other optional flags are detailed below.
in_devid	If the type is **D_LOGDEV**, specifies a dev_t object of the block device. If the type is **D_REMOTE** or **D_SERVER**, specifies a pointer to a strategy routine.
in_thrinfop	Pointer to a **thrpginfo** structure.

Description

The **vm_mounte** kernel service allocates an entry in the paging device table for the device specified. The **vm_mounte** kernel service can also mount a client file system with a thread-level strategy routine. This is done by passing in the **D_THRPGIO** and the **D_ENHANCEDIO** flags.

Flags

Name	Purpose
D_ENHANCEDIO	Indicates an enhanced I/O-aware file system.
D_PREXLATE	Enables pre-translation as the default for all but remote file systems.
D_THRPGIO	Indicates a thread-level strategy routine.

Execution Environment

The **vm_mounte** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
ENOMEM	Indicates that there is no memory for the **buf** or the **thrpginfo** structure.
EINVAL	Indicates one of the following errors:

- The file system strategy pointer is already in the paging device table, or in case of **D_SERVER**, a server is already defined.
- The *in_dtype* parameter is set to the **D_PAGING** or the **D_FILESYSTEM** value.
- The **thrpginfo** structure has not been initialized correctly.
- The **D_THRPGIO** flag has been set without the **D_ENHANCEDIO** flag.

Understanding Virtual Memory Manager Interfaces

vm_move Kernel Service

Purpose

Moves data between a virtual memory object and a buffer specified in the **uio** structure.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
#include <sys/uio.h>
```

int **vm_move** (*vmid, offset, limit, rw, uio*)
vmid_t *vmid*;
caddr_t *offset*;
int *limit*;
enum uio_rw *rw*;
struct uio * *uio*;

Parameters

Item	Description
vmid	Specifies the virtual memory object ID.
offset	Specifies the offset in the virtual memory object.
limit	Indicates the limit on the transfer length. If this parameter is negative or 0, no bytes are transferred.
rw	Specifies a read/write flag that gives the direction of the move. The possible values for this parameter (**UIO_READ**, **UIO_WRITE**) are defined in the **/usr/include/sys/uio.h** file.
uio	Points to the **uio** structure.

Description

The **vm_move** kernel service moves data between a virtual memory object and the buffer specified in a **uio** structure.

This service determines the virtual addressing required for the data movement according to the offset in the object.

The **vm_move** kernel service is similar to the **uiomove** kernel service, but the address for the trusted buffer is specified by the *vmid* and *offset* parameters instead of as a **caddr_t** address. The offset size is also limited to the size of a **caddr_t** address since virtual memory objects must be smaller than this size.

Note: The **vm_move** kernel service does not support use of cross-memory descriptors.

I/O errors for paging space and a lack of paging space are reported as signals.

Execution Environment

The **vm_move** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
EFAULT	Indicates a bad address.

Item	Description
ENOMEM	Indicates insufficient memory.
ENOSPC	Indicates insufficient disk space.
EIO	Indicates an I/O error.

Other file system-specific **errno** global variables are returned by the virtual file system involved in the move function.

Related reference
uiomove Kernel Service

Memory Kernel Services
Understanding Virtual Memory Manager Interfaces

vm_mvc Kernel Service

Purpose

Reads or writes partial pages of files.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

int vm_mvc (*in_sid*, *in_pno*, *in_pgoffs*, *in_count*, *in_cmd*, *in_xmemdp*, *in_ptr***)**
vmid_t *in_sid*;
vpn_t *in_pno*;
int *in_pgoffs*;
int *in_count*;
int *in_cmd*;
struct xmem * *in_xmemdp*;
void * *in_ptr*;

Parameters

Item	Description
in_sid	The primary memory object, m1.
in_pno	The m1 pno object. If it is a read operation, this parameter refers to the source. If not, it refers to a target.
in_pgoffs	The byte offset in the pno object.
in_count	The number of bytes to zero or copy in memory.
in_cmd	The reason for the function call. The possible values could be Zero, Zero(protect), read, or write.
in_xmemd p	The xmem descriptor for the second memory object, m2.
in_ptr	The byte offset in the xmem object.

Description

The **vm_mvc** kernel service is meant to be used by client file systems doing read or write operations to partial pages of files, where the file is denoted by the m1 object and the read or write buffer by the m2 object. Such cases arise on EOF handling, fragments, compression, and holes among other situations.

Given two memory object, m1 and m2, the **vm_mvc** kernel service allows you to do one of the following operations:

- Zero out bytes on the m1 object (**VM_MVC_ZERO**).
- Zero out and protect the m1 object (**VM_MVC_PROTZERO**).
- Copy bytes from the m1 object to the m2 object (**VM_MVC_READ**).
- Copy bytes from the m2 object to the m1 object (**VM_MVC_WRITE**).

The first memory object, m1, is characterized by a *sid* parameter and a *pno* parameter. The second memory object, m2, is characterized by an xmem descriptor and a pointer for an offset. The second memory object is a user or kernel buffer.

Note: The second memory object must be pinned.

Flags

in_cmd	Purpose
VM_MVC_ZERO	Zeros out the bytes on the m1 object.
VM_MVC_READ	Copies bytes from the m1 object to the m2 object.
VM_MVC_WRITE	Copies bytes from the m2 object to the m1 object.
VM_MVC_PROTZERO	Zeros out and protects the m1 object.

Execution Environment

The **vm_mvc** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates that the I/O access operations completed successfully.
ENOENT	Indicates that the (sid, pno) set was not mapped to a real frame.
EINVAL	Indicates one of the following errors:

- The m1 object crosses page boundary.
- The *in_cmd* parameter does not contain a valid command.

Understanding Virtual Memory Manager Interfaces

vm_pattr System Call and kvm_pattr Kernel Service

Purpose

Queries or modifies virtual memory attributes.

Library

Standard C Library (**libc.a**)

Syntax

```
#include <sys/vmpattr.h>
```

int vm_pattr (
long *cmd*,
pid_t *pid*,
void * *attr*,
size_t *attr_size* **);**

int kvm_pattr (
long *cmd*,
pid_t *pid*,
void * *attr*,
size_t *attr_size* **);**

Description

The **vm_pattr** system call queries or modifies memory attributes of the calling process's address space or that of another user process.

The **kvm_pattr** kernel service provides the same function to kernel subsystems (kernel extensions, kernel processes and so on) except that it cannot modify another kernel process' memory attributes.

Parameters

Item	Description
cmd	The following commands can be passed in:
	VM_PA_SET_PSIZE or VM_PA_GET_PSIZE These commands set or retrieve the page size used for a specified memory range.
	VM_PA_GET_RMUSAGE This command retrieves the amount of the real memory in bytes being used for a specified memory range.
	VM_PA_SET_PSPA or VM_PA_GET_PSPA These commands set or retrieve the page size promotion aggressiveness factor for a specified memory range.
	VM_PA_GET_PSPA_ALIGN This command retrieves the minimum memory alignment necessary for memory ranges specified to the **vm_pattr** kernel service when using the **VM_PA_SET_PSPA** command.
	VM_PA_CHECK_PSIZE This command reports if a specified page size can be used for a memory range.
	VM_PA_SET_LSA_POLICY This command allows the shared memory address space allocator to be tuned according to a process requirements. This command should be run before any shared memory regions are created.
	VM_PA_SET_PSIZE_EXTENDED or VM_PA_GET_PSIZE_EXTENDED These commands provide variable large page size segment support.
pid	Specifies the ID of the process whose memory attributes are to be queried or modified. A value of -1 specifies the calling process. The root user can specify any process ID, but other users can only specify processes they own (that is, the target process's user ID must match the calling process's user ID). The **vm_pattr** system call is only supported on user processes while the **kvm_pattr** kernel service can target user processes or its own kernel process (for example, *pid* = -1).

Item	Description
attr	A pointer to a structure describing the effective address range for the memory being queried or modified and additional data depending on the command.

The range is specified through the following **vm_pa_range** structure:

```
struct vm_pa_range
          {
                ptr64_t  rng_start;
                size64_t rng_size;
          };
```

The range specified must be in the target process's address space and must correspond to one of these process areas:

- Main program data (initialized, bss, or heap).
- Shared library data or private module load area data.
- Privately loaded text.
- Initial thread stack area.
- Anonymous shared memory (System V shared memory, extended System V shared through EXTSHM, and POSIX real-time shared memory). The target process must have write access to the memory in order to change the attributes of the shared memory range.
- Anonymous mmap memory.

If the memory range specified includes shared memory or mmap memory, the calling process must have write access to the memory according to the shared memory descriptor or mapping attributes in order to change the attributes of the range. The range can have additional restrictions based on the following commands.

Item	Description
attr (continued)	The structure specified through the *attr* parameter must be a pointer to one of the following structures:

VM_PA_SET_PSIZE or VM_PA_GET_PSIZE
These commands take a pointer to the following structure:

```
struct vm_pa_psize
          {
                      struct vm_pa_range pa_range;
                      psize_t            pa_psize;
          };
```

For the **VM_PA_SET_PSIZE** command, the *pa_psize* parameter is the page size (in bytes) to use for the given range. This is an advisory setting that might or might not be used at the operating system's discretion. This must be a valid page size between the minimum and maximum page sizes of all segments in the range. Additionally, the range must start and end on a multiple of the specified page size. If an error occurs during the processing of this command, any successfully altered page size settings can remain set.

For the **VM_PA_GET_PSIZE** command, the page size (in bytes) backing the specified memory range is returned in the *pa_psize* parameter. The range must start and end on a multiple of the smallest page size supported as reported by the **sysconf(_SC_PAGE_SIZE)** subroutine. If the range is using multiple page sizes, the smallest page size in the range is reported. Unlike the **VM_PAGE_INFO** command of the **vmgetinfo** subroutine that reports the segment's base page size, the page size reported by the **VM_PA_GET_PSIZE** command is the actual page size being used at the time the **vm_pattr** system call was called. The page size reported is transient because the operating system can change the backing page size at any time. Therefore, the page size reported must be for informational purposes only.

Item	Description

VM_PA_SET_PSIZE_EXTENDED
This command takes a pointer to the following structure:

```
struct vm_pa_psize_extended
        {
                struct vm_pa_range    pa_range;
                psize_t               pa_psize;
                size_t                pa_info_size;
                uint64_t             *pa_info;
        }
```

This command is essentially the same as **VM_PA_SET_PSIZE** except that *pa_psize* must be 16 MB and, if not NULL, *pa_info* can be used to pass additional information specifying one or more affinity domains.

The info passed by the parameter is advisory request, and the system might choose to ignore it.

The *pa_range* is scanned for subregions that begin and end on a 16 MB boundary, are fully backed with 4 KB or 64 KB pages, and have uniform page attributes. The page attributes include read or write page protection, storage key protection, and no-execute protection.

The data in qualifying 16 MB subregions is colocated to a 16 MB contiguous block of physical memory, and it uses 16 MB hardware translations.

If the *pa_info* pointer is NULL, the memory for collocation is allocated from any memory SRAD, affinity domain chosen by the operating system.

If parameter value is not NULL, *pa_info* must point to an *rsethandle_t* that describes a set of affinity domains from which the physical memory for the collocation must be allocated. The object should be allocated by a call to *rs_alloc* (RS_EMPTY). It must then be initialized with one *rs_op*(RS_ADDRESOURCE, ..., R_MEMPS, srad#) call per affinity domain being requested.

This command can potentially affect system performance and is not generally recommended; therefore, this command requires you to have either the CAP_BYPASS_RAC_VMM and CAP_PROPAGATE capabilities or root authority.

VM_PA_GET_PSIZE_EXTENDED
This command is essentially the same as the **VM_PA_GET_PSIZE** command except that it can also return the 64 KB and 16 MB subregions that are using an hardware translation page size different from the underlying segments default page size.

attr (continued)

If the *pa_info* field is NULL, this command is identical to the **VM_PA_GET_PSIZE** command.

The *pa_info* field should point to an array containing two 64 bit integers. The *pa_info_size* field should be set to the size of the array.

In the first 64-bit integer, this command reports the number of 64-KB sized and aligned subregions in the specified *pa_range* range that consist of 16 contiguous 4-KB pages that are promoted to using a 64-KB page size hardware translation. In the second 64-bit integer, this command reports the number of 16 MB sized and aligned subregions in the specified range that consist of either 4096 4 KB or 256 64-KB contiguous pages that are promoted to using a 16-MB page size hardware translation.

The *pa_psize* field reports the smallest page size found for the specified range.

The information reported is transient because the operating system can change the backing page size at any time. Therefore, the page size reported must be for informational purposes only.

Item	Description

attr *(continued)*

VM_PA_GET_RMUSAGE

This command takes a pointer to the following structure:

```
struct vm_pa_rmusage
        {
                struct vm_pa_range pa_range;
                size64_t           pa_rbytes;
        };
```

This command reports the amount of real memory (in bytes) used for the given range in the *pa_rbytes* field. This can help an application decide whether it needs to use a large page size for a specific range based on how much real memory the range is using. For example, if a 64KB range is only using 4KB of real memory, then it does not make sense to try to use a 64KB page size for that range. But if it is using all 64KB or some large percentage of it, then the application might decide to use a 64KB page size. The range specified for this command has no alignment requirements for this command, and the command includes only those bytes in the range that are using real memory.

VM_PA_SET_PSPA or VM_PA_GET_PSPA

These commands take a pointer to the following structure:

```
struct vm_pa_pspa
        {
                struct vm_pa_range pa_range;
                int     pa_pspa;
        };
```

The **VM_PA_SET_PSPA** command can set the page size promotion aggressiveness for the specified range. The *pa_pspa* setting is in the same units as the vmm_default_pspa vmo tunable. This setting is the inverse of the real memory occupancy threshold needed to promote to a large page size and ranges from -1 to 100. The value of -1 indicates that no page promotion can occur regardless of the occupancy of the memory range. A value of 0 indicates a page size promotion can only be done when the memory range is fully occupied. A value of 100 indicates a page promotion must be done at the first reference to the memory range.

This setting is only supported at a segment granularity, so the range must start and end on a segment boundary. The alignment requirement for the range can be found using the **VM_PA_GET_PSPA_ALIGN** command with the **vm_pattr** system call.

If an error occurs during the processing of the **VM_PA_SET_PSPA** command, the **vm_pattr** system call can return after altering the page size promotion thresholds for part of the specified range.

The **VM_PA_GET_PSPA** command retrieves the page size promotion aggressiveness factor for the specified range. If the range spans multiple segments consisting of different page promotion thresholds, the *pa_pspa* field is updated with the least aggressive PSPA setting (the smallest PSPA setting across all of the segments).

The PSPA commands are not supported on mmap or EXTSHM memory ranges.

attr *(continued)*

VM_PA_GET_PSPA_ALIGN

This command takes a pointer to the following structure:

```
struct vm_pa_pspa_align
        {
                struct vm_pa_range pa_range;
                size64_t pa_pspa_align;
        };
```

The **VM_PA_GET_PSPA_ALIGN** command returns the minimum memory alignment requirements of a memory range for the **VM_PA_SET_PSPA** command in the *pa_pspa_align* field based on what segments are contained in the specified memory range. If a memory range spans segments with different alignment requirements, this command returns the largest of the alignment requirements.

The alignment requirements for the **VM_PA_SET_PSPA** command are as follows:

Item	Description
attr (continued)	**VM_PA_SET_LSA_POLICY** This command takes a pointer to the following structure:

```
struct vm_pa_lsa_options
 {
 u_int64_t setting;
 size64_t value;
 };
```

The following settings are allowed:

VM_PA_SHM_1TB_SHARED
This setting controls the threshold of the number of 256 MB segments required before a SHM object is considered big enough to be placed in its own 1 TB region to be promoted to the large alias segments. Values can range from 0 to 4 KB.

VM_PA_SHM_1TB_UNSHARED
This setting controls the threshold of the number of 256 MB segments required before a group of SHM object packed in a 1 TB aligned group is promoted to the large alias segments. Values can range from 0 to 4 KB.

Item	Description
attr (continued)	**Process's Memory Area Minimum Alignment**

Main process data 256 MB

Process stack 256 MB

Shared Library data 256 MB

Privately loaded module data 256 MB

Privately loaded module text 256 MB

POSIX Real-Time Shared Memory 256 MB

Anonymous MMAP 256 MB

Anonymous Extended System V Shared memory 256 MB

Anonymous System V Shared memory with page sizes less than or equal to 256 MB 256 MB

Anonymous System V shared memory backed with 16 GB page size 1 TB

Item	Description
attr (continued)	**VM_PA_CHECK_PSIZE** This command takes a pointer to the following structure:

```
struct vm_pa_psize_check
         {
                 struct vm_pa_range pa_range;
                 psize_t            pa_psize;
                 int                pa_reason;
         };
```

The **VM_PA_CHECK_PSIZE** command determines if a specific page size is allowed by the **VM_PA_SET_PSIZE** command for a specified memory range. The **VM_PA_CHECK_PSIZE** command can be used when the application wants more detailed information about why a **VM_PA_SET_PSIZE** operation fails, or to check if a **VM_PA_SET_PSIZE** operation will successfully modify the page size for the range specified.

This command must be used on a memory range that spans a single page and is aligned to the page size specified by the *pa_psize* parameter. If the page size can be used for that range, the *pa_reason* parameter is set to 0. Otherwise, it is set to a reason code defined in the **vmpattr.h** header file.

VMPATTR_SET_PSIZE_VALID The specified page size can be used for the specified range.

VMPATTR_INVALID_MPSS_PSIZE The specified page size is not supported in mixed page size segments.

VMPATTR_NON_MPSS_SEGMENT The address range specified is from a segment that does not support mixed page sizes.

VMPATTR_NON_MPSS_PAGE The size of the target page cannot be modified. For example, this reason code can be returned when trying to set an address range to a 64 KB page size if a portion of the range has page protection settings that do not match the rest of the range.

VMPATTR_RDONLY_MEM The target range cannot be modified because the caller does not have write access to the memory specified.

VMPATTR_PAGE_ATTRIBUTES The address range specified does not have uniform page attributes.

VMPATTR_NOT_FULLY_POPULATED The address range specified does not fully reside in memory.

VMPATTR_PHYSICAL_ATTACHMENTS The address range specified has memory affinity attachments that specify more than one affinity domain.

VMPATTR_MEMORY_TYPE_UNSUPPORTED The address range contains a memory object that does not support the requested page size in a mixed page size segment.

Item	Description
attr_size	The *attr_size* parameter must be the size of the structure needed, or greater for the specified command.

Return Values

When successful, these commands return 0. Otherwise, they return -1 and set the errno global variable to indicate the error.

Error Codes

Item	Description
EPERM	The calling process does not have the appropriate privilege to perform the requested operation.
ESRCH	The target process does not exist or is not in a valid state.
ENOMEM	The range specified contains a hole. A hole is any part of the target process's address space that is not backed by a virtual memory segment or is outside of the valid range of the virtual memory segment specified.

Item	Description
ENOTSUP	Any of the following situations can cause the **ENOTSUP** error:
	• The target process is a kernel process other than the calling process.
	• The command specified was the **VM_PA_SET_PSIZE** command and the page size specified is not supported for multiple page size segments.
	• The command specified was either the **VM_PA_GET_PSPA** or the **VM_PA_SET_PSPA** command and the specified memory range includes mmap or EXTSHM segment(s).
EINVAL	Any of the following situations can cause the **EINVAL** error:
	• The *attr_size* parameter specified is less than the size of the structure needed for this command.
	• The range specified is outside the process's address space (for example, global kernel memory).
	• The command specified was the **VM_PA_SET_PSIZE** command and the page size specified was not a valid page size supported by the system.
	• The command specified was the **VM_PA_SET_PSPA** command and the address range specified was not aligned to the segment size backing the range.
	• The command specified was the **VM_PA_SET_PSPA** command and the page promotion aggressiveness factor specified was not valid.
	• The command specified was the **VM_PA_CHECK_PSIZE** command and the address range specified was not aligned to the page size specified.
ENOMEM	The command specified was **VM_PA_SET_PSIZE_EXTENDED**, and the system was unable to allocate memory from the set of affinity domains specified by the *pa_info* object or the entire set of system affinity domains without potentially causing a performance degradation.
EFAULT	The command specified was either **VM_PA_SET_PSIZE_EXTENDED**, or **VM_PA_GET_PSIZE_EXTENDED** and the *pa_info* address is not valid and is not NULL.
EINVAL	The command specified was either **VM_PA_SET_PSIZE_EXTENDED**, or **VM_PA_GET_PSIZE_EXTENDED** and the *pa_info* field is not-NULL, but the *pa_info_size* field is 0.
ENODEV	The command specified was **VM_PA_SET_PSIZE_EXTENDED**, and an invalid sradid was specified in *pa_info*.

Dynamic variable page size support

vm_protect_kkey Kernel Service

Purpose

Sets kernel-key on a kernel address range.

Syntax

```
#include <sys/types.h>
#include <sys/skeys.h>
#include <sys/vmuser.h>
```

kerrno_t vm_protect_kkey (*eaddr, nbytes, kkey, flags*)
void * *eaddr*;
size_t *nbytes*;
kkey_t *kkey*;
unsigned long *flags*;

Parameters

Item	Description
eaddr	Starting address to protect.
nbytes	Number of bytes to protect.
kkey	Kernel-key value to set on memory.
flags	Defined flag value is:
	• **VMPK_NO_CHECK_AUTHORITY** – This flag indicates that extended authority checking will not be performed.

Description

The **vm_protect_kkey()** kernel service is used to alter the kernel-key associated with a virtual memory range. If set, any code that references the memory needs to include the kernel-key in their active keyset. The kernel-key is set for all pages in the effective address range specified by *eaddr* to *eaddr + nbytes - 1*. If the address range does not specify a page-aligned area consisting of an integral number of full pages, an error will be returned.

By default, an authority check is performed when altering storage-keys. This check requires that the **vm_protect_kkey()** caller has write access to the pages' current kernel-key(s). This authority checking can be overridden by setting the **VMPK_NO_CHECK_AUTHORITY** value, but this is not recommended since the check can protect against some programming errors.

Execution Environment

The **vm_protect_kkey** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Successful.
EINVAL_VM_PROTECT_KKEY	Invalid parameter or execution environment.
EINVAL_VM_PROTECT_KKEY_PPAGE	Request includes a partial page.
EFAULT_VM_PROTECT_KKEY	Invalid address range.
EPERM_VM_PROTECT_KKEY	Insufficient authority to perform the operation.

If the **vm_protect_kkey()** kernel service is unsuccessful because of a condition other than that specified by the **EINVAL_VM_PROTECT_KKEY** error code, the kernel-key for some pages in the (*eaddr, eaddr + nbytes - 1*) range might have been changed.

Related reference
vm_setseg_kkey Kernel Service

vm_protectp Kernel Service

Purpose

Sets the page protection key for a page range.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include  <sys/vmuser.h>
```

int vm_protectp (*vmid*, *pfirst*, *npages*, *key*)
vmid_t *vmid*;
int *pfirst*;
int *npages*;
int *key*;

Description

The **vm_protectp** kernel service is called to set the storage protect key for a given page range. The *key* parameter specifies the value to which the page protection key is set. The protection key is set for all pages touched by the specified page range that are resident in memory. The **vm_protectp** kernel service applies only to client storage.

If a page is not in memory, no state information is saved from a particular call to the **vm_protectp** service. If the page is later paged-in, it receives the default page protection key.

Note: The **vm_protectp** subroutine is not supported for use on large pages.

Parameters

Item	Description
vmid	Specifies the identifier for the virtual memory object for which the page protection key is to be set.
pfirst	Specifies the first page number in the designated page range.
npages	Specifies the number of pages in the designated page range.
key	Specifies the value to be used in setting the page protection key for the designated page range.

Execution Environment

The **vm_protectp** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.

Item	Description
EINVAL	Indicates one of the following errors:

  - Invalid virtual memory object ID.
  - The starting page in the designated page range is negative.
  - The number of pages in the page range is negative.
  - The designated page range exceeds the size of virtual memory object.
  - The target page range does not exist.
  - One or more large pages lie in the target page range.

Memory Kernel Services

Understanding Virtual Memory Manager Interfaces

vm_qmodify Kernel Service

Purpose

Determines whether a mapped file has been changed.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

int vm_qmodify (*vmid***)**
vmid_t *vmid***;**

Parameter

Item	Description
vmid	Specifies the ID of the virtual memory object to check.

Description

The **vm_qmodify** kernel service performs two tests to determine if a mapped file has been changed:

  - The **vm_qmodify** kernel service first checks the virtual memory object modified bit, which is set whenever a page is written out.
  - If the modified bit is 0, the list of page frames holding pages for this virtual memory object are examined to see if any page frame has been modified.

If both tests are false, the **vm_qmodify** kernel service returns a value of False. Otherwise, this service returns a value of True.

If the virtual memory object modified bit was set, it is reset to 0. The page frame modified bits are not changed.

Execution Environment

The **vm_qmodify** kernel service can be called from the process environment only.

Return Values

Item	Description
FALSE	Indicates that the virtual memory object has not been modified.
TRUE	Indicates that the virtual memory object has been modified.

Related information

Memory Kernel Services

Understanding Virtual Memory Manager Interfaces

vm_qpages Kernel Service

Purpose

Returns the number of in-memory page frames associated with the virtual memory object.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

vpn_t vm_qpages (*sid* **)**
vmid_t *sid*;

Parameters

Item	Description
sid	Identifies the base segment.

Description

The **vm_qpages** kernel service routine returns the number of page frames associated with the virtual memory object with the *sid* parameter specified.

Execution Environment

The **vm_qpages** kernel service can be called from the process environment only.

This function can be run for persistent, client, and working storage segments.

Return Values

Item	Description
npages	The number of page frames.
-1	Indicates an invalid *sid* parameter.

Related information

Memory Kernel Services

Understanding Virtual Memory Manager Interfaces

vm_readp Kernel Service

Purpose

Initiates asynchronous page-in for the range of pages specified.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

int vm_readp (*sid*, *pfirst*, *npages*, *flags***)**
vmid_t *sid***;**
vpn_t *pfirst***;**
vpn_t *npages***;**
int *flags***;**

Parameters

Item	Description
sid	Identifies the base segment.
pfirst	The first page number within the range.
npages	The number of pages to read starting from the *pfirst* value. All pages must be in the same segment, unless the **V_READMAKE** flag is used.
flags	Flags used by the function.

Description

The **vm_readp** kernel service routine starts the process of paging within the range of specified pages. This call is strictly advisory and might return without performing any operations.

The *flags* parameter is optional and accepts the following values:

V_IOWAIT
Instructs the **vm_readp** kernel service to wait for any page I/O requests to complete, within the range of specified pages, before initiating the read operation.

V_READMAKE
Instructs the **vm_readp** kernel service to create the segments within the range of the **vm_readp** operation.

Execution Environment

The **vm_readp** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates that the I/O access operations completed successfully.

Item	Description
EINVAL	Indicates one of the following errors:

- *pfirst* = 0 and *npages* = 0.
- *pfirst* < 0.
- *npages* < 0.
- Page interval > Maximum file size.
- The *sid* parameter is not valid.
- Not a file or persistent storage segment.

vm_writep Kernel Service

Related information

Memory Kernel Services

Understanding Virtual Memory Manager Interfaces

vm_release Kernel Service

Note: The **vm_release** subroutine is not supported for use on large pages.

Purpose

Releases virtual memory resources for the specified address range.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include  <sys/vmuser.h>
```

```
int  vm_release ( vaddr,  nbytes)
caddr_t vaddr;
int nbytes;
```

Description

The **vm_release** kernel service releases pages that intersect the specified address range from the *vaddr* parameter to the *vaddr* parameter plus the number of bytes specified by the *nbytes* parameter. The value in the *nbytes* parameter must be nonnegative and the caller must have write access to the pages specified by the address range.

Each page that intersects the byte range is logically reset to 0, and any page frame is discarded. A page frame in I/O state is marked for discard at I/O completion. That is, the page frame is placed on the free list when the I/O operation completes.

Note: All of the pages to be released must be in the same virtual memory object.

Parameters

Item	Description
vaddr	Specifies the address of the first byte in the address range to be released.
nbytes	Specifies the number of bytes to be released.

Execution Environment

The **vm_release** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
EACCES	Indicates that the caller does not have write access to the specified pages.
EINVAL	Indicates one of the following errors:

- The specified region is not mapped.
- The specified region is an I/O region.
- The length specified in the *nbytes* parameter is negative.
- The specified address range crosses a virtual memory object boundary.
- One or more large pages lie in the target page range.

vm_releasep Kernel Service

Purpose

Releases virtual memory resources for the specified page range.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include  <sys/vmuser.h>
```

```
int  vm_releasep ( vmid,  pfirst,  npages)
vmid_t  vmid;
int pfirst;
int npages;
```

Description

The **vm_releasep** kernel service releases pages for the specified page range in the virtual memory object. The values in the *pfirst* and *npages* parameters must be nonnegative.

Each page of the virtual memory object that intersects the page range (*pfirst*, *pfirst* + *npages* -1) is logically reset to 0, and any page frame is discarded. A page frame in the I/O state is marked for discard at I/O completion.

For working storage, paging-space disk blocks are freed and the storage-protect key is reset to the default value.

Note: All of the pages to be released must be in the same virtual memory object.

Note: The **vm_releasep** subroutine is not supported for use on large pages.

Parameters

Item	Description
vmid	Specifies the virtual memory object identifier.
pfirst	Specifies the first page number in the specified page range.
npages	Specifies the number of pages in the specified page range.

Execution Environment

The **vm_releasep** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
EINVAL	Indicates one of the following errors:

- An invalid virtual memory object ID.
- The starting page is negative.
- Number of pages is negative.
- Page range crosses a virtual memory object boundary.
- One or more large pages lie in the target page range.

vm_segmap Kernel Service

Purpose

Creates the segments associated with a range of bytes in a file and attaches them to the kernel's address space.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

int vm_segmap (*basesid*, *pfirst*, *flags*, *basepp***)**
vmid_t *basesid***;**
vpn_t *pfirst***;**
uint *flags***;**
caddr_t * *basepp***;**

Parameters

Item	Description
basesid	Identifies the base segment.
pfirst	The first page number within the range. The *pfirst* parameter is non-negative.
flags	Optional flags passed in by the user. .
basepp	The offset of the object to be attached.

Description

The **vm_segmap** kernel service routine creates segments associated with a range of bytes in a file. Afterwards, it uses the **vm_att** kernel service to map the specified virtual memory object to a region in the virtual address space and returns the effective address of that object in the *basepp* parameter.

Execution Environment

The **vm_segmap** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
caddr_t	The effective address of the attached object.
EINVAL	Indicates one of the following errors: • *pfirst* < 0. • Invalid *sid* parameter.
EFBIG	Indicates the range of values is too large to create.

Related information
Memory Kernel Services
Understanding Virtual Memory Manager Interfaces

vm_setdevid Kernel Service

Purpose

Modifies the paging device table entry for a virtual memory object.

Syntax

```
#include <sys/types.h>
#include <sys/kerrno.h>
#include  <sys/vmuser.h>
```

```
kerrno_t vm_setdevid ( vmid, type,  ptr,  flags)
vmid_t vmid;
int type;
int (*ptr)();
unsigned long flags;
```

Parameters

Item	Description
vmid	Specifies the identifier for the virtual memory object for which the paging device table entry is to be set.
type	Specifies the type of device. The *type* parameter must have a value of D_REMOTE.
ptr	Points to the strategy routine of the file system.
flags	Reserved. You must set the *flags* parameter to zero.

Description

The **vm_setdevid** kernel service binds the paging device table entry associated with the file system strategy routine *ptr,* to the virtual memory object *vmid*. The paging device table entry must have already been mounted as type D_REMOTE through a prior **vm_mount** kernel service call.

After the file system has called the **vm_setdevid** kernel service on a given virtual memory object, subsequent paging I/O will be performed to or from the newly specified paging device table. Any outstanding I/O's to the paging device table formerly associated with the virtual memory object, remain queued, and will complete asynchronously. After they complete, subsequent paging I/O to those file pages will be performed to or from the newly specified paging device table.

The paging device table entry currently associated with the *vmid* object, on input to this call, must be valid and of type D_REMOTE. Any flags specified when the **vm_mount** kernel service gets called must match exactly any flags specified when the **vm_mount** kernel service gets called for the new paging device table entry.

Execution Environment

The **vm_setdevid** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
EINVAL_VM_SETDEVID1	Indicates that the *vmid* value is not a client segment, or the input type does not have the value of D_REMOTE.
ENODEV_VM_SETDEVID2	Indicates that a file system with the strategy routine designated by the *ptr* parameter is not in the paging device table.
EINVAL_VM_SETDEVID3	Indicates that the new paging device table entry is not D_REMOTE or is not valid.
EINVAL_VM_SETDEVID4	Indicates that the paging device table entry currently associated with the *vmid* object is not D_REMOTE or is not valid.
EINVAL_VM_SETDEVID5	Indicates that the **vm_mount** flags for the current and new paging device table entries differ.
EINVAL_VM_SETDEVID6	Indicates that this was called at interrupt level.
EINVAL_VM_SETDEVID7	Indicates that the input flags was nonzero.
EINVAL_VM_SETDEVID8	Indicates that the input *vmid* value is not valid.

Related Information

The **vm_mount** kernel service, **vm_umount** kernel service.

Understanding Virtual Memory Manager Interfaces

vm_setseg_kkey Kernel Service

Purpose

Sets the default kernel-key for a segment.

Syntax

```
#include <sys/types.h>
#include <sys/kerrno.h>
#include <sys/vmuser.h>
```

```
kerrno_t vm_setseg_kkey (vmid, kkey)
vmid_t vmid;
kkey_t kkey;
```

Parameters

Item	Description
vmid	Virtual memory object to act on.
kkey	New kernel key for the virtual memory object.

Description

The **vm_setseg_kkey** kernel service alters the default kernel-key for newly allocated pages in a segment. The kernel-key values for any existing pages in the segment are left unchanged.

Execution Environment

The **vm_setseg_kkey** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Successful.
EINVAL_VM_SETSEG_KKEY	Invalid parameter or execution environment.

vm_thrpgio_pop Kernel Service

Purpose

Retrieves the latest context information.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

void vm_thrpgio_pop (*in_ctxp***)**
ut_pgio_context_t * *in_ctxp***;**

Parameters

Item	Description
in_ctxp	The context structure used by the function.

Description

The **vm_thrpgio_pop** kernel service enables a client file system with a thread-level strategy routine to copy information from a context structure to the current thread. Afterwards, it makes the current thread point to the next context.

This service must be called if a client file system using a thread-level strategy routine has re-entered the Virtual Memory Manager and wishes to return to its strategy routine. This service restores the context that was saved using the **vm_thrpgio_push** kernel service.

Execution Environment

The **vm_thrpgio_pop** kernel service can only be used by client file systems using a thread-level strategy routine.

Return Values

The **vm_thrpgio_pop** kernel service has no return values.

Related reference
vm_thrpgio_push Kernel Service

Understanding Virtual Memory Manager Interfaces

vm_thrpgio_push Kernel Service

Purpose

Saves some context information of the current thread.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

void vm_thrpgio_push (*in_ctxp***)**
ut_pgio_context_t * *in_ctxp***;**

Parameters

Item	Description
in_ctxp	The context structure used by the function.

Description

The **vm_thrpgio_push** kernel service enables a client file system with a thread-level strategy routine to save information about the current thread to a linked list. The linked list is a Last-In-First-Out (LIFO) (stack) data structure, and is pointed to by the thread.

This service must be called if a client file system using a thread-level strategy routine has had its strategy routine invoked and wishes to re-enter the Virtual Memory Manager. This could involve a page fault on one of its client segments, or the use of one of the Virtual Memory Manager (VMM) services that operates on client segments.

The **vm_thrpgio_pop** kernel service must be invoked when all such Virtual Memory Manager callbacks are complete.

Execution Environment

The **vm_thrpgio_push** kernel service can only be used by client file systems using a thread-level strategy routine.

Return Values

The **vm_thrpgio_push** kernel service has no return values.

Understanding Virtual Memory Manager Interfaces

vms_create Kernel Service

Purpose

Creates a virtual memory object of the specified type, size, and limits.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

```
int vms_create (vmid, type, devgno, size,
 uplim, downlim)
vmid_t * vmid;
int    type;
dev_t devgno;
int    size;
int    uplim;
int    downlim;
```

Parameters

Item	Description
vmid	Points to the variable in which the virtual memory object identifier is to be stored.
type	Specifies the virtual memory object type and options as an OR of bits. The *type* parameter must have the value of **V_CLIENT**. The **V_INTRSEG** flag specifies if the process can be interrupted from a page wait on this object.
devgno	Specifies the address of the g-node for client storage. If the *type* parameter has the value of **V_CLIENT**, the third argument is a g-node *ptr* argument, otherwise, it is a *devgno* argument.
size	Specifies the current size of the file (in bytes). This can be any valid file size. If the V_LARGE is specified, it is interpreted as number of pages.
uplim	Ignored. The enforcement of file size limits is done by comparing with the **u_limit** value in the **u** block.
downlim	Ignored.

Description

The **vms_create** kernel service creates a virtual memory object. The resulting virtual memory object identifier is passed back by reference in the *vmid* parameter.

The *size* parameter is used to determine the size in units of bytes of the virtual memory object to be created. This parameter sets an internal variable that determines the virtual memory range to be processed when the virtual memory object is deleted.

An entry for the file system is required in the paging device table when the **vms_create** kernel service is called.

Execution Environment

The **vms_create** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
ENOMEM	Indicates that no space is available for the virtual memory object.
ENODEV	Indicates no entry for the file system in the paging device table.
EINVAL	Indicates incompatible or bad parameters.

Related reference
vms_delete Kernel Service
Related information
Memory Kernel Services

vms_delete Kernel Service

Purpose

Deletes a virtual memory object.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

int vms_delete (*vmid*)
vmid_t *vmid;*

Parameter

Item	Description
vmid	Specifies the ID of the virtual memory object to be deleted.

Description

The **vms_delete** kernel service deallocates the temporary resources held by the virtual memory object specified by the *vmid* parameter and then frees the control block. This delete operation can complete asynchronously, but the caller receives a synchronous return code indicating success or failure.

Releasing Resources

The completion of the delete operation can be delayed if paging I/O is still occurring for pages attached to the object. All page frames not in the I/O state are released.

If there are page frames in the I/O state, they are marked for discard at I/O completion and the virtual memory object is placed in the iodelete state. When an I/O completion occurs for the last page attached to a virtual memory object in the iodelete state, the virtual memory object is placed on the free list.

Execution Environment

The **vms_delete** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
EINVAL	Indicates that the *vmid* parameter is not valid.

Related reference
vms_create Kernel Service
Related information
Memory Kernel Services
Understanding Virtual Memory Manager Interfaces

vms_iowait, vms_iowaitf Kernel Services

Purpose

Waits for the completion of all page-out operations for pages in the virtual memory object.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

```
int vms_iowait ( vmid)
vmid_t vmid;

int vms_iowaitf ( vmid, flags)
vmid_t vmid;
int flags;
```

Parameter

Item	Description
vmid	Identifies the virtual memory object for which to wait.
flags	Optional flags passed in by the user.

Description

The **vms_iowait** kernel service performs two tasks. First, it determines the I/O level at which all currently scheduled page-outs are complete for the virtual memory object specified by the *vmid* parameter. Then, the **vms_iowait** service places the current process in a wait state until this I/O level has been reached.

The I/O level value is a count of page-out operations kept for each virtual memory object.

The I/O level accounts for out-of-order processing by not incrementing the I/O level for new page-out requests until all previous requests are complete. Because of this, processes waiting on different I/O levels can be awakened after a single page-out operation completes.

If the caller holds the kernel lock, the **vms_ iowait** service releases the kernel lock before waiting and reacquires it afterwards.

The **vms_iowait** function is a special case of the **vms_iowaitf** function with the **V_WAITERR** flag set.

Flags

Name	Purpose
V_WAITERR	Waits until the completion of all I/O unless an error occurs.
V_WAITALL	Waits until the completion of all I/O regardless of any occurrence of I/O errors.

Execution Environment

The **vms_iowait** and **vms_iowaitf** kernel services can be called from the process environment only.

They can only be used by file segments.

Return Values

Item	Description
0	Indicates that the page-out operations completed.
EIO	Indicates that an error occurred while performing I/O.

Related reference

Understanding Virtual Memory Manager Interfaces

vm_uiomove Kernel Service

Purpose

Moves data between a virtual memory object and a buffer specified in the uio structure.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
#include <sys/uio.h>

int vm_uiomove (vmid, limit, rw, uio)
vmid_t vmid;
int limit;
enum uio_rw rw;
struct uio *uio;
```

Parameters

Item	Description
vmid	Specifies the virtual memory object ID.
limit	Indicates the limit on the transfer length. If this parameter is negative or 0, no bytes are transferred.
rw	Specifies a read/write flag that gives the direction of the move. The possible values for this parameter (**UIO_READ**, **UIO_WRITE**) are defined in the **/usr/include/sys/uio.h** file.
uio	Points to the **uio** structure.

Description

The **vm_uiomove** kernel service moves data between a virtual memory object and the buffer specified in a uio structure.

This service determines the virtual addressing required for the data movement according to the offset in the object.

The **vm_uiomove** kernel service is similar to the **uiomove** kernel service, but the address for the trusted buffer is specified by the *vmid* parameter and the uio_offset field of *offset* parameters instead of as a **caddr_t** address. The offset size is a 64 bit offset_t, which allows file offsets in client segments which are greater than 2 gigabytes. **vm_uiomove** must be used instead of **vm_move** if the client filesystem supports files which are greater than 2 gigabytes.

Note: The **vm_uiomove** kernel service does not support use of cross-memory descriptors.

I/O errors for paging space and a lack of paging space are reported as signals.

Execution Environment

The **vm_uiomove** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.
EFAULT	Indicates a bad address.
ENOMEM	Indicates insufficient memory.

Item	Description
ENOSPC	Indicates insufficient disk space.
EIO	Indicates an I/O error.

Other file system-specific **errno** global variables are returned by the virtual file system involved in the move function.

Memory Kernel Services

Understanding Virtual Memory Manager Interfaces

vm_umount Kernel Service

Purpose

Removes a file system from the paging device table.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

```
int vm_umount ( type, devid)
int type;
dev_t devid)();
```

Parameters

Item	Description
type	Specifies the type of device. You can specify multiple values. But the *type* parameter must have a value of **D_REMOTE** as one of its values. You can also specify the following optional value:

D_NOWAIT

Indicates that if I/O discovered during a prior **vm_setdevid** call has not yet completed, the paging device table entry will be removed, asynchronously, at a future point in time when all such I/O to it has completed. This particular **vm_umount** kernel service call will return without waiting for the I/O to complete. Any **buf** structures associated with this paging device entry remain allocated until the paging device entry is finally removed.

devid	Points to the strategy routine.

Description

The **vm_umount** kernel service waits for all I/O for the device scheduled by the pager to finish. This service then frees the entry in the paging device table. The associated **buf** structures are also freed.

Execution Environment

The **vm_umount** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
EINVAL	Indicates that a file system with the strategy routine designated by the *devid* parameter is not in the paging device table.

Understanding Virtual Memory Manager Interfaces

vm_write Kernel Service

Purpose

Initiates page-out for a page range in the address space.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include  <sys/vmuser.h>
```

```
int vm_write (vaddr, nbytes, force)
int  vaddr;
int  nbytes;
int  force;
```

Description

The **vm_write** kernel service initiates page-out for pages that intersect the address range *(vaddr, vaddr + nbytes)*.

If the *force* parameter is nonzero, modified pages are written to disk regardless of how recently they have been written.

Page-out is initiated for each modified page. An unchanged page is left in memory with its reference bit set to 0. This makes the unchanged page a candidate for the page replacement algorithm.

The caller must have write access to the specified pages.

The initiated I/O is asynchronous. The **vms_iowait** kernel service can be called to wait for I/O completion.

Note: The **vm_write** subroutine is not supported for use on large pages.

Parameters

Item	Description
vaddr	Specifies the address of the first byte of the page range for which a page-out is desired.
nbytes	Specifies the number of bytes starting at the byte specified by the *vaddr* parameter. This parameter must be nonnegative. All of the bytes must be in the same virtual memory object.
force	Specifies a flag indicating that a modified page is to be written regardless of when it was last written.

Execution Environment

The **vm_write** kernel service can be called from the <u>process environment</u> only.

Return Values

Item	Description
0	Indicates a successful completion.
EINVAL	Indicates one of these four errors:

  - A region is not defined.
  - A region is an I/O region.
  - The length specified by the *nbytes* parameter is negative.
  - The address range crosses a virtual memory object boundary.
  - One or more large pages lie in the target page range.

EACCES	Indicates that access does not permit writing.
EIO	Indicates a permanent I/O error.

Related reference

<u>vms_iowait, vms_iowaitf Kernel Services</u>
Related information
<u>Memory Kernel Services</u>
<u>Understanding Virtual Memory Manager Interfaces</u>

vm_writep Kernel Service

Purpose

Initiates page-out for a page range in a virtual memory object.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

int vm_writep (*vmid*, *pfirst*, *npages*)
vmid_t *vmid*;
int *pfirst*;
int *npages*;

Description

The **vm_writep** kernel service initiates page-out for the specified page range in the virtual memory object. I/O is initiated for modified pages only. Unchanged pages are left in memory, but their reference bits are set to 0.

The caller can wait for the completion of I/O initiated by this and prior calls by calling the **vms_iowait** kernel service.

Note: The **vm_writep** subroutine is not supported for use on large pages.

Parameters

Item	Description
vmid	Specifies the identifier for the virtual memory object.
pfirst	Specifies the first page number at which page-out is to begin.
npages	Specifies the number of pages for which the page-out operation is to be performed.

Execution Environment

The **vm_writep** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
EINVAL	Indicates any one of the following errors:

- *pfirst* = 0 and *npages* = 0.
- The virtual memory object ID is not valid.
- The starting page is negative.
- The number of pages is negative.
- The page range exceeds the size of virtual memory object.
- One or more large pages lie in the target page range.

vn_free Kernel Service

Purpose

Frees a v-node previously allocated by the **vn_get** kernel service.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

int vn_free (*vp*)
struct vnode *vp;**

Parameter

Item	Description
vp	Points to the v-node to be deallocated.

Description

The **vn_free** kernel service provides a mechanism for deallocating v-node objects used within the virtual file system. The v-node specified by the *vp* parameter is returned to the pool of available v-nodes to be used again.

Execution Environment

The **vn_free** kernel service can be called from the process environment only.

Return Values

The **vn_free** service always returns 0.

Related reference
vn_get Kernel Service
Related information
Virtual File System Overview
Virtual File System (VFS) Kernel Services

vn_get Kernel Service

Purpose

Allocates a virtual node.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
```

int vn_get (*vfsp*, *gnp*, *vpp***)**
struct vfs **vfsp***;**
struct gnode **gnp***;**
struct vnode ***vpp***;**

Parameters

Item	Description
vfsp	Points to a **vfs** structure describing the virtual file system that is to contain the v-node. Any returned v-node belongs to this virtual file system.
gnp	Points to the g-node for the object. This pointer is stored in the returned v-node. The new v-node is added to the list of v-nodes in the g-node.
vpp	Points to the place in which to return the v-node pointer. This is set by the **vn_get** kernel service to point to the newly allocated v-node.

Description

The **vn_get** kernel service provides a mechanism for allocating v-node objects for use within the virtual file system environment. A v-node is first allocated from an effectively infinite pool of available v-nodes.

Upon successful return from the **vn_get** kernel service, the pointer to the v-node pointer provided (specified by the *vpp* parameter) has been set to the address of the newly allocated v-node.

The fields in this v-node have been initialized as follows:

Field	Initial Value
`v_count`	Set to 1.
`v_vfsp`	Set to the value in the *vfsp* parameter.
`v_gnode`	Set to the value in the *gnp* parameter.
`v_next`	Set to list of others v-nodes with the same g-node.

All other fields in the v-node are zeroed.

Execution Environment

The **vn_get** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
ENOMEM	Indicates that the **vn_get** kernel service could not allocate memory for the v-node. (This is a highly unlikely occurrence.)

vsx_disable Kernel Service

Purpose

Communicates the status of the vector and the vector-scalar registers to the hypervisor.

Syntax

```
#include <sys/machine.h>
void vsx_disable (old)
char old;
```

Parameters

old
Specifies the value returned by the `vsx_enable` kernel service.

Description

The `vsx_disable` kernel service communicates to the hypervisor that the vector and the vector-scalar registers are no longer in use.

Execution Environment

The `vsx_disable` kernel service can be called from the process environment or the interrupt environment. The `vsx_disable` kernel service must be called while all interrupts from within the INTMAX critical section are disabled.

Return Values

The `vsx_disable` kernel service has no return values.

vsx_enable Kernel Service

Purpose

Communicates the status of the vector and the vector-scalar registers to the hypervisor.

Syntax

```
#include <sys/machine.h>
char vsx_enable ()
```

Description

The `vsx_enable` kernel service communicates to the hypervisor that the vector and the vector-scalar registers are in use.

Execution Environment

The `vsx_enable` kernel service can be called from the process environment or the interrupt environment. The `vsx_enable` kernel service must be called while all the interrupts from within the `INTMAX` critical section are disabled.

Return Values

The `vsx_enable` kernel service returns the current setting.

W

The following kernel services begin with the with the letter w.

waitcfree Kernel Service

Purpose

Checks the availability of a free character buffer.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/cblock.h>
#include <sys/sleep.h>

int waitcfree ( )
```

Description

The **waitcfree** kernel service is used to wait for a buffer which was allocated by a previous call to the **pincf** kernel service. If one is not available, the **waitcfree** kernel service waits until either a character buffer becomes available or a signal is received.

The **waitcfree** kernel service has no parameters.

Execution Environment

The **waitfree** kernel service can be called from the process environment only.

Return Values

Item	Description
EVENT_SUCC	Indicates a successful operation.
EVENT_SIG	Indicates that the wait was terminated by a signal.

Related reference
pincf Kernel Service
putcf Kernel Service

I/O Kernel Services

waitq Kernel Service

Purpose

Waits for a queue element to be placed on a device queue.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/deviceq.h>
```

struct req_qe *waitq (*queue_id*)
cba_id *queue_id*;

Parameter

Item	Description
queue_id	Specifies the device queue identifier.

Description

The **waitq** kernel service is not part of the base kernel but is provided by the device queue management kernel extension. This queue management kernel extension must be loaded into the kernel before loading any kernel extensions referencing these services.

The **waitq** kernel service waits for a queue element to be placed on the device queue specified by the *queue_id* parameter. This service performs these two actions:

- Waits on the event mask associated with the device queue.
- Calls the **readq** kernel service to make the most favored queue element the active one.

Processes can only use the **waitq** kernel service to wait for a single device queue. Use the **et_wait** service to wait on the occurrence of more than one event, such as multiple device queues.

The **waitq** kernel service uses the **EVENT_SHORT** form of the **et_wait** kernel service. Therefore, a signal does not terminate the wait. Use the **et _wait** kernel service if you want a signal to terminate the wait.

The **readq** kernel service can be used to read the active queue element from a queue. It does not wait for a queue element if there are none in the queue.

> **Attention:** The server must not alter any fields in the queue element or the system may halt.

Execution Environment

The **waitq** kernel service can be called from the process environment only.

Return Values

The **waitq** service returns the address of the active queue element in the device queue.

WPAR_CKPT_QUERY (Checkpoint Query) Device Driver ioctl Operation

Purpose

Queries a device driver about its checkpoint capabilities.

Syntax

```
#include <sys/ioctl.h>
```

int **ioctl (** *FileDescriptor*, WPAR_CKPT_QUERY, *Arg* **)**
int *FileDescriptor***;**
wpar_ckpt_resp_t * *Arg***;**

Parameters

Item	Description
FileDescriptor	Open file descriptor that refers to the device being queried for the checkpoint capability.
WPAR_CKPT_QUERY	The command that requests information on the device checkpoint capability.
Arg	Pointer to a **wpar_ckpt_resp_t** structure which will contain a device driver response on the checkpoint capability upon a successful return from the **ioctl** call.

Description

The **WPAR_CKPT_QUERY** operation allows a caller to ask a device driver connected to the ioctl input file descriptor if it supports checkpoint and restart operations. If a device driver supports checkpoint and restart operations, the returned answer can describe what operations are required to accomplish a checkpoint and restart.

If the device is not checkpoint and restart capable, checkpoint-aware devices fail this ioctl request with the **ENOSYS** error. Non-checkpoint-aware devices fail this ioctl request as an unknown ioctl. If the device is checkpoint and restart capable, checkpoint-aware devices return success.

The *arg* parameter to a **WPAR_CKPT_QUERY** ioctl request allows the caller to receive specific information regarding how the device supports checkpoint and restart if it is capable. The caller of a **WPAR_CKPT_QUERY** ioctl request must supply a pointer to a structure of the **wpar_ckpt_resp_t** type in the *arg* parameter.

wpar_ckpt_resp_t structure

The **wpar_ckpt_resp_t** structure is supplied as the input to the **WPAR_CKPT_QUERY** ioctl request.

#define WPAR_CKPT_OP_MAX   5
typedef struct wpar_ckpt_resp_t {
int *opcnt***;**
wpar_ckpt_op_top [*WPAR_CKPT_OP_MAX*]**;**
}wpar_ckpt_resp_t;

The fields of the **wpar_ckpt_resp_t** structure are as follows:

Item	Description
opcnt	Returned from an **WPAR_CKPT_QUERY** ioctl request as the number of the **wpar_ckpt_op_t** sub-structures that contain return information.
wpar_ckpt_op_top	A sub-structure that contains specific information on operation types that must occur on a device for it to save or restore its state correctly.

wpar_ckpt_op_t structure

The **wpar_ckpt_op_t** structure is a sub-structure of the **wpar_ckpt_resp_t** structure.

typedef struct wpar_ckpt_op_t {
int *op***;**
int *opt***;** /*extended options of openx*/
}wpar_ckpt_op_t;

The fields of the **wpar_ckpt_op_t** structure are as follows:

Item	Description
op	Returned from a **WPAR_CKPT_QUERY** ioctl request. Defined as a set of one or more operations that must be performed to successfully checkpoint and restart the device.
opt	Options to supply to the **openx** function if the device is to be re-opened on the arrival server through the **openx** function.

wpar_ckpt_op_t op field

Item	Description
WPAR_CKPT_OP_NULL	Device requires no special handling for checkpoint and restart operations.
WPAR_CKPT_OP_REOPEN	Device needs to be re-opened through the **open** function with the access modes applicable at checkpoint time.
WPAR_CKPT_OP_OPENX	Device needs to be re-opened with the **openx** function. The *opt* field denotes the desired extension argument to the **openx** function.

Return Values

Upon successful completion, this operation returns a value of 0. Otherwise, it returns a value of -1 and the errno global variable is set to one of the following values:

Item	Description
ENOSYS	Device cannot participate in checkpoint and restart operations.
EINVAL	Device does not accept the **WPAR_CKPT_QUERY** operation.

w_clear Kernel Service

Purpose

Removes a watchdog timer from the list of watchdog timers known to the kernel.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/watchdog.h>
```

```
int w_clear ( w)
struct watchdog *w;
```

Parameter

Item	Description
w	Specifies the watchdog timer structure.

Description

The watchdog timer services, including the **w_clear** kernel service, are typically used to verify that an I/O operation completes in a reasonable time.

When the **w_clear** kernel service removes the watchdog timer, the *w->**count*** watchdog count is no longer decremented. In addition, the *w->**func*** watchdog timer function is no longer called.

In a uniprocessor environment, the call always succeeds. This is untrue in a multiprocessor environment, where the call will fail if the watchdog timer is being handled by another processor. Therefore, the function now has a return value, which is set to 0 if successful, or -1 otherwise. Funnelled device drivers do not need to check the return value since they run in a logical uniprocessor environment. Multiprocessor-safe and multiprocessor-efficient device drivers need to check the return value in a loop. In addition, if a driver uses locking, it must release and reacquire its lock within this loop, as shown below:

```
while (w_clear(&watchdog))
  release_then_reacquire_dd_lock;
                   /* null statement if locks not used */
```

Note: The **w_clear** kernel service clears any attributes that were previously set by using the **w_setattr()** kernel service.

Execution Environment

The **w_clear** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates that the watchdog timer was successfully removed.
-1	Indicates that the watchdog timer could not be removed.

Related reference
w_init Kernel Service
w_setattr Kernel Service
Related information
Timer and Time-of-Day Kernel Services

w_init Kernel Service

Purpose

Registers a watchdog timer with the kernel.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/watchdog.h>
```

int w_init (_w_)
struct watchdog *_w_;

Parameter

Item	Description
_w_	Specifies the watchdog timer structure.

Description

The **watchdog** structure must be initialized prior to calling the **w_init** kernel service as follows:

- Set the `next` and `prev` fields to NULL.
- Set the `func` and `restart` fields to the appropriate values.
- Set the `count` field to 0.

> **Attention:** The watchdog structure must be pinned when the **w_init** service is called. It must remain pinned until after the call to the **w_clear** service. During this time, the watchdog structure must not be altered except by the watchdog services.

The watchdog timer services, including the **w_init** kernel service, are typically used to verify that an I/O operation completes in a reasonable time. The watchdog timer is initialized to the stopped state and must be started using the **w_start** service.

In both uniprocessor and multiprocessor environments, the **w_init** kernel service always succeeds.

The calling parameters for the watchdog timer function are:

```
void func (w)
struct watchdog *w;
```

Execution Environment

The **w_init** kernel service can be called from the process environment only.

Return Values

The **w_init** kernel service returns 0 for compatibility with previous releases of AIX.

Related reference
w_clear Kernel Service
w_setattr Kernel Service
Related information
Timer and Time-of-Day Kernel Services

w_setattr Kernel Service

Purpose

Sets attributes for a watchdog timer.

Syntax

```
#include <sys/watchdog.h>
#include <sys/kerrno.h>

kerrno_t w_setattr(struct watchdog *w, char attr)
```

Parameter

Item	Description
w	Specifies the watchdog timer structure.
attr	A bitmask of attributes to be set. Supported flags are: **WD_ATTR_MOVE_OK** Allow timer to migrate from one CPU to another.

Description

The **w_setattr** kernel service sets attributes for the specified watchdog timer. The **WD_ATTR_MOVE_OK** attribute should be set when the caller does not have a dependency on which processor the timer expiration handler is called. This attribute allows the system to move the timer from one processor to another as needed, to improve the effectiveness of processor folding. When this attribute is set, the associated watchdog timer is moved to another processor when the owning processor is folded.

The **w_setattr** kernel service must be called after the **w_init()** kernel service but before the **w_start()** kernel service. Otherwise, the **w_setattr** kernel service may fail.

Execution Environment

The **w_setattr** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
0	The specified attribute was successfully set.
<0	The specified attribute was not set. The failure is indicated with return value set to one of the following values: EINVAL_W_SETATTR_EYEC: An invalid eye catcher was detected. EINVAL_W_SETATTR_ATTR: An invalid attribute flag was detected.

Related reference
w_clear Kernel Service
w_start Kernel Service
w_stop Kernel Service

w_start Kernel Service

Purpose

Starts a watchdog timer.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/watchdog.h>
```

void w_start (_w_)
struct watchdog *_w_;

Parameter

Item	Description
_w_	Specifies the watchdog timer structure.

Description

The watchdog timers, including the **w_start** kernel service, are typically used to verify that an I/O operation completes in a reasonable time. The **w_start** and **w_stop** kernel services are designed to allow the timer to be started and stopped efficiently. The kernel decrements the _w->_**count** watchdog count every second. The kernel calls the _w->_**func** watchdog timer function when the _w->_**count** watchdog count reaches 0. A watchdog timer is ignored when the _w->_**count** watchdog count is less than or equal to 0.

The **w_start** kernel service sets the _w->_**count** watchdog count to a value of _w->_**restart**.

> **Attention:** The watchdog structure must be pinned when the **w_start** kernel service is called. It must remain pinned until after the call to the **w_clear** kernel service. During this time, the watchdog structure must not be altered except by the watchdog services.

Execution Environment

The **w_start** kernel service can be called from the process and interrupt environments.

Return Values

The **w_start** kernel service has no return values.

Related reference
w_stop Kernel Service

Related information
Timer and Time-of-Day Kernel Services

w_stop Kernel Service

Purpose

Stops a watchdog timer.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/watchdog.h>
```

void w_stop (_w_)
struct watchdog *_w_;

Parameter

Item	Description
w	Specifies the watchdog timer structure.

Description

The watchdog timer services, including the **w_stop** kernel service, are typically used to verify that an I/O operation completes in a reasonable time. The **w_start** and **w_stop** kernel services are designed to allow the timer to be started and stopped efficiently. The kernel decrements the *w->**count*** watchdog count every second. The kernel calls the *w->**func*** watchdog timer function when the *w->**count*** watchdog count reaches 0. A watchdog timer is ignored when *w->**count*** is less than or equal to 0.

> **Attention:** The watchdog structure must be pinned when the **w_stop** kernel service is called. It must remain pinned until after the call to the **w_clear** kernel service. During this time, the watchdog structure must not be altered except by the watchdog services.

Execution Environment

The **w_stop** kernel service can be called from the process and interrupt environments.

Return Values

The **w_stop** kernel service has no return values.

Timer and Time-of-Day Kernel Services

X

The following kernel services begin with the with the letter x.

xfidToName() Kernel Service

Purpose

Finds the full path name of the file corresponding to an `xfid_t` structure.

Syntax

```
#include <sys/xfops.h>

int     xfidToName(struct xfid *xfp,
                        void *nrp,
                        char *pathname,
                        unsigned int pbuflen,
                        long flags);
```

Description

The `xfidToName()` kernel service finds a name for an `xfid` value.

Parameters

xfp
Pointer to the `xfid` value for which a name is needed.

nrp
Name resolution structure that is passed to the validation routine.

pathname
Pointer to buffer where the file name will be stored.

pbuflen
Size of path name buffer. A size of MAXPATHLEN is sufficient to hold any path name.

flags
Operation modifiers. This parameter must be set to zero.

Return values

0
Indicates success. The path name for the `xfid` value is returned.

ENOENT
Name not found.

EPERM
No permission for lookup.

EINVAL
Invalid parameter is specified.

E2BIG
Path is larger than `pbuflen` bytes.

xlate_create Kernel Service

Purpose

Creates pretranslation data structures.

Syntax

```
int xlate_create (dp, baddr, count, flags)
struct xmem*dp;
caddr_t baddr;
int count;
uint flags;
```

Description

The **xlate_create** kernel service creates pretranslation data structures capable of pretranslating all pages of the virtual buffer indicated by the *baddr* parameter for length of *count* into a list of physical page numbers, appended to the cross memory descriptor pointed to by *dp*.

If the **XLATE_ALLOC** flag is set, only the data structures are created and no pretranslation is done. If the flag is not set, in addition to the data structures being created, each page of the buffer is translated and the access permissions verified, requiring read-write access to each page. The **XLATE_ALLOC** flag is useful when the buffer will be pinned and utilized later, through the **xlate_pin** and **xlate_unpin** kernel services.

The **XLATE_SPARSE** flag can be used to indicate that only selected portions of a pretranslated region may be valid (pinned and pretranslated) at any given time. The **XLATE_SPARSE** flag can be used in conjunction with the **XLATE_ALLOC** flag to preallocate the pretranslation data structures for an address region that will be dynamically managed.

The **xlate_create** kernel service is primarily for use when memory buffers will be reused for I/O. The use of this service to create a pretranslation for the memory buffer avoids page translation and access checking overhead for all future DMAs involving the memory buffer until the **xlate_remove** kernel service is called.

Parameters

Item	Description
dp	Points to the cross memory descriptor.
baddr	Points to the virtual buffer.
count	Specifies the length of the virtual buffer.
flags	Specifies the operation. Valid values are as follows:

XLATE_PERSISTENT
   Indicates that the pretranslation data structures should be persistent across calls to pretranslation services.

XLATE_ALLOC
   Indicates that the pretranslation data structures should be allocated only, and no translation should be performed.

XLATE_SPARSE
   Indicates that the pretranslation information will be sparse, allowing for the coexistence of valid (active) pretranslation regions and invalid (inactive) pretranslation regions.

Return Values

Item	Description
ENOMEM	Unable to allocate memory
XMEM_FAIL	No physical translation, or No Access to a Page
XMEM_SUCC	Successful pretranslation created

Execution Environment

The **xlate_create** kernel service can only be called from the process environment. The entire buffer must be pinned (unless the **XLATE_ALLOC** flag is set), and the cross memory descriptor valid.

Related reference
xlate_remove Kernel Service
xlate_pin Kernel Service
xlate_unpin Kernel Service

xlate_pin Kernel Service

Purpose

Pins all pages of a virtual buffer.

Syntax

```
int xlate_pin (dp, baddr, count, rw)
struct xmem *dp;
caddr_t baddr;
int count;
int rw;
```

Description

The **xlate_pin** kernel service pins all pages of the virtual buffer indicated by the *baddr* parameter for length of *count* and also appends pretranslation information to the cross memory descriptor pointed to by the *dp* parameter.

The **xlate_pin** kernel service results in a short-term pin, which will support **mmap** and **shmatt** allocated memory buffers.

In addition to pinning and translating each page, the access permissions to the page are verified according to the desired access (as specified by the *rw* parameter). For a setting of **B_READ**, write access to the page must be allowed. For a setting of **B_WRITE**, only read access to the page must be allowed.

The caller can preallocate pretranslation data structures and append them to the cross memory descriptor prior to the call (through a call to the **xlate_create** kernel service) , or have this service allocate the necessary data structures. If the cross memory descriptor is already of type **XMEM_XLATE**, it is assumed that the data structures are already allocated. If callers want to have the pretranslation data structures persist across the subsequent **xlate_unpin** call, they should also set the **XLATE_PERSISTENT** flag on the call to the **xlate_create** kernel service.

Parameters

Item	Description
dp	Points to the cross memory descriptor.
baddr	Points to the virtual buffer.
count	Specifies the length of the virtual buffer.
rw	Specifies the access permissions for each page.

Return Values

If successful, the **xlate_pin** kernel service returns 0. If unsuccessful, one of the following is returned:

Item	Description
EINVAL	Invalid cross memory descriptor or parameters.
ENOMEM	Unable to allocate memory.
ENOSPC	Out of Paging Resources.
XMEM_FAIL	Page Access violation.

Execution Environment

The **xlate_pin** kernel service is only callable from the process environment, and the cross memory descriptor must be valid.

Related reference
xm_det Kernel Service
xm_mapin Kernel Service
xlate_unpin Kernel Service

xlate_remove Kernel Service

Purpose

Removes physical translation information from an xmem descriptor from a prior **xlate_create** call.

Syntax

```
caddr_t xlate_remove (dp)
struct xmem *dp;
```

Description

See the **xlate_create** kernel service.

Parameters

Item	Description
dp	Points to the cross memory descriptor.

Return Values

Item	Description
XMEM_FAIL	No pretranslation information present in the xmem descriptor.
XMEM_SUCC	Pretranslation successfully removed.

Execution Environment

The **xlate_remove** kernel service can only be called from the process environment.

Related reference
xm_det Kernel Service
xlate_pin Kernel Service
xlate_unpin Kernel Service

xlate_unpin Kernel Service

Purpose

Unpins all pages of a virtual buffer.

Syntax

```
int xlate_unpin (dp, baddr, count)
struct xmem *dp;
caddr_t baddr;
int count;
```

Description

The **xlate_unpin** kernel service unpins pages from a prior call to the **xlate_pin** kernel service based on the *baddr* and *count* parameters. It does this by utilizing the pretranslated real page numbers appended to the cross memory descriptor pointed to by *dp*.

If the **XLATE_PERSISTENT** flag is not set in the **prexflags** flag word of the pretranslation data structure, the pretranslation data structures are also freed.

Parameters

Item	Description
dp	Points to the cross memory descriptor.

Item	Description
baddr	Points to the virtual buffer.
count	Specifies the length of the virtual buffer.

Return Values

If successful, the **xlate_unpin** kernel service returns 0. If unsuccessful, one of the following is returned:

Item	Description
EINVAL	Invalid cross memory descriptor or parameters.
ENOSPC	Unable to allocate paging space (case of **mmap** segment).
ENOSPC	Out of Paging Resources.
XMEM_FAIL	Page Access violation.

xm_det Kernel Service
xm_mapin Kernel Service
xlate_pin Kernel Service

xm_det Kernel Service

Purpose

Releases the addressability to the address space described by an xmem descriptor.

Syntax

```
void xm_det (baddr, dp)
caddr_t baddr;
struct xmem *dp;
```

Description

See the **xm_mapin** Kernel Service for more information.

Parameters

Item	Description
baddr	Specifies the effective address previously returned from the **xm_mapin** kernel service.
dp	Cross memory descriptor that describes the above memory object.

Related reference
xlate_create Kernel Service
xlate_remove Kernel Service
xm_mapin Kernel Service

xm_mapin Kernel Service

Purpose

Sets up addressability in the current process context.

Syntax

```
#include <sys/adspace.h>

int xm_mapin (dp, baddr, count, eaddr)
struct xmem *dp;caddr_t baddr;
size_t count;
caddr_t *eaddr;
```

Description

The **xm_mapin** kernel service sets up addressability in the current process context to the address space indicated by the cross memory descriptor pointed to by the *dp* parameter for the addresses [*baddr*, *baddr* + *count* - 1].

This service is created specifically for Client File Systems, or others who need to setup addressability to an address space defined by an xmem descriptor.

If the requested mapping spans a segment boundary, no mapping will be performed, and a return code of **EAGAIN** is returned to indicate that individual calls to the **xm_mapin** kernel service are necessary to map the portions of the buffer in each segment. The **xm_mapin** kernel service must be called again with the original *baddr* and a *count* indicating the number of bytes to the next segment. (The number of bytes to the next segment boundary can be obtained using the `xm_maxmap` kernel service.) This will provide an effective address to use for accessing this portion of the buffer. Then, iteratively, **xm_mapin** must be called with the segment boundary address (previous *baddr* + *count*), and a new *count* indicating the remainder of the buffer or the next segment boundary, whichever is smaller. This will provide another effective address to use for accessing the next portion of the buffer.

Each address set up by the **xm_mapin** kernel service must be undone with the **xm_det** kernel service when it is no longer needed because the **xm_mapin** kernel service currently uses the **vm_att** kernel service.

Parameters

Item	Description
dp	Points to the cross memory descriptor.
baddr	Points to the virtual buffer.
count	Specifies the length of the virtual buffer to map.
eaddr	Points to where the effective address to access the data buffer is returned.

Return Values

Item	Description
0	Successful. (Reference Parameter *eaddr* contains the address to use)
XMEM_FAIL	Invalid cross memory descriptor.
EAGAIN	Segment boundary crossing encountered. Caller should make separate **xm_mapin** calls to map each segments worth.

Execution Environment

The **xm_mapin** kernel service can be called from the process or interrupt environments.

Related reference

xm_det Kernel Service

xm_maxmap Kernel Service

Purpose

Determines the maximum permissible count value for a subsequent call to `xm_mapin`.

Syntax

```
#include <sys/adspace.h>

int xm_maxmap (dp, uaddr, len)
    struct xmem *dp;
    void *uaddr;
    size_t *len;
```

Parameters

Item	Description
dp	Points to the cross memory descriptor.
uaddr	Points to the virtual buffer.
len	Points to where the maximum permissible count is returned.

Description

The `xm_maxmap` kernel service determines the maximum permissible count value (in bytes) for a subsequent `xm_mapin` call. The value is determined based on the input cross-memory descriptor *dp* and the starting address *uaddr*, and it is returned in the *len* parameter. There is no guarantee that `xm_mapin` will succeed; however, it is guaranteed that $uaddr + *len - 1$ is in the same segment as *uaddr*, and therefore `xm_mapin` will not return EAGAIN.

Execution Environment

The `xm_maxmap` interface can be called from the process or interrupt environment.

Return Values

Item	Description
`XMEM_SUCC`	Successful (Reference parameter *len* contains the maximum permissible value for a subsequent `xm_mapin` call)
`XMEM_FAIL`	Invalid cross memory descriptor.
`EAGAIN`	Segment boundary crossing encountered. Caller should make separate `xm_mapin` calls to map each segment's worth.

Related reference
xm_mapin Kernel Service

xmalloc Kernel Service

Purpose

Allocates memory.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/malloc.h>
```

caddr_t xmalloc (*size,* *align,* *heap*)
int *size;*
int *align;*
caddr_t *heap;*

Parameters

Item	Description
size	Specifies the number of bytes to allocate.
align	Specifies the alignment characteristics for the allocated memory.
heap	Specifies the address of the heap from which the memory is to be allocated.

Description

The **xmalloc** kernel service allocates an area of memory out of the heap specified by the *heap* parameter. This area is the number of bytes in length specified by the *size* parameter and is aligned on the byte boundary specified by the *align* parameter. The *align* parameter is actually the log base 2 of the desired address boundary. For example, an *align* value of 4 requests that the allocated area be aligned on a 2^4 (16) byte boundary.

There are multiple heaps provided by the kernel for use by kernel extensions. Two primary kernel heaps are **kernel_heap** and **pinned_heap**. Kernel extensions should use the **kernel_heap** value when allocating memory that is not pinned, and should use the **pinned_heap** value when allocating memory that should always be pinned or pinned for long periods of time. When allocating from the **pinned_heap** heap, the **xmalloc** kernel service will pin the memory before a successful return. The **pin** and **unpin** kernel services should be used to pin and unpin memory from the **kernel_heap** heap when the memory should only be pinned for a limited amount of time. Memory from the **kernel_heap** heap must be unpinned before freeing it. Memory from the **pinned_heap** heap should not be unpinned.

The **kernel_heap** heap points to one of the following heaps: **kernel_heap_4K_64K** and **kernel_heap_16M**. The **pinned_heap** heap points to one of the following heaps: **pinned_heap_4K_64K** and **pinned_heap_16M**. Each of the target heaps differ in the size of the pages that back them. **kernel_heap_4K_64K** or **pinned_heap_4K_64K** will be backed by either medium (64 KB) or regular (4 KB) pages, depending on the page size supported by the machine. **kernel_heap_16M** or **pinned_heap_16M** will return memory backed by large pages if large page heaps are enabled. If large page heaps are not enabled, **kernel_heap** or **pinned_heap** will point to the default heap. If the size of the backing pages are not important, use the **kernel_heap** value and the **pinned_heap** value. They will point to the heap that you prefer. For more information about large page heap support, see **vmo**.

Kernel extensions can use these services to allocate memory out of the kernel heaps. For example, the **xmalloc** (**128**,**3**,**kernel_heap**) kernel service allocates a 128-byte double word aligned area out of the kernel heap.

A kernel extension must use the **xmfree** kernel service to free the allocated memory. If it does not, subsequent allocations eventually are unsuccessful.

The **xmalloc** kernel service has two compatibility interfaces: **malloc** and **palloc**.

The following additional interfaces to the **xmalloc** kernel service are provided:

- **malloc** (*size*) is equivalent to **xmalloc** (*size*, **0**, **kernel_heap**).
- **palloc** (*size*, *align*) is equivalent to **xmalloc** (*size*, *align*, **kernel_heap**).

Execution Environment

The **xmalloc** kernel service can be called from the process environment only.

Return Values

Upon successful completion, the **xmalloc** kernel service returns the address of the allocated area. A null pointer is returned under the following circumstances:

- The requested memory cannot be allocated.
- The heap has not been initialized for memory allocation.

Memory Kernel Services

xmattach Kernel Service

Purpose

Attaches to a user buffer for cross-memory operations.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/xmem.h>
```

int xmattach (*addr, count, dp, segflag*)
char * *addr*;
int *count*;
struct xmem * *dp*;
int *segflag*;

Parameters

Item	Description
addr	Specifies the address of the user buffer to be accessed in a cross-memory operation.
count	Indicates the size of the user buffer to be accessed in a cross-memory operation.
dp	Specifies a cross-memory descriptor. The *dp*->**aspace_id** variable must be set to a value of **XMEM_INVAL**.
segflag	Specifies a segment flag. This flag is used to determine the address space of the memory that the cross-memory descriptor applies to, as well as for other purposes. The valid values for this flag can be found in the **/usr/include/xmem.h** file.

Description

The **xmattach** kernel service prepares the user buffer so that a device driver can access it without executing under the process that requested the I/O operation. A device top-half routine calls the **xmattach** kernel service. The **xmattach** kernel service allows a kernel process or device bottom-half routine to access the user buffer with the **xmemin** or **xmemout** kernel services. The device driver must use the **xmdetach** kernel service to inform the kernel when it has finished accessing the user buffer.

The kernel remembers which segments are attached for cross-memory operations. Resources associated with these segments cannot be freed until all cross-memory descriptors have been detached. "Cross Memory Kernel Services" in Memory Kernel Services in in *Kernel Extensions and Device Support Programming Concepts* describes how the cross-memory kernel services use cross-memory descriptors.

Note: When the **xmattach** kernel service remaps user memory containing the cross-memory buffer, the effects are machine-dependent. Also, cross-memory descriptors are not inherited by a child process.

Storage-key protection can be enforced on memory regions described by a cross-memory descriptor. The enforcement is done during normal access checking performed by cross-memory services, such as the **xmemdma** kernel service. A kernel keyset can be contained in the cross-memory descriptor to limit memory accessibility. When a keyset is associated with a cross-memory descriptor, access to the memory region is limited by that keyset. A keyset is required because a cross-memory descriptor can describe a virtual memory region with multiple keys assigned to the pages it contains. Normally, a keyset describes the accessibility of the context that the attach was initiated for. For example, a cross-memory attached to user-space contains a description of the user-mode accessibility (keyset). Adding keysets to kernel cross-memory descriptors can also enhance system RAS, since they limit kernel access by the cross-memory descriptor. Typically it is limited to that of the **xmattach** caller or to specific key(s), to catch cases where a cross-memory descriptor is misused.

User-mode storage-keys are always associated with descriptors attached using **USER_SPACE** or **USERI_SPACE** segflag. These flags were always required to attach to the user address space, so no explicit update is required to enable storage-key protection on user memory attaches. Once attached, existing kernel services that require cross-memory descriptors enforce the user keyset saved at attach time when performing memory accesses or checking user accessibility.

For kernel memory, a keyset is not used to restrict regions attached with **SYS_ADSPACE**. Attaching a region with **SYS_ADSPACE_ASSIGN_KEYSET** associates the caller's keyset with the cross-memory region.

Execution Environment

The **xmattach** kernel service can be called from the process environment only.

Return Values

Item	Description
XMEM_SUCC	Indicates a successful operation.
XMEM_FAIL	Indicates one of the following errors:

- The buffer size indicated by the *count* parameter is less than or equal to 0.
- The cross-memory descriptor is in use (*dp*->**aspace_id != XMEM_INVAL**).
- The area of memory indicated by the *addr* and *count* parameters is not defined.

xmdetach Kernel Service

Purpose

Detaches from a user buffer used for cross-memory operations.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/xmem.h>
```

int xmdetach (*dp***)**
struct xmem **dp***;**

Parameter

Item	Description
dp	Points to a cross-memory descriptor initialized by the **xmattach** kernel service.

Description

The **xmdetach** kernel service informs the kernel that a user buffer can no longer be accessed. This means that some previous caller, typically a device driver bottom half or a kernel process, is no longer permitted to do cross-memory operations on this buffer. Subsequent calls to either the **xmemin** or **xmemout** kernel service using this cross-memory descriptor result in an error return. The cross-memory descriptor is set to *dp*->**aspace_id = XMEM_INVAL** so that the descriptor can be used again. "Cross Memory Kernel Services" in Memory Kernel Services in *Kernel Extensions and Device Support Programming Concepts* describes how the cross-memory kernel services use cross-memory descriptors.

Execution Environment

The **xmdetach** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
XMEM_SUCC	Indicates successful completion.
XMEM_FAIL	Indicates that the descriptor was not valid or the buffer was not defined.

Related reference
xmattach Kernel Service
xmemout Kernel Service

Cross Memory Kernel Services

xmemdma Kernel Service

Purpose

Prepares a page for direct memory access (DMA) I/O or processes a page after DMA I/O is complete.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/xmem.h>
```

```
int xmemdma ( xp, xaddr, flag)
struct xmem *xp;
caddr_t xaddr;
int flag;
```

Parameters

Item	Description
xp	Specifies a cross-memory descriptor.
xaddr	Identifies the address specifying the page for transfer.
flag	Specifies whether to prepare a page for DMA I/O or process it after DMA I/O is complete. Possible values are:

XMEM_ACC_CHK
> Performs access checking on the page. When this flag is set, the page protection attributes are verified.

XMEM_DR_SAFE
> Indicates that the use of the real memory address is DLPAR safe.

XMEM_HIDE
> Prepares the page for DMA I/O. For cache-inconsistent platforms, this preparation includes hiding the page by making it inaccessible.

XMEM_UNHIDE
> Processes the page after DMA I/O. Also, this flag reveals the page and makes it accessible for cache-inconsistent platforms.

XMEM_WRITE_ONLY
> Marks the intended transfer as outbound only. This flag is used with **XMEM_ACC_CHK** to indicate that read-only access to the page is sufficient.

Description

The **xmemdma** kernel service operates on the page specified by the *xaddr* parameter in the region specified by the cross-memory descriptor. If the cross-memory descriptor is for the kernel, the *xaddr* parameter specifies a kernel address. Otherwise, the *xaddr* parameter specifies the offset in the region described in the cross-memory descriptor.

The **xmemdma** kernel service is provided for machines that have processor-memory caches, but that do not perform DMA I/O through the cache. Device handlers for Micro Channel DMA devices use the **d_master** service and **d_complete** kernel service instead of the **xmemdma** kernel service.

If the *flag* parameter indicates **XMEM_HIDE** (that is, **XMEM_UNHIDE** is not set) and this is the first hide for the page, the **xmemdma** kernel service prepares the page for DMA I/O by flushing the cache and making the page invalid. When the **XMEM_UNHIDE** bit is set and this is the last unhide for the page, the following events take place:

1. The page is made valid.

   If the page is not in pager I/O state:

2. Any processes waiting on the page are readied.

3. The modified bit for the page is set unless the page has a read-only storage key.

The page is made not valid during DMA operations so that it is not addressable with any virtual address. This prevents any process from reading or loading any part of the page into the cache during the DMA operation.

The page specified must be in memory and must be pinned.

If the **XMEM_ACC_CHK** bit is set, then the **xmemdma** kernel service also verifies access permissions to the page. If the page access is read-only, then the **XMEM_WRITE_ONLY** bit must be set in the *flag* parameter.

Note:

1. The **xmemdma** kernel service does not hide or reveal the page nor does it perform any cache flushing. The service's primary function is for real-address translation.

2. This service is not supported for large-memory systems with greater than 4GB of physical memory addresses. For such systems, **xmemdma64** should be used.

Execution Environment

The **xmemdma** kernel service can be called from either the process or interrupt environment.

Return Values

On successful completion, the **xmemdma** service returns the real address corresponding to the *xaddr* and *xp* parameters.

Error Codes

The **xmemdma** kernel service returns a value of **XMEM_FAIL** if one of the following are true:

- The descriptor was invalid.
- The page specified by the *xaddr* or *xp* parameter is invalid.
- Access is not allowed to the page.

Related information

Cross Memory Kernel Services
Understanding Direct Memory Access (DMA) Transfer
Dynamic Logical Partitioning

xmemdma64 Kernel Service

Purpose

Prepares a page for direct memory access (DMA) I/O or processes a page after DMA I/O is complete.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/xmem.h>
```

```
unsigned long long xmemdma64 (
struct xmem *dp,
caddr_t xaddr,>
int flags)
```

Parameters

Item	Description
dp	Specifies a cross-memory descriptor.
xaddr	Identifies the address that specify the page for transfer.
flags	Specifies whether to prepare a page for DMA I/O or process it after DMA I/O is complete. Possible values are:

XMEM_HIDE
Prepares the page for DMA I/O. If cache-inconsistent, then the data cache is flushed, the memory page is hidden, and the real page address is returned. If cache-consistent, then the modified bit is set and the real address of the page is returned.

XMEM_UNHIDE
Processes the page after DMA I/O. Also, this flag reveals the page, readies any waiting processes on the page, and sets the modified bit accordingly.

XMEM_ACC_CHK
Performs access checking on the page. When this flag is set, the page protection attributes are verified.

XMEM_WRITE_ONLY
Marks the intended transfer as outbound only. This flag is used with **XMEM_ACC_CHK** to indicate that read-only access to the page is sufficient.

Description

The **xmemdma64** kernel service operates on the page that is specified by the *xaddr* parameter in the region that is specified by the cross-memory descriptor. If the cross-memory descriptor is for the kernel, the *xaddr* parameter specifies a kernel address. Otherwise, the *xaddr* parameter specifies the offset in the region that is described in the cross-memory descriptor.

The **xmemdma64** kernel service is provided for machines that have processor-memory caches, but that do not perform DMA I/O through the cache.

If the *flag* parameter indicates **XMEM_HIDE** (that is, **XMEM_UNHIDE** is not set) and it is the first hide for the page, the **xmemdma64** kernel service prepares the page for DMA I/O by flushing the cache and making the page invalid. When the **XMEM_UNHIDE** bit is set and it is the last unhide for the page, the following events take place:

1. The page is made valid.

   If the page is not in pager I/O state:

2. Any processes that is waiting on the page are readied.
3. The modified bit for the page is set unless the page has a read-only storage key.

The page is made not valid during DMA operations so that it is not addressable with any virtual address. It prevents any process from reading or loading any part of the page into the cache during the DMA operation.

The page that is specified must be in memory and must be pinned.

If the **XMEM_ACC_CHK** bit is set, then the **xmemdma64** kernel service also verifies access permissions to the page. If the page access is read-only, then the **XMEM_WRITE_ONLY** bit must be set in the *flag* parameter.

Note: The **xmemdma64** kernel service does not hide or reveal the page, nor does it perform any cache flushing. The service's primary function is for real-address translation.

Execution Environment

The **xmemdma64** kernel service can be called from either the process or interrupt environment.

Return Values

On successful completion, the **xmemdma64** service returns the real address corresponding to the *xaddr* and *xp* parameters.

Error Codes

The **xmemdma64** kernel service returns a value of **XMEM_FAIL** if one of the following are true:

- The descriptor was invalid.
- The page that is specified by the *xaddr* or *xp* parameter is invalid.
- Access is not allowed to the page.

Related information

Cross Memory Kernel Services

Understanding Direct Memory Access (DMA) Transfer

xmempin Kernel Service

Purpose

Pins the specified address range in user or system memory.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/uio.h>
```

```
int xmempin( base, len, xd)
caddr_t base;
int len;
struct xmem *xd;
```

Parameters

Item	Description
base	Specifies the address of the first byte to pin.
len	Indicates the number of bytes to pin.
xd	Specifies the cross-memory descriptor.

Description

The **xmempin** kernel service is used to pin pages backing a specified memory region which is defined in either system or user address space. Pinning a memory region prohibits the pager from stealing pages from the pages backing the pinned memory region. Once a memory region is pinned, accessing that region does not result in a page fault until the region is subsequently unpinned.

The cross-memory descriptor must have been filled in correctly prior to the **xmempin** call (for example, by calling the **xmattach** kernel service).

Execution Environment

The **xmempin** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
EFAULT	Indicates that the memory region as specified by the *base* and *len* parameters is not within the address space specified by the *xd* parameter.
EINVAL	Indicates that the value of the length parameter is negative or 0. Otherwise, the area of memory beginning at the byte specified by the *base* parameter and extending for the number of bytes specified by the *len* parameter is not defined.
ENOMEM	Indicates that the **xmempin** kernel service is unable to pin the region due to insufficient real memory or because it has exceeded the systemwide pin count.

Related reference

pin Kernel Service

xmemunpin Kernel Service

Related information

Memory Kernel Services

xmemunpin Kernel Service

Purpose

Unpins the specified address range in user or system memory.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/uio.h>
```

int xmemunpin (*base*, *len*, *xd*)
caddr_t *base*;
int *len*;
struct xmem *∗xd*;

Parameters

Item	Description
base	Specifies the address of the first byte to unpin.
len	Indicates the number of bytes to unpin.
xd	Specifies the cross-memory descriptor.

Description

The **xmemunpin** kernel service unpins a region of memory. When the pin count is 0, the page is not pinned and can be paged out of real memory. Upon finding an unpinned page, the **xmemunpin** kernel service returns the **EINVAL** error code and leaves any remaining pinned pages still pinned.

The **xmemunpin** service should be used where the address space might be in either user or kernel space.

The cross-memory descriptor must have been filled in correctly prior to the **xmempin** call (for example, by calling the **xmattach** kernel service).

Execution Environment

The **xmemunpin** kernel service can be called in the process environment when unpinning data that is in either user space or system space. It can be called in the interrupt environment only when unpinning data that is in system space.

Return Values

Item	Description
0	Indicates successful completion.
EFAULT	Indicates that the memory region as specified by the *base* and *len* parameters is not within the address specified by the *xd* parameter.
EINVAL	Indicates that the value of the length parameter is negative or 0. Otherwise, the area of memory beginning at the byte specified by the *base* parameter and extending for the number of bytes specified by the *len* parameter is not defined. If neither cause is responsible, an unpinned page was specified.

Understanding Execution Environments

xmemzero Kernel Service

Purpose

Zeros a buffer described by a cross memory descriptor.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/vmuser.h>
```

int xmemzero (*dp, uaddr, count***)**
struct xmem * *dp***;**
caddr_t *uaddr***;**
long *count***;**

Parameters

Item	Description
dp	The cross memory descriptor.
uaddr	The address in the buffer to begin zeroing.
count	The number of bytes to be zeroed.

Description

The **xmemzero** kernel service zeros a buffer described by a cross memory descriptor. The page specified must be in memory.

Execution Environment

The **xmemzero** kernel service can be called from a <u>process</u> or an <u>interrupt</u> environment.

Return Values

Item	Description
XMEM_SUCC	Indicates the area in the buffer has been zeroed.
XMEM_FAIL	Indicates one of the following errors:

- The descriptor is marked by **XMEM_REMIO**.
- The descriptor is not marked by **XMEM_PROC** and **XMEM_GLOBAL**.
- Count < 0.

Related information

<u>Memory Kernel Services</u>

<u>Understanding Virtual Memory Manager Interfaces</u>

xmemin Kernel Service

Purpose

Performs a cross-memory move by copying data from the specified address space to kernel global memory.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/xmem.h>
```

int xmemin (<u>*uaddr*</u>**,** <u>*kaddr*</u>**,** <u>*count*</u>**,** <u>*dp*</u>**)**
caddr_t * <u>*uaddr*</u>**;**
caddr_t * <u>*kaddr*</u>**;**
int <u>*count*</u>**;**
struct xmem * <u>*dp*</u>**;**

Parameters

Item	Description
uaddr	Specifies the address in memory specified by a cross-memory descriptor.
kaddr	Specifies the address in kernel memory.
count	Specifies the number of bytes to copy.
dp	Specifies the cross-memory descriptor.

Description

The **xmemin** kernel service performs a cross-memory move. A cross-memory move occurs when data is moved to or from an address space other than the address space that the program is executing in. The **xmemin** kernel service copies data from the specified address space to kernel global memory.

The **xmemin** kernel service is provided so that kernel processes and interrupt handlers can safely access a buffer within a user process. Calling the **xmattach** kernel service prepares the user buffer for the cross-memory move.

The **xmemin** kernel service differs from the **copyin** and **copyout** kernel services in that it is used to access a user buffer when not executing under the user process. In contrast, the **copyin** and **copyout** kernel services are used only to access a user buffer while executing under the user process.

Execution Environment

The **xmemin** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
XMEM_SUCC	Indicates successful completion.
XMEM_FAIL	Indicates one of the following errors:

- The user does not have the appropriate access authority for the user buffer.
- The user buffer is located in an address range that is not valid.
- The segment containing the user buffer has been deleted.
- The cross-memory descriptor is not valid.
- A paging I/O error occurred while the user buffer was being accessed.

  If the user buffer is not in memory, the **xmemin** kernel service also returns an **XMEM_FAIL** error when executing on an interrupt level.

Cross Memory Kernel Services

xmemout Kernel Service

Purpose

Performs a cross-memory move by copying data from kernel global memory to a specified address space.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/xmem.h>
```

```
int xmemout (kaddr, uaddr, count, dp)
caddr_t * kaddr;
caddr_t * uaddr;
int  count;
struct xmem * dp;
```

Parameters

Item	Description
kaddr	Specifies the address in kernel memory.
uaddr	Specifies the address in memory specified by a cross-memory descriptor.
count	Specifies the number of bytes to copy.

Item	Description
dp	Specifies the cross-memory descriptor.

Description

The **xmemout** kernel service performs a cross-memory move. A cross-memory move occurs when data is moved to or from an address space other than the address space that the program is executing in. The **xmemout** kernel service copies data from kernel global memory to the specified address space.

The **xmemout** kernel service is provided so that kernel processes and interrupt handlers can safely access a buffer within a user process. Calling the **xmattach** kernel service prepares the user buffer for the cross-memory move.

The **xmemout** kernel service differs from the **copyin** and **copyout** kernel services in that it is used to access a user buffer when not executing under the user process. In contrast, the **copyin** and **copyout** kernel services are only used to access a user buffer while executing under the user process.

Execution Environment

The **xmemout** kernel service can be called from either the process or interrupt environment.

Return Values

Item	Description
XMEM_SUCC	Indicates successful completion.
XMEM_FAIL	Indicates one of the following errors:

- The user does not have the appropriate access authority for the user buffer.
- The user buffer is located in an address range that is not valid.
- The segment containing the user buffer has been deleted.
- The cross-memory descriptor is not valid.
- A paging I/O error occurred while the user buffer was being accessed.

  If the user buffer is not in memory, the **xmemout** service also returns an **XMEM_FAIL** error when executing on an interrupt level.

Cross Memory Kernel Services

xmempsize Kernel Service

Purpose

Reports the page size being used for a specified address range on the 64-bit kernel.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/xmem.h>

long long xmempsize (dp, uaddr, count)

struct xmem * dp;
```

```
void * uaddr;
size_t count;
```

Description

The **xmempsize** kernel service returns the size, in bytes, of the virtual memory pages contained in the memory range starting at *uaddr* and continuing for *count* number of bytes. If the memory range consists of virtual memory pages of different sizes, the size of the smallest pages contained in the range is returned.

The cross-memory descriptor, *dp*, must have been previously initialized to describe the buffer containing the specified range of memory. The **xmattach()** kernel service prepares a buffer and cross-memory descriptor for use with the **xmempsize()** kernel service.

Parameters

Item	Description
dp	Specifies the cross-memory descriptor.
uaddr	Specifies the starting address of the memory range.
count	Specifies the number of bytes.

Execution Environment

The **xmempsize** kernel service can be called from either the process or interrupt environment.

The **xmempsize** kernel service is only supported on the 64-bit kernel.

Return Values

On successful completion, the **xmempsize()** kernel service returns a page size in bytes.

Otherwise, the **xmempsize()** kernel service returns **XMEM_FAIL**.

Cross Memory Kernel Services

xmfree Kernel Service

Purpose

Frees allocated memory.

Syntax

```
#include <sys/types.h>
#include <sys/errno.h>
#include <sys/malloc.h>
```

```
int xmfree ( ptr,   heap)
caddr_t ptr;
caddr_t heap;
```

Parameters

Item	Description
ptr	Specifies the address of the area in memory to free.
heap	Specifies the address of the heap from which the memory was allocated.

Description

The **xmfree** kernel service frees the area of memory pointed to by the *ptr* parameter in the heap specified by the *heap* parameter. This area of memory must be allocated with the **xmalloc** kernel service. In addition, the *ptr* pointer must be the pointer returned from the corresponding **xmalloc** call.

For example, the **xmfree** (*ptr*, **kernel_heap**) kernel service frees the area in the kernel heap allocated by *ptr*=**xmalloc** (*size, align*, **kernel_heap**).

A kernel extension must explicitly free any memory it allocates. If it does not, eventually subsequent allocations are unsuccessful. Pinned memory must also be unpinned before it is freed if allocated from the **kernel_heap**. The kernel does not keep track of which kernel extension owns various allocated areas in the heap. Therefore, the kernel never automatically frees these allocated areas on process termination or device close.

An additional interface to the **xmfree** kernel service is provided. The **free** (*ptr*) is equivalent to **xmfree** (*ptr*, **kernel_heap**).

Execution Environment

The **xmfree** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Indicates successful completion.
-1	Indicates one of the following errors:

- The area to be freed was not allocated with the **xmalloc** kernel service.
- The heap was not initialized for memory allocation.

xmgethkeyset Kernel Service

Purpose

Retrieves the hardware keyset associated with a cross-memory descriptor.

Syntax

```
#include <sys/types.h>
#include <sys/kerrno.h>
#include <sys/xmem.h>
#include <sys/skeys.h>
```

```
kerrno_t xmgethkeyset (dp, keyset, flags)
struct xmem * dp;
hkeyset_t * hkeyset;
long flags;
```

Parameters

Item	Description
dp	Specifies a valid cross-memory descriptor.
hkeyset	Pointer to returned hardware keyset associated with the cross-memory descriptor.
flags	Must be set to zero.

Description

The **xmgethkeyset()** kernel service can be used to obtain the keyset associated with a cross-memory descriptor.

Kernel-key protection can be enforced on memory regions described by a cross-memory descriptor. The enforcement is done during normal access checking performed by cross-memory services, such as **xmemdma()** service.

Execution Environment

The **xmgethkeyset** kernel service can be called from the process or interrupt environment.

Return Values

Item	Description
0	Successful.
EINVAL_XMGETHKEYSET	Invalid parameter.

#include <sys/xmem.h>
#include <sys/skeys.h>
```

```
kerrno_t xmsethkeyset (dp, hkeyset, flags)
struct xmem * dp;
hkeyset_t hkeyset;
long flags;
```

Parameters

Item	Description
dp	Specifies a valid cross-memory descriptor.
hkeyset	Hardware keyset to assign to the cross-memory descriptor.
flags	Must be set to zero.

Description

The **xmsethkeyset()** kernel service can be used to modify the keyset associated with a cross-memory descriptor.

Kernel-key protection can be enforced on memory regions described by a cross-memory descriptor. The enforcement is done during normal access checking performed by cross-memory services, such as the **xmemdma()** service.

Execution Environment

The **xmsethkeyset** kernel service can be called from the process environment only.

Return Values

Item	Description
0	Successful.
EINVAL_XMSETHKEYSET	Invalid parameter or execution environment.

Device Driver Operations

This topic provides a description of standard device driver entry points parameters.

Standard Parameters to Device Driver Entry Points

Purpose

Provides a description of standard device driver entry points parameters.

Description

There are three parameters passed to device driver entry points that always have the same meanings: the *devno* parameter, the *chan* parameter, and the *ext* parameter.

The devno Parameter

This value, defined to be of type **dev_t**, specifies the device or subdevice to which the operation is directed. For convenience and portability, the **/usr/include/sys/sysmacros.h** file defines the following macros for manipulating device numbers:

Macro	Descriptionf
major(_devno_**)**	Returns the major device number.
minor(_devno_**)**	Returns the minor device number.
makedev(_maj_**,** _min_**).**	Constructs a composite device number in the format of _devno_ from the major and minor device numbers given.

The chan Parameter

This value, defined to be of type **chan_t**, is the channel ID for a multiplexed device driver. If the device driver is not multiplexed, _chan_ has the value of 0. If the driver is multiplexed, then the _chan_ parameter is the **chan_t** value returned from the device driver's **ddmpx** routine.

The ext Parameter

The _ext_ parameter, or extension parameter, is defined to be of type **int**. It is meaningful only with calls to such extended subroutines as the **openx**, **readx**, **writex**, and **ioctlx** subroutines. These subroutines allow applications to pass an extra, device-specific parameter to the device driver. This parameter is then passed to the **ddopen**, **ddread**, **ddwrite**, and **ddioctl** device driver entry points as the _ext_ parameter. If the application uses one of the non-extended subroutines (for example, the **read** instead of the **readx** subroutine), then the _ext_ parameter has a value of 0.

Note: Using the _ext_ parameter is highly discouraged because doing so makes an application program less portable to other operating systems.

Device Driver Kernel Extension Overview

buf Structure

Purpose

Describes buffering data transfers between a program and the peripheral device

Introduction to Kernel Buffers

For block devices, kernel buffers are used to buffer data transfers between a program and the peripheral device. These buffers are allocated in blocks of 4096 bytes. At any given time, each memory block is a member of one of two linked lists that the device driver and the kernel maintain:

List	Description
Available buffer queue (avlist)	A list of all buffers available for use. These buffers do not contain data waiting to be transferred to or from a device.
Busy buffer queue (blist)	A list of all buffers that contain data waiting to be transferred to or from a device.

Each buffer has an associated buffer header called the **buf** structure pointing to it. Each buffer header has several parts:

- Information about the block
- Flags to show status information
- Busy list forward and backward pointers
- Available list forward and backward pointers

The device driver maintains the `av_forw` and `av_back` pointers (for the available blocks), while the kernel maintains the `b_forw` and `b_back` pointers (for the busy blocks).

buf Structure Variables for Block I/O

The **buf** structure, which is defined in the **/usr/include/sys/buf.h** file, includes the following fields:

Item	Description
b_flags	Flag bits. The value of this field is constructed by logically ORing 0 or more of the following values:

B_WRITE
This operation is a write operation.

B_READ
This operation is a read data operation, rather than write.

B_DONE
I/O on the buffer has been done, so the buffer information is more current than other versions.

B_ERROR
A transfer error has occurred and the transaction has aborted.

B_BUSY
The block is not on the free list.

B_INFLIGHT
This I/O request has been sent to the physical device driver for processing.

B_AGE
The data is not likely to be reused soon, so prefer this buffer for reuse. This flag suggests that the buffer goes at the head of the free list rather than at the end.

B_ASYNC
Asynchronous I/O is being performed on this block. When I/O is done, release the block.

B_DELWRI
The contents of this buffer still need to be written out before the buffer can be reused, even though this block may be on the free list. This is used by the **write** subroutine when the system expects another write to the same block to occur soon.

B_NOHIDE
Indicates that the data page should not be hidden during direct memory access (DMA) transfer.

B_SETMOD
Allows an enhanced I/O file system to cause a page to be considered modified.

B_STALE
The data conflicts with the data on disk because of an I/O error.

B_ XREADONLY
Indicates a read-only page in the external pager buffer list.

B_MORE_DONE
When set, indicates to the receiver of this **buf** structure that more structures are queued in the **IODONE** level. This permits device drivers to handle all completed requests before processing any new requests.

B_SPLIT
When set, indicates that the transfer can begin anywhere within the data buffer.

Item	Description
b_forw	The forward busy block pointer.
b_back	The backward busy block pointer.
av_forw	The forward pointer for a driver request queue.
av_back	The backward pointer for a driver request queue.
b_iodone	Anyone calling the strategy routine must set this field to point to their I/O done routine. This routine is called on the **INTIODONE** interrupt level when I/O is complete.

Item	Description
b_dev	The major and minor device number.
b_bcount	The byte count for the data transfer.
b_un.b_addr	The memory address of the data buffer.
b_blkno	The block number on the device.
b_resid	Amount of data not transferred after error.
b_event	Anchor for event list.
b_xmemd	Cross-memory descriptor.

Device Driver Kernel Extension Overview

bufx Structure

Purpose

Extends the **buf** structure to accommodate new fields as needed for performance and RAS reasons.

Description

The **bufx** structure is available for use by the 64-bit kernel and 64-bit kernel extensions. The 32-bit kernel and 32-bit kernel extensions only have the option of using the **buf** structure.

bufx Structure Variables for Block I/O

The **bufx** structure, which is defined in the **/usr/include/sys/buf.h** file, includes the following fields:

Item	Description
b_flags	Flag bits. The value of this field is constructed by the logical OR operation with 0 or more of the following values:

B_WRITE
This operation is a write operation.

B_READ
This operation is a read data operation.

B_DONE
I/O on the buffer is done, so the buffer information is more current than other versions.

B_ERROR
A transfer error occurred and the transaction aborted.

B_BUSY
The block is not on the free list.

B_INFLIGHT
This I/O request was sent to the physical device driver for processing.

B_AGE
The data is not likely to be reused soon, so prefer this buffer for reuse. This flag suggests that the buffer goes at the head of the free list rather than at the end.

B_ASYNC
Asynchronous I/O is being performed on this block. When I/O is done, release the block.

B_DELWRI
The contents of this buffer still need to be written out before the buffer can be reused, even though this block may be on the free list. This is used by the **write** subroutine when the system expects another write to the same block to occur soon.

B_NOHIDE
Indicates that the data page should not be hidden during direct memory access (DMA) transfer.

B_STALE
The data conflicts with the data on disk because of an I/O error.

B_MORE_DONE
When set, indicates to the receiver of this **bufx** structure that more structures are queued in the **IODONE** level. This permits device drivers to handle all completed requests before processing any new requests.

B_SPLIT
When set, indicates that the transfer can begin anywhere within the data buffer.

B_BUFX
A buffer is identified as an extended **buf** structure if all of the following conditions are met:

- **B_BUFX** bit is set in the b_flags field.
- The pointer obtained by recombining the bx_refptrtop field and the bx_refptrbot field points to the beginning of the structure.
- The bx_eyecatcher field, which identifies whether the **buf** structure is extended or not, is equal to the ASCII string "bufx".

B_BUFX_INITIAL
When set, indicates that the **buf** is extended.

Item	Description
b_forw	The forward busy block pointer.

Item	Description
`b_back`	The backward busy block pointer.
`av_forw`	The forward pointer for a driver request queue.
`av_back`	The backward pointer for a driver request queue.
`b_iodone`	Anyone calling the strategy routine must set this field to point to their I/O done routine. This routine is called on the **INTIODONE** interrupt level when I/O is complete.
`b_dev`	The major and minor device number.
`b_bcount`	The byte count for the data transfer.
`b_un.b_addr`	The memory address of the data buffer.
`b_blkno`	The block number on the device.
`b_resid`	The amount of data not transferred after error.
`b_event`	The anchor for event list.
`b_xmemd`	The cross-memory descriptor.
`bx_refptrtop`	The top half of the reference pointer.
`bx_refptrbot`	The bottom half of the reference pointer.
`bx_version`	The version of the **bufx** structure.
`bx_eyecatcher`	The field contains the string "bufx", allowing for easy identification of the **bufx** structure in KDB when dumping data and for structure verification in addition to using the **BUFX_VALIDATE** macro.
`bx_flags`	**Bufx** flags with a 64-bit field that can be used for **bufx**-specific flags that are yet to be defined.
`bx_io_priority`	If the underlying storage devices do not support I/O priority, this value is ignored. The `bx_io_priority` must be either the value of IOPRIORITY_UNSET (0) or a value from 1 to 15. Lower I/O priority values are considered to be more important than higher values. For example, a value of 1 is considered the highest priority and a value of 15 is considered the lowest priority. The value of IOPRIORITY_UNSET is defined in the **sys/extendio.h** file.
`bx_io_cache_hint`	If the underlying storage devices do not support I/O cache hints, this value is ignored. The `bx_io_cache_hint` must be either the value of CH_AGE_OUT_FAST or the value of CH_PAGE_WRITE (defined in the **sys/extendio.h** file). These values are mutually exclusive. If CH_AGE_OUT_FAST is set, the I/O buffer can be aged out quickly from the storage device buffer cache. This is useful in the situations where the application is already caching the I/O buffer and redundant caching within the storage layer can be avoided. If CH_PAGE_WRITE is set, the I/O buffer is written only to the storage device cache and not to the disk.

Character Lists Structure

Character device drivers, and other character-oriented support that can perform character-at-a-time I/O, can be implemented by using a common set of services and data buffers to handle characters in the form of *character lists*. A *character list* is a list or queue of characters. Some routines put characters in a list, and others remove the characters from the list.

Character lists, known as **clists**, contain a **clist** header and a chain of one or more data buffers known as character blocks**.** Putting characters on a queue allocates space (character blocks) from the common pool and links the character block into the data structure defining the character queue. Obtaining characters from a queue returns the corresponding space back to the pool.

A character list can be used to communicate between a character device driver top and bottom half. The **clist** header and the character blocks that are used by these routines must be pinned in memory, since they are accessed in the interrupt environment.

Users of the character list services must register (typically in the device driver **ddopen** routine) the number of character blocks to be used at any one time. This allows the kernel to manage the number of pinned character blocks in the character block pool. Similarly, when usage terminates (for example, when the device driver is closed), the using routine should remove its registration of character blocks. The **pincf** kernel service provides registration for character block usage.

The kernel provides four services for obtaining characters or character blocks from a character list: the **getc**, **getcb**, **getcbp**, and **getcx** kernel services. There are also four services that add characters or character blocks to character lists: the **putc**, **putcb**, **putcbp**, and **putcx** kernel services. The **getcf** kernel services allocates a free character block while the **putcf** kernel service returns a character block to the free list. Additionally, the **putcfl** kernel service returns a list of character buffers to the free list. The **waitcfree** kernel service determines if any character blocks are on the free list, and waits for one if none are available.

Using a Character List

For each character list you use, you must allocate a **clist** header structure. This **clist** structure is defined in the **/usr/include/sys/cblock.h** file.

You do not need to be concerned with maintaining the fields in the **clist** header, as the character list services do this for you. However, you should initialize the `c_cc` count field to 0, and both character block pointers (`c_cf` and `c_cl`) to null before using the **clist** header for the first time. The **clist** structure defines these fields.

Each buffer in the character list is a **cblock** structure, which is also defined in the **/usr/include/sys/cblock.h** file.

A character block data area does not need to be completely filled with characters. The **c_first** and **c_last** fields are zero-based offsets within the **c_data** array, which actually contains the data.

Only a limited amount of memory is available for character buffers. All character drivers share this pool of buffers. Therefore, you must limit the number of characters in your character list to a few hundred. When the device is closed, the device driver should make certain all of its character lists are flushed so the buffers are returned to the list of free buffers.

Device Driver Kernel Extension Overview

ddclose Device Driver Entry Point

Purpose

Closes a previously open device instance.

Syntax

```
#include <sys/device.h>
#include <sys/types.h>
```

```
int ddclose ( devno,   chan)
dev_t devno;
chan_t chan;
```

Parameters

Item	Description
devno	Specifies the major and minor device numbers of the device instance to close.
chan	Specifies the channel number.

Description

The **ddclose** entry point is called when a previously opened device instance is closed by the **close** subroutine or **fp_close** kernel service. The kernel calls the routine under different circumstances for non-multiplexed and multiplexed device drivers.

For non-multiplexed device drivers, the kernel calls the **ddclose** routine when the last process having the device instance open closes it. This causes the g-node reference count to be decremented to 0 and the g-node to be deallocated.

For multiplexed device drivers, the **ddclose** routine is called for each close associated with an explicit open. In other words, the device driver's **ddclose** routine is invoked once for each time its **ddopen** routine was invoked for the channel.

In some instances, data buffers should be written to the device before returning from the **ddclose** routine. These are buffers containing data to be written to the device that have been queued by the device driver but not yet written.

Non-multiplexed device drivers should reset the associated device to an idle state and change the device driver device state to closed. This can involve calling the **fp_close** kernel service to issue a close to an associated open device handler for the device. Returning the device to an idle state prevents the device from generating any more interrupt or direct memory access (DMA) requests. DMA channels and interrupt levels allocated for this device should be freed, until the device is re-opened, to release critical system resources that this device uses.

Multiplexed device drivers should provide the same device quiescing, but not in the **ddclose** routine. Returning the device to the idle state and freeing its resources should be delayed until the **ddmpx** routine is called to deallocate the last channel allocated on the device.

In all cases, the device instance is considered closed once the **ddclose** routine has returned to the caller, even if a nonzero return code is returned.

Execution Environment

The **ddclose** routine is executed only in the process environment. It should provide the required serialization of its data structures by using the locking kernel services in conjunction with a private lock word defined in the driver.

Return Values

The **ddclose** entry point can indicate an error condition to the user-mode application program by returning a nonzero return code. This causes the subroutine call to return a value of -1. It also makes the return code available to the user-mode application in the **errno** global variable. The return code used should be one of the values defined in the **/usr/include/sys/errno.h** file.

The device is always considered closed even if a nonzero return code is returned.

When applicable, the return values defined in the POSIX 1003.1 standard for the **close** subroutine should be used.

ddconfig Device Driver Entry Point

Purpose

Performs configuration functions for a device driver.

Syntax

```
#include <sys/device.h>
#include <sys/types.h>

int ddconfig ( devno,  cmd,  uiop)
dev_t devno;
int cmd;
struct uio *uiop;
```

Parameters

Item	Description
devno	Specifies the major and minor device numbers.
cmd	Specifies the function to be performed by the **ddconfig** routine.
uiop	Points to a **uio** structure describing the relevant data area for configuration information.

Description

The **ddconfig** entry point is used to configure a device driver. It can be called to do the following tasks:

- Initialize the device driver.
- Terminate the device driver.
- Request configuration data for the supported device.
- Perform other device-specific configuration functions.

The **ddconfig** routine is called by the device's Configure, Unconfigure, or Change method. Typically, it is called once for each device number (major and minor) to be supported. This is, however, device-dependent. The specific device method and **ddconfig** routine determines the number of times it is called.

The **ddconfig** routine can also provide additional device-specific functions relating to configuration, such as returning device vital product data (VPD). The **ddconfig** routine is usually invoked through the **sysconfig** subroutine by the device-specific Configure method.

Device drivers and their methods typically support these values for the *cmd* parameter:

Value	Description
CFG_INIT	Initializes the device driver and internal data areas. This typically involves the minor number specified by the *devno* parameter, for validity. The device driver's **ddconfig** routine also installs the device driver's entry points in the device switch table, if this was the first time called (for the specified major number). This can be accomplished by using the **devswadd** kernel service along with a **devsw** structure to add the device driver's entry points to the device switch table for the major device number supplied in the *devno* parameter.
	The **CFG_INIT** command parameter should also copy the device-dependent information (found in the device-dependent structure provided by the caller) into a static or dynamically allocated save area for the specified device. This information should be used when the **ddopen** routine is later called.
	The device-dependent structure's address and length are described in the **uio** structure pointed to by the *uiop* parameter. The **uiomove** kernel service can be used to copy the device-dependent structure into the device driver's data area.
	When the **ddopen** routine is called, the device driver passes device-dependent information to the routines or other device drivers providing the device handler role in order to initialize the device. The delay in initializing the device until the **ddopen** call is received is useful in order to delay the use of valuable system resources (such as DMA channels and interrupt levels) until the device is actually needed.
CFG_TERM	Terminates the device driver associated with the specified device number, as represented by the *devno* parameter. The **ddconfig** routine determines if any opens are outstanding on the specified *devno* parameter. If none are, the **CFG_TERM** command processing marks the device as terminated, disallowing any subsequent opens to the device. All dynamically allocated data areas associated with the specified device number should be freed.
	If this termination removes the last minor number supported by the device driver from use, the **devswdel** kernel service should be called to remove the device driver's entry points from the device switch table for the specified *devno* parameter.
	If opens are outstanding on the specified device, the terminate operation is rejected with an appropriate error code returned. The Unconfigure method can subsequently unload the device driver if all uses of it have been terminated.
	To determine if all the uses of the device driver have been terminated, a device method can make a **sysconfig** subroutine call. By using the **sysconfig SYS_QDVSW** operation, the device method can learn whether or not the device driver has removed itself from the device switch table.
CFG_QVPD	Queries device-specific vital product data (VPD).
	For this function, the calling routine sets up a **uio** structure pointed at by the *uiop* parameter to the **ddconfig** routine. This **uio** structure defines an area in the caller's storage in which the **ddconfig** routine is to write the VPD. The **uiomove** kernel service can be used to provide the data copy operation.

The data area pointed at by the *uiop* parameter has two different purposes, depending on the *cmd* function. If the **CFG_INIT** command has been requested, the **uiop** structure describes the location and length of the device-dependent data structure (DDS) from which to read the information. If the **CFG_QVPD** command has been requested, the **uiop** structure describes the area in which to write vital product data information. The content and format of this information is established by the specific device methods in conjunction with the device driver.

The **uiomove** kernel service can be used to facilitate copying information into or out of this data area. The format of the **uio** structure is defined in the **/usr/include/sys/uio.h** file and described further in the **uio** structure.

Execution Environment

The **ddconfig** routine and its operations are called in the process environment only.

Return Values

The **ddconfig** routine sets the return code to 0 if no errors are detected for the operation specified. If an error is to be returned to the caller, a nonzero return code should be provided. The return code used should be one of the values defined in the **/usr/include/sys/errno.h** file.

If this routine was invoked by a **sysconfig** subroutine call, the return code is passed to its caller (typically a device method). It is passed by presenting the error code in the **errno** global variable and providing a -1 return code to the subroutine.

Device Driver Kernel Extension Overview

dddump Device Driver Entry Point

Purpose

Writes system dump data to a device.

Syntax

```
#include <sys/device.h>

int dddump (devno, uiop, cmd, arg, chan, ext)
dev_t  devno;
struct uio * uiop;
int  cmd,  arg;
chan_t  chan;
int  ext;
```

Parameters

Item	Description
devno	Specifies the major and minor device numbers.
uiop	Points to the **uio** structure describing the data area or areas to be dumped.
cmd	The parameter from the kernel dump function that specifies the operation to be performed.
arg	The parameter from the caller that specifies the address of a parameter block associated with the kernel dump command.
chan	Specifies the channel number.
ext	Specifies the extension parameter.

Description

The kernel dump routine calls the **dddump** entry point to set up and send dump requests to the device. The **dddump** routine is optional for a device driver. It is required only when the device driver supports a device as a target for a possible kernel dump.

If this is the case, it is important that the system state change as little as possible when performing the dump. As a result, the **dddump** routine should use the minimal amount of services in writing the dump data to the device.

The *cmd* parameter can specify any of the following dump commands:

Dump Command	Description
DUMPINIT	Initialization a device in preparation for supporting a system dump. The specified device instance must have previously been opened. The *arg* parameter points to a **dumpio_stat** structure, defined in **/usr/include/sys/dump.h**. This is used for returning device-specific status in case of an error.
	The **dddump** routine should pin all code and data that the device driver uses to support dump writing. This is required to prevent a page fault when actually performing a write of the dump data. (Pinned code should include the **dddump** routine.) The **pin** or **pincode** kernel service can be used for this purpose.
DUMPQUERY	Determines the maximum and minimum number of bytes that can be transferred to the device in one **DUMPWRITE** command. For network dumps, the address of the write routine used in transferring dump data to the network dump device is also sent. The *uiop* parameter is not used and is null for this command. The *arg* parameter is a pointer to a **dmp_query** structure, as defined in the **/usr/include/sys/dump.h** file.

The **dmp_query** structure contains the following fields:

min_tsize
    Minimum transfer size (in bytes).

max_tsize
    Maximum transfer size (in bytes).

dumpwrite
    Address of the write routine.

The **DUMPQUERY** command returns the data transfer size information in the **dmp_query** structure pointed to by the *arg* parameter. The kernel dump function then uses a buffer between the minimum and maximum transfer sizes (inclusively) when writing dump data.

If the buffer is not the size found in the `max_tsize` field, then its size must be a multiple of the value in the `min_tsize` field. The `min_tsize` field and the `max_tsize` field can specify the same value.

DUMPSTART	Suspends current device activity and provide whatever setup of the device is needed before receiving a **DUMPWRITE** command. The *arg* parameter points to a **dumpio_stat** structure, defined in **/usr/include/sys/dump.h**. This is used for returning device-specific status in case of an error.

Dump Command	Description
DUMPWRITE	Writes dump data to the target device. The **uio** structure pointed to by the *uiop* parameter specifies the data area or areas to be written to the device and the starting device offset. The *arg* parameter points to a **dumpio_stat** structure, defined in **/usr/ include/sys/dump.h**. This is used for returning device-specific status in case of an error. Code for the **DUMPWRITE** command should minimize its reliance on system services, process dispatching, and such interrupt services as the **INTIODONE** interrupt priority or device hardware interrupts. **Note:** The **DUMPWRITE** command must never cause a page fault. This is ensured on the part of the caller, since the data areas to be dumped have been determined to be in memory. The device driver must ensure that all of its code, data and stack accesses are to pinned memory during its **DUMPINIT** command processing.
DUMPEND	Indicates that the kernel dump has been completed. Any cleanup of the device state should be done at this time.
DUMPTERM	Indicates that the specified device is no longer a selected dump target device. If no other devices supported by this **dddump** routine have a **DUMPINIT** command outstanding, the **DUMPTERM** code should unpin any resources pinned when it received the **DUMPINIT** command. (The **unpin** kernel service is available for unpinning memory.) The **DUMPTERM** command is received before the device is closed.
DUMPREAD	Receives the acknowledgment packet for previous **DUMPWRITE** operations to a communications device driver. If the device driver receives the acknowledgment within the specified time, it returns a 0 and the response data is returned to the kernel dump function in the *uiop* parameter. If the device driver does not receive the acknowledgment within the specified time, it returns a value of **ETIMEDOUT**. The *arg* parameter contains a timeout value in milliseconds.

Execution Environment

The **DUMPINIT dddump** operation is called in the process environment only. The **DUMPQUERY**, **DUMPSTART**, **DUMPWRITE**, **DUMPEND**, and **DUMPTERM dddump** operations can be called in both the process environment and interrupt environment.

Return Values

The **dddump** entry point indicates an error condition to the caller by returning a nonzero return code.

Device Driver Kernel Extension Overview

ddioctl Device Driver Entry Point

Purpose

Performs the special I/O operations requested in an **ioctl** or **ioctlx** subroutine call.

Syntax

```
#include <sys/device.h>
```

```
int ddioctl (devno, cmd, arg, devflag, chan, ext)
dev_t  devno;
int  cmd;
void *arg;
ulong  devflag;
chan_t  chan;
int  ext;
```

Description

When a program issues an **ioctl** or **ioctlx** subroutine call, the kernel calls the **ddioctl** routine of
the specified device driver. The **ddioctl** routine is responsible for performing whatever functions are
requested. In addition, it must return whatever control information has been specified by the original
caller of the **ioctl** subroutine. The *cmd* parameter contains the name of the operation to be performed.

Most ioctl operations depend on the specific device involved. However, all ioctl routines must respond to
the following command:

Item	Description
IOCINFO	Returns a **devinfo** structure (defined in the **/usr/include/sys/devinfo.h** file) that describes the device. (Refer to the description of the special file for a particular device in the Application Programming Interface.) Only the first two fields of the data structure need to be returned if the remaining fields of the structure do not apply to the device.

The *devflag* parameter indicates one of several types of information. It can give conditions in which
the device was opened. (These conditions can subsequently be changed by the **fcntl** subroutine call.)
Alternatively, it can tell which of two ways the entry point was invoked:

- By the file system on behalf of a using application
- Directly by a kernel routine using the **fp_ioctl** kernel service

Thus flags in the *devflag* parameter have the following definitions, as defined in the **/usr/include/sys/
device.h** file:

Item	Description
DKERNEL	Entry point called by kernel routine using the **fp_ioctl** service.
DREAD	Open for reading.
DWRITE	Open for writing.
DAPPEND	Open for appending.
DNDELAY	Device open in nonblocking mode.

Parameters

Item	Description
devno	Specifies the major and minor device numbers.
cmd	The parameter from the **ioctl** subroutine call that specifies the operation to be performed.
arg	The parameter from the **ioctl** subroutine call that specifies an additional argument for the *cmd* operation.
devflag	Specifies the device open or file control flags.
chan	Specifies the channel number.
ext	Specifies the extension parameter.

Execution Environment

The **ddioctl** routine is executed only in the process environment. It should provide the required serialization of its data structures by using the locking kernel services in conjunction with a private lock word defined in the driver.

Return Values

The **ddioctl** entry point can indicate an error condition to the user-mode application program by returning a nonzero return code. This causes the **ioctl** subroutine to return a value of -1 and makes the return code available to the user-mode application in the **errno** global variable. The error code used should be one of the values defined in the **/usr/include/sys/errno.h** file.

When applicable, the return values defined in the POSIX 1003.1 standard for the **ioctl** subroutine should be used.

Device Driver Kernel Extension Overview

ddmpx Device Driver Entry Point

Purpose

Allocates or deallocates a channel for a multiplexed device driver.

Syntax

```
#include <sys/device.h>
#include <sys/types.h>
```

int ddmpx (*devno*, *chanp*, *channame***)**
dev_t *devno*;
chan_t *∗chanp*;
char *∗channame*;

Parameters

Item	Description
devno	Specifies the major and minor device numbers.
chanp	Specifies the channel ID, passed by reference.
channame	Points to the path name extension for the channel to be allocated.

Description

Only multiplexed character class device drivers can provide the **ddmpx** routine, and *every* multiplexed driver must do so. The **ddmpx** routine cannot be provided by block device drivers even when providing *raw* read/write access.

A multiplexed device driver is a character class device driver that supports the assignment of channels to provide finer access control to a device or virtual subdevice. This type of device driver has the capability to decode special channel-related information appended to the end of the path name of the device's special file. This path name extension is used to identify a logical or virtual subdevice or channel.

When an **open** or **creat** subroutine call is issued to a device instance supported by a multiplexed device driver, the kernel calls the device driver's **ddmpx** routine to allocate a channel.

The kernel calls the **ddmpx** routine when a channel is to be allocated or deallocated. Upon allocation, the kernel dynamically creates g-nodes (in-core i-nodes) for channels on a multiplexed device to allow the protection attributes to differ for various channels.

To allocate a channel, the **ddmpx** routine is called with a *channame* pointer to the path name extension. The path name extension starts after the first **/** (slash) character that follows the special file name in the path name. The **ddmpx** routine should perform the following actions:

- Parse this path name extension.
- Allocate the corresponding channel.
- Return the channel ID through the *chanp* parameter.

If no path name extension exists, the *channame* pointer points to a null character string. In this case, an available channel should be allocated and its channel ID returned through the *chanp* parameter.

If no error is returned from the **ddmpx** routine, the returned channel ID is used to determine if the channel was already allocated. If already allocated, the g-node for the associated channel has its reference count incremented. If the channel was not already allocated, a new g-node is created for the channel. In either case, the device driver's **ddopen** routine is called with the channel number assigned by the **ddmpx** routine. If a nonzero return code is returned by the **ddmpx** routine, the channel is assumed not to have been allocated, and the device driver's **ddopen** routine is not called.

If a close of a channel is requested so that the channel is no longer used (as determined by the channel's g-node reference count going to 0), the kernel calls the **ddmpx** routine. The **ddmpx** routine deallocates the channel after the **ddclose** routine was called to close the last use of the channel. If a nonzero return code is returned by the **ddclose** routine, the **ddmpx** routine is still called to deallocate the channel. The **ddclose** routine's return code is saved, to be returned to the caller. If the **ddclose** routine returned no error, but a nonzero return code was returned by the **ddmpx** routine, the channel is assumed to be deallocated, although the return code is returned to the caller.

To deallocate a channel, the **ddmpx** routine is called with a null *channame* pointer and the channel ID passed by reference in the *chanp* parameter. If the channel g-node reference count has gone to 0, the kernel calls the **ddmpx** routine to deallocate the channel after invoking the **ddclose** routine to close it. The **ddclose** routine should not itself deallocate the channel.

Execution Environment

The **ddmpx** routine is called in the process environment only.

Return Values

If the allocation or deallocation of a channel is successful, the **ddmpx** routine should return a return code of 0. If an error occurs on allocation or deallocation, this routine returns a nonzero value.

The return code should conform to the return codes described for the **open** and **close** subroutines in the POSIX 1003.1 standard, where applicable. Otherwise, the return code should be one defined in the **/usr/include/sys/errno.h** file.

Device Driver Kernel Extension Overview

ddopen Device Driver Entry Point

Purpose

Prepares a device for reading, writing, or control functions.

Syntax

#include <sys/device.h>

int ddopen (*devno*, *devflag*, *chan*, *ext*)
dev_t *devno*;
ulong *devflag*;
chan_t *chan*;
int *ext*;

Parameters

Item	Description
devno	Indicates major and minor device numbers.
devflag	Specifies open file control flags.
chan	Specifies the channel number.
ext	Specifies the extension parameter.

Description

The kernel calls the **ddopen** routine of a device driver when a program issues an **open** or **creat** subroutine call. It can also be called when a system call, kernel process, or other device driver uses the **fp_opendev** or **fp_open** kernel service to use the device.

The **ddopen** routine must first ensure exclusive access to the device, if necessary. Many character devices, such as printers and plotters, should be opened by only one process at a time. The **ddopen** routine can enforce this by maintaining a static flag variable, which is set to 1 if the device is open and 0 if not.

Each time the **ddopen** routine is called, it checks the value of the flag. If the value is other than 0, the **ddopen** routine returns with a return code of **EBUSY** to indicate that the device is already open. Otherwise, the **ddopen** routine sets the flag and returns normally. The **ddclose** entry point later clears the flag when the device is closed.

Since most block devices can be used by several processes at once, a block driver should not try to enforce opening by a single user.

The **ddopen** routine must initialize the device if this is the first open that has occurred. Initialization involves the following steps:

1. The **ddopen** routine should allocate the required system resources to the device (such as DMA channels, interrupt levels, and priorities). It should, if necessary, register its device interrupt handler for the interrupt level required to support the target device. (The **i_init** and **d_init** kernel services are available for initializing these resources.)

2. If this device driver is providing the head role for a device and another device driver is providing the handler role, the **ddopen** routine should use the **fp_opendev** kernel service to open the device handler.

   Note: The **fp_opendev** kernel service requires a *devno* parameter to identify which device handler to open. This *devno* value, taken from the appropriate device dependent structure (DDS), should have been stored in a special save area when this device driver's **ddconfig** routine was called.

Flags Defined for the devflag Parameter

The *devflag* parameter has the following flags, as defined in the **/usr/include/sys/device.h** file:

Item	Description
DKERNEL	Entry point called by kernel routine using the **fp_opendev** or **fp_open** kernel service.
DREAD	Open for reading.
DWRITE	Open for writing.
DAPPEND	Open for appending.
DNDELAY	Device open in nonblocking mode.

Execution Environment

The **ddopen** routine is executed only in the process environment. It should provide the required serialization of its data structures by using the locking kernel services in conjunction with a private lock word defined in the driver.

Return Values

The **ddopen** entry point can indicate an error condition to the user-mode application program by returning a nonzero return code. Returning a nonzero return code causes the **open** or **creat** subroutines to return a value of -1 and makes the return code available to the user-mode application in the **errno** global variable. The return code used should be one of the values defined in the **/usr/include/errno.h** file.

If a nonzero return code is returned by the **ddopen** routine, the open request is considered to have failed. No access to the device instance is available to the caller as a result. In addition, for nonmultiplexed drivers, if the failed open was the first open of the device instance, the kernel calls the driver's **ddclose** entry point to allow resources and device driver state to be cleaned up. If the driver was multiplexed, the kernel does not call the **ddclose** entry point on an open failure.

When applicable, the return values defined in the POSIX 1003.1 standard for the **open** subroutine should be used.

Programming in the Kernel Environment Overview

ddread Device Driver Entry Point

Purpose

Reads in data from a character device.

Syntax

```
#include <sys/device.h>
#include <sys/types.h>

int ddread ( devno, uiop, chan, ext)
dev_t devno;
struct uio *uiop;
chan_t chan;
int ext;
```

Parameters

Item	Description
devno	Specifies the major and minor device numbers.
uiop	Points to a **uio** structure describing the data area or areas in which to be written.
chan	Specifies the channel number.
ext	Specifies the extension parameter.

Description

When a program issues a **read** or **readx** subroutine call or when the **fp_rwuio** kernel service is used, the kernel calls the **ddread** entry point.

This entry point receives a pointer to a **uio** structure that provides variables used to specify the data transfer operation.

Character device drivers can use the **ureadc** and **uiomove** kernel services to transfer data into and out of the user buffer area during a **read** subroutine call. These services receive a pointer to the **uio** structure and update the fields in the structure by the number of bytes transferred. The only fields in the **uio** structure that cannot be modified by the data transfer are the `uio_fmode` and `uio_segflg` fields.

For most devices, the **ddread** routine sends the request to the device handler and then waits for it to finish. The waiting can be accomplished by calling the **e_sleep** kernel service. This service suspends the driver and the process that called it and permits other processes to run until a specified event occurs.

When the I/O operation completes, the device usually issues an interrupt, causing the device driver's interrupt handler to be called. The interrupt handler then calls the **e_wakeup** kernel service specifying the awaited event, thus allowing the **ddread** routine to resume.

The `uio_resid` field initially contains the total number of bytes to read from the device. If the device driver supports it, the `uio_offset` field indicates the byte offset on the device from which the read should start.

The `uio_offset` field is a 64 bit integer (`offset_t`); this allows the file system to send I/O requests to a device driver's read & write entry points which have logical offsets beyond 2 gigabytes. Device drivers must use care not to cause a loss of significance by assigning the offset to a 32 bit variable or using it in calculations that overflow a 32 bit variable.

If no error occurs, the `uio_resid` field should be 0 on return from the **ddread** routine to indicate that all requested bytes were read. If an error occurs, this field should contain the number of bytes remaining to be read when the error occurred.

If a read request starts at a valid device offset but extends past the end of the device's capabilities, no error should be returned. However, the `uio_resid` field should indicate the number of bytes not transferred. If the read starts at the end of the device's capabilities, no error should be returned. However, the `uio_resid` field should not be modified, indicating that no bytes were transferred. If the read starts past the end of the device's capabilities, an **ENXIO** return code should be returned, without modifying the `uio_resid` field.

When the **ddread** entry point is provided for raw I/O to a block device, this routine usually translates requests into block I/O requests using the **uphysio** kernel service.

Execution Environment

The **ddread** routine is executed only in the process environment. It should provide the required serialization of its data structures by using the locking kernel services in conjunction with a private lock word defined in the driver.

Return Values

The **ddread** entry point can indicate an error condition to the caller by returning a nonzero return code. This causes the subroutine call to return a value of -1. It also makes the return code available to the user-mode program in the **errno** global variable. The error code used should be one of the values defined in the **/usr/include/sys/errno.h** file.

When applicable, the return values defined in the POSIX 1003.1 standard for the **read** subroutine should be used.

Programming in the Kernel Environment Overview

ddrevoke Device Driver Entry Point

Purpose

Ensures that a secure path to a terminal is provided.

Syntax

```
#include <sys/device.h>
#include <sys/types.h>

int ddrevoke ( devno,  chan,  flag)
dev_t devno;
chan_t chan;
int flag;
```

Parameters

Item	Description
devno	Specifies the major and minor device numbers.
chan	Specifies the channel number. For a multiplexed device driver, a value of -1 in this parameter means access to all channels is to be revoked.
flag	Currently defined to have the value of 0. (Reserved for future extensions.)

Description

The **ddrevoke** entry point can be provided only by character class device drivers. It cannot be provided by block device drivers even when providing raw read/write access. A **ddrevoke** entry point is required only by device drivers supporting devices in the Trusted Computing Path to a terminal (for example, by the **/dev/ lft** and **/dev/tty** files for the low function terminal and teletype device drivers). The **ddrevoke** routine is called by the **frevoke** and **revoke** subroutines.

The **ddrevoke** routine revokes access to a specific device or channel (if the device driver is multiplexed). When called, the **ddrevoke** routine should terminate all processes waiting in the device driver while accessing the specified device or channel. It should terminate the processes by sending a SIGKILL signal to all processes currently waiting for a specified device or channel data transfer. The current process is not to be terminated.

If the device driver is multiplexed and the channel ID in the *chan* parameter has the value -1, all channels are to be revoked.

Execution Environment

The **ddrevoke** routine is called in the process environment only.

Return Values

The **ddrevoke** routine should return a value of 0 for successful completion, or a value from the **/usr/include/errno.h** file on error.

Files

Item	Description
/dev/lft	Specifies the path of the LFT special file.
/dev/tty	Specifies the path of the tty special file.

Related information

revoke subroutine
TTY Subsystem Overview

ddselect Device Driver Entry Point

Purpose

Checks to see if one or more events has occurred on the device.

Syntax

```
#include <sys/device.h>
#include <sys/poll.h>
```

```
int ddselect ( devno, events, reventp, chan)
dev_t devno;
ushort events;
ushort *reventp;
int chan;
```

Parameters

Item	Description
devno	Specifies the major and minor device numbers.
events	Specifies the events to be checked.
reventp	Returned events pointer. This parameter, passed by reference, is used by the **ddselect** routine to indicate which of the selected events are true at the time of the call. The returned events location pointed to by the *reventp* parameter is set to 0 before entering this routine.
chan	Specifies the channel number.

Description

The **ddselect** entry point is called when the **select** or **poll** subroutine is used, or when the **fp_select** kernel service is invoked. It determines whether a specified event or events have occurred on the device.

Only character class device drivers can provide the **ddselect** routine. It cannot be provided by block device drivers even when providing raw read/write access.

Requests for Information on Events

The *events* parameter represents possible events to check as flags (bits). There are three basic events defined for the **select** and **poll** subroutines, when applied to devices supporting select or poll operations:

Event	Description
POLLIN	Input is present on the device.
POLLOUT	The device is capable of output.
POLLPRI	An exceptional condition has occurred on the device.

A fourth event flag is used to indicate whether the **ddselect** routine should record this request for later notification of the event using the **selnotify** kernel service. This flag can be set in the *events* parameter if the device driver is not required to provide asynchronous notification of the requested events:

Event	Description
POLLSYNC	This request is a synchronous request only. The routine need not call the **selnotify** kernel service for this request even if the events later occur.

Additional event flags in the *events* parameter are left for device-specific events on the **poll** subroutine call.

Select Processing

If one or more events specified in the *events* parameter are true, the **ddselect** routine should indicate this by setting the corresponding bits in the *reventp* parameter. Note that the *reventp* returned events parameter is passed by reference.

If none of the requested events are true, then the **ddselect** routine sets the returned events parameter to 0. It is passed by reference through the *reventp* parameter. It also checks the **POLLSYNC** flag in the *events* parameter. If this flag is true, the **ddselect** routine should just return, since the event request was a synchronous request only.

However, if the **POLLSYNC** flag is false, the **ddselect** routine must notify the kernel when one or more of the specified events later happen. For this purpose, the routine should set separate internal flags for each event requested in the *events* parameter.

When any of these events become true, the device driver routine should use the **selnotify** service to notify the kernel. The corresponding internal flags should then be reset to prevent re-notification of the event.

Sometimes the device can be in a state in which a supported event or events can never be satisfied (such as when a communication line is not operational). In this case, the **ddselect** routine should simply set the corresponding *reventp* flags to 1. This prevents the **select** or **poll** subroutine from waiting indefinitely. As a result however, the caller will not in this case be able to distinguish between satisfied events and unsatisfiable ones. Only when a later request with an **NDELAY** option fails will the error be detected.

Note: Other device driver routines (such as the **ddread**, **ddwrite** routines) may require logic to support select or poll operations.

Execution Environment

The **ddselect** routine is executed only in the process environment. It should provide the required serialization of its data structures by using the locking kernel services in conjunction with a private lock word defined in the driver.

Return Values

The **ddselect** routine should return with a return code of 0 if the select or poll operation requested is valid for the resource specified. Requested operations are not valid, however, if either of the following is true:

- The device driver does not support a requested event.
- The device is in a state in which poll and select operations are not accepted.

In these cases, the **ddselect** routine should return with a nonzero return code (typically **EINVAL**), and without setting the relevant *reventp* flags to 1. This causes the **poll** subroutine to return to the caller with the **POLLERR** flag set in the returned events parameter associated with this resource. The **select** subroutine indicates to the caller that all requested events are true for this resource.

When applicable, the return values defined in the POSIX 1003.1 standard for the **select** subroutine should be used.

select subroutine
Programming in the Kernel Environment Overview

ddstrategy Device Driver Entry Point

Purpose

Performs block-oriented I/O by scheduling a read or write to a block device.

Syntax

```
void ddstrategy ( bp)
struct buf *bp;
```

Parameter

Item	Description
bp	Points to a **buf** structure describing all information needed to perform the data transfer.

Description

When the kernel needs a block I/O transfer, it calls the **ddstrategy** strategy routine of the device driver for that device. The strategy routine schedules the I/O to the device. This typically requires the following actions:

- The request or requests must be added on the list of I/O requests that need to be processed by the device.
- If the request list was empty before the preceding additions, the device's start I/O routine must be called.

Required Processing

The **ddstrategy** routine can receive a single request with multiple **buf** structures. However, it is not required to process requests in any specific order.

The strategy routine can be passed a list of operations to perform. The `av_forw` field in the **buf** header describes this null-terminated list of **buf** headers. This list is not doubly linked: the `av_back` field is undefined.

Block device drivers must be able to perform multiple block transfers. If the device cannot do multiple block transfers, or can only do multiple block transfers under certain conditions, then the device driver must transfer the data with more than one device operation.

Kernel Buffers and Using the buf Structure

An area of memory is set aside within the kernel memory space for buffering data transfers between a program and the peripheral device. Each kernel buffer has a header, the **buf** structure, which contains all necessary information for performing the data transfer. The **ddstrategy** routine is responsible for updating fields in this header as part of the transfer.

The caller of the strategy routine should set the b_iodone field to point to the caller's I/O done routine. When an I/O operation is complete, the device driver calls the **iodone** kernel service, which then calls the I/O done routine specified in the b_iodone field. The **iodone** kernel service makes this call from the **INTIODONE** interrupt level.

The value of the b_flags field is constructed by logically ORing zero or more possible b_flags field flag values.

> ⚠️ **Attention:**
>
> - Do not modify any of the following fields of the **buf** structure passed to the **ddstrategy** entry point: the b_forw, b_back, b_dev, b_un, or b_blkno field. Modifying these fields can cause unpredictable and disastrous results.
> - Do not modify any of the following fields of a **buf** structure acquired with the **geteblk** service: the b_flags, b_forw, b_back, b_dev, b_count, or b_un field. Modifying any of these fields can cause unpredictable and disastrous results.

Execution Environment

The **ddstrategy** routine must be coded to execute in an interrupt handler execution environment (device driver bottom half). That is, the routine should neither touch user storage, nor page fault, nor sleep.

Return Values

The **ddstrategy** routine, unlike other device driver routines, does not return a return code. Any error information is returned in the appropriate fields within the **buf** structure pointed to by the *bp* parameter.

When applicable, the return values defined in the POSIX 1003.1 standard for the **read** and **write** subroutines must be used.

ddwrite Device Driver Entry Point

Purpose

Writes out data to a character device.

Syntax

```
#include <sys/device.h>
#include <sys/types.h>
```

```
int ddwrite (devno, uiop, chan, ext)
dev_t  devno;
```

```
struct uio * uiop;
chan_t   chan;
int   ext;
```

Parameters

Item	Description
devno	Specifies the major and minor device numbers.
uiop	Points to a **uio** structure describing the data area or areas from which to be written.
chan	Specifies the channel number.
ext	Specifies the extension parameter.

Description

When a program issues a **write** or **writex** subroutine call or when the **fp_rwuio** kernel service is used, the kernel calls the **ddwrite** entry point.

This entry point receives a pointer to a **uio** structure, which provides variables used to specify the data transfer operation.

Character device drivers can use the **uwritec** and **uiomove** kernel services to transfer data into and out of the user buffer area during a **write** subroutine call. These services are passed a pointer to the **uio** structure. They update the fields in the structure by the number of bytes transferred. The only fields in the **uio** structure that are not potentially modified by the data transfer are the uio_fmode and uio_segflg fields.

For most devices, the **ddwrite** routine queues the request to the device handler and then waits for it to finish. The waiting is typically accomplished by calling the **e_sleep** kernel service to wait for an event. The **e_sleep** kernel service suspends the driver and the process that called it and permits other processes to run.

When the I/O operation is completed, the device usually causes an interrupt, causing the device driver's interrupt handler to be called. The interrupt handler then calls the **e_wakeup** kernel service specifying the awaited event, thus allowing the **ddwrite** routine to resume.

The uio_resid field initially contains the total number of bytes to write to the device. If the device driver supports it, the uio_offset field indicates the byte offset on the device from where the write should start.

The uio_offset field is a 64 bit integer (offset_t); this allows the file system to send I/O requests to a device driver's read & write entry points which have logical offsets beyond 2 gigabytes. Device drivers must use care not to cause a loss of significance by assigning the offset to a 32 bit variable or using it in calculations that overflow a 32 bit variable.

If no error occurs, the uio_resid field should be 0 on return from the **ddwrite** routine to indicate that all requested bytes were written. If an error occurs, this field should contain the number of bytes remaining to be written when the error occurred.

If a write request starts at a valid device offset but extends past the end of the device's capabilities, no error should be returned. However, the uio_resid field should indicate the number of bytes not transferred. If the write starts at or past the end of the device's capabilities, no data should be transferred. An error code of **ENXIO** should be returned, and the uio_resid field should not be modified.

When the **ddwrite** entry point is provided for raw I/O to a block device, this routine usually uses the **uphysio** kernel service to translate requests into block I/O requests.

Execution Environment

The **ddwrite** routine is executed only in the process environment. It should provide the required serialization of its data structures by using the locking kernel services in conjunction with a private lock word defined in the driver.

Return Values

The **ddwrite** entry point can indicate an error condition to the caller by returning a nonzero return value. This causes the subroutine to return a value of -1. It also makes the return code available to the user-mode program in the **errno** global variable. The error code used should be one of the values defined in the **/usr/include/sys/errno.h** file.

When applicable, the return values defined in the POSIX 1003.1 standard for the **write** subroutine should be used.

Select/Poll Logic for ddwrite and ddread Routines

Description

The **ddread** and **ddwrite** entry points require logic to support the **select** and **poll** operations. Depending on how the device driver is written, the interrupt routine may also need to include this logic as well.

The select/poll logic is required wherever code checks on the occurrence of desired events. At each point where one of the selection criteria is found to be true, the device driver should check whether a notification is due for that selection. If so, it should call the **selnotify** kernel service to notify the kernel of the event.

The *devno, chan,* and *revents* parameters are passed to the **selnotify** kernel service to indicate which device and which events have become true.

Device Driver Kernel Extension Overview

uio Structure

Purpose

Describes a memory buffer to be used in a data transfer.

Introduction

The user I/O or **uio** structure is a data structure describing a memory buffer to be used in a data transfer. The **uio** structure is most commonly used in the read and write interfaces to device drivers supporting character or raw I/O. It is also useful in other instances in which an input or output buffer can exist in different kinds of address spaces, and in which the buffer is not contiguous in virtual memory.

The **uio** structure is defined in the **/usr/include/sys/uio.h** file.

Description

The **uio** structure describes a buffer that is not contiguous in virtual memory. It also indicates the address space in which the buffer is defined. When used in the character device read and write interface, it also contains the device open-mode flags, along with the device read/write offset.

The kernel provides services that access data using a **uio** structure. The **ureadc**, **uwritec**, **uiomove**, and **uphysio** kernel services all perform data transfers into or out of a data buffer described by a **uio** structure. The **ureadc** kernel service writes a character into the buffer described by the **uio** structure. The **uwritec** kernel service reads a character from the buffer. These two services have names opposite from what you would expect, since they are named for the user action initiating the operation. A read on the part of the user thus results in a device driver writing to the buffer, while a write results in a driver reading from the buffer.

The **uiomove** kernel service copies data to or from a buffer described by a **uio** structure from or to a buffer in the system address space. The **uphysio** kernel service is used primarily by block device drivers providing raw I/O support. The **uphysio** kernel service converts the character read or write request into a block read or write request and sends it to the **ddstrategy** routine.

The buffer described by the **uio** structure can consist of multiple noncontiguous areas of virtual memory of different lengths. This is achieved by describing the data buffer with an array of elements, each of which consists of a virtual memory address and a byte length. Each element is defined as an `iovec` element. The **uio** structure also contains a field specifying the total number of bytes in the data buffer described by the structure.

Another field in the **uio** structure describes the address space of the data buffer, which can either be system space, user space, or cross-memory space. If the address space is defined as cross memory, an additional array of cross-memory descriptors is specified in the **uio** structure to match the array of `iovec` elements.

The **uio** structure also contains a byte offset (`uio_offset`). This field is a 64 bit integer (`offset_t`); it allows the file system to send I/O requests to a device driver's read & write entry points which have logical offsets beyond 2 gigabytes. Device drivers must use care not to cause a loss of significance by assigning the offset to a 32 bit variable or using it in calculations that overflow a 32 bit variable.

The called routine (device driver) is permitted to modify fields in the **uio** and **iovec** structures as the data transfer progresses. The final `uio_resid` count is in fact used to determine how much data was transferred. Therefore this count must be decremented, with each operation, by the number of bytes actually copied.

The **uio** structure contains the following fields:

Field	Description
uio_iov	A pointer to an array of **iovec** structures describing the user buffer for the data transfer.
uio_xmem	A pointer to an array of **xmem** structures containing the cross-memory descriptors for the **iovec** array.

Field	Description
uio_iovcnt	The number of yet-to-be-processed **iovec** structures in the array pointed to by the `uio_iov` pointer. The count must be at least 1. If the count is greater than 1, then a *scatter-gather* of the data is to be performed into or out of the areas described by the **iovec** structures.
uio_iovdcnt	The number of already processed **iovec** structures in the **iovec** array.
uio_offset	The file offset established by a previous **lseek**, **llseek** subroutine call. Most character devices ignore this variable, but some, such as the **/dev/mem** pseudo-device, use and maintain it.
uio_segflg	A flag indicating the type of buffer being described by the **uio** structure. This flag typically describes whether the data area is in user or kernel space or is in cross-memory. Refer to the **/usr/include/sys/uio.h** file for a description of the possible values of this flag and their meanings.
uio_fmode	The value of the file mode that was specified on opening the file or modified by the **fcntl** subroutine. This flag describes the file control parameters. The **/usr/include/sys/fcntl.h** file contains specific values for this flag.
uio_resid	The byte count for the data transfer. It must not exceed the sum of all the `iov_len` values in the array of **iovec** structures. Initially, this field contains the total byte count, and when the operation completes, the value must be decremented by the actual number of bytes transferred.

The **iovec** structure contains the starting address and length of a contiguous data area to be used in a data transfer. The **iovec** structure is the element type in an array pointed to by the `uio_iov` field in the **uio** structure. This array can contain any number of **iovec** structures, each of which describes a single unit of contiguous storage. Taken together, these units represent the total area into which, or from which, data is to be transferred. The `uio_iovcnt` field gives the number of **iovec** structures in the array.

The **iovec** structure contains the following fields:

Field	Description
iov_base	A variable in the **iovec** structure containing the base address of the contiguous data area in the address space specified by the `uio_segflag` field. The length of the contiguous data area is specified by the `iov_len` field.
iov_len	A variable in the **iovec** structure containing the byte length of the data area starting at the address given in the **iov_base** variable.

Virtual File System Operations

The following topic provides entry points specified by the virtual file system interface for performing operations on vfs structures.

The following entry points are specified by the virtual file system interface for performing operations on **vfs** structures:

Entry Point	Description
vfs_aclxcntl	Issues ACL related control operations for a file system.

Entry Point	Description
vfs_cntl	Issues control operations for a file system.
vfs_init	Initializes a virtual file system.
vfs_mount	Mounts a virtual file system.
vfs_root	Finds the root v-node of a virtual file system.
vfs_statfs	Obtains virtual file system statistics.
vfs_sync	Forces file system updates to permanent storage.
vfs_umount	Unmounts a virtual file system.
vfs_vget	Gets the v-node corresponding to a file identifier.

The following entry points are specified by the Virtual File System interface for performing operations on v-node structures:

Entry Point	Description
vnop_access	Tests a user's permission to access a file.
vnop_close	Releases the resources associated with a v-node.
vnop_create	Creates and opens a new file.
vnop_create_attr	Creates and opens a new file with initial attributes.
vnop_fclear	Releases portions of a file (by zeroing bytes).
vnop_fid	Builds a file identifier for a v-node.
vnop_finfo	Returns pathconf information about a file or file system.
vnop_fsync	Flushes in-memory information and data to permanent storage.
vnop_fsync_range	Flushes in-memory information and data for a given range to permanent storage.
vnop_ftrunc	Decreases the size of a file.
vnop_getacl	Gets information about access control, by retrieving the access control list.
vnop_getattr	Gets the attributes of a file.
vnop_getxacl	Gets information about access control by retrieving the ACL. Provides an advanced interface when compared to `vnop_getacl`.
vnop_hold	Assures that a v-node is not destroyed, by incrementing the v-node's use count.
vnop_ioctl	Performs miscellaneous operations on devices.
vnop_link	Creates a new directory entry for a file.
vnop_lockctl	Sets, removes, and queries file locks.
vnop_lookup	Finds an object by name in a directory.
vnop_map	Associates a file with a memory segment.
vnop_map_lloff	Associates a file with a memory segment using 64 bit offset.
vnop_memcntl	Manages physical attachment of a file.
vnop_mkdir	Creates a directory.
vnop_mknod	Creates a file of arbitrary type.
vnop_open	Gets read and/or write access to a file.
vnop_rdwr	Reads or writes a file.
vnop_rdwr_attr	Reads or writes a file and returns attributes.
vnop_readdir	Reads directory entries in standard format.
vnop_readdir_eofp	Reads directories and returns end of file indication.
vnop_readlink	Reads the contents of a symbolic link.
vnop_rele	Releases a reference to a virtual node (v-node).
vnop_remove	Unlinks a file or directory.

Entry Point	Description
vnop_rename	Renames a file or directory.
vnop_revoke	Revokes access to an object.
vnop_rmdir	Removes a directory.
vnop_seek	Moves the current offset in a file.
vnop_select	Polls a v-node for pending I/O.
vnop_setacl	Sets information about access control for a file.
vnop_setattr	Sets attributes of a file.
vnop_setxacl	Sets information about access control for a file. Provides an advanced interface compared to `vnop_setacl`.
vnop_strategy	Reads or writes blocks of a file.
vnop_symlink	Creates a symbolic link.
vnop_unmap	Destroys a file or memory association.

Virtual File System Overview

Virtual File System Kernel Extensions Overview

vfs_aclxcntl Entry Point

Purpose

Implements access-control-specific control operations for a file system.

Syntax

```
int vfs_aclxcntl (vfsp, vp, cmd, uiop, argsize, crp)

struct vfs       *vfsp;
struct vnode     *vp;
int               cmd;
struct uio       *uiop;
size_t           *argsize;
struct ucred     *crp;
```

Description

The **vfs_aclxcntl** entry point is invoked to perform various ACL-specific control operations on the underlying physical file system. If a file system is implemented to support this interface, it needs to adhere to the various commands and arguments defined for the interface. A file system implementation can define *cmd* parameter values and corresponding control functions that are specific to the file system. The *cmd* parameter for these functions has values defined globally for all the physical file systems. These control operations can be issued with the ACL library interfaces.

Parameters

Item	Description
vfsp	Points to the file system for which the control operation is to be issued.
vp	Points to the virtual node pointer to the file path of the file system for which the control operation is being requested.

Item	Description
cmd	Specifies which control operation to perform. Has one of the following values:

ACLCNTL_GETACLXTYPES

Returns the various ACL types supported for the file system instance. This area is of the following structure type:

```
typedef struct   _acl_types_list_t  {
        uint32_t   num_entries;  // in the buffer to follow
        uint32_t   pad;          // reserved space
        acl_type_t entries[MAX_ACL_TYPES];
 // Array of ACL types
} acl_types_list_t ;
```

If the buffer space is not enough to accommodate ACL types supported by the physical file system, **errno** is set to **ENOSPC** and the necessary size of the buffer is returned in *argsize*.

ACLCNTL_GETACLXTYPEINFO

Returns the characteristics information related to an ACL type for the file system instance. This area is of the following structure type:

```
typedef struct       _acl_type_info_t  {
        acl_type_t    acl_type;
// ACL type for which info is needed
        uint8_t     acl_type_info;
// Start of ACL characteristics data
} _acl_type_info_t ;
```

acl_type_info is the start byte of the ACL-related characteristics information. ACL characteristics information depends on the ACL type. ACL characteristics for NFS4 ACL type have the following structure:

```
typedef struct       _nfs4_acl_type_info_t  {
        uint32_t  version;
// Version of this structure
        uint32_t  acl_suport;
// Support of Access control entry types.
} nfs4_acl_type_info_t ;
```

If the buffer space is not enough to accommodate the ACL types supported by the physical file system, **errno** is set to **ENOSPC** and the necessary size of the buffer is returned in *argsize*.

Item	Description
uiop	Identifies data specific to the control operation. If the *cmd* parameter has a value of **ACLCNTL_GETACLXTYPES**, *uiop* points to a buffer area where the file system stores the supported ACL types. If the *cmd* parameter has a value of **ACLCNTL_GETACLXTYPEINFO**, *uiop* points to a buffer area where the file system stores the ACL characteristics information.
argsize	Identifies the length of the data specified by the *arg* parameter. This buffer is used to return the necessary buffer size, in case the buffer size provided by the user is not enough.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Execution Environment

The **vfs_aclxcntl** entry point can be called from the process environment only.

Return Values

Upon successful completion, the **vfs_aclxcntl** entry point returns 0. Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Item	Description
EACCES	The *cmd* parameter requires a privilege that the current process does not have.
EINVAL	Indicates that the *cmd* parameter is not a supported control, or the *arg* parameter is not a valid argument for the command.
ENOSPC	The input buffer was not sufficient for storing the requested information.

Virtual File System Overview

Virtual File System Kernel Extensions Overview

Logical File System Overview

vfs_cntl Entry Point

Purpose

Implements control operations for a file system.

Syntax

```
int vfs_cntl (vfsp, cmd, arg, argsize, crp)
struct vfs * vfsp;
int   cmd;
caddr_t   arg;
unsigned long   argsize;
struct ucred * crp;
```

Parameters

Item	Description
vfsp	Points to the file system for which the control operation is to be issued.
cmd	Specifies which control operation to perform.
arg	Identifies data specific to the control operation.
argsize	Identifies the length of the data specified by the *arg* parameter.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vfs_cntl** entry point is invoked by the logical file system to request various control operations on the underlying file system. A file system implementation can define file system-specific *cmd* parameter values and corresponding control functions. The *cmd* parameter for these functions should have a minimum value of 32768. These control operations can be issued with the **fscntl** subroutine.

Note: The only system-supported control operation is **FS_EXTENDFS**. This operation increases the file system size and accepts an *arg* parameter that specifies the new size. The **FS_EXTENDFS** operation ignores the *argsize* parameter.

Execution Environment

The **vfs_cntl** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Non-zero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure. Typical values include:

Item	Description
EINVAL	Indicates that the *cmd* parameter is not a supported control, or the *arg* parameter is not a valid argument for the command.
EACCES	Indicates that the *cmd* parameter requires a privilege that the current process does not have.

Related information

Virtual File System Overview

Virtual File System Kernel Extensions Overview

vfs_hold or vfs_unhold Kernel Service

Purpose

Holds or releases a **vfs** structure.

Syntax

```
#include <sys/vfs.h>
```

```
void vfs_hold(vfsp)
struct vfs *vfsp;
```

```
int vfs_unhold(vfsp)
struct vfs *vfsp;
```

Parameter

Item	Description
vfsp	Points to a **vfs** structure.

Description

The **vfs_hold** kernel service holds a **vfs** structure and the **vfs_unhold** kernel service releases it. These routines manage a use count for a virtual file system (VFS). A use count greater than 1 prevents the virtual file system from being unmounted.

Execution Environment

These kernel services can be called from the process environment only.

Return Values

The **vfs_hold** kernel service has no return value.

The **vfs_unhold** kernel service returns the original value of the hold count.

vfs_init Entry Point

Purpose

Initializes a virtual file system.

Syntax

int vfs_init (*gfsp***)**
struct gfs **gfsp***;**

Parameter

Item	Description
gfsp	Points to a file system's attribute structure.

Description

The **vfs_init** entry point is invoked to initialize a file system. It is called when a file system implementation is loaded to perform file system-specific initialization.

The **vfs_init** entry point is not called through the virtual file system switch. Instead, it is called indirectly by the **gfsadd** kernel service when the **vfs_init** entry point address is stored in the **gfs** structure passed to the **gfsadd** kernel service as a parameter. (The **vfs_init** address is placed in the gfs_init field of the **gfs** structure.) The **gfs** structure is defined in the **/usr/include/sys/gfs.h** file.

Note: The return value for the **vfs_init** entry point is passed back as the return value from the **gfsadd** kernel service.

Execution Environment

The **vfs_init** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

vfs_mount Entry Point

Purpose

Mounts a virtual file system.

Syntax

```
int vfs_mount ( vfsp)
struct vfs *vfsp;
struct ucred * crp;
```

Parameter

Item	Description
vfsp	Points to the newly created **vfs** structure.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vfs_mount** entry point is called by the logical file system to mount a new file system. This entry point is called after the **vfs** structure is allocated and initialized. Before this structure is passed to the **vfs_mount** entry point, the logical file system:

- Guarantees the syntax of the **vmount** or **mount** subroutines.
- Allocates the **vfs** structure.
- Resolves the stub to a virtual node (v-node). This is the `vfs_mntdover` field in the **vfs** structure.
- Initializes the following virtual file system fields:

Field	Description
`vfs_flags`	Initialized depending on the type of mount. This field takes the following values: **VFS_MOUNTOK** The user has write permission in the stub's parent directory and is the owner of the stub. **VFS_SUSER** The user has root user authority. **VFS_NOSUID** Execution of **setuid** and **setgid** programs from this mount are not allowed. **VFS_NODEV** Opens of devices from this mount are not allowed.
`vfs_type`	Initialized to the / (root) file system type when the **mount** subroutine is used. If the **vmount** subroutine is used, the **vfs_type** field is set to the *type* parameter supplied by the user. The logical file system verifies the existence of the *type* parameter.
`vfs_ops`	Initialized according to the `vfs_type` field.
`vfs_mntdover`	Identifies the v-node that refers to the stub path argument. This argument is supplied by the **mount** or **vmount** subroutine.
`vfs_date`	Holds the time stamp. The time stamp specifies the time to initialize the virtual file system.
`vfs_number`	Indicates the unique number sequence representing this virtual file system.
`vfs_mdata`	Initialized with the **vmount** structure supplied by the user. The virtual file system data is detailed in the **/usr/include/sys/vmount.h** file. All arguments indicated by this field are copied to kernel space.

Execution Environment

The **vfs_mount** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related information

mount subroutine
Virtual File System Overview
Logical File System Overview

vfs_root Entry Point

Purpose

Returns the root v-node of a virtual file system (VFS).

Syntax

```
int vfs_root ( vfsp,   vpp,   crp)
struct vfs *vfsp;
struct vnode **vpp;
struct ucred *crp;
```

Parameters

Item	Description
vfsp	Points to the **vfs** structure.
vpp	Points to the place to return the v-node pointer.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vfs_root** entry point is invoked by the logical file system to get a pointer to the root v-node of the file system. When successful, the *vpp* parameter points to the root virtual node (v-node) and the v-node hold count is incremented.

Execution Environment

The **vfs_root** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Understanding Data Structures and Header Files for Virtual File Systems

Logical File System Overview

vfs_search Kernel Service

Purpose

Searches the vfs list.

Syntax

```
int vfs_search ( vfs_srchfcn,  srchargs)
(int (*vfs_srchfcn)(struct vfs *, caddr_t);
caddr_t srchargs;
```

Parameters

Item	Description
vfs_srchfcn	Points to a search function. The search function is identified by the *vfs_srchfcn* parameter. This function is used to examine or modify an entry in the vfs list. The search function is called once for each currently active VFS. If the search function returns a value of 0, iteration through the vfs list continues to the next entry. If the return value is nonzero, **vfs_search** kernel service returns to its caller, passing back the return value from the search function. When the system invokes this function, the system passes it a pointer to a virtual file system (VFS) and the *srchargs* parameter.
srchargs	Points to data to be used by the search function. This pointer is not used by the **vfs_search** kernel service but is passed to the search function.

Description

The **vfs_search** kernel service searches the vfs list. This kernel service allows a process outside the file system to search the vfs list. The **vfs_search** kernel service locks out all activity in the vfs list during a search. Then, the kernel service iterates through the vfs list and calls the search function on each entry.

The search function must not request locks that could result in deadlock. In particular, any attempt to do lock operations on the vfs list or on other VFS structures could produce deadlock.

The performance of the **vfs_search** kernel service may not be acceptable for functions requiring quick response. Iterating through the vfs list and making an indirect function call for each structure is inherently slow.

Execution Environment

The **vfs_search** kernel service can be called from the process environment only.

Return Values

This kernel service returns the value returned by the last call to the search function.

vfs_statfs Entry Point

Purpose

Returns virtual file system statistics.

Syntax

```
int vfs_stafs ( vfsp, stafsp, crp)
struct vfs *vfsp;
struct statfs *stafsp;
struct ucred *crp;
```

Parameters

Item	Description
vfsp	Points to the **vfs** structure being queried. This structure is defined in the **/usr/include/sys/vfs.h** file.
stafsp	Points to a **statfs** structure. This structure is defined in the **/usr/include/sys/statfs.h** file.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vfs_stafs** entry point is called by the logical file system to obtain file system characteristics. Upon return, the **vfs_statfs** entry point has filled in the following fields of the **statfs** structure:

Field	Description
f_blocks	Specifies the number of blocks.
f_files	Specifies the total number of file system objects.
f_bsize	Specifies the file system block size.
f_bfree	Specifies the number of free blocks.
f_ffree	Specifies the number of free file system objects.
f_fname	Specifies a 32-byte string indicating the file system name.
f_fpack	Specifies a 32-byte string indicating a pack ID.
f_name_max	Specifies the maximum length of an object name.

Fields for which a **vfs** structure has no values are set to 0.

Execution Environment

The **vfs_statfs** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related information

statfs subroutine

Virtual File System Overview

Virtual File System Kernel Extensions Overview

vfs_sync Entry Point

Purpose

Requests that file system changes be written to permanent storage.

Syntax

```
int vfs_sync (* gfsp)
struct gfs *gfsp;
```

Parameter

Item	Description
gfsp	Points to a **gfs** structure. The **gfs** structure describes the file system type. This structure is defined in the **/usr/include/sys/gfs.h** file.

Description

The **vfs_sync** entry point is used by the logical file system to force all data associated with a particular virtual file system type to be written to its storage. This entry point is used to establish a known consistent state of the data.

Note: The **vfs_sync** entry point is called once per file system type rather than once per virtual file system.

Execution Environment

The **vfs_sync** entry point can be called from the process environment only.

Return Values

The **vfs_sync** entry point is advisory. It has no return values.

Related information

sync subroutine

Virtual File System Overview

Virtual File System Kernel Extensions Overview

Logical File System Overview

vfs_umount Entry Point

Purpose

Unmounts a virtual file system.

Syntax

```
int vfs_umount ( vfsp,  crp)
struct vfs *vfsp;
struct ucred *crp;
```

Parameters

Item	Description
vfsp	Points to the **vfs** structure being unmounted. This structure is defined in the **/usr/include/sys/vfs.h** file.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vfs_umount** entry point is called to unmount a virtual file system. The logical file system performs services independent of the virtual file system that initiate the unmounting. The logical file system services:

- Guarantee the syntax of the **uvmount** subroutine.
- Perform permission checks:
  - If the *vfsp* parameter refers to a device mount, then the user must have root user authority to perform the operation.
  - If the *vfsp* parameter does not refer to a device mount, then the user must have root user authority or write permission in the parent directory of the mounted-over virtual node (v-node), as well as write permission to the file represented by the mounted-over v-node.
- Ensure that the virtual file system being unmounted contains no mount points for other virtual file systems.
- Ensure that the root v-node is not in use except for the mount. The root v-node is also referred to as the mounted v-node.
- Clear the `v_mvfsp` field in the stub v-node. This prevents lookup operations already in progress from traversing the soon-to-be unmounted mount point.

The logical file system assumes that, if necessary, successful **vfs_umount** entry point calls free the root v-node. An error return from the **vfs_umount** entry point causes the mount point to be re-established. A 0 (zero) returned from the **vfs_umount** entry point indicates the routine was successful and that the **vfs** structure was released.

Execution Environment

The **vfs_umount** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related information

umount subroutine

vmount subroutine

Understanding Data Structures and Header Files for Virtual File Systems

vfs_vget Entry Point

Purpose

Converts a file identifier into a virtual node (v-node).

Syntax

```
int vfs_vget ( vfsp, vpp, fidp, crp)
struct vfs *vfsp;
struct vnode **vpp;
struct fileid *fidp;
struct ucred *crp;
```

Parameters

Item	Description
vfsp	Points to the virtual file system that is to contain the v-node. Any returned v-node should belong to this virtual file system.
vpp	Points to the place to return the v-node pointer. This is set to point to the new v-node. The fields in this v-node should be set as follows:

v_vntype
> The type of v-node dependent on private data.

v_count
> Set to at least 1 (one).

v_pdata
> If a new file, set to the private data for this file system.

Item	Description
fidp	Points to a file identifier. This is a file system-specific file identifier that must conform to the **fileid** structure.

> **Note:** If the *fidp* parameter is invalid, the *vpp* parameter should be set to a null value by the **vfs_vget** entry point.

Item	Description
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vfs_vget** entry point is called to convert a file identifier into a v-node. This entry point uses information in the *vfsp* and *fidp* parameters to create a v-node or attach to an existing v-node. This v-node represents, logically, the same file system object as the file identified by the *fidp* parameter.

If the v-node already exists, successful operation of this entry point increments the v-node use count and returns a pointer to the v-node. If the v-node does not exist, the **vfs_vget** entry point creates it using the **vn_get** kernel service and returns a pointer to the new v-node.

Execution Environment

The **vfs_vget** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure. A typical value includes:

Item	Description
EINVAL	Indicates that the remote virtual file system specified by the *vfsp* parameter does not support chained mounts.

Related reference
vn_get Kernel Service
Related information
access subroutine
Virtual File System Overview

vnop_access Entry Point

Purpose

Requests validation of user access to a virtual node (v-node).

Syntax

```
int vnop_access ( vp, mode, who, crp)
struct vnode *vp;
int mode;
int who;
struct ucred *crp;
```

Parameters

Item	Description
vp	Points to the v-node.
mode	Identifies the access mode.

Item	Description
who	Specifies the IDs for which to check access. This parameter should be one of the following values, which are defined in the **/usr/include/sys/access.h** file:

ACC_SELF
Determines if access is permitted for the current process. The effective user and group IDs and the supplementary group ID of the current process are used for the calculation.

ACC_ANY
Determines if the specified access is permitted for any user, including the object owner. The *mode* parameter must contain only one of the valid modes.

ACC_OTHERS
Determines if the specified access is permitted for any user, excluding the owner. The *mode* parameter must contain only one of the valid modes.

ACC_ALL
Determines if the specified access is permitted for all users. (This is a useful check to make when files are to be written blindly across networks.) The *mode* parameter must contain only one of the valid modes.

Item	Description
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_access** entry point is used by the logical volume file system to validate access to a v-node. This entry point is used to implement the **access** subroutine. The v-node is held for the duration of the **vnop_access** entry point. The v-node count is unchanged by this entry point.

In addition, the **vnop_access** entry point is used for permissions checks from within the file system implementation. The valid types of access are listed in the **/usr/include/sys/access.h** file. Current modes are read, write, execute, and existence check.

Note: The **vnop_access** entry point must ensure that write access is not requested on a read-only file system.

Execution Environment

The **vnop_access** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure. A typical value includes:

Item	Description
EACCES	Indicates no access is allowed.

Related information
access subroutine
Virtual File System Overview
Virtual File System Kernel Extensions Overview

vnop_close Entry Point

Purpose

Closes a file associated with a v-node (virtual node).

Syntax

```
int vnop_close ( vp,   flag,   vinfo,   crp)
struct vnode *vp;
int flag;
caddr_t vinfo;
struct ucred *crp;
```

Parameters

Item	Description
vp	Points to the v-node.
flag	Identifies the flag word from the file pointer.
vinfo	This parameter is not used.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_close** entry point is used by the logical file system to announce that the file associated with a given v-node is now closed. The v-node continues to remain active but will no longer receive read or write requests through the **vnop_rdwr** entry point.

A **vnop_close** entry point is called only when the use count of an associated file structure entry goes to 0 (zero).

Note: The v-node is held over the duration of the **vnop_close** entry point.

Execution Environment

The **vnop_close** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Note: The **vnop_close** entry point may fail and an error will be returned to the application. However, the v-node is considered closed.

Related reference
vnop_open Entry Point
Related information
close subroutine
Virtual File System Overview

vnop_create Entry Point

Purpose

Creates a new file.

Syntax

```
int vnop_create (dp, vpp, flag, pname, mode, vinfop, crp)
struct vnode * dp;
struct vnode ** vpp;
int   flag;
char * pname;
int   mode;
caddr_t * vinfop;
struct ucred * crp;
```

Parameters

Item	Description
dp	Points to the virtual node (v-node) of the parent directory.
vpp	Points to the place in which the pointer to a v-node for the newly created file is returned.
flag	Specifies an integer flag word. The **vnop_create** entry point uses this parameter to open the file.
pname	Points to the name of the new file.
mode	Specifies the mode for the new file.
vinfop	This parameter is unused.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_create** entry point is invoked by the logical file system to create a regular (v-node type **VREG**) file in the directory specified by the *dp* parameter. (Other v-node operations create directories and special files.) Virtual node types are defined in the **/usr/include/sys/vnode.h** file. The v-node of the parent directory is held during the processing of the **vnop_create** entry point.

To create a file, the **vnop_create** entry point does the following:

- Opens the newly created file.
- Checks that the file system associated with the directory is not read-only.

  Note: The logical file system calls the **vnop_lookup** entry point before calling the **vnop_create** entry point.

Execution Environment

The **vnop_create** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related reference
vnop_lookup Entry Point

Virtual File System Overview
Virtual File System Kernel Extensions Overview

vnop_create_attr Entry Point

Purpose

Creates a new file.

Syntax

int vnop_create_attr *(dvp, vpp, flags, name, vap, vcf, finfop, crp)* **struct vnode** **dvp*; **struct vnode** **vpp*; **int flags**; **char** **name*; **struct vattr** **vap*; **int** *vcf*; **caddr_t** *finfop*; **struct ucred** **crp*;

Parameters

Item	Description
dvp	Points to the directory vnode.
vpp	Points to the newly created vnode pointer.
flags	Specifies file creation flags.
name	Specifies the name of the file to create.
vattr	Points to the initial attributes.
vcf	Specifies create flags.
finfop	Specifies address of finfo field.
crp	Specifies user's credentials.

Description

The **vnop_create_attr** entry point is used to create a new file. This operation is similar to the vnop_create entry point except that the initial file attributes are passed in a vattr structure.

The va_mask field in the vattr structure identifies which attributes are to be applied. For example, if the AT_SIZE bit is set, then the file system should use va_size for the initial file size. For all vnop_create_attr calls, at least AT_TYPE and AT_MODE must be set.

The vcf parameter controls how the new vnode is to be activated. If vcf is set to VC_OPEN, then the new object should be opened. If vcf is VC_LOOKUP, then the new object should be created, but not opened. If vcf is VC_DEFAULT, then the new object should be created, but the vnode for the object is not activated.

File systems that do not define GFS_VERSION421 in their gfs flags do not need to supply a vnop_create_attr entry point. The logical file system will funnel all creation requests through the old vnop_create entry point.

Execution Environment

The **vnop_create_attr** entry point can be called from the process environment only.

Return Values

Item	Description
Zero	Indicates a successful operation; *vpp* contains a pointer to the new vnode.
Nonzero	Indicates that the operation failed; return values should be chosen from the **/usr/include/sys/errno.h** file.

vnop_fclear Entry Point

Purpose

Releases portions of a file.

Syntax

```
int vnop_fclear (vp, flags, offset, len, vinfo, crp)
struct vnode * vp;
int   flags;
offset_t  offset;
offset_t  len;
caddr_t   vinfo;
struct ucred * crp;
```

Parameters

Item	Description
vp	Points to the virtual node (v-node) of the file.
flags	Identifies the flags from the open file structure.
offset	Indicates where to start clearing in the file.
len	Specifies the length of the area to be cleared.
vinfo	This parameter is unused.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_fclear** entry point is called from the logical file system to clear bytes in a file, returning whole free blocks to the underlying file system. This entry point performs the clear regardless of whether the file is mapped.

Upon completion of the **vnop_fclear** entry point, the logical file system updates the file offset to reflect the number of bytes cleared. Also upon completion, if either the starting or ending offset is past the starting end of file, the file is extended.

Execution Environment

The **vnop_fclear** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related information
fclear subroutine
Virtual File System Overview

vnop_fid Entry Point

Purpose

Builds a file identifier for a virtual node (v-node).

Syntax

```
int vnop_fid ( vp,   fidp,   crp)
struct vnode *vp;
struct fileid *fidp;
struct ucred *crp;
```

Parameters

Item	Description
vp	Points to the v-node that requires the file identifier.
fidp	Points to where to return the file identifier.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_fid** entry point is invoked to build a file identifier for the given v-node. This file identifier must contain sufficient information to find a v-node that represents the same file when it is presented to the **vfs_get** entry point.

Execution Environment

The **vnop_fid** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related information
Virtual File System Overview
Virtual File System Kernel Extensions Overview

vnop_finfo Entry Point

Purpose

Returns information about a file.

Syntax

int vnop_finfo *(vp, cmd, bufp, length, crp)* **struct vnode** **vp*; **int** *cmd*; **void** **bufp*; **int** *length*; **struct ucred** **crp*;

Parameters

Item	Description
vp	Points to the vnode to be queried.
cmd	Specifies the command parameter.
bufp	Points to the buffer for the information.
length	Specifies the length of the buffer.
crp	Specifies user's credentials.

Description

The **vnop_finfo** entry point is used to query a file system. It is used primarily to implement the **pathconf** and **fpathconf** subroutines. The **command** parameter defines what type of query is being done. The query commands and the associated data structures are defined in **<sys/finfo.h>**. If the file system does not support the particular query, it should return ENOSYS.

File systems that do not define GFS_VERSION421 in their gfs flags do not need to supply a **vnop_finfo** entry point. If the command is FI_PATHCONF, then the logical file system returns generic pathconf information. If the query is other than FI_PATHCONF, then the request fails with EINVAL.

Execution Environment

The **vnop_finfo** entry point can be called from the process environment only.

Return Values

Item	Description
Zero	Indicates a successful operation.
Nonzero	Indicates that the operation failed; return values should be chosen from the **/usr/include/sys/errno.h** file.

Related information

pathconf, fpathconf
Virtual File System Overview
Logical File System Overview

vnop_fsync, vnop_fsync_range Entry Points

Purpose

Flushes file data from memory to disk.

Syntax

int vnop_fsync (*vp*, *flags*, *vinfo*, *crp***)**
struct vnode **vp***;**
long *flags***;**
long *vinfo***;**
struct ucred **crp***;**

int vnop_fsync_range (*vp*, *flags*, *vinfo*, *offset*, *length*, *crp***)**
struct vnode **vp***;**
long *flags***;**
long *vinfo***;**
offset_t *offset***;**
offset_t *length***;**
struct ucred **crp***;**

Parameters

Item	Description
vp	Points to the virtual node (v-node) of the file.
flags	Identifies flags from the open file and the flags that govern the action to be taken. It can be one of the following values:
	FDATASYNC The changed data in the range specified by the `offset` and `length` parameters is written to the storage. If the metadata of the file is changed and this changed metadata must read the data, the metadata is also written to the storage. Otherwise, the metadata is not updated.
	FFILESYNC The changed data in the range specified by the `offset` and `length` parameters is written to the storage. If any metadata is changed, all of the changed user data is written to the storage. Metadata changes and file attributes including time stamps are also written to the storage.
	FNOCACHE The changed data is written to the storage similar to the FDATASYNC flag value. The full pages in the range specified by the `offset` and `length` parameters are removed from the memory cache. The pages are removed from the cache even if the pages are not changed. This operation is also applicable to the files that are open only for reading.
vinfo	This parameter is currently not used.
offset	Specifies the starting offset in the file of the data to be flushed.
length	Specifies the length of the data to be flushed. If you specify the value as zero, all cached data is flushed.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_fsync** entry point is called by the logical file system to request that all modifications associated with a given v-node to be flushed out to permanent storage. This must be done synchronously so that the caller can assure that all I/O has completed successfully. The **vnop_fsync_range** entry point provides the same function but limits the data to be written to a specified range in the file.

Execution Environment

The **vnop_fsync** and **vnop_fsync_range** entry points can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

vnop_ftrunc Entry Point

Purpose

Truncates a file.

Syntax

```
int vnop_ftrunc (vp, flags, length, vinfo, crp)
struct vnode * vp;
int   flags;
offset_t  length;
caddr_t  vinfo;
struct ucred * crp;
```

Parameters

Item	Description
vp	Points to the virtual node (v-node) of the file.
flags	Identifies flags from the open file structure.
length	Specifies the length to which the file should be truncated.
vinfo	This parameter is unused.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_ftrunc** entry point is invoked by the logical file system to decrease the length of a file by truncating it. This operation is unsuccessful if any process other than the caller has locked a portion of the file past the specified offset.

Execution Environment

The **vnop_ftrunc** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related information

vnop_getacl Entry Point

Purpose

Retrieves the access control list (ACL) for a file.

Syntax

```
#include <sys/acl.h>

int vnop_getacl ( vp, uiop, crp)
struct vnode *vp;
struct uio *uiop;
struct ucred *crp;
```

Description

The **vnop_getacl** entry point is used by the logical file system to retrieve the access control list (ACL) for a file to implement the **getacl** subroutine.

Parameters

Item	Description
vp	Specifies the virtual node (v-node) of the file system object.
uiop	Specifies the **uio** structure that defines the storage for the ACL.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Execution Environment

The **vnop_getacl** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates a successful operation.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure. A valid value includes:

Item	Description
ENOSPC	Indicates that the buffer size specified in the *uiop* parameter was not large enough to hold the ACL. If this is the case, the first word of the user buffer (data in the **uio** structure specified by the *uiop* parameter) is set to the appropriate size.

vnop_getattr Entry Point

Purpose

Gets the attributes of a file.

Syntax

```
int vnop_getattr ( vp,   vap,   crp)
struct vnode *vp;
struct vattr *vap;
struct ucred *crp;
```

Parameters

Item	Description
vp	Specifies the virtual node (v-node) of the file system object.
vap	Points to a **vattr** structure.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_getattr** entry point is called by the logical file system to retrieve information about a file. The **vattr** structure indicated by the *vap* parameter contains all the relevant attributes of the file. The **vattr** structure is defined in the **/usr/include/sys/vattr.h** file. This entry point is used to implement the **stat**, **fstat**, and **lstat** subroutines.

Note: The indicated v-node is held for the duration of the **vnop_getattr** subroutine.

Execution Environment

The **vnop_getattr** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related information

statx subroutine

Virtual File System Overview

Virtual File System Kernel Extensions Overview

vnop_getxacl Entry Point

Purpose

Retrieves the access control list (ACL) for a file. This is an advanced version of **vnop_getacl** interface.

Syntax

```
#include <sys/acl.h>
int vnop_getxacl (vp, ctl_flags, acl_type, uiop, acl_len, mode_info, crp)

struct vnode    *vp;
uint64_t        ctl_flags;
acl_type_t      *acl_type;
struct uio      *uiop;
size_t          *acl_len;
mode_t          *mode_info;
struct ucred    *crp;
```

Description

The **vnop_getxacl** entry point retrieves the access control list (ACL) for a file system object. It is an advanced version of **vnop_getacl** interface and provides for ACL-type-based operations. Note that this interface can be used to obtain the ACL type and length information, without actually retrieving the ACL data (see the *ctl_flags* description for more details).

Parameters

Item	Description
vp	Specifies the virtual node (v-node) of the file system object.

Item	Description
acl_type	Points to buffer space for file systems to return the ACL type associated with the file system object. The value should normally be set to **ACL_ANY** or 0 when the call is made. Some physical file systems can solicit ACL requests for a particular ACL type. In such cases, the caller provides the ACL type requested in this buffer.
	Note: The latter issue is file system implementation specific. For example, when ACL information is requested with an input ACL type, a physical file system might return an error if the existing ACL associated with the file system object is of a different ACL type. Or, the file system might emulate an ACL of the type requested and return.
acl_len	Pointer to a *length* variable. The space pointed to is used as an input, as well as output, parameter. As input, the value will indicate the size of buffer *uiop*. When the call returns, this space holds the actual length of the ACL (true for when the call is successful or when the call fails with **errno** set to **ENOSPC**).
ctl_flags	A 64-bit bit mask that provides control over the ACL retrieval and for any future variations in the interface. The following value is defined for these flags:
	GET_ACLINFO_ONLY Gets only the ACL type and length information from the underlying file system. When this bit is set, arguments such as *mode_info* can be set to NULL. All other cases must be valid buffer pointers or else an error is returned. If this bit is not specified, all the other information about the ACL (such as ACL data and mode information) is returned.
uiop	Specifies the **uio** structure that provides space for the store of the ACL.
mode_info	This value indicates any mode word information that needs to be retrieved for the file system object as part of this ACL get operation.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Execution Environment

The **vnop_getxacl** entry point can be called from the process environment only.

Return Values

Upon successful completion, the **vnop_getxacl** entry point returns 0. Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Item	Description
ENOSPC	Indicates that the buffer size specified in the *uiop* parameter was not large enough to hold the ACL.

Note: This list of error numbers is not complete and is dependent on the particular physical file system implementation supporting the ACL.

Related reference
uio Structure

chacl subroutine
Virtual File System Overview

vnop_hold Entry Point

Purpose

Assures that a virtual node (v-node) is not destroyed.

Syntax

int vnop_hold (*vp***)**
struct vnode **vp***;**

Parameter

Item	Description
vp	Points to the v-node.

Description

The **vnop_hold** entry point increments the `v_count` field, the hold count on the v-node, and the v-node's underlying g-node (generic node). This incrementation assures that the v-node is not deallocated.

Execution Environment

The **vnop_hold** entry point can be called from the process environment only.

Return Values

The **vnop_hold** entry point cannot fail and therefore has no return values.

Related information

Virtual File System Overview

vnop_ioctl Entry Point

Purpose

Requests I/O control operations on special files.

Syntax

int vnop_ioctl (*vp, cmd, arg, flags, ext, crp***)**
struct vnode * *vp***;**
int *cmd***;**
caddr_t *arg***;**
int *flags, ext***;**
struct ucred * *crp***;**

Parameters

Item	Description
vp	Points to the virtual node (v-node) on which to perform the operation.

Item	Description
cmd	Identifies the specific command. Common operations for the **ioctl** subroutine are defined in the **/usr/include/sys/ioctl.h** file. The file system implementation can define other **ioctl** operations.
arg	Defines a command-specific argument. This parameter can be a single word or a pointer to an argument (or result structure).
flags	Identifies flags from the open file structure.
ext	Specifies the extended parameter passed by the **ioctl** subroutine. The **ioctl** subroutine always sets the *ext* parameter to 0.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_ioctl** entry point is used by the logical file system to perform miscellaneous operations on special files. If the file system supports special files, the information is passed down to the **ddioctl** entry point of the device driver associated with the given v-node.

Execution Environment

The **vnop_ioctl** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure. A valid value includes:

Item	Description
EINVAL	Indicates the file system does not support the entry point.

Related information
ioctl subroutine
Logical File System Overview

vnop_link Entry Point

Purpose

Requests a hard link to a file.

Syntax

```
int vnop_link ( vp,   dp,   name,   crp)
struct vnode *vp;
struct vnode *dp;
caddr_t *name;
struct ucred *crp;
```

Parameters

Item	Description
vp	Points to the virtual node (v-node) to link to. This v-node is held for the duration of the linking process.
dp	Points to the v-node for the directory in which the link is created. This v-node is held for the duration of the linking process.
name	Identifies the new name of the entry.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_link** entry point is invoked to create a new hard link to an existing file as part of the link subroutine. The logical file system ensures that the *dp* and *vp* parameters reside in the same virtual file system, which is not read-only.

Execution Environment

The **vnop_link** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related information

vnop_lockctl Entry Point

Purpose

Sets, checks, and queries record locks.

Syntax

```
int vnop_lockctl (vp, offset, lckdat, cmd, retry_fn, retry_id, crp)
struct vnode * vp;
offset_t   offset;
struct eflock * lckdat;
int   cmd;
int (* retry_fn)();
caddr_t   retry_id;
struct ucred * crp;
```

Parameters

Item	Description
vp	Points to the file's virtual node (v-node).
offset	Indicates the file offset from the open file structure. This parameter is used to establish where the lock region begins.
lckdat	Points to the **elock** structure. This structure describes the lock operation to perform.
cmd	Identifies the type of lock operation the **vnop_lockctl** entry point is to perform. It is a bit mask that takes the following lock-control values:

SETFLCK
  If set, performs a lock set or clear. If clear, returns the lock information. The `l_type` field in the **eflock** structure indicates whether a lock is set or cleared.

SLPFLCK
  If the lock is unavailable immediately, wait for it. This is only valid when the **SETFLCK** flag is set.

retry_fn	Points to a subroutine that is called when a lock is retried. This subroutine is not used if the lock is granted immediately.

  Note: If the *retry_fn* parameter is not a null value, the **vnop_lockctl** entry point will not sleep, regardless of the **SLPFLCK** flag.

retry_id	Points to the location where a value can be stored. This value can be used to correlate a retry operation with a specific lock or set of locks. The retry value is only used in conjunction with the *retry_fn* parameter.

  Note: This value is an opaque value and should not be used by the caller for any purpose other than a lock correlation. (This value should not be used as a pointer.)

crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_lockctl** entry point is used to request record locking. This entry point uses the information in the **eflock** structure to implement record locking.

If a requested lock is blocked by an existing lock, the **vnop_lockctl** entry point should establish a sleeping lock with the retry subroutine address (specified by the *retry_fn* parameter) stored in the entry point. The **vnop_lockctl** entry point then returns a correlating ID value to the caller (in the *retry_id* parameter), along with an exit value of **EAGAIN**. When the sleeping lock is later awakened, the retry subroutine is called with the *retry_id* parameter as its argument.

eflock Structure

The **eflock** structure is defined in the **/usr/include/sys/flock.h** file and includes the following fields:

Field	Description
l_type	Specifies type of lock. This field takes the following values:

F_RDLCK
Indicates read lock.

F_WRLCK
Indicates write lock.

F_UNLCK
Indicates unlock this record. A value of **F_UNLCK** starting at 0 until 0 for a length of 0 means unlock all locks on this file. Unlocking is done automatically when a file is closed.

Field	Description
l_whence	Specifies location that the l_start field offsets.
l_start	Specifies offset from the l_whence field.
l_len	Specifies length of record. If this field is 0, the remainder of the file is specified.
l_vfs	Specifies virtual file system that contains the file.
l_sysid	Specifies value that uniquely identifies the host for a given virtual file system. This field must be filled in before the call to the **vnop_lockctl** entry point.
l_pid	Specifies process ID (PID) of the lock owner. This field must be filled in before the call to the **vnop_lockctl** entry point.

Execution Environment

The **vnop_lockctl** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure. Valid values include:

Item	Description
EAGAIN	Indicates a blocking lock exists and the caller did not use the **SLPFLCK** flag to request that the operation sleep.
ERRNO	Returns an error number from the **/usr/include/sys/errno.h** file on failure.

Related information
Virtual File System Overview
Logical File System Overview

vnop_lookup Entry Point

Purpose

Returns a v-node for a given name in a directory.

Syntax

```
int vnop_lookup (dvp, vpp, name, vattrp , crp)
struct vnode * dvp;
struct vnode ** vpp;
char * name;
struct vattr * vattrp;
struct ucred * crp;
```

Parameters

Item	Description
dvp	Points to the virtual node (v-node) of the directory to be searched. The logical file system verifies that this v-node is of a VDIR type.
name	Points to a null-terminated character string containing the file name to look up.
vattrp	Points to a **vattr** structure. If this pointer is NULL, no action is required of the file system implementation. If it is not NULL, the attributes of the file specified by the *name* parameter are returned at the address passed in the *vattrp* parameter.
vpp	Points to the place to which to return the v-node pointer, if the pointer is found. Otherwise, a null character should be placed in this memory location.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_lookup** entry point is invoked by the logical file system to find a v-node. It is used by the kernel to convert application-given path names to the v-nodes that represent them.

The use count in the v-node specified by the *dvp* parameter is incremented for this operation, and it is not decremented by the file system implementation.

If the name is found, a pointer to the desired v-node is placed in the memory location specified by the *vpp* parameter, and the v-node hold count is incremented. (In this case, this entry point returns 0.) If the file name is not found, a null character is placed in the *vpp* parameter, and the function returns a **ENOENT** value. Errors are reported with a return code from the **/usr/include/sys/errno.h** file. Possible errors are usually specific to the particular virtual file system involved.

Execution Environment

The **vnop_lookup** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Logical File System Overview

vnop_map Entry Point

Purpose

Validates file mapping requests.

Syntax

```
int vnop_map (vp, addr, length, offset, flags, crp)
struct vnode * vp;
caddr_t   addr;
uint   length;
uint   offset;
uint   flags;
struct ucred * crp;
```

Parameters

Note: The *addr, offset*, and *length* parameters are unused in the current implementation. The file system is expected to store the segment ID with the file in the gn_seg field of the g-node for the file.

Item	Description
vp	Points to the virtual node (v-node) of the file.
addr	Identifies the location within the process address space where the mapping is to begin.
length	Specifies the maximum size to be mapped.
offset	Specifies the location within the file where the mapping is to begin.
flags	Identifies what type of mapping to perform. This value is composed of bit values defined in the **/usr/include/sys/shm.h** file. The following values are of particular interest to file system implementations:

SHM_RDONLY
   The virtual memory object is read-only.

SHM_COPY
   The virtual memory object is copy-on-write. If this value is set, updates to the segment are deferred until an **fsync** operation is performed on the file. If the file is closed without an **fsync** operation, the modifications are discarded. The application that called the **vnop_map** entry point is also responsible for calling the **vnop_fsync** entry point.

   Note: Mapped segments do not reflect modifications made to a copy-on-write segment.

Item	Description
crp	Points to the **cred** structure. This structure contains data that applications can use to validate access permission.

Description

The **vnop_map** entry point is called by the logical file system to validate mapping requests resulting from the **mmap** or **shmat** subroutines. The logical file system creates the virtual memory object (if it does not already exist) and increments the object's use count.

Execution Environment

The **vnop_map** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related reference

shmat subroutine
Virtual File System Kernel Extensions Overview

vnop_map_lloff Entry Point

Purpose

Announces intention to map a file.

Syntax

int vnop_map_lloff *(vp, addr, length, offset, mflags, fflags, crp)* **struct vnode** **vp*; **caddr_t** *addr*; **offset_t** *length*; **offset_t** *offset*; **int** *mflags*; **int** *fflags*; **struct ucred** **crp*;

Parameters

Item	Description
vp	Points to the vnode to be queried.
addr	Unused.
length	Specifies the length of the mapping request.
offset	Specifies the starting offset for the map request.
mflags	Specifies the mapping flags.
fflags	Specifies the file flags.
crp	Specifies user's credentials.

Description

The **vnop_map_lloff** entry point is used to tell the file system that the file is going to be accessed by memory mapped loads and stores. The file system should fail the request if it does not support memory mapping. This interface allows applications to specify starting offsets that are larger than 2 gigabytes.

File systems that do not define GFS_VERSION421 in their gfs flags do not need to supply a **vnop_map_lloff** entry point.

Execution Environment

The **vnop_map_lloff** entry point can be called from the process environment only.

Return Values

Item	Description
Zero	Indicates a successful operation.
Nonzero	Indicates that the operation failed; return values should be chosen from the **/usr/include/sys/errno.h** file.

Related information

shmat subroutine

mmap subroutine

Virtual File System Kernel Extensions Overview

vnop_memcntl Entry Point

Purpose

Changes or queries the physical attachment of a file.

Syntax

```
#include <sys/vnode.h>
#include <sys/fcntl.h>
```

int vnop_memcntl (*vnode*, *cmd*, *arg*, *crp*)
struct gnode * *vnode*;
int *cmd*;
void * *arg*;
struct ucred * *crp*;

Parameters

Item	Description
vnode	Points to the virtual node of the file
cmd	Specifies the operation to be performed. The *cmd* parameter can be one of the following values: • **F_ATTACH** • **F_DETACH** • **F_ATTINFO**
arg	Points to a structure containing the attach_desc_t, detach_desc_t or attinfo_desc_t information according to the specified *cmd* parameter. **F_ATTACH** attach_desc_t **F_DETACH** detach_desc_t **F_ATTINFO** attinfo_desc_t
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_memcntl** entry point requests memory attachment operations as specified by the *cmd* parameter. The *cmd* parameter determines the *arg* structure.

Execution Environment

The **vnop_memcntl** entry point can be called from the process environment only.

Return Values

Item	Description
0	Success.
non-zero	Failure.

Related information
Workload management

vnop_mkdir Entry Point

Purpose

Creates a directory.

Syntax

```
int vnop_mkdir ( dp,   name,   mode,   crp)
struct vnode *dp;
caddr_t name;
int mode;
struct ucred *crp;
```

Parameters

Item	Description
dp	Points to the virtual node (v-node) of the parent directory of a new directory. This v-node is held for the duration of the entry point.
name	Specifies the name of a new directory.
mode	Specifies the permission modes of a new directory.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_mkdir** entry point is invoked by the logical file system as the result of the **mkdir** subroutine. The **vnop_mkdir** entry point is expected to create the named directory in the parent directory associated with the *dp* parameter. The logical file system ensures that the *dp* parameter does not reside on a read-only file system.

Execution Environment

The **vnop_mkdir** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related information

mkdir subroutine

Virtual File System Overview

Logical File System Overview

vnop_mknod Entry Point

Purpose

Creates a special file.

Syntax

```
int vnop_mknod (dvp, name, mode, dev, crp)
struct vnode * dvp;
caddr_t * name;
int   mode;
dev_t  dev;
struct ucred * crp;
```

Parameters

Item	Description
dvp	Points to the virtual node (v-node) for the directory to contain the new file. This v-node is held for the duration of the **vnop_mknod** entry point.
name	Specifies the name of a new file.
mode	Identifies the integer mode that indicates the type of file and its permissions.
dev	Identifies an integer device number.
crp	Points to the **cred** structure. This structure contains data that applications can use to validate access permission.

Description

The **vnop_mknod** entry point is invoked by the logical file system as the result of a **mknod** subroutine. The underlying file system is expected to create a new file in the given directory. The file type bits of the *mode* parameter indicate the type of file (regular, character special, or block special) to be created. If a special file is to be created, the *dev* parameter indicates the device number of the new special file.

The logical file system verifies that the *dvp* parameter does not reside in a read-only file system.

Execution Environment

The **vnop_mknod** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related information
mknod subroutine
Virtual File System Overview
Logical File System Overview

vnop_open Entry Point

Purpose

Requests that a file be opened for reading or writing.

Syntax

```
int vnop_open (vp, flag, ext, vinfop, crp)
struct vnode * vp;
int   flag;
caddr_t   ext;
caddr_t   vinfop;
struct ucred * crp;
```

Parameters

Item	Description
vp	Points to the virtual node (v-node) associated with the desired file. The v-node is held for the duration of the open process.
flag	Specifies the type of access. Access modes are defined in the **/usr/include/sys/fcntl.h** file. **Note:** The **vnop_open** entry point does not use the FCREAT mode.
ext	Points to external data. This parameter is used if the subroutine is opening a device.
vinfop	This parameter is not currently used.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_open** entry point is called to initiate a process access to a v-node and its underlying file system object. The operation of the **vnop_open** entry point varies between virtual file system (VFS) implementations. A successful **vnop_open** entry point must leave a v-node count of at least 1.

The logical file system ensures that the process is not requesting write access (with the FWRITE or FTRUNC mode) to a read-only file system.

Execution Environment

The **vnop_open** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

vnop_rdwr, vnop_rdwr_attr Entry Points

Purpose

Requests file I/O.

Syntax

int vnop_rdwr (*vp, op, flags, uiop, ext, vinfo, vattrp, crp*)
struct vnode * *vp*;
enum uio_rw *op*;
int *flags*;
struct uio * *uiop*;
int *ext*;
caddr_t *vinfo*;
struct vattr * *vattrp;*
struct ucred * *crp*;

int vnop_rdwr_attr (*vp, op, flags, uiop, ext, vinfo, vpre, vpost, crp*)
struct vnode * *vp*;
enum uio_rw *op*;
long *flags*;
struct uio * *uiop*;
ext_t *ext*;
caddr_t *vinfo*;
struct vattr * *vpre;*
struct vattr * *vpost;*
struct ucred * *crp*;

Parameters

Item	Description
vp	Points to the virtual node (v-node) of the file.
op	Specifies a number that indicates a read or write operation. This parameter has a value of either **UIO_READ** or **UIO_WRITE**. These values are found in the **/usr/include/sys/uio.h** file.
flags	Identifies flags from the open file structure.
uiop	Points to a **uio** structure. This structure describes the count, data buffer, and other I/O information.
ext	Provides an extension for special purposes. Its use and meaning are specific to virtual file systems, and it is usually ignored except for devices.
vinfo	This parameter is currently not used.
vattrp	Points to a **vattr** structure. If this pointer is NULL, no action is required of the file system implementation. If it is not NULL, the attributes of the file specified by the *vp* parameter are returned at the address passed in the *vattrp* parameter.
vpre	Points to an attributes structure for pre-operation attributes.
vpost	Points to an attributes structure for post-operation attributes.

Item	Description
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_rdwr** entry point is used to request that data to be read or written from an object represented by a v-node. The **vnop_rdwr** entry point does the indicated data transfer and sets the number of bytes *not* transferred in the uio_resid field. This field is 0 (zero) on successful completion.

The **vnop_rdwr_attr** kernel service performs the same function as the **vnop_rdwr** kernel service but also allows the caller to retrieve attributes of the object either before the I/O, after or both.

Execution Environment

The **vnop_rdwr** and **vnop_rdwr_attr** entry points can be called from the process environment only.

Return Values

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure. The **vnop_rdwr** entry point returns an error code if an operation did not transfer all the data requested. The only exception is if an end of file is reached on a read request. In this case, the operation still returns 0.

Related reference
vnop_create Entry Point
vnop_open Entry Point
Related information
Virtual File System Kernel Extensions Overview

vnop_readdir Entry Point

Purpose

Reads directory entries in standard format.

Syntax

```
int vnop_readdir ( vp,  uiop,  crp)
struct vnode *vp;
struct uio *uiop;
struct ucred *crp;
```

Parameters

Item	Description
vp	Points to the virtual node (v-node) of the directory.
uiop	Points to the **uio** structure that describes the data area into which to put the block of **dirent** structures. The starting directory offset is found in the uiop->uio_offset field and the size of the buffer area is found in the uiop->uio_resid field.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_readdir** entry point is used to access directory entries in a standard way. These directories should be returned as an array of **dirent** structures. The **/usr/include/sys/dir.h** file contains the definition of a **dirent** structure.

The **vnop_readdir** entry point does the following:

- Copies a block of directory entries into the buffer specified by the *uiop* parameter.
- Sets the `uiop->uio_resid` field to indicate the number of bytes read.

The End-of-file character should be indicated by not reading any bytes (not by a partial read). This provides directories with the ability to have some hidden information in each block.

The virtual file system-specific implementation is also responsible for setting the `uio_offset` field to the offset of the next whole block to be read.

Notes:

- If the call is meant for a JFS2 filesystem, extra processing is needed to avoid duplicate entries being returned in the user data area. The caller can check the VFS type from the directory vnode.
- The caller must allocate a two-element array of type `struct` **iovec** to pass with the **uio** structure. The first element is initialized to point to the user data area to receive the **dirent** structures. If the file pointer of the directory has a non-NULL `f_vinfo` field, the second `iovec` element is initialized to point to the `f_vinfo` field and the length is set to 0; the number of elements in the **uio** structure is set to 2. If the `f_vinfo` field is NULL, then the number of elements in the **uio** structure is set to 1 and the second `iovec` element remains uninitialized.
- If the caller does not have access to the directory file pointer, a **dirent** structure can be allocated in place of the `f_vinfo` field. The caller must not change this allocated structure between calls to the **vnop_readdir** entry point.

Execution Environment

The **vnop_readdir** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related information

readdir subroutine
Virtual File System Overview
Logical File System Overview

vnop_readdir_eofp Entry Point

Purpose

Returns directory entries.

Syntax

int vnop_readdirr_eofp *(vp, uiop, eofp, crp)* **struct vnode** **vp*; **struct uio** **uiop*; **int** **eofp*; **struct ucred** **crp*;

Parameters

Item	Description
vp	Points to the directory vnode to be processed.
uiop	Points to the uiop structure describing the user's buffer.
eofp	Points to a word that places the eop structure.
crp	Specifies user's credentials.

Description

The **vnop_readdir_eofp** entry point is used to read directory entries. It is similar to **vnop_readdir** except that it takes the additional parameter, *eofp*. The location pointed to by the *eofp* parameter should be set to 1 if the readdir request reached the end of the directory. Otherwise, it should be set to 0.

File systems that do not define GFS_VERSION421 in their gfs flags do not need to supply a **vnop_readdir_eofp** entry point.

Note: If the call is meant for a JFS2 file system, extra processing is needed to avoid duplicate entries being returned in the user data area, similar to the vnop_readdir entry point.

Execution Environment

The **vnop_readdir_eofp** entry point can be called from the process environment only.

Return Values

Item	Description
Zero	Indicates a successful operation.
Nonzero	Indicates that the operation failed; return values should be chosen from the **/usr/include/sys/errno.h** file.

Related reference

vnop_readlink Entry Point

Purpose

Reads the contents of a symbolic link.

Syntax

```
int vnop_readlink ( vp,  uio,  crp)
struct vnode *vp;
struct uio *uio;
struct ucred *crp;
```

Parameters

Item	Description
vp	Points to a virtual node (v-node) structure. The **vnop_readlink** entry point holds this v-node for the duration of the routine.
uio	Points to a **uio** structure. This structure contains the information required to read the link. In addition, it contains the return buffer for the **vnop_readlink** entry point.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_readlink** entry point is used by the logical file system to get the contents of a symbolic link, if the file system supports symbolic links. The logical file system finds the v-node (virtual node) for the symbolic link, so this routine simply reads the data blocks for the symbol link.

Execution Environment

The **vnop_readlink** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related reference
uio Structure
Related information
Virtual File System Kernel Extensions Overview
Logical File System Overview

vnop_rele Entry Point

Purpose

Releases a reference to a virtual node (v-node).

Syntax

```
int vnop_rele ( vp,)
struct vnode *vp;
```

Parameter

Item	Description
vp	Points to the v-node.

Description

The **vnop_rele** entry point is used by the logical file system to release the object associated with a v-node. If the object was the last reference to the v-node, the **vnop_rele** entry point then calls the **vn_free** kernel service to deallocate the v-node.

If the virtual file system (VFS) was unmounted while there were open files, the logical file system sets the **VFS_UNMOUNTING** flag in the **vfs** structure. If the flag is set and the v-node to be released is the last v-node on the chain of the **vfs** structure, then the virtual file system must be deallocated with the **vnop_rele** entry point.

Execution Environment

The **vnop_rele** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related reference
vn_free Kernel Service

vnop_remove Entry Point

Purpose

Unlinks a file or directory.

Syntax

```
int vnop_remove ( vp, dvp, name, crp)
struct vnode *vp;
struct vnode *dvp;
char *name;
struct ucred *crp;
```

Parameters

Item	Description
vp	Points to a virtual node (v-node). The v-node indicates which file to remove and is held over the duration of the **vnop_remove** entry point.
dvp	Points to the v-node of the parent directory. This directory contains the file to be removed. The directory's v-node is held for the duration of the **vnop_remove** entry point.
name	Identifies the name of the file.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_remove** entry point is called by the logical file system to remove a directory entry (or link) as the result of a call to the **unlink** subroutine.

The logical file system assumes that the **vnop_remove** entry point calls the **vnop_rele** entry point. If the link is the last reference to the file in the file system, the disk resources that the file is using are released.

The logical file system ensures that the directory specified by the *dvp* parameter does not reside in a read-only file system.

Execution Environment

The **vnop_remove** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related reference
vnop_rele Entry Point

Virtual File System Overview

vnop_rename Entry Point

Purpose

Renames a file or directory.

Syntax

```
int vnop_rename (srcvp, srcdvp, oldname, destvp, destdvp, newname, crp)
struct vnode * srcvp;
struct vnode * srcdvp;
char * oldname;
struct vnode * destvp;
struct vnode * destdvp;
char * newname;
struct ucred * crp;
```

Parameters

Item	Description
srcvp	Points to the virtual node (v-node) of the object to rename.
srcdvp	Points to the v-node of the directory where the *srcvp* parameter resides. The parent directory for the old and new object can be the same.
oldname	Identifies the old name of the object.
destvp	Points to the v-node of the new object. This pointer is used only if the new object exists. Otherwise, this parameter is the null character.

Item	Description
destdvp	Points to the parent directory of the new object. The parent directory for the new and old objects can be the same.
newname	Points to the new name of the object.
crp	Points to the **cred** structure. This structure contains data that applications can use to validate access permission.

Description

The **vnop_rename** entry point is invoked by the logical file system to rename a file or directory. This entry point provides the following renaming actions:

- Renames an old object to a new object that exists in a different parent directory.
- Renames an old object to a new object that does not exist in a different parent directory.
- Renames an old object to a new object that exists in the same parent directory.
- Renames an old object to a new object that does not exist in the same parent directory.

To ensure that this entry point routine executes correctly, the logical file system guarantees the following:

- File names are not renamed across file systems.
- The old and new objects (if specified) are not the same.
- The old and new parent directories are of the same type of v-node.

Execution Environment

The **vnop_rename** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

vnop_revoke Entry Point

Purpose

Revokes all access to an object.

Syntax

```
int vnop_revoke (vp, cmd, flag, vinfop, crp)
struct vnode * vp;
int     cmd;
int     flag;
caddr_t   vinfop;
struct ucred * crp;
```

Parameters

Item	Description
vp	Points to the virtual node (v-node) containing the object.
cmd	Indicates whether the calling process holds the file open. This parameter takes the following values:

> **0**
>> The process did not have the file open.
>
> **1**
>> The process had the file open.
>
> **2**
>> The process had the file open and the reference count in the file structure was greater than 1.

Item	Description
flag	Identifies the flags from the **file** structure.
vinfop	This parameter is currently unused.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_revoke** entry point is called to revoke further access to an object.

Execution Environment

The **vnop_revoke** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related information

Virtual File System Overview

vnop_rmdir Entry Point

Purpose

Removes a directory.

Syntax

```
int vnop_rmdir ( vp,    dp,    pname,    crp)
struct vnode *vp;
struct vnode *dp;
char *pname;
struct ucred *crp;
```

Parameters

Item	Description
vp	Points to the virtual node (v-node) of the directory.
dp	Points to the parent of the directory to remove.
pname	Points to the name of the directory to remove.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_rmdir** entry point is invoked by the logical file system to remove a directory object. To remove a directory, the directory must be empty (except for the current and parent directories). Before removing the directory, the logical file system ensures the following:

- The *vp* parameter is a directory.
- The *vp* parameter is not the root of a virtual file system.
- The *vp* parameter is not the current directory.
- The *dp* parameter does not reside on a read-only file system.

    Note: The *vp* and *dp* parameters' v-nodes (virtual nodes) are held for the duration of the routine.

Execution Environment

The **vnop_rmdir** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related information
rmdir subroutine

vnop_seek Entry Point

Purpose

Validates file offsets.

Syntax

```
int vnop_seek (vp, offsetp, crp)
struct vnode * vp;
offset_t * offp;
struct ucred * crp;
```

Parameters

Item	Description
vp	Points to the virtual node (vnode) of the file.
offp	Points to the location of the new offset to validate.
crp	Points to the user's credential.

Description

The **vnop_seek** entry point is called by the logical file system to validate a new offset that is computed by the **lseek**, **llseek**, and **lseek64** subroutines. The file system implementation must check the offset that is pointed to by the *offp* parameter and, if it is acceptable for the file, return zero. If the offset is not acceptable, the routine must return a non-zero value. **EINVAL** is the suggested error value for invalid offsets.

File system that do not want to do offset validation can simply return 0. File system that do not provide the **vnop_seek** entry point has a maximum offset of **OFF_MAX** (2 gigabytes minus 1) enforced by the logical file system.

Execution Environment

The **vnop_seek** *entry* point is to be called from the process environment only.

Return Values

Item	Description
0	Indicates success.
Non-zero	Return values are returned the **/usr/include/sys/errno.h** file to indicate failure.

Related information

lseek, llseek, and, lseek64

vnop_select Entry Point

Purpose

Polls a virtual node (v-node) for immediate I/O.

Syntax

```
int vnop_select (vp, correl, e, re, notify, vinfo, crp)
struct vnode * vp;
int  correl;
int  e;
int  re;
int (* notify)();
caddr_t  vinfo;
struct ucred * crp;
```

Parameters

Item	Description
vp	Points to the v-node to be polled.

Item	Description
correl	Specifies the ID used for correlation in the **selnotify** kernel service.
e	Identifies the requested event.
re	Returns an events list. If the v-node is ready for immediate I/O, this field should be set to indicate the requested event is ready.
notify	Specifies the subroutine to call when the event occurs. This parameter is for nested polls.
vinfo	Is currently unused.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Description

The **vnop_select** entry point is invoked by the logical file system to poll a v-node to determine if it is immediately ready for I/O. This entry point is used to implement the **select** and **poll** subroutines.

File system implementation can support constructs, such as devices or pipes, that support the select semantics. The **fp_select** kernel service provides more information about select and poll requests.

Execution Environment

The **vnop_select** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Virtual File System Kernel Extensions Overview

vnop_setacl Entry Point

Purpose

Sets the access control list (ACL) for a file.

Syntax

```
#include <sys/acl.h>
```

```
int vnop_setacl ( vp,  uiop,  crp)
struct vnode *vp;
struct uio *uiop;
struct ucred *crp;
```

Description

The **vnop_setacl** entry point is used by the logical file system to set the access control list (ACL) on a file.

Parameters

Item	Description
vp	Specifies the virtual node (v-node) of the file system object.
uiop	Specifies the **uio** structure that defines the storage for the call arguments.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Execution Environment

The **vnop_setacl** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure. Valid values include:

Item	Description
ENOSPC	Indicates that the space cannot be allocated to hold the new ACL information.
EPERM	Indicates that the effective user ID of the process is not the owner of the file and the process is not privileged.

Related information

chacl subroutine
statacl subroutine

vnop_setattr Entry Point

Purpose

Sets attributes of a file.

Syntax

```
int vnop_setattr (vp, cmd, arg1, arg2, arg3, crp)
struct vnode * vp;
int   cmd;
int   arg1;
int   arg2;
int   arg3;
struct ucred * crp;
```

Description

The **vnop_setattr** entry point is used by the logical file system to set the attributes of a file. This entry point is used to implement the **chmod**, **chownx**, and **utime** subroutines.

The values that the *arg* parameters take depend on the value of the *cmd* parameter. The **vnop_setattr** entry point accepts the following *cmd* values and *arg* parameters:

Possible cmd Values for the vnop_setattr Entry Point			
Command	V_OWN	V_UTIME	V_MODE
arg1	**int** *flag*;	**int** *flag*;	**int** *mode*;
arg2	**int** *uid*;	**timestruc_t** **atime*;	Unused
arg3	**int** *gid*;	**timestruc_t** **mtime*;	Unused

Note: For **V_UTIME**, if arg2 or arg3 is NULL, then the corresponding time field, *atime* and *mtime*, of the file should be left unchanged.

Parameters

Item	Description
vp	Points to the virtual node (v-node) of the file.
cmd	Defines the setting operation. This parameter takes the following values:

> **V_OWN**
> Sets the user ID (UID) and group ID (GID) to the UID and GID values of the new file owner. The *flag* argument indicates which ID is affected.
>
> **V_UTIME**
> Sets the access and modification time for the new file. If the *flag* parameter has the value of **T_SETTIME**, then the specific values have not been provided and the access and modification times of the object should be set to current system time. If the **T_SETTIME** value is not specified, the values are specified by the *atime* and *mtime* variables.
>
> **V_MODE**
> Sets the file mode.
>
> The **/usr/include/sys/vattr.h** file contains the definitions for the three command values.

Item	Description
arg1, arg2, arg3	Specify the command arguments. The values of the command arguments depend on which command calls the **vnop_setattr** entry point.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Execution Environment

The **vnop_setattr** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related information

Understanding Virtual Nodes (V-nodes)

vnop_setxacl Entry Point

Purpose

Sets the access control list (ACL) for a file system object. This is an advanced interface compared to **vnop_setacl** and provides for ACL-type-based operations.

Syntax

```
#include <sys/acl.h>
int vnop_setxacl (vp, ctl_flags, acl_type, uiop, mode_info, crp)

struct vnode    *vp;
uint64_t         ctl_flags;
acl_type_t       acl_type;
struct uio      *uiop;
mode_t           mode_info;
struct ucred    *crp;
```

Description

The **vnop_setxacl** entry point sets the access control list (ACL) on a file. It is an advanced version of **vnop_setacl** interface and provides for ACL-type-based operations. This interface can also be used to manage special bits in mode word (such as SUID, SGID and SVTX) in case the ACL type does not support these bits through ACL.

Parameters

Item	Description
vp	Specifies the virtual node (v-node) of the file system object for which the ACL needs to be set.
acl_type	Specifies the ACL type of the ACL information that needs to be set for the file system object. **Note:** If the underlying physical file system does not support the ACL type being requested, the system could return an error.
acl_len	Pointer to a *length* variable. The space pointed to is used as an input, as well as output, parameter. As input, the value will indicate the size of buffer *uiop*. When the call returns, this space holds the actual length of the ACL (true for when the call is successful or when the call fails with **errno** set to **ENOSPC**).

Item	Description
ctl_flags	This 64-bit bit mask provides for control over the ACL setting and for any future variations in the interface. The following flag values have been defined:

SET_MODE_S_BITS
Indicates that the *mode_info* value is set by the caller and the ACL put operation must consider this value to complete the ACL put operation.

SET_ACL
Indicates that the ACL arguments point to valid ACL data that must be considered while the ACL put operation is being performed.

Note: Both of the preceding values can be specified by the caller by ORing the two masks.

Item	Description
uiop	Specifies the **uio** structure that defines the storage for the call arguments.
mode_info	This value indicates any mode word information that needs to be set for the file system object as part of this ACL put operation. When mode bits are altered by specifying the **SET_MODE_S_BITS** flag (in *ctl_flags*), the entire ACL put operation will fail if the caller does not have the required privileges.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Execution Environment

The **vnop_setxacl** entry point can be called from the process environment only.

Return Values

Upon successful completion, the **vnop_setxacl** entry point returns 0. Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Item	Description
EPERM	Indicates that the effective user ID of the process is not authorized to change the ACL on the specified file system object.
EINVAL	Invalid operation. File system might not support the ACL type being set.

Note: This list of error numbers is not complete and is dependent on the particular physical file system implementation supporting the ACL.

Logical File System Overview

vnop_strategy Entry Point

Purpose

Accesses blocks of a file.

Syntax

```
int vnop_strategy ( vp,  bp,  crp)
struct vnode *vp;
struct buf *bp;
struct ucred *crp;
```

Description

Note: The **vnop_strategy** entry point is not implemented in Version 3.2 of the operating system.

The **vnop_strategy** entry point accesses blocks of a file. This entry point is intended to provide a block-oriented interface for servers for efficiency in paging.

Parameters

Item	Description
vp	Points to the virtual node (v-node) of the file.
bp	Points to a **buf** structure that describes the buffer.
crp	Points to the **cred** structure. This structure contains data that applications can use to validate access permission.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Virtual File System Kernel Extensions Overview

vnop_symlink Entry Point

Purpose

Creates a symbolic link.

Syntax

```
int vnop_symlink ( vp,  linkname,  target,  crp)
struct vnode *vp;
char *linkname;
char *target;
struct ucred *crp;
```

Description

The **vnop_symlink** entry point is called by the logical file system to create a symbolic link. The path name specified by the *linkname* parameter is the name of the new symbolic link. This symbolic link points to the object named by the *target* parameter.

Parameters

Item	Description
vp	Points to the virtual node (v-node) of the parent directory where the link is created.
linkname	Points to the name of the new symbolic link. The logical file system guarantees that the new link does not already exit.
target	Points to the name of the object to which the symbolic link points. This name need not be a fully qualified path name or even an existing object.
crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Execution Environment

The **vnop_symlink** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Related information

vnop_unmap Entry Point

Purpose

Unmaps a file.

Syntax

```
int vnop_unmap ( vp,   flag,   crp)
struct vnode *vp;
ulong flag;
struct ucred *crp;
```

Description

The **vnop_unmap** entry point is called by the logical file system to unmap a file. When this entry point routine completes successfully, the use count for the memory object should be decremented and (if the use count went to 0) the memory object should be destroyed. The file system implementation is required to perform only those operations that are unique to the file system. The logical file system handles virtual-memory management operations.

Parameters

Item	Description
vp	Points to the v-node (virtual node) of the file.
flag	Indicates how the file was mapped. This flag takes the following values:

    SHM_RDONLY
        The virtual memory object is read-only.

    SHM_COPY
        The virtual memory object is copy-on-write.

crp	Points to the **cred** structure. This structure contains data that the file system can use to validate access permission.

Execution Environment

The **vnop_unmap** entry point can be called from the process environment only.

Return Values

Item	Description
0	Indicates success.

Nonzero return values are returned from the **/usr/include/sys/errno.h** file to indicate failure.

Configuration Subsystem

System users cannot operate devices until device configuration occurs. To configure devices, the Device Configuration Subsystem is available.

Adapter-Specific Considerations for the Predefined Attribute (PdAt) Object Class

Description

The various bus resources required by an adapter card are represented as attributes in the Predefined Attribute (PdAt) object class. If the currently assigned values differ from the default values, they are represented with other device attributes in the Customized Attribute (CuAt) object class. To assign bus resources, the Bus Configurator obtains the bus resource attributes for an adapter from both the PdAt and CuAt object classes. It also updates the CuAt object class, as necessary, to resolve any bus resource conflicts.

The following additional guidelines apply to bus resource attributes.

The Attribute Type descriptor must indicate the type of bus resource. The values are as follows:

Value	Description
A	Indicates a DMA arbitration level.

Value	Description
B	Indicates a bus memory address which is not associated with DMA transfers.
M	Indicates a bus memory address to be used for DMA transfers.
I	Indicates a bus interrupt level that can be shared with another device.
N	Indicates a bus interrupt level that cannot be shared with another device.
O	Indicates a bus I/O address.
P	Indicates an interrupt-priority class.
W	Indicates an amount in bytes of bus memory or bus I/O space.
G	Indicates a group.
S	Indicates an attribute that must be shared with another adapter.

For bus memory and bus I/O addresses, the amount of address space to be assigned must also be specified. This value can be specified by either the attribute's Width descriptor or by a separate type W attribute.

If the value is specified in the attribute's Width descriptor, it is fixed at that value and cannot be customized. If a separate type W attribute is used, the bus memory or bus I/O attribute's Width descriptor must be set to a null string. The type W attribute's Width descriptor must indicate the name of the bus memory or bus I/O attribute to which it applies.

Attribute types G and S are special-purpose types that the Bus Configurator recognizes. If an adapter has resources whose values cannot be assigned independently of each other, a Group attribute will identify them to the Bus Configurator. For example, an adapter card might have an interrupt level that depends on the bus memory address assigned. Suppose that interrupt level 3 must be used with bus memory address 0x1000000, while interrupt level 4 must be used with bus memory address 0x2000000. This relationship can be described using the Group attribute as discussed in "Predefined Attribute (PdAt) Object Class" .

Occasionally, all cards of a particular type or types must use the same bus resource when present in the system. This is especially true of interrupt levels. Although most adapter's resources can be assigned independently of other adapters, even those of the same type, it is not uncommon to find adapters that must share an attribute value. An adapter card having a bus resource that must be shared with another adapter needs a type S attribute to describe the relationship.

PdAt Descriptors for Type S Attributes

The PdAt descriptors for a type S attribute should be set as follows:

PdAt Descriptor Setting	Description
Unique Type	Indicates the unique type of the adapter.
Attribute Name	Specifies the name assigned to this attribute.
Default Value	Set to a null string.
Possible Values	Contains the name of the attribute that must be shared with another adapter or adapters.
Width	Set to a null string.
Attribute Type	Set to S.
Generic Attribute Flags	Set to a null string. This attribute must neither be displayed nor set by the user.
Attribute Representation Flags	Set to s1, indicating an enumerated list of strings, even though the list consists of only one item.
NLS Index	Set to 0 since the attribute is not displayable.

The type S attribute identifies a bus resource attribute that must be shared. The other adapters are identifiable by attributes of type S with the same attribute name. The attribute name for the type S attribute serves as a key to identify all the adapters.

For example, suppose an adapter with unique type `adapter/mca/X` must share its interrupt level with an adapter of unique type `adapter/mca/Y`. The following attributes describe such a relationship:

The Predefined Attribute object for X's interrupt level:

- Attribute Name = `int_level`
- Default Value = 3
- Possible Values = `2 - 9, 1`
- Width = `null string`
- Unique Type = `adapter/mca/X`
- Attribute Type = `I`
- Generic Attribute Flags = D (displayable, but cannot be set by user)
- Attribute Representation Flags = `nr`
- NLS Index = 12 (message number for text description)

The predefined attribute object describing X's shared interrupt level:

- Unique Type = `adapter/mca/X`
- Attribute Name = `shared_intr`
- Default Value = `null string`
- Possible Values = `"int_level"`
- Width = `null string`
- Attribute Type = S
- Generic Attribute Flags = `null string`
- Attribute Representation Flags = `sl`
- NLS Index = 0

The Predefined Attribute object for Y's interrupt level:

- Unique Type = `adapter/mca/Y`
- Attribute Name = `interrupt`
- Default Value = 7
- Possible Values = `2, 3, 4, 5, 7, 9`
- Width = `null string`
- Attribute Type = I
- Generic Attribute Flags = D (displayed, but cannot be set by user)
- Attribute Representation Flags = `nl`
- NLS Index = 6 (message number for text description).

The Predefined Attribute object describing Y's *shared* interrupt level:

- Unique Type = `adapter/mca/Y`
- Attribute Name = `shared_intr`
- Default Value = null string
- Possible Values = `"interrupt"`
- Width = `null string`
- Attribute Type = S
- Generic Attribute Flags = `null string`

- Attribute Representation Flags = `sl`
- NLS Index = `0`

Note that the two adapters require different attributes to describe their interrupt levels. The attribute name is also different. However, their attributes describing what must be shared have the same name: `shared_intr`.

Adapter bus resource attributes except those of type W can be displayed but not set by the user. That is, the Generic Attribute Flags descriptor can either be a null string or the character D, but cannot be U or DU. The Bus Configurator has total control over the assignment of bus resources. These resources cannot be changed to user-supplied values by the Change method.

The Bus Configurator uses type W attributes to allocate bus memory address and bus I/O address attributes but never changes the value of a type W attribute. Attributes of type W can be set by users by setting the Generic Attribute flags descriptor to DU. This allows the Change method to change the type W attribute values to a user-supplied value.

The Bus Configurator does not use or modify any other attribute the adapter may have with attribute type R.

Adapter-Specific Considerations for the Predefined Devices (PdDv) Object Class

Description

The information to be populated into the Predefined Devices object class is described in the Predefined Devices (PdDv) Object Class. The following descriptors should be set as indicated:

Item	Description
Device Class	Set to `adapter`.
Device ID	Must identify the values that are obtained from the POS(0) and POS(1) registers on the adapter card. The format is `0xAABB`, where AA is the hexadecimal value obtained from POS(0), and BB the value from POS(1). This descriptor is used by the Bus Configurator to match up the physical device with its corresponding information in the Configuration database.
Bus Extender Flag	Usually set to FALSE, which indicates that the adapter card is not a bus extender. This descriptor is set to TRUE for a multi-adapter card requiring different sets of bus resources assigned to each adapter. The Standard I/O Planar is an example of such a card.

The Bus Configurator behaves slightly differently for cards that are bus extenders. Typically, it finds an adapter card and returns the name of the adapter to the Configuration Manager so that it can be configured.

However, for a bus extender, the Bus Configurator directly invokes the device's Configure method. The bus extender's Configure method defines the various adapters on the card as separate devices (each needing its own predefined information and device methods), and writes the names to standard output for the Bus Configurator to intercept. The Bus Configurator adds these names to the list of device names for which it is to assign bus resources.

An example of a type of adapter card that would be a bus extender is one which allows an expansion box with additional card slots to be connected to the system.

attrval Device Configuration Subroutine

Purpose

Verifies that attribute values are within range.

Syntax

```
#include <cf.h>
#include <sys/cfgodm.h>
#include <sys/cfgdb.h>
```

int attrval (*uniquetype, pattr, errattr*)
char * *uniquetype*;
char * *pattr*;
char ** *errattr*;

Parameters

Item	Description
uniquetype	Identifies the predefined device object, which is a pointer to a character string of the form `class/subclass/type`.
pattr	Points to a character string containing the attribute-value pairs to be validated, in the form `attr1=val1 attr2=val2`.
errattr	Points a pointer to a null-terminated character string. On return from the **attrval** subroutine, this string will contain the names of invalid attributes, if any are found. Each attribute name is separated by spaces.

Description

The **attrval** subroutine is used to validate each of a list of input attribute values against the legal range. If no illegal values are found, this subroutine returns a value of 0. Otherwise, it returns the number of incorrect attributes.

If any attribute values are invalid, a pointer to a string containing a list of invalid attribute names is returned in the *errattr* parameter. These attributes are separated by spaces.

Allocation of the error buffer is done in the **attrval** subroutine. However, a character pointer (for example, `char *errorb;`) must be declared in the calling routine. Thereafter, the address of that pointer is passed to the **attrval** subroutine (for example, `attrval(...,&errorb);`) as one of the parameters.

Return Values

Item	Description
0	Indicates that all values are valid.
Nonzero	Indicates the number of erroneous attributes.

Files

Item	Description
/usr/lib/libcfg.a	Archive of device configuration subroutines.

busresolve Device Configuration Subroutine

Purpose

Allocates bus resources for adapters on an I/O bus.

Syntax

```
#include <cf.h>
#include <sys/cfgodm.h>
#include <sys/cfgdb.h>
```

```
int busresolve
(logname, flag, conf_list,
not_res_list, busname)
char *  logname;
int     flags;
char *  conf_list;
char *   not_res_list;
char *  busname;
```

Parameters

Item	Description
logname	Specifies the device logical name.
flags	Specifies either the boot phase or 0.
conf_list	Points to an array of at least 512 characters.
not_res_list	Points to an array of at least 512 characters.
busname	Specifies the logical name of the bus.

Description

The **busresolve** device configuration subroutine is invoked by a device's configuration method to allocate bus resources for all devices that have predefined bus resource attributes. It also is invoked by the bus Configuration method to resolve attributes of all devices in the Defined state.

This subroutine first queries the Customized Attribute and Predefined Attribute object classes to retrieve a list of current bus resource attribute settings and a list of possible settings for each attribute. To resolve conflicts between the values assigned to an already available device and the current device, the subroutine adjusts the values for attributes of devices in the Defined state. For example, the **busresolve** subroutine makes sure that the current device is not assigned the same interrupt level as an already available device when invoked at run time. These values are updated in the customized Attribute object class.

The **busresolve** subroutine never modifies attributes of devices that are already in the Available state. It ignores devices in the Defined state if their `chgstatus` field in the Customized Devices object class indicates that they are missing.

When the *logname* parameter is set to the logical name of a device, the **busresolve** subroutine adjusts the specified device's bus resource attributes if necessary to resolve any conflicts with devices that are already in the Available state. A device's Configuration method must invoke the **busresolve** subroutine to ensure that its bus resources are allocated properly when configuring the device at run time. The Configuration method does not need to do it when run as part of system boot because the bus device's Configuration method would have already performed it.

If the *logname* parameter is set to a null string, the **busresolve** subroutine allocates bus resources for all devices that are not already in the Available state. The bus device's Configuration method invokes the **busresolve** subroutine in this way during system boot.

The *flags* parameter is set to 1 for system boot phase 1; 2 for system boot phase 2; and 0 when the **busresolve** subroutine is invoked during run time. The **busresolve** subroutine can be invoked only to resolve a specific device's bus resources at run time. That is, the *flags* parameter must be 0 when the *logname* parameter specifies a device logical name.

The **E_BUSRESOURCE** value indicates that the **busresolve** subroutine was not able to resolve all conflicts. In this case, the *conf_list* parameter will contain a list of the logical names of the devices for which it successfully resolved attributes. The *not_res_list* parameter also contains a list of the logical names of the devices for which it can not successfully resolve all attributes. Devices whose names appear in the *not_res_list* parameter must not be configured into the Available state.

When you write a Configure method for a device that has bus resources, make sure that it fails and returns a value of **E_BUSRESOURCE** if the **busresolve** subroutine does not return an **E_OK** value.

Note: If the *conf_list* and *not_res_list* strings are not at least 512 characters, there might be insufficient space to hold the device names.

Return Values

Item	Description
E_OK	Indicates that all bus resources were resolved and allocated successfully.
E_ARGS	Indicates that the parameters to the **busresolve** subroutine were not valid. For example, the *logname* parameter specifies a device logical name, but the *flags* parameter is not set to 0 for run time.
E_MALLOC	Indicates that the **malloc** operation if necessary memory storage failed.
E_NOCuDv	Indicates that there is no customized device data for the bus device whose logical name is specified by the *busname* parameter.
E_ODMGET	Indicates that an ODM error occurred while retrieving data from the Configuration database.
E_PARENTSTATE	Indicates that the bus device whose name is specified by the *busname* parameter is not in the Available state.
E_BUSRESOLVE	Indicates that a bus resource for a device did not resolve. The *logname* parameter can identify the particular device. However, if this parameter is null, then an **E_BUSRESOLVE** value indicates that the bus resource for some unspecified device in the system did not resolve.

Item	Description
/usr/lib/libcfg.a	Archive of device configuration subroutines.

Configuration Rules (Config_Rules) Object Class

Description

The Configuration Rules (Config_Rules) object class contains the configuration rules used by the Configuration Manager. The Configuration Manager runs in two phases during system boot. The first phase is responsible for configuring the base devices so that the real root device can be configured and made ready for operation. The second phase configures the rest of the devices in the system after the root file system is up and running. The Configuration Manager can also be invoked at run time. The Configuration Manager routine is driven by the rules in the Config_Rules object class.

The Config_Rules object class is preloaded with predefined configuration rules when the system is delivered. There are three types of rules: phase 1, phase 2, and phase 2 service. You can use the ODM commands to add, remove, change, and show new or existing configuration rules in this object class to customize the behavior of the Configuration Manager. However, any changes to a phase 1 rule must be written to the boot file system to be effective. This is done with the **bosboot** command.

All logical and physical devices in the system are organized in clusters of tree structures called nodes. For information on nodes or tree structures, see the "Device Configuration Manager Overview" in *Kernel Extensions and Device Support Programming Concepts*. The rules in the Config_Rules object class specify program names that the Configuration Manager executes. Usually, these programs are the configuration programs for the top of the nodes. When these programs are invoked, the names of the next lower-level devices that need to be configured are returned in standard output.

The Configuration Manager configures the next lower-level devices by invoking the Configure method for those devices. In turn, those devices return a list of device names to be configured. This process is repeated until no more device names are returned. All devices in the same node are configured in a transverse order.

The second phase of system boot requires two sets of rules: phase 2 and service. The position of the key on the front panel determines which set of rules is used. The service rules are used when the key is in the service position. If the key is in any other position, the phase 2 rules are used. Different types of rules are indicated in the Configuration Manager Phase descriptor of this object class.

Each configuration rule has an associated boot mask. If this mask has a nonzero value, it represents the type of boot to which the rule applies. For example, if the mask has a **DISK_BOOT** value, the rule applies to system boots where disks are base devices. The type of boot masks are defined in the **/usr/include/sys/cfgdb.h** file.

Descriptors

The **Config_Rules** object class contains the following descriptors:

ODM Type	Descriptor Name	Description	Descriptor Status
ODM_SHORT	**phase**	Configuration Manager Phase	Required
ODM_SHORT	**seq**	Sequence Value	Required
ODM_LONG	**boot_mask**	Type of boot	Required
ODM_VCHAR	**rule_value[RULESIZE]**	Rule Value	Required

These descriptors are described as follows:

Descriptor	Description
Configuration Manager Phase	This descriptor indicates which phase a rule should be executed under phase 1, phase 2, or phase 2 service.

1
    Indicates that the rule should be executed in phase 1.

2
    Indicates that the rule should be executed in phase 2.

3
    Indicates that the rule should be executed in phase 2 service mode.

Descriptor	Description
Sequence Value	In relation to the other rules of this phase, the seq number indicates the order in which to execute this program. In general, the lower the seq number, the higher the priority. For example, a rule with a seq number of 2 is executed before a rule with a seq number of 5. There is one exception to this: a value of 0 indicates a DONT_CARE condition, and any rule with a seq number of 0 is executed last.
Type of boot	If the boot_mask field has a nonzero value, it represents the type of boot to which the rule applies. If the **-m** flag is used when invoking the **cfgmgr** command, the **cfgmgr** command applies the specified mask to this field to determine whether to execute the rule. By default, the **cfgmgr** command always executes a rule for which the boot_mask field has a 0 value.

Descriptor	Description
Rule Value	This is the full path name of the program to be invoked. The rule value descriptor may also contain any options that should be passed to that program. However, options must follow the program name, as the whole string will be executed as if it has been typed in on the command line. **Note:** There is one rule for each program to execute. If multiple programs are needed, then multiple rules must be added.

```
Rule Values

Phase    Sequence    Type of boot    Rule Value

1        1           0               /usr/lib/methods/

3        15          0               /usr/lib/methods/
starttty
```

Customized Attribute (CuAt) Object Class

Description

The Customized Attribute (CuAt) object class contains customized device-specific attribute information.

Device instances represented in the Customized Devices (CuDv) object class have attributes found in either the Predefined Attribute (PdAt) object class or the CuAt object class. There is an entry in the CuAt object class for attributes that take nondefault values. Attributes taking the default value are found in the PdAt object class. Each entry describes the current value of the attribute.

When changing the value of an attribute, the Predefined Attribute object class must be referenced to determine other possible attribute values.

Both attribute object classes must be queried to get a complete set of current values for a particular device's attributes. Use the **getattr** and **putattr** subroutines to retrieve and modify, respectively, customized attributes.

Descriptors

The Customized Attribute object class contains the following descriptors:

ODM Type	Descriptor Name	Description	Descriptor Status
ODM_CHAR	**name[NAMESIZE]**	Device Name	Required
ODM_CHAR	**attribute[ATTRNAMESIZE]**	Attribute Name	Required
ODM_VCHAR	**value[ATTRVALSIZE]**	Attribute Value	Required
ODM_CHAR	**type[FLAGSIZE]**	Attribute Type	Required
ODM_CHAR	**generic[FLAGSIZE]**	Generic Attribute Flags	Optional

ODM Type	Descriptor Name	Description	Descriptor Status
ODM_CHAR	**rep[FLAGSIZE]**	Attribute Representation Flags	Required
ODM_SHORT	**nls_index**	NLS Index	Optional

These descriptors are described as follows:

Descriptor	Description
Device Name	Identifies the logical name of the device instance to which this attribute is associated.
Attribute Name	Identifies the name of a customized device attribute.
Attribute Value	Identifies a customized value associated with the corresponding Attribute Name. This value is a nondefault value.
Attribute Type	Identifies the attribute type associated with the Attribute Name. This descriptor is copied from the Attribute Type descriptor in the corresponding PdAt object when the CuAt object is created.
Generic Attribute Flags	Identifies the Generic Attribute flag or flags associated with the Attribute Name. This descriptor is copied from the Generic Attribute Flags descriptor in the corresponding PdAt object when the CuAt object is created.
Attribute Representation Flags	Identifies the Attribute Value's representation. This descriptor is copied from the Attribute Representation flags descriptor in the corresponding Predefined Attribute object when the Customized Attribute object is created.
NLS Index	Identifies the message number in the NLS message catalog that contains a textual description of the attribute. This descriptor is copied from the NLS Index descriptor in the corresponding Predefined Attribute object when the Customized Attribute object is created.

Customized Dependency (CuDep) Object Class

Description

The Customized Dependency (CuDep) object class describes device instances that depend on other device instances. Dependency does not imply a physical connection. This object class describes the dependence links between logical devices and physical devices as well as dependence links between logical devices, exclusively. Physical dependencies of one device on another device are recorded in the Customized Device (CuDev) object class.

Descriptors

The Customized Dependency object class contains the following descriptors:

ODM Type	Descriptor Name	Description	Descriptor Status
ODM_CHAR	**name[NAMESIZE]**	Device Name	Required
ODM_CHAR	**dependency[NAMESIZE]**	Dependency (device logical name)	Required

These descriptors are described as follows:

Descriptor	Description
Device Name	Identifies the logical name of the device having a dependency.

Item	Description
Dependency	Identifies the logical name of the device instance on which there is a dependency. For example, a mouse, keyboard, and display might all be dependencies of a device instance of `lft0`.

Customized Device Driver (CuDvDr) Object Class

Description

The Customized Device Driver (CuDvDr) object class stores information about critical resources that need concurrence management through the use of the Device Configuration Library subroutines. You should only access this object class through these five Device Configuration Library subroutines: the **genmajor**, **genminor**, **relmajor**, **reldevno**, and **getminor** subroutines.

These subroutines exclusively lock this class so that accesses to it are serialized. The **genmajor** and **genminor** routines return the major and minor number, respectively, to the calling method. Similarly, the **reldevno** and **relmajor** routines release the major or minor number, respectively, from this object class.

Descriptors

The Customized Device Driver object class contains the following descriptors:

ODM Type	Descriptor Name	Description	Descriptor Status
ODM_CHAR	**resource[RESOURCESIZE]**	Resource Name	Required
ODM_CHAR	**value1[VALUESIZE]**	Value1	Required
ODM_CHAR	**value2[VALUESIZE]**	Value2	Required
ODM_CHAR	**value3[VALUESIZE]**	Value3	Required

The Resource descriptor determines the nature of the values in the Value1, Value2, and Value3 descriptors. Possible values for the Resource Name descriptor are the strings **devno** and **ddins**.

The following table specifies the contents of the Value1, Value2, and Value3 descriptors, depending on the contents of the Resource Name descriptor.

Resource	Value1	Value2	Value3
devno	Major number	Minor number	Device instance name
ddins	Dd instance name	Major number	Null string

When the Resource Name descriptor contains the **devno** string, the `Value1` field contains the device major number, `Value2` the device minor number, and `Value3` the device instance name. These value

descriptors are filled in by the **genminor** subroutine, which takes a major number and device instance name as input and generates the minor number and resulting **devno** Customized Device Driver object.

When the Resource Name descriptor contains the **ddins** string, the `Value1` field contains the device driver instance name. This is typically the device driver name obtained from the Device Driver Name descriptor of the Predefined Device object. However, this name can be any unique string and is used by device methods to obtain the device driver major number. The `Value2` field contains the device major number and the `Value3` field is not used. These value descriptors are set by the **genmajor** subroutine, which takes a device instance name as input and generates the corresponding major number and resulting **ddins** Customized Device Driver object.

Customized Devices (CuDv) Object Class

Description

The Customized Devices (CuDv) object class contains entries for all device instances defined in the system. As the name implies, a defined device object is an object that a Define method has created in the CuDv object class. A defined device instance may or may not have a corresponding actual device attached to the system.

A CuDv object contains attributes and connections specific to the device instance. Each device instance, distinguished by a unique logical name, is represented by an object in the CuDv object class. The Customized database is updated twice, during system boot and at run time, to define new devices, remove undefined devices, or update the information for a device whose attributes have been changed.

Descriptors

The Customized Devices object class contains the following descriptors:

ODM Type	Descriptor Name	Description	Descriptor Status
ODM_CHAR	**name[NAMESIZE]**	Device Name	Required
ODM_SHORT	**status**	Device Status Flag	Required
ODM_SHORT	**chgstatus**	Change Status Flag	Required
ODM_CHAR	**ddins[TYPESIZE]**	Device Driver Instance	Optional
ODM_CHAR	**location[LOCSIZE]**	Location Code	Optional
ODM_CHAR	**parent[NAMESIZE]**	Parent Device Logical Name	Optional
ODM_CHAR	**connwhere[LOCSIZE]**	Location Where Device Is Connected	Optional
ODM_LINK	**PdDvLn**	Link to Predefined Devices Object Class	Required

These descriptors are described as follows:

Descriptor	Description
Device Name	A Customized Device object for a device instance is assigned a unique logical name to distinguish the instance from other device instances. The device logical name of a device instance is derived during Define method processing. The rules for deriving a device logical name are:

- The name should start with a *prefix name* pre-assigned to the device instance's associated device type. The prefix name can be retrieved from the Prefix Name descriptor in the Predefined Device object associated with the device type.

- To complete the logical device name, a *sequence number* is usually appended to the prefix name. This sequence number is unique among all defined device instances using the same prefix name. Use the following subrules when generating sequence numbers:

  - A sequence number is a non-negative integer represented in character format. Therefore, the smallest available sequence number is 0.
  - The next available sequence number relative to a given prefix name should be allocated when deriving a device instance logical name.
  - The next available sequence number relative to a given prefix name is defined to be the smallest sequence number not yet allocated to defined device instances using the same prefix name.

    For example, if `tty0`, `tty1`, `tty3`, `tty5`, and `tty6` are currently assigned to defined device instances, then the next available sequence number for a device instance with the `tty` prefix name is 2. This results in a logical device name of `tty2`.

  The **genseq** subroutine can be used by a Define method to obtain the next available sequence number.

Device Status Flag	Identifies the current status of the device instance. The device methods are responsible for setting Device Status flags for device instances. When the Define method defines a device instance, the device's status is set to `defined`. When the Configure method configures a device instance, the device's status is typically set to `available`. The Configure method takes a device to the Stopped state only if the device supports the Stopped state.

When the Start method starts a device instance, its device status is changed from the Stopped state to the Available state. Applying a Stop method on a started device instance changes the device status from the Available state to the Stopped state. Applying an Unconfigure method on a configured device instance changes the device status from the Available state to the Defined state. If the device supports the Stopped state, the Unconfigure method takes the device from the Stopped state to the Defined state.

The possible status values are:

DEFINED
Identifies a device instance in the Defined state.

AVAILABLE
Identifies a device instance in the Available state.

STOPPED
Identifies a device instance in the Stopped state.

Descriptor	Description
Change Status Flag	This flag tells whether the device instance has been altered since the last system boot. The diagnostics facility uses this flag to validate system configuration. The flag can take these values:

NEW

> Specifies whether the device instance is new to the current system boot.

DONT_CARE

> Identifies the device as one whose presence or uniqueness cannot be determined. For these devices, the new, same, and missing states have no meaning.

SAME

> Specifies whether the device instance was known to the system prior to the current system boot.

MISSING

> Specifies whether the device instance is missing. This is true if the device is in the CuDv object class, but is not physically present.

Descriptor	Description
Device Driver Instance	This descriptor typically contains the same value as the Device Driver Name descriptor in the Predefined Devices (PdDv) object class if the device driver supports only one major number. For a driver that uses multiple major numbers (for example, the logical volume device driver), unique instance names must be generated for each major number. Since the logical volume uses a different major number for each volume group, the volume group logical names would serve this purpose. This field is filled in with a null string if the device instance does not have a corresponding device driver.
Location Code	Identifies the location code of the device. This field provides a means of identifying physical devices. The location code format is defined as **AB-CD-EF-GH**, where:

AB

> Identifies the CPU and Async drawers with a drawer ID.

CD

> Identifies the location of an adapter, memory card, or Serial Link Adapter (SLA) with a slot ID.

EF

> Identifies the adapter connector that something is attached to with a connector ID.

GH

> Identifies a port, device, or field replaceable unit (FRU), with a port or device or FRU ID, respectively.

Descriptor	Description
Parent Device Logical Name	Identifies the logical name of the parent device instance. In the case of a real device, this indicates the logical name of the parent device to which this device is connected. More generally, the specified parent device is the device whose Configure method is responsible for returning the logical name of this device to the Configuration Manager for configuring this device. This field is filled in with a null string for a node device.

Descriptor	Description
Location Where Device Is Connected	Identifies the specific location on the parent device instance where this device is connected. The term *location* is used in a generic sense. For some device instances such as the operating system bus, location indicates a slot on the bus. For device instances such as the SCSI adapter, the term indicates a logical port (that is, a SCSI ID and Logical Unit Number combination). For example, for a bus device the location can refer to a specific slot on the bus, with values 1, 2, 3 ... . For a multiport serial adapter device, the location can refer to a specific port on the adapter, with values 0, 1, ...
Link to Predefined Devices Object Class	Provides a link to the device instance's predefined information through the Unique Type descriptor in the PdDv object class.

Customized VPD (CuVPD) Object Class

Description

The Customized Vital Product Data (CuVPD) object class contains the Vital Product Data (VPD) for customized devices. VPD can be either machine-readable VPD or manually entered user VPD information.

Descriptors

The Customized VPD object class contains the following descriptors:

ODM Type	Descriptor Name	Description	Descriptor Status
ODM_CHAR	**name[NAMESIZE]**	Device Name	Required
ODM_SHORT	**vpd_type**	VPD Type	Required
ODM_LONGCHAR	**vpd[VPDSIZE]**	VPD	Required

These fields are described as follows:

Descriptor	Description
Device Name	Identifies the device logical name to which this VPD information belongs.

VPD Type	Identifies the VPD as either machine-readable or manually-entered. The possible values:
	
	HW_VPD
	    Identifies machine-readable VPD.
	
	USER_VPD
	    Identifies manually entered VPD.

VPD	Identifies the VPD for the device. For machine-readable VPD, an entry in this field might include such information as serial numbers, engineering change levels, and part numbers.

Device Methods for Adapter Cards: Guidelines

The device methods for an adapter card are essentially the same as for any other device. They need to perform roughly the same tasks as those described in "Writing a Device Method" in *Kernel Extensions and Device Support Programming Concepts*. However, there is one additional important consideration. The Bus Configure method, or Bus Configurator, is responsible for discovering the adapter cards present in the system and for assigning bus resources to each of the adapters. These resources include interrupt levels, DMA arbitration levels, bus memory, and bus I/O space.

Adapters are typically defined and configured at boot time. However, if an adapter is not configured due to unresolvable bus resource conflicts, or if an adapter is unconfigured at run time with the **rmdev** command, an attempt to configure an adapter at run time may occur.

If an attempt is made, the Configure method for the adapter must take these steps to ensure system integrity:

1. Ensure the card is present in the system by reading the POS(0) and POS(1) registers from the slot that is supposed to contain the card and comparing these values with what they are supposed to be for the card.

2. Invoke the **busresolve** subroutine to ensure that the adapter's bus resource attributes, as represented in the database, do not conflict with any of the configured adapters.

Additional guidelines must be followed when adding support for a new adapter card. They are discussed in:

- Adapter-Specific Considerations for the Predefined Attributes (PdAt) object class
- Writing a Configure Method
- Adapter-Specific Considerations for the Predefined Devices (PdDv) object class

genmajor Device Configuration Subroutine

Purpose

Generates the next available major number for a device driver instance.

Syntax

```
#include <cf.h>
#include <sys/cfgodm.h>
#include <sys/cfgdb.h>
```

int **genmajor** (*device_driver_instance_name*)
char *device_driver_instance_name*;

Parameters

Item	Description
device_driver_instance_name	Points to a character string containing the device driver instance name.

Description

The **genmajor** device configuration subroutine is one of the routines designated for accessing the Customized Device Driver (CuDvDr) object class. If a major number already exists for the given device driver instance, it is returned. Otherwise, a new major number is generated.

The **genmajor** subroutine creates an entry (object) in the CuDvDr object class for the major number information. The lowest available major number or the major number that has already been allocated is returned. The CuDvDr object class is locked exclusively by this routine until its completion.

Return Values

If the **genmajor** subroutine executes successfully, a major number is returned. This major number is either the lowest available major number or the major number that has already been allocated to the device instance.

A value of -1 is returned if the **genmajor** subroutine fails.

Files

Item	Description
/usr/lib/libcfg.a	Archive of device configuration subroutines.

genminor Device Configuration Subroutine

Purpose

Generates either the smallest unused minor number available for a device, a preferred minor number if it is available, or a set of unused minor numbers for a device.

Syntax

```
#include <cf.h>
#include <sys/cfgodm.h>
#include <sys/cfgdb.h>
```

int *genminor (*device_instance, major_no, preferred_minor,*
    minors_in_grp, inc_within_grp, inc_btwn_grp)
char * *device_instance*;
int *major_no*;
int *preferred_minor*;
int *minors_in_grp*;
int *inc_within_grp*;
int *inc_btwn_grp*;

Parameters

Item	Description
device_instance	Points to a character string containing the device instance name.
major_no	Contains the major number of the device instance.
preferred_minor	Contains a single preferred minor number or a starting minor number for generating a set of numbers. In the latter case, the **genminor** subroutine can be used to get a set of minor numbers in a single call.
minors_in_grp	Indicates how many minor numbers are to be allocated.
inc_within_grp	Indicates the interval between minor numbers.
inc_btwn_grp	Indicates the interval between groups of minor numbers.

Description

The **genminor** device configuration subroutine is one of the designated routines for accessing the Customized Device Driver (CuDv) object class. To ensure that unique numbers are generated, the object class is locked by this routine until its completion.

If a single preferred minor number needs to be allocated, it should be given in the *preferred_minor* parameter. In this case, the other parameters should contain an integer value of 1. If the desired number is available, it is returned. Otherwise, a null pointer is returned, indicating that the requested number is in use.

If the caller has no preference and only requires one minor number, this should be indicated by passing a value of -1 in the *preferred_minor* parameter. The other parameters should all contain the integer value of 1. In this case, the **genminor** subroutine returns the lowest available minor number.

If a set of numbers is desired, then every number in the designated set must be available. An unavailable number is one that has already been assigned. To get a specific set of minor numbers allocated, the *preferred_minor* parameter contains the starting minor number. If this set has a minor number that is unavailable, then the **genminor** subroutine returns a null pointer indicating failure.

If the set of minor numbers needs to be allocated with the first number beginning on a particular boundary (that is, a set beginning on a multiple of 8), then a value of -1 should be passed in the *preferred_minor* parameter. The *inc_btwn_grp* parameter should be set to the multiple desired. The **genminor** subroutine uses the *inc_btwn_grp* parameter to find the first complete set of available minor numbers.

If a list of minor numbers is to be returned, the return value points to the first in a list of preferred minor numbers. This pointer can then be incremented to move through the list to access each minor number. The minor numbers are returned in ascending sorted order.

Return Values

In the case of failure, a null pointer is returned. If the **genminor** subroutine succeeds, a pointer is returned to the lowest available minor number or to a list of minor numbers.

Files

Item	Description
/usr/lib/libcfg.a	Archive of device configuration subroutines.

genseq Device Configuration Subroutine

Purpose

Generates a unique sequence number for creating a device's logical name.

Syntax

```
#include <cf.h>
#include <sys/cfgodm.h>
#include <sys/cfgdb.h>
```

```
int genseq (prefix)
char *prefix;
```

Parameters

Item	Description
prefix	Points to the character string containing the prefix name of the device.

Description

The **genseq** device configuration subroutine generates a unique sequence number to be concatenated with the device's prefix name. The device name in the Customized Devices (CuDv) object class is the concatenation of the prefix name and the sequence number. The rules for generating sequence numbers are as follows:

- A sequence number is a nonnegative integer. The smallest sequence number is 0.
- When deriving a device instance logical name, the next available sequence number (relative to a given prefix name) is allocated. This next available sequence number is defined to be the smallest sequence number not yet allocated to device instances using the same prefix name.

- Whether a sequence number is allocated or not is determined by the device instances in the CuDv object class. If an entry using the desired prefix exists in this class, then the sequence number for that entry has already been allocated.

It is up to the application to convert this sequence number to character format so that it can be concatenated to the prefix to form the device name.

Return Values

If the **genseq** subroutine succeeds, it returns the generated sequence number in integer format. If the subroutine fails, it returns a value of -1.

Files

Item	Description
/usr/lib/libcfg.a	Archive of device configuration subroutines.

getattr Device Configuration Subroutine

Purpose

Returns current values of an attribute object.

Library

Object Data Manager Library (**libodm.a**)

Syntax

```
#include <cf.h>
#include <sys/cfgodm.h>
#include <sys/cfgdb.h>
```

struct CuAt *getattr (*devname, attrname, getall, how_many*)
char * *devname*;
char * *attrname*;
int *getall*;
int * *how_many*;

Parameters

Item	Description
devname	Specifies the device logical name.
attrname	Specifies the attribute name.
getall	Specifies a Boolean flag that, when set to True, indicates that a list of attributes is to be returned to the calling routine.
how_many	Points to how many attributes the **getattr** subroutine has found.

Description

The **getattr** device configuration subroutine returns the current value of an attribute object or a list of current values of attribute objects from either the Customized Attribute (CuAt) object class or the Predefined Attribute (PdAt) object class. The **getattr** device configuration subroutine queries the CuAt object class for the attribute object matching the device logical name and the attribute name. It is the application's responsibility to lock the Device Configuration object classes.

The **getattr** subroutine allocates memory for CuAt object class structures that are returned. This memory is automatically freed when the application exits. However, the application must free this memory if it invokes **getattr** several times and runs for a long time.

To get a single attribute, the *getall* parameter should be set to False. If the object exists in the CuAt object class, a pointer to this structure is returned to the calling routine.

However, if the object is not found, the **getattr** subroutine assumes that the attribute takes the default value found in the PdAt object class. In this case, the PdAt object class is queried for the attribute information. If this information is found, the relevant attribute values (that is, default value, flag information, and the NLS index) are copied into a CuAt structure. This structure is then returned to the calling routine. Otherwise, a null pointer is returned indicating an error.

To get all the customized attributes for the device name, the *getall* parameter should be set to True. In this case, the *attrname* parameter is ignored. The PdAt and CuAt object classes are queried and a list of CuAt structures is returned. The PdAt objects are copied to CuAt structures so that one list may be returned.

Note: The **getattr** device configuration subroutine will fail unless you first call the **odm_initialize** subroutine.

Return Values

Upon successful completion, the **getattr** subroutine returns a pointer to a list of CuAt structures. If the operation is unsuccessful, a null pointer is returned.

Item	Description
/usr/lib/libcfg.a	Archive of device configuration subroutines.

getminor Device Configuration Subroutine

Purpose

Gets the minor numbers associated with a major number from the Customized Device Driver (CuDvDr) object class.

Syntax

```
#include <cf.h>
#include <sys/cfgodm.h>
#include <sys/cfgdb.h>
```

```
int *getminor (major_no, how_many, device_instance)
int    major_no;
int *  how_many;
char * device_instance;
```

Parameters

Item	Description
major_no	Specifies the major number for which the corresponding minor number or numbers is desired.
how_many	Points to the number of minor numbers found corresponding to the *major_no* parameter.
device_instance	Specifies a device instance name to use when searching for minor numbers. This parameter is used in conjunction with the *major_no* parameter.

Description

The **getminor** device configuration subroutine is one of the designated routines for accessing the CuDvDr object class. This subroutine queries the CuDvDr object class for the minor numbers associated with the given major number or device instance or both.

If the *device_instance* parameter is null, then only the *major_no* parameter is used to obtain the minor numbers. Otherwise, both the *major_no* and *device_instance* parameters should be used. The number of minor numbers found in the query is returned in the *how_many* parameter.

The CuDvDr object class is locked exclusively by the **getminor** subroutine for the duration of the routine.

The return value pointer points to a list that contains the minor numbers associated with the major number. This pointer is then used to move through the list to access each minor number. The minor numbers are returned in ascending sorted order.

The **getminor** subroutine also returns the number of minor numbers in the list to the calling routine in the *how_many* parameter.

Return Values

If the **getminor** routine fails, a null pointer is returned.

If the **getminor** subroutine succeeds, one of two possible values is returned. If no minor numbers are found, null is returned. In this case, the *how_many* parameter points to an integer value of 0. However, if minor numbers are found, then a pointer to a list of minor numbers is returned. The minor numbers are returned in ascending sorted order. In the latter case, the *how_many* parameter points to the number of minor numbers found.

Files

Item	Description
/usr/lib/libcfg.a	Archive of device configuration subroutines.

How Device Methods Return Errors

Device methods indicate errors to the Configuration Manager and run-time configuration commands by exiting with a nonzero exit code. The Configuration Manager and configuration commands can understand only the exit codes defined in the **cf.h** file.

More than one error code can describe a given error. This is because many exit codes correspond to highly specific errors, while others are more general. Whenever possible, use the most specific error code possible.

For example, if your Configure method obtains an attribute from the Customized Attributes (CuAt) object class for filling in the device-dependent structure (DDS), but the value is invalid (possibly due to a corrupted database), you might exit with an **E_BADATTR** error. Otherwise, you might choose the **E_DDS** exit code, due to another error condition that occurred while building the DDS.

loadext Device Configuration Subroutine

Purpose

Loads or unloads kernel extensions, or queries for kernel extensions in the kernel.

Syntax

```
#include <sys/types.h>
```

```
mid_t loadext ( dd_name,  load,  query)
char *dd_name;
int load, query;
```

Parameters

Item	Description
dd_name	Specifies the name of the kernel extension to be loaded, unloaded, or queried.
load	Specifies whether the **loadext** subroutine should load the kernel extension.
query	Specifies whether a query of the kernel extension should be performed.

Description

The **loadext** device configuration subroutine provides the capability to load or unload kernel extensions. It can also be used to obtain the kernel module identifier (kmid) of a previously loaded object file. The kernel extension name passed in the *dd_name* parameter is either the base name of the object file or contains directory path information. If the kernel extension path name supplied in the *dd_name* parameter has no leading **./** (dot, slash), **../** double-dot, slash), or **/** (slash) characters, then the **loadext** subroutine concatenates the **/usr/lib/drivers** file and the base name passed in the *dd_name* parameter to arrive at an absolute path name. Otherwise, the path name provided in the *dd_name* parameter is used unmodified.

If the *load* parameter has a value of True, the specified kernel extension and its **kmid** are loaded. If the specified object file has already been loaded into the kernel, its load count is incremented and a new copy is not loaded.

If the *load* parameter has a value of False, the action taken depends on the value of the *query* parameter. If *query* is False, the **loadext** routine requests an unload of the specified kernel extension. This causes the kernel to decrement the load count associated with the object file. If the load count and use count of the object file become 0, the kernel unloads the object file. If the *query* parameter is True, then the **loadext** subroutine queries the kernel for the kmid of the specified object file. This kmid is then returned to the caller.

If both the *load* and *query* parameters have a value of True, the load function is performed.

> **Attention:** Repeated loading and unloading of kernel extensions may cause a memory leak.

Files

Item	Description
/usr/lib/libcfg.a	Archive of device configuration subroutines.

Return Values

Upon successful completion, the **loadext** subroutine returns the kmid. If an error occurs or if the queried object file is not loaded, the routine returns a null value.

Loading a Device Driver

The **loadext** subroutine is used to load and unload device drivers. The name of the device driver is passed as a parameter to the **loadext** routine. If the device driver is located in the **/usr/lib/drivers** directory, just the device driver name without path information can be specified to the **loadext** subroutine. If the device driver is located in another directory, the fully qualified path name of the device driver must be specified.

The Device Driver Name descriptor of Predefined Devices (PdDv) object class objects is intended to contain only the device driver name and not the fully qualified path name. For device drivers located in the **/usr/lib/drivers** directory, a Configure method can obtain the name of the driver from the Device

Driver Name descriptor to pass to the **loadext** routine. This is convenient since most drivers are located in the **/usr/lib/drivers** directory.

If a device driver is located in a directory other than the **/usr/lib/drivers** directory, the path name must be handled differently. The Configure method could be coded to assume a particular path name, or for more flexibility the path name could be stored as an attribute in the Predefined Attribute (PdAt) object class. The Configure method is responsible for knowing how to obtain the fully qualified path name to pass to the **loadext** subroutine.

Files

Item	Description
/usr/lib/drivers directory	Contains device drivers.

Machine Device Driver

The machine device driver provides an interface to platform-specific hardware for the system configuration and reliability, availability, and serviceability (RAS) subsystems. The machine device driver supports these special files for accessing this hardware from user mode: **/dev/nvram** and **/dev/bus0** ... **/dev/bus**N where N is the bus number. The **/dev/nvram** special file provides access to special nonvolatile random access memory (RAM) for the purposes of storing or retrieving error information and system boot information. The **/dev/bus**N special files provide access to the I/O buses for system configuration and diagnostic purposes. The presence and use of this device driver and its associated special files are platform-specific and must not be used by general applications.

A program must have the appropriate privilege to open special files **/dev/nvram** or **/dev/bus**N. It must also have the appropriate privilege to open Common Hardware Reference Platform (CHRP) bus special files **/dev/pci**N, or **/dev/isa**N.

Driver Initialization and Termination

Special initialization and termination requirements do not exist for the machine device driver. This driver is statically bound to the operating system kernel and is initialized during kernel initialization. This device driver does not support termination and cannot be unloaded.

/dev/nvram Special File Support

open and close Subroutines

The machine device driver supports the **/dev/nvram** special file as a multiplexed character special file. This special file and the support for NVRAM is provided exclusively on this hardware platform to support the system configuration and RAS subsystems. These subsystems open the **/dev/nvram/**n special file with a channel name, *n*, specifying the data area to be accessed. An exception is the **/dev/nvram** file with no channel specified, which provides access to general NVRAM control functions and the LED display on the front panel.

A special channel name of **base** can be used to read the base customize information that is stored as part of the boot record. This information was originally copied to the disk by the **savebase** command and is only copied by the driver at boot time. The **base** customize information can be read only once. When the **/dev/nvram/base** file is closed for the first time, the buffer that contains the base customize information is freed. Subsequent opens return an **ENOENT** error code.

read and write Subroutines

The **write** subroutine is not supported and returns an **ENODEV** error code. The **read** subroutine is supported after a successful open of the **base** channel only. The **read** subroutine transfers data from the data area that is associated with the specified channel. The transfer starts at the offset (within the channel's data area) specified by the `offset` field that is associated with the file pointer used on the subroutine call.

On a **read** subroutine, if the end of the data area is reached before the transfer count is reached, the number of bytes read before the end of the data area was reached is returned. If the **read** subroutine starts at the end of the data area, zero bytes are read. If the **read** subroutine starts after the end of the data area, an **ENXIO** error code is returned by the driver.

The **lseek** subroutine can be used to change the starting data-area offset to be used on a subsequent **read** call.

ioctl Operations

The following ioctl operations can be issued to the machine device driver after a successful open of the **/dev/nvram/** special file:

Operation	Description
IOCINFO	Returns machine device driver information in the caller's **devinfo** structure (pointed to by the *arg* parameter). This structure is defined in the **/usr/include/sys/devinfo.h** file. The device type for this device driver is **DD_PSEU**.
MIOGETKEY	Returns the status of the keylock. The *arg* parameter must point to a **mach_dd_io** structure. The md_data field must point to an integer; this field contains the status of the keylock on return. **Note:** Not all platforms have a physical keylock that software can read. For these platforms, status is established at boot time.
MIOGETPS	Returns the power status. The *arg* parameter must point to a **mach_dd_io** structure. The md_data field must point to an integer; this field contains the power status on return. **Note:** Not all platforms provide power status.
MIOIPLCB	Returns the contents of the boot control block. The *arg* parameter is set to point to a **mach_dd_io** structure, which describes the data area where the boot control block is to be placed. The format of this control block is specified in the **/usr/include/sys/iplcb.h** file and the **mach_dd_io** structure is defined in the **/usr/include/sys/mdio.h** file. This **ioctl** operation uses the following fields in the **mach_dd_io** structure: **md_data** Points to a buffer at least the size of the value in the md_size field. **md_size** Specifies the size (in bytes) of the buffer pointed to by the md_data field and is the number of bytes to be returned from the boot control block. **md_addr** Specifies an offset into the boot control block where data is to be obtained. **Note:** Regions within this control block are platform-dependent.
MIONVGET	Reads data from an NVRAM address and returns data in the buffer that is provided by the caller. This operation is useful for reading the ROS area of NVRAM. A structure that defines this area is in the **/usr/include/sys/mdio.h** file. Use of this **ioctl** operation is not supported for systems that are compliant with the PowerPC Reference Platform or the Common Hardware Reference Platform and, in AIX 4.2.1 and later, cause the operation to fail with an **EINVAL** error code.

Operation	Description
MIONVLED	Writes the value found in the *arg* parameter to the system front panel LED display. On this panel, three digits are available and the *arg* parameter value can range from 0 to hex FFF. An explanation of the LED codes can be found in the **/usr/include/sys/mdio.h** file.
	Note: Not all platforms have an LED.
MIONVPUT	Writes data to an NVRAM address from the buffer that is provided by the caller. This operation is used only to update the ROS area of NVRAM and only by system commands. Use of this operation in other areas of NVRAM can cause unpredictable results to occur. If the NVRAM address provided is within the ROS area, a new cyclic redundancy code (CRC) for the ROS area is generated.
	Use of this **ioctl** operation is not supported on systems that are compliant with the PowerPC Reference Platform or the Common Hardware Reference Platform and cause the operation to fail with an **EINVAL** error code.

ioctl Operations for Systems

The following four **ioctl** operations can be used only with the POWER® processor-based architecture. If used with other systems, or if an invalid offset address, size, or slot number is supplied, these operations return an **EINVAL** error code.

These **ioctl** operations can be called from user space or kernel space (by using the **fp_ioctl** kernel service), but they are available only in the process environment.

The **ioctl** argument must be a pointer to a **mach_dd_io** structure.

The lock is obtained to serialize access to the bus slot configuration register.

MIOVPDGET

This **ioctl** operation allows read access to VPD/ROM address space.

The following structure members must be supplied:

Structure Member	Description
ulong md_addr	Specifies the offset into the feature or VPD address space to begin reading.
ulong md_size	Specifies the number of bytes to be transferred.
char md_data	Specifies a pointer to user buffer for data.
int md_sla	Specifies a slot number (bus slot configuration select).
int md_incr	Requires byte access (**MV_BYTE**).

The read begins at base address 0xFFA00000. The offset is added to the base address to obtain the starting address for reading.

The **buc_info** structure for the selected bus slot is used to obtain the word increment value. This value performs correct addressing when it reads the data.

MIOCFGGET

This **ioctl** operation allows read access to the architected configuration registers.

The following structure members must be supplied:

Structure Member	Description
ulong md_addr	Specifies the offset into the configuration register address space.

Structure Member	Description
ulong md_size	Specifies a value of 1.
char md_data	Specifies a pointer to user buffer for data.
int md_sla	Specifies a slot number (bus slot configuration select).
int md_incr	Requires byte or word access (**MV_BYTE**, **MV_SHORT**, or **MV_WORD**).

The base address 0xFF200000 is added to the offset to obtain the address for the read.

MIOCFGPUT

This **ioctl** operation allows write access to the architected configuration registers.

The following structure members must be supplied:

Structure Member	Description
ulong md_addr	Specifies the offset into the configuration register address space.
ulong md_size	Specifies a value of 1.
char md_data	Specifies a pointer to user buffer of data to write.
int md_sla	Specifies a slot number (bus slot configuration select).
int md_incr	Requires byte or word access (**MV_BYTE**, **MV_SHORT**, or **MV_WORD**).

The base address 0xFF200000 is added to the offset to obtain the address for the read.

MIORESET

This **ioctl** operation allows access to the architected bus slot reset register.

The following structure members must be supplied:

Structure Member	Description
ulong md_addr	Specifies reset hold time (in nanoseconds).
ulong md_size	Not used.
char md_data	Not used.
int md_sla	Specifies a slot number (bus slot configuration select).
int md_incr	Not used.

The bus slot reset register bit corresponding to the specified bus slot is set to 0. After the specified delay, the bit is set back to 1 and control returns to the calling program.

If a reset hold time of 0 is passed, the bus slot remains reset on return to the calling process.

ioctl Operations for the PowerPC Reference Platform Specification and the Common Hardware Reference Platform

The following four **ioctl** operations can be used only with the PowerPC Reference Platform and the Common Hardware Reference Platform.

MIOGEARD

Scans for the variable name in the Global Environment Area, and, if found, the null terminated string is returned to the caller. A global variable is of the form "variablename=". The returned string is of the form "variablename=string". If the supplied global variable is "*=", all of the variable strings in the Global Environment Area is returned.

The following structure members must be supplied:

Structure Member	Description
ulong md_addr	Pointer to global variable string which is null terminated with an equal sign as the last non-null character.
ulong md_size	Number of bytes in data buffer.
int md_incr	Not used.
char md_data	Pointer to the data buffer.
int md_sla	Not used.
ulong md_length	It is a pointer to the length of the returned global variable strings including the null terminators if md_length is non-zero.

MIOGEAUPD

The specified global variable is added to the Global Environment Area if it does not exist. If the specified variable does exist in the Global Environment Area, the new contents replace the old after adjusting any size deltas. Further, any information that is moved toward a lower address has the original area zeroed. If there is no string that follows the variable name and equal sign, the specified variable is deleted. If the variable to be deleted is not found, a successful return occurs. The new information is written to **NVRAM**. Further, the header in the **NVRAM** operation is updated to include the update time of the Global Environment Area and the CRC value are recomputed.

The following structure members must be supplied:

Structure Member	Description
ulong md_addr	Pointer to global variable string which is null terminated.
ulong md_size	Not used.
int md_incr	Not used.
char md_data	Not used.
int md_sla	Not used.
ulong md_length	It is a pointer to the amount of space that is left in the Global Environment Area after the update. It is computed as the size of the area minus the length of all global variable strings minus the threshold value.

MIOGEAST

The specified threshold is set so that any updates done do not exceed the Global Environment Area size minus the threshold. In place of the **mdio** structure an integer value is used to specify the threshold. The threshold does not persist across IPLs.

MIOGEARDA

The attributes of the Global Environment Area are returned to the data area specified by the caller. The **gea_attrib** structure is added to **mdio.h**. It contains the following information:

Structure Member	Description
long gea_length	number of bytes in the Global Environment Area of **NVRAM**.
long gea_used	number of bytes used in the Global Environment Area.
long gea_thresh	Global Environment Area threshold value.
ulong md_addr	Not used.
ulong md_size	Size of the data buffer. It must be greater than or equal to the size of (**gea_attrib**).

Structure Member	Description
int md_incr	Not used.
char md_data	Address of the buffer to copy the **gea_attrib** structure.
int md_sla	Not used.
ulong md_length	Not used.

MIONVPARTLEN

The length of the CHRP **NVRAM** partition is returned to the data area specified by the caller. The following structure members must be supplied:

Structure Member	Description
ulong md_addr	Specifies the partition signature.
ulong *md_length	Specifies a pointer to the name of the partition.
int md_incr	Not used.
ulong md_size	Specifies the data area for the returned partition length.
char *md_data	Not used.
int md_sla	Not used.

MIONVPARTRD

MIONVPARTRD performs read actions on CHRP **NVRAM** partitions. The following structure members must be supplied:

Structure Member	Description
ulong md_addr	Specifies the partition signature.
ulong *md_length	Specifies a pointer to the name of the partition.
int md_incr	Specifies the start offset into the partition.
ulong md_size	Specifies the number of bytes to be read.
char *md_data	Specifies a pointer to the user buffer where data is to be copied.
int md_sla	Not used.

MIONVPARTUPD

MIONVPARTUPD performs write actions to CHRP **NVRAM** partitions. The following structure members must be supplied:

Structure Member	Description
ulong md_addr	Specifies the partition signature.
ulong *md_length	Specifies a pointer to the name of the partition.
int md_incr	Specifies the start offset into the partition.
ulong md_size	Specifies the number of bytes to be read.
char *md_data	Specifies a pointer to the user buffer for data to write.
int md_sla	Not used.

Error Codes

The following error conditions might be returned when you access the machine device driver with the **/dev/nvram/**_n_ special file:

Error Condition	Description
EACCES	A write was requested to a file opened for read access only.
ENOENT	An open of **/dev/nvram/base** was attempted after the first close.
EFAULT	A buffer that is specified by the caller was invalid on a **read**, **write**, or **ioctl** subroutine call.
EINVAL	An invalid **ioctl** operation was issued.
ENXIO	A read was attempted past the end of the data area that is specified by the channel.
ENODEV	A write was attempted.
ENOMEM	A request was made with a user-supplied buffer that is too small for the requested data or not enough memory can be allocated to complete the request.

Bus Special File Support

All models have at least one bus. For non-CHRP systems, the names are of the form **/dev/bus**_N_. CHRP systems have the form **/dev/pci**_N_ and **/dev/isa**_N_.

open and close Subroutines

The machine device driver supports the bus special files as character special files. These special files, and support for access to the I/O buses and controllers, are provided on this hardware platform to support the system configuration and diagnostic subsystems, exclusively. The configuration subsystem accesses the I/O buses and controllers through the machine device driver to determine the I/O configuration of the system. This driver can also be used to configure the I/O controllers and devices as required for proper system operation. If the system diagnostic tests are unable to access a device through the diagnostic functions that are provided by the device's own device driver, they might use the machine device driver to attempt further failure isolation.

read and write Subroutines

The **read** and **write** subroutines are not supported by the machine device driver through the bus special files and, if called, return an **ENOENT** return code in the **errno** global variable.

ioctl Operations

The bus **ioctl** operations allow transfers of data between the system I/O controller or the system I/O bus and a caller-supplied data area. Because these **ioctl** operations use the **mach_dd_io** structure, the _arg_ parameter on the **ioctl** subroutine must point to such a structure. The bus address, the pointer to the caller's buffer, and the number and length of the transfer are all specified in the **mach_dd_io** structure. The **mach_dd_io** structure is defined in the **/usr/include/sys/mdio.h** file and provides the following information:

- The md_addr field contains an I/O controller or I/O bus address.
- The md_data field points to a buffer at least the size of the value in the md_size field.
- The md_size field contains the number of items to be transferred.
- The md_incr field specifies the length of the transferred item. It must be set to **MV_BYTE**, **MV_SHORT**, or **MV_WORD**.

The following commands can be issued to the machine device driver after a successful open of the bus special file:

Command	Description
IOCINFO	Returns machine device driver information in the caller's **devinfo** structure, as specified by the *arg* parameter. This structure is defined in the **/usr/include/sys/devinfo.h** file. The device type for this device driver is **DD_PSEU**.
MIOBUSGET	Reads data from the bus I/O space and returns it in a caller-provided buffer.
MIOBUSPUT	Writes data that is supplied in the caller's buffer to the bus I/O space.
MIOMEMGET	Reads data from the bus memory space and returns it to the caller-provided buffer.
MIOMEMPUT	Writes data that is supplied in the caller-provided buffer to the bus memory space.
MIOPCFGET	Reads data from the PCI bus configuration space and returns it in a caller-provided buffer. The **mach_dd_io** structure field **md_sla** must contain the Device Number and Function Number for the device to be accessed.
MIOPCFPUT	Writes data that is supplied in the caller's buffer to the PCI bus configuration space. The **mach_dd_io** structure field **md_sla** must contain the Device Number and Function Number for the device to be accessed.

Error Codes

Item	Description
EFAULT	A buffer that is specified by the caller was invalid on an **ioctl** call.
EIO	An unrecoverable I/O error occurred on the requested data transfer.
ENOMEM	No memory can be allocated by the machine device driver for use in the data transfer.

Files

Item	Description
/dev/pciN	Provides access to the I/O bus (CHRP and the AIX operating system).
/dev/isaN	Provides access to the I/O bus (CHRP and the AIX operating system).
/dev/nvram	Provides access to platform-specific nonvolatile RAM.
/dev/nvram/base	Allows read access to the base customize information that is stored as part of the boot record.

ODM Device Configuration Object Classes

A list of the ODM Device Configuration Object Classes follows:

Item	Description
PdDv	Predefined Devices
PdCn	Predefined Connection
PdAt	Predefined Attribute
Config_Rules	Configuration Rules
CuDv	Customized Devices
CuDep	Customized Dependency

Item	Description
CuAt	Customized Attribute
CuDvDr	Customized Device Driver
CuVPD	Customized Vital Product Data

Predefined Attribute (PdAt) Object Class

Description

The Predefined Attribute (PdAt) object class contains an entry for each existing attribute for each device represented in the Predefined Devices (PdDv) object class. An attribute, in this sense, is any device-dependent information not represented in the PdDv object class. This includes information such as interrupt levels, bus I/O address ranges, baud rates, parity settings, block sizes, and microcode file names.

Each object in this object class represents a particular attribute belonging to a particular device class-subclass-type. Each object contains the attribute name, default value, list or range of all possible values, width, flags, and an NLS description. The flags provide further information to describe an attribute.

Note: For a device being defined or configured, only the attributes that take a nondefault value are copied into the Customized Attribute (CuAt) object class. In other words, for a device being customized, if its attribute value is the default value in the PdDv object class, then there will not be an entry for the attribute in the CuAt object class.

Types of Attributes

There are three types of attributes. Most are *regular* attributes, which typically describe a specific attribute of a device. The *group* attribute type provides a grouping of regular attributes. The *shared* attribute type identifies devices that must all share a given attribute.

A shared attribute identifies another regular attribute as one that must be shared. This attribute is always a bus resource. Other regular attributes (for example, bus interrupt levels) can be shared by devices but are not themselves *shared* attributes. *Shared* attributes require that relevant devices have the same values for this attribute. The Attribute Value descriptor for the shared attribute gives the name of the regular attribute that must be shared.

A group attribute specifies a set of other attributes whose values are chosen as the group, as well as the group attribute number used to choose default values. Each attribute listed within a group has an associated list of possible values it can take. These values must be represented as a list, not as a range. For each attribute within the group, the list of possible values must also have the same number of choices. For example, if the possible number of values is n, the group attribute number itself can range from 0 to n-1. The particular value chosen for the group indicates the value to pick for each of the attributes in the group. For example, if the group attribute number is 0, then the value for each of the attributes in the group is the first value from their respective lists.

Predefined Attribute Object Class Descriptors

The Predefined Attribute object class contains the following descriptors:

ODM Type	Descriptor Name	Description	Descriptor Status
ODM_CHAR	**uniquetype[UNIQUESIZE]**	Unique Type	Required
ODM_CHAR	**attribute[ATTRNAMESIZE]**	Attribute Name	Required
ODM_VCHAR	**deflt[DEFAULTSIZE]**	Default Value	Required
ODM_VCHAR	**values[ATTRVALSIZE]**	Attribute Values	Required
ODM_CHAR	**width[WIDTHSIZE]**	Width	Optional

ODM Type	Descriptor Name	Description	Descriptor Status
ODM_CHAR	**type[FLAGSIZE]**	Attribute Type Flags	Required
ODM_CHAR	**generic[FLAGSIZE]**	Generic Attribute Flags	Optional
ODM_CHAR	**rep[FLAGSIZE]**	Attribute Representation Flags	Required
ODM_SHORT	**nls_index**	NLS index	Optional

These descriptors are described as follows:

Descriptor	Description
Unique Type	Identifies the class-subclass-type name of the device to which this attribute is associated. This descriptor is the same as the Unique Type descriptor in the PdDv object class.
Attribute Name	Identifies the name of the device attribute. This is the name that can be passed to the **mkdev** and **chdev** configuration commands and device methods in the attribute-name and attribute-value pairs.
Default Value	If there are several choices or even if there is only one choice for the attribute value, the default is the value to which the attribute is normally set. For groups, the default value is the group attribute number. For example, if the possible number of choices in a group is n, the group attribute number is a number between 0 and n-1. For shared attributes, the default value is set to a null string.
	When a device is defined in the system, attributes that take nondefault values are found in the CuAt object class. Attributes that take the default value are found in this object class; these attributes are not copied over to the CuAt object class. Therefore, both attribute object classes must be queried to get a complete set of customized attributes for a particular device.

Descriptor	Description
Attribute Values	Identifies the possible values that can be associated with the attribute name. The format of the value is determined by the attribute representation flags. For regular attributes, the possible values can be represented as a string, hexadecimal, octal, or decimal. In addition, they can be represented as either a range or an enumerated list. If there is only one possible value, then the value can be represented either as a single value or as an enumerated list with one entry. The latter is recommended, since the use of enumerated lists allows the **attrval** subroutine to check that a given value is in fact a possible choice.

If the value is hexadecimal, it is prefixed with the 0x notation. If the value is octal, the value is prefixed with a leading zero. If the value is decimal, its value is represented by its significant digits. If the value is a string, the string itself should not have embedded commas, since commas are used to separate items in an enumerated list.

A range is represented as a triplet of values: *lowerlimit*, *upperlimit*, and *increment value*. The *lowerlimit* variable indicates the value of the first possible choice. The *upperlimit* variable indicates the value of the last possible choice. The *lowerlimit* and *upperlimit* values are separated by a - (hyphen). Values between the *lowerlimit* and *upperlimit* values are obtained by adding multiples of the *increment value* variable to the *lowerlimit* variable. The *upperlimit* and *increment value* variables are separated by a comma.

Only numeric values are used for ranges. Also, discontinuous ranges (for example, 1-3, 6-8) are disallowed. A combination of list and ranges is not allowed.

An enumerated list contains values that are comma-separated.

If the attribute is a group, the Possible Values descriptor contains a list of attributes composing the group, separated by commas.

If the attribute is shared, the Possible Values descriptor contains the name of the bus resource regular attribute that must be shared with another device.

For type T attributes, the Possible Values descriptor contains the message numbers in a comma-separated list. |
| **Width** | If the attribute is a regular attribute of type M for a bus memory address or of type O for a bus I/O address, the Width descriptor can be used to identify the amount in bytes of the bus memory or bus I/O space that must be allocated. Alternatively, the `Width` field can be set to a null string, which indicates that the amount of bus memory or bus I/O space is specified by a width attribute, that is, an attribute of type W.

If the attribute is a regular attribute of type W, the Width descriptor contains the name of the bus memory address or bus I/O address attribute to which this attribute corresponds. The use of a type W attribute allows the amount of bus memory or bus I/O space to be configurable, whereas if the amount is specified in the bus memory address or bus I/O address attribute's Width descriptor, it is fixed at that value and cannot be customized.

For all other attributes, a null string is used to fill in this field. |

Descriptor	Description
Attribute Type	Identifies the attribute type. Only one attribute type must be specified. The characters A, B, M, I, N, O, P, and W represent bus resources that are regular attributes.

For regular attributes that are not bus resources, the following attribute types are defined:

L

Indicates the microcode file base name and the text from the label on the diskette containing the microcode file. Only device's with downloadable microcode have attributes of this type. The L attribute type is used by the **chkmcode** program to determine whether a device which is present has any version of its microcode installed. If none is installed, the user is prompted to insert the microcode diskette with the label identified by this attribute. The base name is stored in the `Default Value` field and is the portion of the microcode file name not consisting of the level and version numbers. The label text is stored in the `Possible Values` field.

T

Indicates message numbers corresponding to possible text descriptions of the device. These message numbers are within the catalog and set identified in the device's PdDv object.

A single PdDv object can represent many device types. Normally, the message number in a device's PdDv object also identifies its text description. However, there are cases where a single PdDv object represents different device types. This happens when the parent device which detects them cannot distinguish between the types. For example, a single PdDv object is used for both the 120MB and 160MB Direct Attached Disk drives. For these devices, unique device descriptions can be assigned by setting the message number in the device's PdDv object to 0 and having a T attribute type, indicating the set of possible message numbers. The device's configure method determines the actual device type and creates a corresponding CuAt object indicating the message number of the correct text description.

R

Indicates any other regular attribute that is not a bus resource.

Z

If the attribute name is `led`, than this indicates the LED number for the device. Normally, the LED number for a device is specified in the device's PdDv object. However, in cases where the PdDv object may be used to respresent multiple device types, unique LED numbers can be assigned to each device type by having a type **Z** attribute with an attribute name of `led`. In this case, the LED number in the PdDv object is set to 0. The device's configure method determines the actual LED number for the device, possibly by obtaining the value from the device, and creates a corresponding CuAt object indicating the LED number. The default value specified in the type **Z** PdAt object with the attribute name of `led` is the LED number to be used until the device's configure method has determined the LED number for the device.

The following are the bus resources types for regular attributes:

Descriptor	Description
	A
	Indicates DMA arbitration level.
	B
	Indicates a bus memory address which is not associated with DMA transfers.
	M
	Indicates a bus memory address to be used for DMA transfers.
	I
	Indicates bus interrupt level that can be shared with another device.
	N
	Indicates a bus interrupt level that cannot be shared with another device.
	O
	Indicates bus I/O address.
	P
	Indicates priority class.
	W
	Indicates an amount in bytes of bus memory or bus I/O space.
	For non-regular attributes, the following attribute types are defined:
	G
	Indicates a group.
	S
	Indicates a shared attribute.
Generic Attribute Flags	Identifies the flags that can apply to any regular attribute. Any combination (one, both, or none) of these flags is valid. This descriptor should be a null string for group and shared attributes. This descriptor is always set to a null string for type T attributes.
	These are the defined generic attribute flags:
	D
	Indicates a displayable attribute**.** The **lsattr** command displays only attributes with this flag.
	U
	Indicates an attribute whose value can be set by the user.

Descriptor	Description
Attribute Representation Flags	Indicates the representation of the regular attribute values. For group and shared attributes, which have no associated attribute representation, this descriptor is set to a null string. Either the **n** or **s** flag, both of which indicate value representation, must be specified.

The **r**, **l**, and **m** flags indicate, respectively, a range, an enumerated list, and a multi-select value list, and are optional. If neither the **r** flag nor the **l** flag is specified, the **attrval** subroutine will not verify that the value falls within the range or the list.

These are the defined attribute representation flags:

n
Indicates that the attribute value is numeric: either decimal, hex, or octal.

s
Indicates that the attribute value is a character string.

r
Indicates that the attribute value is a range of the form: *lowerlimit-upperlimit,increment value*.

l
Indicates that the attribute value is an enumerated list of values.

m
Indicates that multiple values can be assigned to this attribute. Multiple values for an attribute are represented as a comma separated list.

b
Indicates that value is a boolean type, and can only have 2 values. Typical values are `yes`,`no`, `true`,`false`, `on`,`off`, `disable`,`enable` or `0`,`1`.

d
Indicates that the default value for the attribute has been altered by the **chdef** command.

The attribute representation flags are always set to **nl** (numeric list) for type T attributes.

Descriptor	Description
NLS Index	Identifies the message number in the NLS message catalog of the message containing a textual description of the attribute. Only displayable attributes, as identified by the Generic Attribute Flags descriptor, need an NLS message. If the attribute is not displayable, the NLS index can be set to a value of 0. The catalog file name and the set number associated with the message number are stored in the PdDv object class.

Predefined Attribute Extended (PdAtXtd) Object Class

The Predefined Attribute Extended (PdAtXtd) object class is used to supplement existing device attributes that are represented in the Predefined Attribute (PdAt) object class with information that can be used by Device Management User Interface.

Types of attributes to represent in PdAtXtd

Not all existing device attributes in PdAt must be represented in the PdAtXtd object class. Non-displayable attributes (that is, attributes with a null string in the 'generic' field of the PdAt object class) must not have a corresponding PdAtXtd entry, otherwise, it becomes displayable.

The PdAtXtd object class can also be used to override the current value or possible values of an attribute.

Predefined Attribute Extended Object Class Descriptors

The Predefined Attribute Extended object class contains the following descriptors:

ODM Type	Descriptor Name	Description	Required
ODM_CHAR	**uniquetype**	Unique Type	Yes
ODM_CHAR	**attribute**	Attribute Name	No
ODM_CHAR	**classification**	Attribute Classification	No
ODM_CHAR	**sequence**	Sequence number	No
ODM_VCHAR	**operation**	Operation Name	No
ODM_VCHAR	**operation_value**	Operation Value	No
ODM_VCHAR	**description**	Attribute Description	No
ODM_VCHAR	**list_cmd**	Command to list Attribute value	No
ODM_VCHAR	**list_values_cmd**	Command to list Attribute values	No
ODM_VCHAR	**change_cmd**	Command to change Attribute value	No
ODM_VCHAR	**help**	Help text	NO
ODM_VCHAR	**nls_values**	Translated Attribute values	No

These descriptors are described as follows:

Descriptor	Description
uniquetype	Identifies the class-subclass-type name of the device to which this attribute is associated. This descriptor is the same as the Unique Type descriptor in the PdAt object class.
attribute	Identifies the device attribute. This name can be passed to **mkdev** and **chdev** configuration commands and device methods in the attribute-name and attribute-value pairs.
classification	Identifies the classification of the device attribute. The followings characters are valid values: **B** Indicates a basic attribute. **A** Indicates an advanced attribute. **R** Indicates a required attribute.
sequence	Identifies the number that is used to position the attribute in relation to others on a panel or menu. This field is identical to the `id_seq_num` currently in the `sm_cmd_opt` (SMIT Dialog/Selector Command Option) object class.
operation	Identifies the type of operation that is associated with the unique device type. Operation and attribute name fields are mutually exclusive.

Descriptor	Description
operation_value	Identifies the value that is associated with the `Operation` field.
	When the operation is add_*device*, the operation_value field can contain the command that is used to make the device, if the **mkdev** command cannot be used.
description	Identifies the attribute description.
list_cmd	Identifies the command to override the current value of the attribute, except when the operation field is set. If the operation field is set, it identifies the command to return information that is associated with the operation.
	For example, in the case of the add_ttyoperation, the `list_cmd` field contains the following value:

```
lsdev -P -c tty -s rs232 -Fdescription
```

list_values_cmd	Identifies the command to obtain the possible values of an attribute. The values that are returned override the values field in the Predefined Attribute object class.
change_cmd	Identifies the command to change the attribute value if the **chdev**command cannot be used.
help	Identifies the help text that is associated with the attribute. The help text format follows:

```
message file,set id,msg id,default text
```

OR

```
a numeric string equal to a SMIT identifier tag.
```

nls_values	Identifies the text that is associated with the attribute values. These values are displayed in place of the values that are stored in the Predefined Attribute object class. This field must be of the following form:

```
message file,set id,msg id,default text
```

The ordering of values must match the ordering in the **Predefined Attribute values** field.

Predefined Connection (PdCn) Object Class

Description

The Predefined Connection (PdCn) object class contains connection information for intermediate devices. This object class also includes predefined dependency information. For each connection location, there are one or more objects describing the subclasses of devices that can be connected. This information is useful, for example, in verifying whether a device instance to be defined and configured can be connected to a given device.

Descriptors

The Predefined Connection object class contains the following descriptors:

ODM Type	Descriptor Name	Description	Descriptor Status
ODM_CHAR	**uniquetype[UNIQUESIZE]**	Unique Type	Required

ODM Type	Descriptor Name	Description	Descriptor Status
ODM_CHAR	**connkey[KEYSIZE]**	Connection Key	Required
ODM_CHAR	**connwhere[LOCSIZE]**	Connection Location	Required

These fields are described as follows:

Field	Description
Unique Type	Identifies the intermediate device's class-subclass-type name. For a device with dependency information, this descriptor identifies the unique type of the device on which there is a dependency. This descriptor contains the same information as the Unique Type descriptor in the Predefined Devices (PdDv) object class.
Connection Key	Identifies a subclass of devices that can connect to the intermediate device at the specified location. For a device with dependency information, this descriptor serves to identify the device indicated by the Unique Type field to the devices that depend on it.
Connection Location	Identifies a specific location on the intermediate device where a child device can be connected. For a device with dependency information, this descriptor is not always required and consequently may be filled with a null string.
	The term *location* is used in a generic sense. For example, for a bus device the location can refer to a specific slot on the bus, with values 1, 2, 3, ... For a multiport serial adapter device, the location can refer to a specific port on the adapter with values 0, 1, ...

Predefined Devices (PdDv) Object Class

Description

The Predefined Devices (PdDv) object class contains entries for all device types currently on the system. It can also contain additional device types if the user has specifically installed certain packages that contain device support for devices that are not on the system. The term *devices* is used generally to mean both intermediate devices (for example, adapters) and terminal devices (for example, disks, printers, display terminals, and keyboards). Pseudo-devices (for example, pseudo terminals, logical volumes, and TCP/IP) are also included there. Pseudo-devices can either be intermediate or terminal devices.

Each device type, as determined by class-subclass-type information, is represented by an object in the PdDv object class. These objects contain basic information about the devices, such as device method names and instructions for accessing information contained in other object classes. The PdDv object class is referenced by the Customized Devices (CuDv) object class using a link that keys into the Unique Type descriptor. This descriptor is uniquely identified by the class-subclass-type information.

Typically, the Predefined database is consulted but never modified during system boot or run time, except when a new device is added to the Predefined database. In this case, the predefined information for the new device must be added into the Predefined database. However, any new predefined information for a new base device must be written to the boot file system to be effective. This is done with the **bosboot** command.

You build a Predefined Device object by defining the objects in a file in stanza format and then processing the file with the **odmadd** command or the **odm_add_obj** subroutine. See the **odmadd** command or the **odm_add_obj** subroutine for information on creating the input file and compiling the object definitions into objects.

Note: When coding an object in this object class, set unused empty strings to "" (two double-quotation marks with no separating space) and unused integer fields to 0 (zero).

Descriptors

Each Predefined Devices object corresponds to an instance of the PdDv object class. The descriptors for the Predefined Devices object class are as follows:

Predefined Devices			
ODM Type	**Descriptor Name**	**Description**	**Descriptor Status**
ODM_CHAR	**type[TYPESIZE]**	Device Type	Required
ODM_CHAR	**class[CLASSIZE]**	Device Class	Required
ODM_CHAR	**subclass[CLASSIZE]**	Device Subclass	Required
ODM_CHAR	**prefix[PREFIXSIZE]**	Prefix Name	Required
ODM_CHAR	**devid[DEVIDSIZE]**	Device ID	Optional
ODM_SHORT	**base**	Base Device Flag	Required
ODM_SHORT	**has_vpd**	VPD Flag	Required
ODM_SHORT	**detectable**	Detectable/Non-detectable Flag	Required
ODM_SHORT	**chgstatus**	Change Status Flag	Required
ODM_SHORT	**bus_ext**	Bus Extender Flag	Required
ODM_SHORT	**inventory_only**	Inventory Only Flag	Required
ODM_SHORT	**fru**	FRU Flag	Required
ODM_SHORT	**led**	LED Value	Required
ODM_SHORT	**setno**	Set Number	Required
ODM_SHORT	**msgno**	Message Number	Required
ODM_VCHAR	**catalog[CATSIZE]**	Catalog File Name	Required
ODM_CHAR	**DvDr[DDNAMESIZE]**	Device Driver Name	Optional
ODM_METHOD	**Define**	Define Method	Required
ODM_METHOD	**Configure**	Configure Method	Required
ODM_METHOD	**Change**	Change Method	Required
ODM_METHOD	**Unconfigure**	Unconfigure Method	Optional*
ODM_METHOD	**Undefine**	Undefine Method	Optional*
ODM_METHOD	**Start**	Start Method	Optional
ODM_METHOD	**Stop**	Stop Method	Optional
ODM_CHAR	**uniquetype[UNIQUESIZE]**	Unique Type	Required

These descriptors are described as follows:

Descriptor	Description
Device Type	Specifies the product name or model number. For example, IBM 3812-2 Model 2 Page printer and IBM 4201 Proprinter II are two types of printer device types. Each device type supported by the system should have an entry in the PdDv object class.
Device Class	Specifies the functional class name. A functional class is a group of device instances sharing the same high-level function. For example, `printer` is a functional class name representing all devices that generate hardcopy output.
Device Subclass	Identifies the device subclass associated with the device type. A device class can be partitioned into a set of device subclasses whose members share the same interface and typically are managed by the same device driver. For example, parallel and serial printers form two subclasses within the class of printer devices.
	The configuration process uses the subclass to determine valid parent-child connections. For example, an rs232 8-port adapter has information that indicates that each of its eight ports only supports devices whose subclass is rs232. Also, the subclass for one device class can be a subclass for a different device class. In other words, several device classes can have the same device subclass.
Prefix Name	Specifies the Assigned Prefix in the Customized database, which is used to derive the device instance name and **/dev** name. For example, `tty` is a Prefix Name assigned to the tty port device type. Names of tty port instances would then look like `tty0`, `tty1`, or `tty2`. The rules for generating device instance names are given in the Customized Devices object class under the Device Name descriptor.
Base Device Flag	A base device is any device that forms part of a minimal base system. During the first phase of system boot, a minimal base system is configured to permit access to the root volume group and hence to the root file system. This minimal base system can include, for example, the standard I/O diskette adapter and a SCSI hard drive.
	The Base Device flag is a bit mask representing the type of boot for which the device is considered a base device. The **bosboot** command uses this flag to determine what predefined device information to save in the boot file system. The **savebase** command uses this flag to determine what customized device information to save in the boot file system. Under certain conditions, the **cfgmgr** command also uses the Base Device flag to determine whether to configure a device.

Descriptor	Description
VPD Flag	Specifies whether device instances belonging to the device type contain extractable vital product data (VPD). Certain devices contain VPD that can be retrieved from the device itself. A value of TRUE means that the device has extractable VPD, and a value of FALSE that it does not. These values are defined in the **/usr/include/sys/cfgdb.h** file.
Detectable/Nondetectable Flag	Specifies whether the device instance is detectable or nondetectable. A device whose presence and type can be electronically determined, once it is actually powered on and attached to the system, is said to be detectable. A value of TRUE means that the device is detectable, and a value of FALSE that it is not. These values are defined in the **/usr/include/sys/cfgdb.h** file.
Change Status Flag	Indicates the initial value of the Change Status flag used in the Customized Devices (CuDv) object class. Refer to the corresponding descriptor in the CuDv object class for a complete description of this flag. A value of NEW means that the device is to be flagged as new, and a value of DONT_CARE means "it is not important." These values are defined in the **/usr/include/sys/cfgdb.h** file.
Bus Extender Flag	Indicates that the device is a bus extender. The Bus Configurator uses the Bus Extender flag descriptor to determine whether it should directly invoke the device's Configure method. A value of TRUE means that the device is a bus extender, and a value of FALSE that it is not. These values are defined in the **/usr/include/sys/cfgdb.h** file. This flag is further described in "Device Methods for Adapter Cards: Guidelines" .
Inventory Only Flag	Distinguishes devices that are represented solely for their replacement algorithm from those that actually manage the system. There are several devices that are represented solely for inventory or diagnostic purposes. Racks, drawers, and planars represent such devices. A value of TRUE means that the device is used solely for inventory or diagnostic purposes, and a value of FALSE that it is not used solely for diagnostic or inventory purposes. These values are defined in the **/usr/include/sys/cfgdb.h** file

Descriptor	Description
FRU Flag	Identifies the type of field replaceable unit (FRU) for the device. The three possible values for this field are:
	NO_FRU
	Indicates that there is no FRU (for pseudo-devices).
	SELF_FRU
	Indicates that the device is its own FRU.
	PARENT_FRU
	Indicates that the FRU is the parent.
	These values are defined in the **/usr/include/sys/cfgdb.h** file.
LED Value	Indicates the hexadecimal value displayed on the LEDs when the Configure method executes.
Catalog File Name	Identifies the file name of the NLS message catalog that contains all messages pertaining to this device. This includes the device description and its attribute descriptions. All NLS messages are identified by a catalog file name, set number, and message number.
Set Number	Identifies the set number that contains all the messages for this device in the specified NLS message catalog. This includes the device description and its attribute descriptions.
Message Number	Identifies the message number in the specified set of the NLS message catalog. The message corresponding to the message number contains the textual description of the device.
Device Driver Name	Identifies the base name of the device driver associated with all device instances belonging to the device type. For example, a device driver name for a keyboard could be `ktsdd`. For the tape device driver, the name could be `tapedd`. The Device Driver Name descriptor can be passed as a parameter to the **loadext** routine to load the device driver, if the device driver is located in the **/usr/lib/drivers** directory. If the driver is located in a different directory, the full path must be appended in front of the Device Driver Name descriptor before passing it as a parameter to the **loadext** subroutine.
Define Method	Names the Define method associated with the device type. All Define method names start with the **def** prefix.
Configure Method	Names the Configure method associated with the device type. All Configure method names start with the **cfg** prefix.
Change Method	Names the Change method associated with the device type. All Change method names start with the **chg** prefix.

Descriptor	Description
Unconfigure Method	Names the Unconfigure method associated with the device type. All Unconfigure method names start with the **ucfg** prefix.
	Note: The Optional* descriptor status indicates that this field is optional for those devices (for example, the bus) that are never unconfigured or undefined. For all other devices, this descriptor is required.
Undefine Method	Names the Undefine method associated with the device type. All Undefine method names start with the **und** prefix.
	Note: The Optional* descriptor status indicates that this field is optional for those devices (for example, the bus) that are never unconfigured or undefined. For all other devices, this descriptor is required.
Start Method	Names the Start method associated with the device type. All Start method names start with the **stt** prefix. The Start method is optional and only applies to devices that support the Stopped device state.
Stop Method	Names the Stop method associated with the device type. All Stop method names start with the **stp** prefix. The Stop method is optional and only applies to devices that support the Stopped device state.
Unique Type	A key that is referenced by the **PdDvLn** link in CuDv object class. The key is a concatenation of the Device Class, Device Subclass, and Device Type values with a **/** (slash) used as a separator. For example, for a class of `disk`, a subclass of `scsi`, and a type of 670mb, the Unique Type is `disk/scsi/670mb`.
	This descriptor is needed so that a device instance's object in the CuDv object class can have a link to its corresponding PdDv object. Other object classes in both the Predefined and Customized databases also use the information contained in this descriptor.

Files

Item	Description
/usr/lib/drivers directory	Contains device drivers.

putattr Device Configuration Subroutine

Purpose

Updates, deletes, or creates an attribute object in the Customized Attribute (CuAt) object class.

Library

Object Data Manager Library (**libodm.a**)

Syntax

```
#include <cf.h>
#include <sys/cfgodm.h>
#include <sys/cfgdb.h>

int putattr ( cuobj)
struct CuAt *cuobj;
```

Parameters

Item	Description
cuobj	Specifies the attribute object.

Description

The **putattr** device configuration subroutine either updates an old attribute object, creates a new object for the attribute information, or deletes an existing object in the CuAt object class. The **putattr** subroutine queries the CuAt object class to determine whether an object already exists with the device name and attribute name specified by the *cuobj* parameter.

If the attribute is found in the CuAt object class and its value (as given in the *cuobj* parameter) is to be changed back to the default value for this attribute, the customized object is deleted. Otherwise, the customized object is simply updated.

If the attribute object does not already exist and its attribute value is being changed to a non-default value, a new object is added to the CuAt object class with the information given in the *cuobj* parameter.

Note: The **putattr** device configuration subroutine will fail unless you first call the **odm_initialize** subroutine.

Return Values

Item	Description
0	Indicates a successful operation.
-1	Indicates a failed operation.

Files

Item	Description
/usr/lib/libcfg.a	Archive of device configuration subroutines.

reldevno Device Configuration Subroutine

Purpose

Releases the minor or major number, or both, for a device instance.

Syntax

#include <cf.h> #include <sys/cfgodm.h> #include <sys/cfgdb.h> int reldevno (*device_instance_name*, *release*) char **device_instance_name***; int** *release***;**

Parameters

Item	Description
device_instance_name	Points to the character string containing the device instance name.
release	Specifies whether the major number should be released. A value of True releases the major number; a value of False does not.

Description

The **reldevno** device configuration subroutine is one of the designated access routines to the Customized Device Driver (CuDvDr) object class. This object class is locked exclusively by this routine until its completion. All minor numbers associated with the device instance name are deleted from the CuDvDr object class. That is, each object is deleted from the class. This releases the minor numbers for reuse.

The major number is released for reuse if the following two conditions exist:

- The object to be deleted contains the last minor number for a major number.
- The *release* parameter is set to True.

If you prefer to release the major number yourself, then the **relmajor** device configuration subroutine can be called. In this case, you should also set the *release* parameter to False. All special files, including symbolically linked special files, corresponding to the deleted objects are deleted from the file system.

Return Values

Item	Description
0	Indicates successful completion.
-1	Indicates a failure to release the minor number or major number, or both.

Files

Item	Description
/usr/lib/libcfg.a	Archive of device configuration subroutines.

relmajor Device Configuration Subroutine

Purpose

Releases the major number associated with the specified device driver instance name.

Syntax

#include <cf.h> #include <sys/cfgodm.h> #include <sys/cfgdb.h> int relmajor (*device_driver_instance_name*) char **device_driver_instance_name***;**

Parameter

Item	Description
device_driver_instance_name	Points to a character string containing the device driver instance name.

Description

The **relmajor** device configuration subroutine is one of the designated access routines to the <u>Customized Device Driver (CuDvDr) object class</u>. To ensure that unique major numbers are generated, the CuDvDr object class is locked exclusively by this routine until the major number has been released.

The **relmajor** routine deletes the object containing the major number of the device driver instance name.

Return Values

Item	Description
0	Indicates successful completion.
-1	Indicates a failure to release the major number.

Files

Item	Description
/usr/lib/libcfg.a	Archive of device configuration subroutines.

Writing a Change Method

This article describes how a Change device method works. It also suggests guidelines for programmers writing their own Change device configuration methods.

Syntax

chg*Dev* **-l** *Name* [<u>**-p**</u> *Parent*] [<u>**-w**</u> *Connection*] [<u>**-P**</u> | <u>**-T**</u>] [<u>**-a**</u> *Attr=Value* [**-a** *Attr=Value ...*] ...]

Description

The Change method applies configuration changes to a device. If the device is in the Defined state, the changes are simply recorded in the Customized database. If the device is in the Available state, the Change method must also apply the changes to the actual device by reconfiguring it.

A Change method does not need to support all the flags described for Change methods. For example, if your device is a pseudo-device with no parent, it need not support parent and connection changes. For devices that have parents, it may be desirable to disallow parent and connection changes. For printers, such changes are logical because they are easily moved from one port to another. By contrast, an adapter card is not usually moved without first shutting off the system. It is then automatically configured at its new location when the system is rebooted. Consequently, there may not be a need for a Change method to support parent and connection changes.

Note: In deciding whether to support the **-T** and **-P** flags, remember that these options allow a device's configuration to get out of sync with the Configuration database. The **-P** flag is useful for devices that are typically kept open by the system. The Change methods for most supported devices do not support the **-T** flag.

In applying changes to a device in the Available state, the Change method could terminate the device from the driver, rebuild the device-dependent structure (DDS) using the new information, and redefine the device to the driver using the new DDS. The method may also need to reload adapter software or perform other device-specific operations. An alternative is to invoke the device's Unconfigure method, update the Customized database, and invoke the device's Configure method.

By convention, the first three characters of the name of the Change method should be **chg**. The remainder of the name (*Dev*) can be any characters, subject to operating system file-name restrictions, that identify the device or group of devices that use the method.

Flags

Item	Description
-l *Name*	Identifies the logical name of the device to be changed.
-p *Parent*	Identifies the logical name of a new parent for the device. This flag is used to move a device from one parent to another.
-w *Connection*	Identifies a new connection location for the device. This flag either identifies a new connection location on the device's existing parent, or if the **-p** flag is also used, it identifies the connection location on the new parent device.
-P	Indicates that the changes are to be recorded in the Customized database without those changes being applied to the actual device. This is a useful option for a device which is usually kept open by the system such that it cannot be changed. Changes made to the database with this flag are later applied to the device when it is configured at system reboot.
-T	Indicates that the changes are to be applied only to the actual device and not recorded in the database. This is a useful option for allowing temporary configuration changes that will not apply once the system is rebooted.
-a *Attr=Value*	Specifies the device attribute value pairs used for changing specific attribute values. The *Attr=Value* parameter contains one or more attribute value pairs for the **-a** flag. If you use a **-a** flag with multiple attribute value pairs, the list of pairs must be enclosed in quotes with spaces between the pairs. For example, entering **-a** *Attr=Value* lists one attribute value pair, while entering **-a** '*Attr1=Value1 Attr2=Value2*' lists more than one attribute value pair.

Guidelines for Writing a Change Method

This list of tasks is intended as a guideline for writing a Change method. When writing for a specific device, some tasks may be omitted. For example, if a device does not support the changing of a parent or connection, there is no need to include those tasks. A device may have special needs that are not included in these tasks.

If the Change method is written to invoke the Unconfigure and Configure methods, it must:

1. Validate the input parameters. The **-l** flag must be supplied to identify the device that is to be changed. If your method does not support the specified flag, exit with an error.

2. Initialize the Object Data Manager (ODM). Use the **odm_initialize** subroutine and lock the Configuration database using the **odm_lock** subroutine. See "Writing a Define Method" for an example.

3. Retrieve the Customized Device (CuDv) object for the device to be changed by getting the CuDv object whose Device Name descriptor matches the name supplied with the **-l** flag. If no object is found with the specified name, exit with an error.

4. Validate all attributes being changed. Make certain that the attributes apply to the specified device, that they can be set by the user, and that they are being set to valid values. The **attrval** subroutine can be used for this purpose. If some attributes have values that are dependent on each other, write the code to cross check them. If invalid attributes are found, the method needs to write information to standard error describing them.

5. Determine if a new parent device exists. If a new parent device has been specified, find out whether it exists by querying the CuDv object class for an object whose Device Name descriptor matches the new parent name. If no match is found, the method exits with an error.

6. If a new connection has been specified, validate that this device can be connected there. Do this by querying the Predefined Connection (PdCn) object class for an object whose Unique Type descriptor

matches the link to the Predefined Devices (PdDv) object class descriptor of the parent's CuDv object. The Connection Key descriptor of the CuDv object must match the subclass name of the device being changed, and the Connection Location descriptor of the CuDv object must match the new connection value. If no match is found, the method exits with an error.

7. If a match is found, the new connection is valid. If the device is in the Available state, then it should still be available after being moved to the new connection. Since only one device can be available at a particular connection, the Change method must check for other available devices at that connection. If one is found, the method exits with an error.

8. If the device state is Available and the **-P** flag was not specified, invoke the device's Unconfigure method using the **odm_run_method** command. This fails if the device has Available child devices, which is why the Change method does not need to check explicitly for child devices.

9. If any attribute settings were changed, update the database to reflect the new settings. If a parent or connection changed, update the Parent Device Logical Name, Location Where Connected on Parent Device, and Location Code descriptors of the device's CuDv object.

10. If the device state was in the Available state before being unconfigured, invoke the device's Configure method using the **odm_run_method** command. If this returns an error, leaving the device unconfigured, the Change method should restore the Customized database to its pre-change state.

11. Close all object classes and terminate the ODM. Exit with an exit code of 0 if there were no errors.

Handling Invalid Attributes

If the Change method detects attributes that are in error, it must write information to the **stderr** file to identify them. This consists of writing the attribute name followed by the attribute description. Only one attribute and its description is to be written per line. If an attribute name was mistyped so that it does not match any of the device's attributes, write the attribute name supplied on a line by itself.

The **mkdev** and **chdev** configuration commands intercept the information written to the standard error file by the Change method. These commands write out the information following an error message describing that there were invalid attributes. Both the attribute name and attribute description are needed to identify the attribute. By invoking the **mkdev** or **chdev** command directly, the attributes can be identified by name. When using SMIT, these attributes can be identified by description.

The attribute description is obtained from the appropriate message catalog. A message is identified by catalog name, set number, and message number. The catalog name and set number are obtained from the device's PdDv object. The message number is obtained from the NLS Index descriptor in either the Predefined Attribute (PdAt) or Customized Attribute (CuAt) object corresponding to the attribute.

Writing a Configure Method

This article describes how a Configure device method works. It also suggests guidelines for programmers writing their own Configure device configuration methods.

Syntax

cfgDev **-l** *Name* [**-1** | **-2**]

Description

The Configure method moves a device from Defined (not available for use in the system) to Available (available for use in the system). If the device has a driver, the Configure method loads the device driver into the kernel and describes the device characteristics to the driver. For an intermediate device (such as a SCSI bus adapter), this method determines which attached child devices are to be configured and writes their logical names to standard output.

The Configure method is invoked by either the **mkdev** configuration command or by the Configuration Manager. Because the Configuration Manager runs a second time in phase 2 system boot and can also be invoked repeatedly at run time, a device's Configure method can be invoked to configure an Available

device. This is not an error condition. In the case of an intermediate device, the Configure method checks for the presence of child devices. If the device is not an intermediate device, the method simply returns.

In general, the Configure method obtains all the information it needs about the device from the Configuration database. The options specifying the phase of system boot are used to limit certain functions to specific phases.

If the device has a parent device, the parent must be configured first. The Configure method for a device fails if the parent is not in the Available state.

By convention, the first three characters of the name of the Configure method are **cfg**. The remainder of the name (*Dev*) can be any characters, subject to operating system file-name restrictions, that identify the device or group of devices that use the method.

Flags

Item	Description
-l *Name*	Identifies the logical name of the device to be configured.
-1	Specifies that the device is being configured in phase 1 of the System boot processing. This option cannot be specified with the -2 flag. If neither the -1 nor the -2 flags are specified, the Configure method is invoked at runtime.
-2	Specifies that the device is being configured in phase 2 of the system boot. This option cannot be specified with the -1 flag. If neither the -1 nor the -2 flags are specified, the Configure method is invoked at runtime.

Handling Device Vital Product Data (VPD)

Devices that provide vital product data (VPD) are identified in the Predefined Device (PdDv) object class by setting the VPD flag descriptor to TRUE in each of the device's PdDv objects. The Configure method must obtain the VPD from the device and store it in the Customized VPD (CuVPD) object class. Consult the appropriate hardware documentation to determine how to retrieve the device's VPD. In many cases, VPD is obtained from the device driver using the **sysconfig** subroutine.

Once the VPD is obtained from the device, the Configure method queries the CuVPD object class to see if the device has hardware VPD stored there. If so, the method compares the VPD obtained from the device with that from the CuVPD object class. If the VPD is the same in both cases, no further processing is needed. If they are different, update the VPD in the CuVPD object class for the device. If there is no VPD in the CuVPD object class for the device, add the device's VPD.

By first comparing the device's VPD with that in the CuVPD object class, modifications to the CuVPD object class are reduced. This is because the VPD from a device typically does not change. Reducing the number of database writes increases performance and minimizes possible data loss.

Understanding Configure Method Errors

For many of the errors detected, the Configure method exits with the appropriate exit code. In other cases, the Configure method may need to undo some of the operations it has performed. For instance, after loading the device driver and defining the device to the driver, the Configure method may encounter an error while downloading microcode. If this happens, the method will terminate the device from the driver using the **sysconfig** subroutine and unload the driver using the **loadext** subroutine.

The Configure method does not delete the special files or unassign the major and minor numbers if they were successfully allocated and the special file created before the error was encountered. This is because the operating system's configuration scheme allows both major and minor numbers and special files to be maintained for a device even though the device is unconfigured.

If the device is configured again, the Configure method will recognize that the major and minor numbers are allocated and that the special files exist.

By the time the Configure method checks for child devices, it has successfully configured the device. Errors that occur while checking for child devices are indicated with the **E_FINDCHILD** exit code. The **mkdev** command detects whether the Configure method completed successfully. If needed, it will display a message indicating that an error occurred while looking for child devices.

Guidelines for Writing a Configure Method

The following tasks are guidelines for writing a Configure method. When writing for a specific device, some tasks may be omitted. For example, if the device is not an intermediate device or does not have a driver, the method is written accordingly. A device may also have special requirements not listed in these tasks.

The Configure method must:

1. Validate the input parameters. The **-l** logical name flag must be supplied to identify the device that is to be configured. The **-1** and **-2** flags cannot be supplied at the same time.

2. Initialize the Object Data Manager (ODM). Use the **odm_initialize** subroutine and lock the Configuration database using the **odm_lock** subroutine. See "Writing a Define Method" for an example.

3. Retrieve the Customized Device (CuDv) object for the device to be configured. The CuDv object's Device Name descriptor must match the name supplied with the **-l** logical name flag. If no object is found with the specified name, the method exits with an error.

4. Retrieve the Predefined Device (PdDv) object for the device to be configured. The PdDv object's Unique Type descriptor must match the link to PdDv object class descriptor of the device's CuDv object.

5. Obtain the LED value descriptor of the device's PdDv object. Retrieve the LED Value descriptor of the device's PdDv object and display this value on the system LEDs using the **setleds** subroutine if either the **-1** or **-2** flag is specified. This specifies when the Configure method will execute at boot time. If the system hangs during configuration at boot time, the displayed LED value indicates which Configure method created the problem.

   If the device is already configured (that is, the Device State descriptor of the device's CuDv object indicates the Available state) and is an intermediate device, skip to the task of detecting child devices. If the device is configured but is not an intermediate device, the Configure method will exit with no error.

   If the device is in the Defined state, the Configure Method must check the parent device, check for the presence of a device, obtain the device VPD, and update the device's CuDv object.

6. If the device has a parent, the Configure method validates the parent's existence and verifies that the parent is in the Available state. The method looks at the Parent Device Logical Name descriptor of the device's CuDv object to obtain the parent name. If the device does not have a parent, the descriptor will be a null string.

   When the device has a parent, the Configure method will obtain the parent device's CuDv object and check the Device State descriptor. If the object does not exist or is not in the Available state, the method exits with an error.

   Another check must be made if a parent device exists. The Configure method must verify that no other device connected to the same parent (at the same connection location) has been configured. For example, two printers can be connected to the same port using a switch box. While each printer has the same parent and connection, only one can be configured at a time.

   The Configure method performs this check by querying the CuDv object class. It queries for objects whose Device State descriptor is set to the Available state and whose Parent Device Logical Name and Location Where Connected on Parent Device descriptors match those for the device being configured. If a match is found, the method exits with an error.

7. Check the presence of the device. If the device is an adapter card and the Configure method has been invoked at run time (indicated by the absence of both the **-1** and **-2** flags), the Configure method must verify the adapter card's presence. This is accomplished by reading POS registers from the card. (The POS registers are obtained by opening and accessing the **/dev/bus0** or **/dev/bus1** special file.) This

is essential, because if the card is present, the Configure method must invoke the **busresolve** library routine to assign bus resources to avoid conflict with other adapter cards in the system. If the card is not present or the **busresolve** routine fails to resolve bus resources, the method exits with an error.

8. Determine if the device has a device driver. The Configure method obtains the name of the device driver from the Device Driver Name descriptor of the device's PdDv object. If this descriptor is a null string, the device does not have a device driver.

   If the device has a device driver, the Configure method must:

   a. Load the device driver using the **loadext** subroutine.

   b. Determine the device's major number using the **genmajor** subroutine.

   c. Determine the device's minor number using the **getminor** or **genminor** subroutine or by your own device-dependent routine.

   d. Create special files in the **/dev** directory if they do not already exist. Special files are created with the **mknod** subroutine.

   e. Build the device-dependent structure (DDS). This structure contains information describing the characteristics of the device to the device driver. The information is usually, but not necessarily, obtained from the device's attributes in the Configuration database. Refer to the appropriate device driver information to determine what the device driver expects the DDS to look like. The "Device Dependent Structure (DDS) Overview" topic describes the DDS structure.

   f. Use the **sysconfig** subroutine to pass the DDS to the device driver.

   g. If code needs to be downloaded to the device, read in the required file and pass the code to the device through the interface provided by the device driver. The file to be downloaded might be identified by a Predefined Attribute (PdAt) or Customized Attribute (CuAt) object. By convention, microcode files are in the **/etc/microcode** directory (which is a symbolic link to the **/usr/lib/ microcode** directory). Downloaded adapter software is in the **/usr/lib/asw** directory.

9. Obtain the device VPD. After the tasks relating to the device driver are complete, or if the device did not have a device driver, the Configure method will determine if it needs to obtain vital product data (VPD) from the device. The VPD Flag descriptor of the device's PdDv object specifies whether or not it has VPD.

10. Update the CuDv object. At this point, if no errors have been encountered, the device is configured. The Configure method will update the Device Status descriptor of the device's CuDv object to indicate that it is in the Available state. Also, set the Change Status descriptor to SAME if it is currently set to MISSING. This can occur if the device was not detected at system boot and is being configured at run time.

11. Define detected child devices not currently represented in the CuDv object class. To accomplish this, invoke the Define method for each new child device. For each detected child device already defined in the CuDv object class, the Configure method looks at the child device's CuDv Change Status Flag descriptor to see if it needs to be updated. If the descriptor's value is **DONT_CARE**, nothing needs to be done. If it has any other value, it must be set to SAME and the child device's CuDv object must be updated. The Change Status Flag descriptor is used by the system to indicate configuration changes.

    If the device is an intermediate device but cannot detect attached child devices, query the CuDv object class about this information. The value of the Change Status Flag descriptor for these child devices should be **DONT_CARE** because the parent device cannot detect them. Sometimes a child device has an attribute specifying to the Configure method whether the child device is to be configured. The **autoconfig** attribute of TTY devices is an example of this type of attribute.

    Regardless of whether the child devices are detectable, the Configure method will write the device logical names of the child devices to be configured to standard output, separated by space characters. If the method was invoked by the Configuration Manager, the Manager invokes the Configure method for each of the child device names written to standard output.

12. Close all object classes and terminate the ODM. Close all object classes and terminate the ODM. If there are no errors, use a 0 (zero) code to exit.

Files

Item	Description
/dev/bus0	Contains POS registers.
/dev/bus1	Contains POS registers.
/etc/microcode directory	Contains microcode files. A symbolic link to the **/usr/lib/ microcode** directory.
/usr/lib/asw directory	Contains downloaded adapter software.

Writing a Define Method

This article describes how a Define device method works. It also suggests guidelines for programmers writing their own Define device configuration methods.

Syntax

def*Dev* **-c** *Class* **-s** *SubClass* **-t** *Type* [**-p** *Parent* **-w** *Connection*] [**-l** *Name*]

Description

The Define method is responsible for creating a customized device in the Customized database. It does this by adding an object for the device into the Customized Devices (CuDv) object class. The Define method is invoked either by the **mkdev** configuration command, by a node configuration program, or by the Configure method of a device that is detecting and defining child devices.

The Define method uses information supplied as input, as well as information in the Predefined database, for filling in the CuDv object. If the method is written to support a single device, it can ignore the class, subclass, and type options. In contrast, if the method supports multiple devices, it may need to use these options to obtain the PdDv device object for the type of device being customized.

By convention, the first three characters of the name of the Define method should be **def**. The remainder of the name (*Dev*) can be any characters that identify the device or group of devices that use the method, subject to operating system file-name restrictions.

Flags

Item	Description
-c *Class*	Specifies the class of the device being defined. Class, subclass, and type are required to identify the Predefined Device object in the Predefined Device (PdDv) object class for which a customized device instance is to be created.
-s *SubClass*	Specifies the subclass of the device being defined. Class, subclass, and type are required to identify the Predefined Device object in the PdDv object class for which a customized device instance is to be created.
-t *Type*	Specifies the type of the device being defined. Class, subclass, and type are required to identify the predefined device object in the PdDv object class for which a customized device instance is to be created.
-p *Parent*	Specifies the logical name of the parent device. This logical name is required for devices that connect to a parent device. This option does not apply to devices that do not have parents; for example, most pseudo-devices.
-w *Connection*	Specifies where the device connects to the parent. This option applies only to devices that connect to a parent device.

Item	Description
-l *Name*	Passed by the **mkdev** command, specifies the name for the device if the user invoking the command is defining a new device and wants to select the name for the device. The Define method assigns this name as the logical name of the device in the Customized Devices (CuDv) object, if the name is not already in use. If this option is not specified, the Define method generates a name for the device. Not all devices support or need to support this option.

Guidelines for Writing a Define Method

This list of tasks is meant to serve as a guideline for writing a Define method. In writing a method for a specific device, some tasks may be omitted. For instance, if a device does not have a parent, there is no need to include all of the parent and connection validation tasks. Additionally, a device may have special needs that are not listed in these tasks.

The Define method must:

1. Validate the input parameters. Generally, a Configure method that invokes the child-device Define method is coded to pass the options expected by the child-device Define method. However, the **mkdev** command always passes the class, subclass, and type options, while only passing the other options based on user input to the **mkdev** command. Thus, the Define method may need to ensure that all of the options it requires have been supplied. For example, if the Define method expects parent and connection options for the device being defined, it must ensure that the options are supplied. Also, a Define method that does not support the **-l** name specification option will exit with an error if the option is supplied.

2. Initialize the Object Data Manager (ODM) using the **odm_initialize** subroutine and lock the configuration database using the **odm_lock** subroutine. The following code fragment illustrates this process:

```
#include <cf.h>

if (odm_initialize() < 0)
        exit(E_ODMINIT);          /* initialization failed */

if (odm_lock("/etc/objrepos/config_lock",0) == -1) {
        odm_terminate();
        exit(E_ODMLOCK);          /* database lock failed */
}
```

3. Retrieve the predefined PdDv object for the type of device being defined. This is done by obtaining the object from the PdDv object class whose class, subclass, and type descriptors match the class, subclass, and type options supplied to the Define method. If no match is found, the Define method will exit with an error. Information will be taken from the PdDv device object in order to create the CuDv device object.

4. Ensure that the parent device exists. If the device being defined connects to a parent device and the name of the parent has been supplied, the Define method must ensure that the specified device actually exists. It does this by retrieving the CuDv object whose Device Name descriptor matches the name of the parent device supplied using the **-p** flag. If no match is found, the Define method will exit with an error.

5. If the device has a parent and that parent device exists in the CuDv object class, validate that the device being defined can be connected to the specified parent device. To do this, retrieve the predefined connection object from the Predefined Connection (PdCn) object class whose Unique Type, Connection Key, and Connection Location descriptors match the Link to Predefined Devices Object Class descriptor of the parent's CuDv object obtained in the previous step and the subclass and connection options input into the Define method, respectively. If no match is found, an invalid connection is specified. This may occur because the specified parent is not an intermediate device, does not accept the type of device being defined (as described by subclass), or does not have the connection location identified by the connection option.

6. Assign a logical name to the device. Each newly assigned logical name must be unique to the system. If a name has been supplied using the **-l** flag, make certain it is unique before assigning it to the device. This is done by checking the CuDv object class for any object whose Device Name descriptor matches the desired name. If a match is found, the name is already used and the Define method must exit with an error.

   If the Define method is to generate a name, it can do so by obtaining the prefix name from the Prefix Name descriptor of the device's PdDv device object and invoking the **genseq** subroutine to obtain a unique sequence number for this prefix. Appending the sequence number to the prefix name results in a unique name. The **genseq** routine looks in the CuDv object class to ensure that it assigns a sequence number that has not been used with the specified prefix to form a device name.

   In some cases, a Define method may need to ensure that only one device of a particular type has been defined. For example, there can only be one pty device customized in the CuDv object class. The pty Define method does this by querying the CuDv object class to see if a device by the name pty0 exists. If it does, the pty device has already been defined. Otherwise, the Define method proceeds to define the pty device using the name pty0.

7. Determine the device's location code. If the device being defined is a physical device, it has a location code.

8. Create the new CuDv object.

   Set the CuDv object descriptors as follows:

Descriptor	Setting
Device name	Use the name as determined in step 6.
Device status flag	Set to the Defined state.
Change status flag	Set to the same value as that found in the Change Status Flag descriptor in the device's PdDv object.
Device driver instance	Set to the same value as the Device Driver Name descriptor in the device's PdDv object. This value may be used later by the Configure method.
Device location code	Set to a null string if the device does not have a location code. Otherwise, set it to the value computed.
Parent device logical name	Set to a null string if the device does not have a parent. Otherwise, set this descriptor to the parent name as specified by the parent option.
Location where connected on parent device	Set to a null string if the device does not have a parent. Otherwise, set this descriptor to the value specified by the connection option.
Link to predefined devices object class	Set to the value obtained from the Unique Type descriptor of the device's PdDv object.

9. Write the name of the device to standard output. A blank should be appended to the device name to serve as a separator in case other methods write device names to standard output. Either the **mkdev** command or the Configure method that invoked the Define method will intercept standard output to obtain the device name assigned to the device.

10. Close all object classes and terminate the ODM. Exit with an exit code of 0 if there were no errors.

Writing an Unconfigure Method

This article describes how an Unconfigure device method works. It also suggests guidelines for programmers writing their own Unconfigure device configuration method.

Syntax

ucfgDev **-l** *Name*

Description

The Unconfigure method takes an Available device (available for use in the system) to a Defined state (not available for use in the system). All the customized information about the device is retained in the database so that the device can be configured again exactly as it was before.

The actual operations required to make a device defined depend on how the Configure method made the device available in the first place. For example, if the device has a device driver, the Configure method must have loaded a device driver in the kernel and described the device to the driver through a device dependent structure (DDS). Then, the Unconfigure method must tell the driver to delete the device instance and request an unload of the driver.

If the device is an intermediate device, the Unconfigure method must check the states of the child devices. If any child device is in the Available state, the Unconfigure method fails and leaves the device configured. To ensure proper system operation, all child devices must be unconfigured before the parent can be unconfigured.

Although the Unconfigure method checks child devices, it does not check the device dependencies recorded in the Customized Dependency (CuDep) object class.

The Unconfigure method also fails if the device is currently open. In this case, the device driver returns a value for the **errno** global variable of **EBUSY** to the Unconfigure method when the method requests the driver to delete the device. The device driver is the only component at that instant that knows the device is open. As in the case of configured child devices, the Unconfigure method fails and leaves the device configured.

When requesting the device driver to terminate the device, the **errno** global variable values other than **EBUSY** can be returned. The driver should return **ENODEV** if it does not know about the device. Under the best circumstances, however, this case should not occur. If **ENODEV** is returned, the Unconfigure method should unconfigure the device so that the database and device driver are in agreement. If the device driver returns any other **errno** global value, it deletes any stored characteristics for the specified device instance. The Unconfigure method indicates that the device is unconfigured by setting the state to Defined.

The Unconfigure method does not generally release the major and minor number assignments for a device, or delete the device's special files in the **/dev** directory.

By convention, the first four characters of the name of the Unconfigure method should be **ucfg**. The remainder of the name (*Dev*) can be any characters, subject to operating system file-name restrictions, that identify the device or group of devices that use the method.

Flags

Item	Description
-l *Name*	Identifies the logical name of the device to be unconfigured.

Guidelines for Writing an Unconfigure Method

This list of tasks is intended as a guideline for writing an Unconfigure method. When you write a method for a specific device, some tasks may be omitted. For example, if a device is not an intermediate device or does not have a driver, the method can be written accordingly. The device may have special needs that are not listed in these tasks.

The Unconfigure method must:

1. Validate the input parameters. The **-l** flag must be supplied to identify the device that is to be unconfigured.
2. Initialize the Object Data Manager (ODM) using the **odm_initialize** subroutine and lock the Configuration database using the **odm_lock** subroutine. See "Writing a Define Method" for an example.

3. Retrieve the customized device (CuDv) object for the device to be unconfigured. Use the CuDv object whose Device Name descriptor matches the name supplied with the **-l** flag. If no object is found with the specified name, the method exits with an error.

4. Check the state of the device. If the Device Status descriptor indicates that the device is in the Defined state, then it is already unconfigured. In this case, exit.

5. Check for child devices in the available state. This can be done by querying the CuDv object class for objects whose Parent Device Logical Name descriptor matches this device's name and whose Device Status descriptor is not Defined. If a match is found, this method must exit with an error.

6. Retrieve the Predefined Device (PdDv) object for the device to be unconfigured by getting the PdDv object whose Unique Type descriptor matches the Link to Predefined Devices Object Class descriptor of the device's CuDv object. This object will be used to get the device driver name.

7. Delete device instance from driver and unload driver. Determine if the device has a driver. The Unconfigure method obtains the name of the device from the Device Driver Name descriptor of the PdDv object. If this descriptor is a null string, the device does not have a driver. In this situation, skip to the task of updating the device's state.

   If the device has a device driver, the Unconfigure method needs to include the following tasks:

   a. Determine the device's major and minor numbers using the **genmajor** and **getminor** subroutines. These are used to compute the device's devno, using the **makedev** macro defined in the **/usr/include/sysmacros.h** file, in preparation for the next task.

   b. Use the **sysconfig** subroutine to tell the device driver to terminate the device. If a value of **EBUSY** for the **errno** global variable is returned, this method exits with an error.

   c. Use the **loadext** routine to unload the device driver from the kernel. The **loadext** subroutine will not actually unload the driver if there is another device still configured for the driver.

8. Set defined status. The device is now unconfigured. The Unconfigure method will update the Device Status descriptor of the device's CuDv object to the Defined state.

9. Close all object classes and terminate the ODM. If there are no errors, exit with an exit code of 0 (zero).

Files

Item	Description
/usr/include/sysmacros.h	Contains macro definitions.

Writing an Undefine Method

This article describes how an Undefine device method works. It also suggests guidelines for programmers writing their own Undefine device configuration methods.

Syntax

undDev **-l** *Name*

Description

The Undefine method deletes a Defined device from the Customized database. Once a device is deleted, it cannot be configured until it is once again defined by the Define method.

The Undefine method is also responsible for releasing the major and minor number assignments for the device instance and deleting the device's special files from the **/dev** directory. If minor number assignments are registered with the **genminor** subroutine, the Undefine method can release the major and minor number assignments and delete the special files by using the **reldevno** subroutine.

By convention, the first three characters of the name of the Undefine method are **und**. The remainder of the name (*Dev*) can be any characters, subject to operating system file-name restrictions, that identify the device or group of devices that use the method.

Flags

Item	Description
-l *Name*	Identifies the logical name of the device to be undefined.

Guidelines for Writing an Undefine Method

This list of tasks is intended as a guideline for writing an Undefine method. Some devices may have specials needs that are not addressed in these tasks.

The Undefine method must:

1. Validate the input parameters. The **-l** flag must be supplied to identify the device to be undefined.
2. Initialize the Object Data Manager (ODM) using the **odm_initialize** subroutine and lock the configuration database using the **odm_lock** subroutine. See "Writing a Device Method" for an example.
3. Retrieve the Customized Device (CuDv) object for the device to be undefined. This is done by getting the CuDv object whose Device Name descriptor matches the name supplied with the **-l** flag. If no object is found with the specified name, this method exits with an error.
4. Check the device's current state. If the Device Status descriptor indicates that the device is not in the Defined state, then it is not ready to be undefined. If this is the case, this method exits with an error.
5. Check for any child devices. This check is accomplished by querying the CuDv object class for any objects whose Parent Device Logical Name descriptor matches this device's name. If the device has child devices, regardless of the states they are in, the Undefine method will fail. All child devices must be undefined before the parent can be undefined.
6. Check to see if this device is listed as a dependency of another device. This is done by querying the Customized Dependency (CuDep) object class for objects whose Dependency descriptor matches this device's logical name. If a match is found, the method exits with an error. A device may not be undefined if it has been listed as a dependent of another device.
7. Delete Special Files and major and minor numbers. If no errors have been encountered, the method can delete customized information. First, delete the special files from the **/dev** directory. Next, delete all minor number assignments. If the last minor number has been deleted for a particular major number, release the major number as well, using the **relmajor** subroutine. The Undefine method should never delete objects from the Customized Device Driver (CuDvDr) object class directly, but should always use the routines provided. If the minor number assignments are registered with the **genminor** subroutine, all of the above can be accomplished using the **reldevno** subroutine.
8. Delete all attributes for the device from the Customized Attribute (CuAt) object class. Simply delete all CuAt objects whose Device Name descriptor matches this device's logical name. It is not an error if the ODM routines used to delete the attributes indicate that no objects were deleted. This indicates that the device has no attributes that have been changed from the default values.
9. Delete the Customized VPD (CuVPD) object for the device, if it has one.
10. Delete the Customized Dependency (CuDep) objects that indicate other devices that are dependents of this device.
11. Delete the Customized Device (CuDv) object for the device.
12. Close all object classes and terminate the ODM. Exit with an exit code of 0 (zero) if there are no errors.

Files

Item	Description
/dev directory	Contains the device special files.

Writing Optional Start and Stop Methods

This article describes how optional Start and Stop device methods work. It also suggests guidelines for programmers writing their own optional Start and Stop device configuration methods.

Syntax

stt*Dev* **-l** *Name* **stp***Dev* **-l** *Name*

Description

The Start and Stop methods are optional. They allow a device to support the additional device state of Stopped. The Start method takes the device from the Stopped state to the Available state. The Stop method takes the device from the Available state to the Stopped state. Most devices do not have Start and Stop methods.

The Stopped state keeps a configured device in the system, but renders it unusable by applications. In this state, the device's driver is loaded and the device is defined to the driver. This might be implemented by having the Stop method issue a command telling the device driver not to accept any normal I/O requests. If an application subsequently issues a normal I/O request to the device, it will fail. The Start method can then issue a command to the driver telling it to start accepting I/O requests once again.

If Start and Stop methods are written, the other device methods must be written to account for the Stopped state. For example, if a method checks for a device state of Available, it might now need to check for Available and Stopped states.

Additionally, write the Configure method so that it takes the device from the Defined state to the Stopped state. Also, the Configure method may invoke the Start method, taking the device to the Available state. The Unconfigure method must change the device to the Defined state from either the Available or Stopped states.

When used, Start and Stop methods are usually device-specific.

By convention, the first three characters of the name of the Start method are **stt**. The first three characters of the name of the Stop method are **stp**. The remainder of the names (*Dev*) can be any characters, subject to operating system file-name restrictions, that identify the device or group of devices that use the methods.

Flags

Item	Description
-l *name*	Identifies the logical name of the device to be started or stopped.

SCSI Subsystem

IOCINFO (Device Information) tmscsi Device Driver ioctl Operation

Purpose

Returns a structure defined in the **/usr/include/sys/devinfo.h** file.

Note: This operation is not supported by all SCSI I/O controllers.

Description

The **IOCINFO ioctl** operation returns a structure defined in the **/usr/include/sys/devinfo.h** header file. The caller supplies the address to an area of type `struct devinfo` in the *arg* parameter to the **IOCINFO** operation. The `device-type` field for this component is **DD_TMSCSI**; the `subtype` is **DS_TM**. The

information returned includes the device's device dependent structure (DDS) information and the host SCSI adapter maximum transfer size for initiator-mode requests. The **IOCINFO** ioctl operation is allowed for both target and initiator modes. This command is not required for the caller, but it is useful for programs that need to know what the maximum transfer length is for **write** subroutines. It is also useful for calling programs that need the SCSI ID or logical unit number (LUN) of the device instance in use.

Files

Item	Description
/dev/tmscsi0, **/dev/tmscsi1**,**...**, **/dev/tmscsi**_n_	Support processor-to-processor communications through the SCSI target-mode device driver.

Parallel SCSI Adapter Device Driver

Purpose

Supports the SCSI adapter.

Syntax

```
<#include /usr/include/sys/scsi.h>
<#include /usr/include/sys/devinfo.h>
```

Description

The **/dev/scsi**_n_ and **/dev/vscsi**_n_ special files provide interfaces to allow SCSI device drivers to access SCSI devices. These files manage the adapter resources so that multiple SCSI device drivers can access devices on the same SCSI adapter simultaneously. The **/dev/vscsi**_n_ special file provides the interface for the SCSI-2 Fast/Wide Adapter/A and SCSI-2 Differential Fast/Wide Adapter/A, while the **/dev/scsi**_n_ special file provides the interface for the other SCSI adapters. SCSI adapters are accessed through the special files **/dev/scsi0**, **/dev/scsi1**, ... and **/dev/vscsi0**, **/dev/vscsi1**, ...

The **/dev/scsi**_n_ and **/dev/vscsi**_n_ special files provide interfaces for access for both initiator and target mode device instances. The host adapter is an initiator for access to devices such as disks, tapes, and CD-ROMs. The adapter is a target when accessed from devices such as computer systems, or other devices that can act as SCSI initiators.

Device-Dependent Subroutines

The SCSI adapter device driver supports only the **open**, **close**, and **ioctl** subroutines. The **read** and **write** subroutines are not supported.

open and close Subroutines

The **openx** subroutine provides an adapter diagnostic capability. The **openx** subroutine provides an *ext* parameter. This parameter selects the adapter mode and accepts the **SC_DIAGNOSTIC** value. This value is defined in the **/usr/include/sys/scsi.h** file and places the adapter in Diagnostic mode.

Note: Some of the SCSI adapter device driver's open and close subroutines do not support the diagnostic mode *ext* parameter. (**SC_DIAGNOSTIC**). If such an open is attempted, the subroutine returns a value of -1 and the **errno** global value is set to **EINVAL**. The standalone diagnostic package provides all diagnostic capability.

In Diagnostic mode, only the **close** subroutine and ioctl operations are accepted. All other valid subroutines to the adapter return a value of -1 and set the **errno** global variable to a value of **EACCES**. In Diagnostic mode, the SCSI adapter device driver can accept the following requests:

- Run various adapter diagnostic tests.
- Download adapter microcode.

The **openx** subroutine requires appropriate authority to run. Attempting to run this subroutine without the proper authority causes the subroutine to return a value of -1, and set the **errno** global variable value to **EPERM**. Attempting to open a device already opened for normal operation, or when another **openx** subroutine is in progress, causes the subroutine to return a value of -1, and set the **errno** global variable to a value of **EACCES**.

Any kernel process can open the SCSI adapter device driver in Normal mode. For Normal mode the *ext* parameter is set to 0. However, a non-kernel process must have at least **dev_config** authority to open the SCSI adapter device driver in Normal mode. Attempting to execute a normal **open** subroutine without the proper authority causes the subroutine to return a value of -1, and set the **errno** global variable to a value of **EPERM**.

ioctl Subroutine

Along with the **IOCINFO** operation, the SCSI device driver defines specific operations for devices in non-diagnostic and diagnostic mode.

The **IOCINFO** operation is defined for all device drivers that use the **ioctl** subroutine, as follows:

- The operation returns a **devinfo** structure. This structure is defined in the **/usr/include/sys/devinfo.h** file. The device type in this structure is **DD_BUS**, and the subtype is **DS_SCSI**. The `flags` field is not used and is set to 0. Diagnostic mode is not required for this operation.
- The **devinfo** structure includes unique data such as the card SCSI ID and the maximum initiator mode data transfer size allowed (in bytes). A calling SCSI device driver uses this information to learn the maximum transfer size allowed for a device it controls on the SCSI adapter. In this way, the SCSI device driver can control devices across various SCSI adapters, with each device possibly having a different maximum initiator mode transfer size.

SCSI ioctl Operations for Adapters in Non-Diagnostic mode

The non-diagnostic operations are SCSI adapter device driver functions, rather than general device driver facilities. SCSI adapter device driver ioctl operations require that the adapter device driver is not in diagnostic mode. If these operations are attempted while the adapter is in diagnostic mode, a value of -1 is returned and the **errno** global variable is set to a value of **EACCES**.

The following SCSI operations are for adapters in non-diagnostic mode:

Operation	Description
SCIODNLD	Provides the means to download microcode to the adapter. The IBM SCSI-2 Fast/Wide Adapter/A device driver does not support this operation. Microcode download for the Fast/Wide adapter is supported in the standalone diagnostics package only.
SCIOEVENT	Registers the selected SCSI device instance to receive asynchronous event notification.
SCIOGTHW	Allows the caller to verify SCSI adapter device driver support for gathered writes.
SCIOHALT	Aborts the current command (if there is one), clears the queue of any pending commands, and places the device queue in a halted state for a particular device.
SCIOINQU	Provides the means to issue an inquire command to a SCSI device.
SCIOREAD	Sends a single block read command to the selected SCSI device.
SCIORESET	Allows the caller to force a SCSI device to release all current reservations, clear all current commands, and return to an initial state.
SCIOSTART	Opens a logical path to a SCSI target device. The host SCSI adapter acts as an initiator.
SCIOSTARTTGT	Opens a logical path to a SCSI initiator device. The host SCSI adapter acts as a target.
SCIOSTOP	Closes the logical path to a SCSI target device, where the SCSI adapter acts as an initiator.

Operation	Description
SCIOSTOPTGT	Closes the logical path to a SCSI initiator device, where the host SCSI adapter was acting as a target.
SCIOSTUNIT	Provides the means to issue a SCSI Start Unit command to a selected SCSI device.
SCIOTUR	Sends a Test Unit Ready command to the selected SCSI device.

SCSI ioctl Operations for Adapters in Diagnostic Mode

The following operations for the **ioctl** subroutine are allowed only when the adapter has been successfully opened in Diagnostic mode. If these commands are attempted for an adapter not in Diagnostic mode, a value of -1 is returned and the **errno** global variable is set to a value of **EACCES**.

Operation	Description
SCIODIAG	Provides the means to issue adapter diagnostic commands.
SCIODNLD	Provides the means to download microcode to the adapter.
SCIOTRAM	Provides the means to issue various adapter commands to test the card DMA interface and buffer RAM.

Note: Some of the SCSI adapter device drivers do not support the diagnostic mode ioctl operations.

To allow these operations to be run on multiple SCSI adapter card interfaces, a special return value is defined. A return value of -1 with an **errno** value of **ENXIO** indicates that the requested **ioctl** subroutine is not applicable to the current adapter card. This return value should not be considered an error for commands that require Diagnostic mode for execution.

Summary of SCSI Error Conditions

Possible **errno** values for the adapter device driver are:

Value	Description
EACCES	Indicates that an **openx** subroutine was attempted while the adapter had one or more devices in use.
EACCES	Indicates that a subroutine other than **ioctl** or **close** was attempted while the adapter was in Diagnostic mode.
EACCES	Indicates that a call to the **SCIODIAG** command was attempted while the adapter was not in Diagnostic mode.
EBUSY	Indicates that a delete operation was unsuccessful. The adapter is still open.
EFAULT	Indicates that the adapter is registering a diagnostic error in response to the **SCIODIAG** command. The **SCIODIAG** resume option must be issued to continue processing.
EFAULT	Indicates that a severe I/O error has occurred during an **SCIODNLD** command. Discontinue operations to this card.
EFAULT	Indicates that a copy between kernel and user space failed.
EINVAL	Indicates an invalid parameter or that the device has not been opened.
EIO	Indicates an invalid command. A **SCIOSTART** operation must be executed prior to this command, or an invalid SCSI ID and LUN combination must be passed in.
EIO	Indicates that the command has failed due to an error detected on the adapter or the SCSI bus.
EIO	Indicates that the device driver was unable to pin code.

Value	Description
EIO	Indicates that a kernel service failed, or that an unrecoverable I/O error occurred.
ENOCONNECT	Indicates that a SCSI bus fault occurred.
ENODEV	Indicates that the target device cannot be selected or is not responding.
ENOMEM	Indicates that the command could not be completed due to an insufficient amount of memory.
ENXIO	Indicates that the requested ioctl is not supported by this adapter.
EPERM	Indicates that the caller did not have the required authority.
ETIMEDOUT	Indicates that a SCSI command or adapter command has exceeded the time-out value.

Reliability and Serviceability Information

Errors detected by the adapter device driver may be one of the following:

- Permanent adapter or system hardware errors
- Temporary adapter or system hardware errors
- Permanent unknown adapter microcode errors
- Temporary unknown adapter microcode errors
- Permanent unknown adapter device driver errors
- Temporary unknown adapter device driver errors
- Permanent unknown system errors
- Temporary unknown system errors
- Temporary SCSI bus errors

Permanent errors are either errors that cannot be retried or errors not recovered before a prescribed number of retries has been exhausted. Temporary errors are either noncatastrophic errors that cannot be retried or retriable errors that are successfully recovered before a prescribed number of retries has been exhausted.

Error-Record Values for Permanent Hardware Errors

The error record template for permanent hardware errors detected by the SCSI adapter device driver is described below. Refer to the **rc** structure for the actual definition of the detail data. The **rc** structure is defined in the **/usr/include/sys/scsi.h** file:

SCSI_ERR1:

Field	Description
Comment	Permanent SCSI adapter hardware error.
Class	H, indicating a hardware error.
Report	TRUE, indicating this error should be included when an error report is generated.
Log	TRUE, indicating an error log entry should be created when this error occurs.
Alert	FALSE, indicating this error is not alertable.
Err_Type	PERM, indicating a permanent failure.
Err_Desc	0x1010, indicating an adapter error.

SCSI_ERR1: *(continued)*

Field	Description
Prob_Causes	The following:
	0x3330 Adapter hardware
	0x3400 Cable
	0x3461 Cable terminator
	0x6000 Device
Fail_Causes	The following:
	0x3300 Adapter
	0x3400 Cable loose or defective
	0x6000 Device
Fail_Actions	The following:
	0x000 Perform problem determination procedures.
	0x0301 Check the cable and its connections.
Detail_Data1	108, 11, and HEX

Error-Record Values for Temporary Hardware Errors

The error record template for temporary hardware errors detected by the SCSI adapter device driver follows:

SCSI_ERR2:

Field	Description
Comment	Temporary SCSI adapter hardware error.
Class	H, indicating a hardware error.
Report	TRUE, indicating this error should be included when an error report is generated.
Log	TRUE, indicating an error-log entry should be created when this error occurs.
Alert	FALSE, indicating this error is not alertable.
Err_Type	TEMP, indicating a temporary failure.
Err_Desc	0x1010, indicating an adapter error.

Field	Description
Prob_Causes	The following:
	0x3330 Adapter hardware
	0x3400 Cable
	0x3461 Cable terminator
	0x6000 Device
Fail_Causes	The following:
	0x3300 Adapter
	0x3400 Cable loose or defective
	0x6000 Device
Fail_Actions	The following:
	0x000 Perform problem-determination procedures.
	0x0301 Check the cable and its connections.
Detail_Data1	108, 11, and HEX

Error-Record Values for Permanent Unknown Adapter Microcode Errors

The error-record template for permanent unknown SCSI adapter microcode errors detected by the SCSI adapter device driver follows:

SCSI_ERR3:

Field	Description
Comment	Permanent SCSI adapter software error.
Class	H, indicating a hardware error.
Report	TRUE, indicating this error should be included when an error report is generated.
Log	TRUE, indicating an error log entry should be created when this error occurs.
Alert	FALSE, indicating this error is not alertable.
Err_Type	PERM, indicating a permanent failure.
Err_Desc	0x6100, indicating an adapter error.
Prob_Causes	0x3331, indicating an adapter microcode.
Fail_Causes	0x3300, indicating the adapter.

Field	Description
Fail_Actions	The following:

0x000
   Perform problem determination procedures.

0x3301
   If the problem persists (0x3000) contact the appropriate service representatives.

Detail_Data1	108, 11 and HEX

Error-Record Values for Temporary Unknown Adapter Microcode Errors

The error-record template for temporary unknown SCSI adapter microcode errors detected by the SCSI adapter device driver follows:

SCSI_ERR4:

Field	Description
Comment	Temporary unknown SCSI adapter software error.
Class	H.
Report	TRUE, indicating this error should be included when an error report is generated.
Log	TRUE, indicating an error log entry should be created when this error occurs.
Alert	FALSE, indicating this error is not alertable.
Err_Type	TEMP, indicating a temporary failure.
Err_Desc	Equal to 0x6100, indicating a microcode program error.
Prob_Causes	3331, indicating adapter microcode.
Fail_Causes	3300, indicating the adapter.
Fail_Actions	The following:

0x000
   Perform problem determination procedures.

0x3301
   If the problem persists then (0x3000) contact the appropriate service representatives.

Detail_Data1	108, 11, and HEX

Error-Record Values for Permanent Unknown Adapter Device Driver Errors

The error-record template for permanent unknown SCSI adapter device driver errors detected by the SCSI adapter device driver follows:

SCSI_ERR5:

Field	Description
Comment	Permanent unknown driver error.
Class	S.
Report	TRUE, indicating this error should be included when an error report is generated.
Log	TRUE, indicating an error log entry should be created when this error occurs.
Alert	FALSE, indicating this error is not alertable.

SCSI_ERR5: *(continued)*

Field	Description
Err_Type	PERM, indicating a permanent failure.
Err_Desc	0x2100, indicating a software program error.
Prob_Causes	0X1000, indicating a software program.
Fail_Causes	0X1000, indicating a software program.
Fail_Actions	0x3301, indicating that if the problem persists, then (0x3000) contact the appropriate service representatives.
Detail_Data1	108, 11, and HEX

Error-Record Values for Temporary Unknown Adapter Device Driver Errors

The error-record template for temporary unknown SCSI adapter device driver errors detected by the SCSI adapter device driver follows:

SCSI_ERR6:

Field	Description
Comment	Temporary unknown driver error.
Class	S.
Report	TRUE, indicating this error should be included when an error report is generated.
Log	TRUE, indicating an error log entry should be created when this error occurs.
Alert	FALSE, indicating this error is not alertable.
Err_Type	TEMP, indicating a temporary failure.
Err_Desc	0x2100, indicating a software program error.
Prob_Causes	0X1000, indicating a software program.
Fail_Causes	0X1000, indicating a software program.
Fail_Actions	0x3301, indicating that if the problem persists then (0x3000) contact the appropriate service representatives.
Detail_Data1	108, 11, and HEX

Error-Record Values for Permanent Unknown System Errors

The error-record template for permanent unknown system errors detected by the SCSI adapter device driver follows:

SCSI_ERR7:

Field	Description
Comment	Permanent unknown system error.
Class	H.
Report	TRUE, indicating this error should be included when an error report is generated.
Log	TRUE, indicating an error log entry should be created when this error occurs.
Alert	FALSE, indicating this error is not alertable.
Err_Type	UNKN, indicating an unknown error.
Err_Desc	0xFE00, indicating an undetermined error.

SCSI_ERR7: *(continued)*

Field	Description
Prob_Causes	0X1000, indicating a software program.
Fail_Causes	0X1000, indicating a software program.
Fail_Actions	0x0000 and 0x3301, indicating that problem-determination procedures should be performed; if the problem persists, then (0x3000) contact the appropriate service representatives.
Detail_Data1	108, 11, and HEX

Error-Record Values for Temporary Unknown System Errors

The error-record template for temporary unknown system errors detected by the SCSI adapter device driver follows:

SCSI_ERR8:

Field	Description
Comment	Temporary unknown system error.
Class	H.
Report	TRUE, indicating this error should be included when an error report is generated.
Log	TRUE, indicating an error log entry should be created when this error occurs.
Alert	FALSE, indicating this error is not alertable.
Err_Type	UNKN, indicating an unknown error.
Err_Desc	0xFE00, indicating an undetermined error.
Prob_Causes	0X1000, indicating a software program.
Fail_Causes	0X1000, indicating a software program.
Fail_Actions	0x0000 and 0x3301, indicating that problem-determination procedures should be performed; if the problem persists, then (0x3000) contact the appropriate service representatives.
Detail_Data1	108, 11, and HEX

Error-Record Values for Temporary SCSI Bus Errors

The error-record template for temporary SCSI bus errors by the SCSI adapter device driver follows:

SCSI_ERR10:

Field	Description
Comment	Temporary SCSI bus error.
Class	H, indicating a hardware error.
Report	True, indicating an error log entry should be created when this error occurs.
Alert	FALSE, indicating this error is not alertable.
Err_Type	TEMP, indicating a termporary failure.
Err_Desc	0x942, indicating a SCSI bus error.

Field	Description

Prob_Causes	The following:
	
	0x3400
	  Cable
	
	0x3461
	  Cable terminator
	
	0x6000
	  Device
	
	0x3300
	  Adapter Hardware

Fail_Causes	The following:
	
	0x3400
	  Cable loose or defective
	
	0x6000
	  Device
	
	0x3300
	  Adapter

Fail_Actions	The following:
	
	0x000
	  Perform problem determination procedures.
	
	0x0301
	  Check the cable and its connections.

Detail_Data	108, 11, and HEX.

Managing Dumps

The SCSI adapter device driver is a target for the system dump facility. The **DUMPINIT** and **DUMPSTART** options to the **dddump** entry point support multiple or redundant calls.

The **DUMPQUERY** option returns a minimum transfer size of 0 bytes and a maximum transfer size equal to the maximum transfer size supported by the SCSI adapter device driver.

To be processed, calls to the SCSI adapter device driver **DUMPWRITE** option should use the *arg* parameter as a pointer to the **sc_buf** structure. Using this interface, a SCSI **write** command can be run on a previously started (opened) target device. The *uiop* parameter is ignored by the SCSI adapter device driver. Spanned, or consolidated, commands are not supported using **DUMPWRITE**.

Note: The various **sc_buf** status fields, including the b_error field, are not set at completion of the **DUMPWRITE**. Error logging is, of necessity, not supported during the dump.

Successful completion of the **dddump** entry point is indicated by a 0. If unsuccessful, the entry point returns one of the following:

Value	Description
EINVAL	Indicates that the adapter device driver was passed a request that was not valid, such as attempting a **DUMPSTART** option before successfully executing a **DUMPINIT** option.
EIO	Indicates that the adapter device driver was unable to complete the command due to a lack of required resources or due to an I/O error.
ETIMEDOUT	Indicates that the adapter did not respond with status before the passed command time-out value expired.

Files

Item	Description
/dev/scsi0, **/dev/scsi1,...**, **/dev/scsi***n*	Provide an interface to allow SCSI device drivers to access SCSI devices or adapters.
/dev/vscsi0, **/dev/vscsi1,...**, **/dev/vscsi***n*	Provide an interface to allow SCSI-2 Fast/Wide Adapter/A and SCSI-2 Differential Fast/Wide Adapter/A device drivers to access SCSI devices or adapters.

scdisk SCSI Device Driver

Purpose

Supports the small computer system interface (SCSI) hard disk, CD-ROM (compact-disc read-only memory), and read/write optical (optical memory) devices.

Syntax

```
#include <sys/devinfo.h>
#include <sys/scsi.h>
#include <sys/scdisk.h>
#include <sys/pcm.h>
#include <sys/mpio.h>
```

Device-Dependent Subroutines

Typical hard disk, CD-ROM, and read/write optical drive operations are implemented by using the **open**, **close, read**, **write**, and **ioctl** subroutines. The scdisk device driver has additional support added for MPIO capable devices.

open and close Subroutines

The **open** subroutine applies a reservation policy that is based on the ODM **reserve_policy** attribute. In the past, the **open** subroutine always applied an SCSI2 reserve. The **open** and **close** subroutines support working with multiple paths to a device if the device is an MPIO capable device.

The **openx** subroutine is intended primarily for use by diagnostic commands and utilities. Appropriate authority is required for execution. If an attempt is made to run the **open** subroutine without the proper authority, the subroutine returns a value of **-1** and sets the *errno* global variable to a value of **EPERM**.

The *ext* parameter that is passed to the **openx** subroutine selects the operation to be used for the target device. The **/usr/include/sys/scsi.h** file defines possible values for the *ext* parameter.

The *ext* parameter can contain any combination of the following flag values logically ORed together:

Item	Description
SC_DIAGNOSTIC	Places the selected device in Diagnostic mode. This mode is singularly entrant; that is, only one process at a time can open it. When a device is in Diagnostic mode, SCSI operations are performed during **open** or **close** operations, and error logging process is disabled. In Diagnostic mode, only the **close** and **ioctl** subroutine operations are accepted. All other device-supported subroutines return a value of -1 and set the errno global variable to a value of **EACCES**.
	A device can be opened in Diagnostic mode only if the target device is not currently opened. If an attempt is made to open a device in Diagnostic mode and the target device is already open, the subroutine returns a value of -1 and sets the errno global variable to a value of **EACCES**.
SC_FORCED_OPEN_LUN	On a device that supports Lun Level Reset, the device is reset regardless of any reservation that is placed by another initiator before the open sequence takes place. If the device does not support Lun Level Reset, and both **SC_FORCED_OPEN_LUN** and **SC_FORCE_OPEN** flags are set, then a target reset occurs before the open sequence takes place.
SC_FORCED_OPEN	Forces a bus device reset, regardless of whether another initiator has the device reserved. The SCSI bus device reset is sent to the device before the **open** sequence begins. In other respects, the **open** operation runs normally.
SC_RETAIN_RESERVATION	Retains the reservation of the device after a **close** operation by not issuing the release. This flag prevents other initiators from using the device unless they break the host machine's reservation.
SC_NO_RESERVE	Prevents the reservation of a device during an **openx** subroutine call to that device. This operation is provided so a device can be controlled by two processors that synchronize their activity by their own software means.
SC_SINGLE	Places the selected device in Exclusive Access mode. Only one process at a time can open a device in Exclusive Access mode.
	A device can be opened in Exclusive Access mode only if the device is not currently open. If an attempt is made to open a device in Exclusive Access mode and the device is already open, the subroutine returns a value of -1 and sets the errno global variable to a value of **EBUSY**. If the **SC_DIAGNOSTIC** flag is specified along with the **SC_SINGLE** flag, the device is placed in Diagnostic mode.
SC_PR_SHARED_REGISTER	In a multi-initiator shared device environment, a Persistent Reserve with service action `Register and Ignore Key` is sent to the device as part of the open sequence. This feature is aimed at the cluster environment, where an upper management software needs to follow an advisory lock mechanism to control when the initiator reads or writes. The device is required to support Persistent Reserve (refer to SCSI Primary Command version 2 description of Persistent Reserve).

SCSI Options to the openx Subroutine in *Kernel Extensions and Device Support Programming Concepts* gives more specific information about the **open** operations.

readx and writex Subroutines

The **readx** and **writex** subroutines provide additional parameters which affect the raw data transfer. These subroutines pass the *ext* parameter, which specifies request options. The options are constructed by logically ORing zero or more of the following values:

Item	Description
HWRELOC	Indicates a request for hardware relocation (safe relocation only)
UNSAFEREL	Indicates a request for unsafe hardware relocation
WRITEV	Indicates a request for write verification

ioctl Subroutine

ioctl subroutine operations that are used for the **scdisk** device driver are specific to the following categories:

- Hard disk and read/write optical devices only
- CD-ROM devices only
- Hard disk, CD-ROM, and read/write optical devices

Hard disk and read/write optical devices

The following **ioctl** operations are available for the hard disk and read/write optical devices:

Item	Description
DKIOWRSE	Provides a means for issuing a **write** command to the device and obtaining the target-device sense data when an error occurs. If the **DKIOWRSE** operation returns a value of -1 and the **status_validity** field is set to a value of **sc_valid_sense**, valid sense data is returned. Otherwise, target sense data is omitted.
	The **DKIOWRSE** operation is provided for diagnostic use. It allows the limited use of the target device when it is operating in an active system environment. The *arg* parameter to the **DKIOWRSE** operation contains the address of an **sc_rdwrt** structure. This structure is defined in the **/usr/include/sys/scsi.h** file.
	The **devinfo** structure defines the maximum transfer size for a **write** operation. If an attempt is made to transfer more than the maximum, the subroutine returns a value of -1 and sets the errno global variable to a value of **EINVAL**. Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

Item	Description
DKLOGSENSE	Provides a means to issue the **LOG SENSE** command on devices that is successfully opened. Any application that issues this **ioctl** operation must pass the address of the **struct sc_log_sense** (defined in **/usr/include/sys/scsi.h**) and the structure is filled as follows:

1. **page_code** and **subpage_code** for the requested LOG Page

2. **pc** set to the value **CUMUL_VAL**.

3. **allocation_length** – If this field is set to zero, only the log page header that consists of the **page code** and the log page length is returned. If this field is nonzero, it must equal the length of the log page excluding the log page header of size 4 bytes. If the user specifies an allocation length less than the actual log page length, then only the requested length of log data is returned.

4. **log_data** contains the allocated memory address for storing the data that is returned from the **ioctl** operation.

If the requested log page is **SCSI_BSR_LOG_PAGE** (defined in **/usr/include/sys/scsi.h**) then the **log_data** points to the **struct sc_bsr_log_data** allocated by the caller. The caller also allocates the memory for the **struct sc_bms_log_data** such that total of **sizeof struct sc_bsr_log_data** and memory allocated for the **struct sc_bms_log_data** is equal to the **allocation_length**.

Otherwise (for log pages other than **SCSI_BSR_LOG_PAGE**), it points to a chunk of memory equal to **allocation_length**.

Following is the example code for filling the **sc_log_sense** structure:

```
struct sc_log_sense log_sense;

melog_sense, '\0', sizeof(struct sc_log_sense));
log_sense.page_code = SCSI_BSR_LOG_PAGE ;
log_sense.subpage_code = 0;
log_sense.pc = CUMUL_VAL;
log_sense.allocation_length = 16;
if (log_sense.allocation_length)
 {
 if (log_sense.page_code == SCSI_BSR_LOG_PAGE)
  {
   log_sense.log_data = (struct sc_bsr_log_data *) malloc(sizeof(struct sc_bsr_log_data));
  }
 else
  {
   log_sense.log_data = (char *) malloc(log_sense.allocation_length);
  }
 if (log_sense.log_data == NULL)
 exit(-1);
 if (log_sense.page_code == SCSI_BSR_LOG_PAGE)
  {
   bms_param_len = log_sense.allocation_length - sizeof(struct sc_scan_status);
   ((struct sc_bsr_log_data *)(log_sense.log_data))-> bms_log_data = (struct
sc_bms_log_data *)
     malloc(bms_param_len);
   if (((struct sc_bsr_log_data *)(log_sense.log_data))-> bms_log_data == NULL)
   exit(-1);
  }
 }
 rc = ioctl(fd, DKLOGSENSE,&log_sense);
```

Item	Description

The **DKLOGSENSE ioctl** operation returns the following data by using the struct **sc_log_sense** (**rc=0** indicates success):

1. **returned_length** field contains the length of the bytes requested or zero if the user specified an allocation length of zero.

2. **adapter_status**, **scsi_status**, **sense_key**, **scsi_asc**, **scsi_ascq** set with the error return status for the **LOG SENSE** command.

3. **log_data** field points to the memory containing the data returned by the **LOG SENSE** command. Driver will parse and fill fields for the **struct sc_bsr_log_data** and **struct bms_log_data** for the **Background Scan Results log page**. The **ioctl** caller prints structure fields to view the data. Otherwise, this memory is a **char *** to the log data of **returned_length**. The data excludes the log page header.

```
if (log_sense.page_code == SCSI_BSR_LOG_PAGE)
{
    bms_cnt = (log_sense.returned_length - 16)/24;
    printf("Background Scan Results Log Page:\n");
    printf("Scanning Status Parameter:\n");
    bsr_log_data = (struct sc_bsr_log_data *)log_sense.log_data;
    scan_status  = &(bsr_log_data->scan_status);
    printf("Parameter Code \t:\t %x\n", scan_status->param_code);
    printf("Parameter Control Byte \t:\t %x",scan_status->param_ctrl_bits);
    printf("Parameter Length \t:\t %x\n", scan_status->param_length);
    printf("Power Age \t:\t %x\n", scan_status->power_age);
    printf("Scan Status \t:\t %x\n", scan_status->scan_status);
    printf("Scan Count \t:\t %x\n", scan_status->scan_count);
    printf("Scan Progress \t:\t %x \n", scan_status->scan_progress);
    printf("BMS Count \t:\t %x\n", scan_status->bms_count);
    printf("Background Medium Scan Parameter for %d Elements:\n",bms_cnt);

    for (i=0; <ibms_cnt; i++)
    {
        bms_data = bsr_log_data->bms_log_data;
        printf("Parameter Code \t:\t %x\n", bms_data->param_code);
        printf("Parameter Control Byte \t:\t%x",bms_data->param_ctrl_bits);
        printf("Parameter Length \t:\t %x\n", bms_data->param_length);
        printf("Power Age \t:\t %x\n", bms_data->power_age);
        printf("SenseKey & Reassign Status \t:\t %x\n",bms_data->status_snskey);
        printf("ASC \t:\t %x\n", bms_data->asc);
        printf("ASCQ \t:\t %x\n", bms_data->ascq);

        for (j=0; j<5; j++)
            printf("vendor_data[%d] \t:\t%x\n",j,bms_data->vendor_data[j]);

        printf("LBA \t:\t %llx\n", bms_data->lba);
    }
} else {
    Log data received is a char buffer of 'returned_length' size.
    So print the data byte by byte.
}
```

DKLOGSELECT	Provides a means to issue the **LOG SELECT** command.

Any application that issues the **DKLOGSELECT ioctl** operation is expected to pass the address of the **DKLOGSELECT** (defined in **/usr/include/sys/scsi.h**) filled as follows:

1. **page_code** and **subpage_code** for the requested LOG Page

2. **pcr**, **sp**, **pc**, and **param_length** as per the SCSI Primary Commands Standard Version 4 (SPC4) requirements.

3. **log_data** points to the memory that contains the parameters that must be sent to the **LOG SELECT** command.

Following is an example for filling the **sc_log_select** structure to clear the **SCSI_BSR_LOG_PAGE data****.

```
struct sc_log_select log_select;

memset(&log_select, '\0', sizeof(struct sc_log_select));
log_select.page_code = SCSI_BSR_LOG_PAGE;
log_select.subpage_code = 0;
log_select.pcr = 1;
log_select.sp = 0;
log_select.pc = CUMUL_VAL;
log_select.param_length = 0;
if (log_select.param_length)
{
 log_select.log_data = (char *)malloc(log_select.param_length);
 if (log_select.log_data == NULL) exit(-1);
}
rc = ioctl(fd, DKLOGSELECT,&log_select);
```

This **ioctl** operation returns the following data by using the **struct sc_log_select** (**rc=0** indicates success) **adapter_status**,**scsi_status**, **sense_key**, **scsi_asc**, and **scsi_ascq** fields reporting the error completion status of the **LOG SELECT** command.

CD-ROM Devices Only

The following **ioctl** operation is available for CD-ROM devices only:

Item	Description
CDIOCMD	Allows SCSI commands to be issued directly to the attached CD-ROM device. The **CDIOCMD** operation preserves binary compatibility for CD-ROM applications that were compiled on earlier releases of the operating system. It is recommended that newly written CD-ROM applications use the **DKIOCMD** operation instead. For the **CDIOCMD** operation, the device must be opened in Diagnostic mode. The **CDIOCMD** operation parameter specifies the address of a **sc_iocmd** structure. This structure is defined in the **/usr/include/sys/scsi.h** file.

If this operation is attempted on a device other than CD-ROM, it is interpreted as a **DKIORDSE** operation. In this case, the *arg* parameter is treated as an **sc_rdwrt** structure.

If the **CDIOCMD** operation is attempted on a device not in Diagnostic mode, the subroutine returns a value of -1 and sets the errno global variable to a value of **EACCES**. Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

Note: Diagnostic mode is required only for the **CDIOCMD** and **DKIOCMD** operations.

Hard disk, CD-ROM, and read/write optical devices

The following **ioctl** operations are available for hard disk, CD-ROM, and read/write optical devices:

Item	Description
IOCINFO	Returns the **devinfo** structure that is defined in the **/usr/include/sys/devinfo.h** file. The **IOCINFO** operation is the only operation that is defined for all device drivers that use the **ioctl** subroutine. The remaining operations are all specific to hard disk, CD-ROM, and read/write optical devices.
DKIORDSE	Provides a means for issuing a **read** command to the device and obtaining the target-device sense data when an error occurs. If the **DKIORDSE** operation returns a value of -1 and the **status_validity** field is set to a value of **sc_valid_sense**, valid sense data is returned. Otherwise, target sense data is omitted.

The **DKIORDSE** operation is provided for diagnostic use. It allows the limited use of the target device when it is operating in an active system environment. The *arg* parameter to the **DKIORDSE** operation contains the address of an **sc_rdwrt** structure. This structure is defined in the **/usr/include/sys/scsi.h** file.

The **devinfo** structure defines the maximum transfer size for a **read** operation. If an attempt is made to transfer more than the maximum, the subroutine returns a value of -1 and sets the errno global variable to a value of **EINVAL**. Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

Note: The **CDIORDSE** operation might be substituted for the **DKIORDSE** operation when you issue a **read** command to and obtain sense data from a CD-ROM device. **DKIORDSE** is the recommended operation.

Item	Description
DKIOCMD	When the device is successfully opened in the Diagnostic mode, the **DKIOCMD** operation provides the means for issuing any SCSI command to the specified device. If the **DKIOCMD** operation is issued when the device is not in Diagnostic mode, the subroutine returns a value of -1 and sets the errno global variable to a value of **EACCES**. The device driver performs no error recovery or logging on failures of this operation.

The SCSI status byte and the adapter status bytes are returned through the *arg* parameter, which contains the address of a **sc_iocmd** structure (defined in the **/usr/include/sys/scsi.h** file). If the **DKIOCMD** operation fails, the subroutine returns a value of -1 and sets the errno global variable to a nonzero value. In this case, the caller must evaluate the returned status bytes to determine why the operation was unsuccessful and what recovery actions must be taken.

The **devinfo** structure defines the maximum transfer size for the command. If an attempt is made to transfer more than the maximum, the subroutine returns a value of -1 and sets the errno global variable to a value of **EINVAL**. Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

Note: Diagnostic mode is required only for the **CDIOCMD** and **DKIOCMD** operations. |
DKPMR	Issues a SCSI prevent media removal command when the device is successfully opened. This command prevents media from being ejected until the device is closed, powered off and back on, or until a **DKAMR** operation is issued. The *arg* parameter for the **DKPMR** operation is null. If the **DKPMR** operation is successful, the subroutine returns a value of 0. If the device is a SCSI hard disk, the **DKPMR** operation fails, and the subroutine returns a value of -1 and sets the errno global variable to a value of **EINVAL**. If the **DKPMR** operation fails for any other reason, the subroutine returns a value of -1 and sets the errno global variable to a value of **EIO**.
DKAMR	Issues an allow media removal command when the device is successfully opened. As a result media can be ejected by using either the drive's eject button or the **DKEJECT** operation. The *arg* parameter for this **ioctl** is null. If the **DKAMR** operation is successful, the subroutine returns a value of 0. If the device is a SCSI hard disk, the **DKAMR** operation fails, and the subroutine returns a value of -1 and sets the errno global variable to a value of **EINVAL**. For any other failure of this operation, the subroutine returns a value of -1 and sets the errno global variable to a value of **EIO**.
DKEJECT	Issues an eject media command to the drive when the device is successfully opened. The *arg* parameter for this operation is null. If the **DKEJECT** operation is successful, the subroutine returns a value of 0. If the device is a SCSI hard disk, the **DKEJECT** operation fails, and the subroutine returns a value of -1 and sets the errno global variable to a value of **EINVAL**. For any other failure of this operation, the subroutine returns a value of -1 and sets the errno global variable to a value of **EIO**.

Item	Description
DKFORMAT	Issues a format unit command to the specified device when the device is successfully opened.
	If the *arg* parameter for this operation is null, the format unit sets the format options valid (FOV) bit to 0 (that is, it uses the drive's default setting). If the *arg* parameter for the **DKFORMAT** operation is not null, the first byte of the defect list header is set to the value specified in the first byte addressed by the *arg* parameter. It allows the creation of applications to format a particular type of read/write optical media uniquely.
	The driver initially tries to set the FmtData and CmpLst bits to 0. If that fails, the driver tries the remaining 3 permutations of these bits. If all four permutations fail, this operation fails, and the subroutine sets the errno global variable to a value of **EIO**.
	If the **DKFORMAT** operation is specified for a hard disk, the subroutine returns a value of -1 and sets the errno global variable to a value of **EINVAL**. If the **DKFORMAT** operation is attempted when the device is not in Exclusive Access mode, the subroutine returns a value of -1 and sets the errno global variable to a value of **EACCES**. If the media is write-protected, the subroutine returns a value of -1 and sets the errno global variable to a value of **EWRPROTECT**. If the format unit exceeds its timeout value, the subroutine returns a value of -1 and sets the errno global variable to a value of **ETIMEDOUT**. For any other failure of this operation, the subroutine returns a value of -1 and sets the errno global variable to a value of **EIO**.
DKAUDIO	Issues play audio commands to the specified device and controls the volume on the device's output ports. Play audio commands include: play, pause, resume, stop, determine the number of tracks, and determine the status of a current audio operation. The **DKAUDIO** operation plays audio only through the CD-ROM drive's output ports. The *arg* parameter of this operation is the address of a **cd_audio_cmds** structure, which is defined in the **/usr/include/sys/scdisk.h** file. Exclusive Access mode is required.
	If **DKAUDIO** operation is attempted when the device's audio-supported attribute is set to No, the subroutine returns a value of -1 and sets the errno global variable to a value of **EINVAL**. If the **DKAUDIO** operation fails, the subroutine returns a value of -1 and sets the errno global variable to a nonzero value. In this case, the caller must evaluate the returned status bytes to determine why the operation failed and what recovery actions must be taken.

Item	Description
DK_CD_MODE	Determines or changes the CD-ROM data mode for the specified device. The CD-ROM data mode specifies what block size and special file are used for data read across the SCSI bus from the device. The **DK_CD_MODE** operation supports the following CD-ROM data modes:

CD-ROM Data Mode 1
> 512-byte block size through both raw (**dev/rcd***) and block special (**/dev/cd***) files

CD-ROM Data Mode 2 Form 1
> 2048-byte block size through both raw (**dev/rcd***) and block special (**/dev/cd***) files

CD-ROM Data Mode 2 Form 2
> 2336-byte block size through the raw (**dev/rcd***) special file only

CD-DA (Compact Disc Digital Audio)
> 2352-byte block size through the raw (**dev/rcd***) special file only

DVD-ROM
> 2048-byte block size through both raw (**/dev/rcd***) and block special (**/dev/cd***) files

DVD-RAM
> 2048-byte block size through both raw (**/dev/rcd***) and block special (**/dev/cd***) files

DVD-RW
> 2048-byte block size through both raw (**/dev/rcd***) and block special (**/dev/cd***) files

The **DK_CD_MODE** *arg* parameter contains the address of the **mode_form_op** structure that is defined in the **/usr/include/sys/scdisk.h** file. To have the **DK_CD_MODE** operation determine or change the CD-ROM data mode, set the `action` field of the **change_mode_form** structure to one of the following values:

CD_GET_MODE
> Returns the current CD-ROM data mode in the `cd_mode_form` field of the **mode_form_op** structure, when the device is successfully opened.

CD_CHG_MODE
> Changes the CD-ROM data mode to the mode specified in the `cd_mode_form` field of the **mode_form_op** structure, when the device is successfully opened in the exclusive access mode.

If a CD-ROM is not configured for different data modes (through mode-select density codes), and an attempt is made to change the CD-ROM data mode (by setting the `action` field of the **change_mode_form** structure set to **CD_CHG_MODE**), the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EINVAL**. Attempts to change the CD-ROM mode to any of the DVD modes also results in a return value of -1 and the **errno** global variable set to **EINVAL**.

If the **DK_CD_MODE** operation for **CD_CHG_MODE** is attempted when the device is not in Exclusive Access mode, the subroutine returns a value of -1 and sets the errno global variable to a value of **EACCES**. For any other failure of this operation, the subroutine returns a value of -1 and sets the errno global variable to a value of **EIO**.

Item	Description
DK_PASSTHRU	When the device is successfully opened, the **DK_PASSTHRU** operation provides the means for issuing any SCSI command to the specified device. The device driver will perform limited error recovery if this operation fails. The **DK_PASSTHRU** operation differs from the **DKIOCMD** operation in that it does not require an **openx** command with the *ext* argument of **SC_DIAGNOSTIC**. Because of this, a **DK_PASSTHRU** operation can be issued to devices that are in use by other operations.

The SCSI status byte and the adapter status bytes are returned through the *arg* parameter, which contains the address of a **sc_passthru** structure (defined in the **/usr/include/sys/scsi.h** file). If the **DK_PASSTHRU** operation fails, the subroutine returns a value of -1 and sets the errno global variable to a nonzero value. If this happens the caller must evaluate the returned status bytes to determine why the operation was unsuccessful and what recovery actions must be taken.

If a **DK_PASSTHRU** operation fails because a field in the **sc_passthru** structure has an invalid value, the subroutine returns a value of -1 and set the errno global variable to **EINVAL**. The **einval_arg** field is set to the field number (starting with 1 for the version field) of the field that had an invalid value. A value of 0 for the **einval_arg** field indicates that no additional information on the failure is available.

DK_PASSTHRU operations are further subdivided into requests which quiesce other I/O requests before issuing the request and requests that do not quiesce I/O requests. These subdivisions are based on the **devflags** field of the **sc_passthru** structure. When the **devflags** field of the **sc_passthru** structure has a value of **SC_MIX_IO**, the **DK_PASSTHRU** operation will be mixed with other I/O requests. **SC_MIX_IO** requests that write data to devices are prohibited and will fail. When this happens -1 is returned, and the errno global variable is set to **EINVAL**. When the **devflags** field of the **sc_passthru** structure has a value of **SC_QUIESCE_IO**, all other I/O requests will be quiesced before the **DK_PASSTHRU** request is issued to the device. If an **SC_QUIESCE_IO** request has its **timeout_value** field set to 0, the **DK_PASSTHRU** request will be failed with a return code of -1, the errno global variable will be set to **EINVAL**, and the **einval_arg** field will be set to a value of **SC_PASSTHRU_INV_TO** (defined in the **/usr/include/sys/scsi.h** file). If an **SC_QUIESCE_IO** request has a nonzero timeout value that is too large for the device, the **DK_PASSTHRU** request will be failed with a return code of -1, the errno global variable will be set to **EINVAL**, the **einval_arg** field will be set to a value of **SC_PASSTHRU_INV_TO** (defined in the **/usr/include/sys/scsi.h** file), and the **timeout_value** will be set to the largest allowed value.

Item	Description
	The version field of the **sc_passthru** structure can be set to the value of SC_VERSION_2, and the user can provide the following fields:

- **variable_cdb_ptr** is a pointer to a buffer that contains the Variable SCSI cdb.
- **variable_cdb_length** determines the length of the *cdb* variable to which the **variable_cdb_ptr** field points.

On completion of the **DK_PASSTHRU** ioctl request, the **residual** field indicates the leftover data that device did not fully satisfy for this request. On a successful completion, the **residual** field would indicate that the device does not have the all data that is requested or the device has less than the amount of data that is requested. On a failure completion, the user must check the **status_validity** field to determine whether a valid SCSI bus problem exists. In this case, the **residual** field would indicate the number bytes that the device failed to complete for this request.

The **devinfo** structure defines the maximum transfer size for the command. If an attempt is made to transfer more than the maximum transfer size, the subroutine returns a value of -1, sets the errno global variable to a value of **EINVAL**, and sets the **einval_arg** field to a value of **SC_PASSTHRU_INV_D_LEN** (defined in the **/usr/include/sys/scsi.h** file).

Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

DKPRES_READKEYS

When the device is successfully opened, the **DKPRES_READKEYS** operation provides a means to read the Persistent Reserve Registration Keys on the device. The *arg* parameter to the **DKPRES_READKEYS** contains the address of the **dk_pres_in** structure. This structure is defined in **/usr/include/sys/scdisk.h**. The user must provide a buffer area and size for the registered keys to be returned. The *returned_length* variable sets the number of bytes returned.

In a shared-access or clustered environment, this operation identifies all registered keys for a particular lun.

Note: For the **DKPRES_READKEYS** operation and following Persistent Reserve related operation, the interpretation of the returned value and scsi status is as follows:

- On successful attempt of the call, a 0 is returned.
- After a call fails, a -1 is returned and the **errno** global variable is set. For a specific description of the **errno** value, refer to **/usr/include/erno.h**. In addition, the SCSI status, along with the Sense Code, ASC and ASCQ, is set to provide further information about why the command failed. Refer to SCSI Specification on the interpretation of the SCSI status failure code.

DKPRES_READRES

When the device is successfully opened, the **DKPRES_READRES** operation provides a means to read the Persistent Reserve Reservation Keys on the device. The *arg* parameter to the **DKPRES_READKEYS** contains the address of the **dk_pres_in** structure. This structure is defined in **/usr/include/sys/scdisk.h**. The user must provide a buffer area and size for the reservation information to be returned. The *returned_length* variable sets the number of bytes returned. In a shared-access or clustered environment, this operation identifies the primary initiator that holds the reservation.

Item	Description
DKPRES_CLEAR	When the device is successfully opened, the **DKPRES_CLEAR** operation provides a means to clear all Persistent Reserve Reservation Keys and Registration Keys on the device. The *arg* parameter to **DKPRES_CLEAR** contains the address of the **dk_pres_clear** structure. This structure is defined in **/usr/include/sys/scdisk.h**.

⚠️ **Attention: Attention:** Exercise care when issuing the **DKPRES_CLEAR** operation. This operation leaves the device unreserved, which could allow a foreign initiator to access the device.

Item	Description
DKPRES_PREEMPT	When the device is successfully opened, the **DKPRES_PREEMPT** operation provides a means to preempt a Persistent Reserve Reservation Key or Registration Key on the device. The *arg* parameter to the **DKPRES_PREEMPT** contains the address of the **dk_pres_preempt** structure. This structure is defined in **/usr/include/sys/scdisk.h**. The user must provide the second party initiator key on the device to be preempted. If the second party initiator holds the reservation to the device, then the initiator that issues the preemption becomes the owner of the reservation. Otherwise, the second party initiator access is revoked.
	In order for this operation to succeed, the initiator must be registered with the device first before any preemption can occur. In a shared-access or clustered environment, this operation is used to preempt any operative or inoperative initiator, or any initiator that is not recognized to be part of the shared group.
DKPRES_PREEMPT_ABORT	This operation is the same as the **DKPRES_PREEMPT**, except the device follows the SCSI Primary Command Specification in aborting tasks that belong to the preempted initiator.
DKPRES_REGISTER	When the device is successfully opened, the **DKPRES_REGISTER** operation provides a means to register a Key with the device. The Key is extracted from ODM Customize Attribute and passed to the device driver during configuration. The *arg* parameter to the **DKPRES_REGISTER** contains the address of the **dk_pres_register** structure. This structure is defined in **/usr/include/sys/scdisk.h**.
	In a shared-access or clustered environment, this operation attempts a registration with the device, then follows with a read reservation to determine whether the device is reserved. If the device is not reserved, then a reservation is placed with the device.

Item	Description
DK_RWBUFFER	When the device is successfully opened, the **DK_RWBUFFER** operation provides the means for issuing one or more SCSI Write Buffer commands to the specified device. The device driver performs full error recovery upon failures of this operation. The **DK_RWBUFFER** operation differs from the **DKIOCMD** operation in that it does not require an exclusive open of the device (for example, **openx** with the *ext* argument of **SC_DIAGNOSTIC**). Thus, a **DK_RWBUFFER** operation can be issued to devices that are in use by others. It can be used with the **DK_PASSTHRU ioctl** operation, which (like **DK_RWBUFFER**) does not require an exclusive open of the device.

The *arg* parameter contains the address of a **sc_rwbuffer** structure (defined in the **/usr/include/sys/scsi.h** file). Before the **DK_RWBUFFER** ioctl is invoked, the fields of this structure must be set according to the required behavior. The **mode** field corresponds to the **mode** field of the SCSI Command Descriptor Block (CDB) as defined in the *SCSI Primary Commands (SPC) Specification*. Supported modes are listed in the header file **/usr/include/sys/scsi.h**.

The device driver quiesces all other I/O requests from the initiator that issues the Write Buffer ioctl until the entire operation completes. Once the write buffer ioctl completes, all quiesced I/O requests are resumed.

The SCSI status byte and the adapter status bytes are returned through the *arg* parameter, which contains the address of a **sc_rwbuffer** structure (defined in the **/usr/include/sys/scsi.h** file). If the **DK_RWBUFFER** operation fails, the subroutine returns a value of -1 and sets the **errno** global variable to a nonzero value. In this case, the caller must evaluate the returned status bytes to determine why the operation was unsuccessful and what recovery actions must be taken.

If a **DK_RWBUFFER** operation fails because a field in the **sc_rwbuffer** structure has an invalid value, the subroutine returns a value of -1 and set the **errno** global variable to **EINVAL**.

The **DK_RWBUFFER** ioctl allows the user to issue multiple SCSI Write Buffer commands (CDBs) to the device through a single ioctl invocation. It is useful for applications such as microcode download where the user provides a pointer to the entire microcode image, but, because of size restrictions of the device buffers, desires that the images be sent in fragments until the entire download is complete.

If the **DK_RWBUFFER** ioctl is invoked with the **fragment_size** member of the **sc_rwbuffer** struct equal to **data_length**, a single Write Buffer command is issued to the device with the **buffer_offset** and **buffer_ID** of the SCSI CDB set to the values provided in the **sc_rwbuffer** struct.

If **data_length** is greater than **fragment_size** and **fragment_size** is a nonzero value, multiple write buffer is issued to the device. The number of Write Buffer commands (SCSI CDBs) issued is calculated by dividing the **data_length** by the required **fragment_size**. This value is incremented by 1 if the **data_length** is not an even multiple of **fragment_size**, and the final data transfer is the size of this residual amount. For each Write Buffer command that is issued, the **buffer_offset** is set to the value provided in the **sc_rwbuffer** struct (microcode downloads to SCSD devices requires this value to be set to 0).

Item	Description
	For the first command issued, the **buffer_ID** is set to the value provided in the **sc_rwbuffer** struct. For each subsequent Write Buffer command that is issued, the **buffer_ID** is incremented by 1 until all fragments are sent. Writing to noncontiguous **buffer_ID**s through a single **DK_RWBUFFER** ioctl is not supported. If this functionality is wanted, multiple **DK_RWBUFFER** ioctls must be issued with the **buffer_ID** set appropriately for each invocation.
	Note: No I/O request is quiesced between ioctl invocations.
	If **fragment_size** is set to zero, an **errno** of **EINVAL** is returned. If the desire is to send the entire buffer with one SCSI Write buffer command, this field must be set equal to **data_length**. An error of **EINVAL** is also returned if the **fragment_size** is greater than the **data_length**.
	The Parameter List Length (**fragment_size**) plus the Buffer Offset cannot exceed the capacity of the specified buffer of the device. It is the responsibility of the caller of the Write Buffer ioctl to ensure that the **fragment_size** setting satisfies this requirement. A **fragment_size** larger than the device can accommodate results in a SCSI error at the device, and the Write Buffer ioctl reports this error but take no action to recover.
	The **devinfo** structure defines the maximum transfer size for the command. If an attempt is made to transfer more than the maximum transfer size, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EINVAL**. Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request sense data for a particular device.
DKPATHIOCMD	This command is only available for MPIO capable devices. The **DKPATHIOCMD** command takes as input a pointer argument which points to a single **scdisk_pathiocmd** structure. The **DKPATHIOCMD** command behaves exactly like the **DKIOCMD** command, except that the input path is used rather than normal path selection. The **DKPATHIOCMD** path is used for the **DKIOCMD** command regardless of any path specified by a **DKPATHFORCE** ioctl command. A path cannot be unconfigured while it is being forced.
DKPATHFORCE	This command is only available for MPIO capable devices. The **DKPATHFORCE** command takes as input a ushort path id. The path id must correspond to one of the path ids in CuPath ODM. The path id specifies a path to be used for all subsequent I/O commands, overriding any previous **DKPATHFORCE** path. A zero argument specifies that path forcing is terminated and that normal MPIO path selection is to be resumed. I/O commands sent in with the **DKPATHIOCMD** command overrides the **DKPATHFORCE** option and send the I/O command down the path that is specified in **scdisk_pathiocmd** structure.
DKPATHRWBUFFER	This command is only available for MPIO capable devices. The **DKPATHRWBUFFER** command takes as input a pointer argument which points to a single **scdisk_pathiocmd** structure. The **DKPATHRWBUFFER** command behaves exactly like the **DKRWBUFFER** command, except that the input path is used rather than normal path selection. The **DKPATHRWBUFFER** path is used for the **DKRWBUFFER** command regardless of any path that is specified by a **DKPATHFORCE** ioctl command.

Item	Description
DKPATHPASSTHRU	This command is only available for MPIO capable devices. The **DKPATHPASSTHRU** command takes as input a pointer argument which points to a single **scdisk_pathiocmd** structure. The **DKPATHPASSTHRU** command behaves exactly like the **DKPASSTHRU** command, except that the input path is used rather than normal path selection. The **DKPATHPASSTHRU** path is used for the **DKPASSTHRU** command regardless of any path that is specified by a **DKPATHFORCE** ioctl command.
DKPCMPASSTHRU	This command is only available for MPIO capable devices. The **DKPCMPASSTHRU** command takes as input a structure which is PCM-specific, it is not defined by AIX. The PCM-specific structure is passed to the PCM directly. This structure can be used to move information to or from a PCM.

Device Requirements

SCSI hard disk, CD-ROM, and read/write optical drives have the following hardware requirements:

- SCSI hard disks and read/write optical drives must support a block size of 512 bytes per block.
- If mode sense is supported, the write-protection (WP) bit must also be supported for SCSI hard disks and read/write optical drives.
- SCSI hard disks and read/write optical drives must report the hardware retry count in bytes 16 and 17 of the request sense data for recovered errors. If the hard disk or read/write optical drive does not support it, the system error log might indicate premature drive failure.
- SCSI CD-ROM and read/write optical drives must support the 10-byte SCSI read command.
- SCSI hard disks and read/write optical drives must support the SCSI write and verify command and the 6-byte SCSI write command.
- To use the **format** command operation on read/write optical media, the drive must support setting the format options valid (FOV) bit to 0 for the defect list header of the SCSI format unit command. If the drive does not support this, the user can write an application for the drive so that it formats media by using the **DKFORMAT** operation.
- If a SCSI CD-ROM drive uses **CD_ROM Data Mode 1**, it must support a block size of 512 bytes per block.
- If a SCSI CD-ROM drive uses **CD_ROM data Mode 2 Form 1**, it must support a block size of 2048 bytes per block.
- If a SCSI CD-ROM drive uses **CD_ROM data Mode 2 Form 2**, it must support a block size of 2336 bytes per block.
- If a SCSI CD-ROM drive uses **CD_DA** mode, it must support a block size of 2352 bytes per block.
- To control volume by using the **DKAUDIO** (play audio) operation, the device must support SCSI-2 mode data page 0xE.
- To use the **DKAUDIO** (play audio) operation, the device must support the following SCSI-2 optional commands:
  - read subchannel
  - pause resume
  - play audio MSF
  - play audio track index
  - read TOC

Error Conditions

Possible **errno** values for **ioctl**, **open**, **read**, and **write** subroutines when you use the **scdisk** device driver include:

Item	Description
EACCES	Indicates one of the following circumstances:

- An attempt was made to open a device currently open in Diagnostic or Exclusive Access mode.
- An attempt was made to open a Diagnostic mode session on a device already open.
- The user attempted a subroutine other than an **ioctl** or **close** subroutine while in Diagnostic mode.
- A **DKIOCMD** or **CDIOCMD** operation was attempted on a device not in Diagnostic mode.
- A **DK_CD_MODE ioctl** subroutine operation was attempted on a device not in Exclusive Access mode.
- A **DKFORMAT** operation was attempted on a device not in Exclusive Access mode.

Item	Description
EBUSY	Indicates one of the following circumstances:

- An attempt was made to open a session in Exclusive Access mode on a device already opened.
- The target device is reserved by another initiator.

Item	Description
EFAULT	Indicates an invalid user address.
EFORMAT	Indicates that the target device has unformatted media or media in an incompatible format.
EINPROGRESS	Indicates that a CD-ROM drive has a play-audio operation in progress.
EINVAL	Indicates one of the following circumstances:

- A **DKAUDIO** (play-audio) operation was attempted for a device that is not configured to use the SCSI-2 play-audio commands.
- The **read** or **write** subroutine supplied an *nbyte* parameter that is not an even multiple of the block size.
- A sense data buffer length of greater than 255 bytes is not valid for a **CDIORDSE**, **DKIOWRSE**, or **DKIORDSE ioctl** subroutine operation.
- The data buffer length exceeded the maximum defined in the **devinfo** structure for a **CDIORDSE**, **CDIOCMD**, **DKIORDSE**, **DKIOWRSE**, or **DKIOCMD ioctl** subroutine operation.
- An unsupported **ioctl** subroutine operation was attempted.
- A data buffer length greater than the allowed length by the CD-ROM drive is not valid for a **CDIOCMD ioctl** subroutine operation.
- An attempt was made to configure a device that is still open.
- An incorrect configuration command is given.
- A **DKPMR** (Prevent Media Removal), **DKAMR** (Allow Media Removal), or **DKEJECT** (Eject Media) command was sent to a device that does not support removable media.
- A **DKEJECT** (Eject Media) command was sent to a device that currently has its media that are locked in the drive.
- The data buffer length exceeded the maximum defined for a **strategy** operation.

Item	Description
EIO	Indicates one of the following circumstances:

- The target device cannot be located or is not responding.
- The target device indicated an unrecoverable hardware error.

Item	Description
EMEDIA	Indicates one of the following circumstances:

- The target device indicated an unrecoverable media error.
- The media was changed.

Item	Description
EMFILE	Indicates that an **open** operation was attempted for an adapter that already has the maximum permissible number of opened devices.
ENODEV	Indicates one of the following circumstances:

- An attempt was made to access an undefined device.
- An attempt was made to close an undefined device.

Item	Description
ENOTREADY	Indicates that no media is in the drive.
ENXIO	Indicates one of the following circumstances:

- The **ioctl** subroutine supplied an invalid parameter.
- A **read** or **write** operation was attempted beyond the end of the hard disk.

Item	Description
EPERM	Indicates that the attempted subroutine requires appropriate authority.
ESTALE	Indicates that a read-only optical disk was ejected (without first being closed by the user) and then either reinserted or replaced with a second optical disk.
ETIMEDOUT	Indicates an I/O operation exceeded the specified timer value.
EWRPROTECT	Indicates one of the following circumstances:

- An **open** operation that requested the **read/write** mode was attempted on read-only media.
- A **write** operation was attempted to read-only media.

Reliability and Serviceability Information

SCSI hard disk devices, CD-ROM drives, and read/write optical drives return the following errors:

Item	Description
ABORTED COMMAND	Indicates that the device ended the command
ADAPTER ERRORS	Indicates that the adapter returned an error
GOOD COMPLETION	Indicates that the command completed successfully
HARDWARE ERROR	Indicates that an unrecoverable hardware failure occurred during command execution or during a self-test
ILLEGAL REQUEST	Indicates an incorect command or command parameter
MEDIUM ERROR	Indicates that the command ended with an unrecoverable media error condition
NOT READY	Indicates that the logical unit is offline or media is missing
RECOVERED ERROR	Indicates that the command was successful after some recovery was applied
UNIT ATTENTION	Indicates that the device is reset or the power is turned on

Error Record Values for Media Errors

The fields that are defined in the error record template for hard disk, CD-ROM, and read/write optical media errors are:

Item	Description
Comment	Indicates hard disk, CD-ROM, or read/write optical media error.
Class	Equals a value of H, which indicates a hardware error.
Report	Equals a value of True, which indicates this error must be included when an error report is generated.
Log	Equals a value of True, which indicates an error log entry must be created when this error occurs.
Alert	Equals a value of False, which indicates this error is not alertable.
Err_Type	Equals a value of Perm, which indicates a permanent failure.
Err_Desc	Equals a value of 1312, which indicates a disk operation failure.
Prob_Causes	Equals a value of 5000, which indicates media.
User_Causes	Equals a value of 5100, which indicates the media is defective.
User_Actions	Equals the following values: • 0000, which indicates problem-determination procedures must be performed • 1601, which indicates the removable media must be replaced and retried
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	Equals the following values: • 5000, which indicates a media failure • 6310, which indicates a disk drive failure
Fail_Actions	Equals the following values: • 0000, which indicates problem-determination procedures must be performed • 1601, which indicates the removable media must be replaced and tried again
Detail_Data	Equals a value of 156, 11, HEX. This value indicates hexadecimal format. **Note:** The Detail_Data field in the **err_rec** structure contains the **sc_error_log_df** structure. The **err_rec** structure is defined in the **/usr/include/sys/errids.h** file. The **sc_error_log_df** structure is defined in the **/usr/include/sys/scsi.h** file. The **sc_error_log_df** structure contains the following fields: **req_sense_data** Contains the request-sense information from the particular device that had the error, if it is valid. **reserved2** Contains the segment count, which is the number of megabytes read from the device at the time the error occurred. **reserved3** Contains the number of bytes read since the segment count was last increased.

Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

Error Record Values for Hardware Errors

The fields that are defined in the error record template for hard disk, CD-ROM, and read/write optical hardware errors, as well as hard-aborted command errors are:

Item	Description
Comment	Indicates hard disk, CD-ROM, or read/write optical hardware error.
Class	Equals a value of H, which indicates a hardware error.
Report	Equals a value of True, which indicates this error must be included when an error report is generated.
Log	Equals a value of True, which indicates an error log entry must be created when this error occurs.
Alert	Equal to a value of FALSE, which indicates this error is not alertable.
Err_Type	Equals a value of Perm, which indicates a permanent failure.
Err_Desc	Equals a value of 1312, which indicates a disk operation failure.
Prob_Causes	Equals a value of 6310, which indicates disk drive.
User_Causes	None.
User_Actions	None.
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	Equals the following values: • 6310, which indicates a disk drive failure • 6330, which indicates a disk drive electronics failure
Fail_Actions	Equals a value of 0000, which indicates problem-determination procedures must be performed.
Detail_Data	Equals a value of 156, 11, HEX. This value indicates hexadecimal format. **Note:** The Detail_Data field in the **err_rec** structure contains the **sc_error_log_df** structure. The **err_rec** structure is defined in the **/usr/include/sys/errids.h** file. The **sc_error_log_df** structure is defined in the **/usr/include/sys/scsi.h** file. The **sc_error_log_df** structure contains the following fields: **req_sense_data** Contains the request-sense information from the particular device that had the error, if it is valid. **reserved2** Contains the segment count, which is the number of megabytes read from the device at the time the error occurred. **reserved3** Contains the number of bytes read since the segment count was last increased.

Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

Error Record Values for Adapter-Detected Hardware Failures

The fields that are defined in the error record template for hard disk, CD-ROM, and read/write optical media errors adapter-detected hardware errors are:

Item	Description
`Comment`	Indicates adapter-detected hard disk, CD-ROM, or read/write optical hardware failure.
`Class`	Equals a value of H, which indicates a hardware error.
`Report`	Equals a value of True, which indicates this error must be included when an error report is generated.
`Log`	Equals a value of True, which indicates an error-log entry must be created when this error occurs.
`Alert`	Equal to a value of FALSE, which indicates this error is not alertable.
`Err_Type`	Equals a value of Perm, which indicates a permanent failure.
`Err_Desc`	Equals a value of 1312, which indicates a disk operation failure.
`Prob_Causes`	Equals the following values: • 3452, which indicates a device cable failure • 6310, which indicates a disk drive failure
`User_Causes`	None.
`User_Actions`	None.
`Inst_Causes`	None.
`Inst_Actions`	None.
`Fail_Causes`	Equals the following values: • 3452, which indicates a storage device cable failure • 6310, which indicates a disk drive failure • 6330, which indicates a disk-drive electronics failure
`Fail_Actions`	Equals a value of 0000, which indicates problem-determination procedures must be performed.
`Detail_Data`	Equals a value of 156, 11, HEX. This value indicates hexadecimal format. **Note:** The `Detail_Data` field in the **err_rec** structure contains the **sc_error_log_df** structure. The **err_rec** structure is defined in the **/usr/include/sys/errids.h** file. The **sc_error_log_df** structure is defined in the **/usr/include/sys/scsi.h** file. The **sc_error_log_df** structure contains the following fields: **req_sense_data** Contains the request-sense information from the particular device that had the error, if it is valid. **reserved2** Contains the segment count, which is the number of megabytes read from the device at the time the error occurred. **reserved3** Contains the number of bytes read since the segment count was last increased.

Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

Error Record Values for Recovered Errors

The fields that are defined in the error record template for hard disk, CD-ROM, and read/write optical media errors recovered errors are:

Item	Description
Comment	Indicates hard disk, CD-ROM, or read/write optical recovered error.
Class	Equals a value of H, which indicates a hardware error.
Report	Equals a value of True, which indicates this error must be included when an error report is generated.
Log	Equals a value of True, which indicates an error log entry must be created when this error occurs.
Alert	Equal to a value of FALSE, which indicates this error is not alertable.
Err_Type	Equals a value of Temp, which indicates a temporary failure.
Err_Desc	Equals a value of 1312, which indicates a physical volume operation failure.
Prob_Causes	Equals the following values: • 5000, which indicates a media failure • 6310, which indicates a disk drive failure
User_Causes	Equals a value of 5100, which indicates media is defective.
User_Actions	Equals the following values: • 0000, which indicates problem-determination procedures must be performed • 1601, which indicates the removable media must be replaced and tried again
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	Equals the following values: • 5000, which indicates a media failure • 6310, which indicates a disk drive failure
Fail_Actions	Equals the following values: • 0000, which indicates problem-determination procedures must be performed • 1601, which indicates the removable media must be replaced and tried again

Item	Description
Detail_Data	Equals a value of 156, 11, HEX. This value indicates hexadecimal format.

> **Note:**
> The Detail_Data field in the **err_rec** structure contains the **sc_error_log_df** structure. The **err_rec** structure is defined in the **/usr/include/sys/errids.h** file. The **sc_error_log_df** structure is defined in the **/usr/include/sys/scsi.h** file.
>
> The **sc_error_log_df** structure contains the following fields:
>
> **req_sense_data**
> Contains the request-sense information from the particular device that had the error, if it is valid.
>
> **reserved2**
> Contains the segment count, which is the number of megabytes read from the device at the time the error occurred.
>
> **reserved3**
> Contains the number of bytes read since the segment count was last increased.

Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

Error Record Values for Unknown Errors

The fields that are defined in the error record template for hard disk, CD-ROM, and read/write optical media errors unknown errors are:

Item	Description
Comment	Indicates hard disk, CD-ROM, or read/write optical unknown failure.
Class	Equals a value of H, which indicates a hardware error.
Report	Equals a value of True, which indicates this error must be included when an error report is generated.
Log	Equals a value of True, which indicates an error log entry must be created when this error occurs.
Alert	Equal to a value of FALSE, which indicates this error is not alertable.
Err_Type	Equals a value of Unkn, which indicates the type of error is unknown.
Err_Desc	Equals a value of FE00, which indicates an undetermined error.
Prob_Causes	Equals the following values: 3300, which indicates an adapter failure 5000, which indicates a media failure 6310, which indicates a disk drive failure
User_Causes	None.
User_Actions	None.
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	Equals a value of FFFF, which indicates the failure causes are unknown.

Item	Description
Fail_Actions	Equals the following values:

Equals the following values:

- 0000, which indicates problem-determination procedures must be performed
- 1601, which indicates the removable media must be replaced and tried again

Item	Description
Detail_Data	Equals a value of 156, 11, HEX. This value indicates hexadecimal format.

Note:

The Detail_Data field in the **err_rec** structure contains the **sc_error_log_df** structure. The **err_rec** structure is defined in the **/usr/include/sys/errids.h** file. The **sc_error_log_df** structure is defined in the **/usr/include/sys/scsi.h** file.

The **sc_error_log_df** structure contains the following fields:

req_sense_data
Contains the request-sense information from the particular device that had the error, if it is valid.

reserved2
Contains the segment count, which is the number of megabytes read from the device at the time the error occurred.

reserved3
Contains the number of bytes read since the segment count was last increased.

Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

Special Files

The **scdisk** SCSI device driver uses raw and block special files in performing its functions.

⚠️ **Attention:** Data corruption, loss of data, or loss of system integrity (system crash) occurs if devices that support paging, logical volumes, or mounted file systems are accessed by using block special files. Block special files are provided for logical volumes and disk devices and are solely for system use in managing file systems, paging devices, and logical volumes. These files must not be used for other purposes.

The special files that are used by the **scdisk** device driver include the following (listed by type of device):

- Hard disk devices:

Item	Description
/dev/rhdisk0, **/dev/rhdisk1**,..., **/dev/rhdisk**n	Provides an interface to allow SCSI device drivers character access (raw I/O access and control functions) to SCSI hard disks.
/dev/hdisk0, **/dev/hdisk1**,..., **/dev/hdisk**n	Provides an interface to allow SCSI device drivers block I/O access to SCSI hard disks.

- CD-ROM devices:

Item	Description
/dev/rcd0, **/dev/rcd1**,..., **/dev/rcd**n	Provides an interface to allow SCSI device drivers character access (raw I/O access and control functions) to SCSI CD-ROM disks.
/dev/cd0, **/dev/cd1**,..., **/dev/cd**n	Provides an interface to allow SCSI device drivers block I/O access to SCSI CD-ROM disks.

- Read/write optical devices:

Item	Description
/dev/romd0, **/dev/romd1**,..., **/dev/romd**n	Provides an interface to allow SCSI device drivers character access (raw I/O access and control functions) to SCSI read/write optical devices.
/dev/omd0, **/dev/omd1**,..., **/dev/omd**n	Provides an interface to allow SCSI device drivers block I/O access to SCSI read/write optical devices.

Note: The prefix **r** on a special file name indicates that the drive is accessed as a raw device rather than a block device. Performing raw I/O with a hard disk, CD-ROM, or read/write optical drive requires that all data transfers be in multiples of the device block size. All **lseek** subroutines that are made to the raw device driver must result in a file pointer value that is a multiple of the device block size.

SCIOCMD SCSI Adapter Device Driver ioctl Operation

Purpose

Provides a means to issue any SCSI command to a SCSI device.

Description

The **SCIOCMD** operation allows the caller to issue a SCSI command to a selected adapter. This command can be used by system management routines to aid in the configuration of SCSI devices.

The *arg* parameter for the **SCIOCMD** operation is the address of a **sc_passthru** structure, which is defined in the **/usr/include/sys/scsi.h** field. The *sc_passthru* parameter allows the caller to select which SCSI and LUN IDS to send the command.

The SCSI status byte and the adapter status bytes are returned through the **sc_passthru** structure. If the **SCIOCMD** operation returns a value of -1 and the errno global variable is set to a nonzero value, the requested operation has failed. If it happens, the caller must evaluate the returned status bytes to determine why the operation failed and what recovery actions must be taken.

If the **SCIOCMD** operation fails because a field in the **sc_passthru** structure has an invalid value, the subroutine returns a value of -1, the errno global variable is set to **EINVAL**, and the **einval_arg** field is set to the field number (starting with 1 for the version field) of the field that had an invalid value. A value of 0 for the **einval_arg** field indicates that no additional information is available.

The version field of the **sc_passthru** structure can be set to the value of SC_VERSION_2 in the **/usr/include/sys/scsi.h** file, and the user can provide the following fields:

- **variable_cdb_ptr** is a pointer to a buffer that contains the Variable SCSI cdb.
- **variable_cdb_length** determines the length of the *cdb* variable to which the **variable_cdb_ptr** field points.

On completion of the **SCIOCMD** ioctl request, the **residual** field indicates the leftover data that device did not fully satisfy for this request. On a successful completion, the **residual** field would indicate that the device does not have the all data that is requested or the device has less than the amount of data that is requested. On a failure completion, the user must check the **status_validity** field to determine whether a valid SCSI bus problem exists. In this case, the **residual** field would indicate the number bytes that the device failed to complete for this request.

The **devinfo** structure defines the maximum transfer size for the command. If an attempt is made to transfer more than the maximum transfer size, the subroutine returns a value of -1, sets the errno global variable to a value of **EINVAL**, and sets the **einval_arg** field to a value of 18.

Refer to the *Small Computer System Interface (SCSI) Specification* to find out the format of the request-sense data for a particular device.

Return Values

The **SCIOCMD** operation returns a value of 0 when successfully completed. If unsuccessful, a value of -1 is returned, and the errno global variable is set to one of the following values:

Item	Description
EIO	A system error occurred. Consider trying the operation several (three) times because another attempt might be successful. If an **EIO** error occurs and the **status_validity** field is set to **SC_SCSI_ERROR**, the **scsi_status** field has a valid value and must be inspected.
	If the **status_validity** field is zero and remains so on successive trials, an unrecoverable error occurred.
	If the **status_validity** field is **SC_SCSI_ERROR** and the **scsi_status** field contains a *Check Condition* status, a SCSI request sense must be issued by using the **SCIOCMD** ioctl to recover the sense data.
EFAULT	A user process copy failed.
EINVAL	The device is not opened, or the caller set a field in the **sc_passthru** structure to an invalid value.
EACCES	The adapter is in diagnostics mode.
ENOMEM	A memory request failed.
ETIMEDOUT	The command timed out. Consider trying the operation several times because another attempt might be successful.
ENODEV	The device is not responding.
ETIMEDOUT	The operation did not complete before the timeout value was exceeded.

Files

Item	Description
/dev/scsi0, /dev/scsi1, ... /dev/scsin	Provides an interface for all SCSI device drivers to access SCSI devices or adapters.

SCIODIAG (Diagnostic) SCSI Adapter Device Driver ioctl Operation

Purpose

Provides the means to issue adapter diagnostic commands.

Description

The **SCIODIAG** operation allows the caller to issue various adapter diagnostic commands to the selected SCSI adapter. These diagnostic command options are:

- Run the card Internal Diagnostics test
- Run the card SCSI Wrap test

- Run the card Read/Write Register test
- Run the card POS Register test
- Run the card SCSI Bus Reset test

An additional option allows the caller to resume the card Internal Diagnostics test from the point of a failure, which is indicated by the return value. The *arg* parameter for the **SCIODIAG** operation specifies the address of a **sc_card_diag** structure. This structure is defined in the **/usr/include/sys/scsi.h** file.

The actual adapter error-status information from each error reported by the card diagnostics is passed as returned parameters to the caller. Refer to the **sc_card_diag** structure defined in the **/usr/include/sys/scsi.h** file for the format of the returned data.

When the card diagnostics have completed (with previous errors), a value of **ENOMSG** is returned. At this point, no further **SCIODIAG** resume options are required, as the card internal diagnostics test has completed.

Adapter error status is always returned when a **SCIODIAG** operation results in an **errno** value of **EFAULT**. Because this error information is returned for each such volume, the final **ENOMSG** value returned for the card Internal Diagnostics test includes no error status information. Also, because this is a diagnostic command, these errors are not logged in the system error log.

Note: The SCSI adapter device driver performs no internal retries or other error-recovery procedures during execution of this operation. Error logging is also inhibited when running this command.

Return Values

When completed successfully, this operation returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to one of the following values:

Value	Description
EFAULT	Indicates that a bad copy between user and kernel space occurred.
EFAULT	For the integrated SCSI adapter on the 7008 and 7011 system models, this return value also indicates that the SCSI adapter device driver detected an error while attempting to run the **SCIODIAG** operation. In this case, the returned adapter status information must be analyzed to discover the cause of the error. Because this is a diagnostic command, this error is not logged in the system error log.
	For all other SCSI adapters, this value indicates that the card internal diagnostics have detected an error and paused. To continue, the caller must issue another **SCIODIAG** operation with the resume option. In response to this option, the card continues the diagnostics until either the end is reached or another error is detected. The caller must continue to issue **SCIODIAG** operations until the **EFAULT** error no longer returns.
EINVAL	Indicates a bad input parameter.
EIO	Indicates that the SCSI adapter device driver detected an error while attempting to run the **SCIODIAG** operation. In this case, the returned adapter status information must be analyzed to discover the cause of the error. Because this is a diagnostic command, this error is not logged in the system error log.
ENOMSG	Indicates that the card Internal Diagnostics test has completed.
ENXIO	Indicates that the operation or suboption selected is not supported on this adapter. This should not be treated as an error. The caller must check for this return value first (before checking for other **errno** values) to avoid mistaking this for a failing command.
ETIMEDOUT	Indicates that the adapter did not respond with status before the passed command time-out value expired. The **SCIODIAG** operation is a diagnostic command, so its errors are not logged in the system error log.

Files

/dev/scsi0, **/dev/scsi1,...**, **/dev/scsi***n*	Provide an interface to allow SCSI device drivers to access SCSI devices/adapters.

SCIODNLD (Download) SCSI Adapter Device Driver ioctl Operation

Purpose

Provides the means to download microcode to the adapter.

Description

The **SCIODNLD** operation provides for downloading microcode to the selected adapter. This operation can be used by system management routines to prepare the adapter for operation. The adapter can be opened in Normal or Diagnostic mode when the **SCIODNLD** operation is run.

There are two options for executing the **SCIODNLD** operation. The caller can either download microcode to the adapter or query the version of the currently downloaded microcode.

If the download microcode option is selected, a pointer to a download buffer and its length must be supplied in the caller's memory space. The maximum length of this microcode is adapter-dependent. If the adapter requires transfer of complete blocks, the microcode to be sent must be padded to the next largest block boundary. The block size, if any, is adapter-dependent. Refer to the reference manual for the particular SCSI adapter to find the adapter-specific requirements of the microcode buffer to be downloaded.

The SCSI adapter device driver validates the parameter values for such things as maximum length and block boundaries, as required. The *arg* parameter for the **SCIODNLD** operation specifies the address of a **sc_download** structure. This structure is defined in the **/usr/include/sys/scsi.h** file.

If the query version option is selected, the pointer and length fields in the passed parameter block are ignored. On successful completion of the **SCIODNLD** operation, the microcode version is contained in the `version_number` field.

The SCSI adapter device driver performs normal error-recovery procedures during execution of the **SCIODNLD** operation.

Return Values

When completed successfully, this operation returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to one of the following values:

Value	Description
EFAULT	Indicates that a severe I/O error has occurred, preventing completion of the download. In this case, further operations are not possible on the card, and the caller should discontinue commands to the card. The adapter error-status information is logged in the system error log.
EFAULT	Indicates that a bad copy between kernel and user space occurred.
EINVAL	Indicates that the adapter device driver was unable to run the command due to incorrect input parameters. Check microcode length and block boundary for errors.

Value	Description
EIO	Indicates that the adapter device driver was unable to complete the command due to an unrecoverable I/O error or microcode cyclical redundancy check (CRC) error. If the card has on-board microcode, it may be able to continue running, and further commands may still be possible on this adapter. The adapter error-status information is logged in the system error log.
ENOMEM	Indicates insufficient memory is available to complete the command.
ENXIO	Indicates that the operation or suboption selected is not supported on this adapter and should not be treated as an error. The caller must check for this return value first (before checking for other **errno** values) to avoid mistaking this for a failing command.
ETIMEDOUT	Indicates that the adapter did not respond with status before the passed command time-out value expired. Since the download operation may not have completed, further operations on the card may not be possible. The caller should discontinue sending commands to the card. This error is also logged in the system error log.

Item	Description
/dev/scsi0, **/dev/scsi1**,**...**, **/dev/scsi***n*	Provide an interface to allow SCSI device drivers to access SCSI devices and adapters.

SCIOEVENT (Event) SCSI Adapter Device Driver ioctl Operation

Purpose

Registers the selected SCSI device instance to receive asynchronous event notification.

Description

The **SCIOEVENT** operation registers the selected initiator or target-mode device for receiving asynchronous event notification. Only kernel mode processes or device drivers can call this function. If a user-mode process attempts an **SCIOEVENT** operation, the **ioctl** command is unsuccessful and the **errno** global value is set to **EPERM**.

The *arg* parameter to the **SCIOEVENT** operation should be set to the address of an **sc_event_struct** structure, which is in the **/usr/include/sys/scsi.h** file. If this is a target-mode instance, the **SCIOSTARTTGT** operation was used to open the device session; the caller then fills in the ID field with the SCSI ID of the SCSI initiator and sets the `logical unit number` (LUN) field to a value of 0. If this is an initiator-mode instance, the **SCIOSTART** operation was used to open the device session; the ID field is then set to the SCSI ID of the SCSI target, and the LUN is set to the LUN ID of the SCSI target. The device must have been previously opened using one of the start ioctls for this operation to succeed. If the device session is not opened, the **ioctl** command is unsuccessful and the returned **errno** global value is set to **EINVAL**.

The event registration performed by this ioctl is only allowed once per device session; only the first **SCIOEVENT** operation is accepted after the device is opened. Succeeding **SCIOEVENT** operations are unsuccessful, and the **errno** global value is set to **EINVAL**. The event registration is cancelled automatically when the device session is closed.

The caller fills in the mode field with one of the following values, which are defined in the **/usr/include/sys/scsi.h** file:

```
#define SC_IM_MODE   /* this is an initiator mode device */
```

```
#define SC_TM_MODE   /* this is a target mode device    */
```

The `async_func` field is filled in with the address of a pinned routine (in the calling program) that should be called by the SCSI adapter device driver whenever asynchronous event status is available for a registered device. The **struct sc_event_info** structure, defined in the **/usr/include/sys/scsi.h** file, is passed by address to the caller's **async_func** routine.

The `async_correlator` field can optionally be used by the caller to provide an efficient means of associating event information with the appropriate device. This field is saved by the SCSI adapter device driver and is returned, unchanged, with information passed back to the caller's **async_func** routine.

Reserved fields must be set to 0 by the caller.

Return Values

When completed successfully, this operation returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to one of the following values:

Value	Description
EFAULT	Indicates that a bad copy between kernel and user space occurred.
EINVAL	Either an **SCIOSTART** or **SCIOSTARTTGT** operator has not been issued to this device instance, or this device is already registered for async events.
EPERM	Indicates the caller is not running in kernel mode, which is the only mode allowed to execute this operation.

Files

Item	Description

SCIOGTHW (Gathered Write) SCSI Adapter Device Driver ioctl Operation

Purpose

Allows the caller to verify that the SCSI adapter device driver to which this device instance is attached supports gathered writes.

Description

This operation allows the caller to verify that the gathered write function is supported by the SCSI adapter device driver before the caller attempts such an operation. The **SCIOGTHW** operation fails if a SCSI adapter device driver does not support gathered writes.

The *arg* parameter to the **SCIOGTHW** operation is set to null by the caller to indicate no input parameter is passed.

Note: This operation is not supported by all SCSI I/O Controllers. If not supported, **errno** is set to **EINVAL** and a value of -1 is returned.

Return Values

When completed successfully, the **SCIOGTHW** operation returns a value of 0, meaning gathered writes are supported. Otherwise, a value of -1 is returned and **errno** global variable is set to **EINVAL**.

Files

Item	Description
/dev/scsi0, **/dev/scsi1**,..., **/dev/scsi**n	Provide an interface to allow SCSI device drivers to access SCSI devices or adapters.

SCIOHALT (Halt) SCSI Adapter Device Driver ioctl Operation

Purpose

Ends the current command (if there is one), clears the queue of any pending commands, and places the device queue in a halted state.

Description

The **SCIOHALT** operation allows the caller to end the current command (if there is one) to a selected device, clear the queue of any pending commands, and place the device queue in a halted state. The command causes the attached SCSI adapter to execute a SCSI abort message to the selected target device. This command is used by an upper-level SCSI device driver to end a running operation instead of waiting for the operation to complete or time out.

Once the **SCIOHALT** operation is sent, the calling device driver must set the **SC_RESUME** flag. This bit is located in the `flags` field of the next **sc_buf** structure to be processed by the SCSI adapter device driver. Any **sc_buf** structure sent without the **SC_RESUME** flag, after the device queue is in the halted state, is rejected.

The *arg* parameter to the **SCIOHALT** operation allows the caller to specify the SCSI identifier of the device to be reset. The least significant byte in the *arg* parameter is the LUN ID (logical unit number identifier) of the LUN on the SCSI controller to be halted. The next least significant byte is the SCSI ID. The remaining two bytes are reserved and must be set to a value of 0.

The SCSI adapter device driver performs normal error-recovery procedures during execution of this command. For example, if the abort message causes the SCSI bus to hang, a SCSI bus reset is initiated to clear the condition.

Return Values

When completed successfully, this operation returns a value of 0. Otherwise, a value of -1 is returned, and the **errno** global variable is set to one of the following values:

Value	Description
EINVAL	Indicates a **SCIOSTART** operation was not issued prior to this operation.
EIO	Indicates an unrecoverable I/O error occurred. In this case, the adapter error-status information is logged in the system error log.
EIO	Indicates either the device is already stopping or the device driver was unable to pin code.
ENOCONNECT	Indicates a SCSI bus fault occurred.

Value	Description
ENODEV	Indicates the target SCSI ID could not be selected or is not responding. This condition is not necessarily an error and is not logged.
ENOMEM	Indicates insufficient memory is available to complete the command.
ETIMEDOUT	Indicates the adapter did not respond with status before the internal command time-out value expired. This error is logged in the system error log.

Files

Item	Description
/dev/scsi0, **/dev/scsi1**, **...**, **/dev/scsi***n*	Provide an interface to allow SCSI device drivers to access SCSI devices and adapters.
/dev/vscsi0, /dev/vscsi1,..., /dev/vscsi*n*	Provide an interface to allow SCSI-2 Fast/Wide Adapter/A and SCSI-2 Differential Fast/Wide Adapter/A device drivers to access SCSI devices or adapters.

SCIOINQU (Inquiry) SCSI Adapter Device Driver ioctl Operation

Purpose

Provides the means to issue an inquiry command to a SCSI device.

Description

The **SCIOINQU** operation allows the caller to issue a SCSI device inquiry command to a selected adapter. This command can be used by system management routines to aid in configuration of SCSI devices.

The *arg* parameter for the **SCIOINQU** operation is the address of an **sc_inquiry** structure. This structure is defined in the **/usr/include/sys/scsi.h** file. The **sc_inquiry** parameter block allows the caller to select the SCSI and LUN IDs to be queried.

The **SC_ASYNC** flag byte of the parameter block must not be set on the initial call to this operation. This flag is only set if a bus fault occurs and the caller intends to attempt more than one retry.

If successful, the returned inquiry data can be found at the address specified by the caller in the **sc_inquiry** structure. Successful completion occurs if a device responds at the requested SCSI ID, but the returned inquiry data must be examined to see if the requested LUN exists. Refer to the *Small Computer System Interface (SCSI) Specification* for the applicable device for the format of the returned data.

Note: The SCSI adapter device driver performs normal error-recovery procedures during execution of this command.

Return Values

When completed successfully this operation returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to one of the following values:

Value	Description
EFAULT	Indicates that a bad copy between kernel and user space occurred.
EINVAL	Indicates that a **SCIOSTART** command was not issued prior to this command.

Value	Description
EIO	Indicates that an unrecoverable I/O error has occurred. If **EIO** is returned, the caller should retry the **SCIOINQU** operation since the first command may have cleared an error condition with the device. In case of an unrecovered error, the adapter error-status information is logged in the system error log.
ENOCONNECT	Indicates that a bus fault has occurred. The caller should respond by retrying with the **SC_ASYNC** flag set in the flag byte of the passed parameters. If more than one retry is attempted, only the last retry should be made with the **SC_ASYNC** flag set. Generally the SCSI adapter device driver cannot determine which device caused the SCSI bus fault, so this error is not logged.
ENODEV	Indicates that no SCSI controller responded to the requested SCSI ID. This return value implies that no LUNs exist on the requested SCSI ID. Therefore, when the **ENODEV** return value is encountered, the caller can skip this SCSI ID (and all LUNs on it) and go on to the next SCSI ID. This condition is not necessarily an error and is not logged.
ENOMEM	Indicates insufficient memory is available to complete the command.
ETIMEDOUT	Indicates that the adapter did not respond with a status before the internal command time-out value expired. On receiving the **ETIMEDOUT** return value, the caller should retry this command at least once, since the first command may have cleared an error condition with the device. This error is logged in the system error log.

Files

Item	Description
/dev/scsi0, **/dev/scsi1**, **...**, **/dev/scsi***n*	Provide an interface to allow SCSI device drivers to access SCSI devices/adapters.
/dev/vscsi0, /dev/vscsi1,..., /dev/vscsi*n*	Provide an interface to allow SCSI-2 Fast/Wide Adapter/A and SCSI-2 Differential Fast/Wide Adapter/A device drivers to access SCSI devices or adapters.

SCIOREAD (Read) SCSI Adapter Device Driver ioctl Operation

Purpose

Issues a single block SCSI **read** command to a selected SCSI device.

Description

The **SCIOREAD** operation allows the caller to issue a SCSI device **read** command to a selected adapter. System management routines use this command for configuring SCSI devices.

The *arg* parameter of the **SCIOREAD** operation is the address of an **sc_readblk** structure. This structure is defined in the **/usr/include/sys/scsi.h** header file.

This command results in the SCSI adapter device driver issuing a 6-byte format ANSI SCSI-1 **read** command. The command is set up to read only a single block. The caller supplies:

- Target device SCSI and LUN ID
- Logical block number to be read
- Length (in bytes) of the block on the device
- Time-out value (in seconds) for the command

- Pointer to the application buffer where the returned data is to be placed
- Flags parameter

The maximum block length for this command is 4096 bytes. The command will be rejected if the length is found to be larger than this value.

The **SC_ASYNC** flag of the flag parameter must not be set on the initial call to this operation. This flag is set only if a bus fault occurs and only if this is the caller's last retry attempt after this error occurs.

Note: The SCSI adapter device driver performs normal error-recovery procedures during execution of this command.

Return Values

When completed successfully this operation returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to one of the following values:

Value	Description
EFAULT	Indicates that a bad copy between kernel and user space occurred.
EINVAL	Indicates that an **SCIOSTART** command was not issued prior to this command. If the **SCIOSTART** command was issued, then this indicates the block length field value is too large.
EIO	Indicates that an I/O error has occurred. If an **EIO** value is returned, the caller should retry the **SCIOREAD** operation since the first command may have cleared an error condition with the device. In the case of an adapter error, the system error log records the adapter error status information.
ENOCONNECT	Indicates that a bus fault has occurred. The caller should respond by retrying with the **SC_ASYNC** flag set in the flag byte of the passed parameters. If more than one retry is attempted, only the last retry should be made with the **SC_ASYNC** flag set. Generally, the SCSI adapter device driver cannot determine which device caused the bus fault, so this error is not logged.
ENODEV	Indicates that no SCSI controller responded to the requested SCSI ID. This return value implies that no logical unit numbers (LUNs) exist on the specified SCSI ID. This condition is not necessarily an error and is not logged.
ENOMEM	Indicates insufficient memory is available to complete the command.
ETIMEDOUT	Indicates the adapter did not respond with status before the internal time-out value expired. The caller should retry this command at least once, since the first command may have cleared an error condition with the device. The system error log records this error.

SCIORESET (Reset) SCSI Adapter Device Driver ioctl Operation

Purpose

Allows the caller to force a SCSI device to release all current reservations, clear all current commands, and return to an initial state.

Description

The **SCIORESET** operation allows the caller to force a SCSI device to release all current reservations, clear all current commands, and return to an initial state. This operation is used by system management routines to force a SCSI controller to release a competing SCSI initiator's reservation in a multi-initiator environment.

This operation actually executes a SCSI bus device reset (BDR) message to the selected SCSI controller on the selected adapter. The BDR message is directed to a SCSI ID. Therefore, all logical unit numbers (LUNs) associated with that SCSI ID are affected by the execution of the BDR.

For the operation to work effectively, a SCSI Reserve command should be issued after the **SCIORESET** operation through the appropriate SCSI device driver. Typically, the SCSI device driver open logic issues a SCSI Reserve command. This prevents another initiator from claiming the device.

There is a finite amount of time between the release of all reservations (by a **SCIORESET** operation) and the time the device is again reserved (by a SCSI Reserve command from the host). During this interval, another SCSI initiator can reserve the device instead. If this occurs, the SCSI Reserve command from this host fails and the device remains reserved by a competing initiator. The capability needed to prevent or recover from this event is beyond the SCSI adapter device driver and SCSI device driver components.

The *arg* parameter to the **SCIORESET** operation allows the caller to specify the SCSI ID of the device to be reset. The least significant byte in the *arg* parameter is the LUN ID of the LUN on the SCSI controller. The device indicated by the LUN ID should have been successfully started by a call to the **SCIOSTART** operation. The next least significant byte is the SCSI ID. The remaining two bytes are reserved and must be set to a value of 0.

Examples

1. The following example demonstrates actual use of this command. A SCSI ID of 1 is assumed, and an LUN of 0 exists on this SCSI controller.

```
open SCSI adapter device driver
SCIOSTART SCSI ID=1, LUN=0
SCIORESET SCSI ID=1, LUN=0 (to free any reservations)
SCIOSTOP SCSI ID=1, LUN=0
close SCSI adapter device driver
open SCSI device driver (normal open) for SCSI ID=1, LUN=0
...
Use device as normal
...
```

2. To make use of the **SC_FORCED_OPEN** flag of the SCSI device driver:

```
open SCSI device driver (with SC_FORCED_OPEN flag)
for SCSI ID=1, LUN=0
...
```

Use the device as normal.

Both examples assume that the SCSI device driver **open** call executes a SCSI Reserve command on the selected device.

The SCSI adapter device driver performs normal error-recovery procedures during execution of this command. For example, if the BDR message causes the SCSI bus to hang, a SCSI bus reset will be initiated to clear the condition.

Return Values

When completed successfully, this operation returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to one of the following values:

Value	Description
EINVAL	Indicates an **SCIOSTART** command was not issued prior to this command.
EIO	Indicates an unrecoverable I/O error occurred. In this case, the adapter error-status information is logged in the system error log.
EIO	Indicates either the device is already stopping or the device driver is unable to pin code.
ENOCONNECT	Indicates that a bus fault has occurred. The caller should respond by retrying with the **SC_ASYNC** flag set in the flag byte of the passed parameters. If more than one retry is attempted, only the last retry should be made with the **SC_ASYNC** flag set. Generally, the SCSI adapter device driver cannot determine which device caused the bus fault, so this error is not logged in the system error log.
ENODEV	Indicates the target SCSI ID could not be selected or is not responding. This condition is not necessarily an error and is not logged.
ENOMEM	Indicates insufficient memory is available to complete the command.
ETIMEDOUT	Indicates the adapter did not respond with status before the internal command time-out value expired. This error is logged.

Files

Item	Description
/dev/scsi0, **/dev/scsi1**, **...**, **/dev/scsi**_n_	Provide an interface to allow SCSI device drivers to access SCSI devices or adapters.

SCIOSTART (Start SCSI) Adapter Device Driver ioctl Operation

Purpose

Opens a logical path to a SCSI target device.

Description

The **SCIOSTART** operation opens a logical path to a SCSI device. The host SCSI adapter acts as an initiator device. This operation causes the adapter device driver to allocate and initialize the data areas needed to manage commands to a particular SCSI target.

The **SCIOSTART** operation must be issued prior to any of the other non-diagnostic mode operations, such as **SCIOINQU** and **SCIORESET**. However, the **SCIOSTART** operation is not required prior to calling the **IOCINFO** operation. Finally, when the caller is finished issuing commands to the SCSI target, the **SCIOSTOP** operation must be issued to release allocated data areas and close the path to the device.

The _arg_ parameter to **SCIOSTART** allows the caller to specify the SCSI and LUN (logical unit number) identifier of the device to be started. The least significant byte in the _arg_ parameter is the LUN, and the next least significant byte is the SCSI ID. The remaining two bytes are reserved and must be set to a value of 0.

Return Values

If completed successfully this operation returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable set to one of the following values:

Value	Description
EIO	Indicates either an unrecoverable I/O error, or the device driver is unable to pin code.
EINVAL	Indicates either that the SCSI ID and LUN combination was incorrect (the combination may already be in use) or that the passed SCSI ID is the same as that of the adapter.

If the **SCIOSTART** operation is unsuccessful, the caller must not attempt other operations to this SCSI ID and LUN combination, since it is either already in use or was never successfully started.

Files

Item	Description

/dev/vscsi0, /dev/vscsi1,..., /dev/vscsi_n_	Provide an interface to allow SCSI-2 Fast/Wide Adapter/A and SCSI-2 Differential Fast/Wide Adapter/A device drivers to access SCSI devices or adapters.

SCIOSTARTTGT (Start Target) SCSI Adapter Device Driver ioctl Operation

Purpose

Opens a logical path to a SCSI initiator device.

Description

The **SCIOSTARTTGT** operation opens a logical path to a SCSI initiator device. The host SCSI adapter acts as a target. This operation causes the adapter device driver to allocate and initialize device-dependent information areas needed to manage data received from the initiator. It also makes the adapter device driver allocate system buffer areas to hold data received from the initiator. Finally, it makes the host adapter ready to receive data from the initiator.

This operation may only be called from a kernel process or device driver, as it requires that both the caller and the SCSI adapter device driver be able to directly access each other's code in memory.

Note: This operation is not supported by all SCSI I/O controllers. If not supported, **errno** is set to **ENXIO** and a value of -1 is returned.

The *arg* parameter to the **SCIOSTARTTGT** ioctl operation should be set to the address of an **sc_strt_tgt** structure, which is defined in the **/usr/include/sys/scsi.h** file. The caller fills in the ID field with the SCSI ID of the SCSI initiator and sets the `logical unit number` (LUN) field to 0, as the initiator LUN is ignored for received data.

The caller sets the `buf_size` field to the desired size for all receive buffers allocated for this host target instance. This is an adapter-dependent parameter, which should be set to 4096 bytes for the SCSI I/O Controller. The `num_bufs` field is set to indicate how many buffers the caller wishes to have allocated for the device. This is also an adapter-dependent parameter. For the SCSI I/O Controller, it should be set to 16 or greater.

The caller fills in the `recv_func` field with the address of a pinned routine from its module, which the adapter device driver calls to pass received-data information structures. These structures tell the caller where the data is located and if any errors occurred.

The `tm_correlator` field can optionally be used by the caller to provide an efficient means of associating received data with the appropriate device. This field is saved by the SCSI adapter device driver and is returned, with information passed back to the caller's **recv_func** routine.

The `free_func` field is an output parameter for this operation. The SCSI adapter device driver fills this field with the address of a pinned routine in its module, which the caller calls to pass processed received-data information structures.

Currently, the host SCSI adapter acts only as LUN 0 when accessed from other SCSI initiators. This means the remotely-attached SCSI initiator can only direct data at one logical connection per host SCSI adapter. At most, only one calling process can open the logical path from the host SCSI adapter to a remote SCSI initiator. This does not prevent a single process from having multiple target devices opened simultaneously.

Note: Two or more SCSI target devices can have the same SCSI ID if they are physically attached to separate SCSI adapters.

Return Values

When completed successfully, this operation returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to one of the following values:

Value	Description
EINVAL	An **SCIOSTARTTGT** command has already been issued to this SCSI ID, the passed SCSI ID is the same as that of the adapter, the LUN field is not set to 0, the `buf_size` field is greater than 4096 bytes, the num_bufs field is less than 16, or the `recv_func` field is set to null.
EIO	Indicates an I/O error or kernel service failure occurred, preventing the device driver from enabling the selected SCSI ID.
ENOMEM	Indicates that a memory allocation error has occurred.
EPERM	Indicates the caller is not running in kernel mode, which is the only mode allowed to execute this operation.

Files

Item	Description
/dev/scsi0, /dev/scsi1,...,/dev/scsi_n_	Provide an interface to allow SCSI device drivers to access SCSI devices or adapters.
/dev/vscsi0, /dev/vscsi1,..., /dev/vscsi_n_	Provide an interface to allow SCSI-2 Fast/Wide Adapter/A and SCSI-2 Differential Fast/Wide Adapter/A device drivers to access SCSI devices or adapters.

SCIOSTOP (Stop) Device SCSI Adapter Device Driver ioctl Operation

Purpose

Closes the logical path to a SCSI target device.

Description

The **SCIOSTOP** operation closes the logical path to a SCSI device. The host SCSI adapter acts as an initiator. The **SCIOSTOP** operation causes the adapter device driver to deallocate data areas allocated in response to a **SCIOSTART** operation. This command must be issued when the caller wishes to cease

communications to a particular SCSI target. The **SCIOSTOP** operation should only be issued for a device successfully opened by a previous call to an **SCIOSTART** operation.

The **SCIOSTOP** operation passes the *arg* parameter. This parameter allows the caller to specify the SCSI and logical unit number (LUN) IDs of the device to be stopped. The least significant byte in the *arg* parameter is the LUN, and the next least significant byte is the SCSI ID. The remaining two bytes are reserved and must be set to 0.

Return Values

When completed successfully this operation returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to one of the following values:

Value	Description
EINVAL	Indicates that the device has not been opened. An **SCIOSTART** operation should be issued prior to calling the **SCIOSTOP** operation.
EIO	Indicates that the device drive was unable to pin code.

Files

Item	Description
/dev/scsi0, **/dev/scsi1**, **...**, **/dev/scsi**n	Provide an interface to allow SCSI device drivers to access SCSI devices or adapters.
/dev/vscsi0, /dev/vscsi1,..., /dev/vscsin	Provide an interface to allow SCSI-2 Fast/Wide Adapter/A and SCSI-2 Differential Fast/Wide Adapter/A device drivers to access SCSI devices or adapters.

SCIOSTOPTGT (Stop Target) SCSI Adapter Device Driver ioctl Operation

Purpose

Closes a logical path to a SCSI initiator device.

Description

The **SCIOSTOPTGT** operation closes a logical path to a SCSI initiator device, where the host SCSI adapter acts as a target. This operation causes the adapter device driver to deallocate device-dependent information areas allocated in response to the **SCIOSTARTTGT** operation. It also causes the adapter device driver to deallocate system buffer areas used to hold data received from the initiator. Finally, it disables the host adapter's ability to receive data from the selected initiator.

This operation may only be called from a kernel process or device driver.

Note: This operation is not supported by all SCSI I/O Controllers. If not supported, **errno** is set to **ENXIO** and a value of -1 is returned.

The *arg* parameter to the **SCIOSTOPTGT** operation should be set to the address of an **sc_stop_tgt** structure, which is defined in the **/usr/include/sys/scsi.h** file. The caller fills in the `id` field with the SCSI ID of the initiator and sets the `logical unit number (LUN)` field to 0 as the initiator LUN is ignored for received data.

Note: The calling device driver should have previously freed any received-data areas by passing their information structures to the SCSI adapter device driver's **free_func** routine. All buffers allocated for this device are deallocated by the **SCIOSTOPTGT** operation regardless of whether the calling device driver has finished processing those buffers and has called the **free_func** routine.

Return Values

When completed successfully, this operation returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to one of the following values:

Item	Description
EINVAL	An **SCIOSTOPTGT** command has not been previously issued to this SCSI ID.
EPERM	Indicates the caller is not running in kernel mode, which is the only mode allowed to execute this operation.

Files

Item	Description
/dev/scsi0, /dev/scsi1, ...	Provide an interface to allow SCSI device drivers to access SCSI devices or adapters.
/dev/vscsi0, /dev/vscsi1, ...,**/dev/vscsi***n*	Provide an interface to allow SCSI-2 Fast/Wide Adapter/A and SCSI-2 Differential Fast/Wide Adapter/A device drivers to access SCSI devices or adapters.

SCIOSTUNIT (Start Unit) SCSI Adapter Device Driver ioctl Operation

Purpose

Provides the means to issue a SCSI Start Unit command to a selected SCSI device.

Description

The **SCIOSTUNIT** operation allows the caller to issue a SCSI Start Unit command to a selected SCSI adapter. This command can be used by system management routines to aid in configuration of SCSI devices. For the **SCIOSTUNIT** operation, the *arg* parameter operation is the address of an **sc_startunit** structure. This structure is defined in the **/usr/include/sys/scsi.h** file.

The **sc_startunit** structure allows the caller to specify the SCSI and logical unit number (LUN) IDs of the device on the SCSI adapter that is to be started. The **SC_ASYNC** flag (in the flag byte of the passed parameter block) must not be set on the initial attempt of this command.

The start_flag field in the parameter block allows the caller to indicate the start option to the **SCIOSTUNIT** operation. When the start_flag field is set to TRUE, the logical unit is to be made ready for use. When FALSE, the logical unit is to be stopped.

> **Attention:** When the immed_flag field is set to TRUE, the SCSI adapter device driver allows simultaneous **SCIOSTUNIT** operations to any or all attached devices. It is important that when executing simultaneous SCSI Start Unit commands, the caller should allow a delay of at least 10 seconds between succeeding SCSI Start Unit command operations. The delay ensures that adequate power is available to devices sharing a common power supply. Failure to delay in this manner can cause damage to the system unit or to attached devices. Consult the technical specifications manual for the particular device and the appropriate hardware technical reference for your system.

The immed_flag field allows the caller to indicate the immediate option to the **SCIOSTUNIT** operation. When the immed_flag field is set to TRUE, status is to be returned as soon as the command is received by the device. When the field is set to FALSE, the status is to be returned after the operation is completed. The caller should set the immed_flag field to TRUE to allow overlapping **SCIOSTUNIT** operations to multiple devices on the SCSI bus. In this case, the **SCIOTUR** operation can be used to determine when the **SCIOSTUNIT** has actually completed.

Note: The SCSI adapter device driver performs normal error-recovery procedures during execution of the **SCIOSTUNIT** operation.

Return Values

When completed successfully, the **SCIOSTUNIT** operation returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to one of the following values:

Value	Description
EFAULT	Indicates that a bad copy between kernel and user space occurred.
EINVAL	Indicates that an **SCIOSTART** command was not issued prior to this command.
EIO	Indicates that an unrecoverable I/O error has occurred. If **EIO** is received, the caller should retry this command at least once, as the first command may have cleared an error condition with the device. In case of an unrecovered error, the adapter error-status information is logged in the system error log.
ENOCONNECT	Indicates that a bus fault has occurred. The caller should respond by retrying with the **SC_ASYNC** flag set in the flag byte of the passed parameters. If more than one retry is attempted, only the last retry should be made with the **SC_ASYNC** flag set. Generally the SCSI adapter device driver cannot determine which device caused the SCSI bus fault, so this error is not logged.
ENODEV	Indicates that no SCSI controller responded to the requested SCSI ID. This condition is not necessarily an error and is not logged.
ENOMEM	Indicates insufficient memory is available to complete the command.
ETIMEDOUT	Indicates that the adapter did not respond with status before the internal command time-out value expired. If **ETIMEDOUT** is received, the caller should retry this command at least once, as the first command may have cleared an error condition with the device. This error is logged in the system error log.

Files

Item	Description
/dev/scsi0, **/dev/scsi1,..., /dev/scsi**n	Provide an interface to allow SCSI device drivers to access SCSI devices or adapters.
/dev/vscsi0, /dev/vscsi1,..., /dev/vscsin	Provide an interface to allow SCSI-2 Fast/Wide Adapter/A and SCSI-2 Differential Fast/Wide Adapter/A device drivers to access SCSI devices or adapters.

SCIOTRAM (Diagnostic) SCSI Adapter Device Driver ioctl Operation

Purpose

Provides the means to issue various adapter commands to test the card DMA interface and buffer RAM.

Description

The **SCIOTRAM** operation allows the caller to issue various adapter commands to test the card DMA interface and buffer RAM. The *arg* parameter block to the **SCIOTRAM** operation is the **sc_ram_test** structure. This structure is defined in the **/usr/include/sys/scsi.h** file and contains the following information:

• A pointer to a read or write test pattern buffer

- The length of the buffer
- An option field indicating whether a read or write operation is requested

  Note: The SCSI adapter device driver is not responsible for comparing read data with previously written data. After successful completion of **write** or **read** operations, the caller is responsible for performing a comparison test to determine the final success or failure of this test.

The SCSI adapter device driver performs no internal retries or other error recovery procedures during execution of this operation. Error logging is inhibited when running this command.

Return Values

When completed successfully, this operation returns a value of 0. Otherwise, a value of -1 is returned and the **errno** global variable is set to one of the following values:

Value	Description
EIO	Indicates that the adapter device driver detected an error. The specific adapter status is returned in the **sc_ram_test** parameter block. The SCIOTRAM operation is a diagnostic command and, as a result, this error is not logged in the system error log.
ENXIO	Indicates that the operation or suboption selected is not supported on this adapter. This should not be treated as an error. The caller must check for this return value first (before other **errno** values) to avoid mistaking this for a failing command.
ETIMEDOUT	Indicates the adapter did not respond with status before the passed command time-out value expired. The **SCIOTRAM** operation is a diagnostic command, so this error is not logged in the system error log.

Files

Item	Description
/dev/scsi0, **/dev/scsi1**,..., **/dev/scsi**_n_	Provide an interface to allow SCSI device drivers to access SCSI devices or adapters.

SCIOTUR (Test Unit Ready) SCSI Adapter Device Driver ioctl Operation

Purpose

Sends a Test Unit Ready command to the selected SCSI device.

Description

The **SCIOTUR** operation allows the caller to issue a SCSI Test Unit Read (**SCIOSTUNIT**) command to a selected SCSI adapter. This command is used by system management routines to help configure SCSI devices.

The **sc_ready** structure allows the caller to specify the SCSI and the logical unit number (LUN) ID of the device on the SCSI adapter that is to receive the **SCIOTUR** operation. The **SC_ASYNC** flag (in the flag byte of the *arg* parameter block) must not be set during the initial attempt of this command. The **sc_ready** structure provides two output fields: `status_validity` and `scsi_status`. Using these two fields, the **SCIOTUR** operation returns the status to the caller. The *arg* parameter for the **SCIOTUR** operation specifies the address of the **sc_ready** structure, defined in the **/usr/include/sys/scsi.h** file.

When an **errno** value of **EIO** is received, the caller should evaluate the returned status in the `status_validity` and `scsi_status` fields. The `status_validity` field is set to the value **SC_SCSI_ERROR** to indicate that the `scsi_status` field has a valid SCSI bus status in it. The **/usr/include/sys/scsi.h** file contains typical values for the `scsi_status` field.

Following an **SCIOSTUNIT** operation, a calling program can tell by the SCSI bus status whether the device is ready. If an **errno** value of **EIO** is returned and the `status_validity` field is set to 0, an unrecovered error has occurred. If, on retry, the same result is obtained, the device should be skipped. If the `status_validity` field is set to **SC_SCSI_ERROR** and the `scsi_status` field indicates a Check Condition status, then another **SCIOTUR** command should be sent after a delay of several seconds.

After one or more attempts, the **SCIOTUR** operation should return a successful completion, indicating that the device was successfully started. If, after several seconds, the **SCIOTUR** operation still returns a `scsi_status` field set to a Check Condition status, the device should be skipped.

Note: The SCSI adapter device driver performs normal error-recovery procedures during execution of this command.

Return Values

When completed successfully, this operation returns a value of 0. For the **SCIOTUR** operation, this means the target device has been successfully started and is ready for data access. If unsuccessful, this operation returns a value of -1 and the **errno** global variable is set to one of the following values:

Value	Description
EFAULT	Indicates that a bad copy between kernel and user space occurred.
EINVAL	Indicates the **SCIOSTART** operation was not issued prior to this command.
EIO	Indicates the adapter device driver was unable to complete the command due to an unrecoverable I/O error. If **EIO** is received, the caller should retry this command at least once, as the first command may have cleared an error condition with the device. Following an unrecovered I/O error, the adapter error status information is logged in the system error log.
ENOCONNECT	Indicates a bus fault has occurred. The caller should retry after setting the **SC_ASYNC** flag in the flag byte of the passed parameters. If more than one retry is attempted, only the last retry should be made with the **SC_ASYNC** flag set. In general, the SCSI adapter device driver cannot determine which device caused the SCSI bus fault, so this error is not logged.
ENODEV	Indicates no SCSI controller responded to the requested SCSI ID. This condition is not necessarily an error and is not logged.
ENOMEM	Indicates insufficient memory is available to complete the command.
ETIMEDOUT	Indicates the adapter did not respond with a status before the internal command time-out value expired. If this return value is received, the caller should retry this command at least once, as the first command may have cleared an error condition with the device. This error is logged in the system error log.

Files

Item	Description
/dev/scsi0, **/dev/scsi1**,..., **/dev/scsi**n	Provide an interface to allow SCSI device drivers to access SCSI devices or adapters.
/dev/vscsi0, /dev/vscsi1,..., /dev/vscsi$m$	Provide an interface to allow SCSI-2 Fast/Wide Adapter/A and SCSI-2 Differential Fast/Wide Adapter/A device drivers to access SCSI devices or adapters.

scsesdd SCSI Device Driver

Purpose

Device driver supporting the **SCSI Enclosure Services** device.

Syntax

```
#include <sys/devinfo.h>
#include <sys/scsi.h>
#include <sys/scses.h>
```

Description

The special files **/dev/ses0**, **/dev/ses1**, **...,** provide I/O access and control functions to the SCSI enclosure devices.

Typical SCSI enclosure services operations are implemented using the **open, ioctl**, and **close** subroutines.

Open places the selected **device** in Exclusive Access mode. This mode is singularly entrant; that is, only one process at a time can open it.

A **device** can be opened only if the device is not currently opened. If an attempt is made to open a **device** and the device is already open, a value of -1 is returned and the **errno** global variable is set to a value of **EBUSY**.

ioctl Subroutine

The following ioctl operations are available for **SCSI Enclosure Services** devices:

Operation	Description
IOCINFO	Returns the **devinfo** structure defined in the **/usr/include/sys/devinfo.h** file.
SESIOCMD	When the device has been successfully opened, this operation provides the means for issuing any SCSI command to the specified enclosure. The device driver performs no error recovery or logging-on failures of this ioctl operation.

The SCSI status byte and the adapter status bytes are returned via the *arg* parameter, which contains the address of a **sc_iocmd** structure (defined in the **/usr/include/sys/scsi.h** file). If the **SESIOCMD** operation returns a value of -1 and the errno global variable is set to a nonzero value, the requested operation has failed. In this case, the caller should evaluate the returned status bytes to determine why the operation failed and what recovery actions should be taken.

The **devinfo** structure defines the maximum transfer size for the command. If an attempt is made to transfer more than the maximum, a value of -1 is returned and the errno global variable set to a value of **EINVAL.** Refer to the *Small Computer System Interface* (**SCSI**) *Specification* for the applicable device to get request sense information.

Device Requirements

The following hardware requirements exist for SCSI enclosure services devices:

- The device must support the SCSI-3 Enclosure Services Specification Revision 4 or later.
- The device can be addressed from a SCSI id different from the SCSI ids of the the SCSI devices inside the enclosure.
- The device must be "well behaved", when receiving SCSI inquiries to page code 0xC7. This means that if the device fails the inquiry to page code C7 with a check condition, then the check condition will be cleared by the next SCSI command. An explicit request sense is not required.

- If the device reports its ANSI version to be 3 (SCSI-3) in the standard inquiry data, then it must correctly reject all invalid requests for luns 8-31 (that is,the device cannot ignore the upper bits in Lun id and thus cannot treat Lun 8 as being Lun 0, etc).

Error Conditions

Ioctl and **open** subroutines against this device fail in the following circumstances:

Error	Description
EBUSY	An attempt was made to open a device already opened.
EFAULT	An illegal user address was entered.
EINVAL	The data buffer length exceeded the maximum defined in the **devinfo** structure for a **SESIOCMD** ioctl operation.
EINVAL	An unsupported ioctl operation was attempted.
EINVAL	An attempt was made to configure a device that is still open.
EINVAL	An illegal configuration command has been given.
EIO	The target device cannot be located or is not responding.
EIO	The target device has indicated an unrecovered hardware error.
EMFILE	An open was attempted for an adapter that already has the maximum permissible number of opened devices.
ENODEV	An attempt was made to access a device that is not defined.
ENODEV	An attempt was made to close a device that has not been defined.
ENXIO	The ioctl subroutine supplied an invalid parameter.
EPERM	The attempted subroutine requires appropriate authority.
ETIMEDOUT	An I/O operation has exceeded the given timer value.

Reliability and Serviceability Information

The following errors are returned from SCSI enclosure services devices:

Error	Description
ABORTED COMMAN	The device cancelled the command.
ADAPTER ERRORS	The adapter returned an error.
GOOD COMPLETION	The command completed successfully.
HARDWARE ERROR	An unrecoverable hardware failure occurred during command execution or during a self test.
ILLEGAL REQUEST	An illegal command or command parameter.
MEDIUM ERROR	The command terminated with a unrecovered media error condition.
NOT READY	The logical unit is off-line or media is missing.
RECOVERED ERROR	The command was successful after some recovery applied.
UNIT ATTENTION	The device has been reset or the power has been turned on.

Files

Item	Description
/dev/ses0,/dev/ses1...,/dev/sesn	Provides an interface to allow SCSI device drivers access to SCSI enclosure services devices.

scsidisk SAM Device Driver

Purpose

Supports the Fibre Channel Protocol for SCSI (FCP), Serial Attached SCSI (SAS), and the SCSI protocol over Internet (iSCSI) hard disk, CD-ROM (compact-disk read-only memory), and read/write optical (optical memory) devices.

Syntax

```
#include <sys/devinfo.h>
#include <sys/scsi.h>
#include <sys/scdisk.h>
#include <sys/pcm.h>
#include <sys/mpio.h>
```

Device-Dependent Subroutines

Typical hard disk, CD-ROM, and read/write optical drive operations are implemented by using the **open**, **close, read**, **write**, and **ioctl** subroutines. The scsidisk device driver has additional support added for MPIO capable devices.

open and close Subroutines

The **open** subroutine applies a reservation policy that is based on the ODM **reserve_policy** attribute, previously the **open** subroutine always applied an SCSI2 reserve. The **open** and **close** subroutines support working with multiple paths to a device if the device is an MPIO capable device.

The **openx** subroutine is intended primarily for use by the diagnostic commands and utilities. Appropriate authority is required for execution. If an attempt is made to run the **open** subroutine without the proper authority, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EPERM**.

The *ext* parameter that is passed to the **openx** subroutine selects the operation to be used for the target device. The **/usr/include/sys/scsi.h** file defines possible values for the *ext* parameter.

The *ext* parameter can contain any combination of the following flag values logically ORed together:

Item	Description
SC_DIAGNOSTIC	Places the selected device in Diagnostic mode. This mode is singularly entrant; that is, only one process at a time can open it. When a device is in Diagnostic mode, SCSI operations are performed during **open** or **close** operations, and error logging is disabled. In Diagnostic mode, only the **close** and **ioctl** subroutine operations are accepted. All other device-supported subroutines return a value of -1 and set the **errno** global variable to a value of **EACCES**.
	A device can be opened in Diagnostic mode only if the target device is not currently opened. If an attempt is made to open a device in Diagnostic mode and the target device is already open, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EACCES**.

Item	Description
SC_FORCED_OPEN_LUN	On a device that supports Lun Level Reset, the device is reset regardless of any reservation that is placed by another initiator before the open sequence takes place. If the device does not support Lun Level Reset, and both **SC_FORCED_OPEN_LUN** and **SC_FORCE_OPEN** flags are set, then a target reset occurs before the open sequence takes place.
SC_FORCED_OPEN	Initiates actions during the **open** operation to break any reservation that might exist on the device. This action might include a target reset. **Note:** A target reset resets all luns on the SCSI ID.
SC_RETAIN_RESERVATION	Retains the reservation of the device after a **close** operation by not issuing the release. This flag prevents other initiators from using the device unless they break the host machine's reservation.
SC_NO_RESERVE	Prevents the reservation of a device during an **openx** subroutine call to that device. This operation is provided so a device can be controlled by two processors that synchronize their activity by their own software means.
SC_SINGLE	Places the selected device in Exclusive Access mode. Only one process at a time can open a device in Exclusive Access mode. A device can be opened in Exclusive Access mode only if the device is not currently open. If an attempt is made to open a device in Exclusive Access mode and the device is already open, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EBUSY**. If the **SC_DIAGNOSTIC** flag is specified along with the **SC_SINGLE** flag, the device is placed in Diagnostic mode.
SC_PR_SHARED_REGISTER	In a multi-initiator shared device environment, a Persistent Reserve with service action `Register and Ignore Key` is sent to the device as part of the open sequence. This feature is aimed at the cluster environment, where an upper management software must follow an advisory lock mechanism to control when the initiator reads or writes. The device is required to support Persistent Reserve (refer to SCSI Primary Command version 2 description of Persistent Reserve).

Options to the openx Subroutine in *Kernel Extensions and Device Support Programming Concepts* gives more specific information about the **open** operations.

readx and writex Subroutines

The **readx** and **writex** subroutines provide additional parameters that affect the raw data transfer. These subroutines pass the *ext* parameter, which specifies request options. The options are constructed by logically ORing zero or more of the following values:

Item	Description
HWRELOC	Indicates a request for hardware relocation (safe relocation only).
UNSAFEREL	Indicates a request for unsafe hardware relocation.
WRITEV	Indicates a request for write verification.

ioctl Subroutine

ioctl subroutine operations that are used for the **scsidisk** device driver are specific to the following categories:

- Hard disk and read/write optical devices only
- CD-ROM devices only
- Hard disk, CD-ROM, and read/write optical devices

Hard disk and read/write optical devices

The following **ioctl** operation is available for hard disk and read/write optical devices only:

Item	Description
DKIOLWRSE	Provides a means for issuing a **write** command to the device and obtaining the target-device sense data when an error occurs. If the **DKIOLWRSE** operation returns a value of -1 and the `status_validity` field is set to a value of **SC_SCSI_ERROR**, valid sense data is returned. Otherwise, target sense data is omitted.
	The **DKIOLWRSE** operation is provided for diagnostic use. It allows the limited use of the target device when it operates in an active system environment. The *arg* parameter to the **DKIOLWRSE** operation contains the address of an **scsi_rdwrt** structure. This structure is defined in the **/usr/include/sys/scsi_buf.h** file.
	The **devinfo** structure defines the maximum transfer size for a **write** operation. If an attempt is made to transfer more than the maximum, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EINVAL**. Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

Hard disk, CD-ROM, and read/write optical devices

The following **ioctl** operations are available for hard disk, CD-ROM, and read/write optical devices:

Item	Description
IOCINFO	Returns the **devinfo** structure that is defined in the**/usr/include/sys/devinfo.h** file. The **IOCINFO** operation is the only operation defined for all device drivers that use the **ioctl** subroutine. The remaining operations are all specific to hard disk, CD-ROM, and read/write optical devices.
DKIOLRDSE	Provides a means for issuing a **read** command to the device and obtaining the target-device sense data when an error occurs. If the **DKIOLRDSE** operation returns a value of -1 and the `status_validity` field is set to a value of **SC_SCSI_ERROR**, valid sense data is returned. Otherwise, target sense data is omitted.
	The **DKIOLRDSE** operation is provided for diagnostic use. It allows the limited use of the target device when it operates in an active system environment. The *arg* parameter to the **DKIOLRDSE** operation contains the address of an **scsi_rdwrt** structure. This structure is defined in the **/usr/include/sys/scsi_buf.h** file.
	The **devinfo** structure defines the maximum transfer size for a **read** operation. If an attempt is made to transfer more than the maximum, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EINVAL**. Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

Item	Description
DKIOLCMD	When the device is successfully opened in the Diagnostic mode, the **DKIOLCMD** operation provides the means for issuing any SCSI command to the specified device. If the **DKIOLCMD** operation is issued when the device is not in Diagnostic mode, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EACCES**. The device driver performs no error recovery or logging on failures of this operation.
	The SCSI status byte and the adapter status bytes are returned through the *arg* parameter, which contains the address of a **scsi_iocmd** structure (defined in the **/usr/include/sys/scsi_buf.h** file). If the **DKIOLCMD** operation fails, the subroutine returns a value of -1 and sets the **errno** global variable to a nonzero value. In this case, the caller must evaluate the returned status bytes to determine why the operation was unsuccessful and what recovery actions must be taken.
	The version field of the **scsi_iocmd** structure can be set to the value of SCSI_VERSION_2, and the user can provide the following fields:
	• **variable_cdb_ptr** is a pointer to a buffer that contains the Variable SCSI cdb.
	• **variable_cdb_length** determines the length of the *cdb* variable to which the **variable_cdb_ptr** field points.
	On completion of the **DKIOLCMD** ioctl request, the **residual** field indicates that the leftover data that device did not fully satisfy for this request. On a successful completion, the **residual** field would indicate that the device does not have the all data that is requested or the device has less than the amount of data that is requested. On a failure completion, the user must check the **status_validity** field to determine if a valid SCSI bus problem exists. In this case, the **residual** field would indicate the number bytes that the device failed to complete for this request.
	The **devinfo** structure defines the maximum transfer size for the command. If an attempt is made to transfer more than the maximum, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EINVAL**. Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.
DKPMR	Issues a SCSI prevent media removal command when the device is successfully opened. This command prevents media from being ejected until the device is closed, powered off and then back on, or until a **DKAMR** operation is issued. The *arg* parameter for the **DKPMR** operation is null. If the **DKPMR** operation is successful, the subroutine returns a value of 0. If the device is a SCSI hard disk, the **DKPMR** operation fails, and the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EINVAL**. If the **DKPMR** operation fails for any other reason, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EIO**.
DKAMR	Issues an allow media removal command when the device is successfully opened. As a result media can be ejected by using either the drives eject button or the **DKEJECT** operation. The *arg* parameter for this ioctl is null. If the **DKAMR** operation is successful, the subroutine returns a value of 0. If the device is a SCSI hard disk, the **DKAMR** operation fails, and the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EINVAL**. For any other failure of this operation, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EIO**.

Item	Description
DKEJECT	Issues an eject media command to the drive when the device is successfully opened. The *arg* parameter for this operation is null. If the **DKEJECT** operation is successful, the subroutine returns a value of 0. If the device is a SCSI hard disk, the **DKEJECT** operation fails, and the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EINVAL**. For any other failure of this operation, the subroutine returns a value of -1 and sets the **errno** variable to a value of **EIO**.
DKFORMAT	Issues a format unit command to the specified device when the device is successfully opened.
	If the *arg* parameter for this operation is null, the format unit sets the format options valid (FOV) bit to 0 (that is, it uses the drives default setting). If the *arg* parameter for the **DKFORMAT** operation is not null, the first byte of the defect list header is set to the value specified in the first byte addressed by the *arg* parameter. It allows the creation of applications to format a particular type of read/write optical media uniquely.
	The driver initially tries to set the FmtData and CmpLst bits to 0. If that fails, the driver tries the remaining three permutations of these bits. If all four permutations fail, this operation fails, and the subroutine sets the **errno** variable to a value of **EIO**.
	If the **DKFORMAT** operation is specified for a hard disk, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EINVAL**. If the **DKFORMAT** operation is attempted when the device is not in Exclusive Access mode, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EACCES**. If the media is write-protected, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EWRPROTECT**. If the format unit exceeds its timeout value, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **ETIMEDOUT**. For any other failure of this operation, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EIO**.
DKAUDIO	Issues play audio commands to the specified device and controls the volume on the device's output ports. Play audio commands include: play, pause, resume, stop, determine the number of tracks, and determine the status of a current audio operation. The **DKAUDIO** operation plays audio only through the CD-ROM drives output ports. The *arg* parameter of this operation is the address of a **cd_audio_cmds** structure, which is defined in the **/usr/include/sys/ scdisk.h** file. Exclusive Access mode is required.
	If **DKAUDIO** operation is attempted when the device's audio-supported attribute is set to No, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EINVAL**. If the **DKAUDIO** operation fails, the subroutine returns a value of -1 and sets the **errno** global variable to a nonzero value. In this case, the caller must evaluate the returned status bytes to determine why the operation failed and what recovery actions must be taken.

Item	Description
DK_CD_MODE	Determines or changes the CD-ROM data mode for the specified device. The CD-ROM data mode specifies what block size and special file are used for data read across the SCSI bus from the device. The **DK_CD_MODE** operation supports the following CD-ROM data modes:

CD-ROM Data Mode 1
  512-byte block size through both raw (**dev/rcd***) and block special (**/dev/cd***) files

CD-ROM Data Mode 2 Form 1
  2048-byte block size through both raw (**dev/rcd***) and block special (**/dev/cd***) files

CD-ROM Data Mode 2 Form 2
  2336-byte block size through the raw (**dev/rcd***) special file only

CD-DA (Compact Disc Digital Audio)
  2352-byte block size through the raw (**dev/rcd***) special file only

DVD-ROM
  2048-byte block size through both raw (**/dev/rcd***) and block special (**/dev/cd***) files

DVD-RAM
  2048-byte block size through both raw (**/dev/rcd***) and block special (**/dev/cd***) files

DVD-RW
  2048-byte block size through both raw (**/dev/rcd***) and block special (**/dev/cd***) files

The **DK_CD_MODE** *arg* parameter contains the address of the **mode_form_op** structure that is defined in the **/usr/include/sys/scdisk.h** file. To have the **DK_CD_MODE** operation determine or change the CD-ROM data mode, set the `action` field of the **change_mode_form** structure to one of the following values:

CD_GET_MODE
  Returns the current CD-ROM data mode in the `cd_mode_form` field of the **mode_form_op** structure, when the device is successfully opened.

CD_CHG_MODE
  Changes the CD-ROM data mode to the mode specified in the `cd_mode_form` field of the **mode_form_op** structure, when the device is successfully opened in the Exclusive Access mode.

If a CD-ROM is not configured for different data modes (through mode-select density codes), and an attempt is made to change the CD-ROM data mode (by setting the `action` field of the **change_mode_form** structure set to **CD_CHG_MODE**), the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EINVAL**. Attempts to change the CD-ROM mode to any of the DVD modes also result in a return value of -1 and the **errno** global variable set to **EINVAL**.

If the **DK_CD_MODE** operation for **CD_CHG_MODE** is attempted when the device is not in Exclusive Access mode, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EACCES**. For any other failure of this operation, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EIO**.

Item	Description
DK_PASSTHRU	When the device is successfully opened, **DK_PASSTHRU** provides the means for issuing any SCSI command to the specified device. The device driver performs limited error recovery if this operation fails. The **DK_PASSTHRU** operation differs from the **DKIOCMD** operation in that it does not require an **openx** command with the *ext* argument of **SC_DIAGNOSTIC**. As a result, **DK_PASSTHRU** can be issued to devices that are in use by other operations.

The SCSI status byte and the adapter status bytes are returned through the *arg* parameter, which contains the address of a **sc_passthru** structure (defined in the **/usr/include/sys/scsi.h** file). If the **DK_PASSTHRU** operation fails, the subroutine returns a value of -1 and sets the errno global variable to a nonzero value. If it happens the caller must evaluate the returned status bytes to determine why the operation was unsuccessful and what recovery actions must be taken.

If a **DK_PASSTHRU** operation fails because a field in the **sc_passthru** structure has an invalid value, the subroutine returns a value of -1 and sets the errno global variable to **EINVAL**. The **einval_arg** field is set to the field number (starting with 1 for the version field) of the field that had an invalid value. A value of 0 for the **einval_arg** field indicates that no additional information about the failure is available.

DK_PASSTHRU operations are further subdivided into requests which quiesce other I/O before issuing the request and requests that do not quiesce I/O. These subdivisions are based on the **devflags** field of the **sc_passthru** structure. When the **devflags** field of the **sc_passthru** structure has a value of **SC_MIX_IO**, the **DK_PASSTHRU** operation is mixed with other I/O requests. **SC_MIX_IO** requests that write data to devices are prohibited and fail. When it happens, -1 is returned, and the errno global variable is set to **EINVAL**. When the **devflags** field of the **sc_passthru** structure has a value of **SC_QUIESCE_IO**, all other I/O requests are quiesced before the **DK_PASSTHRU** request is issued to the device. If an **SC_QUIESCE_IO** request has its **timeout_value** field set to 0, the **DK_PASSTHRU** request fails with a return code of -1, the errno global variable is set to **EINVAL**, and the **einval_arg** field is set to a value of **SC_PASSTHRU_INV_TO** (defined in the **/usr/include/sys/scsi.h** file). If an **SC_QUIESCE_IO** request has a nonzero timeout value that is too large for the device, the **DK_PASSTHRU** request fails with a return code of -1, the errno global variable is set to **EINVAL**, the **einval_arg** field is set to a value of **SC_PASSTHRU_INV_TO** (defined in the **/usr/include/sys/scsi.h** file), and the **timeout_value** is set to the largest allowed value.

Item	Description
	The version field of the **sc_passthru** structure can be set to the value of SCSI_VERSION_2, and the user can provide the following fields:

• **variable_cdb_ptr** is a pointer to a buffer that contains the Variable SCSI cdb.
• **variable_cdb_length** determines the length of the *cdb* variable to which the **variable_cdb_ptr** field points.

On completion of the **DK_PASSTHRU** ioctl request, the **residual** field indicates that the leftover data that device did not fully satisfy for this request. On a successful completion, the **residual** field would indicate the device does not have the all data that is requested or the device has less than the amount of data that is requested. On a failure completion, the user must check the **status_validity** field to determine whether a valid SCSI bus problem exists. In this case, the **residual** field indicates the number of bytes that the device failed to complete for this request.

The **devinfo** structure defines the maximum transfer size for the command. If an attempt is made to transfer more than the maximum transfer size, the subroutine returns a value of -1, sets the errno global variable to a value of **EINVAL**, and sets the **einval_arg** field to a value of **SC_PASSTHRU_INV_D_LEN** (defined in the **/usr/include/sys/scsi.h** file). Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

Note: Calling **DK_PASSTHRU** ioctl as a non-root user fails with **EACCES** instead of **EPERM**.

Item	Description
DKPRES_READKEYS	When the device is successfully opened, the **DKPRES_READKEYS** operation provides a means to read the Persistent Reserve Registration Keys on the device. The *arg* parameter to the **DKPRES_READKEYS** contains the address of the **dk_pres_in** structure. This structure is defined in **/usr/include/sys/scdisk.h**. The user must provide a buffer area and size for the registered keys to be returned. The *returned_length* variable sets the number of bytes returned.

In a shared-access or clustered environment, this operation identifies all registered keys for a particular lun.

Note: For the **DKPRES_READKEYS** operation and following Persistent Reserve related operation, the interpretation of the returned value and scsi status is as follows:

• On successful attempt of the call, a 0 is returned.
• After a call fails, a -1 is returned and the **errno** global variable is set. For a specific description of the **errno** value, refer to **/usr/include/erno.h**. In addition, the SCSI status, along with the Sense Code, ASC and ASCQ, is set to provide further information about why the command failed. Refer to SCSI Specification on the interpretation of the SCSI status failure code.

Item	Description
DKPRES_READRES	When the device is successfully opened, the **DKPRES_READRES** operation provides a means to read the Persistent Reserve Reservation Keys on the device. The *arg* parameter to the **DKPRES_READKEYS** contains the address of the **dk_pres_in** structure. This structure is defined in **/usr/include/sys/scdisk.h**. The user must provide a buffer area and size for the reservation information to be returned. The *returned_length* variable sets the number of bytes returned. In a shared-access or clustered environment, this operation identifies the primary initiator that holds the reservation.

Item	Description
DKPRES_CLEAR	When the device is successfully opened, the **DKPRES_CLEAR** operation provides a means to clear all Persistent Reserve Reservation Keys and Registration Keys on the device. The *arg* parameter to **DKPRES_CLEAR** contains the address of the **dk_pres_clear** structure. This structure is defined in **/usr/include/sys/scdisk.h**.

⚠️ **Attention:** Exercise care when issuing the **DKPRES_CLEAR** operation. This operation leaves the device unreserved, which allows a foreign initiator to access the device.

Item	Description
DKPRES_PREEMPT	When the device is successfully opened, the **DKPRES_PREEMPT** operation provides a means to preempt a Persistent Reserve Reservation Key or Registration Key on the device. The *arg* parameter to the **DKPRES_PREEMPT** contains the address of the **dk_pres_preempt** structure. This structure is defined in **/usr/include/sys/scdisk.h**. The user must provide the second party initiator key on the device to be preempted. If the second party initiator holds the reservation to the device, then the initiator that issues the preemption becomes the owner of the reservation. Otherwise, the second party initiator access is revoked.
	In order for this operation to succeed, the initiator must be registered with the device first before any preemption can occur. In a shared-access or clustered environment, this operation is used to preempt any operative or inoperative initiator, or any initiator that is not recognized to be part of the shared group.
DKPRES_PREEMPT_ABORT	This operation is the same as the **DKPRES_PREEMPT**, except the device follows the SCSI Primary Command Specification in canceling tasks that belong to the preempted initiator.
DKPRES_REGISTER	When the device is successfully opened, the **DKPRES_REGISTER** operation provides a means to register a Key with the device. The Key is extracted from ODM Customize Attribute and passed to the device driver during configuration. The *arg* parameter to the **DKPRES_REGISTER** contains the address of the **dk_pres_register** structure. This structure is defined in **/usr/include/sys/scdisk.h**.
	In a shared-access or clustered environment, this operation attempts a registration with the device, then follows with a read reservation to determine whether the device is reserved. If the device is not reserved, then a reservation is placed with the device.

Item	Description
DK_RWBUFFER	When the device is successfully opened, the **DK_RWBUFFER** operation provides the means for issuing one or more SCSI Write Buffer commands to the specified device. The device driver performs full error recovery upon failures of this operation. The **DK_RWBUFFER** operation differs from the **DKIOCMD** operation in that it does not require an exclusive open of the device (for example, **openx** with the *ext* argument of **SC_DIAGNOSTIC**). Thus, a **DK_RWBUFFER** operation can be issued to devices that are in use by others. It can be used with the **DK_PASSTHRU** ioctl, which (like **DK_RWBUFFER**) does not require an exclusive open of the device.

The *arg* parameter contains the address of a **sc_rwbuffer** structure (defined in the **/usr/include/sys/scsi.h** file). Before the **DK_RWBUFFER** ioctl is invoked, the fields of this structure must be set according to the required behavior. The **mode** field corresponds to the **mode** field of the SCSI Command Descriptor Block (CDB) as defined in the *SCSI Primary Commands (SPC) Specification*. Supported modes are listed in the header file **/usr/include/sys/scsi.h**.

The device driver quiesces all other I/O from the initiator by issuing the Write Buffer ioctl until the entire operation completes. Once the Write Buffer ioctl completes, all quiesced I/O are resumed.

The SCSI status byte and the adapter status bytes are returned through the *arg* parameter, which contains the address of a **sc_rwbuffer** structure (defined in the **/usr/include/sys/scsi.h** file). If the **DK_RWBUFFER** operation fails, the subroutine returns a value of -1 and sets the **errno** global variable to a nonzero value. In this case, the caller must evaluate the returned status bytes to determine why the operation was unsuccessful and what recovery actions must be taken.

If a **DK_RWBUFFER** operation fails because a field in the **sc_rwbuffer** structure has an invalid value, the subroutine returns a value of -1 and sets the **errno** global variable to **EINVAL**.

The **DK_RWBUFFER** ioctl allows the user to issue multiple SCSI Write Buffer commands (CDBs) to the device through a single ioctl invocation. It is useful for applications such as microcode download where the user provides a pointer to the entire microcode image, but, because of size restrictions of the device buffers, desires that the images be sent in fragments until the entire download is complete.

If the **DK_RWBUFFER** ioctl is invoked with the **fragment_size** member of the **sc_rwbuffer** struct equal to **data_length**, a single Write Buffer command is issued to the device with the **buffer_offset** and **buffer_ID** of the SCSI CDB set to the values provided in the **sc_rwbuffer** struct.

If **data_length** is greater than **fragment_size** and **fragment_size** is a nonzero value, multiple Write Buffer commands are issued to the device. The number of Write Buffer commands (SCSI CDBs) issued are calculated by dividing the **data_length** by the required **fragment_size**. This value is incremented by 1 if the **data_length** is not an even multiple of **fragment_size**, and the final data transfer is the size of this residual amount.

Item	Description
DK_RWBUFFER continued	For each Write Buffer command that is issued, the **buffer_offset** is set to the value provided in the **sc_rwbuffer** struct (microcode downloads to SCSD devices requires this to be set to 0). For the first command issued, the **buffer_ID** is set to the value provided in the **sc_rwbuffer** struct. For each subsequent Write Buffer command that is issued, the **buffer_ID** is incremented by 1 until all fragments are sent. Writing to noncontiguous **buffer_ID**s through a single **DK_RWBUFFER** ioctl is not supported. If this functionality is desired, multiple **DK_RWBUFFER** ioctls must be issued with the **buffer_ID** set appropriately for each invocation. **Note:** No I/O request is quiesced between ioctl invocations.
DK_RWBUFFER continued	If **fragment_size** is set to zero, an **errno** of **EINVAL** is returned. If the desire is to send the entire buffer with one SCSI Write buffer command, this field must be set equal to **data_length**. An error of **EINVAL** is also returned if the **fragment_size** is greater than the **data_length**. The Parameter List Length (**fragment_size**) plus the Buffer Offset can not exceed the capacity of the specified buffer of the device. It is the responsibility of the caller of the Write Buffer ioctl to ensure that the **fragment_size** setting satisfies this requirement. A **fragment_size** larger than the device can accommodate results in an SCSI error at the device, and the Write Buffer ioctl results this error but take no action to recover. The **devinfo** structure defines the maximum transfer size for the command. If an attempt is made to transfer more than the maximum transfer size, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EINVAL**. Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request sense data for a particular device.
DKPATHIOLCMD	This command is only available for MPIO capable devices. The **DKPATHIOLCMD** command takes as input a pointer argument which points to a single **scsidisk_pathiocmd** structure. The **DKPATHIOLCMD** command behaves exactly like the**DKIOLCMD** command, except that the input path is used instead of the normal path selection. The **DKPATHIOLCMD** path is used for the **DKIOLCMD** command regardless of any path that is specified by a **DKPATHFORCE** ioctl command. A path cannot be unconfigured while it is being forced.
DKPATHFORCE	This command is only available for MPIO capable devices. The **DKPATHFORCE** command takes as input a ushort path id. The path id must correspond to one of the path ids in CuPath ODM. The path id specifies a path to be used for all subsequent I/O commands, overriding any previous **DKPATHFORCE** path. A zero argument specifies that path forcing is terminated and that normal MPIO path selection is to be resumed. The PCM KE tracks the forcing of I/O on a path. The Device Driver is unaware of this state except I/O commands sent in with the **DKPATHIOLCMD** command overrides the **DKPATHFORCE** option and send the I/O down the path that is specified in **scsidisk_pathiocmd** structure.
DKPATHRWBUFFER	This command is only available for MPIO capable devices. The **DKPATHRWBUFFER** command takes as input a pointer argument which points to a single **scsidisk_pathiocmd** structure. The **DKPATHRWBUFFER** command behaves exactly like the **DKRWBUFFER** command, except that the input path is used rather than normal path selection. The **DKPATHRWBUFFER** path is used for the **DKRWBUFFER** command regardless of any path that is specified by a **DKPATHFORCE** ioctl command.

Item	Description
DKPATHPASSTHRU	This command is only available for MPIO capable devices. The **DKPATHPASSTHRU** command takes as input a pointer argument which points to a single **scsidisk_pathiocmd** structure. The **DKPATHPASSTHRU** command behaves exactly like the **DKPASSTHRU** command, except that the input path is used rather than normal path selection. The **DKPATHPASSTHRU** path is used for the **DKPASSTHRU** command regardless of any path that is specified by a **DKPATHFORCE** ioctl command.
DKPCMPASSTHRU	This command is only available for MPIO capable devices. The **DKPCMPASSTHRU** command takes as input a structure, which is PCM-specific, it is not defined by AIX. The PCM-specific structure is passed to the PCM directly. This structure can be used to move information to or from a PCM.

Device Requirements

SCSI architectural model hard disk, CD-ROM, and read/write optical drives have the following hardware requirements:

- SAM hard disks and read/write optical drives must support a block size of 512 bytes per block.
- If mode sense is supported, the write-protection (WP) bit must also be supported for SAM hard disks and read/write optical drives.
- SAM hard disks and read/write optical drives must report the hardware retry count in bytes 16 and 17 of the request sense data for recovered errors. If the hard disk or read/write optical drive does not support this feature, the system error log might indicate premature drive failure.
- SAM CD-ROM and read/write optical drives must support the 10-byte SCSI read command.
- SAM hard disks and read/write optical drives must support the SCSI write and verify command and the 6-byte SCSI write command.
- To use the **format** command operation on read/write optical media, the drive must support setting the format options valid (FOV) bit to 0 for the defect list header of the SCSI format unit command. If the drive does not support this feature, the user can write an application for the drive so that it formats media by using the **DKFORMAT** operation.
- If a SAM CD-ROM drive uses **CD_ROM Data Mode 1**, it must support a block size of 512 bytes per block.
- If a SAM CD-ROM drive uses **CD_ROM data Mode 2 Form 1**, it must support a block size of 2048 bytes per block.
- If a SAM CD-ROM drive uses **CD_ROM data Mode 2 Form 2**, it must support a block size of 2336 bytes per block.
- If a SAM CD-ROM drive uses **CD_DA** mode, it must support a block size of 2352 bytes per block.
- To control volume by using the **DKAUDIO** (play audio) operation, the device must support SCSI-2 mode data page 0xE.
- To use the **DKAUDIO** (play audio) operation, the device must support the following SCSI-2 optional commands:
  - read subchannel
  - pause resume
  - play audio MSF
  - play audio track index
  - read TOC

Error Conditions

Possible **errno** values for **ioctl**, **open**,**read**, and **write** subroutines when you use the **scsidisk** device driver include:

Item	Description
EACCES	Indicates one of the following circumstances:
	• An attempt was made to open a device currently open in Diagnostic or Exclusive Access mode.
	• An attempt was made to open a Diagnostic mode session on a device already open.
	• The user attempted a subroutine other than an **ioctl** or **close** subroutine while in Diagnostic mode.
	• A **DKIOLCMD** operation was attempted on a device not in Diagnostic mode.
	• A **DK_CD_MODE ioctl** subroutine operation was attempted on a device not in Exclusive Access mode.
	• A **DKFORMAT** operation was attempted on a device not in Exclusive Access mode.
EBUSY	Indicates one of the following circumstances:
	• An attempt was made to open a session in Exclusive Access mode on a device already opened.
	• The target device is reserved by another initiator.
EFAULT	Indicates an invalid user address.
EFORMAT	Indicates that the target device has unformatted media or media in an incompatible format.
EINPROGRESS	Indicates that a CD-ROM drive has a play-audio operation in progress.
EINVAL	Indicates one of the following circumstances:
	• A **DKAUDIO** (play-audio) operation was attempted for a device that is not configured to use the SCSI-2 play-audio commands.
	• The **read** or **write** subroutine supplied an *nbyte* parameter that is not an even multiple of the block size.
	• A sense data buffer length of greater than 255 bytes is not valid for a **DKIOLWRSE**, or **DKIOLRDSE ioctl** subroutine operation.
	• The data buffer length exceeded the maximum defined in the **devinfo** structure for a **DKIOLRDSE**, **DKIOLWRSE**, or **DKIOLCMD ioctl** subroutine operation.
	• An unsupported **ioctl** subroutine operation was attempted.
	• An attempt was made to configure a device that is still open.
	• An incorrect configuration command is given.
	• A **DKPMR** (Prevent Media Removal), **DKAMR** (Allow Media Removal), or **DKEJECT** (Eject Media) command was sent to a device that does not support removable media.
	• A **DKEJECT** (Eject Media) command was sent to a device that currently has its media locked in the drive.
	• The data buffer length exceeded the maximum defined for a **strategy** operation.
EIO	Indicates one of the following circumstances:
	• The target device cannot be located or is not responding.
	• The target device is indicated an unrecoverable hardware error.
EMEDIA	Indicates one of the following circumstances:
	• The target device is indicated an unrecoverable media error.
	• The media was changed.

Item	Description
EMFILE	Indicates that an **open** operation was attempted for an adapter that already has the maximum permissible number of opened devices.
ENODEV	Indicates one of the following circumstances: • An attempt was made to access an undefined device. • An attempt was made to close an undefined device.
ENOTREADY	Indicates that no media is in the drive.
ENXIO	Indicates one of the following circumstances: • The **ioctl** subroutine supplied an invalid parameter. • A **read** or **write** operation was attempted beyond the end of the hard disk.
EPERM	Indicates that the attempted subroutine requires appropriate authority.
ESTALE	Indicates that a read-only optical disk was ejected (without first being closed by the user) and then either reinserted or replaced with a second optical disk.
ETIMEDOUT	Indicates that an I/O operation exceeded the specified timer value.
EWRPROTECT	Indicates one of the following circumstances: • An **open** operation that requests **read/write** mode was attempted on read-only media. • A **write** operation was attempted to read-only media.

Reliability and Serviceability Information

SCSI hard disk devices, CD-ROM drives, and read/write optical drives return the following errors:

Item	Description
ABORTED COMMAND	Indicates that the device ended the command.
ADAPTER ERRORS	Indicates that the adapter returned an error.
GOOD COMPLETION	Indicates that the command completed successfully.
HARDWARE ERROR	Indicates an that unrecoverable hardware failure occurred during command execution or during a self-test.
ILLEGAL REQUEST	Indicates that an incorrect command or command parameter.
MEDIUM ERROR	Indicates that the command ended with an unrecoverable media error condition.
NOT READY	Indicates that the logical unit is offline or media is missing.
RECOVERED ERROR	Indicates that the command was successful after some recovery was applied.
UNIT ATTENTION	Indicates that the device is reset or the power is turned on.

Error Record Values for Media Errors

The fields that are defined in the error record template for hard disk, CD-ROM, and read/write optical media errors are:

Item	Description
Comment	Indicates hard disk, CD-ROM, or read/write optical media error.
Class	Equals a value of H, which indicates a hardware error.
Report	Equals a value of True, which indicates this error must be included when an error report is generated.

Item	Description
Log	Equals a value of True, which indicates an error log entry must be created when this error occurs.
Alert	Equals a value of False, which indicates this error is not alertable.
Err_Type	Equals a value of Perm, which indicates a permanent failure.
Err_Desc	Equals a value of 1312, which indicates a disk operation failure.
Prob_Causes	Equals a value of 5000, which indicates media.
User_Causes	Equals a value of 5100, which indicates the media is defective.
User_Actions	Equals the following values: • 1601, which indicates the removable media must be replaced and tried again • 00E1 Perform problem determination procedures
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	Equals the following values: • 5000, which indicates a media failure • 6310, which indicates a disk drive failure
Fail_Actions	Equals the following values: • 1601, which indicates the removable media must be replaced and tried again • 00E1 Perform problem determination procedures
Detail_Data	Equals a value of 156, 11, HEX. This value indicates hexadecimal format. **Note:** The Detail_Data field in the **err_rec** structure contains the **scsi_error_log_df** structure. The **err_rec** structure is defined in the **/usr/include/sys/errids.h** file. The **scsi_error_log_df** structure is defined in the **/usr/include/sys/scsi_buf.h** file. The **scsi_error_log_df** structure contains the following fields: **req_sense_data** 　Contains the request-sense information from the particular device that had the error, if it is valid. **dd1** 　Contains the segment count, which is the number of megabytes read from the device at the time the error occurred. **dd2** 　Contains the number of bytes read since the segment count was last increased. **dd3** 　Contains the number of opens since the device was configured.

Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

Error Record Values for Hardware Errors

The fields that are defined in the error record template for hard disk, CD-ROM, and read/write optical hardware errors, as well as hard-aborted command errors are:

Item	Description
Comment	Indicates hard disk, CD-ROM, or read/write optical hardware error.

Item	Description
Class	Equals a value of H, which indicates a hardware error.
Report	Equals a value of True, which indicates this error must be included when an error report is generated.
Log	Equals a value of True, which indicates an error log entry must be created when this error occurs.
Alert	Equal to a value of FALSE, which indicates this error is not alertable.
Err_Type	Equals a value of Perm, which indicates a permanent failure.
Err_Desc	Equals a value of 1312, which indicates a disk operation failure.
Prob_Causes	Equals a value of 6310, which indicates disk drive.
User_Causes	None.
User_Actions	None.
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	Equals the following values: • 6310, which indicates a disk drive failure • 6330, which indicates a disk drive electronics failure
Fail_Actions	Equals a value of 00E1, which indicates problem-determination procedures must be performed.

Detail_Data	Equals a value of 156, 11, HEX. This value indicates hexadecimal format.
	
	Note: The Detail_Data field in the **err_rec** structure contains the **scsi_error_log_df** structure. The **err_rec**structure is defined in the **/usr/include/sys/errids.h** file. The **scsi_error_log_df** structure is defined in the **/usr/include/sys/scsi_buf.h** file.
	
	The **scsi_error_log_df** structure contains the following fields:
	
	req_sense_data
	    Contains the request-sense information from the particular device that had the error, if it is valid.
	
	dd1
	    Contains the segment count, which is the number of megabytes read from the device at the time the error occurred.
	
	dd2
	    Contains the number of bytes read since the segment count was last increased.
	
	dd3
	    Contains the number of opens since the device was configured.

Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

Error Record Values for Adapter-Detected Hardware Failures

The fields that are defined in the error record template for hard disk, CD-ROM, and read/write optical media errors adapter-detected hardware errors are:

Item	Description
Comment	Indicates adapter-detected hard disk, CD-ROM, or read/write optical hardware failure.
Class	Equals a value of H, which indicates a hardware error.

Item	Description
Report	Equals a value of True, which indicates this error must be included when an error report is generated.
Log	Equals a value of True, which indicates an error-log entry must be created when this error occurs.
Alert	Equal to a value of FALSE, which indicates this error is not alertable.
Err_Type	Equals a value of Perm, which indicates a permanent failure.
Err_Desc	Equals a value of 1312, which indicates a disk operation failure.
Prob_Causes	Equals the following values: • 3452, which indicates a device cable failure • 6310, which indicates a disk drive failure
User_Causes	None.
User_Actions	None.
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	Equals the following values: • 3452, which indicates a storage device cable failure • 6310, which indicates a disk drive failure • 6330, which indicates a disk-drive electronics failure
Fail_Actions	Equals a value of 0000, which indicates problem-determination procedures must be performed.
Detail_Data	Equals a value of 156, 11, HEX. This value indicates hexadecimal format. **Note:** The Detail_Data field in the **err_rec** structure contains the **scsi_error_log_df** structure. The **err_rec**structure is defined in the **/usr/include/sys/errids.h** file. The **scsi_error_log_df** structure is defined in the **/usr/include/sys/scsi_buf.h** file. The **scsi_error_log_df** structure contains the following fields: **req_sense_data** Contains the request-sense information from the particular device that had the error, if it is valid. **dd1** Contains the segment count, which is the number of megabytes read from the device at the time the error occurred. **dd2** Contains the number of bytes read since the segment count was last increased. **dd3** Contains the number of opens since the device was configured.

Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

Error Record Values for Recovered Errors

The fields that are defined in the error record template for hard disk, CD-ROM, and read/write optical media errors recovered errors are:

Item	Description
Comment	Indicates hard disk, CD-ROM, or read/write optical recovered error.
Class	Equals a value of H, which indicates a hardware error.
Report	Equals a value of True, which indicates this error must be included when an error report is generated.
Log	Equals a value of True, which indicates an error log entry must be created when this error occurs.
Alert	Equal to a value of FALSE, which indicates this error is not alertable.
Err_Type	Equals a value of Temp, which indicates a temporary failure.
Err_Desc	Equals a value of 1312, which indicates a physical volume operation failure.
Prob_Causes	Equals the following values:
	• 5000, which indicates a media failure
	• 6310, which indicates a disk drive failure
User_Causes	Equals a value of 5100, which indicates media is defective.
User_Actions	Equals the following values:
	• 0000, which indicates problem-determination procedures must be performed
	• 1601, which indicates the removable media must be replaced and tried again
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	Equals the following values:
	• 5000, which indicates a media failure
	• 6310, which indicates a disk drive failure
Fail_Actions	Equals the following values:
	• 1601, which indicates the removable media must be replaced and tried again
	• 00E1 Perform problem determination procedures
Detail_Data	Equals a value of 156, 11, HEX. This value indicates hexadecimal format.

Note: The Detail_Data field in the **err_rec** structure contains the **scsi_error_log_df** structure. The **err_rec** structure is defined in the **/usr/include/sys/errids.h** file. The **scsi_error_log_df** structure is defined in the **/usr/include/sys/scsi_buf.h** file.

The **scsi_error_log_df** structure contains the following fields:

req_sense_data
Contains the request-sense information from the particular device that had the error, if it is valid.

dd1
Contains the segment count, which is the number of megabytes read from the device at the time the error occurred.

dd2
Contains the number of bytes read since the segment count was last increased.

dd3
Contains the number of opens since the device was configured.

Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

Error Record Values for Unknown Errors

The fields that are defined in the error record template for hard disk, CD-ROM, and read/write optical media errors unknown errors are:

Item	Description
`Comment`	Indicates hard disk, CD-ROM, or read/write optical unknown failure.
`Class`	Equals a value of H, which indicates a hardware error.
`Report`	Equals a value of True, which indicates this error must be included when an error report is generated.
`Log`	Equals a value of True, which indicates an error log entry must be created when this error occurs.
`Alert`	Equal to a value of FALSE, which indicates this error is not alertable.
`Err_Type`	Equals a value of Unkn, which indicates the type of error is unknown.
`Err_Desc`	Equals a value of FE00, which indicates an undetermined error.
`Prob_Causes`	Equals the following values:
	• 3300, which indicates an adapter failure
	• 5000, which indicates a media failure
	• 6310, which indicates a disk drive failure
`User_Causes`	None.
`User_Actions`	None.
`Inst_Causes`	None.
`Inst_Actions`	None.
`Fail_Causes`	Equals a value of FFFF, which indicates the failure causes are unknown.
`Fail_Actions`	Equals the following values:
	• 00E1 Perform problem determination procedures
	• 1601, which indicates the removable media must be replaced and tired again
`Detail_Data`	Equals a value of 156, 11, HEX. This value indicates hexadecimal format.

Detail_Data (continued):

Note: The `Detail_Data` field in the **err_rec** structure contains the **scsi_error_log_df** structure. The **err_rec**structure is defined in the **/usr/include/sys/errids.h** file. The **scsi_error_log_df** structure is defined in the **/usr/include/sys/scsi_buf.h** file.

The **scsi_error_log_df** structure contains the following fields:

req_sense_data
Contains the request-sense information from the particular device that had the error, if it is valid.

dd1
Contains the segment count, which is the number of megabytes read from the device at the time the error occurred.

dd2
Contains the number of bytes read since the segment count was last increased.

dd3
Contains the number of opens since the device was configured.

Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

Special Files

The **scsidisk** SCSI device driver uses raw and block special files in performing its functions.

Attention: Data corruption, loss of data, or loss of system integrity (system crash) occurs if devices that support paging, logical volumes, or mounted file systems are accessed by using block special files. Block special files are provided for logical volumes and disk devices and are solely for system use in managing file systems, paging devices, and logical volumes. These files must not be used for other purposes.

The special files that are used by the **scsidisk** device driver include the following (listed by type of device):

- Hard disk devices:

Item	Description
/dev/rhdisk0, **/dev/rhdisk1**,..., **/dev/rhdisk***n*	Provide an interface to allow SCSI device drivers character access (raw I/O access and control functions) to SCSI hard disks.
/dev/hdisk0, **/dev/hdisk1**,..., **/dev/hdisk***n*	Provide an interface to allow SCSI device drivers block I/O access to SCSI hard disks.

- CD-ROM devices:

Item	Description
/dev/rcd0, **/dev/rcd1**,..., **/dev/rcd***n*	Provide an interface to allow SCSI device drivers character access (raw I/O access and control functions) to SCSI CD-ROM disks.
/dev/cd0, **/dev/cd1**,..., **/dev/cd***n*	Provide an interface to allow SCSI device drivers block I/O access to SCSI CD-ROM disks.

- Read/write optical devices:

Item	Description
/dev/romd0, **/dev/romd1**,..., **/dev/romd***n*	Provide an interface to allow SCSI device drivers character access (raw I/O access and control functions) to SCSI read/write optical devices.
/dev/omd0, **/dev/omd1**,..., **/dev/omd***n*	Provide an interface to allow SCSI device drivers block I/O access to SCSI read/write optical devices.

- **Note:** The prefix **r** on a special file name indicates that the drive is accessed as a raw device rather than a block device. Performing raw I/O with a hard disk, CD-ROM, or read/write optical drive requires that all data transfers be in multiples of the device block size. Also, all **lseek** subroutines that are made to the raw device driver must result in a file pointer value that is a multiple of the device block size.

scsisesdd SAM Device Driver

Purpose

Supports the **Serial Attached SCSI Enclosure Services** device.

Syntax

```
#include <sys/devinfo.h>
#include <sys/scsi.h>
#include <sys/scses.h>
```

Description

The special files **/dev/ses0**, **/dev/ses1** ... provide I/O access and control functions to the SCSI enclosure devices.

Typical SCSI enclosure services operations are implemented using the **open**, **ioctl**, and **close** subroutines.

The **open** subroutine places the selected **device** in Exclusive Access mode. This mode is singularly entrant; that is, only one process at a time can open it. A **device** can be opened only if it is not currently opened. If an attempt is made to open a **device** that is already open, a value of -1 is returned and the **errno** global variable is set to a value of **EBUSY**.

ioctl Subroutine

The following ioctl operations are available for **SCSI Enclosure Services** devices:

Operation	Description
IOCINFO	Returns the **devinfo** structure defined in the **/usr/include/sys/devinfo.h** file.
SESPASSTHRU	When a device has been successfully opened, this operation provides the means for issuing any SCSI command to the specified enclosure. The device driver performs no error recovery or logging-on failures of this ioctl operation.
	The SCSI status byte and the adapter status bytes are returned through the *arg* parameter, which contains the address of an **sc_passthru** structure (defined in the **/usr/include/sys/scsi.h** file). If the **SESPASSTHRU** operation returns a value of -1 and the **errno** global variable is set to a nonzero value, the requested operation has failed. In this case, the caller must evaluate the returned status bytes to determine why the operation failed and what recovery actions must be taken.
	The **version** field of the **sc_passthru** structure should be set to the value of **SCSI_VERSION_1**, and SES does not support Variable length CDBs.
	On completion of the SESPASSTHRU ioctl request, the **residual** field indicates the leftover data that the device did not fully satisfy for this request. Upon successful completion, the **residual** field indicates that the device does not have all the data that was requested or the device has less than the amount of data that was requested. Upon failure, the user needs to check the **status_validity** field to determine if a valid SCSI bus problem exists. In this case, the **residual** field indicates the number bytes that the device failed to complete for this request.
	The **devinfo** structure defines the maximum transfer size for the command. If an attempt is made to transfer more than the maximum transfer size, the subroutine returns a value of -1, sets the **errno** global variable to a value of **EINVAL**, and sets the **einval_arg** field to a value of **SC_PASSTHRU_INV_D_LEN** (defined in the **/usr/include/sys/scsi.h** file). Refer to the *Small Computer System Interface (SCSI) Specification* for the format of the request-sense data for a particular device.

Device Requirements

The following hardware requirements exist for SCSI enclosure services devices:

- The device must support the SCSI-3 Enclosure Services Specification Revision 4 or later.
- The device can be addressed from an SCSI ID different from the SCSI IDs of the SCSI devices inside the enclosure.
- The device must be "well behaved", when receiving SCSI inquiries to page code 0xC7. This means that if the device fails the inquiry to page code C7 with a check condition, then the check condition is cleared by the next SCSI command. An explicit request sense is not required.

- If the device reports its ANSI version to be 3 (SCSI-3) in the standard inquiry data, then it must correctly reject all requests that are not valid for luns 8-31 (that is, the device cannot ignore the upper bits in Lun ID and thus cannot treat Lun 8 as being Lun 0, and so on).

Examples

This is the example code for filling the **sc_passthru** structure for the **SESPASSTHRU** ioctl to issue Standard Inquiry SCSI CDB:

```
struct sc_passthru passthru;
passthru.version = SCSI_VERSION_1;
passthru.timeout_value = 30;
passthru.command_length = 6;
passthru.q_tag_msg = SC_SIMPLE_Q;
passthru.flags = B_READ;
passthru.autosense_length = SENSE_LEN;
passthru.autosense_buffer_ptr = &sense_data[0];    /* Buffer for Auto Sense Data */
passthru.data_length = 0xFF;
passthru.buffer = data;              /* Data buffer address to store inquiry data */
passthru.scsi_cdb[0] = SCSI_INQUIRY;
passthru.scsi_cdb[1] = 0x00;
passthru.scsi_cdb[2] = 00; /* Page Code */
passthru.scsi_cdb[3] = 00;
passthru.scsi_cdb[4] = 0xFF;
passthru.scsi_cdb[5] = 0x00;
```

Error Conditions

ioctl and **open** subroutines against this device fail in the following circumstances:

Error	Description
EBUSY	An attempt was made to open a device already opened.
EEXIST	Device already exists in the device table.
ENOMEM	Memory allocation failed.
EFAULT	An illegal user address was entered.
EINVAL	The data buffer length exceeded the maximum defined in the **devinfo** structure for a **SESPASSTHRU** ioctl operation.
EINVAL	An unsupported ioctl operation was attempted.
EINVAL	An attempt was made to configure a device that is still open.
EINVAL	An illegal configuration command was given.
EINVAL	The **variable_cdb_ptr** or **variable_cdb_length** fields are set in the **sc_passthru** struct.
EIO	The target device cannot be located or is not responding.
EIO	The target device has indicated an unrecovered hardware error.
EMFILE	An open operation was attempted for an adapter that already has the maximum permissible number of opened devices.
ENODEV	An attempt was made to access a device that was not defined.
ENODEV	An attempt was made to close a device that was not defined.
ENXIO	The parameter or device number supplied by the **ioctl** subroutine is not valid, or the device is not configured.
EPERM	The attempted subroutine requires appropriate authority.
ETIMEDOUT	An I/O operation has exceeded the given timer value.

Files

Item	Description
/dev/ses0, /dev/ ses1... /dev/sesn	Provides an interface to allow SCSI device drivers access to SCSI enclosure services devices.

sctape FC Device Driver

Note: The **/dev/rmt0** through **/dev/rmt255** special files provide access to magnetic tapes. Magnetic tapes are used primarily for backup, file archives, and other offline storage.

Purpose

Supports the Fibre Channel Protocol for SCSI (FCP) for sequential access bulk storage medium device driver.

Syntax

```
#include <sys/devinfo.h>
#include <sys/scsi.h>
#include <sys/tape.h>
#include <sys/pcm.h>
#include <sys/mpio.h>
```

Device-Dependent Subroutines

Most tape operations are implemented using the open, read, write, and close subroutines. However, the openx subroutine must be used if the device is to be opened in Diagnostic mode.

open and close Subroutines

The **openx** subroutine is intended for use by the diagnostic commands and utilities. Appropriate authority is required for execution. Attempting to execute this subroutine without the proper authority causes the subroutine to return a value of -1 and sets the **errno** global variable to **EPERM**.

The **openx** subroutine allows the device driver to enter Diagnostic mode and disables command-retry logic. This action allows for execution of ioctl operations that perform special functions associated with diagnostic processing. Other **openx** capabilities, such as forced opens and retained reservations, are also available.

The **open** subroutine applies a reservation policy based on the ODM **reserve_policy** attribute.

The *ext* parameter passed to the **openx** subroutine selects the operation to be used for the target device. The *ext* parameter is defined in the **/usr/include/sys/scsi.h** file. This parameter can contain any combination of the following flag values logically ORed together:

Item	Description
SC_DIAGNOSTIC	Places the selected device in Diagnostic mode. This mode is singularly entrant. When a device is in Diagnostic mode, SCSI operations are performed during **open** or **close** operations, and error logging is disabled. In Diagnostic mode, only the **close** and ioctl operations are accepted. All other device-supported subroutines return a value of -1 and set the **errno** global variable to a value of **EACCES**.
	A device can be opened in Diagnostic mode only if the target device is not currently opened. If an attempt is made to open a device in Diagnostic mode and the target device is already open, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EACCES**.

Item	Description
SC_FORCED_OPEN	Forces a bus device reset (BDR) regardless of whether another initiator has the device reserved. The SCSI bus device reset is sent to the device before the open sequence begins. Otherwise, the **open** operation executes normally.
SC_RETAIN_RESERVATION	Retains the reservation of the device after a **close** operation by not issuing the release. This flag prevents other initiators from using the device unless they break the host machine's reservation.

FCP Options to the openx Subroutine in *Kernel Extensions and Device Support Programming Concepts* gives more specific information on the **open** operations.

ioctl Subroutine

The **STIOCMD** ioctl operation provides the means for sending SCSI commands directly to a tape device. This allows an application to issue specific SCSI commands that are not directly supported by the tape device driver.

To use the **STIOCMD** operation, the device must be opened in Diagnostic mode. If this command is attempted while the device is not in Diagnostic mode, a value of -1 is returned and the **errno** global variable is set to a value of **EACCES**. The **STIOCMD** operation passes the address of a **sc_iocmd** structure. This structure is defined in the **/usr/include/sys/scsi.h** file.

The following ioctl operations are only available for MPIO capable FC tape devices:

Item	Description
STPATHIOCMD	The **STPATHIOCMD** command will take as input a pointer argument which points to a single sctape_pathiocmd structure. The **STPATHIOCMD** command will behave exactly like the **STIOCMD** command, except that the input path is used rather than normal path selection performed by the PCM. The **STPATHIOCMD** path is used for the **STIOCMD** command regardless of any path specified by a **STPATHFORCE** ioctl command. A path cannot be unconfigured while it is being forced.
STPATHFORCE	The **STPATHFORCE** command takes as input a *ushort* path ID. The path ID should correspond to one of the path IDs in the **CuPath** ODM. The path ID specifies a path to be used for all subsequent I/O commands, overriding any previous **STPATHFORCE** paths. A zero (0) argument specifies that path forcing is terminated and that normal MPIO path selection is to be resumed. The PCM KE keeps track of the forcing of I/O on a path. The Device Driver is unaware of this state. I/O commands sent in with **STPATHIOCMD** will override the **STPATHFORCE** option and send the I/O down the path specified in the **st_pathiocmd** structure.
STPATHPASSTHRU	The **STPATHPASSTHRU** command takes as input a pointer argument that points to a single **sctape_pathiocmd** structure. The **STPATHPASSTHRU** command will behave exactly like **STIOCMD**, except that the input path is used rather than normal path selection.
STPCMPASSTHRU	The **STPCMPASSTHRU** command takes as input a structure that is PCM-specific; it is not defined by AIX. The PCM-specific structure is passed to the PCM directly. This structure can be used to move information to or from a PCM.

Error Conditions

In addition to those errors listed, **ioctl**, **open**, **read**, and **write** subroutines against this device are unsuccessful in the following circumstances:

Item	Description
EAGAIN	Indicates that an attempt was made to open a device that was already open.

Item	Description
EBUSY	Indicates that the target device is reserved by another initiator.
EINVAL	Indicates that a value of **O_APPEND** is supplied as the mode in which to open.
EINVAL	Indicates that the *nbyte* parameter supplied by a **read** or **write** operation is not a multiple of the block size.
EINVAL	Indicates that a parameter to an ioctl operation is not valid.
EINVAL	Indicates that the requested ioctl operation is not supported on the current device.
EIO	Indicates that the tape drive has been reset or that the tape has been changed. This error is returned on open if the previous operation to tape left the tape positioned beyond the beginning of the tape upon closing.
EIO	Indicates that the device could not space forward or reverse the number of records specified by the **st_count** field before encountering an EOM (end of media) or a file mark.
EMEDIA	Indicates an **open** operation was attempted for an adapter that already has the maximum permissible number of opened devices.
ENOTREADY	Indicates that there is no tape in the drive or the drive is not ready.
ENXIO	Indicates that there was an attempt to write to a tape that is at EOM.
EPERM	Indicates that this subroutine requires appropriate authority.
ETIMEDOUT	Indicates a command has timed out.
EWRPROTECT	Indicates an **open** operation requesting read/write mode was attempted on a read-only tape.
EWRPROTECT	Indicates that an ioctl operation that affects the media was attempted on a read-only tape.

Reliability and Serviceability Information

Errors returned from tape devices are as follows:

Item	Description
ABORTED COMMAND	Indicates the device ended the command.
BLANK CHECK	Indicates that a **read** command encountered a blank tape.
DATA PROTECT	Indicates that a write was attempted on a write-protected tape.
GOOD COMPLETION	Indicates the command completed successfully.
HARDWARE ERROR	Indicates an unrecoverable hardware failure occurred during command execution or during a self-test.
ILLEGAL REQUEST	Indicates an illegal command or command parameter.
MEDIUM ERROR	Indicates the command ended with an unrecoverable media error condition. This condition may be caused by a tape flaw or a dirty head.
NOT READY	Indicates the logical unit is offline.
RECOVERED ERROR	Indicates the command was successful after some recovery was applied.
UNIT ATTENTION	Indicates the device has been reset or the power has been turned on.

Medium, hardware, and aborted command errors from the preceding list are to be logged every time they occur. The **ABORTED COMMAND** error might be recoverable, but the error is logged if recovery fails. For the **RECOVERED ERROR** and recovered **ABORTED COMMAND** error types, thresholds are maintained; when they are exceeded, an error is logged. The thresholds are then cleared.

Note: There are device-related adapter errors that are logged every time they occur.

Error Record Values for Tape Device Media Errors

The fields defined in the error record template for tape-device media errors are:

Item	Description
Comment	Equal to tape media error.
Class	Equal to H, indicating a hardware error.
Report	Equals a value of True, which indicates this error should be included when an error report is generated.
Log	Equals a value of True, which indicates an error log entry should be created when this error occurs.
Alert	Equals a value of False, which indicates this error is not alertable.
Err_Type	Equals a value of Perm, which indicates a permanent failure.
Err_Desc	Equals a value of 1332, which indicates a tape operation failure.
Prob_Causes	Equals a value of 5003, which indicates tape media.
User_Causes	Equals a value of 5100 and 7401, which indicates a cause originating with the tape and defective media, respectively.
User_Actions	Equal to 1601 and 0000, which indicates, respectively, that the removable media should be replaced and the operation retried, and that problem determination procedures should be performed.
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	Equal to 5003, which indicates tape media.
Fail_Actions	Equal to 1601 and 0000, which indicates, respectively, that the removable media should be replaced and the operation retried and that problem determination procedures should be performed.

The **Detail_Data** field contains the command type, device and adapter status, and the request-sense information from the particular device in error. The **Detail_Data** field is contained in the **err_rec** structure. This structure is defined in the **/usr/include/sys/errids.h** file. The **sc_error_log_df** structure, which describes information contained in the **Detail_Data** field, is defined in the **/usr/include/sys/scsi.h** file.

Error Record Values for Tape or Hardware Aborted Command Errors

The fields in the **err_hdr** structure, as defined in the **/usr/include/sys/erec.h** file for hardware errors and aborted command errors, are:

Item	Description
Comment	Equal to a tape hardware or aborted command error.
Class	Equals a value of H, which indicates a hardware error.
Report	Equals a value of True, which indicates this error should be included when an error report is generated.
Log	Equals a value of True, which indicates an error log entry should be created when this error occurs.

Item	Description
Alert	Equal to a value of FALSE, which indicates this error is not alertable.
Err_Type	Equals a value of Perm, which indicates a permanent failure.
Err_Desc	Equals a value of 1331, which indicates a tape drive failure.
Prob_Causes	Equals a value of 6314, which indicates a tape drive error.
User_Causes	None.
User_Actions	Equal to 0000, indicating that problem determination procedures should be performed.
Inst_Actions	None.
Fail_Causes	Equal to 5003 and 6314, indicating the failure cause is the tape and the tape drive, respectively.
Fail_Actions	Equal to 0000 to perform problem determination procedures.

The **Detail_Data** field contains the command type, device and adapter status, and the request-sense information from the particular device in error. The **Detail_Data** field is contained in the **err_rec** structure. This structure is defined in the **/usr/include/sys/errids.h** file. The **sc_error_log_df** structure, which describes information contained in the **Detail_Data** field, is defined in the **/usr/include/sys/scsi.h** file.

Error Record Values for Tape-Recovered Error Threshold Exceeded

The fields defined in the **err_hdr** structure, as defined in the **/usr/include/sys/erec.h** file for recovered errors that have exceeded the threshold counter, are:

Item	Description
Comment	Indicates the tape-recovered error threshold has been exceeded.
Class	Equals a value of H, which indicates a hardware error.
Report	Equals a value of True, which indicates this error should be included when an error report is generated.
Log	Equals a value of True, which indicates an error-log entry should be created when this error occurs.
Alert	Equal to a value of FALSE, which indicates this error is not alertable.
Err_Type	Equals a value of TEMP, which indicates a temporary failure.
Err_Desc	Equals a value of 1331, which indicates a tape drive failure.
Prob_Causes	Equal to 6314, which indicates the probable cause is the tape drive.
User_Causes	Equal to 5100 and 7401, which indicates that the media is defective and the read/write head is dirty, respectively.
User_Actions	Equal to 1601 and 0000, which indicates that removable media should be replaced and the operation retried and that problem-determination procedures should be performed, respectively.
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	Equal to 5003 and 6314, which indicates the cause is the tape and tape drive, respectively.
Fail_Actions	Equals a value of 0000, which indicates problem-determination procedures should be performed.

The **Detail_Data** field contains the command type, device and adapter status, and the request-sense information from the particular device in error. This field is contained in the **err_rec** structure. The **err_rec** structure is defined in the **/usr/include/sys/errids.h** file. The **Detail_Data** field also specifies the error type of the threshold exceeded. The **sc_error_log_df** structure, which describes information contained in the **Detail_Data** field, is defined in the **/usr/include/sys/scsi.h** file.

Error Record Values for Tape SCSI Adapter-Detected Errors

The fields in the **err_hdr** structure, as defined in the **/usr/include/sys/erec.h** file for adapter-detected errors, are:

Item	Description
Comment	Equal to a tape FC adapter-detected error.
Class	Equals a value of H, which indicates a hardware error.
Report	Equals a value of True, which indicates this error should be included when an error report is generated.
Log	Equals a value of True, which indicates an error log entry should be created when this error occurs.
Alert	Equal to a value of FALSE, which indicates this error is not alertable.
Err_Type	Equals a value of PERM, which indicates a permanent failure.
Err_Desc	Equals a value of 1331, which indicates a tape drive failure.
Prob_Causes	Equals values of 3300 and 6314, which indicates an adapter and tape drive failure, respectively.
User_Causes	None.
User_Actions	Equals a value of 0000, which indicates that problem determination procedures should be performed.
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	Equals values of 3300 and 6314, which indicates an adapter and tape drive failure, respectively.
Fail_Actions	Equals a value of 0000, which indicates problem-determination procedures should be performed.

The **Detail_Data** field contains the command type and adapter status. This field is contained in the **err_rec** structure, which is defined by the **/usr/include/sys/err_rec.h** file. Request-sense information is not available with this type of error. The **sc_error_log_df** structure describes information contained in the **Detail_Data** field and is defined in the **/usr/include/sys/scsi.h** file.

Error Record Values for Tape Drive Cleaning Errors

Some tape drives return errors when they need cleaning. Errors that occur when the drive needs cleaning are grouped under this class.

Item	Description
Comment	Indicates that the tape drive needs cleaning.
Class	Equals a value of H, which indicates a hardware error.
Report	Equals a value of True, which indicates this error should be included when an error report is generated.
Log	Equals a value of True, which indicates an error log entry should be created when this error occurs.

Item	Description
Alert	Equal to a value of FALSE, which indicates this error is not alertable.
Err_Type	Equals a value of TEMP, which indicates a temporary failure.
Err_Desc	Equals a value of 1332, which indicates a tape operation error.
Prob_Causes	Equals a value of 6314, which indicates that the probable cause is the tape drive.
User_Causes	Equal to 7401, which indicates a dirty read/write head.
User_Actions	Equals a value of 0000, which indicates that problem determination procedures should be performed.
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	Equals a value of 6314, which indicates that the cause is the tape drive.
Fail_Actions	Equals a value of 0000, which indicates problem-determination procedures should be performed.

The **Detail_Data** field contains the command type and adapter status, and also the request-sense information from the particular device in error. This field is contained in the **err_rec** structure, which is defined by the **/usr/include/sys/errids.h** file. The **sc_error_log_df** structure describes information contained in the **Detail_Data** field and is defined in the **/usr/include/sys/scsi.h** file.

Error Record Values for Unknown Errors

Errors that occur for unknown reasons are grouped in this class. Data-protect errors fall into this class. These errors, detected by the tape device driver, are never seen at the tape drive.

The **err_hdr** structure for unknown errors describes the following fields:

Item	Description
Comment	Equal to a tape unknown error.
Class	Equal to all error classes.
Report	Equals a value of True, which indicates this error should be included when an error report is generated.
Log	Equals a value of True, which indicates an error log entry should be created when this error occurs.
Alert	Equal to a value of FALSE, which indicates this error is not alertable.
Err_Type	Equals a value of UNKN, which indicates the type of error is unknown.
Err_Desc	Equals a value of 0xFE00, which indicates the error description is unknown.
Prob_Causes	Equals the following values: • 3300, which indicates a tape drive failure • 5003, which indicates a tape failure • 6314, which indicates an adapter failure
User_Causes	None.
User_Actions	None.
Inst_Causes	None.
Inst_Actions	None.

Item	Description
Fail_Causes	Equals a value of 0xFFFF, which indicates the failure causes are unknown.
Fail_Actions	Equals 0000, which indicates that problem-determination procedures should be performed.

The **Detail_Data** field contains the command type and adapter status, and the request-sense information from the particular device in error. The **Detail_Data** field is contained in the **err_rec** structure. This field is contained in the **/usr/include/sys/errids.h** file. The **sc_error_log_df** structure describes information contained in the **Detail_Data** field and is defined in the **/usr/include/sys/scsi.h** file.

Refer to the *Fibre Channel (FC) Specification* for the applicable device for the format of the particular request-sense information.

tape SCSI Device Driver

Purpose

Supports the sequential access bulk storage medium device driver.

Syntax

```
#include  <sys/devinfo.h>
#include  <sys/scsi.h>
#include  <sys/tape.h>
```

Note: The **/dev/rmt0** through **/dev/rmt255** special files provide access to magnetic tapes. Magnetic tapes are used primarily for backup, file archives, and other offline storage.

Device-Dependent Subroutines

Most tape operations are implemented using the **open**, **read**, **write**, and **close** subroutines. However, the **openx** subroutine must be used if the device is to be opened in Diagnostic mode.

open and close Subroutines

The **openx** subroutine is intended for use by the diagnostic commands and utilities. Appropriate authority is required for execution. Attempting to execute this subroutine without the proper authority causes the subroutine to return a value of -1 and sets the **errno** global variable to **EPERM**.

The **openx** subroutine allows the device driver to enter Diagnostic mode and disables command-retry logic. This action allows for execution of ioctl operations that perform special functions associated with diagnostic processing. Other **openx** capabilities, such as forced opens and retained reservations, are also available.

The *ext* parameter passed to the **openx** subroutine selects the operation to be used for the target device. The *ext* parameter is defined in the **/usr/include/sys/scsi.h** file. This parameter can contain any combination of the following flag values logically ORed together:

Flag Value	Description
SC_DIAGNOSTIC	Places the selected device in Diagnostic mode. This mode is singularly entrant. When a device is in Diagnostic mode, SCSI operations are performed during **open** or **close** operations and error logging is disabled. In Diagnostic mode, only the **close** and ioctl operations are accepted. All other device-supported subroutines return a value of -1, with the **errno** global variable set to a value of **EACCES**.
	A device can be opened in Diagnostic mode only if the target device is not currently opened. If an attempt is made to open a device in Diagnostic mode and the target device is already open, a value of -1 is returned and the **errno** global variable is set to **EACCES**.
SC_FORCED_OPEN	Forces a bus device reset (BDR) regardless of whether another initiator has the device reserved. The SCSI bus device reset is sent to the device before the **open** sequence begins. Otherwise, the **open** operation executes normally.
SC_RETAIN_RESERVATION	Retains the reservation of the device after a **close** operation by not issuing the release. This flag prevents other initiators from using the device unless they break the host machine's reservation.

"SCSI Options to the openx Subroutine" in *Kernel Extensions and Device Support Programming Concepts* gives more specific information on the open operations.

ioctl Subroutine

The **STIOCMD** ioctl operation provides the means for sending SCSI commands directly to a tape device. This allows an application to issue specific SCSI commands that are not directly supported by the tape device driver.

To use the **STIOCMD** operation, the device must be opened in Diagnostic mode. If this command is attempted while the device is not in Diagnostic mode, a value of -1 is returned and the **errno** global variable is set to a value of **EACCES**. The **STIOCMD** operation passes the address of a **scsi_iocmd** structure. This structure is defined in the **/usr/include/sys/scsi_buf.h** file.

Refer to the *Small Computer System Interface (SCSI) Specification* for the applicable device for information on issuing the parameters.

Error Conditions

In addition to those errors listed, ioctl, **open**, **read**, and **write** subroutines against this device are unsuccessful in the following circumstances:

Error	Description
EACCES	Indicates that a diagnostic command was issued to a device not in Diagnostic mode.
EAGAIN	Indicates that an attempt was made to open a device that was already open.
EBUSY	Indicates that the target device is reserved by another initiator.
EINVAL	Indicates that a value of **O_APPEND** is supplied as the mode in which to open.
EINVAL	Indicates that the *nbyte* parameter supplied by a **read** or **write** operation is not a multiple of the block size.
EINVAL	Indicates that a parameter to an ioctl operation is not valid.
EINVAL	Indicates that the requested ioctl operation is not supported on the current device.
EIO	Indicates that the tape drive has been reset or that the tape has been changed. This error is returned on open if the previous operation to tape left the tape positioned beyond beginning of tape upon closing.

Error	Description
EIO	Indicates that the device could not space forward or reverse the number of records specified by the `st_count` field before encountering an EOM (end of media) or a file mark.
EMEDIA	Indicates that the tape device has encountered an unrecoverable media error.
EMFILE	Indicates that an **open** operation was attempted for a SCSI adapter that already has the maximum permissible number of open devices.
ENOTREADY	Indicates that there is no tape in the drive or the drive is not ready.
ENXIO	Indicates that there was an attempt to write to a tape that is at EOM.
EPERM	Indicates that this subroutine requires appropriate authority.
ETIMEDOUT	Indicates a command has timed out.
EWRPROTECT	Indicates an **open** operation requesting read/write mode was attempted on a read-only tape.
EWRPROTECT	Indicates that an ioctl operation that affects the media was attempted on a read-only tape.

Reliability and Serviceability Information

Errors returned from tape devices are as follows:

Error	Description
ABORTED COMMAND	Indicates the device ended the command.
BLANK CHECK	Indicates that a read command encountered a blank tape.
DATA PROTECT	Indicates that a write was attempted on a write-protected tape.
GOOD COMPLETION	Indicates that the command completed successfully.
HARDWARE ERROR	Indicates that an unrecoverable hardware failure occurred during command execution or during a self-test.
ILLEGAL REQUEST	Indicates an illegal command or command parameter.
MEDIUM ERROR	Indicates that the command terminated with a unrecovered media error condition. This condition may be caused by a tape flaw or a dirty head.
NOT READY	Indicates that the logical unit is offline.
RECOVERED ERROR	Indicates that the command was successful after some recovery was applied.
UNIT ATTENTION	Indicates the device has been reset or powered on.

Medium, hardware, and aborted command errors from the above list are to be logged every time they occur. The **ABORTED COMMAND** error may be recoverable, but the error is logged if recovery fails. For the **RECOVERED ERROR** and recovered **ABORTED COMMAND** error types, thresholds are maintained; when they are exceeded, an error is logged. The thresholds are then cleared.

Note: There are device-related adapter errors that are logged every time they occur.

Error Record Values for Tape Device Media Errors

The fields defined in the error record template for tape-device media errors are:

Field	Description
`Comment`	Equal to tape media error.
`Class`	Equal to H, indicating a hardware error.

Field	Description
Report	Equal to TRUE, indicating this error should be included when an error report is generated.
Log	Equal to TRUE, indicating an error log entry should be created when this error occurs.
Alert	Equal to FALSE, indicating this error is not alertable.
Err_Type	Equal to PERM, indicating a permanent failure.
Err_Desc	Equal to 1332, indicating a tape operation failure.
Prob_Causes	Equal to 5003, indicating tape media.
User_Causes	Equal to 5100 and 7401, indicating a cause originating with the tape and defective media, respectively.
User_Actions	Equal to 1601 and 0000, indicating respectively that the removable media should be replaced and the operation retried, and that problem determination procedures should be performed.
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	Equal to 5003, indicating tape media.
Fail_Actions	Equal to 1601 and 0000, indicating respectively that the removable media should be replaced and the operation retried and that problem determination procedures should be performed.

The Detail_Data field contains the command type, device and adapter status, and the request-sense information from the particular device in error. The Detail_Data field is contained in the **err_rec** structure. This structure is defined in the **/usr/include/sys/errids.h** file. The **sc_error_log_df** structure, which describes information contained in the Detail_Data field, is defined in the **/usr/include/sys/scsi.h** file.

Refer to the *Small Computer System Interface (SCSI) Specification* for the applicable device for the format of the particular request-sense information.

Error-Record Values for Tape or Hardware Aborted Command Errors

The fields in the **err_hdr** structure, as defined in the **/usr/include/sys/erec.h** file for hardware errors and aborted command errors, are:

Field	Description
Comment	Equal to a tape hardware or aborted command error.
Class	Equal to H, indicating a hardware error.
Report	Equal to TRUE, indicating this error should be included when an error report is generated.
Log	Equal to TRUE, indicating an error log entry should be created when this error occurs.
Alert	FALSE, indicating this error is not alertable.
Err_Type	Equal to PERM, indicating a permanent failure.
Err_Desc	Equal to 1331, indicating a tape drive failure.
Prob_Causes	Equal to 6314, indicating a tape drive error.
User_Causes	None.

Field	Description
`User_Actions`	Equal to 0000, indicating that problem determination procedures should be performed.
`Inst_Actions`	None.
`Fail_Causes`	Equal to 5003 and 6314, indicating the failure cause is the tape and the tape drive, respectively.
`Fail_Actions`	Equal to 0000 to perform problem determination procedures.

The `Detail_Data` field contains the command type, device and adapter status, and the request-sense information from the particular device in error. The `Detail_Data` field is contained in the **err_rec** structure. This structure is defined in the **/usr/include/sys/errids.h** file. The **sc_error_log_df** structure, which describes information contained in the `Detail_Data` field, is defined in the **/usr/include/sys/scsi.h** file.

Refer to the *Small Computer System Interface (SCSI) Specification* for the applicable device for the format of the particular request-sense information.

Error-Record Values for Tape-Recovered Error Threshold Exceeded

The fields defined in the **err_hdr** structure, as defined in the **/usr/include/sys/erec.h** file for recovered errors that have exceeded the threshold counter, are:

Field	Description
`Comment`	Indicates the tape-recovered error threshold has been exceeded.
`Class`	Equal to H, indicating a hardware error.
`Report`	Equal to TRUE, indicating this error should be included when an error report is generated.
`Log`	Equal to TRUE, indicating an error log entry should be created when this error occurs.
`Alert`	Equal to FALSE, indicating this error is not alertable.
`Err_Type`	Equal to PERM, indicating a permanent failure.
`Err_Desc`	Equal to 1331, indicating a tape drive failure.
`Prob_Causes`	Equal to 5003 and 6314, indicating the probable cause is the tape and tape drive, respectively.
`User_Causes`	Equal to 5100 and 7401, indicating that the media is defective and the read/write head is dirty, respectively.
`User_Actions`	Equal to 1601 and 0000, indicating that removable media should be replaced and the operation retried and that problem-determination procedures should be performed, respectively.
`Inst_Causes`	None.
`Inst_Actions`	None.
`Fail_Causes`	Equal to 5003 and 6314, indicating the cause is the tape and tape drive, respectively.
`Fail_Actions`	Equal to 0000, to perform problem determination procedures.

The `Detail_Data` field contains the command type, device and adapter status, and the request-sense information from the particular device in error. This field is contained in the **err_rec** structure. The **err_rec** structure is defined in the **/usr/include/sys/errids.h** file. The `Detail_Data` field also specifies the error type of the threshold exceeded. The **sc_error_log_df** structure, which describes information contained in the `Detail_Data` field, is defined in the **/usr/include/sys/scsi.h** file.

Refer to the *Small Computer System Interface (SCSI) Specification* for the applicable device for the format of the particular request-sense information.

Error Record Values for Tape SCSI Adapter-Detected Errors

The fields in the **err_hdr** structure, as defined in the **/usr/include/sys/erec.h** file for adapter-detected errors, are:

Field	Description
Comment	Equal to a tape SCSI adapter-detected error.
Class	Equal to H, indicating a hardware error.
Report	Equal to TRUE, indicating this error should be included when an error report is generated.
Log	Equal to TRUE, indicating an error log entry should be created when this error occurs.
Alert	Equal to FALSE, indicating this error is not alertable.
Err_Type	Equal to PERM, indicating a permanent failure.
Err_Desc	Equal to 1331, indicating a tape drive failure.
Prob_Causes	Equal to 3300 and 6314, indicating an adapter and tape drive failure, respectively.
User_Causes	None.
User_Actions	Equal to 0000, indicating that problem determination procedures should be performed.
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	Equal to 3300 and 6314, indicating an adapter and tape drive failure, respectively.
Fail_Actions	Equal to 0000, to perform problem-determination procedures.

The Detail_Data field contains the command type and adapter status. This field is contained in the **err_rec** structure, which is defined by the **/usr/include/sys/err_rec.h** file. Request-sense information is not available with this type of error. The **sc_error_log_df** structure describes information contained in the Detail_Data field and is defined in the **/usr/include/sys/scsi.h** file.

Refer to the *Small Computer System Interface (SCSI) Specification* for the applicable device for the format of the particular request-sense information.

Error-Record Values for Tape Drive Cleaning Errors

Some tape drives return errors when they need cleaning. Errors that occur when the drive needs cleaning are grouped under this class.

Field	Description
Comment	Indicates that the tape drive needs cleaning.
Class	Equal to H, indicating a hardware error.
Report	Equal to TRUE, indicating that this error should be included when an error report is generated.
Log	Equal to TRUE, indicating that an error-log entry should be created when this error occurs.
Alert	Equal to FALSE, indicating this error is not alertable.
Err_Type	Equal to TEMP, indicating a temporary failure.
Err_Desc	Equal to 1332, indicating a tape operation error.

Field	Description
`Prob_Causes`	Equal to 6314, indicating that the probable cause is the tape drive.
`User_Causes`	Equal to 7401, indicating a dirty read/write head.
`User_Actions`	Equal to 0000, indicating that problem determination procedures should be performed.
`Inst_Causes`	None.
`Inst_Actions`	None.
`Fail_Causes`	Equal to 6314, indicating that the cause is the tape drive.
`Fail_Actions`	Equal to 0000, indicating to perform problem-determination procedures.

The `Detail_Data` field contains the command type and adapter status and also the request-sense information from the particular device in error. This field is contained in the **err_rec** structure, which is defined by the **/usr/include/sys/errids.h** file. The **sc_error_log_df** structure describes information contained in the `Detail_Data` field and is defined in the **/usr/include/sys/scsi.h** file.

Refer to the *Small Computer System Interface (SCSI) Specification* for the applicable device for the format of the particular request-sense information.

Error-Record Values for Unknown Errors

Errors that occur for unknown reasons are grouped in this class. Data-protect errors fall into this class. These errors, detected by the tape device driver, are never seen at the tape drive.

The **err_hdr** structure for unknown errors describes the following fields:

Field	Description
`Comment`	Equal to tape unknown error.
`Class`	Equal to all error classes.
`Report`	Equal to TRUE, indicating this error should be included when an error report is generated.
`Log`	Equal to TRUE, indicating an error-log entry should be created when this error occurs.
`Alert`	Equal to FALSE, indicating this error is not alertable.
`Err_Type`	Equal to UNKN, indicating the error type is unknown.
`Err_Desc`	Equal to 0xFE00, indicating the error description is unknown.
`Prob_Causes`	None.
`User_Causes`	None.
`User_Actions`	None.
`Inst_Causes`	None.
`Inst_Actions`	None.
`Fail_Causes`	Equal to 0xFFFF, indicating the failure cause is unknown.
`Fail_Actions`	Equal to 0000, indicating that problem-determination procedures should be performed.

The `Detail_Data` field contains the command type and adapter status, and the request-sense information from the particular device in error. The `Detail_Data` field is contained in the **err_rec** structure. This field is contained in the **/usr/include/sys/errids.h** file. The **sc_error_log_df** structure describes information contained in the `Detail_Data` field and is defined in the **/usr/include/sys/scsi.h** file.

Refer to the *Small Computer System Interface (SCSI) Specification* for the applicable device for the format of the particular request-sense information.

TMCHGIMPARM (Change Parameters) tmscsi Device Driver ioctl Operation

Purpose

Allows the caller to change parameters used by the target-mode device driver.

Note: This operation is not supported by all SCSI I/O controllers.

Description

The **TMCHGIMPARM** ioctl operation allows the caller to change certain parameters used by the target-mode device driver for a particular device instance. This operation is allowed only for the initiator-mode device. The *arg* parameter to the **TMCHGIMPARM** operation specifies the address of the **tm_chg_im_parm** structure defined in **/usr/include/sys/tmscsi.h** file.

Default values used by the device driver for these parameters usually do not require change. However, for certain calling programs, default values can be changed to fine-tune timing parameters related to error recovery.

The initiator-mode device must be open for this command to succeed. Once a parameter is changed through the **TMCHGIMPARM** operation, it remains changed until another **TMCHGIMPARM** operation is received or until the device is closed. At open time, these parameters are set to the default values.

Parameters that can be changed with this operation are the amount of delay (in seconds) between device driver-initiated retries of SCSI **send** commands and the amount of time allowed before the running of any **send** command times out. To indicate which of the possible parameters are being changed, the caller sets the appropriate bit in the `chg_option` field. Values of 0, 1, or multiple flags can be set in this field to indicate which parameters are being changed.

To change the delay between **send** command retries, the caller sets the **TM_CHG_RETRY_DELAY** flag in the `chg_option` field and places the desired delay value (in seconds) in the `new_delay` field of the structure. The retry delay can be changed with this command to any value between 0 and 255, inclusive, where 0 instructs the device driver to use as little delay as possible between retries. The default value is approximately 2 seconds.

To change the **send** command timeout value, the caller sets the **TM_CHG_SEND_TIMEOUT** flag in the `chg_option` field, sets the desired flag in the `timeout_type` field, and places the desired timeout value in the `new_timeout` field of the structure. A single flag must be set in the `time_out` field to indicate the desired form of the timeout. If the **TM_FIXED_TIMEOUT** flag is set in the `timeout_type` field, then the value placed in the `new_timeout` field is a fixed timeout value for all **send** commands. If the **TM_SCALED_TIMEOUT** flag is set in the `timeout_type` field, then the value placed in the `new_timeout` field is a scaling-factor used in the calculation for timeout as shown under the description of the write entry point. The default **send** command timeout value is a scaled timeout with scaling factor of 10.

Regardless of the value of the `timeout_type` field, if the `new_timeout` field is set to a value of 0, the caller specifies "no timeout" for the **send** command, allowing the command to take an indefinite amount of time. If the calling program wants to end a **write** operation, it generates a signal.

Files

Item	Description
/dev/tmscsi0, **/dev/tmscsi1**,..., **/dev/tmscsi***n*	Support processor-to-processor communications through the SCSI target-mode device driver.

TMGETSENS (Request Sense) tmscsi Device Driver ioctl Operation

Purpose

Runs a SCSI **request sense** command and returns the sense data to the user.

Note: This operation is not supported by all SCSI I/O controllers.

Description

The **TMGETSENS** ioctl operation runs a SCSI **request sense** command and returns the sense data to the user. This operation is allowed only for the initiator-mode device. It is issued by the caller in response to a **write** subroutine **errno** global variable set to a value of **ENXIO**. This operation must be the next command issued to the device for this initiator or the sense data is lost. The *arg* parameter to the ioctl operation is the address of the **tm_get_sens** structure defined in the **/usr/include/sys/tmscsi.h** file. The caller must supply the address and length of a buffer used for holding the returned device-sense data in this structure. The maximum length for request-sense data is 255 bytes. The caller should refer to the SCSI specification for the target device to determine the correct length for the device's request-sense data. The lesser of either the sense data length requested or the actual sense data length is returned in the buffer passed by the caller. For the definition of the returned data, refer to the detailed SCSI specification for the device in use.

After each **TMGETSENS** operation, the target-mode device driver generates the appropriate **errno** global variable. If an error occurs, the return value is set to a value of -1 and the **errno** global variable is set to the value generated by the target-mode device driver. The device driver also updates a status area that is kept for the last command to each device. For certain errors, and upon successful completion, the caller can read this status area to get more detailed error status for the command. The **TMIOSTAT** operation can be used for this purpose. The **errno** global variables covered by this status include **EIO**, **EBUSY**, **ENXIO**, and **ETIMEDOUT**.

Files

Item	Description
/dev/tmscsi0, **/dev/tmscsi1**,..., **/dev/tmscsi***n*	Support processor-to-processor communications through the SCSI target-mode device driver.

TMIOASYNC (Async) tmscsi Device Driver ioctl Operation

Purpose

Allows future initiator-mode commands for an attached target device to use asynchronous data transfer.

Note: This operation is not supported by all SCSI I/O controllers.

Description

The **TMIOASYNC** ioctl operation enables asynchronous data transfer for future initiator-mode commands on attached target devices. Only an initiator-mode device may use this operation. The *arg* parameter of the **TMIOASYNC** operation is set to a null value by the caller.

This operation is required when the caller is intending to retry a previous initiator SCSI command (other than those sent through the **TMIOCMD** operation) that was unsuccessful with a **SC_SCSI_BUS_FAULT** status in the `general_card_status` field in the status structure returned by the **TMIOSTAT** operation. If more than one retry is attempted, this operation should be issued only before the last retry attempt.

This operation allows the device to run in asynchronous mode if the device does not negotiate for synchronous transfers. This operation affects all future initiator commands for this device. However, a SCSI reset or power-on to the device results in an attempt to again run synchronous data transfers. At open time, synchronous data transfers are attempted.

Item	Description
/dev/tmscsi0, **/dev/tmscsi1**,**...**, **/dev/tmscsi**n	Support processor-to-processor communications through the SCSI target-mode device driver.

TMIOCMD (Direct) tmscsi Device Driver ioctl Operation

Purpose

Sends SCSI commands directly to the attached device.

Note: This operation is not supported by all SCSI I/O controllers.

Description

> **Attention:** The **TMIOCMD** operation is a very powerful operation. Extreme care must be taken by the caller before issuing any general SCSI command, as this may adversely affect the attached device, other SCSI devices on the SCSI bus, or even general system availability. It should only be used when no other means are available to run the required function or functions on the attached device. This operation requires at least **dev_config** authority to run.

The **TMIOCMD** operation provides a means of sending SCSI commands directly to the attached device. This operation is only allowed for the initiator-mode device. It enables a caller to issue specific SCSI commands that are not directly supported by the device driver. The caller is responsible for any and all error recovery associated with the sending of the SCSI command. No error recovery is performed by the device driver when the command is issued. The device driver does not log errors that occur while running the command.

The *arg* parameter to this command specifies the address of the **sc_iocmd** structure defined in the **/usr/include/sys/scsi.h** file. The caller fills in the SCSI command descriptor block area, command length (SCSI command block length), the time-out value for the command, and a `flags` field. If a data transfer is involved, the data length and buffer pointer areas, as well as the **B_READ** flag in the `flags` field, must be filled in. The **B_READ** is set to a value of 1 to indicate the command's data transfer is incoming, and **B_READ** is set to a value of 0 to indicate the data is outgoing. If there is no data transfer, these fields and flags are set to 0 values.

The target-mode device driver builds the appropriate command block to execute this operation, including ORing in the 3-bit logical unit number (LUN) identifier in the SCSI command based on the configuration information for this device instance. The returned **errno** global variable is generated and the `status validity`, `SCSI bus status`, and `adapter status` fields are updated to reflect the completion status for the command. These status areas are defined in the **/usr/include/sys/scsi.h** file.

Files

Item	Description
/dev/tmscsi0, **/dev/tmscsi1**,**...**, **/dev/tmscsi**n	Support processor-to-processor communications through the SCSI target-mode device driver.

TMIOEVNT (Event) tmscsi Device Driver ioctl Operation

Purpose

Allows the caller to query the device driver for event status.

Note: This operation is not supported by all SCSI I/O controllers.

Description

The **TMIOEVNT** ioctl operation allows the caller to query the device driver for status on certain events. The *arg* parameter to the **TMIOEVNT** operation specifies the address of the **tm_event_info** structure defined in the **/usr/include/sys/tmscsi.h** file. This operation conveys status that is generally not tied to a specific application program subroutine and would not otherwise be known to the application. For example, failure of an adapter function not associated directly with a SCSI command is reported through this facility.

Although this operation can be used independently of other commands to the target-mode device driver, it is most effective when issued in conjunction with the select entry point **POLLPRI** option. For this device driver, the **POLLPRI** option indicates an event has occurred that is reported through the **TMIOEVNT** operation. This allows the caller to be asynchronously notified of events occurring to the device instance, which means the **TMIOEVNT** operation need only be issued when an event occurs. Without the select entry point, it would be necessary for the caller to issue the **TMIOEVNT** operation after every **read** or **write** subroutine to know when an event has occurred. The select entry point allows the caller to monitor events on one or more target or initiator devices.

Because the caller is not generally aware of which adapter a particular device is attached to, event information in the **TMIOEVNT** operation is maintained for each device instance. Application programs should not view any information from one device's **TMIOEVNT** operation as necessarily affecting other devices opened through this device driver. Rather, the application must base its error recovery for each device on that device's particular **TMIOEVNT** information.

Event information is reported through the `events` field of the **tm_event_info** structure and can have the following values:

Value	Description
TM_FATAL_HDW_ERR	Adapter fatal hardware failure
TM_ADAP_CMD_FAILED	Unrecoverable adapter command failure
TM_SCSI_BUS_RESET	SCSI Bus Reset detected
TM_BUFS_EXHAUSTED	Maximum buffer usage detected

Some of the events that can be reported apply to any SCSI device, whether they are initiator-mode or target-mode devices. These events include **adapter fatal hardware failure**, **unrecoverable adapter command failure**, and **SCSI BUS Reset** detected. The **maximum buffer usage detected** event applies only to the target mode device and is never reported for an initiator-mode device instance.

The **adapter fatal hardware failure** event is intended to indicate a fatal condition. This means no further commands are likely to complete successfully to or from this SCSI device, as the adapter it is attached to has failed. In this case, the application should end the session with the device.

The **unrecoverable adapter command failure** event is not necessarily a fatal condition but can indicate that the adapter is not functioning properly. The application program has these possible actions:

- End the session with the device in the near future.
- End the session after multiple (two or more) such events.
- Attempt to continue the session indefinitely.

The **SCSI Bus Reset detection** event is mainly intended as information only but can be used by the application to perform further actions, if necessary. The Reset information can also be conveyed to the

application during command execution, but the Reset must occur during the SCSI command for this to occur.

The **maximum buffer usage detected** event only applies to a given target-mode device; it is not be reported for an initiator device. This event indicates to the application that this particular target-mode device instance has filled its maximum allotted buffer space. The application should perform **read** subroutines fast enough to prevent this condition. If this event occurs, data is not lost, but it is delayed to prevent further buffer usage. Data reception is restored when the application empties enough buffers to continue reasonable operations. The **num_bufs** attribute may need to be increased from the default value to help minimize this problem.

Return Values

Item	Description
EFAULT	Operation failed due to a kernel service error.
EINVAL	Attempted to execute an ioctl operation for a device instance that is not configured, not open, or is not in the proper mode (initiator versus target) for this operation.
EIO	An I/O error occurred during the operation.
EPERM	For the **TMIOCMD** operation, the caller did not have **dev_config** authority.
ETIMEDOUT	The operation did not complete before the timeout expired.

Files

Item	Description
/dev/tmscsi0, **/dev/tmscsi1**,..., **/dev/tmscsi**n	Support processor-to-processor communications through the SCSI target-mode device driver.

TMIORESET (Reset Device) tmscsi Device Driver ioctl Operation

Purpose

Sends a Bus Device Reset (BDR) message to an attached target device.

Note: This operation is not supported by all SCSI I/O controllers.

Description

The **TMIORESET** ioctl operation allows the caller to send a Bus Device Reset (BDR) message to a selected target device. Only an initiator-mode device may use this operation. The *arg* parameter of the **TMIORESET** operation is set to a null value by the caller.

The attached target device typically uses this BDR message to reset certain operating characteristics. Such an action may be needed during severe error recovery between the host initiator and the attached target device. The specific effects of the BDR message are device dependent. Since the effects of this operation are potentially adverse to the target device, care should be taken by the caller before issuing this message. To run this operation requires at least **dev_config** authority.

Files

Item	Description
/dev/tmscsi0, **/dev/tmscsi1**,..., **/dev/tmscsi**n	Support processor-to-processor communications through the SCSI target-mode device driver.

TMIOSTAT (Status) tmscsi Device Driver ioctl Operation

Purpose

Allows the caller to get detailed status about the previous **write** or **TMGETSENS** operation.

Note: This operation is not supported by all SCSI I/O controllers.

Description

The **TMIOSTAT** operation allows the caller to get detailed status about a previous **write** or **TMGETSENS** operation. This operation is allowed only for the initiator-mode device. The *arg* parameter to this operation specifies the address of the **tm_get_stat** structure defined in **/usr/include/sys/tmscsi.h** file. The status returned by the **TMIOSTAT** operation is updated for both successful and unsuccessful completions of these commands. This status is not valid for all **errno** global variables.

Files

Item	Description
/dev/tmscsi0,/dev/tmscsi1,..., **/dev/tmscsi***n*	Support processor-to-processor communications through the SCSI target-mode device driver.

tmscsi SCSI Device Driver

Purpose

Supports processor-to-processor communications through the SCSI target-mode device driver.

Note: This operation is not supported by all SCSI I/O controllers.

Syntax

```
#include </usr/include/sys/devinfo.h>
#include </usr/include/sys/tmscsi.h>
#include </usr/include/sys/scsi.h>
```

Description

The Small Computer Systems Interface (SCSI) target-mode device driver provides an interface to allow processor-to-processor data transfer using the SCSI **send** command. This single device driver handles both SCSI initiator and SCSI target mode roles.

The user accesses the data transfer functions through the special files **/dev/tmscsi0.***xx*, **/dev/ tmscsi1.***xx*, ... These are all character special files. The *xx* can be either **im**, initiator-mode interface, or **tm**, target-mode interface. The initiator-mode interface is used by the caller to transmit data, and the target-mode interface is used to receive data.

The least significant bit of the minor device number indicates to the device driver which mode interface is selected by the caller. When the least significant bit of the minor device number is set to a value of 1, the target-mode interface is selected. When the least significant bit is set to a value of 0, the initiator-mode interface is selected. For example, **tmscsi0.im** should be defined as an even-numbered minor device number to select the initiator-mode interface, and **tmscsi0.tm** should be defined as an odd-numbered minor device number to select the target-mode interface.

When the caller opens the initiator-mode special file a logical path is established, allowing data to be transmitted. The user-mode caller issues a **write**, **writev**, **writex**, or **writevx** system call to initiate data transmission. The kernel-mode user issues an **fp_write** or **fp_rwuio** service call to initiate data transmission. The SCSI target-mode device driver then builds a SCSI **send** command to describe the

transfer, and the data is sent to the device. Once the write entry point returns, the calling program can access the transmit buffer.

When the caller opens the target-mode special file a logical path is established, allowing data to be received. The user-mode caller issues a **read**, **readv**, **readx**, or **readvx** system call to initiate data reception. The kernel-mode caller issues an **fp_read** or **fp_rwuio** service call to initiate data reception. The SCSI target-mode device driver then returns data received for the application.

The SCSI target mode device driver allows access as an initiator mode device through the **write** entry point. Target mode device access is made through the **read** entry point. Simultaneous access to the **read** and **write** entry points is possible by using two separate processes, one running **read** subroutines and the other running **write** subroutines.

The SCSI target mode device driver does not implement any protocol to manage the sending and receiving of data, with the exception of attempting to prevent an application from excessive received-data buffer usage. Any protocol required to maintain or otherwise manage the communications of data must be implemented in the calling program. The only delays in sending or receiving data through the target mode device driver are those inherent to the hardware and software driver environment.

Configuration Information

When the **tmscsi0** special file is configured, both the **tmscsi0.im** and **tmscsi0.tm** special files are created. An initiator-mode/target-mode pair for each device instance should exist, even if only one of the modes is being used. The target-mode SCSI ID for an attached device should be the same as the initiator-mode SCSI ID, but the logical unit number (LUN) is ignored in target mode, because the host SCSI adapter can only respond as LUN 0.

If multiple LUNs are supported on the attached initiator device, a pair of **tmscsi**n special files (where n is the device instance) are generated for each SCSI ID/LUN combination. The initiator-mode special files allow simultaneous access to the associated SCSI ID/LUN combinations. However, only one of the target-mode special files for this SCSI ID can be opened at one time. This is because only one LUN 0 is supported on the host adapter and only one logical connection can be actively using this ID at one time. If a target-mode special file is open for a given SCSI ID, attempts to open other target-mode special files for the same ID will fail.

The target-mode device driver configuration entry point must be called only for the initiator-mode device number. The driver configuration routine automatically creates the configuration data for the target-mode device minor number based on the initiator-mode data.

Device-Dependent Subroutines

The target-mode device driver supports the **open**, **close**, **read**, **write**, **select**, and **ioctl** subroutines.

open Subroutine

The **open** subroutine allocates and initializes target or initiator device-dependent structures. No SCSI commands are sent to the device as a result of running the **open** subroutine.

The SCSI initiator or target-mode device must be configured and not already opened for that mode for the **open** subroutine to work. For the initiator-mode device to be successfully opened, its special file must be opened for writing only. For the target-mode device to be successfully opened, its special file must be opened for reading only.

Possible return values for the **errno** global variable include:

Value	Description
EAGAIN	Lock kernel service failed.
EBUSY	Attempted to execute an open for a device instance that is already open.
EINVAL	Attempted to execute an open for a device instance using an incorrect open flag, or device is not yet configured .

Value	Description
EIO	An I/O error occurred.
ENOME M	The SCSI device is lacking memory resources.

close Subroutine

The **close** subroutine deallocates resources local to the target device driver for the target or initiator device. No SCSI commands are sent to the device as a result of running the **close** subroutine. Possible return values for the **errno** global variable include:

Value	Description
EINVAL	Attempted to execute a close for a device instance that is not configured.
EIO	An I/O error occurred.

read Subroutine

The **read** subroutine is supported only for the target-mode device. Data scattering is supported through the user-mode **readv** or **readvx** subroutine, or the kernel-mode **fp_rwuio** service call. If the **read** subroutine is unsuccessful, the return value is set to a return value of -1, and the **errno** global variable is set to the return value from the device driver. If the return value is something other than -1, then the read was successful and the return code indicates the number of bytes read. This should be validated by the caller. File offsets are not applicable and are therefore ignored for target-mode reads.

SCSI **send** commands provide the boundary for satisfying read requests. If more data is received in the **send** command than is requested in the current **read** operation, the requested data is passed to the caller, and the remaining data is retained and returned for the next **read** operation for this target device. If less data is received in the **send** command than is requested, the received data is passed for the read request, and the return value indicates how many bytes were read.

If a **send** command has not been completely received when a read request is made, the request blocks and waits for data. However, if the target device is opened with the **O_NDELAY** flag set, then the read does not block; it returns immediately. If no data is available for the read request, the **read** is unsuccessful and the **errno** global variable is set to **EAGAIN**. If data is available, it is returned and the return value indicates the number of bytes received. This is true even if the **send** command for this data has not ended.

Note: Without the **O_NDELAY** flag set, the **read** subroutine can block indefinitely, waiting for data. Since the read data can come at any time, the device driver does not maintain an internal timer to interrupt the read. Therefore, if a time-out function is desired, it must be implemented by the calling program.

If the calling program wishes to break a blocked **read** subroutine, the program can generate a signal. The target-mode device driver receives the signal and ends the current **read** subroutine with failure. The **errno** global variable is then set to **EINTR**. The read returns with whatever data has been received, even if the **send** command has not completed. If and when the remaining data for the **send** command is received, it is queued, waiting for either another read request or a close. When the target receives the signal and the current read is returned, another read can be initiated or the target can be closed. If the read request that the calling program wishes to break completes before the signal is generated, the read completes normally and the signal is ignored.

The target-mode device driver attempts to queue received data ahead of requests from the application. A read-ahead buffer area (whose length is determined by the product of 4096 and the **num_bufs** attribute value in the configuration database) is used to store the queued data. As the application program executes **read** subroutines, the queued data is copied to the application data buffer and the read-ahead buffer space is again made available for received data. If an error occurs while copying the data to the caller's data buffer, the read fails and the **errno** global variable is set to **EFAULT**. If the **read** subroutines are not executed quickly enough, so that almost all the read-ahead buffers for the device are filled, data reception will be delayed until the application runs a **read** subroutine again. When enough area is freed, data reception is restored from the device. Data may be delayed, but it is not lost or ignored. If almost all the read-ahead buffers are filled, status information is saved indicating this condition. The application

may optionally query this status through the **TMIOEVNT** operation. If the application uses the optional **select/poll** operation, it can receive asynchronous notification of this and other events affecting the target-mode instance.

The target-mode device driver handles only received data in its read entry point. All other initiator-sent SCSI commands are handled without intervention by the target-mode device driver. This also means the target-mode device driver does not directly generate any SCSI sense data or SCSI status.

The read entry point may optionally be used in conjunction with the select entry point to provide a means of asynchronous notification of received data on one or more target devices.

Possible return values for the **errno** global variable include:

Value	Description
EAGAIN	Indicates a non-blocking read request would have blocked, because no data is available.
EFAULT	An error occurred while copying data to the caller's buffer.
EINTR	Interrupted by a signal.
EINVAL	Attempted to execute a **read** for a device instance that is not configured, not open, or is not a target-mode minor device number.
EIO	I/O error occurred.

write Subroutine

The write entry point is supported only for the initiator-mode device driver. The write entry point generates a single SCSI **send** command in response to a calling program's write request. If the write request is for a length larger than the host SCSI adapter's maximum transfer length or if the request cannot be pinned as a single request, then the **write** request fails with the **errno** global variable set to **EINVAL**. The maximum transfer size for this device is discovered by issuing an **IOCINFO ioctl** call to the target-mode device driver.

Some target mode capable adapters support data gathering of writes through the **user_mode writev** or **writevx** subroutine or the kernel-mode **fp_wruio** service call. The write buffers are gathered so that they are transferred, in order, as a single **send** command. The target-mode device driver passes information to the SCSI adapter device driver to allow it to perform the gathered write. Since the SCSI adapter device driver can be performing the gather function in software (when the hardware does not directly support data gathering), it is possible for the function to be unsuccessful because of a lack of memory or a copy error. The returned **errno** global variable is set to **ENOMEM** or **EFAULT**. Due to how gathered writes are handled, it is not possible for the target-mode device driver to perform retries. When an error does occur, the caller must retry or otherwise recover the operation.

If the **write** operation is unsuccessful, the return value is set to -1 and the **errno** global variable is set to the value of the return value from the device driver. If the return value is a value other than -1, the **write** operation was successful and the return value indicates the number of bytes written. The caller should validate the number of bytes sent to check for any errors. Since the entire data transfer length is sent in a single **send** command, a return code not equal to the expected total length should be considered an error. File offsets are not applicable and are ignored for target-mode writes.

If the calling program needs to break a blocked **write** operation, a signal should be generated. The target-mode device driver receives the signal and ends the current **write** operation. A **write** operation in progress fails, and the **errno** global variable is set to **EINTR**. The calling program may then continue by issuing another **write** operation, an **ioctl** operation, or may close the device. If the **write** operation the caller attempts to break completes before the signal is generated, the write completes normally and the signal is ignored.

The target-mode device driver automatically retries (up to the number of attempts specified by the value **TM_MAXRETRY** defined in the **/usr/include/sys/tmscsi.h** file) the **send** command if either a SCSI Busy response or no device response status is received for the command. By default, the target mode device driver delays each retry attempt by approximately two seconds to allow the target device to respond successfully. The caller can change the amount of time delayed through the **TMCHGIMPARM** operation. If

retries are exhausted and the command is still unsuccessful, the write fails. The calling program can retry the **write** operation or perform other appropriate error recovery. All other error conditions are not retried but are returned with the appropriate **errno** global variable.

The target-mode device driver, by default, generates a time-out value, which is the amount of time allowed for the **send** command to complete. If the **send** command does not complete before the time-out value expires, the write fails. The time-out value is based on the length of the requested transfer, in bytes, and calculated as follows:

```
timeout_value = ((transfer_length / 65536) +1) *
10
```

In the calculation, 10 is the default scaling factor used to generate the time-out value. The caller can customize the time-out value through the **TMCHGIMPARM** operation.

One of the errors that can occur during a write is a SCSI status of check condition. A check-condition error requires a SCSI **request sense** command to be issued to the device. This returns the device's SCSI sense data, which must be examined to discover the exact cause of the check condition. To allow the target-mode device driver to work with a variety of target devices when in initiator mode, the device driver does not evaluate device sense data on check conditions. Therefore, the caller is responsible for evaluating the sense data to determine the appropriate error recovery. The **TMGETSENS** operation is provided to allow the caller to get the sense data. A unique **errno** global variable, **ENXIO**, is used to identify check conditions so that the caller knows when to issue the **TMGETSENS** operation. This error is not logged in the system error log by the SCSI device driver. The writer of the calling program must be aware that according to SCSI standards, the **request sense** command must be the next command received by the device following a check-condition error. If any other command is sent to the device by this initiator, the sense data is cleared and the error information lost.

After each **write** subroutine, the target-mode device driver generates the appropriate return value and **errno** global variable. The device driver also updates a status area that is kept for the last command to each device. On certain errors, as well as successful completions, the caller may optionally read this status area to get more detailed error status for the command. The **TMIOSTAT** operation can be used for this purpose. The **errno** global variables covered by this status include **EIO**, **EBUSY**, **ENXIO**, and **ETIMEDOUT**.

Other possible return values for the **errno** global variable include:

Value	Description
EBUSY	SCSI reservation conflict detected. Try again later or make sure device reservation is ended before proceeding.
EFAULT	This is applicable only during data gathering. The **write** operation was unsuccessful due to a kernel service error.
EINTR	Interrupted by signal.
EINVAL	Attempted to execute a **write** operation for a device instance that is not configured, not open, or is not an initiator-mode minor device number.
	Transfer length too long, or could not pin entire transfer. Try command again with a smaller transfer length.
EIO	I/O error occurred. Either an unreproducible error occurred or retries were exhausted without success on an unreproducible error. Perform appropriate error recovery.
ENOCONNECT	Indicates a SCSI bus fault has occurred. The caller should respond by retrying with asynchronous data transfer allowed. This is accomplished by issuing a **TMIOASYNC** operation to this device prior to the retry. If more than one retry is attempted, the **TMIOASYNC** operation should be performed only before the last retry.
ENOMEM	This is applicable only during data gathering. The **write** operation was unsuccessful due to lack of system memory.

Value	Description
ENXIO	SCSI check condition occurred. Execute a **TMGETSENS** operation to get the device sense data and then perform required error recovery.
ETIMEDOUT	The command has timed out. Perform appropriate error recovery.

ioctl Subroutine

The following ioctl operations are provided by the target-mode device driver. Some are specific to either the target-mode device or the initiator-mode device. All require the respective device instance be open for the operation run.

Operation	Description
IOCINFO	Returns a structure defined in the **/usr/include/sys/devinfo.h** file.
TMCHGIMPARM	Allows the caller to change certain parameters used by the target mode device driver for a particular device instance.
TMGETSENS	Runs a SCSI **request sense** command and returns the sense data to the user.
TMIOASYNC	Allows succeeding initiator-mode commands to a particular target-mode device to use asynchronous data transfer.
TMIOCMD	Sends SCSI commands directly to the attached device.
TMIOEVNT	Allows the caller to query the device driver for status on certain events.
TMIORESET	Sends a Bus Device Reset message to an attached target-mode device.
TMIOSTAT	Allows the caller to get detailed status information about the previously-run **write** or **TMGETSENS** ioctl operation.

select Entry Point

The **select** entry point allows the caller to know when a specified event has occurred on one or more target-mode devices. The *events input* parameter allows the caller to specify which of one or more conditions it wants to be notified of by a bitwise OR of one or more flags. The target-mode device driver supports the following **select** events:

Event	Description
POLLIN	Check if received data is available.
POLLPRI	Check if status is available.
POLLSYNC	Return only events that are currently pending. No asynchronous notification occurs.

An additional event, **POLLOUT**, is not applicable and therefore is not supported by the target-mode device driver.

The *reventp output* parameter points to the result of the conditional checks. A bitwise OR of the following flags can be returned by the device driver:

Flag	Description
POLLIN	Received data is available.
POLLPRI	Status is available.

The *chan input* parameter is used for specifying a channel number. This is not applicable for non-multiplexed device drivers and should be set to a value of 0 for the target-mode device driver.

The **POLLIN** event is indicated by the device driver when any data is received for this target instance. A non-blocking **read** subroutine, if subsequently issued by the caller, returns data. For a blocking **read**

subroutine, the read does not return until either the requested length is received or the **send** command completes, whichever comes first.

The **POLLPRI** event is indicated by the device driver when an exceptional event occurs. To determine the cause of the exceptional event, the caller must issue a **TMIOEVNT** operation to the device reporting the **POLLPRI** event.

The possible return value for the **errno** global variable includes:

Value	Description
EINVAL	A specified event is not supported, or the device instance is either not configured or not open.

Error Logging

Errors detected by the target-mode device driver can be one of the following:

- Unreproducible hardware error while receiving data
- Unreproducible hardware error during initiator command
- Unrecovered hardware error
- Recovered hardware error
- Device driver-detected software error

The target-mode device driver passes error-recovery responsibility for most detected errors to the caller. For these errors, the target-mode device driver does not know if this type of error is permanent or temporary. These types of errors are logged as temporary errors.

Only errors the target-mode device driver can itself recover through retries can be determined to be either temporary or permanent. The error is logged as temporary if it succeeds during retry (a recovered error) or as permanent if retries are unsuccessful (an unrecovered error). The return code to the caller indicates success if a recovered error occurs or failure if an unrecovered error occurs. The caller can elect to retry the command or operation, but the probability of retry success is low for unrecovered errors.

NVMe subsystem

Provides device driver support for Non-Volatile Memory Express (NVMe). The device driver supports Peripheral Component Interconnect Express (PCIe) and Fibre Channel (FC) attachment of storage that conforms to the NVMe specification.

The NVMe protocol stack consists of a single device driver that supports interfaces to both the NVMe controller device and corresponding NVMe storage (hdisk) devices.

NVMe storage (hdisk) device driver

Purpose

Supports Peripheral Component Interconnect Express (PCIe) and Fibre Channel (FC) attached Non-Volatile Memory Express (NVMe) storage devices.

Syntax

```
<#include /usr/include/sys/nvme.h>
<#include /usr/include/sys/devinfo.h>
```

Description

The /dev/hdiskn special file provides interfaces to the NVMe storage device driver.

Device-dependent subroutines

The NVMe storage device driver supports the open, close, read, write, and ioctl subroutines.

ioctl subroutine

Along with the IOCINFO operation, the NVMe storage device driver defines operations for NVMe storage devices.

The IOCINFO operation is defined for all device drivers that use the ioctl subroutine, as follows:

The IOCINFO operation returns a devinfo structure. The devinfo structure is defined in the /usr/include/sys/devinfo.h header file. The device type in this structure is DD_SCDISK, and the subtype is DS_PV. The flags field is used to indicate the values DF_SSD and DF_NVME. When the **DF_4B_ALINGED** flag is preset, the flag indicates that all host data buffer addresses must be aligned to a 4 byte address.

NVMe storage ioctl operations

The following ioctl operations are supported for NVMe storage devices:

NVME_PASSTHRU

Provides options to send a **passthru** command to an NVMe storage device. The *arg* parameter for the NVME_PASSTHRU operation is the address of an NVME_PASSTHRU structure that is defined in the /usr/include/sys/nvme.h header file.

Note: You can send an **admin** command only to the adapter device, and an **NVM** command only to the storage (hdisk) device. Otherwise, the commands can result in undefined behavior such as data corruption. The opcodes of all the NVMe commands are unique only within a command set and the opcode value can be used for different operations in different command sets.

When an **NVMe passthru** command is issued to the NVMe storage device, a specific path_id can be specified. If you want to use specific path_id for the **passthru** command, you need to configure both the **NVME_PASS_PASSTHRU** flag in the flags field and the path_id to be used in the path_id field.

You can write the dword_10 to dword_15 data in endian format that is used by the host such that (leftmost) bit 31 is the most significant bit and (rightmost) bit 0 is the least significant bit according to the NVMe specification. For example, to read 0xAC blocks and to set FUA, dword_10 in the passthru structure is set to 0x400000AB.

You must *byte reverse* any two fields in the data that is transferred by using the **passthru** command. For example, to read the name space size (NSZE) from data that is returned by Identify Namespace, bytes 0 - 7 in the data buffer must be *byte reversed*.

The **passthru** command is unsuccessful if the ioctl subroutine returns -1. A return value of -1 indicates that the driver failed to send the command to the controller or the controller did not respond before the timeout occurred. If the errno flag is set to the EINVAL value, the **resp.status** parameter contains a code that indicates the invalid field.

The **passthru** command is successful if the ioctl subroutine returns 0 and if the **resp.status** parameter contains 0. The **passthru** command runs in parallel with commands that are initiated by another user by running read or write operation.

NVMe controller device driver

Purpose

Supports the Non-Volatile Memory Express (NVMe) controller.

Syntax

```
<#include /usr/include/sys/nvme.h>
<#include /usr/include/sys/devinfo.h>
```

Description

The `/dev/nvmen` special file provides interfaces to the NVMe controller device driver.

Device-dependent subroutines

The NVMe controller device driver supports the `open`, `close`, and `ioctl` subroutines only. The `read` and `write` subroutines are not supported by the NVMe controller special file.

ioctl Subroutine

Along with the IOCINFO operation, the NVMe controller device driver defines operations for NVMe controller devices.

The IOCINFO operation is defined for all device drivers that use the `ioctl` subroutine as follows:

- The IOCINFO operation returns a `devinfo` structure. The `devinfo` structure is defined in the `/usr/include/sys/devinfo.h` header file. The device type in this structure is DD_BUS, and the subtype is DS_NVME. The `flags` field is not used and it is set to 0.
- The `devinfo` structure includes unique data such as version information and the data transfer size that is allowed in the maximum initiator mode. The transfer size is specified in bytes.

NVMe controller ioctl operations

The following `ioctl` operations are supported for NVMe controller devices:

NVME_PASSTHRU

Provides options to send a **passthru** command to an NVMe controller device. The **arg** parameter for the NVME_PASSTHRU operation is the address of an NVME_PASSTHRU structure that is defined in the `/usr/include/sys/nvme.h` header file.

Note: You can send an **admin** command only to the adapter device, and an **NVM** command only to the storage (`hdisk`) device. Otherwise, the commands can result in undefined behavior such as data corruption. The opcodes of all the NVMe commands are unique only within a command set and the opcode value can be used for different operations in different command sets.

When an **NVMe passthru** command is issued to the NVMe controller device, a specific `path_id` can be specified. If you want to use specific `path_id` for the **passthru** command, you need to configure both the **NVME_PASS_PASSTHRU** flag in the `flags` field and the `path_id` to be used in the `path_id` field.

You can write the `dword_10` to `dword_15` data in the endian format that is used by the host such that (leftmost) bit 31 is the most significant bit and (rightmost) bit 0 is the least significant bit according to the NVMe specification. For example, to read 0xAC blocks and to set FUA, `dword_10` in the `passthru` structure is set to 0x400000AB.

You must *byte reverse* any fields in the data that is transferred by using the **passthru** command. For example, to read the name space size (NSZE) from data that is returned by Identify Namespace, bytes 0 - 7 in the data buffer must be *byte reversed*.

The **passthru** command is unsuccessful if the `ioctl` subroutine returns -1. A return value of -1 indicates that the driver failed to send the command to the controller or the controller did not respond before the timeout occurred. If the `errno` flag is set to the EINVAL value, the **resp.status** parameter contains a code that indicates the invalid field.

The **passthru** command is successful if the `ioctl` subroutine returns 0 and if the **resp.status** parameter contains 0. The **passthru** command runs in parallel with commands that are initiated by another user by running read or write operation.

NVME_CNTL

Provides the options to submit a control request to the NVMe controller device driver. The **arg** parameter of the NVME_CNTL operation is the address of an `nvme_cntl` structure that is defined in the `/usr/include/sys/nvme.h` header file. The types of control operations that are supported for the NVMe controller device driver are documented in the `nvme_cntl` structure.

USB Subsystem

The protocol stack of the Universal Serial Bus (USB) device driver for the AIX operating system consists of several drivers that communicate with each other in a layered fashion. These layers of drivers in the USB subsystem work together to support the attachment of a range of USB devices, such as flash drives, removable disk drive (RDX), tape, keyboard, mouse, speakers, and optical devices (for example, CD-ROM, CD-R, CD-RW, DVD-R, DVD-RW, and DVD-RAM).

Extensible Host Controller Adapter Device Driver

Purpose

Supports the Universal Serial Bus (USB) 3.0 Extensible Host Controller Interface (xHCI) specification for adapter device drivers.

Syntax

```
#include <sys/hcdi.h>
#include <sys/usbdi.h>
#include <sys/usb.h>
```

Description

The `/dev/usbhcn` special files provide interfaces that allow access to the USB host controller adapter devices. These files manage the adapter resources so that multiple USB client drivers and the USB system (or the protocol driver) can access the USB devices on the same USB host controller adapter simultaneously.

The AIX operating system supports the USB host controllers with various interface architectures, such as the Open Host Controller Interface (OHCI) and the Enhanced Host Controller Interface (EHCI). The binary interface to the USB 3.0 adapters is called the Extensible Host Controller Interface (xHCI). The AIX operating system currently supports the 0.96 and 1.0 versions of the xHCI specification. The xHCI specification defines a new host controller architecture that replaces the existing OHCI or EHCI specification and also extends to new specifications, for example, USB Version 3.0, or later.

The `/usr/lib/drivers/pci/xhcidd` device driver handles the xHCI adapters and the `/usr/lib/methods/cfgxhci` device driver is the corresponding AIX configuration method.

The `max_slots` Object Data Manager (ODM) attribute for the adapter driver specifies the maximum number of USB devices that are supported by an xHCI adapter. The default value of the attribute is 8. You can modify this value to a maximum value of 32 to support more devices.

Note: If the `max_slots` values is set to 8 and if you connect more than 8 USB devices to the USB adapter, the adapter configures only 8 devices. The configuration for the remaining device fails.

Adapter device driver entry point subroutines

The USB adapter device driver supports only the `open`, `close`, `ioctl`, and `config` entry points. The `read` and `write` entry points are not supported.

open and close subroutines

The open subroutine associates the device number, which is specified as a parameter to the open system call, with the internal adapter device structure. If the open subroutine finds an adapter structure, it verifies that the corresponding adapter device is configured and is not marked inactive. If the open subroutine does not find an adapter structure, it returns an error. If the Enhanced Error Handling (EEH) feature is enabled, the open subroutine prevents access to the device when an EEH event is being processed.

ioctl subroutine

The xHCI adapter device driver supports the following `ioctl` suboperation:

Operation	Description
HCD_REGISTER_HC	Registers the call vectors between the USB system (or the protocol driver) and the host controller driver. After the call vectors are registered, all further communication between the USB system (or protocol driver) and the host controller driver is handled by these vectors.

Summary of error conditions returned by the xHCI adapter device driver

The following Transfer Request Block (TRB) completion status codes are returned by the xHCI during status update if the associated error condition is detected. The TRB status values are specified in the xHCI specification. These completion codes in turn are mapped to the following *USBstatus* values:

TRB status	*USBstatus* value	Description
XHCI_TRB_STATUS_BAB_DET_ERR	USBD_STALL	Babbling during transaction
XHCI_TRB_STATUS_BW_ERR	USBD_ERROR	Bandwidth is not available for periodic endpoint connection
XHCI_TRB_STATUS_BW_OVERRUN_ERR	USBD_ERROR	Isochronous transfer descriptor (TD) exceeded bandwidth of the endpoints
XHCI_TRB_STATUS_CMDRING_ABORT_ERR	USBD_ERROR	Command abort operation
XHCI_TRB_STATUS_CMDRING_STOP_ERR	USBD_ERROR	Command ring stopped
XHCI_TRB_STATUS_CTXT_STATE_ERR	USBD_ERROR	Invalid context state change command
XHCI_TRB_STATUS_DATA_BUF_ERR	USBD_ERROR	Overrun or underrun
XHCI_TRB_STATUS_EP_NE_ERR	USBD_ERROR	Endpoint is in a disabled state
XHCI_TRB_STATUS_EVENT_LOST_ERR	USBD_ERROR	Internal event overrun
XHCI_TRB_STATUS_EVTRING_FULL_ERR	USBD_ERROR	Event ring is full
XHCI_TRB_STATUS_INCOMPAT_DEV_ERR	USBD_ERROR	Incompatible device
XHCI_TRB_STATUS_INVALID	USBD_ERROR	Completion update error
XHCI_TRB_STATUS_INVALID_SID_ERR	USBD_ERROR	Invalid stream ID
XHCI_TRB_STATUS_INVALID_STR_TYP_ERR	USBD_ERROR	Invalid stream of context (`Ctxt`) type
XHCI_TRB_STATUS_ISOCH_BUF_OVR_ERR	USBD_ERROR	Isochronous buffer overrun

TRB status	USBstatus value	Description
XHCI_TRB_STATUS_MAXEL_LARGE_ERR	USBD_ERROR	Maximum exit latency is too large
XHCI_TRB_STATUS_MIS_SERV_ERR	USBD_ERROR	Isochronous endpoint is not serviced
XHCI_TRB_STATUS_NOPING_RESP_ERR	USBD_ERROR	No ping response within endpoint service interval time (ESIT)
XHCI_TRB_STATUS_NOSLOTS_ERR	USBD_ERROR	Exceeded maximum slots
XHCI_TRB_STATUS_PARAM_ERR	USBD_ERROR	Context parameter is invalid
XHCI_TRB_STATUS_RESOURCE_ERR	USBD_ERROR	No adequate resources
XHCI_TRB_STATUS_RING_OVERRUN_ERR	USBD_ERROR	Ring overrun
XHCI_TRB_STATUS_RING_UNDERRUN_ERR	USBD_ERROR	Ring underrun
XHCI_TRB_STATUS_SEC_BW_ERR	USBD_ERROR	Secondary bandwidth error
XHCI_TRB_STATUS_SHORT_PKT_ERR	USBD_SUCCESS	The packet size is lesser than the transfer descriptor size in the transfer request.
XHCI_TRB_STATUS_SLOT_DISABLED_ERR	USBD_ERROR	Slot is in a disabled state
XHCI_TRB_STATUS_SPLIT_TR_ERR	USBD_ERROR	Split transaction error
XHCI_TRB_STATUS_STALL_ERR	USBD_STALL	Delay detected on TRB
XHCI_TRB_STATUS_STOP_LEN_ERR	USBD_ERROR	Transfer event length is invalid
XHCI_TRB_STATUS_STOPPED_ERR	USBD_ERROR	Stop endpoint command is received
XHCI_TRB_STATUS_SUCCESS	USBD_SUCCESS	Command success
XHCI_TRB_STATUS_TRB_ERR	USBD_ERROR	TRB parameter error
XHCI_TRB_STATUS_UNDEFINED_ERR	USBD_ERROR	Undefined error condition
XHCI_TRB_STATUS_USB_TSX_ERR	USBD_ERROR	No valid response from the device
XHCI_TRB_STATUS_VF_EVTRING_FULL_ERR	USBD_ERROR	Virtual Function (VF) event ring is full

Call vectors

Whenever the USB configuration method is run, it opens the /dev/usb0 USB system driver (USBD) special file and attempts to register each detected and available USB host controller with the USBD by using a USBD_REGISTER_HC ioctl operation. When the USBD_REGISTER_HC ioctl operation is processed, the USBD opens the host controller driver and requests for the registration of call vectors stored within the host controller driver by using an HCD_REGISTER_HC ioctl operation. After the call vectors are registered with the USBD, all further communication between the USBD and the host controller driver is handled by the call vectors. The summary of call vectors follows:

Call vector	Description
hcdConfigPipes	This call vector is provided by the USBD during the enumeration of USB logical device.
	This call vector supports the xHCD with USBD, however it does not support EHCI or OHCI drivers. It issues a configure endpoint command to the USB device to make the non-control endpoints on the device operational. This call vector is called by the USBD after the configuration selection is complete on the USB device.
hcdDevAlloc	Detects the attachment of a USB logical device. This call vector is provided by the USBD.
	This call vector supports the Extensible Host Controller Driver (xHCD) with USBD, however it does not support EHCI or OHCI drivers. It enables the slot, sets the USB device address, and allocates the HCD driver resources to use the USB device. It returns the USB address value to the USBD. After this call, the default control endpoint on the USB device is enabled to query the USB protocol-specific data.
hcdDevFree	Detects the removal of a USB logical device. This call vector is provided by the USBD.
	This call vector supports the xHCD with USBD, however it does not support EHCI or OHCI drivers. It disables the slot and also deallocates the resources that are allocated by the `hcdDevAlloc` call vector.
hcdGetFrame	Obtains the current frame number from the connected host controller. This call vector is provided by the USBD.
hcdPipeAbort	Cancels the processing of an I/O buffer. The pipe that is specified by the I/O buffer is already halted before the `hcdPipeAbort` call vector is called. This call vector is provided by the USBD.
hcdPipeAddIOB	Increases the maximum number of outstanding I/O buffers. This call vector is provided by the USBD.
hcdPipeClear	Clears, unhalts, and restarts the I/O operations on a specific endpoint. When this call vector is called, the function checks whether the ring is in the halted state.
hcdPipeConnect	Creates a pipe connection to an endpoint on a specific USB device.
hcdPipeDisconnect	Removes the previously established pipe connection with the endpoint on a specific USB device.
hcdPipeHalt	Halts a pipe from the perspective of the host controller. All pending I/O operations remain in a pending state. This call vector is provided by the USBD.
hcdPipeIO	Performs the I/O operations on the USB device. The I/O operations can be of the following transfer types: control, bulk, isochronous, and interrupt.
hcdPipeResetToggle	Resets the data synchronization toggle bit to DATA0. This call vector is provided by the USBD.
hcdPipeStatus	Obtains the status of the pipe from the host perspective. This call vector is provided by the USBD.
hcdShutdownComplete	Informs the host controller driver that the `usbdReqHCshutdown` request is completed. This call vector is provided by the USBD.

Call vector	Description
hcdUnconfigPipes	Detects that a device is removed from the system. This call vector is provided by the USBD.
	This call vector supports the xHCD with USBD, however it does not support EHCI or OHCI drivers. It issues a configure endpoint command with the `Unconfig` bit set to disable all the non-control endpoints on the USB device and deallocate the resources that are allocated by the `hcdConfigPipes` call vector.
hcdUnregisterHC	Unregisters a host controller from the USBD.
usbdBusMap	Maps the memory for bus mastering. This call vector is provided by the xHCD.
usbdPostIOB	Retires an I/O buffer. This call vector is provided by the adapter driver.
usbdReqHCrestart	This call is provided when an error is detected with the adapter and the recovery of adapter driver from this error requires you to restart the adapter.
usbdReqHCshutdown	This call vector is provided during the removal of host controller.
usbdReqHCunregister	The `CFG TERM` function of the adapter driver requests the USBD to unregister the host controller. This call vector is provided during the removal of the host controller.

Enhanced Host Controller Adapter Device Driver

Purpose

Supports the Enhanced Host Controller Interface (EHCI) specification for adapter device drivers.

Syntax

```
#include <sys/hcdi.h>
#include <sys/usbdi.h>
#include <sys/usb.h>
```

Description

The `/dev/usbhc`*n* special files provide interfaces that allow access to the Universal Serial Bus (USB) host controller adapter devices. These files manage the adapter resources so that multiple USB client drivers and the USB system (or the protocol driver) can access the USB devices on the same USB host controller adapter simultaneously.

In the USB 2.0 design, the USB Implementers Forum (USB-IF) implemented single specification, which is known as EHCI, that supports only high-speed data transfers. EHCI-based adapters are multi-function Peripheral Component Interconnect (PCI) devices that consist of virtual host controller functions that are called companion controllers to support Open Host Controller Interface (OHCI) connectivity to USB 1.0 and 1.1 devices. The Object Data Manager (ODM) `alt_usb_ctrl` attribute of the EHCI adapter provides the location values for the companion OHCI controllers.

Adapter device driver entry point subroutines

The USB adapter device driver supports only the open, `close`, `ioctl`, and `config` entry points. The `read` and `write` entry points are not supported.

open and close subroutines

The open subroutine associates the device number, which is specified as a parameter to the open system call, with the internal adapter device structure. If the open subroutine finds an adapter structure, it verifies that the corresponding adapter device is configured and is not marked inactive. If the open subroutine does not find an adapter structure, it returns an error. If the Enhanced Error Handling (EEH) feature is enabled, the open subroutine does not access the device when an EEH event is being processed.

ioctl subroutine

The EHCI adapter device driver supports the following `ioctl` suboperations:

Operation	Description
HCD_REGISTER_HC	Registers the call vectors between the USB system (or the protocol driver) and the host controller driver. After the call vectors are registered, all further communication between the USB system (or the protocol driver) and the host controller driver is handled by these vectors.
HCD_REQUEST_COMPANIONS	Requests port routing information about the companion OHCI host controllers.

Summary of error conditions returned by the EHCI adapter device driver

Possible values of the *USBstatus* return value for the EHCI adapter device driver are as follows:

Error code	Description
USBD_ABORTED	The associated IRP has ended.
USBD_ABORTING	The associated I/O request packet (IRP) is failing.
USBD_ACTIVE	The logical pipe is in operation and is not halted.
USBD_BADHANDLE	The handle that is passed as parameter through the call vector interface is invalid.
USBD_BANDWIDTH	The logical pipe connection has failed because of bandwidth requirements.
USBD_CONNECT	The logical pipe is already connected.
USBD_DATA	Invalid response from the device.
USBD_DISCONNECT	The device that is associated with the transaction is disconnected or removed.
USBD_ERROR	General error condition.
USBD_HALTED	The logical pipe that is associated with the transaction is halted.
USBD_POWER	The device exceeded power budget.
USBD_SPEED	The port reset operation has failed because of device speed mismatch.
USBD_STALL	The logical pipe that is associated with the transaction is delayed.
USBD_TIMEOUT	The I/O operation has timed out.

Call vectors

Whenever the USB configuration method is run, it opens the /dev/usb0 USB system driver (USBD) special file, and attempts to register each detected and available USB host controller with the USBD by using a USBD_REGISTER_HC `ioctl` operation. When the USBD_REGISTER_HC `ioctl` operation is processed, the USBD opens the host controller driver and requests for the registration of call vectors

that are stored within the host controller driver by using an `HCD_REGISTER_HC ioctl` operation. After the call vectors are registered with the USBD, all further communication between the USBD and the host controller driver is handled by the call vectors. The summary of call vectors follows:

Call vector	Description
hcdGetFrame	Obtains the current frame number from the connected host controller. This call vector is provided by the USBD.
hcdPipeAbort	Cancels the processing of an I/O buffer. The pipe that is specified by the I/O buffer is already halted before the `hcdPipeAbort` call vector is called. This call vector is provided by the USBD.
hcdPipeAddIOB	Increases the maximum number of outstanding I/O buffers. This call vector is provided by the USBD.
hcdPipeClear	Clears, unhalts, and restarts the I/O operations on a specific endpoint. When this call vector is called, the function checks whether the ring is in the halted state.
hcdPipeConnect	Creates a pipe connection to an endpoint on a specific USB device.
hcdPipeDisconnect	Removes the previously established pipe connection with the endpoint on a specific USB device.
hcdPipeHalt	Halts a pipe from the perspective of the host controller. All pending I/O operations remain in the pending state. This call vector is provided by the USBD.
hcdPipeIO	Performs the I/O operations on the USB device. The I/O operations can be of the following transfer types: control, bulk, isochronous, and interrupt.
hcdPipeResetToggle	Resets the data synchronization toggle bit to DATA0. This call vector is provided by the USBD.
hcdPipeStatus	Obtains the status of the pipe from the perspective of the host controller. This call vector is provided by the USBD.
hcdShutdownComplete	Informs the host controller driver that the `usbdReqHCshutdown` request is completed. This call vector is provided by the USBD.
hcdUnregisterHC	Unregisters a host controller from the USBD.
usbdBusMap	Maps the memory for bus-mastering. This call vector is provided by the Extensible Host Controller Driver (xHCD).
usbdPostIOB	Retires an I/O buffer. This call vector is provided by the adapter driver.
usbdReqHCrestart	This call vector is provided when an error is detected in the adapter and the recovery of adapter driver from this error requires you to restart the adapter.
usbdReqHCshutdown	This call vector is provided during the removal of the host controller.
usbdReqHCunregister	The CFG TERM function of the adapter driver requests the USBD to unregister the host controller. This call vector is provided during the removal of the host controller.

HCD_REQUEST_COMPANIONS Adapter Device Driver ioctl Operation

Purpose

Requests port routing information about the Open Host Controller Interface (OHCI) companion controllers.

Description

This `ioctl` command is used by the configuration application to determine information about the OHCI companion controller. This information includes the number of root hub ports, the number of companion controllers, and the number of ports per companion controller.

Return values

The following return values are supported:

Value	Description
0	Successful completion.
DEFAULT	The user has insufficient authority to access the data.
EIO	A permanent I/O error occurred.

Open Host Controller Adapter Device Driver

Purpose

Supports the Open Host Controller Interface (OHCI) specification for adapter device drivers.

Syntax

```
#include <sys/hcdi.h>
#include <sys/usbdi.h>
#include <sys/usb.h>
```

Description

The /dev/usbhc*n* special files provide interfaces that allow access to the Universal Serial Bus (USB) host controller adapter devices. These files manage the adapter resources so that multiple USB client drivers and the USB system (or the protocol driver) can access low and full speed of the USB devices on the same USB host controller adapter simultaneously.

The OHCI adapter supports the USB devices (for example, keyboard and mouse) that operate at USB 1.0 and USB 1.1 speeds.

Adapter device driver entry point subroutines

The USB adapter device driver supports only the open, `close`, `ioctl`, and `config` entry points. The `read` and `write` entry points are not supported.

open and close subroutines

The open subroutine associates the device number, which is specified as a parameter to the open system call, with the internal adapter device structure. If the open subroutine finds an adapter structure, it verifies that the corresponding adapter device is configured and is not marked inactive. If the open subroutine does not find an adapter structure, it returns an error. If the Enhanced Error Handling (EEH) feature is enabled, the open subroutine prevents access to the device when an EEH event is being processed.

ioctl subroutine

The OHCI adapter device driver supports the following `ioctl` suboperation:

Operation	Description
HCD_REGISTER_HC	Registers the call vectors between the USB system (or the protocol driver) and the host controller driver. After the call vectors are registered, all further communication between the USB system (or protocol driver) and the host controller driver is handled by these vectors.

Summary of error conditions returned by the OHCI adapter device driver

The following error condition codes for OHCI are translated into a *USBstatus* value to inform the USB protocol driver and the client drivers about the error condition. Possible OHCI error conditions and the corresponding *USBstatus* values follow:

OHCI error condition code	*USBstatus* value	Description
OHCI_CC_BitStuffing	USBD_ERROR	General error condition
OHCI_CC_BufferOverrun	USBD_ERROR	General error condition
OHCI_CC_BufferUnderrun	USBD_ERROR	General error condition
OHCI_CC_CRC	USBD_ERROR	General error condition
OHCI_CC_DataOverrun	USBD_ERROR	General error condition
OHCI_CC_DataToggleMismatch	USBD_ERROR	General error condition
OHCI_CC_DataUnderrun	USBD_ERROR	General error condition
OHCI_CC_DeviceNotResponding	USBD_ERROR	General error condition
OHCI_CC_NotAccessed_0	USBD_ERROR	General error condition
OHCI_CC_NotAccessed_1	USBD_ERROR	General error condition
OHCI_CC_NoError	USBD_SUCCESS	Completion of successful transaction
OHCI_CC_PIDCheckFailure	USBD_ERROR	General error condition
OHCI_CC_STALL	USBD_STALL	The logical pipe is delayed
OHCI_CC_UnexpectedPID	USBD_ERROR	General error condition

Call vectors

Whenever the USB configuration method is run, it opens the /dev/usb0 USB system driver (USBD) special file and attempts to register each detected and available USB host controller with the USBD by using a USBD_REGISTER_HC ioctl operation. When the USBD_REGISTER_HC ioctl operation is processed, the USBD opens the host controller driver and requests for the registration of call vectors stored within the host controller driver by using an HCD_REGISTER_HC ioctl operation. After the call vectors are registered with the USBD, all further communication between the USBD and the host controller driver is handled by the call vectors. The summary of the call vectors follows:

Call vector	Description
hcdGetFrame	Obtains the current frame number from the connected host controller. This call vector is provided by the USBD.

Call vector	Description
hcdPipeAbort	Cancels the processing of an I/O buffer. The pipe that is specified by the I/O buffer is already halted before the `hcdPipeAbort` call vector is called. This call vector is provided by the USBD.
hcdPipeAddIOB	Increases the maximum number of outstanding I/O buffers. This call vector is provided by the USBD.
hcdPipeClear	Clears, unhalts, and restarts the I/O operations on a specific endpoint. When this call vector is called, the function checks whether the ring is in halted state. This call vector is provided by the USBD.
hcdPipeConnect	Creates a pipe connection to an endpoint on a specific USB device.
hcdPipeDisconnect	Removes the previously established pipe connection with the endpoint on a specific USB device.
hcdPipeHalt	Halts a pipe from the perspective of the host controller. All pending I/O operations remain in a pending state. This call vector is provided by the USBD.
hcdPipeIO	Performs I/O operations on the USB device. The I/O operation can be of the following transfer types: control, bulk, isochronous, and interrupt.
hcdPipeResetToggle	Resets the data synchronization toggle bit to DATA0. This call vector is provided by the USBD.
hcdPipeStatus	Obtains the status of the pipe from the host perspective. This call vector is provided by the USBD.
hcdShutdownComplete	Informs the host controller driver that the `usbdReqHCshutdown` request is completed. This call vector is provided by the USBD.
hcdUnregisterHC	Unregisters a host controller from the USBD.
usbdBusMap	Maps memory for bus mastering by the host controller. This call vector is provided by the Extensible Host Controller Driver (xHCD).
usbdPostIOB	Retires an I/O buffer. This call vector is provided by the adapter driver.
usbdReqHCrestart	This call is provided when an error is detected with the adapter and the recovery of adapter driver from this error requires you to restart the adapter.
usbdReqHCshutdown	This call vector is provided during the removal of host controller.
usbdReqHCunregister	The CFG TERM function of the adapter driver requests the USBD to unregister the host controller. This call vector is provided during the removal of the host controller.

HCD_REGISTER_HC Adapter Device Driver ioctl Operation

Purpose

Registers the host controller with the Universal Serial Bus (USB) protocol driver.

Description

This `ioctl` command is issued by the USB system driver (USBD) during the registration of host controller with the USBD. During the processing of this `ioctl` operation, the call vectors of the adapter device driver

are registered with USBD. After the call vectors are registered with the USBD, all further communication between the USBD and the Host Controller Driver (HCD) is handled by these call vectors.

Return values

The following return values are supported:

Value	Description
0	Successful completion.
DEFAULT	Incorrect size of the call vector or incorrect version of the call vector data structure.
EBUSY	Adapter hardware is inaccessible.
EINVAL	Host controller is already registered with the USBD.

USB Audio Device Driver

Purpose

Supports the Universal Serial Bus (USB) audio devices.

Syntax

```
#include <sys/usbdi.h>
```

Description

The USB audio device driver supports isochronous USB devices such as USB audio speakers. Each USB audio device is represented as the following interfaces: audio control and audio streaming. Although these interfaces are associated with the single device, the interfaces are treated as separate devices virtually. The `/dev/paud0` special file is created for audio control interface and the `/dev/paudas0` special file is created for audio streaming interface.

The audio control interface is used to access the internal functions of an audio device. Any request to change the audio controls within the audio function's units or terminals is directed to the audio control interface of the function.

The audio streaming interface can be configured to operate in mono or stereo mode. The number of input channel data streams varies based on the selected mode. Audio streaming interface must have isochronous endpoint. This interface can have alternative settings that can be used to change some characteristics of the endpoint.

Note: You must use external or third-party audio software to stream and play audio files on the supported USB audio devices.

The following table lists the `ioctl` operations:

ioctl operation	Description
AUDIO_INIT	The driver searches the interfaces and alternative settings to determine the setting that can support the requested sample rate, bits per sample, mode, and channels.
AUDIO_STATUS	The driver returns information about its internal data structures.
AUDIO_CONTROL	The driver handles requests to change the audio properties, for example, start, stop, and pause.

ioctl operation	Description
AUDIO_BUFFER	The driver calculates and returns the values that are based on the information about its data structures, the amount of data in buffers, the amount of data in requests, the time delay that is specified in the bDelay field, and general class-specific interface descriptor.
AUDIO_WAIT	The driver waits until the requests for all remaining playback data are complete. If the bDelay field is specified, it waits for that amount of time. This operation must be called just before the AUDIO_STOP operation to avoid interruption in the last remaining samples in the playback buffer.
AUDIO_SET_CHANNELS	The driver updates its copies of the record and playback settings in the driver's internal data structures. • If a record path is active and one of the record settings is changed, the driver sends requests to the USB audio device to change the settings in the units. • If the playback path is active and one of the playback settings is changed, the driver sends requests to the USB audio device to change the settings in the units for the playback and playback rider paths. For the playback path, the master settings volume must be included in the calculations before you set the playback path volume.
AUDIO_GET_CHANNELS	The driver returns information that is based on the four input and one output device models.
AUDIO_CHANNEL_STATUS	The driver returns information that is stored in its internal data structures.
AUDIO_SET_GAIN	The driver updates its copy of the settings in its internal data structures. If a record path is active, the driver sends requests to the USB audio device to change the settings in the units.
AUDIO_MODIFY_LIMITS	The driver updates the values in its internal data structures. If a select() call is pending and one of the conditions to unblock the select() call is met, the select() call is unblocked.
AUDIO_MASTER_VOLUME	The driver saves the new master volume value. It calculates the new unit volume value that is based on the new master volume value and the playback volume value. If playback is active, the driver sends requests to the USB audio device to change the settings in the units for the playback and playback rider paths.

USB Keyboard Client Device Driver

Purpose

Supports the Universal Serial Bus (USB) keyboard devices.

Syntax

```
#include <sys/usbdi.h>
```

Description

The keyboard client consists of a back end that interfaces with the USB system driver (USBD) and a front end that interfaces with the AIX applications such as the low function terminal (LFT) and X server applications. The USB keyboard client driver has no knowledge of the underlying USB adapter hardware. Instead, the client driver sends control requests to the USB keyboard through the USBD and receives input events through the USBD. The keyboard client driver identifies itself as a generic keyboard driver by setting the `devid` field in its Object Data Manager (ODM) predefined data to `030101`. The parent device of the keyboard client is the pseudo device, `usb0`. The keyboard client does not have any child. Each keyboard device that is connected to the AIX system is represented as `/dev/kbd0`, `/dev/kbd1`, and so on.

The USB keyboard client driver supports the attachment of multiple USB keyboard devices. Each device is enumerated in the ODM and is marked as available. The client driver treats all keyboards as a single logical device. Light-emitting diode (LED) settings are sent to all keyboards and input events from all keyboards are sent to a single input ring. State tracking by the client driver ensures that a key does not generate consecutive break events and that typematic delay and repeat are handled appropriately.

Special files (for example, `/dev/kbd0`, `/dev/kbd1`, and so on) are created for each USB keyboard device. If there is at least one available USB keyboard device, an application (typically the LFT or X server application) can open any one of the USB keyboard special files.

Special treatment for the keyboard is provided by the USB system device driver configuration method because of the strict configuration and ordering rules of the graphics subsystem. When both the USB host controller and the graphics adapter are in an available state and no existing keyboard is present, the USBD ensures that at least one USB keyboard instance is defined. The USB keyboard client driver uses the `USBD_OPEN_DEVICE_EXT ioctl` operation to open the device that generates a valid handle even when no USB keyboard is attached to the system. The EAGAIN value is returned by the `ioctl` operation if there is no keyboard device and the client driver treats the device as disconnected. When you plug in a USB keyboard, a reconnect call back is made to the keyboard client by the USBD and the device is initialized allowing input events to flow to the LFT and X server applications.

Device-dependent subroutines

The USB adapter device driver supports only the open, close, ioctl, and `config` subroutines.

open and close subroutines

The open subroutine is used to create a channel between the caller and the keyboard client driver. The keyboard special file supports two such channels. The open subroutine call is processed normally except that the **OFlag** and **Mode** parameters are ignored. The keyboard supports an `fp_open` request from a kernel process. The keyboard client driver is multiplexed for an orderly change of control between the LFT and the X server applications. The most recently opened keyboard channel is the active channel to which the input events are sent. Only one channel can be open in the kernel mode at a time. The USB keyboard client supports the attachment of multiple USB keyboard devices. Thus, one or more special files can be defined. If there is at least one available USB keyboard device, an application (typically the LFT or the X server) can open any one special file of the USB keyboard because the keyboard client driver ignores the minor number specification. However, only two channels can be defined regardless of the number of available USB keyboard devices.

The `close` subroutine call is used to end a channel.

Read and write operations

The keyboard client driver does not support `read` and `write` operations. A `read` or `write` operation to the special file of the driver behaves as if a `read` operation or a `write` operation was made to the `/dev/null` file.

ioctl subroutine

The keyboard device driver supports the following **ioctl** suboperations:

Operation	Description
IOCINFO	Returns a `devinfo` structure, which is defined in the `sys/devinfo.h` header file, that describes the device. The first field of the structure (`devtype`) is set to the `DD_INPUT` value; the remaining structure is set to zero.
KSQUERYID	Queries keyboard device identifier.
KSQUERYSV	Queries keyboard service vector.
KSREGRING	Registers input ring.
KSRFLUSH	Flushes input ring.
KSLED	Sets or resets keyboard LEDs.
KSVOLUME	Sets alarm volume.
KSALARM	Sounds alarm.
KSTRATE	Sets typematic rate.
KSTDELAY	Sets typematic delay.
KSKAP	Enables or disables keep-alive poll.

USB Mass Storage Client Device Driver

Purpose

Supports the Universal Serial Bus (USB) protocol for mass storage and bulk type hard disk, Removable Disk Drive (RDX), flash drives, CD-ROM, DVD-RAM, Blu-ray read-only, and read/write optical memory devices.

Syntax

```
#include <sys/devinfo.h>
#include <sys/scsi.h>
#include <sys/scdisk.h>
#include <sys/ide.h>
#include <sys/usb.h>
#include <sys/usbdi.h>
#include <sys/mstor.h>
```

Description

Typical USB hard disk, RDX, flash drives, CD-ROM, DVD-RAM, Blu-ray read-only, and read/write optical drive operations are implemented by using the open, `close`, `read`, `write`, and `ioctl` subroutines.

Device-dependent subroutines

The USB mass storage device driver supports only the open, `close`, `ioctl`, and `config` subroutines.

open and close subroutines

The openx subroutine is primarily used by the diagnostic commands and utilities. Appropriate authority is required to run the subroutine. If you run the open subroutine without the required authority, the subroutine returns a value of -1 and sets the *errno* global variable to a value of EPERM.

The *ext* parameter that is specified in the *openx* subroutine selects the operation to be used for the target device. The `/usr/include/sys/usb.h` file defines the possible values for the *ext* parameter.

The *ext* parameter can contain any logical combination of the following flag values:

Item	Description
SC_DIAGNOSTIC	Places the selected device in the `Diagnostic` mode. This mode is singularly entrant, which means that only one process at a time can open the device at a time. When a device is in the `Diagnostic` mode, the USB devices are initialized during the open or `close` operations, and error logging is disabled. In the `Diagnostic` mode, only the `close` and `ioctl` subroutine operations are accepted. All other device-supported subroutines return a value of -1 and set the *errno* global variable to a value of EACCES.

A device can be opened in the `Diagnostic` mode only if the target device is not currently opened. If you open a device in the `Diagnostic` mode when the target device is already open, the subroutine returns a value of -1 and sets the *errno* global variable to a value of EACCES. |
| SC_SINGLE | Places the selected device in the `Exclusive Access` mode. Only one process can open a device in the `Exclusive Access` mode at a time.

A device can be opened in the `Exclusive Access` mode only if the device is not currently open. If you open a device in the `Exclusive Access` mode and the device is already open, the subroutine returns a value of -1 and sets the *errno* global variable to a value of EBUSY. If the **SC_DIAGNOSTIC** flag is specified along with the **SC_SINGLE** flag, the device is placed in `Diagnostic` mode. |

readx and writex subroutines

The `readx` and `writex` subroutines are not supported on USB devices. Even if they are called, the *ext* parameter is not processed.

ioctl subroutine

The `ioctl` subroutine operations that are used for the `usbcd` device driver are specific to the following categories of USB devices:

- Common `ioctl` operations for all USB devices
- USB hard disk, flash drive, and RDX devices
- USB CD-ROM and read/write optical devices

Common ioctl operations supported for all USB devices

The following `ioctl` operations are available for hard disk, flash drive, RDX, CD-ROM, and read/write optical devices:

Operation	Description
DKIORDSE	Issues a read command to the device and obtains the target-device sense data when an error occurs. If the DKIORDSE operation returns a value of -1 and if the status_validity field is set to the SC_SCSI_ERROR value, valid sense data is returned. Otherwise, target sense data is omitted.
	The DKIORDSE operation is provided for diagnostic use. It allows the limited use of the target device while operating in an active system environment. The **arg** parameter of the DKIORDSE operation contains the address of a sc_rdwrt structure. This structure is defined in the /usr/include/sys/scsi.h file.
	The devinfo structure defines the maximum transfer size for a read operation. If you transfer more than the maximum limit, the subroutine returns a value of -1 and sets the *errno* global variable to a value of EINVAL.
	Note: The CDIORDSE operation can be substituted for the DKIORDSE operation when the read command is issued to obtain sense data from a CD-ROM device. The DKIORDSE operation is the recommended operation.
DKIOCMD	When the device is successfully opened in the Normal or Diagnostic mode, the DKIOCMD operation can issue any Small Computer System Interface (SCSI) command to the specified device. The device driver does not log any error recovery or failures of this operation.
	The SCSI status byte and the adapter status bytes are returned through the **arg** parameter that contains the address of a sc_iocmd structure, which is defined in the /usr/include/sys/scsi.h file. If the DKIOCMD operation fails, the subroutine returns a value of -1 and sets the *errno* global variable to a nonzero value. In this case, the caller must evaluate the returned status bytes to determine the cause of operation failure and the recovery actions.
	The devinfo structure defines the maximum transfer size for the command. If you transfer more than the maximum value, the subroutine returns a value of -1 and sets the *errno* global variable to a value of EINVAL.

Operation	Description
DKIOCMD (continued)	The following example code issues the DKIOCMD ioctl operation to the usbms0 device to get the SCSI standard inquiry data:

```
       char sense_data[255];
       char *data_buffer=NULL;
       struct sc_iocmd sciocmd;
....

       fd = open("/dev/usbms0", O_RDWR);
       if (fd == -1){
           printf("\niocmd: Open FAIL\n");
           exit(-1);
       }

       memset(&sciocmd, '\0', sizeof(struct scsi_iocmd));
       sciocmd.version = SCSI_VERSION_1;
       sciocmd.timeout_value = 30;
       sciocmd.command_length = 6;
       sciocmd.flags = B_READ;
       sciocmd.autosense_length = 255;
       sciocmd.autosense_buffer_ptr = &sense_data[0];

       sciocmd.data_length = 0xFF;
       sciocmd.buffer = inq_data;
       sciocmd.scsi_cdb[0] = SCSI_INQUIRY;
       sciocmd.scsi_cdb[1] = 0x00; /* Standard Inquiry*/
       sciocmd.scsi_cdb[2] = 0x00;
       sciocmd.scsi_cdb[3] = 0x00;
       sciocmd.scsi_cdb[4] = 0xFF;
       sciocmd.scsi_cdb[5] = 0x00;

       if ((rc=ioctl(fd, DKIOCMD, &sciocmd)) != 0){
           printf("iocmd: Ioctl FAIL errno %d\n",errno);
           printf("status_validity: %x, scsi_status: %x,
adapter_status:%x\n",
                   sciocmd.status_validity, sciocmd.scsi_bus_status,
                   sciocmd.adapter_status);
           hexdump(sense_data, (long)20);
           close(fd);
           exit(-1);
       } else {
           printf("cdiocmd : Ioctl PASS\n");
           if (cmd = SCSI_INQUIRY)
               hexdump(inq_data,0x20);
       }

       close(fd);
```

Operation	Description
DKIOLCMD	When the device is successfully opened in the `Normal` or `Diagnostic` mode, the DKIOLCMD operation can issue any SCSI command to the specified device. The device driver does not log any error recovery failures of this operation.
	This `ioctl` operation is similar to the DKIOCMD16 operation that is used to issue 16-byte SCSI commands to the USB mass storage device.
	The SCSI status byte and the adapter status bytes are returned through the **arg** parameter that contains the address of a `sc_iocmd16cdb` structure. This structure is defined in the `/usr/include/sys/scsi.h` file. If the DKIOLCMD operation fails, the subroutine returns a value of -1 and sets the *errno* global variable to a nonzero value. In this case, the caller must evaluate the returned status bytes to determine the cause of operation failure and the recovery actions.
	On completion of the `DKIOLCMD ioctl` request, the residual field indicates the leftover data that the device did not fully satisfy for this request. On a successful completion, the residual field indicates that the device does not have all of the data that is requested or the device has less amount of data than requested. On a request failure, you must check the `status_validity` field to determine whether a valid SCSI bus problem exists. In this case, the residual field indicates the number of bytes that the device failed to complete for this request.
	The `devinfo` structure defines the maximum transfer size for the command. If you transfer more than the maximum value, the subroutine returns a value of -1 and sets the *errno* global variable to a value of EINVAL.

Operation	Description
DKIOLCMD (continued)	The following example code issues the DKIOLCMD ioctl operation to the usbms0 device to get the SCSI standard inquiry data:

```
        char sense_data[255];
        char *data_buffer=NULL;
        struct sc_iocmd16cdb sciocmd;
....

        fd = open("/dev/usbms0", O_RDWR);
        if (fd == -1){
            printf("\niocmd: Open FAIL\n");
            exit(-1);
        }

        memset(&sciocmd, '\0', sizeof(struct scsi_iocmd));
        sciocmd.version = SCSI_VERSION_1;
        sciocmd.timeout_value = 30;
        sciocmd.command_length = 6;
        sciocmd.flags = B_READ;
        sciocmd.autosense_length = 255;
        sciocmd.autosense_buffer_ptr = &sense_data[0];

        sciocmd.data_length = 0xFF;
        sciocmd.buffer = inq_data;
        sciocmd.scsi_cdb[0] = SCSI_INQUIRY;
        sciocmd.scsi_cdb[1] = 0x00; /* Standard Inquiry*/
        sciocmd.scsi_cdb[2] = 0x00;
        sciocmd.scsi_cdb[3] = 0x00;
        sciocmd.scsi_cdb[4] = 0xFF;
        sciocmd.scsi_cdb[5] = 0x00;

        if ((rc=ioctl(fd, DKIOCMD, &sciocmd)) != 0){
            printf("iocmd: Ioctl FAIL errno %d\n",errno);
            printf("status_validity: %x, scsi_status: %x,
adapter_status:%x\n",
                    sciocmd.status_validity, sciocmd.scsi_bus_status,
                    sciocmd.adapter_status);
            hexdump(sense_data, (long)20);
            close(fd);
            exit(-1);
        } else {
            printf("cdiocmd : Ioctl PASS\n");
            if (cmd = SCSI_INQUIRY)
                hexdump(inq_data,0x20);
        }

        close(fd);
```

Operation	Description
DK_PASSTHRU	When the device is successfully opened, the DK_PASSTHRU operation can issue any SCSI command to the specified device. The device driver performs limited error recovery if this operation fails. The DK_PASSTHRU operation differs from the DKIOCMD operation such that it does not require an openx command with the ext argument of the SC_DIAGNOSTIC field. Because of this, the DK_PASSTHRU operation can be issued to devices that are in use by other operations.
	The SCSI status byte and the adapter status bytes are returned through the **arg** parameter that contains the address of a sc_passthru structure. This structure is defined in the /usr/include/sys/scsi.h file. If the DK_PASSTHRU operation fails, the subroutine returns a value of -1 and sets the *errno* global variable to a nonzero value. In this case, the caller must evaluate the returned status bytes to determine the cause of operation failure and the recovery actions.
	If a DK_PASSTHRU operation fails because a field in the sc_passthru structure has an invalid value, the subroutine returns a value of -1 and set the *errno* global variable to EINVAL. The einval_arg field is set to the field number (starting with 1 for the version field) of the field that had an invalid value. A value of 0 for the einval_arg field indicates that no additional information about the failure is available.
	The version field of the sc_passthru structure can be set to the value of SCSI_VERSION_2 and you can specify the following fields:
	• The variable_cdb_ptr field is a pointer to a buffer that contains the *cdb* variable.
	• The variable_cdb_length field determines the length of the *cdb* variable to which the variable_cdb_ptr field points.
	On completion of the DK_PASSTHRU request, the residual field indicates the leftover data that the device did not fully satisfy for this request. On a successful completion, the residual field indicates that the device does not have all of the data that is requested or the device has less amount of data than requested. On a request failure, you must check the status_validity field to determine if a valid SCSI bus problem exists. In this case, the residual field indicates the number of bytes that the device failed to complete for this request.
	The devinfo structure defines the maximum transfer size for the command. If an attempt is made to transfer more than the maximum transfer size, the subroutine returns a value of -1, sets the *errno* global variable to a value of EINVAL, and sets the einval_arg field to a value of SC_PASSTHRU_INV_D_LEN. These values are defined in the /usr/include/sys/scsi.h file.
	Note: If you call the DK_PASSTHRU operation as a non-root user, the operation fails with the EACCES error value instead of the EPERM value.

Operation	Description
DK_PASSTHRU (continued)	The following example code issues the DK_PASSTHRU `ioctl` operation to the usbms0 device to get the SCSI standard inquiry data:

```
      char sense_data[255];
      char *data_buffer=NULL;
      struct sc_passthru sciocmd;
....

      fd = open("/dev/usbms0", O_RDWR);
      if (fd == -1){
          printf("\npassthru: Open FAIL\n");
          exit(-1);
      }

      memset(&sciocmd, '\0', sizeof(struct sc_passthru));
      sciocmd.version = SCSI_VERSION_1;
      sciocmd.timeout_value = 30;
      sciocmd.command_length = 6;
      sciocmd.autosense_length = 255;
      sciocmd.autosense_buffer_ptr = &sense_data[0];

      sciocmd.data_length = 0xFF;
      sciocmd.buffer = inq_data;

      sciocmd.flags = B_READ;

      sciocmd.scsi_cdb[0] = SCSI_INQUIRY;
      sciocmd.scsi_cdb[1] = 0x00; /* Standard Inquiry*/
      sciocmd.scsi_cdb[2] = 0x00;
      sciocmd.scsi_cdb[3] = 0x00;
      sciocmd.scsi_cdb[4] = 0xFF;
      sciocmd.scsi_cdb[5] = 0x00;

      if ((rc=ioctl(fd, DK_PASSTHRU, &sciocmd)) != 0){
          if (sciocmd.adap_set_flags & SC_AUTOSENSE_DATA_VALID) {
              /* look at sense data */
          } /* end SC_AUTOSENSE_DATA_VALID */

          printf("passthru: Ioctl FAIL errno %d\n",errno);
          printf("status_validity: %x, scsi_status: %x,
adapter_status:%x\n",
                  sciocmd.status_validity, sciocmd.scsi_bus_status,
                  sciocmd.adapter_status);
          printf("Residual: %x\n", sciocmd.residual);
          exit(-1);
      } else {
          printf("passthru: Ioctl PASS\n");
          printf("status_validity: %x, scsi_status: %x,
adapter_status:%x\n",
                  sciocmd.status_validity, sciocmd.scsi_bus_status,
                  sciocmd.adapter_status);
          printf("Residual: %x\n", sciocmd.residual);
          /* inq_data buffer has valid Standard Inquiry data */
      }
```

ioctl operations for USB hard disk, flash drive, and RDX devices

The following `ioctl` operations are available for USB hard disk, flash drive, and RDX devices only:

Operation	Description

IOCINFO	Returns the `devinfo` structure that is defined in the `/usr/include/sys/devinfo.h` file. The `IOCINFO` operation is the only operation that is defined for all device drivers that use the `ioctl` subroutine. The following values are returned:
	
	``devinfo.devtype = DD_SCDISK;
	devinfo.flags =(uchar)DF_RAND;
	devinfo.devsubtype = 0x00;
	devinfo.un.scdk.max_request =
	Maximum_transfer_supported_by_usbcd_driver;
	devinfo.un.scdk.numblks = Largest_LBA_supported_by_device+1;
	devinfo.un.scdk.blksize = Block_size_set_for_the_USB_Disk/Flash/
	RDX_Device;```

DKPMR	Issues an SCSI prevent media removal (PMR) command when the device is successfully opened. This command prevents media from being ejected until the device is closed, powered off and restarted, or until a DKAMR operation is issued. The `arg` parameter for the DKAMR operation is null. If the DKAMR operation is successful, the subroutine returns a value of 0. If the device is an SCSI hard disk, the DKAMR operation fails, the subroutine returns a value of -1, and sets the *errno* global variable to a value of EINVAL. If the DKAMR operation fails for any other reason, the subroutine returns a value of -1 and sets the *errno* global variable to a value of EIO. **Note:** This function is provided to support the USB RDX devices that support ejecting the media cartridges.
DKAMR	Issues an allow media removal (AMR) command when the device is successfully opened. The media can then be ejected by using either the driver's eject button or the DKEJECT operation. The `arg` parameter for this `ioctl` operation is null. If the DKAMR operation is successful, the subroutine returns a value of 0. If the device is an SCSI hard disk, the DKAMR operation fails. In addition, the subroutine returns a value of -1 and sets the *errno* global variable to a value of EINVAL. For any other cause of failure of this operation, the subroutine returns a value of -1, and sets the *errno* global variable to a value of EIO. **Note:** This function is provided to support the USB RDX devices that support ejecting the media cartridges.

ioctl operations for CD-ROM and read/write optical devices

The following `ioctl` operations are available for CD-ROM and read/write optical devices:

Operation	Description

IOCINFO	Returns the `devinfo` structure that is defined in the `/usr/include/sys/devinfo.h` file. The `IOCINFO` operation is the only operation that is defined for all device drivers that use the `ioctl` subroutine. The following values are returned:
	
	``devinfo.devtype = DD_CDROM;
	devinfo.flags = (uchar)DF_RAND;
	devinfo.devsubtype = 0x00;
	devinfo.un.idecd.numblks =
	  Largest logical block addressing (LBA) supported by device + 1;
	devinfo.un.idecd.blksize = Block size set for the USB Disk, flash,
	or RDX device;```

Operation	Description
IDEPASSTHRU	Issues an AT Attachment Packet Interface (ATAPI) command to the specified device when the device is successfully opened. The IDEPASSTHRU operation does not require an **openx** command with the `ext` argument of the `SC_DIAGNOSTIC` value. Therefore, an IDEPASSTHRU operation can be issued to devices that are in use by other operations. The AT Attachment (ATA) status bytes and the ATA error bytes are returned through the **arg** parameter. This parameter contains the address of an `ide_ata_passthru` structure that is defined in the `/usr/include/sys/ide.h` file. If the IDEPASSTHRU operation fails, the subroutine returns a value of `-1` and sets the *errno* global variable to a nonzero value. In this case, the caller evaluates the returned status bytes to determine the cause of operation failure and the recovery actions. If the IDEPASSTHRU operation fails, the device driver performs limited error recovery. If this operation fails because a field in the `ide_ata_passthru` structure has an invalid value, the subroutine returns a value of `-1` and sets the *errno* global variable to `EINVAL`. On successful completion of the IDEPASSTHRU request, the residual field indicates that the device does not have all of the data that is requested, or the device has less than the amount of data that is requested. If the IDEPASSTHRU request fails, the residual field indicates the number bytes that the device failed to complete for this request.

Operation	Description

IDEPASSTHRU (continued)	The following example code issues an SCSI inquiry command that uses the IDEPASSTHRU operation:
	
	``c
	    struct ide_atapi_passthru atapicmd;
	    char inq_buffer[255];
	    uchar sense_data[255];
	
	    /* set up the arg parameter block */
	    memset(&atapicmd, '\0', sizeof(struct ide_atapi_passthru));
	    memset(sense_data, '\0', 255);
	
	    atapicmd.ide_device = 0;
	    atapicmd.flags = IDE_PASSTHRU_READ;
	    atapicmd.timeout_value = 30;
	    atapicmd.rsv0 = IDE_PASSTHRU_VERSION_01;
	    atapicmd.rsv1 = 0;
	    atapicmd.atapi_cmd.length = 12;
	    atapicmd.atapi_cmd.resvd = 0;
	    atapicmd.atapi_cmd.resvd1 = 0;
	    atapicmd.atapi_cmd.resvd2 = 0;
	
	    atapicmd.data_ptr = inq_buffer;
	    atapicmd.buffsize = 0xFF;
	
	    atapicmd.atapi_cmd.packet.opcode = SCSI_INQUIRY;
	    atapicmd.atapi_cmd.packet.byte[0] = (0x00 | vpd) ; /*Standard
	Inquiry */
	    atapicmd.atapi_cmd.packet.byte[1] = page_code; /*Page Code-Valid
	if vpd=1 */
	    atapicmd.atapi_cmd.packet.byte[2] = 0x00;
	    atapicmd.atapi_cmd.packet.byte[3] = 0xFF;
	    atapicmd.atapi_cmd.packet.byte[4] = 0x00;
	
	    atapicmd.sense_data = sense_data;
	    atapicmd.sense_data_length = 255;
	
	    fd = openx("/dev/cd0", O_RDWR, NULL, SC_DIAGNOSTIC);
	    if (fd == -1) {
	        printf("IDEPASSTHRU: Openx failed with errno %x \n",
	errno);
	        exit(-1);
	    }
	``
	
	``c
	   if ((rc = ioctl(fd, IDEPASSTHRU, &atapicmd) != 0)) {
	        printf("IDEPASSTHRU: IOCTL Failed");
	        printf("errno %d\n",errno);
	        printf("ata_status: %x, ata_error:%x\n",
	             atapicmd.ata_status, atapicmd.ata_error);
	        close(fd);
	        exit(-1);
	   } else {
	        printf("IDEPASSTHRU : Ioctl PASS\n");
	        printf("ata_status: %x, ata_error: %x\n",
	             atapicmd.ata_status, atapicmd.ata_error);
	   }
	   close(fd);
	``

DKPMR	Issues a Small Computer System Interface (SCSI) prevent media removal command when the device is successfully opened. This command prevents media from ejecting until the device is closed, powered off and then powered on, or until a DKAMR operation is issued. The **arg** parameter for the DKPMR operation is null. If the DKPMR operation is successful, the subroutine returns a value of 0. If the device is an SCSI hard disk, the DKPMR operation fails, the subroutine returns a value of -1, and sets the *errno* global variable to a value of EINVAL. If the DKPMR operation fails because of any other reason, the subroutine returns a value of -1 and sets the *errno* global variable to a value of EIO.

Operation	Description
DKAMR	Issues an allow media removal command when the device is successfully opened. The media can be ejected by using either the drives eject button or the DKEJECT operation. The **arg** parameter for this operation is null. If the DKAMR operation is successful, the subroutine returns a value of 0. If the device is an SCSI hard disk, the DKAMR operation fails, and the subroutine returns a value of -1 and sets the *errno* global variable to a value of EINVAL. For any other cause of operation failure, the subroutine returns a value of -1 and sets the *errno* global variable to a value of EIO.
DKEJECT	Issues an eject media command to the drive when the device is successfully opened. The **arg** parameter for this operation is null. If the DKEJECT operation is successful, the subroutine returns a value of 0. If the device is an SCSI hard disk, the DKEJECT operation fails, the subroutine returns a value of -1, and sets the *errno* global variable to a value of EINVAL. For any other cause of operation failure, the subroutine returns a value of -1 and sets the *errno* variable to a value of EIO.
DKAUDIO	Issues a play audio command to the specified device and controls the volume on the device's output ports. Play audio commands can play, pause, resume, stop, determine the number of tracks, and determine the status of a current audio operation. The DKAUDIO operation plays audio only through the CD-ROM drive's output ports. The **arg** parameter of this operation is the address of a `cd_audio_cmds` structure that is defined in the `/usr/include/sys/scdisk.h` file. Exclusive access mode is required. If the DKAUDIO operation is attempted when the device's audio-supported attribute is set to No, the subroutine returns a value of -1 and sets the *errno* global variable to a value of EINVAL. If the DKAUDIO operation fails, the subroutine returns a value of -1 and sets the *errno* global variable to a nonzero value. In this case, the caller must evaluate the returned status bytes to determine the cause of operation failure and recovery actions.

DK_CD_MODE	Issues one of the following commands:
	
	CD_GET_MODE
	    Returns the current CD-ROM data mode in the `cd_mode_form` field of the `mode_form_op` structure when the device is successfully opened.
	
	CD_CHG_MODE
	    Changes the CD-ROM data mode to the mode that is specified in the `cd_mode_form` field of the `mode_form_op` structure when the device is successfully opened in the exclusive access mode.
	
	If a CD-ROM is not configured for different data modes by using the mode-select density codes, and if you change the CD-ROM data mode by setting the action field of the `change_mode_form` structure to the `CD_CHG_MODE` command, the subroutine returns a value of -1 and sets the *errno* global variable to a value of EINVAL. Attempts to change the CD-ROM mode to any of the DVD modes also results in a return value of -1 and the *errno* global variable is set to EINVAL. If the DK_CD_MODE operation for the CD_CHG_MODE command is attempted when the device is not in exclusive access mode, the subroutine returns a value of -1 and sets the *errno* global variable to a value of EACCES. For any other cause of operation failure, the subroutine returns a value of -1 and sets the *errno* global variable to a value of EIO.

Device hardware requirements

USB hard disk, flash drive, RDX, CD-ROM, and read/write optical drives have the following hardware requirements:

- These drives must support a block size of 512 bytes per block.
- If mode sense is supported, the write-protection (WP) bit must also be supported for sequential access memory (SAM) hard disks and read/write optical drives.
- USB hard disks, flash drives, RDX, and read/write optical drives must report the hardware retry count in bytes of the request sense data for recovered errors. If the USB hard disk or read/write optical drive does not support this feature, the system error log might indicate premature drive failure.
- USB CD-ROM and read/write optical drives must support the 10-byte SCSI read command.
- USB hard disks, flash drives, RDX, and read/write optical drives must support the SCSI write and verify command and the 6-byte SCSI write command.
- The read/write optical drive must set the format options valid (FOV) bit to 0 for the defect list header of the SCSI format unit command to use the format command operation. If the drive does not support this feature, you can write an application for the drive so that it formats the media by using the DKFORMAT operation.
- If a USB CD-ROM drive uses CD_ROM Data Mode 1 format, it must support a block size of 512 bytes per block.
- If a USB CD-ROM drive uses CD_ROM data Mode 2 Form 1 format, it must support a block size of 2048 bytes per block.
- If a USB CD-ROM drive uses CD_ROM data Mode 2 Form 2 format, it must support a block size of 2336 bytes per block.
- If a USB CD-ROM drive uses CD_DA mode, it must support a block size of 2352 bytes per block.
- To control the volume by using the DKAUDIO (play audio) operation, the device must support the SCSI-2 mode data page 0xE.
- To use the DKAUDIO (play audio) operation, the device must support the following SCSI-2 optional commands:
  - read sub-channel
  - pause resume
  - play audio mail summary file (.msf)
  - play audio track index
  - read table of contents (TOC)

Note: Only the International Organization for Standardization (ISO) file system (read-only ISO 9660), Universal Disk Format (UDF) file system Version 2.01, or earlier, are supported on USB devices for the AIX operating system. However, you can create a system backup or data archival on the drives by using the **mksysb**, **tar**, **cpio**, **backup**, or **restore** commands. You can also use the **dd** command to add the ISO images to the drives.

To use the USB flash drive, RDX, CD-ROM, DVD-RAM, and Blu-ray read-only devices, install the following device package:

```
devices.usbif.08025002
```

The AIX operating system does not support plug-and-play feature for USB devices. To make a flash drive, RDX, CD-ROM, Blu-ray, or DVD-RAM drive available to the AIX users, a root user must connect the drive to a system USB port and run the following command:

```
# cfgmgr -l usb0
```

Note: Use caution when you remove the flash drives from ports. If the drives are not properly closed or unmounted before you remove the drives, the data on the drives can be corrupted.

After you remove the drives, the drives remain in the available state in the Object Data Manager (ODM) until the root user runs the following command:

```
# rmdev -l usbmsn
```

or

```
#rmdev -l cdn
```

When a drive is in the available state, you can reconnect the drive to the system, and the drive can be remounted or reopened. If a drive is disconnected from a system USB port while it is still open for a user, that drive is not reusable until you close and reopen it.

AIX Version 6.1 with the 6100-06 Technology Level recognizes and configures USB attached Blu-ray drives as read-only. The AIX operating system does not support the write operation to CD, DVD, or Blu-ray media that are present in the USB Blu-ray drive. Although the write operation is not prevented (if the drive is write-capable), no support is provided for any issues that are encountered during the write operation.

The capability of the AIX operating system to operate on USB original equipment manufacturer (OEM) flash drive, Blu-ray, and optical devices is validated against a sample of industry standard OEM USB devices that are compliant with the USB standards. You might encounter issues with certain USB devices that are not compliant and the AIX operating system does not provide any support for those issues.

Error Conditions for USB Mass Storage Client Device Driver

Possible *errno* values for `ioctl`, `open`, `read`, and `write` subroutines when you use the `scsidisk` device driver include the following values:

Value	Description
EACCES	Indicates one of the following conditions: • An attempt was made to open a device that is currently open in the `Diagnostic` or `Exclusive Access` mode. • An attempt was made to open a `Diagnostic` mode session on a device that is already open. • You attempted to run a subroutine other than an `ioctl` or `close` subroutine while in `Diagnostic` mode. • A `DKIOLCMD` operation was attempted on a device that is not in the `Diagnostic` mode. • A `DK_CD_MODE ioctl` subroutine operation was attempted on a device that is not in the `Exclusive Access` mode.
EBUSY	Indicates one of the following conditions: • An attempt was made to open a session in the `Exclusive Access` mode on a device that is already opened. • The target device is reserved by another initiator.
EFAULT	Indicates an invalid user address.
EFORMAT	Indicates that the target device has unformatted media or the media is in an incompatible format.
EINPROGRESS	Indicates that a CD-ROM drive has a play-audio operation in progress.

Value	Description
EINVAL	Indicates one of the following circumstances:
	• A DKAUDIO (play-audio) operation was attempted for a device that is not configured to use the SCSI-2 play-audio commands.
	• The read or write subroutine supplied an *n*byte parameter that is not an even multiple of the block size.
	• A sense data buffer length of greater than 255 bytes is not valid for a DKIORDSE ioctl subroutine operation.
	• The data buffer length exceeded the maximum value that is defined in the devinfo structure for a DKIORDSE or DKIOLCMD ioctl subroutine operation.
	• An unsupported ioctl subroutine operation was attempted.
	• An attempt was made to configure a device that is still open.
	• An invalid configuration command is provided.
	• A DKPMR (prevent media removal), DKAMR (allow media removal), or DKEJECT (eject media) command was sent to a device that does not support removable media.
	• A DKEJECT (eject media) command was sent to a device that currently has its media locked in the drive.
	• The data buffer length exceeded the maximum value that is defined for a strategy operation.
EIO	Indicates one of the following circumstances:
	• The target device cannot be located or is not responding.
	• The target device indicates an unrecoverable hardware error.
EMEDIA	Indicates one of the following circumstances:
	• The target device indicates an unrecoverable media error.
	• The media was changed.
EMFILE	Indicates that an open operation was attempted for an adapter that already has the maximum permissible number of opened devices.
ENODEV	Indicates one of the following circumstances:
	• An attempt was made to access an undefined device.
	• An attempt was made to close an undefined device.
ENOTREADY	Indicates that there is no media in the drive.
ENXIO	Indicates one of the following circumstances:
	• The ioctl subroutine supplied an invalid parameter.
	• A read or write operation was attempted beyond the end of the hard disk.
EPERM	Indicates that the attempted subroutine requires appropriate authority.
ESTALE	Indicates that a read-only optical disk was ejected (without first being closed by the user) and then either reinserted or replaced with a second optical disk.

Value	Description
ETIMEDOUT	Indicates that an I/O operation exceeded the specified timer value.
EWRPROTECT	Indicates one of the following circumstances: • An open operation that requires read/write mode was attempted on a read-only media. • A `write` operation was attempted to a read-only media.

Reliability and serviceability information

USB hard disk, flash drive, RDX devices, CD-ROM drives, and read/write optical drives return the following errors:

Error	Description
ABORTED COMMAND	Indicates that the device ended the command.
ADAPTER ERRORS	Indicates that the adapter returned an error.
GOOD COMPLETION	Indicates that the command completed successfully.
HARDWARE ERROR	Indicates that an unrecoverable hardware failure occurred when the command was run or during a self-test.
ILLEGAL REQUEST	Indicates an invalid command or command parameter.
MEDIUM ERROR	Indicates that the command ended with an unrecoverable media error condition.
NOT READY	Indicates that the logical unit is offline or the media is missing.
RECOVERED ERROR	Indicates that the command was successful after some recovery was applied.
UNIT ATTENTION	Indicates that the device is reset or the power is turned on.

The fields that are defined in the error record template for hard disk, flash drive, RDX, CD-ROM, and read/write optical media errors are logged as per the following structure:

```
/* Bulk transfer cmd and status blocks */
typedef struct mstor_cbw {
    uint32_t cbw_signature;     /* Always "USBC" little endian */
    uint32_t cbw_tag;           /* Command identification  */
    fld32_t cbw_dlen;           /* Data length  */
    uchar cbw_flags;            /* Indicates data in or data out */
    uchar cbw_lun;              /* Logical unit number, 0-15  */
    uchar cbw_cblen;            /* Significant bytes of the cmd blk */
    uchar cbw_cb[16];           /* Command block itself  */
    uchar cbw_rsvd;
} mstor_cbw_t;

/* For error logging */
struct mstor_err_rec {
    struct err_rec0 log;
    uint cmd_error;
    mstor_cbw_t cbw;
    char sense_data[128];
};

Error record values for media errors

Value	Description
Comment	Indicates hard disk, flash drive, RDX, CD-ROM, or read/write optical media error.
Class	Equals a value of H that indicates a hardware error.
Report	Equals a value of True that indicates this error must be included when an error report is generated.
Log	Equals a value of True that indicates an error log entry must be created when this error occurs.
Alert	Equals a value of False that indicates this error cannot have an alert.
Err_Type	Equals a value of Perm that indicates a permanent failure.
Err_Desc	Equals a value of 1312 that indicates a disk operation failure.
Prob_Causes	Equals a value of 5000 that indicates media.
User_Causes	Equals a value of 5100 that indicates the media is defective.
User_Actions	Equals the following values: • 1601, which indicates the removable media must be replaced and tried again. • 00E1, which instructs to perform problem determination procedures.
Inst_Causes	None.

Value	Description
Inst_Actions	None.
Fail_Causes	Equals the following values: • 5000, which indicates a media failure. • 6310, which indicates a disk drive failure.
Fail_Actions	Equals the following values: • 1601, which indicates that the removable media must be replaced and tried again. • 00E1, which instructs to perform problem determination procedures.
Detail_Data	Equals a value of 156, 11, HEX. This value indicates hexadecimal format. **Note:** The `Detail_Data` field in the `err_rec` structure contains the `mstor_err_rec` structure. The `err_rec` field is defined in the `/usr/include/sys/errids.h` file. The `Detail_Data` field follows the same legend as mentioned in the preceding structure example.

Refer to the Small Computer System Interface (SCSI) specifications for the format of the request-sense data for a particular device.

Error record values for hardware errors

The fields that are defined in the error record template for hard disk, CD-ROM, and read/write optical hardware errors and for hard-aborted command errors are listed in the following table:

Value	Description
Comment	Indicates hard disk, flash drive, RDX, CD-ROM, or read/write optical hardware error.
Class	Equals a value of H that indicates a hardware error.
Report	Equals a value of True that indicates this error must be included when an error report is generated.
Log	Equals a value of True that indicates an error log entry must be created when this error occurs.
Alert	Equals a value of False that indicates this error cannot be alerted.
Err_Type	Equals a value of Perm that indicates a permanent failure.
Err_Desc	Equals a value of 1312 that indicates a disk operation failure.
Prob_Causes	Equals a value of 6310 that indicates disk drive.
User_Causes	None.
User_Actions	None.
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	Equals the following values: • 6310, which indicates a disk drive failure. • 6330, which indicates a disk drive electronics failure.
Fail_Actions	Equals a value of 00E1 that indicates problem-determination procedures must be performed.

Value	Description
Detail_Data	Equals a value of 156, 11, HEX. This value indicates hexadecimal format.
	Note: The `Detail_Data` field in the `err_rec` structure contains the `mstor_err_rec` structure. The `err_rec` field is defined in the `/usr/include/sys/errids.h` file. It follows the same legend as mentioned in the preceding structure example.

Error record values for adapter-detected hardware failures

The following fields are defined in the error record template for hard disk, CD-ROM, and read/write optical media errors and for adapter-detected hardware errors:

Value	Description
Comment	Indicates adapter-detected hard disk, flash drive, RDX, CD-ROM, or read/write optical hardware failure.
Class	Equals a value of H that indicates a hardware error.
Report	Equals a value of True that indicates that this error must be included when an error report is generated.
Log	Equals a value of True that indicates that an error-log entry must be created when this error occurs.
Alert	Equals a value of False that indicates this error cannot be alerted.
Err_Type	Equals a value of Perm that indicates a permanent failure.
Err_Desc	Equals a value of 1312 that indicates a disk operation failure.
Prob_Causes	Equals the following values: • 3452, which indicates a device cable failure • 6310, which indicates a disk drive failure
User_Causes	None.
User_Actions	None.
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	Equals the following values: • 3452, which indicates a storage device cable failure • 6310, which indicates a disk drive failure • 6330, which indicates a disk-drive electronics failure
Fail_Actions	Equals a value of 0000 that indicates that the problem-determination procedures must be performed.
Detail_Data	Equals a value of 156, 11, HEX. This value indicates hexadecimal format.
	Note: The `Detail_Data` field in the `err_rec` structure contains the `mstor_err_rec` structure. The `err_rec` field is defined in the `/usr/include/sys/errids.h` file. It follows the same legend as mentioned in the preceding structure example.

Error record values for recovered errors

The following fields are defined in the error record template for hard disk, CD-ROM, and read/write optical media recovered errors:

Item	Description
Comment	Indicates hard disk, CD-ROM, or read/write optical recovered error.
Class	Equals a value of H that indicates a hardware error.
Report	Equals a value of True that indicates this error must be included when an error report is generated.
Log	Equals a value of True that indicates an error log entry must be created when this error occurs.
Alert	Equal to a value of False that indicates this error cannot be alerted.
Err_Type	Equals a value of Temp that indicates a temporary failure.
Err_Desc	Equals a value of 1312 that indicates a physical volume operation failure.
Prob_Causes	Equals the following values: • 5000, which indicates a media failure • 6310, which indicates a disk drive failure
User_Causes	Equals a value of 5100 that indicates that the media is defective.
User_Actions	Equals the following values: • 0000, which indicates that the problem-determination procedures must be performed • 1601, which indicates that the removable media must be replaced and tried again
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	Equals the following values: • 5000, which indicates a media failure • 6310, which indicates a disk drive failure
Fail_Actions	Equals the following values: • 1601, which indicates that the removable media must be replaced and tried again • 00E1, which performs problem determination procedures
Detail_Data	Equals a value of 156, 11, HEX. This value indicates hexadecimal format. **Note:** The `Detail_Data` field in the `err_rec` structure contains the `mstor_err_rec` structure. The `err_rec` field is defined in the `/usr/include/sys/errids.h` file. It follows the same legend as other errors.

Error record values for unknown errors

The following fields are defined in the error record template for hard disk, CD-ROM, and read/write optical media unknown errors:

Value	Description
Comment	Indicates hard disk, CD-ROM, or read/write optical unknown failure.

Value	Description
Class	Equals a value of H that indicates a hardware error.
Report	Equals a value of True that indicates this error must be included when an error report is generated.
Log	Equals a value of True that indicates an error log entry must be created when this error occurs.
Alert	Equal to a value of False that indicates this error cannot be alerted.
Err_Type	Equals a value of Unkn that indicates the type of error is unknown.
Err_Desc	Equals a value of FE00 that indicates an undetermined error.
Prob_Causes	Equals the following values: • 3300, which indicates an adapter failure • 5000, which indicates a media failure • 6310, which indicates a disk drive failure
User_Causes	None.
User_Actions	None.
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	Equals a value of FFFF that indicates the failure causes are unknown.
Fail_Actions	Equals the following values: • 00E1, which performs problem determination procedures • 1601, which indicates the removable media must be replaced and tried again
Detail_Data	Equals a value of 156, 11, HEX. This value indicates hexadecimal format. **Note:** The `Detail_Data` field in the `err_rec` structure contains the `mstor_err_rec` structure. The `err_rec` field is defined in the `/usr/include/sys/errids.h` file. It follows the same legend as other errors.

Special Files

The usbcd USB client device driver uses raw and block special files for its functions. The special files that are used by the usbcd device driver are listed by the type of device in the following table:

Table 2. Special files for the usbcd device driver

Device	Special file	Description
Hard disk, flash drive, RDX devices	`/dev/rusbms0`, `/dev/rusbms1`, ..., `/dev/rusbms`*n*	Provides an interface for USB client device drivers to access character (raw I/O access and control functions).
	`/dev/usbms0`, `/dev/usbms1`, ..., `/dev/usbms`*n*	Provides an interface for USB client device drivers to access block I/O.

Table 2. Special files for the usbcd device driver (continued)		
Device	**Special file**	**Description**
CD-ROM, DVD-RAM, Blu-ray read-only devices:	`/dev/rcd0`, `/dev/rcd1`, ..., `/dev/rcd`*n*	Provides an interface for USB client device drivers to access character (raw I/O access and control functions).
	`/dev/cd0`, `/dev/cd1`, ..., `/dev/cd`*n*	Provides an interface for USB client device drivers to access block I/O.

Note: The prefix `r` on a special file name indicates that the drive is accessed as a raw device rather than a block device. Performing raw I/O with a hard disk, flash drive, RDX, CD-ROM, or read/write optical drive requires all data transfers to be in multiples of the device block size. Also, all the **lseek** subroutines that are made to the raw device driver must result in a file pointer value that is a multiple of the device block size.

USB Mouse Client Device Driver

Purpose

Supports the Universal Serial Bus (USB) mouse device.

Syntax

```
#include <sys/usbdi.h>
```

Description

The USB mouse client device driver consists of a back end that interfaces with the USB system driver (USBD) and a front end that interfaces with an AIX application such as the X server application. The client driver has no knowledge of the underlying USB adapter hardware. Instead, the client driver sends control requests to the USB mouse through the USBD and receives input events through the USBD. The USB mouse client driver supports the attachment of multiple USB mouse devices. Each device is enumerated in the Object Data Manager (ODM) and marked available. The client driver treats all the mouse devices as a single logical device. Input events from all the devices are sent to a single input ring.

A device special file is created for each USB mouse device. Until there is at least one USB mouse device that is marked available, an application (typically the X server application) can open any one of the USB mouse special files because the client driver ignores the minor number specification. A USB mouse device that is added and configured after the open operation is automatically added to the open set. The device special files (for example, `/dev/mouse0`, `/dev/mouse1`, and so on) are created for each USB mouse device.

Special treatment for the mouse is provided by the USBD configuration method because of the strict configuration and ordering rules of the graphics subsystem. When a USB host controller and a graphics adapter are marked available, and no existing mouse is present, the USBD ensures that at least one USB mouse instance is defined. The USB mouse client driver uses the USBD_OPEN_DEVICE_EXT `ioctl` operation to open the device that generates a valid handle even when there is no USB mouse that is attached to the system. The EAGAIN error code is returned by the USBD_OPEN_DEVICE_EXT operation if there is no mouse device and the client driver treats the device as disconnected. When you plug in a USB mouse, a reconnect call back operation is made to the mouse client by the USBD and the device is initialized for the input events to flow to the X server application.

The following input device driver `ioctl` operations are used for the USB mouse operations:

Operation	Description
IOCINFO	Returns a `devinfo` structure, which is defined in the `sys/devinfo.h` header file, that describes the device. The first field of the structure (`devtype`) is set to `DD_INPUT`; the rest of the structure is set to zero.
MQUERYID	Queries mouse device identifier.
MREGRING	Registers input ring.
MREGRINGEXT	Registers extended input ring.
MRFLUSH	Flushes input ring.
MTHRESHOLD	Sets mouse reporting threshold.
MRESOLUTION	Sets mouse resolution.
MSCALE	Sets mouse scale factor.
MSAMPLERATE	Sets mouse sample rate.

USB Tape Client Device Driver

Purpose

Supports the Universal Serial Bus (USB) protocol for sequential access tape device driver.

Syntax

```
#include <sys/devinfo.h>
#include <sys/usb.h>
#include <sys/tape.h>
#include <sys/usbdi.h>
```

Device-dependent subroutines

Most of the tape operations are implemented by using the open, `close`, `read`, and `write` subroutines. However, the openx subroutine must be used if the device must be opened in the `Diagnostic` mode.

open and close subroutines

The openx subroutine is primarily used for the diagnostic commands and utilities. Appropriate authority is required for to run the subroutine. If you run the openx subroutine without the required authority, the subroutine returns a value of `-1` and sets the *errno* global variable to a value of EPERM.

The openx subroutine enables the `Diagnostic` mode for the device driver and disables command-retry logic. This action allows the `ioctl` operations that perform special functions that are associated with diagnostic processing. The openx subroutine can also force-open and retain reservations.

The open subroutine applies a reservation policy that is based on the Object Data Manager (ODM) `reserve_policy` attribute. The USB tape devices might not support Small Computer System Interface (SCSI) reservation command and therefore, these commands might be ignored.

The *ext* parameter that is passed to the openx subroutine selects the operation to be used for the target device. The `/usr/include/sys/scsi.h` file defines the possible values for the *ext* parameter.

The *ext* parameter can contain any logical combination of the following flag values:

Item	Description
SC_FORCED_OPEN	Forces access to a device by removing any type of reservation on the device that can inhibit access. The type of action to remove the reservation depends upon the specific type of the established reservation. If this flag is specified, a mass storage reset command is issued for a USB tape, which is a mass storage bulk device.
SC_DIAGNOSTIC	Places the selected device in the `Diagnostic` mode. This mode is singularly entrant. It means when a device is in the `Diagnostic` mode, SCSI operations are performed during the open or `close` operations, and error logging is disabled. In the `Diagnostic` mode, only the `close` and `ioctl` operations are accepted. All other device-supported subroutines return a value of -1 and set the *errno* global variable to a value of EACCES. A device can be opened in the `Diagnostic` mode only if the target device is not currently opened. If you open a device in the `Diagnostic` mode and the target device is already open, the subroutine returns a value of -1 and sets the *errno* global variable to a value of EACCES.

ioctl subroutine

The following `ioctl` operations are supported on USB tape devices:

Operation	Description

IOCINFO	Populates the `devinfo` argument that is passed by the caller with the following values:
	
	<pre>devinfo.devtype = DD_SCTAPE;
	devinfo.flags = 0;
	devinfo.devsubtype = 0x00;
	devinfo.un.scmt.type = DT_STREAM;
	devinfo.un.scmt.blksize = *Block Size Set for the Tape Device*;</pre>

Operation	Description
STIOCTOP	Specifies the address of a stop structure that is defined in the `src/bos/usr/include/sys/tape.h` file. The operation that is found in the `st_op` field in the stop structure is run *st_count* times, except for rewind, erase, and retention operations.
	This `ioctl` command supports the following operations with the respective implementation details:
	STREW Issues the REWIND command to the tape device to rewind the tape.
	STERASE Issues the SCSI ERASE command to erase the contents of the tape media. Erase is not allowed with a read-only tape.
	STRETEN or STINSRT Issues the SCSI LOAD command with Load and Reten bits that are set in byte 4 of the command.
	STWEOF Writes the end-of-file mark to the tape. The `Write End-of-Filemark` operation is not allowed with a read-only tape.
	STDEOF Disables the end-of-tape checking command.
	STFSF Issues the `Forward Space File` command. The `st_count` field specifies the number of file marks that the tape advances.
	STFSR Issues the `Forward Space Record` command. The `st_count` field is the number of records that the tape advances.
	STRSF Issues the `Reverse Space File` command. The `st_count` field is the number of file marks that the tape reverses.
	STRSR Issues the `Reverse Space Record` command. The `st_count` field is the number of records that the tape reverses.
	STOFFL or STEJECT Ejects the tape from the tape drive. This operation issues the SCSI LOAD command with Load bit in byte 4 of Command Descriptor Block (CDB) that is set to zero.
	STIOCHGP Defines the `ioctl` command to dynamically change the block size for this tape device. The block size is changed for the length of the open operation and is returned to the original values on the next open operation. The tape is forced to BOT (beginning-of-tape) when this operation is performed. The parameter to this `ioctl` command specifies the address of a `stchgp` structure that is defined in the `src/bos/usr/include/sys/tape.h` file. The `st_blksize` field in the structure specifies the block size value to be set.

Operation	Description
STIOCTOP (continued)	**STIOCMD** When the device is successfully opened, the STIOCMD operation issues an SCSI command to the specified tape device. The SCSI status byte and the adapter status bytes are returned through the **arg** parameter that contains the address of a scsi_iocmd structure. This structure is defined in the /usr/include/sys/scsi_buf.h file. The STIOCMD operation receives the SCSI command in the scsi_cdb section of the scsi_iocmd structure and issues it to the USB tape device. If the STIOCMD operation fails, the subroutine returns a value of -1 and sets the *errno* global variable to a nonzero value. In this case, the caller must evaluate the returned status bytes to determine the cause of operation failure and the recovery actions. The version, command_length, and timeout_value values that are passed by the user is validated and error value EINVAL is returned if they are not valid. If you transfer more than 1 MB of the maximum I/O transfer size, the subroutine returns a value of -1 and sets the *errno* global variable to a value of EINVAL. On a check condition, the following error status values are set in the sc_passthru structure:

```
    status_validity  = SC_SCSI_ERROR
    scsi_bus_status = SC_CHECK_CONDITION
    adap_set_flags will have SC_AUTOSENSE_DATA_VALID flag set.
```

The following example is a pseudo code to issue the STIOCMD operation to the USB tape to issue an INQUIRY SCSI command:

```
    struct scsi_iocmd cmd;
    char inq_data[255];
    char sense_data[255];
..
    fd = open("/dev/rmt0", O_RDWR);
..
    memset(&cmd, '\0', sizeof(struct sc_passthru));
    cmd.version = SCSI_VERSION_1;
    cmd.timeout_value = 30;
    cmd.command_length = 6;
    cmd.autosense_length = 255;
    cmd.autosense_buffer_ptr = &sense_data[0];
    cmd.data_length = 0xFF;
    cmd.buffer = inq_data;

    cmd.flags = B_READ;

    cmd.scsi_cdb[0] = SCSI_INQUIRY;
    cmd.scsi_cdb[1] = (0x00 | vpd);  /* Standard Inquiry - vpd=1
                for Extended Inquiry */
    cmd.scsi_cdb[2] = page_code;    /* Page Code - valid if vpd=1 */
    cmd.scsi_cdb[3] = 0x00;
    cmd.scsi_cdb[4] = 0xFF;
    cmd.scsi_cdb[5] = 0x00;

    if ((rc=ioctl(fd, STIOCMD, &cmd)) != 0){
         if (cmd.adap_set_flags & SC_AUTOSENSE_DATA_VALID) {
         /* look at sense data */
          } /* end SC_AUTOSENSE_DATA_VALID */

         printf("STPASSTHRU: Ioctl FAIL errno %d\n",errno);
         printf("status_validity: %x, scsi_status: %x,
adapter_status:%x\n",
      cmd.status_validity, cmd.scsi_bus_status, cmd.adapter_status);
         printf("Residual: %x\n", cmd.residual);
         exit(-1);
     } else {
         printf("STPASSTHRU : Ioctl PASS\n");
         printf("status_validity: %x, scsi_status: %x,
adapter_status:%x\n",
      cmd.status_validity, cmd.scsi_bus_status, cmd.adapter_status);     }
```

Operation	Description

STPASSTHRU	Takes the SCSI command in the `scsi_cdb` section of the `sc_passthru` structure and issues it to the USB tape driver. This operation is similar to the `STIOCMD ioctl` operation with the only exception of additional informative fields in the `sc_passthru` structure that provides more information on the error.
	
	The following example is a pseudo code to issue the STPASSTHRU operation to the USB tape to issue an `INQUIRY SCSI` command:
	
	``c
	    struct sc_passthru cmd;
	    char inq_data[255];
	    char sense_data[255];
	..
	    fd = open("/dev/rmt0", O_RDWR);
	..
	    memset(&cmd, '\0', sizeof(struct sc_passthru));
	    cmd.version = SCSI_VERSION_1;
	    cmd.timeout_value = 30;
	    cmd.command_length = 6;
	    cmd.autosense_length = 255;
	    cmd.autosense_buffer_ptr = &sense_data[0];
	    cmd.data_length = 0xFF;
	    cmd.buffer = inq_data;
	
	  cmd.flags = B_READ;
	
	  cmd.scsi_cdb[0] = SCSI_INQUIRY;
	  cmd.scsi_cdb[1] = (0x00 | vpd); /* Standard Inquiry - vpd=1
	                               for Extended Inquiry */
	  cmd.scsi_cdb[2] = page_code; /* Page Code - valid if vpd=1
	*/
	  cmd.scsi_cdb[3] = 0x00;
	  cmd.scsi_cdb[4] = 0xFF;
	  cmd.scsi_cdb[5] = 0x00;
	
	  if ((rc=ioctl(fd, STPASSTHRU, &cmd)) != 0){
	      if (cmd.adap_set_flags & SC_AUTOSENSE_DATA_VALID) {
	          /* look at sense data */
	        } /* end SC_AUTOSENSE_DATA_VALID */
	
	        printf("STPASSTHRU: Ioctl FAIL errno %d\n",errno);
	        printf("status_validity: %x, scsi_status: %x,
	adapter_status:%x\n",
	      cmd.status_validity, cmd.scsi_bus_status, cmd.adapter_status);
	        printf("Residual: %x\n", cmd.residual);
	        exit(-1);
	    } else {
	        printf("STPASSTHRU : Ioctl PASS\n");
	        printf("status_validity: %x, scsi_status: %x,
	adapter_status:%x\n",
	      cmd.status_validity, cmd.scsi_bus_status, cmd.adapter_status);
	    }
	``

Error Conditions for USB Tape Client Device Driver

In addition to the listed errors, the `ioctl`, `open`, `read`, and `write` subroutines for USB tape device are unsuccessful in the following circumstances:

Value	Description
EAGAIN	Indicates that an attempt is made to open a device, which is already open.
EBUSY	Indicates that the target device is reserved by another initiator.

Value	Description
EINVAL	• Indicates that the O_APPEND value is supplied as the mode in which the device is to be opened. • Indicates that the *nbyte* parameter that is supplied by a `read` or `write` operation is not a multiple of the block size. • Indicates that a parameter to an `ioctl` operation is not valid. • Indicates that the requested `ioctl` operation is not supported on the current device.
EIO	• Indicates that the tape drive is reset or the tape is changed. This error is returned during the open operation if the tape is positioned beyond the beginning of the tape upon closing as a result of the previous operation to the tape. • Indicates that the device cannot space forward or reverse the number of records that is specified by the `st_count` field before it encounters an end-of-media (EOM) or a file mark.
EMEDIA	Indicates an open operation is attempted for an adapter that already has the maximum permissible number of opened devices.
ENOTREADY	Indicates that there is no tape in the drive or the drive is not ready.
ENXIO	Indicates that there was an attempt to write to a tape, which has already reached EOM.
EPERM	Indicates that the subroutine requires appropriate authority.
ETIMEDOUT	Indicates that a command has timed out.
EWRPROTECT	• Indicates that an open operation is attempted for the read/write mode on a read-only tape. • Indicates that an ioctl operation, which affects the media, was attempted on a read-only tape.

Reliability and serviceability information

The following errors are returned from the tape devices:

Error	Description
ABORTED COMMAND	Indicates that the device ended the command.
BLANK CHECK	Indicates that a read command encountered a blank tape.
DATA PROTECT	Indicates that a write operation was attempted on a write-protected tape.
GOOD COMPLETION	Indicates the command completed successfully.
HARDWARE ERROR	Indicates that an unrecoverable hardware failure occurred during the command execution or during a self-test.
ILLEGAL REQUEST	Indicates an invalid command or an invalid command parameter.
MEDIUM ERROR	Indicates that the command ended with an unrecoverable media error condition. This condition can be caused by a tape flaw or a dirty head.
NOT READY	Indicates that the logical unit is offline.

Error	Description
RECOVERED ERROR	Indicates the command is successful after some recovery operations were applied.
UNIT ATTENTION	Indicates that the device is reset or the power is turned on.

Medium, hardware, and unsuccessful command errors from the preceding list must be logged every time they occur. The ABORTED COMMAND error might be recoverable, but the error is logged if recovery fails. For the RECOVERED ERROR and recovered ABORTED COMMAND error types, thresholds are maintained; when they are exceeded, an error is logged. The thresholds are then cleared.

Note: Device-related adapter errors are logged every time the errors occur.

Error record values for tape device errors

The following table lists the fields that are defined in the error record template for tape device errors:

Error ID	Description
SC_TAPE_ERR1	Permanent tape error. This error is logged when tape medium error is encountered.
SC_TAPE_ERR2	Permanent tape hardware error. This error is logged when tape hardware error is encountered or command is aborted by the drive and all attempts to resolve the error have failed.
SC_TAPE_ERR3	Temporary tape drive failure. This error is not logged in Universal Serial Bus (USB) tape driver.
SC_TAPE_ERR4	Permanent tape drive failure. This error is logged when adapter failure is detected and all attempts have failed.
SC_TAPE_ERR5	Unknown tape error. This error is logged when tape returns a check condition but the sense data does not contain valid information.
SC_TAPE_ERR6	Temporary tape operation error. Tape drive needs to be cleaned.
SC_TAPE_ERR7	Informational error. Remote Access Service (RAS) related error logs due to internal driver sanity check failures.
SC_TAPE_ERR8	Temporary tape drive failure. This error is not logged in USB tape driver.

Error record values for tape device media errors

The following table lists the fields that are defined in the error record template for tape device media errors:

Item	Description
Comment	The tape media error.
Class	A value of H that indicates a hardware error.
Report	A value of True that indicates this error must be included when an error report is generated.
Log	A value of True that indicates an error log entry must be created when this error occurs.
Alert	A value of False that indicates this error cannot be alerted.
Err_Type	A value of Perm that indicates a permanent failure.

Item	Description
Err_Desc	A value of 1332 that indicates a tape operation failure.
Prob_Causes	A value of 5003 that indicates tape media.
User_Causes	A value of 5100 that indicates an error with the tape device and a value of 7401 that indicates an error with the defective media.
User_Actions	A value of 1601 that indicates that the removable media must be replaced and the operation must be tried again. Or, it equals a value of 0000 that indicates that problem determination procedures must be performed.
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	A value of 5003 that indicates tape media.
Fail_Actions	A value of 1601 that indicates that the removable media must be replaced and the operation must be tried again. Or, it equals a value of 0000 that indicates that problem determination procedures must be performed.

The `Detail_Data` field contains the command type, device and adapter status, and the request-sense information from the particular device in error. The `Detail_Data` field is contained in the `err_rec` structure. This structure is defined in the `/usr/include/sys/errids.h` file.

Error record values for tape or hardware aborted command errors

The following fields in the `err_hdr` structure are defined in the `/usr/include/sys/erec.h` file for hardware errors and aborted command errors:

Item	Description
Comment	A value of tape hardware or aborted command error.
Class	A value of H that indicates a hardware error.
Report	A value of True that indicates this error must be included when an error report is generated.
Log	A value of True that indicates an error log entry must be created when this error occurs.
Alert	A value of FALSE that indicates this error cannot be alerted.
Err_Type	A value of Perm that indicates a permanent failure.
Err_Desc	A value of 1331 that indicates a tape drive failure.
Prob_Causes	A value of 6314 that indicates a tape drive error.
User_Causes	None.
User_Actions	A value of 0000 that indicates that problem determination procedures must be performed.
Inst_Actions	None.
Fail_Causes	A value of 5003 that indicates the failure case is the tape and a value of 6314 that indicates the failure case is the tape drive.

Item	Description
Fail_Actions	A value of 0000 that indicates that problem determination procedures must be performed.

The `Detail_Data` field contains the command type, device and adapter status, and the request-sense information from the particular device in error. The `Detail_Data` field is contained in the `err_rec` structure. This structure is defined in the `/usr/include/sys/errids.h` file. The `usbtape_err_rec` structure describes information that is contained in the `Detail_Data` field.

Error record values for tape-recovered error threshold exceeded

The following fields are defined in the `err_hdr` structure that are defined in the `/usr/include/sys/erec.h` file for recovered errors that have exceeded the threshold counter:

Item	Description
Comment	Indicates that the threshold for the tape-recovered errors is exceeded.
Class	A value of H that indicates a hardware error.
Report	A value of True that indicates this error must be included when an error report is generated.
Log	A value of True that indicates an error-log entry must be created when this error occurs.
Alert	A value of False that indicates this error cannot be alerted.
Err_Type	A value of TEMP that indicates a temporary failure.
Err_Desc	A value of 1331 that indicates a tape drive failure.
Prob_Causes	A value of 6314 that indicates the probable cause is the tape drive.
User_Causes	A value of 5100 that indicates the media is defective and a value of 7401 that indicates the read/write head is dirty.
User_Actions	A value of 1601 that indicates that the removable media must be replaced and the operation must be tried again. Or, it equals a value of 0000 that indicates that problem determination procedures must be performed.
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	A value of 5003 that indicates the failure cause is the tape and a value of 6314 that indicates the failure cause is tape drive.
Fail_Actions	A value of 0000 that indicates problem-determination procedures must be performed.

The `Detail_Data` field contains the command type, device and adapter status, and the request-sense information from the particular device in error. This field is contained in the `err_rec` structure. The `err_rec` structure is defined in the `/usr/include/sys/errids.h` file. The `Detail_Data` field also specifies the error type of the threshold exceeded. The `usbtape_err_rec` structure describes information contained in the `Detail_Data` field.

Error record values for tape USB adapter-detected errors

The following fields in the `err_hdr` structure are defined in the `/usr/include/sys/erec.h` file for adapter-detected errors:

Item	Description
Comment	A tape Fibre Channel adapter-detected error.
Class	A value of H that indicates a hardware error.
Report	A value of True that indicates this error must be included when an error report is generated.
Log	A value of True that indicates an error log entry must be created when this error occurs.
Alert	A value of FALSE that indicates this error cannot be alerted.
Err_Type	A value of PERM that indicates a permanent failure.
Err_Desc	A value of 1331 that indicates a tape drive failure.
Prob_Causes	The values of 3300 that indicates adapter failure and a value of 6314 that indicates tape drive failure.
User_Causes	None.
User_Actions	A value of 0000 that indicates that problem determination procedures must be performed.
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	A value of 3300 that indicates adapter failure and a value of 6314 that indicates tape drive failure.
Fail_Actions	A value of 0000 that indicates problem-determination procedures must be performed.

The `Detail_Data` field contains the command type and adapter status. This field is contained in the `err_rec` structure that is defined by the `/usr/include/sys/err_rec.h` file. Request-sense information is not available with this type of error. The `usbtape_err_rec` structure describes information contained in the `Detail_Data` field.

Error record values for tape drive cleaning errors

Some tape drives return errors when they need cleaning. Errors that occur when the drive needs cleaning are grouped under this class.

Item	Description
Comment	Indicates that the tape drive needs cleaning.
Class	A value of H that indicates a hardware error.
Report	A value of True that indicates this error must be included when an error report is generated.
Log	A value of True that indicates an error log entry must be created when this error occurs.
Alert	A value of FALSE that indicates this error cannot be alerted.
Err_Type	A value of TEMP that indicates a temporary failure.
Err_Desc	A value of 1332 that indicates a tape operation error.
Prob_Causes	A value of 6314 that indicates that the probable cause is the tape drive.
User_Causes	A value of 7401 that indicates a dirty read/write head.

Item	Description
User_Actions	A value of 0000 that indicates that problem determination procedures must be performed.
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	A value of 6314 that indicates that the cause is the tape drive.
Fail_Actions	A value of 0000 that indicates problem-determination procedures must be performed.

The `Detail_Data` field contains the command type and adapter status, and also the request-sense information from the particular device in error. This field is contained in the `err_rec` structure that is defined by the `/usr/include/sys/errids.h` file. The `usbtape_err_rec` structure describes information contained in the `Detail_Data` field.

Error record values for unknown errors

Errors that occur for unknown reasons are grouped in this class. Data-protect errors fall into this class. These errors, which are detected by the tape device driver, are never seen at the tape drive.

The err_hdr structure for unknown errors describes the following fields:

Item	Description
Comment	A tape unknown error.
Class	All error classes.
Report	A value of True that indicates this error must be included when an error report is generated.
Log	A value of True that indicates an error log entry must be created when this error occurs.
Alert	A value of FALSE that indicates this error cannot be alerted.
Err_Type	A value of UNKN that indicates the type of error is unknown.
Err_Desc	A value of 0xFE00 that indicates the error description is unknown.
Prob_Causes	Specifies the following values: • 3300, which indicates a tape drive failure • 5003, which indicates a tape failure • 6314, which indicates an adapter failure
User_Causes	None.
User_Actions	None.
Inst_Causes	None.
Inst_Actions	None.
Fail_Causes	A value of 0xFFFF that indicates the causes for failure are unknown.
Fail_Actions	A value of 0000 that indicates that problem-determination procedures must be performed.

The `Detail_Data` field contains the command type and adapter status, and the request-sense information from the particular device in error. The `Detail_Data` field is contained in the `err_rec`

structure. This field is contained in the `/usr/include/sys/errids.h` file. The `usbtape_err_rec` structure describes information that is contained in the `Detail_Data` field.

Refer to the SCSI specification for the applicable device for the format of the particular request-sense information.

USBD Protocol Driver

Purpose

Supports the USB system driver (USBD) protocol.

Syntax

```
#include <sys/usb.h>
#include <sys/usbdi.h>
#include <sys/hubClass.h>
#include <sys/hidClass.h>
```

Description

The USBD protocol driver is the layer between the host controller the and client drivers. The `/dev/usb0` special file provides interface to allow communication between the host controller and the client drivers. This driver is responsible for the device communication to appropriate host controller. The device connection, disconnection, and re-connection are performed at this level. There is no parent for this device and the device's CuDv entry is created by the `/usr/lib/methods/startusb` script that is invoked from the `ConfigRules` field.

The `/usr/lib/drivers/usb/usbd` driver implements the USB protocol and the `/usr/lib/methods/cfgusb` file is the usbd file's configuration method. The USB protocol driver updates the speed ODM attribute that is specific to each individual USB devices. The speed is updated when the USB devices are enumerated during the AIX configuration.

Device-dependant subroutines

The USBD protocol driver supports only the open, `close`, and `ioctl` subroutines. The `read` and `write` subroutines are not supported.

open and close subroutines

The open subroutine associates a specific device number that is passed in as a parameter to the open system call with the internal adapter device structure. If it finds an adapter structure, it verifies that the corresponding adapter device is configured and sets the state as open. Otherwise, the subroutine returns an error.

ioctl subroutine

The `ioctl` operations for USBD protocol drivers are exposed to kernel and user environments.

USBD ioctl operations

The following USBD `ioctl` operations are exposed to kernel threads that are used to open a specific USB logical device:

- USBD_OPEN_DEVICE
- USBD_OPEN_DEVICE_EXT

The following USBD `ioctl` operations are exposed to user threads:

Operation	Description
USBD_REGISTER_MULTI_HC	Registers all the USB host controllers with USB system driver.
USBD_REGISTER_SINGLE_HC	Registers only a single USB host controller with USB system driver.
USBD_ENUMERATE_DEVICE	Gets a list of USB logical devices (excluding hubs) that are connected to a host controller.
USBD_ENUMERATE_ALL	Gets a list of all the USB logical devices that are connected to a host controller.
USBD_ENUMERATE_CFG	Gets a list of USB logical devices that are connected to a host controller along with the client device selection information.
USBD_GET_DESCRIPTORS	Gets standard USB descriptors for a logical device.
USBD_CFG_CLIENT_UPDATE	Updates client connection information.

Summary of USBD error conditions

Possible *errno* values for the adapter device driver are as follows:

Value	Description
EACCES	An openx subroutine was attempted to run while the adapter had one or more devices in use.
EEXIST	The device is already configured.
EINVAL	An invalid parameter or that the device is not opened.
EIO	- The command failed due to an error detected. - The device driver was unable to pin code. - A kernel service failed or an unrecoverable I/O error occurred.
ENOCONNECT	A USB bus fault occurred.
ENODEV	The target device cannot be selected or is not responding.
ENOMEM	The command cannot be completed because of an insufficient amount of memory.
ENXIO	The requested ioctl operation is not supported by this adapter.
EPERM	The caller does not have the required authority.

USBD ioctl Operations

There is a set of input and output control (ioctl) system calls to control I/O operations for Universal Serial Bus (USB) devices.

An `ioctl` call contains the following parameters:

- An open file descriptor.
- A request code.
- An integer value, possibly unsigned that is assigned to the driver.
- A pointer to data that is available in the host controller structure.

USBD_OPEN_DEVICE

Purpose

Opens a specific Universal Serial Bus (USB) logical device.

Syntax

```
int fp_ioctl (file, USBD_OPEN_DEVICE, arg, ext)
```

Parameters

Item	Description
file	File descriptor that is obtained when the USB system driver (USBD) special file was opened.
arg	Address of an initialized DEVOPEN structure.
ext	Not used and must be set to zero.

Description

The client driver uses this `fp_ioctl` operation to establish a connection to a specific USB logical device that is identified by the information within the DEVSELECTOR structure. A USB logical device can be opened by only one client driver at a time. If a client opens the device, it must connect to a pipe before the data can flow to or from the device. This data includes, but is not limited to, the default control pipe. The client driver must close any device that it opened by calling the `usbdCloseDevice` operation when it no longer wants to manage the device. Typically, a client driver must open the USBD, issue a `USBD_OPEN_DEVICE ioctl` operation to open a specific USB device, and close the USBD. Then, the client must communicate with the USBD by using the handle that is returned by the `USBD_OPEN_DEVICE ioctl` operation and the interface macros that are located within the `usbdi.h` file. To properly track the USB device when the device needs to be moved or replaced, the client must open the device when the client is configured, and the client must close the USB device when the client is unconfigured.

Execution environment

This function can be called from the kernel process environment only.

Return values

Value	Description
0	Success.
Nonzero values	Failure.

USBD_OPEN_DEVICE_EXT

Purpose

Opens a specific Universal Serial Bus (USB) logical device.

Syntax

```
int fp_ioctl (file, USBD_OPEN_DEVICE_EXT, arg, ext)
```

Parameters

Item	Description
file	File descriptor that is obtained when the USBD special file was opened.
arg	Address of an initialized DEVOPEN structure.
ext	Not used and must be set to zero.

Description

The client driver uses this `fp_ioctl` operation to establish a connection to a USB logical device that is identified by the information within the DEVSELECTOR structure. The `ioctl` operation is similar to the `USBD_OPEN_DEVICE ioctl` operation except that a client handle is allocated even when a USB logical device that matches the criteria that is specified in the DEVSELECTOR structure is not available. The USB system driver (USBD) returns the EAGAIN error value to indicate this condition. When the EAGAIN value is returned, the client driver must treat the device as disconnected and wait for connection before it proceeds with device initialization.

Execution environment

This function can be called from the kernel process environment only.

Return values

Value	Description
0	Success.
EAGAIN	No device matched the criteria. The client handle is valid but the device is treated as being in the disconnected state.
All other values	Failure.

USBD_REGISTER_MULTI_HC

Purpose

Registers the Universal Serial Bus (USB) host controller with the USB system driver (USBD).

Syntax

```
int ioctl (file, USBD_REGISTER_MULTI_HC, arg)
```

Parameters

Item	Description
file	File descriptor that is obtained when the USBD special file was opened.
arg	Pointer to the information structure of the USB host controller.

Description

This `ioctl` operation registers all the USB host controllers that are listed in the `usb_adapterhc_info` structure with the USBD and allows the clients to communicate to the devices that are connected to the controller. There is no specific `ioctl` operation to unregister a hardware controller. It stays registered until either the USBD is unconfigured or the host controller is unconfigured. In the latter

case, the host controller driver requests the USBD to unregister the host controller through the usbdReqHCunregister call vector. This `ioctl` operation must be invoked only by the `cfgusb` configuration method during enumeration and individual USB adapter configuration methods must use the USBD_REGISTER_SINGLE_HC operation to register single host controller instance.

Execution environment

This function can be called from the user process environment only.

Return values

Value	Description
0	Success.
-1	Failure. Check the `errno` value for specific failure causes.

USBD_REGISTER_SINGLE_HC

Purpose

Registers single Universal Serial Bus (USB) host controller with the USB system driver (USBD).

Syntax

```
int ioctl (file, USBD_REGISTER_SINGLE_HC, arg)
```

Parameters

Item	Description
file	File descriptor that is obtained when the USBD special file was opened.
arg	Pointer to the integer that contains 32-bit devno structure of the USB host controller.

Description

This `ioctl` operation registers the specified host controller with the USBD and allows clients to communicate to the devices that are connected to the controller. There is no specific `ioctl` operation to unregister a hardware controller. It stays registered until either the USBD is unconfigured or the host controller is unconfigured. In the latter case, the host controller driver requests the USBD to unregister the host controller through the usbdReqHCunregister call vector.

Execution environment

This function can be called from the user process environment only.

Return values

Value	Description
0	Success.
-1	Failure. Check the `errno` value for specific failure causes.

USBD_ENUMERATE_DEVICE

Purpose

Gets a list of USB logical devices (excluding hubs) that are connected to a host controller.

Syntax

```
int ioctl (file, USBD_ENUMERATE_DEVICE, arg)
```

Parameters

Item	Description
file	File descriptor that is obtained when the USBD special file was opened.
arg	Address of the USBENUM structure that is aligned on a 4-byte boundary.

Description

This ioctl operation returns a description of each logical USB device that is connected to the specified host controllers without any hubs. The description is returned in the form of a `usb_device_t` structure. The array of returned structures is encapsulated within a USBENUM structure whose length is specified by the caller. When this function is started, the `devno` and `buffSize` fields within the USBENUM structure must be initialized. The `devno` field must contain the 32-bit `devno` value of the host controller to be enumerated while the `buffSize` field must indicate the number of bytes that are available to buffer the returned array of `usb_device_t` structures. If the area is too small, the number of returned structures is truncated to fit the available space. The caller can detect this condition by noting that the number of returned `usb_device_t` structures is less than the number of discovered logical devices.

Execution environment

This function can be called from the user process environment only.

Return values

Value	Description
0	Success.
-1	Failure. Check the `errno` value for specific failure causes.

USBD_ENUMERATE_ALL

Purpose

Gets a list of all the Universal Serial Bus (USB) logical devices that are connected to a host controller.

Syntax

```
int ioctl (file, USBD_ENUMERATE_ALL, arg)
```

Parameters

Item	Description
file	File descriptor that is obtained when the USB system driver (USBD) special file was opened.
arg	Address of the USBENUM structure that is aligned with a 4-byte boundary.

Description

This `ioctl` operation behaves in the same manner as the USBD_ENUMERATE_DEVICE `ioctl` operation except that it includes all hubs other than the root hub.

Execution environment

This function can be called from the user process environment only.

Return values

Value	Description
0	Success.
-1	Failure. Check the `errno` value for specific failure causes.

USBD_ENUMERATE_CFG

Purpose

Gets a list of Universal Serial Bus (USB) logical devices that are connected to a host controller.

Note: This `ioctl` operation is used only by the USB system device driver's configuration method.

Syntax

```
int ioctl (file, USBD_ENUMERATE_CFG, arg)
```

Parameters

Item	Description
file	File descriptor that is obtained when the USB system driver (USBD) special file was opened.
arg	Address of the USBENUMCFG structure that is aligned with a 4-byte boundary.

Description

This `ioctl` operation behaves in the same manner as the USBD_ENUMERATE_DEVICE `ioctl` operation except that it also returns the client device selection information. The selection information uniquely identifies device-client pairing and allows the configuration method to correlate enumerated devices with their Object Data Manager (ODM) instances.

Execution environment

This function can be called from the user process environment only.

Return values

Value	Description
0	Success.
-1	Failure. Check the `errno` value for specific failure causes.

USBD_GET_DESCRIPTORS

Purpose

Gets standard Universal Serial Bus (USB) descriptors for a logical device.

Syntax

```
int ioctl (file, USBD_GET_DESCRIPTORS, arg)
```

Parameters

Item	Description
file	File descriptor that is obtained when the USB system driver (USBD) special file was opened.
arg	Address of the USBDGD structure that is aligned on a 4-byte boundary.

Description

After a successful return from the `ioctl` operation, a DESCIDX structure is placed at the start of the specified buffer that is followed by the standard device descriptor, configuration descriptor, interface descriptor, endpoint descriptors, human interface device (HID) descriptor (if an HID device is used), hub descriptor (if hub device is used), and string descriptors of the specified logical USB device. The DESCIDX structure provides direct addressability to the individual descriptors. String descriptors are reformed to null terminated American Standard Code for Information Interchange (ASCII) strings for ease of use. All other descriptors adhere to the standard USB format. Since the size of the returned data is typically unknown, the `ioctl` operation must be called twice. The first time that you call the `ioctl` operation, set the `bufferLength` field equal to zero and the buffer field to null. The `ioctl` operation might fail with the ENOSPC error, however the `minBuffLength` value is returned that indicates the required size of the buffer. The caller can then allocate the buffer and call the `ioctl` operation again with the `bufferLength` field set to the correct value.

Execution environment

This function can be called from the user process environment only.

Return values

Value	Description
0	Success.
-1	Failure. Check the `errno` value for specific failure causes.

USBD_CFG_CLIENT_UPDATE

Purpose

Updates the client connection information.

Note: This `ioctl` operation is used only by the USB system driver (USBD) configuration method.

Syntax

```
int ioctl (file, USBD_CFG_CLIENT_UPDATE, arg)
```

Parameters

Item	Description
file	File descriptor that is obtained when the USBD special file was opened.
arg	Address of the USBENUMCFG structure that is aligned with a 4-byte boundary.

Description

This `ioctl` operation is used by the USBD's defined children configuration procedure to update the device selection criteria that is used by the client driver. Specifically, it updates the `hcdevno`, `addr`, `cfg`, and `intfc` fields to reflect the current values for the device that are managed by the client.

Execution environment

This function can be called from the user process environment only.

Return values

Value	Description
0	Success.
-1	Failure. Check the `errno` value for specific failure causes.

USBLIBDD Passthru Driver

Purpose

Supports the application drivers that are written by using the **libusb** APIs.

Syntax

```
#include <usbdi.h>
#include <usb.h>
```

Description

The **libusb passthru** driver is the layer between the user-level application driver and the USB protocol driver (USBD). The **/dev/usblibdevX** special file provides interface to **libusb** applications to communicate directly with the device through the **passthru** driver. The **passthru** driver converts the **libusb** APIs to the USBD function vectors that interact with the appropriate Universal Serial Bus (USB) host controllers such as Open Host Controller Interface (OHCI), Enhanced Host Controller Interface (EHCI), or eXtensible Host Controller Interface (xHCI).

The **libusb** devices are created in the **/dev** file system irrespective of the presence of built-in AIX client USB drivers. The parent for this device is the **usb0** and the **libusb** devices that are enumerated by the **/usr/lib/methods/cfgusb** file.

The **/usr/lib/drivers/usb/usblibdd** driver implements the **libusb passthru** driver. The **passthru** driver uses the **/usr/lib/methods/cfgusblibke** configuration method. These devices have two Object Data Manager (ODM) attributes called **usbdevice** and **speed**. If a device belongs to standard classes such as Mass Storage, Tape, human interface device (HID), these devices are claimed by the built-in USB client driver of the AIX operating system. In such case, a **libusb** device is created as a pseudo device. The **usbdevice** attribute identifies the device of the client driver that is associated with a pseudo device. If a device belongs to other classes and if client drivers are not associated with the device, the **usbdevice** attribute is not valid.

For every **libusb** device, which has an AIX operating system built-in client driver, a new attribute that is called **usbdevice** is created in the ODM to identify the client driver device that is associated with the **libusb** device. The following example shows how the device is displayed:

```
# lsattr -El usblibdev0

speed     highspeed  USB Protocol Speed of Device      False

usbdevice usbms0 Actual USB Device with Client Driver False
```

In this example, the USB device that is connected is a flash drive, which has the AIX operating system built-in **/usr/lib/drivers/usb/usbcd** Mass Storage Class client driver. The device of the client driver associated with the **usblibdev0** device is **usbms0**.

By default, this device is claimed by the built-in client driver. The same device is also claimed by the **libusb passthru** driver. Therefore, for one physical USB device, you have two OS devices (**usbms0** and **usblibdev0**) located in the **/dev** file system after you run the configuration method of the parent device, which is USBD protocol driver.

Note: Only the built-in client driver or the **libusb passthru** driver can use this device at a time. You cannot run simultaneous operations on both drivers.

Use the following command to display the USB devices in this scenario:

```
# lsdev -C | grep usb
```

An output similar to the following example is displayed:

```
usb0       Available      USB System Software

usbhc0     Available 00-00 PCIe2 USB 3.0 xHCI 4-Port Adapter (4c10418214109e04)

usblibdev0 Available      USB Library Interface Device

usbms0     Available 0.3  USB Mass Storage
```

In the this example, a USB encryption device (vendor-defined class) is connected to the AIX system. The device does not have a built-in client driver. This device is only claimed by the **libusb passthru** driver and only a single device is displayed. Another example to display the USB devices follows:

```
# lsdev -C | grep usb
```

An output similar to the following example is displayed:

```
usb0       Available      USB System Software

usbhc0     Available 00-00 PCIe2 USB 3.0 xHCI 4-Port Adapter (4c10418214109e04)

usblibdev1 Available 0.4  USB Library Interface Device
```

In this example, **usblibdev1** device is the encryption device of the **libusb** driver.

Device-dependant subroutines

The **libusb passthru** driver supports the following subroutines:

- open
- close
- ioctl

Note: The **read** and **write** subroutines are not supported.

open and close subroutines

The **open** and **close** subroutines are not directly supported on **usblibdevX** devices. You can **open** and **close** subroutines by using the **libusb** APIs.

ioctl subroutine

The **libusb** driver exposes the **ioctl** subroutine to the **libusb** user environments. The **libusb** implementation of operating system backend use these **ioctl** subroutines. The **ioctl** subroutine acts as a pass through between the application and the protocol driver.

The following USBD `ioctl` operations are supported by the **libusb** drivers:

Table 3. USBD ioctl operations	
Operations	**Description**
USBLIB_PIPE_IO	Issues I/O on the wanted endpoint through the **aix_pipeio** structure.
USBLIB_HALT_CLEAR	Issues a request to halt an endpoint.
USBLIB_GETIRP_STATUS	Read the status of the I/O request packet (IRP) that was issued.
USBLIB_SET_CONFIGURATION	Issues a set configuration on a device.
USBLIB_CLAIM_INTERFACE	Ensures sure that the interface is being used by the **libusb passthru** driver.
USBLIB_RELEASE_INTERFACE	Sets the interface to alternate setting value of zero.
USBLIB_SET_ALT_INTFC	Sets the alternate setting on an interface.
USBLIB_RESET_DEVICE	Resets on the device.
USBLIB_ABORT_IO	Aborts or cancels to the submitted I/O.
USBLIB_GET_CONFIG_DESC	Issues request to read the entire configuration descriptor. If a device has X configurations, X number of total configuration descriptor is read and stored in a single buffer.

USBD error conditions

Possible *errno* values for the adapter device driver follow:

Table 4. USBD error conditions	
Value	**Description**
EAGAIN	Indicates that the operation has been to retried.
EEXIST	The device is already configured.
EINVAL	An invalid parameter or the device is not opened.

Table 4. USBD error conditions (continued)	
Value	**Description**
EIO	• The command failed due to an error. • The device driver was unable to pin code. • A kernel service failed or an unrecoverable I/O error occurred.
ENOCONNECT	A USB bus fault occurred.
ENODEV	The target device cannot be selected or is not responding.
ENOMEM	The command cannot be completed because of insufficient memory.
ENXIO	The requested **ioctl** operation is not supported by this adapter.
EPERM	The caller does not have the required authority.

Non-responsive USB devices

USB devices that are associated to `libusb` applications on the AIX operating system might not respond on non-control endpoints. This condition might be because of default behavior of AIX USB protocol driver to send the CLEAR_FEATURE request when the USB devices are opened.

Note: The CLEAR_FEATURE request is a standard USB command to remove the `halt` condition on the device.

To resolve the issues associated with the non-responsive USB devices, the following attributes must be set:

PdAt class object
The Predefined Attribute (PdAt), object class contains an entry for each existing attribute for each USB device. This includes information such as interrupt levels, bus I/O address ranges, baud rates, parity settings, block sizes, and microcode file names. To initialize the PdAt class object set the following values:

```
uniquetype = "generic/usbif/usblibke"
attribute = "<vendorid>_<productid>"
deflt = "toggle_no"
values = "toggle_yes,toggle_no"
width = ""
type = "R"
generic = "U"
rep = "sl"
nls_index = 0
```

VendorId
Vendor ID of the USB device that can be obtained from the descriptor data of the USB device. VendorID must be a hexadecimal number.

ProductID
Product ID of the USB device that can be obtained from the descriptor data of the USB device. ProductID must be a hexadecimal number.

toggle_no
Indicates that the CLEAR_FEATURE request is not sent to the device during pipe initialization.

toggle_yes
Indicates the default behavior of the USB device to send the CLEAR_FEATURE request.

Note: The ODM entry must be added to each device that does not respond on non-control endpoints.

An example ODM attribute follows. This example considers the Kingston USB flash drive (DataTraveler Ultimate G2). The vendor ID of Kingston USB flash drive is 0951 and Product ID is 1656.

```
PdAt:
        uniquetype = "generic/usbif/usblibke"
        attribute = "0951_1656"
        deflt = "toggle_no"
        values = "toggle_yes,toggle_no"
        width = ""
        type = "R"
        generic = "U"
        rep = "sl"
        nls_index = 0
```

To add predefined attributes to the `PdAt` object class complete the following steps:

1. Run the following command to remove a non-responsive USB device from the ODM entries.

   ```
   rmdev -Rl usb0
   ```

   The output might be similar to the following example:

   ```
   usbms0 Defined
   usblibdev0 Defined
   usblibdev1 Defined
   usb0 Defined
   ```

2. Add the odm `PdAt` entry in to a file by using any standard file edit command such as `vi`.

3. Run the following command.

   ```
   odmadd entry
   ```

   The output is not displayed.

4. Run the following command.

   ```
   cfgmgr -l usb0
   ```

   The output is not displayed.

5. Run the `libusb` application. Following example shows the execution of a USB application.

   ```
   # ./xusb -k XXXX:YYYY
   Opening device XXXX:YYYY...
   found /dev/usbhc0
   found 1 devices
   found /dev/usbhc1
   found 0 devices
   found /dev/usbhc2
   found 1 devices

   Reading device descriptor:
              length: 18
        device class: 0
                 S/N: 0
             VID:PID: XXXX:YYYY
           bcdDevice: 0303
     iMan:iProd:iSer: 1:2:0
             nb confs: 1

   Reading BOS descriptor: no descriptor

   Reading first configuration descriptor:
               nb interfaces: 1
                 interface[0]: id = 0
   interface[0].altsetting[0]: num endpoints = 1
      Class.SubClass.Protocol: 03.00.00
          endpoint[0].address: 81
              max packet size: 0008
              polling interval: 0A

   Claiming interface 0...
   ```

```
    in aix_claim_interface

Reading string descriptors:
    String (0x01): "DeviceName"
    String (0x02): "Elitename"

Releasing interface 0...
Closing device...
```

6. Run the following command to delete the PdAt entry of the non-responsive USB device:

```
odmdelete -o PdAt -q 'attribute=0951_1656 and uniquetype="generic/usbif/usblibke"'
```

The output might be similar to the following example:

```
0518-307 odmdelete: 1 object deleted
```
